Problem number: 10.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''' - 4y'' + y' - 4y = \sin(x) - e^{4x}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 4y'' + y' - 4y = 0$$

The characteristic equation is

$$\lambda^3 - 4\lambda^2 + \lambda - 4 = 0$$

The roots of the above equation are

$$\lambda_1 = 4$$
$$\lambda_2 = i$$
$$\lambda_3 = -i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{4x} + c_2 e^{-ix} + e^{ix} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{4x}$$
$$y_2 = e^{-ix}$$
$$y_3 = e^{ix}$$

Now the particular solution to the given ODE is found

$$y''' - 4y'' + y' - 4y = \sin(x) - e^{4x}$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)} \, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} e^{4x} & e^{-ix} & e^{ix} \\ 4\, e^{4x} & -i e^{-ix} & i e^{ix} \\ 16\, e^{4x} & -e^{-ix} & -e^{ix} \end{bmatrix}$$
$$|W| = 34 i e^{4x} e^{-ix} e^{ix}$$

The determinant simplifies to

$$|W| = 34i e^{4x}$$

Now we determine W_i for each U_i.

$$\begin{aligned} W_1(x) &= \det \begin{bmatrix} e^{-ix} & e^{ix} \\ -ie^{-ix} & ie^{ix} \end{bmatrix} \\ &= 2i \end{aligned}$$

$$\begin{aligned} W_2(x) &= \det \begin{bmatrix} e^{4x} & e^{ix} \\ 4\,e^{4x} & ie^{ix} \end{bmatrix} \\ &= (-4+i)\,e^{(4+i)x} \end{aligned}$$

$$\begin{aligned} W_3(x) &= \det \begin{bmatrix} e^{4x} & e^{-ix} \\ 4\,e^{4x} & -ie^{-ix} \end{bmatrix} \\ &= (-4-i)\,e^{(4-i)x} \end{aligned}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned} U_1 &= (-1)^{3-1} \int \frac{F(x) W_1(x)}{a W(x)}\,dx \\ &= (-1)^2 \int \frac{(\sin(x) - e^{4x})\,(2i)}{(1)\,(34ie^{4x})}\,dx \\ &= \int \frac{2i(\sin(x) - e^{4x})}{34ie^{4x}}\,dx \\ &= \int \left(\frac{\sin(x)\,e^{-4x}}{17} - \frac{1}{17} \right) dx \\ &= -\frac{x}{17} - \frac{\cos(x)\,e^{-4x}}{289} - \frac{4\sin(x)\,e^{-4x}}{289} \\ &= -\frac{x}{17} - \frac{\cos(x)\,e^{-4x}}{289} - \frac{4\sin(x)\,e^{-4x}}{289} \end{aligned}$$

$$
\begin{aligned}
U_2 &= (-1)^{3-2} \int \frac{F(x)W_2(x)}{aW(x)}\,dx \\
&= (-1)^1 \int \frac{(\sin(x) - \mathrm{e}^{4x})\left((-4+i)\,\mathrm{e}^{(4+i)x}\right)}{(1)\,(34i\mathrm{e}^{4x})}\,dx \\
&= -\int \frac{(-4+i)\,(\sin(x) - \mathrm{e}^{4x})\,\mathrm{e}^{(4+i)x}}{34i\mathrm{e}^{4x}}\,dx \\
&= -\int \left(\left(\frac{1}{34} + \frac{2i}{17}\right)(\sin(x) - \mathrm{e}^{4x})\,\mathrm{e}^{ix}\right)dx \\
&= \frac{x}{17} - \frac{ix}{68} + \frac{\mathrm{e}^{2ix}}{136} + \frac{i\mathrm{e}^{2ix}}{34} + \frac{4\,\mathrm{e}^{(4+i)x}}{289} + \frac{15i\mathrm{e}^{(4+i)x}}{578} \\
&= \frac{x}{17} - \frac{ix}{68} + \frac{\mathrm{e}^{2ix}}{136} + \frac{i\mathrm{e}^{2ix}}{34} + \frac{4\,\mathrm{e}^{(4+i)x}}{289} + \frac{15i\mathrm{e}^{(4+i)x}}{578}
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{3-3} \int \frac{F(x)W_3(x)}{aW(x)}\,dx \\
&= (-1)^0 \int \frac{(\sin(x) - \mathrm{e}^{4x})\left((-4-i)\,\mathrm{e}^{(4-i)x}\right)}{(1)\,(34i\mathrm{e}^{4x})}\,dx \\
&= \int \frac{(-4-i)\,(\sin(x) - \mathrm{e}^{4x})\,\mathrm{e}^{(4-i)x}}{34i\mathrm{e}^{4x}}\,dx \\
&= \int \left(\left(-\frac{1}{34} + \frac{2i}{17}\right)(\sin(x) - \mathrm{e}^{4x})\,\mathrm{e}^{-ix}\right)dx \\
&= \int \left(-\frac{1}{34} + \frac{2i}{17}\right)(\sin(x) - \mathrm{e}^{4x})\,\mathrm{e}^{-ix}dx
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1y_1 + U_2y_2 + U_3y_3
$$

Hence

$$
\begin{aligned}
y_p = &\left(-\frac{x}{17} - \frac{\cos(x)\,\mathrm{e}^{-4x}}{289} - \frac{4\sin(x)\,\mathrm{e}^{-4x}}{289}\right)(\mathrm{e}^{4x}) \\
&+ \left(\frac{x}{17} - \frac{ix}{68} + \frac{\mathrm{e}^{2ix}}{136} + \frac{i\mathrm{e}^{2ix}}{34} + \frac{4\,\mathrm{e}^{(4+i)x}}{289} + \frac{15i\mathrm{e}^{(4+i)x}}{578}\right)(\mathrm{e}^{-ix}) \\
&+ \left(\int \left(-\frac{1}{34} + \frac{2i}{17}\right)(\sin(x) - \mathrm{e}^{4x})\,\mathrm{e}^{-ix}dx\right)(\mathrm{e}^{ix})
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = \frac{(-17x+8)\,\mathrm{e}^{4x}}{289} + \frac{(9+68i+272x)\cos(x)}{2312} - \frac{\left(\frac{236}{17} + i + 4x\right)\sin(x)}{136}
$$

Which simplifies to

$$y_p = \frac{(-17x+8)\,\mathrm{e}^{4x}}{289} + \frac{(9+68i+272x)\cos(x)}{2312} - \frac{\left(\frac{236}{17}+i+4x\right)\sin(x)}{136}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{4x} + c_2\mathrm{e}^{-ix} + \mathrm{e}^{ix}c_3\right) \\ &\quad + \left(\frac{(-17x+8)\,\mathrm{e}^{4x}}{289} + \frac{(9+68i+272x)\cos(x)}{2312} - \frac{\left(\frac{236}{17}+i+4x\right)\sin(x)}{136}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$\begin{aligned} y &= c_1\mathrm{e}^{4x} + c_2\mathrm{e}^{-ix} + \mathrm{e}^{ix}c_3 + \frac{(-17x+8)\,\mathrm{e}^{4x}}{289} \\ &\quad + \frac{(9+68i+272x)\cos(x)}{2312} - \frac{\left(\frac{236}{17}+i+4x\right)\sin(x)}{136} \end{aligned} \tag{1}$$

Verification of solutions

$$\begin{aligned} y &= c_1\mathrm{e}^{4x} + c_2\mathrm{e}^{-ix} + \mathrm{e}^{ix}c_3 + \frac{(-17x+8)\,\mathrm{e}^{4x}}{289} \\ &\quad + \frac{(9+68i+272x)\cos(x)}{2312} - \frac{\left(\frac{236}{17}+i+4x\right)\sin(x)}{136} \end{aligned}$$

Verified OK.

14.10.1 Maple step by step solution

Let's solve

$y''' - 4y'' + y' - 4y = \sin(x) - \mathrm{e}^{4x}$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - ○ Define new variable $y_1(x)$

    $y_1(x) = y$

  - ○ Define new variable $y_2(x)$

$y_2(x) = y'$

- Define new variable $y_3(x)$

  $y_3(x) = y''$

- Isolate for $y_3'(x)$ using original ODE

  $y_3'(x) = \sin(x) - e^{4x} + 4y_3(x) - y_2(x) + 4y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = \sin(x) - e^{4x} + 4y_3(x) - y_2(x) + 4y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 4 & -1 & 4 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ \sin(x) - e^{4x} \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ \sin(x) - e^{4x} \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 4 & -1 & 4 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[4, \left[\begin{array}{c}\frac{1}{16}\\ \frac{1}{4}\\ 1\end{array}\right]\right], \left[-\mathrm{I}, \left[\begin{array}{c}-1\\ \mathrm{I}\\ 1\end{array}\right]\right], \left[\mathrm{I}, \left[\begin{array}{c}-1\\ -\mathrm{I}\\ 1\end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[4, \left[\begin{array}{c}\frac{1}{16}\\ \frac{1}{4}\\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \mathrm{e}^{4x} \cdot \left[\begin{array}{c}\frac{1}{16}\\ \frac{1}{4}\\ 1\end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \left[\begin{array}{c}-1\\ \mathrm{I}\\ 1\end{array}\right]\right]$$

- Solution from eigenpair

$$\mathrm{e}^{-\mathrm{I}x} \cdot \left[\begin{array}{c}-1\\ \mathrm{I}\\ 1\end{array}\right]$$

- Use Euler identity to write solution in terms of sin and cos

$$(\cos(x) - \mathrm{I}\sin(x)) \cdot \left[\begin{array}{c}-1\\ \mathrm{I}\\ 1\end{array}\right]$$

- Simplify expression

$$\left[\begin{array}{c}-\cos(x) + \mathrm{I}\sin(x)\\ \mathrm{I}(\cos(x) - \mathrm{I}\sin(x))\\ \cos(x) - \mathrm{I}\sin(x)\end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_3(x) = \begin{bmatrix} \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \vec{y}_p(x)$

☐ Fundamental matrix

  - Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} \frac{e^{4x}}{16} & -\cos(x) & \sin(x) \\ \frac{e^{4x}}{4} & \sin(x) & \cos(x) \\ e^{4x} & \cos(x) & -\sin(x) \end{bmatrix}$$

  - The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

  - Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} \frac{e^{4x}}{16} & -\cos(x) & \sin(x) \\ \frac{e^{4x}}{4} & \sin(x) & \cos(x) \\ e^{4x} & \cos(x) & -\sin(x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} \frac{1}{16} & -1 & 0 \\ \frac{1}{4} & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix}}$$

  - Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} \frac{e^{4x}}{17} + \frac{16\cos(x)}{17} - \frac{4\sin(x)}{17} & \sin(x) & \frac{e^{4x}}{17} - \frac{\cos(x)}{17} - \frac{4\sin(x)}{17} \\ \frac{4e^{4x}}{17} - \frac{16\sin(x)}{17} - \frac{4\cos(x)}{17} & \cos(x) & \frac{4e^{4x}}{17} + \frac{\sin(x)}{17} - \frac{4\cos(x)}{17} \\ \frac{16e^{4x}}{17} - \frac{16\cos(x)}{17} + \frac{4\sin(x)}{17} & -\sin(x) & \frac{16e^{4x}}{17} + \frac{\cos(x)}{17} + \frac{4\sin(x)}{17} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

  - Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

$\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

  - Take the derivative of the particular solution

$\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

$\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

$\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

$\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

$\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

$\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \left[\begin{array}{c} \frac{(9-17x)\mathrm{e}^{4x}}{289}+\frac{(-9+34x)\cos(x)}{289}+\frac{(-17x-106)\sin(x)}{578} \\ \frac{(19-68x)\mathrm{e}^{4x}}{289}+\frac{(-17x-38)\cos(x)}{578}+\frac{(-68x+1)\sin(x)}{578} \\ \frac{8(1-34x)\mathrm{e}^{4x}}{289}+\frac{2(-4-17x)\cos(x)}{289}+\frac{\sin(x)(17x-30)}{578} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \left[\begin{array}{c} \frac{(9-17x)\mathrm{e}^{4x}}{289}+\frac{(-9+34x)\cos(x)}{289}+\frac{(-17x-106)\sin(x)}{578} \\ \frac{(19-68x)\mathrm{e}^{4x}}{289}+\frac{(-17x-38)\cos(x)}{578}+\frac{(-68x+1)\sin(x)}{578} \\ \frac{8(1-34x)\mathrm{e}^{4x}}{289}+\frac{2(-4-17x)\cos(x)}{289}+\frac{\sin(x)(17x-30)}{578} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = \frac{(-272x+289c_1+144)\mathrm{e}^{4x}}{4624} + \frac{(-9+34x-289c_2)\cos(x)}{289} - \frac{\left(x-34c_3+\frac{106}{17}\right)\sin(x)}{34}$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 23, page 106
Problem number: 11.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'''' + 3y'' - 4y = 4\,\mathrm{e}^{x} + 3\cos(2x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 3y'' - 4y = 0$$

The characteristic equation is

$$\lambda^4 + 3\lambda^2 - 4 = 0$$

The roots of the above equation are

$$\lambda_1 = 2i$$
$$\lambda_2 = -2i$$
$$\lambda_3 = 1$$
$$\lambda_4 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} + \mathrm{e}^{2ix} c_3 + \mathrm{e}^{-2ix} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= \mathrm{e}^{-x} \\ y_2 &= \mathrm{e}^{x} \\ y_3 &= \mathrm{e}^{2ix} \\ y_4 &= \mathrm{e}^{-2ix} \end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' + 3y'' - 4y = 4\,\mathrm{e}^{x} + 3\cos(2x)$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)}\, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 & y_4 \\ y_1' & y_2' & y_3' & y_4' \\ y_1'' & y_2'' & y_3'' & y_4'' \\ y_1''' & y_2''' & y_3''' & y_4''' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} \mathrm{e}^{-x} & \mathrm{e}^{x} & \mathrm{e}^{2ix} & \mathrm{e}^{-2ix} \\ -\mathrm{e}^{-x} & \mathrm{e}^{x} & 2i\mathrm{e}^{2ix} & -2i\mathrm{e}^{-2ix} \\ \mathrm{e}^{-x} & \mathrm{e}^{x} & -4\,\mathrm{e}^{2ix} & -4\,\mathrm{e}^{-2ix} \\ -\mathrm{e}^{-x} & \mathrm{e}^{x} & -8i\mathrm{e}^{2ix} & 8i\mathrm{e}^{-2ix} \end{bmatrix}$$

$$|W| = -200i\mathrm{e}^{-x}\mathrm{e}^{x}\mathrm{e}^{2ix}\mathrm{e}^{-2ix}$$

The determinant simplifies to

$$|W| = -200i$$

Now we determine W_i for each U_i.

$$W_1(x) = \det\begin{bmatrix} e^x & e^{2ix} & e^{-2ix} \\ e^x & 2ie^{2ix} & -2ie^{-2ix} \\ e^x & -4\,e^{2ix} & -4\,e^{-2ix} \end{bmatrix}$$
$$= -20ie^x$$

$$W_2(x) = \det\begin{bmatrix} e^{-x} & e^{2ix} & e^{-2ix} \\ -e^{-x} & 2ie^{2ix} & -2ie^{-2ix} \\ e^{-x} & -4\,e^{2ix} & -4\,e^{-2ix} \end{bmatrix}$$
$$= -20ie^{-x}$$

$$W_3(x) = \det\begin{bmatrix} e^{-x} & e^x & e^{-2ix} \\ -e^{-x} & e^x & -2ie^{-2ix} \\ e^{-x} & e^x & -4\,e^{-2ix} \end{bmatrix}$$
$$= -10\,e^{-2ix}$$

$$W_4(x) = \det\begin{bmatrix} e^{-x} & e^x & e^{2ix} \\ -e^{-x} & e^x & 2ie^{2ix} \\ e^{-x} & e^x & -4\,e^{2ix} \end{bmatrix}$$
$$= -10\,e^{2ix}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned} U_1 &= (-1)^{4-1}\int \frac{F(x)W_1(x)}{aW(x)}\,dx \\ &= (-1)^3\int \frac{(4\,e^x + 3\cos(2x))\,(-20ie^x)}{(1)\,(-200i)}\,dx \\ &= -\int \frac{-20i(4\,e^x + 3\cos(2x))\,e^x}{-200i}\,dx \\ &= -\int \left(\frac{(4\,e^x + 3\cos(2x))\,e^x}{10}\right)dx \\ &= -\frac{e^{2x}}{5} - \frac{3(\cos(x) + 2\sin(x))\,e^x\cos(x)}{25} + \frac{3\,e^x}{50} \end{aligned}$$

$$
\begin{aligned}
U_2 &= (-1)^{4-2} \int \frac{F(x) W_2(x)}{a W(x)} \, dx \\
&= (-1)^2 \int \frac{(4\,\mathrm{e}^x + 3\cos(2x))\,(-20i\mathrm{e}^{-x})}{(1)\,(-200i)} \, dx \\
&= \int \frac{-20i(4\,\mathrm{e}^x + 3\cos(2x))\,\mathrm{e}^{-x}}{-200i} \, dx \\
&= \int \left(\frac{2}{5} + \frac{3\cos(2x)\,\mathrm{e}^{-x}}{10}\right) dx \\
&= \frac{2x}{5} - \frac{3\cos(2x)\,\mathrm{e}^{-x}}{50} + \frac{3\sin(2x)\,\mathrm{e}^{-x}}{25} \\
&= \frac{2x}{5} - \frac{3\cos(2x)\,\mathrm{e}^{-x}}{50} + \frac{3\sin(2x)\,\mathrm{e}^{-x}}{25}
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{4-3} \int \frac{F(x) W_3(x)}{a W(x)} \, dx \\
&= (-1)^1 \int \frac{(4\,\mathrm{e}^x + 3\cos(2x))\,(-10\,\mathrm{e}^{-2ix})}{(1)\,(-200i)} \, dx \\
&= -\int \frac{-10(4\,\mathrm{e}^x + 3\cos(2x))\,\mathrm{e}^{-2ix}}{-200i} \, dx \\
&= -\int \left(-\frac{i(4\,\mathrm{e}^x + 3\cos(2x))\,\mathrm{e}^{-2ix}}{20}\right) dx \\
&= -\frac{2\,\mathrm{e}^{(1-2i)x}}{25} + \frac{i\mathrm{e}^{(1-2i)x}}{25} + \frac{3ix}{40} - \frac{3\,\mathrm{e}^{-4ix}}{160}
\end{aligned}
$$

$$
\begin{aligned}
U_4 &= (-1)^{4-4} \int \frac{F(x) W_4(x)}{a W(x)} \, dx \\
&= (-1)^0 \int \frac{(4\,\mathrm{e}^x + 3\cos(2x))\,(-10\,\mathrm{e}^{2ix})}{(1)\,(-200i)} \, dx \\
&= \int \frac{-10(4\,\mathrm{e}^x + 3\cos(2x))\,\mathrm{e}^{2ix}}{-200i} \, dx \\
&= \int \left(-\frac{i(4\,\mathrm{e}^x + 3\cos(2x))\,\mathrm{e}^{2ix}}{20}\right) dx \\
&= -\frac{3ix}{40} - \frac{3\,\mathrm{e}^{4ix}}{160} - \frac{2\,\mathrm{e}^{(1+2i)x}}{25} - \frac{i\mathrm{e}^{(1+2i)x}}{25}
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4
$$

Hence

$$
\begin{aligned}
y_p = &\left(-\frac{e^{2x}}{5}-\frac{3(\cos (x)+2\sin (x))\,e^{x}\cos (x)}{25}+\frac{3\,e^{x}}{50}\right)\left(e^{-x}\right)\\
&+\left(\frac{2x}{5}-\frac{3\cos (2x)\,e^{-x}}{50}+\frac{3\sin (2x)\,e^{-x}}{25}\right)\left(e^{x}\right)\\
&+\left(-\frac{2\,e^{(1-2i)x}}{25}+\frac{i e^{(1-2i)x}}{25}+\frac{3ix}{40}-\frac{3\,e^{-4ix}}{160}\right)\left(e^{2ix}\right)\\
&+\left(-\frac{3ix}{40}-\frac{3\,e^{4ix}}{160}-\frac{2\,e^{(1+2i)x}}{25}-\frac{i e^{(1+2i)x}}{25}\right)\left(e^{-2ix}\right)
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = -\frac{63\cos (2x)}{400}-\frac{3x\sin (2x)}{20}+\frac{(10x-9)\,e^{x}}{25}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p\\
&= \left(c_1 e^{-x}+c_2 e^{x}+e^{2ix}c_3+e^{-2ix}c_4\right)+\left(-\frac{63\cos (2x)}{400}-\frac{3x\sin (2x)}{20}+\frac{(10x-9)\,e^{x}}{25}\right)
\end{aligned}
$$

<u>Summary</u>
The solution(s) found are the following

$$
y = c_1 e^{-x}+c_2 e^{x}+e^{2ix}c_3+e^{-2ix}c_4-\frac{63\cos (2x)}{400}-\frac{3x\sin (2x)}{20}+\frac{(10x-9)\,e^{x}}{25} \tag{1}
$$

<u>Verification of solutions</u>

$$
y = c_1 e^{-x}+c_2 e^{x}+e^{2ix}c_3+e^{-2ix}c_4-\frac{63\cos (2x)}{400}-\frac{3x\sin (2x)}{20}+\frac{(10x-9)\,e^{x}}{25}
$$

Verified OK.

14.11.1 Maple step by step solution

Let's solve

$y'''' + 3y'' - 4y = 4\,e^{x} + 3\cos (2x)$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs

- Define new variable $y_1(x)$

  $y_1(x) = y$
- Define new variable $y_2(x)$

  $y_2(x) = y'$
- Define new variable $y_3(x)$

  $y_3(x) = y''$
- Define new variable $y_4(x)$

  $y_4(x) = y'''$
- Isolate for $y_4'(x)$ using original ODE

  $y_4'(x) = 4\,\mathrm{e}^{x} + 3\cos(2x) - 3y_3(x) + 4y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = 4\,\mathrm{e}^{x} + 3\cos(2x) - 3y_3(x) + 4y_1(x)]$

• Define vector

$$\overrightarrow{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

• System to solve

$$\overrightarrow{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 4 & 0 & -3 & 0 \end{bmatrix} \cdot \overrightarrow{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ 4\,\mathrm{e}^{x} + 3\cos(2x) \end{bmatrix}$$

• Define the forcing function

$$\overrightarrow{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 4\,\mathrm{e}^{x} + 3\cos(2x) \end{bmatrix}$$

• Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 4 & 0 & -3 & 0 \end{bmatrix}$$

- Rewrite the system as

  $$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

  $$\left[\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[-2\,\mathrm{I}, \begin{bmatrix} -\frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right], \left[2\,\mathrm{I}, \begin{bmatrix} \frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ -\frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

  $$\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

  $$\vec{y}_1 = \mathrm{e}^{-x} \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

  $$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-2\,\mathrm{I}, \begin{bmatrix} -\frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-2\,\mathrm{I}x} \cdot \begin{bmatrix} -\frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(2x) - \mathrm{I}\sin(2x)) \cdot \begin{bmatrix} -\frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\frac{\mathrm{I}}{8}(\cos(2x) - \mathrm{I}\sin(2x)) \\ -\frac{\cos(2x)}{4} + \frac{\mathrm{I}\sin(2x)}{4} \\ \frac{\mathrm{I}}{2}(\cos(2x) - \mathrm{I}\sin(2x)) \\ \cos(2x) - \mathrm{I}\sin(2x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \begin{bmatrix} -\frac{\sin(2x)}{8} \\ -\frac{\cos(2x)}{4} \\ \frac{\sin(2x)}{2} \\ \cos(2x) \end{bmatrix}, \vec{y}_4(x) = \begin{bmatrix} -\frac{\cos(2x)}{8} \\ \frac{\sin(2x)}{4} \\ \frac{\cos(2x)}{2} \\ -\sin(2x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} -e^{-x} & e^{x} & -\frac{\sin(2x)}{8} & -\frac{\cos(2x)}{8} \\ e^{-x} & e^{x} & -\frac{\cos(2x)}{4} & \frac{\sin(2x)}{4} \\ -e^{-x} & e^{x} & \frac{\sin(2x)}{2} & \frac{\cos(2x)}{2} \\ e^{-x} & e^{x} & \cos(2x) & -\sin(2x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} -e^{-x} & e^{x} & -\frac{\sin(2x)}{8} & -\frac{\cos(2x)}{8} \\ e^{-x} & e^{x} & -\frac{\cos(2x)}{4} & \frac{\sin(2x)}{4} \\ -e^{-x} & e^{x} & \frac{\sin(2x)}{2} & \frac{\cos(2x)}{2} \\ e^{-x} & e^{x} & \cos(2x) & -\sin(2x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -1 & 1 & 0 & -\frac{1}{8} \\ 1 & 1 & -\frac{1}{4} & 0 \\ -1 & 1 & 0 & \frac{1}{2} \\ 1 & 1 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} \frac{2e^{-x}}{5} + \frac{2e^{x}}{5} + \frac{\cos(2x)}{5} & -\frac{2e^{-x}}{5} + \frac{2e^{x}}{5} + \frac{\sin(2x)}{10} & \frac{e^{-x}}{10} + \frac{e^{x}}{10} - \frac{\cos(2x)}{5} & -\frac{e^{-x}}{10} + \frac{e^{x}}{10} - \mathrm{si} \\ -\frac{2e^{-x}}{5} + \frac{2e^{x}}{5} - \frac{2\sin(2x)}{5} & \frac{2e^{-x}}{5} + \frac{2e^{x}}{5} + \frac{\cos(2x)}{5} & -\frac{e^{-x}}{10} + \frac{e^{x}}{10} + \frac{2\sin(2x)}{5} & \frac{e^{-x}}{10} + \frac{e^{x}}{10} - \mathrm{cos} \\ \frac{2e^{-x}}{5} + \frac{2e^{x}}{5} - \frac{4\cos(2x)}{5} & -\frac{2e^{-x}}{5} + \frac{2e^{x}}{5} - \frac{2\sin(2x)}{5} & \frac{e^{-x}}{10} + \frac{e^{x}}{10} + \frac{4\cos(2x)}{5} & -\frac{e^{-x}}{10} + \frac{e^{x}}{10} + 2\mathrm{s} \\ -\frac{2e^{-x}}{5} + \frac{2e^{x}}{5} + \frac{8\sin(2x)}{5} & \frac{2e^{-x}}{5} + \frac{2e^{x}}{5} - \frac{4\cos(2x)}{5} & -\frac{e^{-x}}{10} + \frac{e^{x}}{10} - \frac{8\sin(2x)}{5} & \frac{e^{-x}}{10} + \frac{e^{x}}{10} + 4\mathrm{co} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

$\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \left[\begin{array}{c} \frac{(-15x+8)\sin(2x)}{100} + \frac{\cos(2x)}{25} + \frac{13\,\mathrm{e}^{-x}}{50} + \frac{(4x-3)\mathrm{e}^{x}}{10} \\ \frac{(-15x+8)\cos(2x)}{50} - \frac{13\,\mathrm{e}^{-x}}{50} - \frac{23\sin(2x)}{100} + \frac{(4x+1)\mathrm{e}^{x}}{10} \\ \frac{(15x-8)\sin(2x)}{25} - \frac{19\cos(2x)}{25} + \frac{13\,\mathrm{e}^{-x}}{50} + \frac{(4x+5)\mathrm{e}^{x}}{10} \\ \frac{2(15x-8)\cos(2x)}{25} - \frac{13\,\mathrm{e}^{-x}}{50} + \frac{53\sin(2x)}{25} + \frac{(4x+9)\mathrm{e}^{x}}{10} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \left[\begin{array}{c} \frac{(-15x+8)\sin(2x)}{100} + \frac{\cos(2x)}{25} + \frac{13\,\mathrm{e}^{-x}}{50} + \frac{(4x-3)\mathrm{e}^{x}}{10} \\ \frac{(-15x+8)\cos(2x)}{50} - \frac{13\,\mathrm{e}^{-x}}{50} - \frac{23\sin(2x)}{100} + \frac{(4x+1)\mathrm{e}^{x}}{10} \\ \frac{(15x-8)\sin(2x)}{25} - \frac{19\cos(2x)}{25} + \frac{13\,\mathrm{e}^{-x}}{50} + \frac{(4x+5)\mathrm{e}^{x}}{10} \\ \frac{2(15x-8)\cos(2x)}{25} - \frac{13\,\mathrm{e}^{-x}}{50} + \frac{53\sin(2x)}{25} + \frac{(4x+9)\mathrm{e}^{x}}{10} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = \frac{(-25c_3-30x+16)\sin(2x)}{200} + \frac{(-25c_4+8)\cos(2x)}{200} + \frac{(13-50c_1)\mathrm{e}^{-x}}{50} + \frac{2\left(x+\frac{5c_2}{2}-\frac{3}{4}\right)\mathrm{e}^{x}}{5}$$

```

$$\boxed{y'' + y = e^{3x}(1 + \sin(2x))}$$

14.12.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = e^{3x}(1 + \sin(2x))$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(1)}\\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i\\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i\\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{3x}(1 + \sin(2x))$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{3x}\}, \{e^{3x}\cos(2x), e^{3x}\sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{3x} + A_2 e^{3x}\cos(2x) + A_3 e^{3x}\sin(2x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}10A_1 e^{3x} + 6A_2 e^{3x}\cos(2x) - 12A_2 e^{3x}\sin(2x) + 6A_3 e^{3x}\sin(2x) + 12A_3 e^{3x}\cos(2x) \\ = e^{3x}(1 + \sin(2x))\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{10}, A_2 = -\frac{1}{15}, A_3 = \frac{1}{30}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{3x}}{10} - \frac{e^{3x}\cos(2x)}{15} + \frac{e^{3x}\sin(2x)}{30}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + \left(\frac{e^{3x}}{10} - \frac{e^{3x}\cos(2x)}{15} + \frac{e^{3x}\sin(2x)}{30}\right)\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{e^{3x}}{10} - \frac{e^{3x} \cos(2x)}{15} + \frac{e^{3x} \sin(2x)}{30} \tag{1}$$

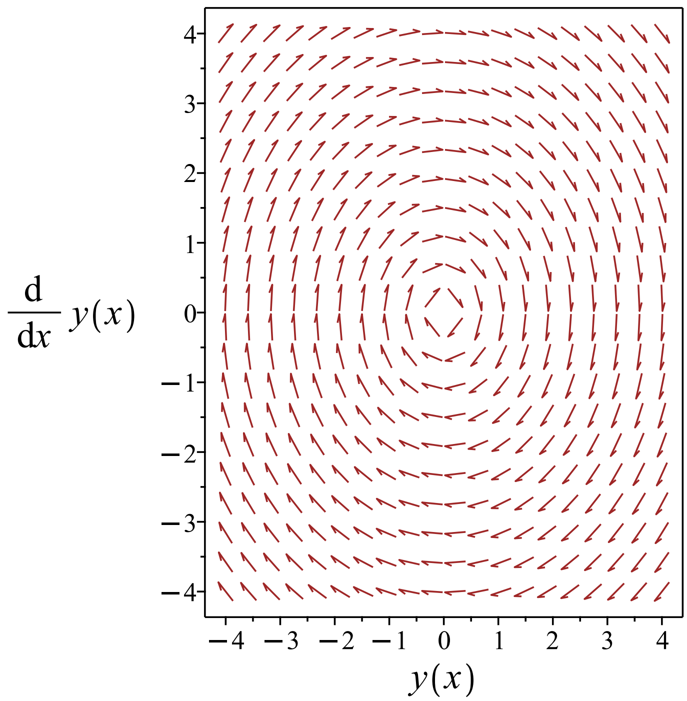

Figure 650: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{e^{3x}}{10} - \frac{e^{3x} \cos(2x)}{15} + \frac{e^{3x} \sin(2x)}{30}$$

Verified OK.

14.12.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 493: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\,dx \\ &= \cos(x)\,(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{3x}(1 + \sin(2x))$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{3x}\}, \{e^{3x}\cos(2x), e^{3x}\sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{3x} + A_2 e^{3x}\cos(2x) + A_3 e^{3x}\sin(2x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$10A_1 e^{3x} + 6A_2 e^{3x}\cos(2x) - 12A_2 e^{3x}\sin(2x) + 6A_3 e^{3x}\sin(2x) + 12A_3 e^{3x}\cos(2x) \\ = e^{3x}(1 + \sin(2x))$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{10}, A_2 = -\frac{1}{15}, A_3 = \frac{1}{30}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{3x}}{10} - \frac{e^{3x}\cos(2x)}{15} + \frac{e^{3x}\sin(2x)}{30}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + \left(\frac{e^{3x}}{10} - \frac{e^{3x}\cos(2x)}{15} + \frac{e^{3x}\sin(2x)}{30}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\cos(x) + c_2\sin(x) + \frac{e^{3x}}{10} - \frac{e^{3x}\cos(2x)}{15} + \frac{e^{3x}\sin(2x)}{30} \tag{1}$$

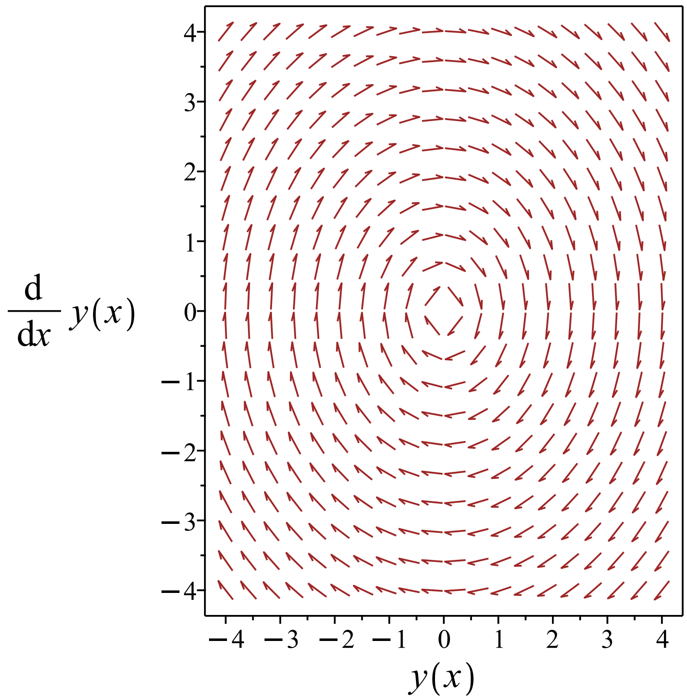

Figure 651: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{e^{3x}}{10} - \frac{e^{3x} \cos(2x)}{15} + \frac{e^{3x} \sin(2x)}{30}$$

Verified OK.

14.12.3 Maple step by step solution

Let's solve

$y'' + y = e^{3x}(1 + \sin(2x))$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

$r=(-\mathrm{I},\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x)=\cos(x)$
- 2nd solution of the homogeneous ODE

  $y_2(x)=\sin(x)$
- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)+y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y=c_1\cos(x)+c_2\sin(x)+y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x)=-y_1(x)\left(\int\frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right)+y_2(x)\left(\int\frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right),f(x)=\mathrm{e}^{3x}(1+\sin(2x))\right]$
- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x),y_2(x))=\left[\begin{array}{cc}\cos(x) & \sin(x)\\ -\sin(x) & \cos(x)\end{array}\right]$
- ○ Compute Wronskian

  $W(y_1(x),y_2(x))=1$
- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x)=-\cos(x)\left(\int\sin(x)\,\mathrm{e}^{3x}(1+\sin(2x))\,dx\right)+\sin(x)\left(\int\cos(x)\,\mathrm{e}^{3x}(1+\sin(2x))\,dx\right)$
- ○ Compute integrals

  $y_p(x)=-\frac{\mathrm{e}^{3x}(2\cos(2x)-\sin(2x)-3)}{30}$

- Substitute particular solution into general solution to ODE

  $y=c_1\cos(x)+c_2\sin(x)-\frac{\mathrm{e}^{3x}(2\cos(2x)-\sin(2x)-3)}{30}$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 2n^2y' + n^4y = \sin(kx)}$$

14.13.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2n^2, C = n^4, f(x) = \sin(kx)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2n^2y' + n^4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2n^2, C = n^4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 2n^2 \lambda \,\mathrm{e}^{\lambda x} + n^4 \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$n^4 + 2n^2 \lambda + \lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2n^2, C = n^4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2n^2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{(2n^2)^2 - (4)\,(1)\,(n^4)}\\ &= -n^2\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = n^2$. Therefore the solution is

$$y = c_1 \mathrm{e}^{-n^2 x} + c_2 x \,\mathrm{e}^{-n^2 x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{-n^2 x} + c_2 x \,\mathrm{e}^{-n^2 x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(kx)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(kx), \sin(kx)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x \,\mathrm{e}^{-n^2 x}, \mathrm{e}^{-n^2 x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(kx) + A_2 \sin(kx)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1k^2 \cos(kx) - A_2k^2 \sin(kx) + 2n^2(-A_1k \sin(kx) + A_2k \cos(kx)) \\ + n^4(A_1 \cos(kx) + A_2 \sin(kx)) = \sin(kx)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{2k\,n^2}{(n^4+k^2)^2}, A_2 = \frac{n^4-k^2}{(n^4+k^2)^2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{2k\,n^2 \cos(kx)}{(n^4+k^2)^2} + \frac{(n^4-k^2)\sin(kx)}{(n^4+k^2)^2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-n^2x} + c_2x\,e^{-n^2x}\right) + \left(-\frac{2k\,n^2 \cos(kx)}{(n^4+k^2)^2} + \frac{(n^4-k^2)\sin(kx)}{(n^4+k^2)^2}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-n^2x}(c_2x + c_1) - \frac{2k\,n^2 \cos(kx)}{(n^4+k^2)^2} + \frac{(n^4-k^2)\sin(kx)}{(n^4+k^2)^2}$$

Summary

The solution(s) found are the following

$$y = e^{-n^2x}(c_2x + c_1) - \frac{2k\,n^2 \cos(kx)}{(n^4+k^2)^2} + \frac{(n^4-k^2)\sin(kx)}{(n^4+k^2)^2} \tag{1}$$

Verification of solutions

$$y = e^{-n^2x}(c_2x + c_1) - \frac{2k\,n^2 \cos(kx)}{(n^4+k^2)^2} + \frac{(n^4-k^2)\sin(kx)}{(n^4+k^2)^2}$$

Verified OK.

14.13.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = 2n^2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int 2n^2\, dx} \\ &= \mathrm{e}^{n^2 x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= \mathrm{e}^{n^2 x} \sin(kx) \\ \left(\mathrm{e}^{n^2 x} y\right)'' &= \mathrm{e}^{n^2 x} \sin(kx) \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{n^2 x} y\right)' = \frac{\mathrm{e}^{n^2 x}\left(-k\cos(kx) + \sin(kx)\, n^2\right)}{n^4 + k^2} + c_1$$

Integrating again gives

$$\left(\mathrm{e}^{n^2 x} y\right) = \frac{\left((n^4 - k^2)\sin(kx) - 2k\, n^2 \cos(kx)\right) \mathrm{e}^{n^2 x} + c_1 x (n^4 + k^2)^2}{(n^4 + k^2)^2} + c_2$$

Hence the solution is

$$y = \frac{\frac{\left((n^4 - k^2)\sin(kx) - 2k\, n^2 \cos(kx)\right) \mathrm{e}^{n^2 x} + c_1 x (n^4 + k^2)^2}{(n^4 + k^2)^2} + c_2}{\mathrm{e}^{n^2 x}}$$

Or

$$\begin{aligned} y = {} & \frac{n^4 \sin(kx)}{(n^4 + k^2)^2} - \frac{2k\, n^2 \cos(kx)}{(n^4 + k^2)^2} - \frac{k^2 \sin(kx)}{(n^4 + k^2)^2} \\ & + \left(\frac{n^8 x\, \mathrm{e}^{-n^2 x}}{(n^4 + k^2)^2} + \frac{2k^2 n^4 x\, \mathrm{e}^{-n^2 x}}{(n^4 + k^2)^2} + \frac{k^4 x\, \mathrm{e}^{-n^2 x}}{(n^4 + k^2)^2}\right) c_1 + c_2 \mathrm{e}^{-n^2 x} \end{aligned}$$

Summary
The solution(s) found are the following

$$
\begin{align*}
y &= \frac{n^4 \sin(kx)}{(n^4+k^2)^2} - \frac{2k\, n^2 \cos(kx)}{(n^4+k^2)^2} - \frac{k^2 \sin(kx)}{(n^4+k^2)^2} \\
&\quad + \left(\frac{n^8 x\, \mathrm{e}^{-n^2 x}}{(n^4+k^2)^2} + \frac{2k^2 n^4 x\, \mathrm{e}^{-n^2 x}}{(n^4+k^2)^2} + \frac{k^4 x\, \mathrm{e}^{-n^2 x}}{(n^4+k^2)^2}\right) c_1 + c_2 \mathrm{e}^{-n^2 x} \tag{1}
\end{align*}
$$

Verification of solutions

$$
\begin{align*}
y &= \frac{n^4 \sin(kx)}{(n^4+k^2)^2} - \frac{2k\, n^2 \cos(kx)}{(n^4+k^2)^2} - \frac{k^2 \sin(kx)}{(n^4+k^2)^2} \\
&\quad + \left(\frac{n^8 x\, \mathrm{e}^{-n^2 x}}{(n^4+k^2)^2} + \frac{2k^2 n^4 x\, \mathrm{e}^{-n^2 x}}{(n^4+k^2)^2} + \frac{k^4 x\, \mathrm{e}^{-n^2 x}}{(n^4+k^2)^2}\right) c_1 + c_2 \mathrm{e}^{-n^2 x}
\end{align*}
$$

Verified OK.

14.13.3 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{align*}
y'' + 2n^2 y' + n^4 y &= 0 \tag{1} \\
Ay'' + By' + Cy &= 0 \tag{2}
\end{align*}
$$

Comparing (1) and (2) shows that

$$
\begin{align*}
A &= 1 \\
B &= 2n^2 \tag{3} \\
C &= n^4
\end{align*}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{align*}
r &= \frac{s}{t} \tag{5} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{align*}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 495: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2n^2}{1}\,dx} \\
&= z_1 e^{-n^2 x} \\
&= z_1 \left(\mathrm{e}^{-n^2 x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-n^2 x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2n^2}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2n^2 x}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-n^2 x}\right) + c_2\left(\mathrm{e}^{-n^2 x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 2n^2 y' + n^4 y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-n^2 x} + c_2 x\,\mathrm{e}^{-n^2 x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
\sin(kx)
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\cos(kx), \sin(kx)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{x\,\mathrm{e}^{-n^2 x}, \mathrm{e}^{-n^2 x}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 \cos(kx) + A_2 \sin(kx)
$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
\begin{aligned}
&-A_1 k^2 \cos(kx) - A_2 k^2 \sin(kx) + 2n^2(-A_1 k \sin(kx) + A_2 k \cos(kx)) \\
&+ n^4(A_1 \cos(kx) + A_2 \sin(kx)) = \sin(kx)
\end{aligned}
$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{2k\,n^2}{\left(n^4+k^2\right)^2}, A_2 = \frac{n^4-k^2}{\left(n^4+k^2\right)^2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{2k\,n^2\cos\left(kx\right)}{\left(n^4+k^2\right)^2} + \frac{\left(n^4-k^2\right)\sin\left(kx\right)}{\left(n^4+k^2\right)^2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-n^2 x} + c_2 x\,\mathrm{e}^{-n^2 x}\right) + \left(-\frac{2k\,n^2\cos\left(kx\right)}{\left(n^4+k^2\right)^2} + \frac{\left(n^4-k^2\right)\sin\left(kx\right)}{\left(n^4+k^2\right)^2}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{-n^2 x}(c_2 x + c_1) - \frac{2k\,n^2\cos\left(kx\right)}{\left(n^4+k^2\right)^2} + \frac{\left(n^4-k^2\right)\sin\left(kx\right)}{\left(n^4+k^2\right)^2}$$

Summary
The solution(s) found are the following

$$y = \mathrm{e}^{-n^2 x}(c_2 x + c_1) - \frac{2k\,n^2\cos\left(kx\right)}{\left(n^4+k^2\right)^2} + \frac{\left(n^4-k^2\right)\sin\left(kx\right)}{\left(n^4+k^2\right)^2} \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{-n^2 x}(c_2 x + c_1) - \frac{2k\,n^2\cos\left(kx\right)}{\left(n^4+k^2\right)^2} + \frac{\left(n^4-k^2\right)\sin\left(kx\right)}{\left(n^4+k^2\right)^2}$$

Verified OK.

14.13.4 Maple step by step solution

Let's solve

$y'' + 2n^2 y' + n^4 y = \sin\left(kx\right)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $n^4 + 2n^2 r + r^2 = 0$

- Factor the characteristic polynomial

  $(n^2 + r)^2 = 0$

- Root of the characteristic polynomial

  $r = -n^2$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-n^2 x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^{-n^2 x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-n^2 x} + c_2 x\,e^{-n^2 x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \sin(kx)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-n^2 x} & x\,e^{-n^2 x} \\ -n^2 e^{-n^2 x} & e^{-n^2 x} - x\,n^2 e^{-n^2 x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = e^{-2n^2 x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = e^{-n^2 x}\left(-\left(\int x \sin(kx)\,e^{n^2 x} dx\right) + x\left(\int e^{n^2 x} \sin(kx)\,dx\right)\right)$

  - Compute integrals

    $y_p(x) = \frac{(n^4 - k^2)\sin(kx) - 2k\,n^2 \cos(kx)}{(n^4 + k^2)^2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-n^2 x} + c_2 x\,e^{-n^2 x} + \frac{(n^4 - k^2)\sin(kx) - 2k\,n^2 \cos(kx)}{(n^4 + k^2)^2}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 4y' + 5y = \frac{e^{x}}{2} + \frac{e^{-x}}{2}}$$

14.14.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 4, C = 5, f(x) = \frac{e^{x}}{2} + \frac{e^{-x}}{2}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 4, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4\lambda\, e^{\lambda x} + 5\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 4, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{4^2 - (4)\,(1)\,(5)}\\ &= -2 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -2 + i\\ \lambda_2 &= -2 - i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -2 + i\\ \lambda_2 &= -2 - i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -2$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-2x}(c_1 \cos(x) + c_2 \sin(x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\frac{e^{x}}{2}+\frac{e^{-x}}{2}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{x}\},\{e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-2x}\cos(x), e^{-2x}\sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{x} + A_2 e^{-x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$10A_1 e^{x} + 2A_2 e^{-x} = \frac{e^{x}}{2}+\frac{e^{-x}}{2}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{20}, A_2 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{x}}{20}+\frac{e^{-x}}{4}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(e^{-2x}(c_1\cos(x)+c_2\sin(x))\right)+\left(\frac{e^{x}}{20}+\frac{e^{-x}}{4}\right)
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{e^{x}}{20} + \frac{e^{-x}}{4} \tag{1}$$

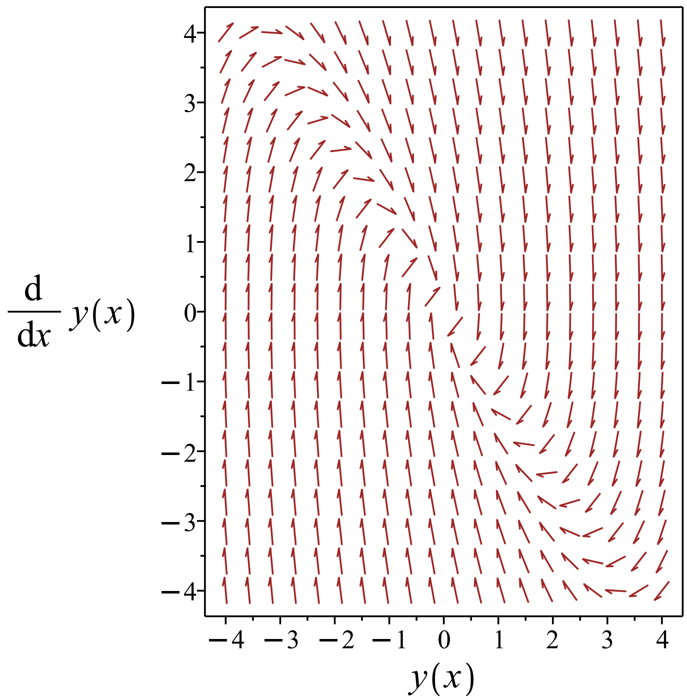

Figure 652: Slope field plot

Verification of solutions

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{e^{x}}{20} + \frac{e^{-x}}{4}$$

Verified OK.

14.14.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 4 \qquad (3) \\
C &= 5
\end{aligned}
$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \qquad (4)$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \qquad (5) \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \qquad (6)$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -1 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \qquad (7)$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 497: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4}{1}\,dx} \\ &= z_1 e^{-2x} \\ &= z_1\left(\mathrm{e}^{-2x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x} \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{4}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-4x}}{(y_1)^2}\,dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-2x}\cos(x)\right) + c_2\left(\mathrm{e}^{-2x}\cos(x)(\tan(x))\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 5y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \cos(x)\,\mathrm{e}^{-2x} c_1 + \sin(x)\,\mathrm{e}^{-2x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\frac{\mathrm{e}^{x}}{2} + \frac{\mathrm{e}^{-x}}{2}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{x}\}, \{e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-2x}\cos(x), e^{-2x}\sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{x} + A_2 e^{-x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$10A_1 e^{x} + 2A_2 e^{-x} = \frac{e^{x}}{2} + \frac{e^{-x}}{2}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{20}, A_2 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{x}}{20} + \frac{e^{-x}}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\cos(x)\, e^{-2x} c_1 + \sin(x)\, e^{-2x} c_2\right) + \left(\frac{e^{x}}{20} + \frac{e^{-x}}{4}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{e^{x}}{20} + \frac{e^{-x}}{4}$$

Summary

The solution(s) found are the following

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{e^{x}}{20} + \frac{e^{-x}}{4} \tag{1}$$

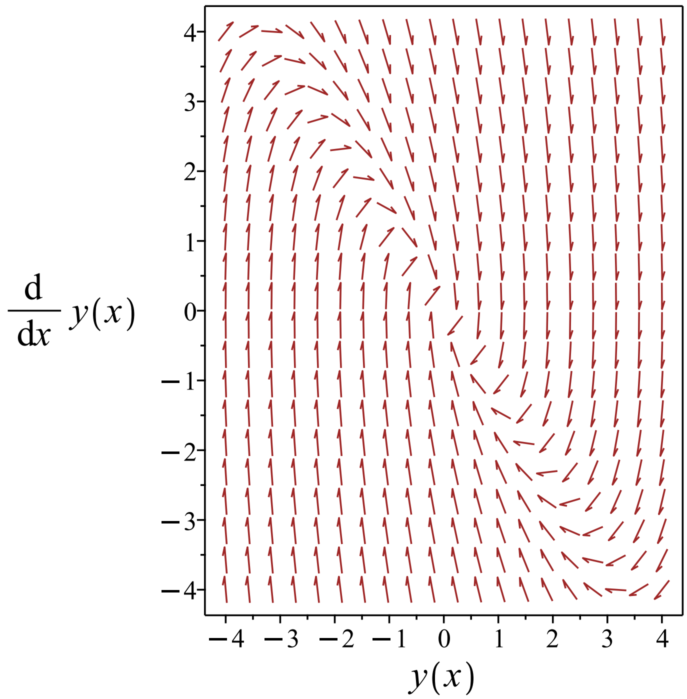

Figure 653: Slope field plot

Verification of solutions

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{e^{x}}{20} + \frac{e^{-x}}{4}$$

Verified OK.

14.14.3 Maple step by step solution

Let's solve

$y'' + 4y' + 5y = \frac{e^{x}}{2} + \frac{e^{-x}}{2}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 + 4r + 5 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-4)\pm(\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-2 - \mathrm{I}, -2 + \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-2x} \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-2x} \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \cos(x)\,\mathrm{e}^{-2x} c_1 + \sin(x)\,\mathrm{e}^{-2x} c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \frac{\mathrm{e}^{x}}{2} + \frac{\mathrm{e}^{-x}}{2}\right]$

- ◦ Wronskian of solutions of the homogeneous equation

  $$W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-2x}\cos(x) & \mathrm{e}^{-2x}\sin(x) \\ -2\,\mathrm{e}^{-2x}\cos(x) - \mathrm{e}^{-2x}\sin(x) & -2\,\mathrm{e}^{-2x}\sin(x) + \mathrm{e}^{-2x}\cos(x) \end{bmatrix}$$

- ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = \mathrm{e}^{-4x}$

- ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = \frac{\mathrm{e}^{-2x}\left(-\cos(x)\left(\int (\mathrm{e}^{2x}+1)\sin(x)\mathrm{e}^{x}dx\right)+\sin(x)\left(\int (\mathrm{e}^{2x}+1)\cos(x)\mathrm{e}^{x}dx\right)\right)}{2}$

- ◦ Compute integrals

  $y_p(x) = \frac{\mathrm{e}^{x}}{20} + \frac{\mathrm{e}^{-x}}{4}$

- Substitute particular solution into general solution to ODE

  $y = \sin(x)\,\mathrm{e}^{-2x} c_2 + \cos(x)\,\mathrm{e}^{-2x} c_1 + \frac{\mathrm{e}^{x}}{20} + \frac{\mathrm{e}^{-x}}{4}$

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + y' - 2y = x\,\mathrm{e}^{-x}}$$

14.15.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = -2, f(x) = x\,\mathrm{e}^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' - 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 1, C = -2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + \lambda\, e^{\lambda x} - 2\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + \lambda - 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 1, C = -2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-1}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{1^2 - (4)\,(1)\,(-2)}\\ &= -\frac{1}{2} \pm \frac{3}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{1}{2} + \frac{3}{2}\\ \lambda_2 &= -\frac{1}{2} - \frac{3}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1\\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(1)x} + c_2 e^{(-2)x}\end{aligned}$$

Or

$$y = c_1 e^{x} + c_2 e^{-2x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{x} + c_2 e^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x\,e^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^{-x}, e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{-2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,e^{-x} + A_2 e^{-x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 e^{-x} - 2A_1 x\,e^{-x} - 2A_2 e^{-x} = x\,e^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{2}, A_2 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\,e^{-x}}{2} + \frac{e^{-x}}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{x} + c_2 e^{-2x}\right) + \left(-\frac{x\,e^{-x}}{2} + \frac{e^{-x}}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{x} + c_2 e^{-2x} - \frac{x\,e^{-x}}{2} + \frac{e^{-x}}{4} \tag{1}$$

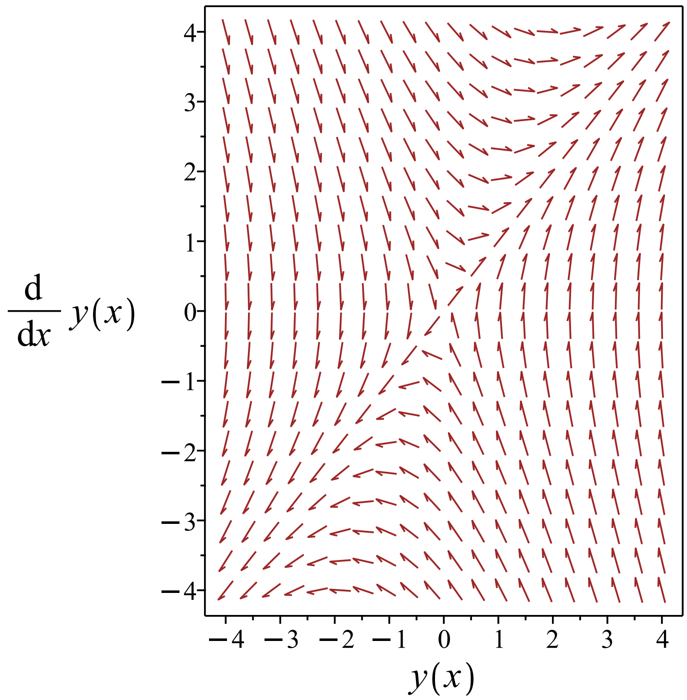

Figure 654: Slope field plot

Verification of solutions

$$y = c_1 e^{x} + c_2 e^{-2x} - \frac{x\,e^{-x}}{2} + \frac{e^{-x}}{4}$$

Verified OK.

14.15.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 1 \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = 9$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 499: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\,dx} \\ &= z_1 e^{-\frac{x}{2}} \\ &= z_1 \left(\mathrm{e}^{-\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{1}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-x}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{\mathrm{e}^{3x}}{3}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-2x}\right) + c_2\left(\mathrm{e}^{-2x}\left(\frac{\mathrm{e}^{3x}}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + y' - 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1\mathrm{e}^{-2x} + \frac{c_2\mathrm{e}^{x}}{3}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
x\,\mathrm{e}^{-x}
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{x\,\mathrm{e}^{-x}, \mathrm{e}^{-x}\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\frac{\mathrm{e}^{x}}{3}, \mathrm{e}^{-2x}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 x\,\mathrm{e}^{-x} + A_2\mathrm{e}^{-x}
$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 \mathrm{e}^{-x} - 2A_1 x \,\mathrm{e}^{-x} - 2A_2 \mathrm{e}^{-x} = x \,\mathrm{e}^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{2}, A_2 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x \,\mathrm{e}^{-x}}{2} + \frac{\mathrm{e}^{-x}}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-2x} + \frac{c_2 \mathrm{e}^{x}}{3}\right) + \left(-\frac{x \,\mathrm{e}^{-x}}{2} + \frac{\mathrm{e}^{-x}}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-2x} + \frac{c_2 \mathrm{e}^{x}}{3} - \frac{x \,\mathrm{e}^{-x}}{2} + \frac{\mathrm{e}^{-x}}{4} \tag{1}$$

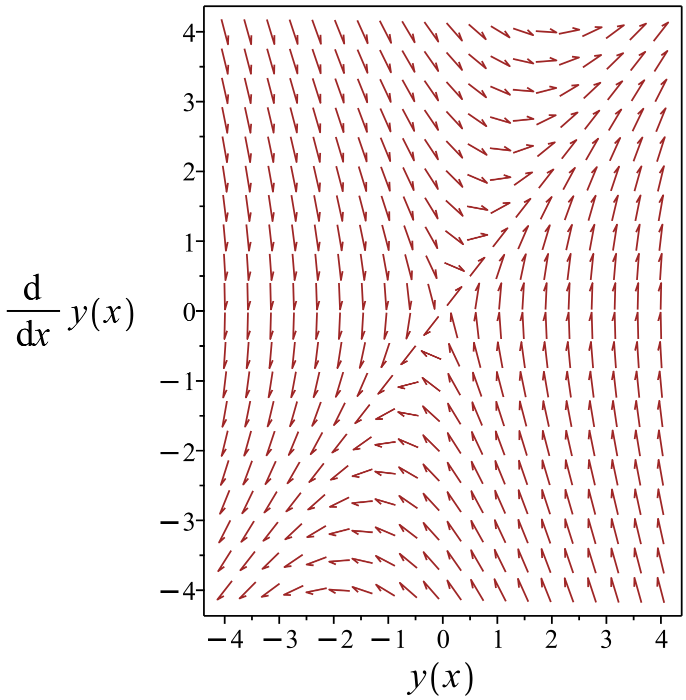

Figure 655: Slope field plot

Verification of solutions

$$y = c_1 e^{-2x} + \frac{c_2 e^{x}}{3} - \frac{x\, e^{-x}}{2} + \frac{e^{-x}}{4}$$

Verified OK.

14.15.3 Maple step by step solution

Let's solve

$y'' + y' - 2y = x\, e^{-x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + r - 2 = 0$

- Factor the characteristic polynomial

  $(r + 2)(r - 1) = 0$

- Roots of the characteristic polynomial

$r = (-2, 1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-2x} + c_2 e^{x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = x\,e^{-x}\right]$

  - Wronskian of solutions of the homogeneous equation

    $$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-2x} & e^{x} \\ -2\,e^{-2x} & e^{x} \end{bmatrix}$$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 3\,e^{-x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = \frac{\left(e^{3x}\left(\int e^{-2x} x dx\right) - \left(\int x\,e^{x} dx\right)\right)e^{-2x}}{3}$

  - Compute integrals

    $y_p(x) = -\frac{e^{-x}(2x-1)}{4}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-2x} + c_2 e^{x} - \frac{e^{-x}(2x-1)}{4}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 4y = x\,e^{x}}$$

14.16.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 4, f(x) = x\,e^{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(4)}\\ &= \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2i\\ \lambda_2 &= -2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2i\\ \lambda_2 &= -2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(2x) + c_2 \sin(2x))$$

Or

$$y = c_1 \cos(2x) + c_2 \sin(2x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(2x) + c_2 \sin(2x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x\,e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^x, e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(2x), \sin(2x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,e^x + A_2 e^x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^x + 5A_1 x\,e^x + 5A_2 e^x = x\,e^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{5}, A_2 = -\frac{2}{25}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x\,e^x}{5} - \frac{2\,e^x}{25}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(2x) + c_2 \sin(2x)) + \left(\frac{x\,e^x}{5} - \frac{2\,e^x}{25}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \cos(2x) + c_2 \sin(2x) + \frac{x\,e^{x}}{5} - \frac{2\,e^{x}}{25} \tag{1}$$

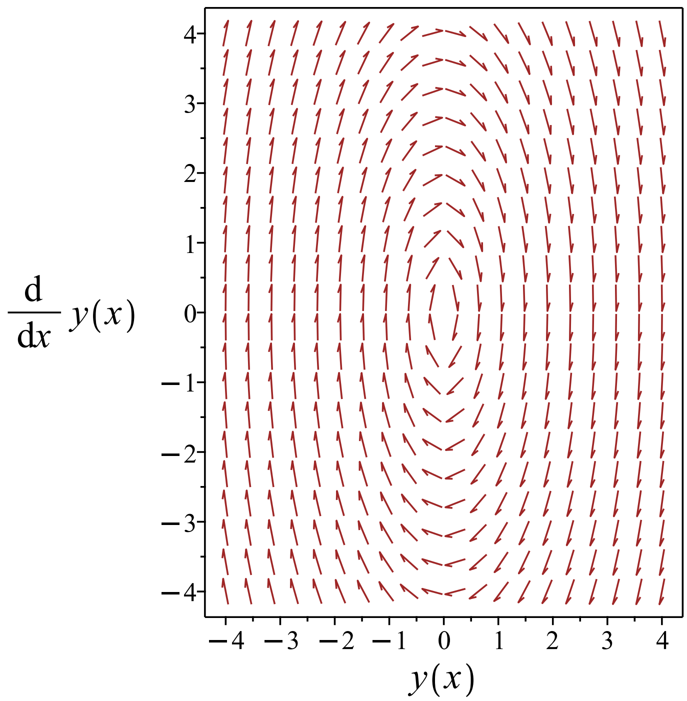

Figure 656: Slope field plot

Verification of solutions

$$y = c_1 \cos(2x) + c_2 \sin(2x) + \frac{x\,e^{x}}{5} - \frac{2\,e^{x}}{25}$$

Verified OK.

14.16.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 0 \\
C &= 4
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\,dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-4}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -4 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = -4z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\,dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 501: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(2x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(2x) \int \frac{1}{\cos(2x)^2}\,dx \\ &= \cos(2x)\left(\frac{\tan(2x)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(2x)) + c_2\left(\cos(2x)\left(\frac{\tan(2x)}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x\,e^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^{x}, e^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sin(2x)}{2}, \cos(2x)\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,e^{x} + A_2 e^{x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{x} + 5A_1 x\,e^{x} + 5A_2 e^{x} = x\,e^{x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{5}, A_2 = -\frac{2}{25}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x\,e^{x}}{5} - \frac{2\,e^{x}}{25}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2}\right) + \left(\frac{x\,e^{x}}{5} - \frac{2\,e^{x}}{25}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2} + \frac{x\,e^{x}}{5} - \frac{2\,e^{x}}{25} \tag{1}$$

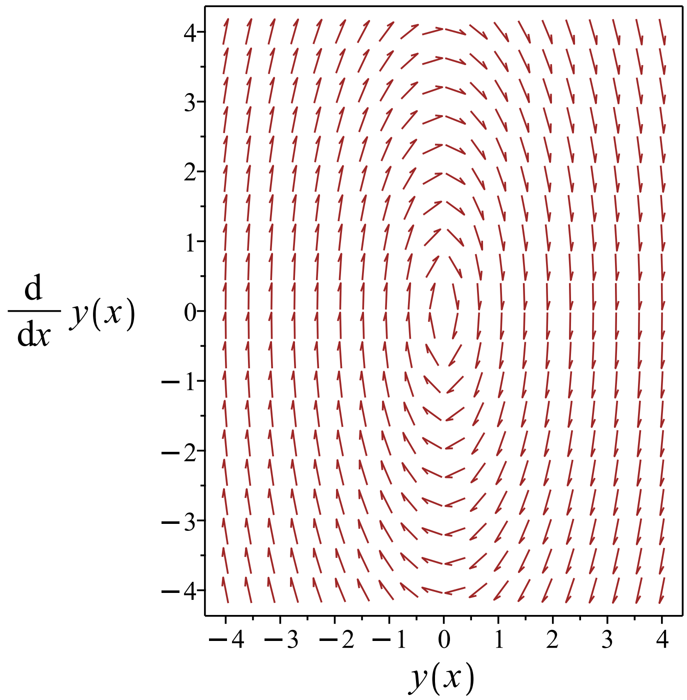

Figure 657: Slope field plot

Verification of solutions

$$y = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2} + \frac{x\,e^x}{5} - \frac{2\,e^x}{25}$$

Verified OK.

14.16.3 Maple step by step solution

Let's solve

$y'' + 4y = x\,e^x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

$r = (-2\,\mathrm{I}, 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(2x) + c_2 \sin(2x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x\,\mathrm{e}^x\right]$

  ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(2x) & \sin(2x) \\ -2\sin(2x) & 2\cos(2x) \end{bmatrix}$

  ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2$

  ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\cos(2x)\left(\int \sin(2x)\mathrm{e}^x x dx\right)}{2} + \frac{\sin(2x)\left(\int \cos(2x)\mathrm{e}^x x dx\right)}{2}$

  ○ Compute integrals

  $y_p(x) = \frac{\mathrm{e}^x(5x-2)}{25}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(2x) + c_2 \sin(2x) + \frac{\mathrm{e}^x(5x-2)}{25}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 2y = x^2 \mathrm{e}^{-x}}$$

14.17.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 2, f(x) = x^2 \mathrm{e}^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 2\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(2)}\\ &= \pm i\sqrt{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i\sqrt{2}\\ \lambda_2 &= -i\sqrt{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i\sqrt{2}\\ \lambda_2 &= -i\sqrt{2}\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = \sqrt{2}$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0\left(c_1 \cos\left(\sqrt{2}\,x\right) + c_2 \sin\left(\sqrt{2}\,x\right)\right)$$

Or

$$y = c_1 \cos\left(\sqrt{2}\,x\right) + c_2 \sin\left(\sqrt{2}\,x\right)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos\left(\sqrt{2}\, x\right) + c_2 \sin\left(\sqrt{2}\, x\right)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 \mathrm{e}^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,\mathrm{e}^{-x}, x^2\mathrm{e}^{-x}, \mathrm{e}^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\cos\left(\sqrt{2}\, x\right), \sin\left(\sqrt{2}\, x\right)\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,\mathrm{e}^{-x} + A_2 x^2 \mathrm{e}^{-x} + A_3 \mathrm{e}^{-x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1\mathrm{e}^{-x} + 3A_1 x\,\mathrm{e}^{-x} + 2A_2\mathrm{e}^{-x} - 4A_2 x\,\mathrm{e}^{-x} + 3A_2 x^2\mathrm{e}^{-x} + 3A_3\mathrm{e}^{-x} = x^2\mathrm{e}^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{4}{9}, A_2 = \frac{1}{3}, A_3 = \frac{2}{27}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{4x\,\mathrm{e}^{-x}}{9} + \frac{x^2\mathrm{e}^{-x}}{3} + \frac{2\,\mathrm{e}^{-x}}{27}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \cos\left(\sqrt{2}\, x\right) + c_2 \sin\left(\sqrt{2}\, x\right)\right) + \left(\frac{4x\,\mathrm{e}^{-x}}{9} + \frac{x^2\mathrm{e}^{-x}}{3} + \frac{2\,\mathrm{e}^{-x}}{27}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \cos\left(\sqrt{2}\, x\right) + c_2 \sin\left(\sqrt{2}\, x\right) + \frac{4x\,\mathrm{e}^{-x}}{9} + \frac{x^2\mathrm{e}^{-x}}{3} + \frac{2\,\mathrm{e}^{-x}}{27} \tag{1}$$

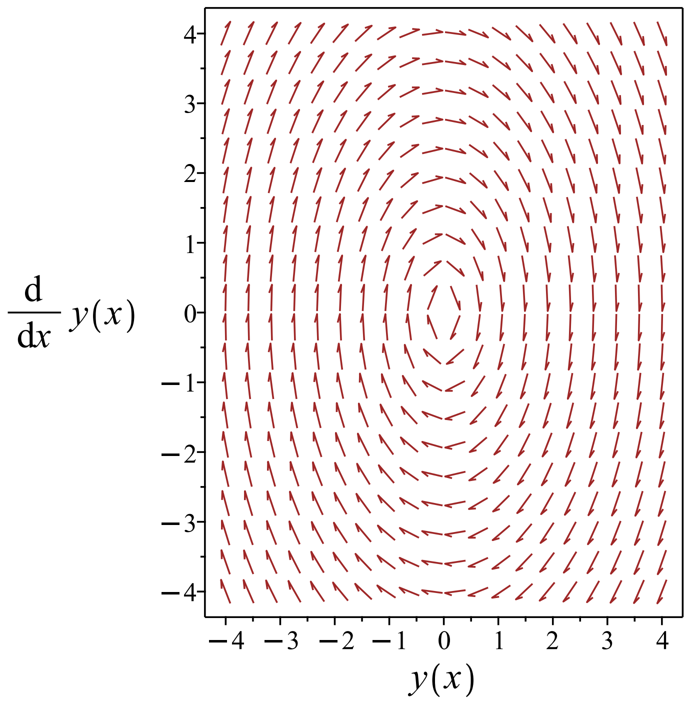

Figure 658: Slope field plot

Verification of solutions

$$y = c_1 \cos\left(\sqrt{2}\, x\right) + c_2 \sin\left(\sqrt{2}\, x\right) + \frac{4x\,\mathrm{e}^{-x}}{9} + \frac{x^2\mathrm{e}^{-x}}{3} + \frac{2\,\mathrm{e}^{-x}}{27}$$

Verified OK.

14.17.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -2 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -2z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 503: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -2$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos\left(\sqrt{2}\, x\right)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos\left(\sqrt{2}\, x\right) \end{aligned}$$

Which simplifies to

$$y_1 = \cos\left(\sqrt{2}\, x\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \cos\left(\sqrt{2}\, x\right) \int \frac{1}{\cos\left(\sqrt{2}\, x\right)^2}\, dx \\
&= \cos\left(\sqrt{2}\, x\right) \left(\frac{\sqrt{2}\, \tan\left(\sqrt{2}\, x\right)}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\cos\left(\sqrt{2}\, x\right)\right) + c_2 \left(\cos\left(\sqrt{2}\, x\right) \left(\frac{\sqrt{2}\, \tan\left(\sqrt{2}\, x\right)}{2}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos\left(\sqrt{2}\, x\right) + \frac{c_2 \sqrt{2}\, \sin\left(\sqrt{2}\, x\right)}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 e^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^{-x}, x^2 e^{-x}, e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sqrt{2}\,\sin\left(\sqrt{2}\,x\right)}{2}, \cos\left(\sqrt{2}\,x\right)\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,e^{-x} + A_2 x^2 e^{-x} + A_3 e^{-x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 e^{-x} + 3A_1 x\,e^{-x} + 2A_2 e^{-x} - 4A_2 x\,e^{-x} + 3A_2 x^2 e^{-x} + 3A_3 e^{-x} = x^2 e^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{4}{9}, A_2 = \frac{1}{3}, A_3 = \frac{2}{27}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{4x\,e^{-x}}{9} + \frac{x^2 e^{-x}}{3} + \frac{2\,e^{-x}}{27}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \cos\left(\sqrt{2}\,x\right) + \frac{c_2 \sqrt{2}\,\sin\left(\sqrt{2}\,x\right)}{2}\right) + \left(\frac{4x\,e^{-x}}{9} + \frac{x^2 e^{-x}}{3} + \frac{2\,e^{-x}}{27}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos\left(\sqrt{2}\, x\right) + \frac{c_2 \sqrt{2}\, \sin\left(\sqrt{2}\, x\right)}{2} + \frac{4x\, e^{-x}}{9} + \frac{x^2 e^{-x}}{3} + \frac{2\, e^{-x}}{27} \tag{1}$$

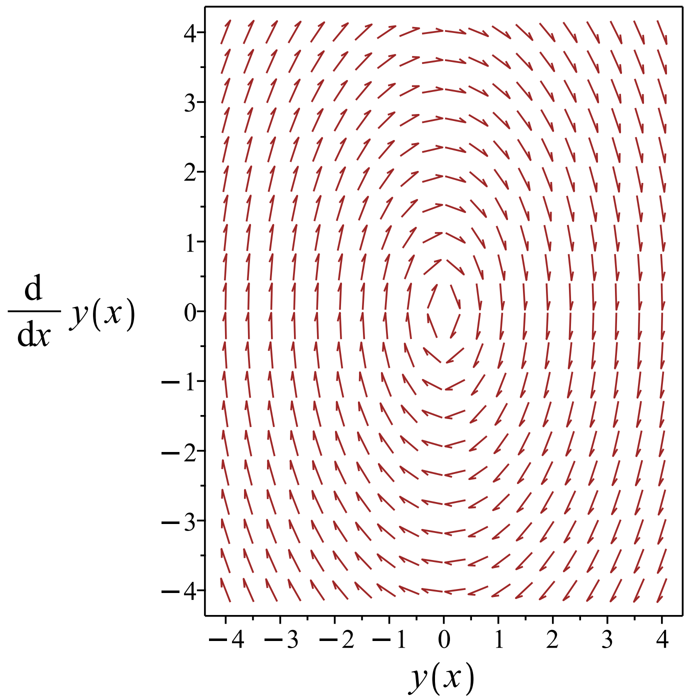

Figure 659: Slope field plot

Verification of solutions

$$y = c_1 \cos\left(\sqrt{2}\, x\right) + \frac{c_2 \sqrt{2}\, \sin\left(\sqrt{2}\, x\right)}{2} + \frac{4x\, e^{-x}}{9} + \frac{x^2 e^{-x}}{3} + \frac{2\, e^{-x}}{27}$$

Verified OK.

14.17.3 Maple step by step solution

Let's solve

$y'' + 2y = x^2 e^{-x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 + 2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-8})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}\sqrt{2}, \mathrm{I}\sqrt{2})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos\left(\sqrt{2}\, x\right)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin\left(\sqrt{2}\, x\right)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos\left(\sqrt{2}\, x\right) + c_2 \sin\left(\sqrt{2}\, x\right) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x^2 \mathrm{e}^{-x}\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos\left(\sqrt{2}\, x\right) & \sin\left(\sqrt{2}\, x\right) \\ -\sqrt{2}\, \sin\left(\sqrt{2}\, x\right) & \sqrt{2}\, \cos\left(\sqrt{2}\, x\right) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = \sqrt{2}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\frac{\sqrt{2}\left(\cos\left(\sqrt{2}\, x\right)\left(\int \sin\left(\sqrt{2}\, x\right) x^2 \mathrm{e}^{-x} dx\right) - \sin\left(\sqrt{2}\, x\right)\left(\int \cos\left(\sqrt{2}\, x\right) x^2 \mathrm{e}^{-x} dx\right)\right)}{2}$

  - Compute integrals

    $y_p(x) = \frac{\mathrm{e}^{-x}(9x^2 + 12x + 2)}{27}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos\left(\sqrt{2}\, x\right) + c_2 \sin\left(\sqrt{2}\, x\right) + \frac{\mathrm{e}^{-x}(9x^2 + 12x + 2)}{27}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - y' - 2y = x^2 - 8}$$

14.18.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -1, C = -2, f(x) = x^2 - 8$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' - 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -1, C = -2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - \lambda \,\mathrm{e}^{\lambda x} - 2\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \lambda - 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -1, C = -2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{1}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-1^2 - (4)\,(1)\,(-2)} \\ &= \frac{1}{2} \pm \frac{3}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= \frac{1}{2} + \frac{3}{2} \\ \lambda_2 &= \frac{1}{2} - \frac{3}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2 \\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(2)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{-x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{-x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 + 1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-x}, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_3x^2 + A_2x + A_1$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_3x^2 - 2A_2x - 2xA_3 - 2A_1 - A_2 + 2A_3 = x^2 - 8$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{13}{4}, A_2 = \frac{1}{2}, A_3 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{1}{2}x^2 + \frac{1}{2}x + \frac{13}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1e^{2x} + c_2e^{-x}\right) + \left(-\frac{1}{2}x^2 + \frac{1}{2}x + \frac{13}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1e^{2x} + c_2e^{-x} - \frac{x^2}{2} + \frac{x}{2} + \frac{13}{4} \tag{1}$$

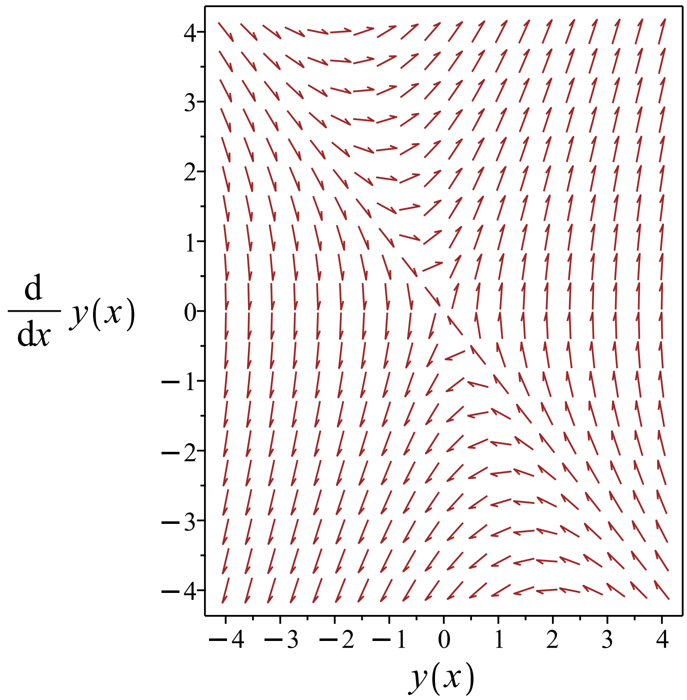

Figure 660: Slope field plot

Verification of solutions

$$y = c_1 e^{2x} + c_2 e^{-x} - \frac{x^2}{2} + \frac{x}{2} + \frac{13}{4}$$

Verified OK.

14.18.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -1 \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = 9$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 505: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = e^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-1}{1}\,dx} \\ &= z_1 e^{\frac{x}{2}} \\ &= z_1 \left(e^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{x}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{e^{3x}}{3}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{3x}}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - y' - 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{2x}}{3}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
x^2 + 1
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{1, x, x^2\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\frac{\mathrm{e}^{2x}}{3}, \mathrm{e}^{-x}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_3 x^2 + A_2 x + A_1
$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_3x^2 - 2A_2x - 2xA_3 - 2A_1 - A_2 + 2A_3 = x^2 - 8$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{13}{4}, A_2 = \frac{1}{2}, A_3 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{1}{2}x^2 + \frac{1}{2}x + \frac{13}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + \frac{c_2 e^{2x}}{3}\right) + \left(-\frac{1}{2}x^2 + \frac{1}{2}x + \frac{13}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + \frac{c_2 e^{2x}}{3} - \frac{x^2}{2} + \frac{x}{2} + \frac{13}{4} \tag{1}$$

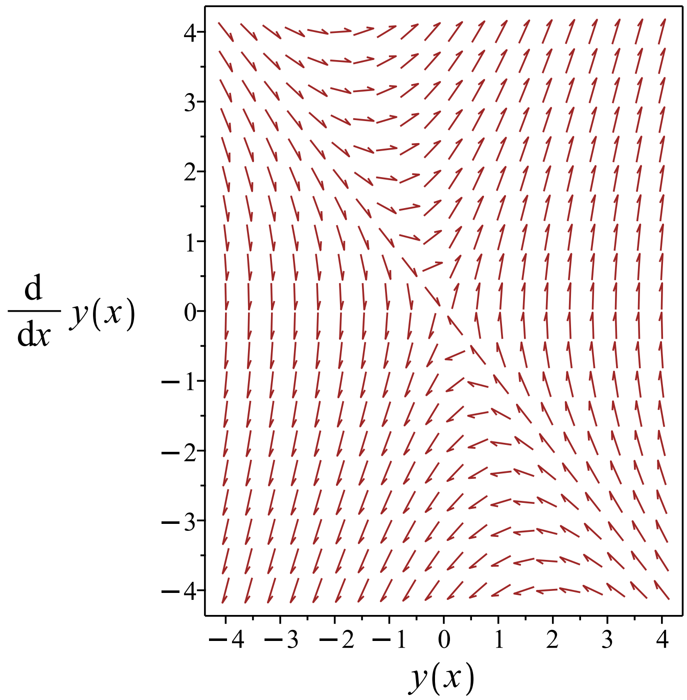

Figure 661: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + \frac{c_2 e^{2x}}{3} - \frac{x^2}{2} + \frac{x}{2} + \frac{13}{4}$$

Verified OK.

14.18.3 Maple step by step solution

Let's solve

$y'' - y' - 2y = x^2 - 8$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - r - 2 = 0$

- Factor the characteristic polynomial

  $(r+1)(r-2) = 0$

- Roots of the characteristic polynomial

$r = (-1, 2)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-x} + c_2 e^{2x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x^2 - 8\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x} & e^{2x} \\ -e^{-x} & 2e^{2x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 3e^{x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\frac{e^{-x}\left(\int (x^2-8)e^{x} dx\right)}{3} + \frac{e^{2x}\left(\int e^{-2x}(x^2-8) dx\right)}{3}$

  - Compute integrals

    $y_p(x) = -\frac{1}{2}x^2 + \frac{1}{2}x + \frac{13}{4}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-x} + c_2 e^{2x} - \frac{x^2}{2} + \frac{x}{2} + \frac{13}{4}$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 23, page 106
Problem number: 19.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _with_linear_symmetries]]
```

$$\boxed{y''' - y = x^2}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - y = 0$$

The characteristic equation is

$$\lambda^3 - 1 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$$
$$\lambda_3 = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^x + e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_2 + e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^x$$

$$y_2 = e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x}$$

$$y_3 = e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x}$$

Now the particular solution to the given ODE is found

$$y''' - y = x^2$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^x, e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x}, e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_3 x^2 + A_2 x + A_1$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_3 x^2 - A_2 x - A_1 = x^2$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 0, A_3 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^x + e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_2 + e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_3\right) + \left(-x^2\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^x + e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_2 + e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_3 - x^2 \tag{1}$$

Verification of solutions

$$y = c_1 e^x + e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_2 + e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_3 - x^2$$

Verified OK.

14.19.1 Maple step by step solution

Let's solve

$y''' - y = x^2$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = x^2 + y_1(x)$

Convert linear ODE into a system of first order ODEs

$$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = x^2 + y_1(x)]$$

- Define vector

$$\vec{y}(x) = \left[\begin{array}{c} y_1(x) \\ y_2(x) \\ y_3(x) \end{array}\right]$$

- System to solve

$$\vec{y}'(x) = \left[\begin{array}{ccc} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{array}\right] \cdot \vec{y}(x) + \left[\begin{array}{c} 0 \\ 0 \\ x^2 \end{array}\right]$$

- Define the forcing function

$$\vec{f}(x) = \left[\begin{array}{c} 0 \\ 0 \\ x^2 \end{array}\right]$$

- Define the coefficient matrix

$$A = \left[\begin{array}{ccc} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{array}\right]$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \end{array}\right]\right], \left[-\frac{1}{2} - \frac{\mathrm{I}\sqrt{3}}{2}, \left[\begin{array}{c} \frac{1}{\left(-\frac{1}{2} - \frac{\mathrm{I}\sqrt{3}}{2}\right)^2} \\ \frac{1}{-\frac{1}{2} - \frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{array}\right]\right], \left[-\frac{1}{2} + \frac{\mathrm{I}\sqrt{3}}{2}, \left[\begin{array}{c} \frac{1}{\left(-\frac{1}{2} + \frac{\mathrm{I}\sqrt{3}}{2}\right)^2} \\ \frac{1}{-\frac{1}{2} + \frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c}1 \\ 1 \\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_{1} = e^{x} \cdot \left[\begin{array}{c}1 \\ 1 \\ 1\end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\frac{1}{2}-\frac{I\sqrt{3}}{2}, \left[\begin{array}{c}\frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^{2}} \\ \frac{1}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ 1\end{array}\right]\right]$$

- Solution from eigenpair

$$e^{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)x} \cdot \left[\begin{array}{c}\frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^{2}} \\ \frac{1}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ 1\end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$e^{-\frac{x}{2}} \cdot \left(\cos\left(\frac{\sqrt{3}\, x}{2}\right) - I\sin\left(\frac{\sqrt{3}\, x}{2}\right)\right) \cdot \left[\begin{array}{c}\frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^{2}} \\ \frac{1}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ 1\end{array}\right]$$

- Simplify expression

$$e^{-\frac{x}{2}} \cdot \left[\begin{array}{c}\frac{\cos\left(\frac{\sqrt{3}\, x}{2}\right)-I\sin\left(\frac{\sqrt{3}\, x}{2}\right)}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^{2}} \\ \frac{\cos\left(\frac{\sqrt{3}\, x}{2}\right)-I\sin\left(\frac{\sqrt{3}\, x}{2}\right)}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ \cos\left(\frac{\sqrt{3}\, x}{2}\right)-I\sin\left(\frac{\sqrt{3}\, x}{2}\right)\end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = \mathrm{e}^{-\frac{x}{2}} \cdot \left[\begin{array}{c} -\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} - \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2} \\ -\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2} \\ \cos\left(\frac{\sqrt{3}\,x}{2}\right) \end{array}\right], \vec{y}_3(x) = \mathrm{e}^{-\frac{x}{2}} \cdot \left[\begin{array}{c} -\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2} \\ \frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2} \\ -\sin\left(\frac{\sqrt{3}\,x}{2}\right) \end{array}\right]\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($
  $\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \left[\begin{array}{ccc} \mathrm{e}^{x} & \mathrm{e}^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} - \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2}\right) & \mathrm{e}^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2}\right) \\ \mathrm{e}^{x} & \mathrm{e}^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2}\right) & \mathrm{e}^{-\frac{x}{2}}\left(\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2}\right) \\ \mathrm{e}^{x} & \mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right) & -\mathrm{e}^{-\frac{x}{2}}\sin\left(\frac{\sqrt{3}\,x}{2}\right) \end{array}\right]$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t
  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$
- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \left[\begin{array}{ccc} \mathrm{e}^{x} & \mathrm{e}^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} - \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2}\right) & \mathrm{e}^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2}\right) \\ \mathrm{e}^{x} & \mathrm{e}^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2}\right) & \mathrm{e}^{-\frac{x}{2}}\left(\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2}\right) \\ \mathrm{e}^{x} & \mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right) & -\mathrm{e}^{-\frac{x}{2}}\sin\left(\frac{\sqrt{3}\,x}{2}\right) \end{array}\right] \cdot \frac{1}{\left[\begin{array}{ccc} 1 & -\frac{1}{2} & -\frac{\sqrt{\ }}{2} \\ 1 & -\frac{1}{2} & \frac{\sqrt{3}}{2} \\ 1 & 1 & 0 \end{array}\right.}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \left[\begin{array}{ccc} \frac{2\,\mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{3} + \frac{\mathrm{e}^{x}}{3} & \frac{\mathrm{e}^{x}}{3} - \frac{\mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{3} + \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\mathrm{e}^{-\frac{x}{2}}\sqrt{3}}{3} & \frac{\mathrm{e}^{x}}{3} - \frac{\mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}}{2}\right.}{3} \\ \frac{\mathrm{e}^{x}}{3} - \frac{\mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{3} - \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\mathrm{e}^{-\frac{x}{2}}\sqrt{3}}{3} & \frac{2\,\mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{3} + \frac{\mathrm{e}^{x}}{3} & \frac{\mathrm{e}^{x}}{3} - \frac{\mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}}{2}\right.}{3} \\ \frac{\mathrm{e}^{x}}{3} - \frac{\mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{3} + \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\mathrm{e}^{-\frac{x}{2}}\sqrt{3}}{3} & \frac{\mathrm{e}^{x}}{3} - \frac{\mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{3} - \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\mathrm{e}^{-\frac{x}{2}}\sqrt{3}}{3} & \frac{2\,\mathrm{e}^{-\frac{x}{2}}\cos}{3} \end{array}\right.$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

$\overrightarrow{y}_p(x) = \Phi(x) \cdot \overrightarrow{v}(x)$

- Take the derivative of the particular solution

  $\overrightarrow{y}'_p(x) = \Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \overrightarrow{v}'(x) = \overrightarrow{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\overrightarrow{v}'(x) = \frac{1}{\Phi(x)} \cdot \overrightarrow{f}(x)$

- Integrate to solve for $\overrightarrow{v}(x)$

  $\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$

- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\overrightarrow{y}_p(x) = \left[\begin{array}{c} \frac{2\,\mathrm{e}^{x}}{3}-x^{2}-\frac{2 \sin \left(\frac{\sqrt{3}\, x}{2}\right) \mathrm{e}^{-\frac{x}{2}} \sqrt{3}}{3}-\frac{2\,\mathrm{e}^{-\frac{x}{2}} \cos \left(\frac{\sqrt{3}\, x}{2}\right)}{3} \\ \frac{2\,\mathrm{e}^{x}}{3}+\frac{2 \sin \left(\frac{\sqrt{3}\, x}{2}\right) \mathrm{e}^{-\frac{x}{2}} \sqrt{3}}{3}-2x-\frac{2\,\mathrm{e}^{-\frac{x}{2}} \cos \left(\frac{\sqrt{3}\, x}{2}\right)}{3} \\ \frac{2\,\mathrm{e}^{x}}{3}-2+\frac{4\,\mathrm{e}^{-\frac{x}{2}} \cos \left(\frac{\sqrt{3}\, x}{2}\right)}{3} \end{array}\right]$$

- Plug particular solution back into general solution

$$\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2(x) + c_3\overrightarrow{y}_3(x) + \left[\begin{array}{c} \frac{2\,\mathrm{e}^{x}}{3}-x^{2}-\frac{2 \sin \left(\frac{\sqrt{3}\, x}{2}\right) \mathrm{e}^{-\frac{x}{2}} \sqrt{3}}{3}-\frac{2\,\mathrm{e}^{-\frac{x}{2}} \cos \left(\frac{\sqrt{3}\, x}{2}\right)}{3} \\ \frac{2\,\mathrm{e}^{x}}{3}+\frac{2 \sin \left(\frac{\sqrt{3}\, x}{2}\right) \mathrm{e}^{-\frac{x}{2}} \sqrt{3}}{3}-2x-\frac{2\,\mathrm{e}^{-\frac{x}{2}} \cos \left(\frac{\sqrt{3}\, x}{2}\right)}{3} \\ \frac{2\,\mathrm{e}^{x}}{3}-2+\frac{4\,\mathrm{e}^{-\frac{x}{2}} \cos \left(\frac{\sqrt{3}\, x}{2}\right)}{3} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = -\frac{\left(c_3\sqrt{3}+c_2+\frac{4}{3}\right)\mathrm{e}^{-\frac{x}{2}} \cos \left(\frac{\sqrt{3}\, x}{2}\right)}{2}-\frac{\left(\left(c_2+\frac{4}{3}\right)\sqrt{3}-c_3\right)\mathrm{e}^{-\frac{x}{2}} \sin \left(\frac{\sqrt{3}\, x}{2}\right)}{2}+\frac{(6c_1+4)\mathrm{e}^{x}}{6}-x^{2}$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 23, page 106
Problem number: 20.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' + 4y'' - 5y' = x^2 \mathrm{e}^{-x}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + 4y'' - 5y' = 0$$

The characteristic equation is

$$\lambda^3 + 4\lambda^2 - 5\lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 1$$
$$\lambda_3 = -5$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + c_2 e^x + e^{-5x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = e^x$$
$$y_3 = e^{-5x}$$

Now the particular solution to the given ODE is found

$$y''' + 4y'' - 5y' = x^2 e^{-x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 e^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\, e^{-x}, x^2 e^{-x}, e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^x, e^{-5x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\, e^{-x} + A_2 x^2 e^{-x} + A_3 e^{-x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-10A_1 e^{-x} + 8A_1 x\, e^{-x} + 2A_2 e^{-x} - 20A_2 x\, e^{-x} + 8A_2 x^2 e^{-x} + 8A_3 e^{-x} = x^2 e^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{5}{16}, A_2 = \frac{1}{8}, A_3 = \frac{23}{64}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{5x\,e^{-x}}{16} + \frac{x^2 e^{-x}}{8} + \frac{23\,e^{-x}}{64}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + c_2 e^x + e^{-5x} c_3\right) + \left(\frac{5x\,e^{-x}}{16} + \frac{x^2 e^{-x}}{8} + \frac{23\,e^{-x}}{64}\right) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 + c_2 e^x + e^{-5x} c_3 + \frac{5x\,e^{-x}}{16} + \frac{x^2 e^{-x}}{8} + \frac{23\,e^{-x}}{64} \tag{1}$$

<u>Verification of solutions</u>

$$y = c_1 + c_2 e^x + e^{-5x} c_3 + \frac{5x\,e^{-x}}{16} + \frac{x^2 e^{-x}}{8} + \frac{23\,e^{-x}}{64}$$

Verified OK.

14.20.1 Maple step by step solution

Let's solve

$y''' + 4y'' - 5y' = x^2 e^{-x}$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

$y_3'(x) = x^2 \mathrm{e}^{-x} - 4y_3(x) + 5y_2(x)$

Convert linear ODE into a system of first order ODEs

$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = x^2 \mathrm{e}^{-x} - 4y_3(x) + 5y_2(x)]$

- Define vector

$$\vec{y}(x) = \left[\begin{array}{c} y_1(x) \\ y_2(x) \\ y_3(x) \end{array}\right]$$

- System to solve

$$\vec{y}'(x) = \left[\begin{array}{ccc} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 5 & -4 \end{array}\right] \cdot \vec{y}(x) + \left[\begin{array}{c} 0 \\ 0 \\ x^2 \mathrm{e}^{-x} \end{array}\right]$$

- Define the forcing function

$$\vec{f}(x) = \left[\begin{array}{c} 0 \\ 0 \\ x^2 \mathrm{e}^{-x} \end{array}\right]$$

- Define the coefficient matrix

$$A = \left[\begin{array}{ccc} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 5 & -4 \end{array}\right]$$

- Rewrite the system as

$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-5, \left[\begin{array}{c} \frac{1}{25} \\ -\frac{1}{5} \\ 1 \end{array}\right]\right], \left[0, \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]\right], \left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-5, \left[\begin{array}{c} \frac{1}{25} \\ -\frac{1}{5} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \mathrm{e}^{-5x} \cdot \left[\begin{array}{c} \frac{1}{25} \\ -\frac{1}{5} \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[0, \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_2 = \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_3 = \mathrm{e}^{x} \cdot \left[\begin{array}{c} 1 \\ 1 \\ 1 \end{array}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{y}_p($

$$\overrightarrow{y}(x) = c_1 \overrightarrow{y}_1 + c_2 \overrightarrow{y}_2 + c_3 \overrightarrow{y}_3 + \overrightarrow{y}_p(x)$$

□ Fundamental matrix

- ○ Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} \frac{e^{-5x}}{25} & 1 & e^{x} \\ -\frac{e^{-5x}}{5} & 0 & e^{x} \\ e^{-5x} & 0 & e^{x} \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} \frac{e^{-5x}}{25} & 1 & e^{x} \\ -\frac{e^{-5x}}{5} & 0 & e^{x} \\ e^{-5x} & 0 & e^{x} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} \frac{1}{25} & 1 & 1 \\ -\frac{1}{5} & 0 & 1 \\ 1 & 0 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} 1 & -\frac{(-25\,e^{6x}+24\,e^{5x}+1)e^{-5x}}{30} & -\frac{(-5\,e^{6x}+6\,e^{5x}-1)e^{-5x}}{30} \\ 0 & \frac{(5\,e^{6x}+1)e^{-5x}}{6} & \frac{(e^{6x}-1)e^{-5x}}{6} \\ 0 & \frac{5(e^{6x}-1)e^{-5x}}{6} & \frac{(e^{6x}+5)e^{-5x}}{6} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

$\overrightarrow{v}'(x) = \frac{1}{\Phi(x)} \cdot \overrightarrow{f}(x)$

- Integrate to solve for $\overrightarrow{v}(x)$

  $\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$

- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\overrightarrow{y}_p(x) = \begin{bmatrix} \frac{(120x^2+300x+345)e^{-5x}e^{4x}}{960} + \frac{(-384\,e^{5x}+40\,e^{6x}-1)e^{-5x}}{960} \\ \frac{(-24x^2-12x-9)e^{-5x}e^{4x}}{192} + \frac{(8\,e^{6x}+1)e^{-5x}}{192} \\ \frac{(24x^2-36x-3)e^{-5x}e^{4x}}{192} + \frac{(8\,e^{6x}-5)e^{-5x}}{192} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2 + c_3\overrightarrow{y}_3 + \begin{bmatrix} \frac{(120x^2+300x+345)e^{-5x}e^{4x}}{960} + \frac{(-384\,e^{5x}+40\,e^{6x}-1)e^{-5x}}{960} \\ \frac{(-24x^2-12x-9)e^{-5x}e^{4x}}{192} + \frac{(8\,e^{6x}+1)e^{-5x}}{192} \\ \frac{(24x^2-36x-3)e^{-5x}e^{4x}}{192} + \frac{(8\,e^{6x}-5)e^{-5x}}{192} \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = \frac{e^{-5x}\left((8x^2+20x+23)e^{4x}+64c_2e^{5x}+64c_3e^{6x}+\frac{64c_1}{25}-\frac{128\,e^{5x}}{5}+\frac{8\,e^{6x}}{3}-\frac{1}{15}\right)}{64}$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 23, page 106
Problem number: 21.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_y]]
```

$$\boxed{y'''' - 2y''' + y'' = x^2}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - 2y''' + y'' = 0$$

The characteristic equation is

$$\lambda^4 - 2\lambda^3 + \lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = 1$$
$$\lambda_4 = 1$$

Therefore the homogeneous solution is

$$y_h(x) = c_2 x + c_1 + c_3 \mathrm{e}^{x} + c_4 x \,\mathrm{e}^{x}$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = x$$
$$y_3 = \mathrm{e}^{x}$$
$$y_4 = x \,\mathrm{e}^{x}$$

Now the particular solution to the given ODE is found

$$y'''' - 2y''' + y'' = x^2$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, x\,\mathrm{e}^{x}, \mathrm{e}^{x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x, x^2, x^3\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2, x^3, x^4\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_3 x^4 + A_2 x^3 + A_1 x^2$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$12x^2A_3 + 6xA_2 - 48xA_3 + 2A_1 - 12A_2 + 24A_3 = x^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 3, A_2 = \frac{2}{3}, A_3 = \frac{1}{12}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{12}x^4 + \frac{2}{3}x^3 + 3x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2x + c_1 + c_3\mathrm{e}^x + c_4x\,\mathrm{e}^x) + \left(\frac{1}{12}x^4 + \frac{2}{3}x^3 + 3x^2\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^x(c_4x + c_3) + c_2x + c_1 + \frac{x^4}{12} + \frac{2x^3}{3} + 3x^2$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^x(c_4x + c_3) + c_2x + c_1 + \frac{x^4}{12} + \frac{2x^3}{3} + 3x^2 \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^x(c_4x + c_3) + c_2x + c_1 + \frac{x^4}{12} + \frac{2x^3}{3} + 3x^2$$

Verified OK.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' - y' = e^{x} \left(\sin \left(x \right) - x^{2}\right)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - y' = 0$$

The characteristic equation is

$$\lambda^{3} - \lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 1$$
$$\lambda_3 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 + c_3 e^{x}$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= \mathrm{e}^{-x} \\
y_2 &= 1 \\
y_3 &= \mathrm{e}^{x}
\end{aligned}
$$

Now the particular solution to the given ODE is found

$$
y''' - y' = \mathrm{e}^{x} \left(\sin \left(x \right)-x^{2}\right)
$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
\mathrm{e}^{x} \left(\sin \left(x \right)-x^{2}\right)
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\cos \left(x \right) \mathrm{e}^{x}, \sin \left(x \right) \mathrm{e}^{x}\}, \{x \,\mathrm{e}^{x}, x^{2} \mathrm{e}^{x}, \mathrm{e}^{x}\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{1, \mathrm{e}^{x}, \mathrm{e}^{-x}\}
$$

Since e^{x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$
[\{\cos \left(x \right) \mathrm{e}^{x}, \sin \left(x \right) \mathrm{e}^{x}\}, \{x \,\mathrm{e}^{x}, x^{2} \mathrm{e}^{x}, \mathrm{e}^{x} x^{3}\}]
$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$
y_p = A_{1} \cos \left(x \right) \mathrm{e}^{x}+A_{2} \sin \left(x \right) \mathrm{e}^{x}+A_{3} x \,\mathrm{e}^{x}+A_{4} x^{2} \mathrm{e}^{x}+A_{5} \mathrm{e}^{x} x^{3}
$$

The unknowns $\{A_{1}, A_{2}, A_{3}, A_{4}, A_{5}\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
\begin{aligned}
&-3 A_{1} \cos \left(x \right) \mathrm{e}^{x}-A_{1} \sin \left(x \right) \mathrm{e}^{x}-3 A_{2} \sin \left(x \right) \mathrm{e}^{x}+A_{2} \cos \left(x \right) \mathrm{e}^{x}+2 A_{3} \mathrm{e}^{x} \\
&+6 A_{4} \mathrm{e}^{x}+4 A_{4} x \,\mathrm{e}^{x}+6 A_{5} \mathrm{e}^{x} x^{2}+18 A_{5} \mathrm{e}^{x} x +6 A_{5} \mathrm{e}^{x} = \mathrm{e}^{x} \left(\sin \left(x \right)-x^{2}\right)
\end{aligned}
$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{10}, A_2 = -\frac{3}{10}, A_3 = -\frac{7}{4}, A_4 = \frac{3}{4}, A_5 = -\frac{1}{6}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{\cos(x)\,\mathrm{e}^x}{10} - \frac{3\sin(x)\,\mathrm{e}^x}{10} - \frac{7x\,\mathrm{e}^x}{4} + \frac{3x^2\mathrm{e}^x}{4} - \frac{\mathrm{e}^x x^3}{6}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\ &= \left(c_1\mathrm{e}^{-x} + c_2 + c_3\mathrm{e}^x\right) + \left(-\frac{\cos(x)\,\mathrm{e}^x}{10} - \frac{3\sin(x)\,\mathrm{e}^x}{10} - \frac{7x\,\mathrm{e}^x}{4} + \frac{3x^2\mathrm{e}^x}{4} - \frac{\mathrm{e}^x x^3}{6}\right)\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\mathrm{e}^{-x} + c_2 + c_3\mathrm{e}^x - \frac{\cos(x)\,\mathrm{e}^x}{10} - \frac{3\sin(x)\,\mathrm{e}^x}{10} - \frac{7x\,\mathrm{e}^x}{4} + \frac{3x^2\mathrm{e}^x}{4} - \frac{\mathrm{e}^x x^3}{6} \tag{1}$$

Verification of solutions

$$y = c_1\mathrm{e}^{-x} + c_2 + c_3\mathrm{e}^x - \frac{\cos(x)\,\mathrm{e}^x}{10} - \frac{3\sin(x)\,\mathrm{e}^x}{10} - \frac{7x\,\mathrm{e}^x}{4} + \frac{3x^2\mathrm{e}^x}{4} - \frac{\mathrm{e}^x x^3}{6}$$

Verified OK.

14.22.1 Maple step by step solution

Let's solve

$y''' - y' = \mathrm{e}^x(\sin(x) - x^2)$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  - ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

- Define new variable $y_3(x)$

  $y_3(x) = y''$

- Isolate for $y_3'(x)$ using original ODE

  $y_3'(x) = -x^2 \mathrm{e}^x + \sin(x)\,\mathrm{e}^x + y_2(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = -x^2 \mathrm{e}^x + \sin(x)\,\mathrm{e}^x + y_2(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ -x^2 \mathrm{e}^x + \sin(x)\,\mathrm{e}^x \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ -x^2 \mathrm{e}^x + \sin(x)\,\mathrm{e}^x \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \left[\begin{array}{c}1 \\ -1 \\ 1\end{array}\right]\right], \left[0, \left[\begin{array}{c}1 \\ 0 \\ 0\end{array}\right]\right], \left[1, \left[\begin{array}{c}1 \\ 1 \\ 1\end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c}1 \\ -1 \\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{-x} \cdot \left[\begin{array}{c}1 \\ -1 \\ 1\end{array}\right]$$

- Consider eigenpair

$$\left[0, \left[\begin{array}{c}1 \\ 0 \\ 0\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \left[\begin{array}{c}1 \\ 0 \\ 0\end{array}\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c}1 \\ 1 \\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = \mathrm{e}^{x} \cdot \left[\begin{array}{c}1 \\ 1 \\ 1\end{array}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2 + c_3\overrightarrow{y}_3 + \overrightarrow{y}_p(x)$

- ☐ Fundamental matrix
  - Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

    $$\phi(x) = \begin{bmatrix} \mathrm{e}^{-x} & 1 & \mathrm{e}^{x} \\ -\mathrm{e}^{-x} & 0 & \mathrm{e}^{x} \\ \mathrm{e}^{-x} & 0 & \mathrm{e}^{x} \end{bmatrix}$$

  - The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

    $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

  - Substitute the value of $\phi(x)$ and $\phi(0)$

    $$\Phi(x) = \begin{bmatrix} \mathrm{e}^{-x} & 1 & \mathrm{e}^{x} \\ -\mathrm{e}^{-x} & 0 & \mathrm{e}^{x} \\ \mathrm{e}^{-x} & 0 & \mathrm{e}^{x} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & 1 & 1 \\ -1 & 0 & 1 \\ 1 & 0 & 1 \end{bmatrix}}$$

  - Evaluate and simplify to get the fundamental matrix

    $$\Phi(x) = \begin{bmatrix} 1 & -\frac{\mathrm{e}^{-x}}{2} + \frac{\mathrm{e}^{x}}{2} & \frac{\mathrm{e}^{-x}}{2} - 1 + \frac{\mathrm{e}^{x}}{2} \\ 0 & \frac{\mathrm{e}^{x}}{2} + \frac{\mathrm{e}^{-x}}{2} & -\frac{\mathrm{e}^{-x}}{2} + \frac{\mathrm{e}^{x}}{2} \\ 0 & -\frac{\mathrm{e}^{-x}}{2} + \frac{\mathrm{e}^{x}}{2} & \frac{\mathrm{e}^{x}}{2} + \frac{\mathrm{e}^{-x}}{2} \end{bmatrix}$$

- ☐ Find a particular solution of the system of ODEs using variation of parameters
  - Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(x)$ and solve for $\overrightarrow{v}(x)$

    $\overrightarrow{y}_p(x) = \Phi(x) \cdot \overrightarrow{v}(x)$

  - Take the derivative of the particular solution

    $\overrightarrow{y}'_p(x) = \Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x)$

  - Substitute particular solution and its derivative into the system of ODEs

    $\Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

  - The fundamental matrix has columns that are solutions to the homogeneous system so its der

    $A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

  - Cancel like terms

$\Phi(x)\cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)}\cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)}\cdot \vec{f}(s)\,ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x)\cdot\left(\int_0^x \frac{1}{\Phi(s)}\cdot \vec{f}(s)\,ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \left[\begin{array}{c} \frac{9\,\mathrm{e}^{-x}}{40}-\frac{5}{2}+\frac{\left(-20x^3+90x^2-210x-12\cos(x)-36\sin(x)+285\right)\mathrm{e}^{x}}{120} \\ -\frac{9\,\mathrm{e}^{-x}}{40}+\frac{\left(-20x^3+30x^2-30x-48\cos(x)-24\sin(x)+75\right)\mathrm{e}^{x}}{120} \\ \frac{9\,\mathrm{e}^{-x}}{40}+\frac{\left(-20x^3-30x^2+30x-72\cos(x)+24\sin(x)+45\right)\mathrm{e}^{x}}{120} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3 + \left[\begin{array}{c} \frac{9\,\mathrm{e}^{-x}}{40}-\frac{5}{2}+\frac{\left(-20x^3+90x^2-210x-12\cos(x)-36\sin(x)+285\right)\mathrm{e}^{x}}{120} \\ -\frac{9\,\mathrm{e}^{-x}}{40}+\frac{\left(-20x^3+30x^2-30x-48\cos(x)-24\sin(x)+75\right)\mathrm{e}^{x}}{120} \\ \frac{9\,\mathrm{e}^{-x}}{40}+\frac{\left(-20x^3-30x^2+30x-72\cos(x)+24\sin(x)+45\right)\mathrm{e}^{x}}{120} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = -\frac{5}{2}+\frac{(9+40c_1)\mathrm{e}^{-x}}{40}+\frac{\left(-20x^3+90x^2-210x+120c_3-12\cos(x)-36\sin(x)+285\right)\mathrm{e}^{x}}{120}+c_2$$

Section: Exercise 23, page 106
Problem number: 23.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' - 4y'' = e^{2x}(x - 3)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 4y'' = 0$$

The characteristic equation is

$$\lambda^3 - 4\lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = 4$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_2 x + c_1 + e^{4x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= 1 \\
y_2 &= x \\
y_3 &= e^{4x}
\end{aligned}
$$

Now the particular solution to the given ODE is found

$$y''' - 4y'' = e^{2x}(x - 3)$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{2x}(x - 3)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^{2x}, e^{2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, e^{4x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,e^{2x} + A_2 e^{2x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 e^{2x} - 8A_1 x\,e^{2x} - 8A_2 e^{2x} = e^{2x}(x - 3)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{8}, A_2 = \frac{7}{16}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\,e^{2x}}{8} + \frac{7\,e^{2x}}{16}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_2 x + c_1 + e^{4x} c_3) + \left(-\frac{x\, e^{2x}}{8} + \frac{7\, e^{2x}}{16}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_2 x + c_1 + e^{4x} c_3 - \frac{x\, e^{2x}}{8} + \frac{7\, e^{2x}}{16} \tag{1}
$$

Verification of solutions

$$
y = c_2 x + c_1 + e^{4x} c_3 - \frac{x\, e^{2x}}{8} + \frac{7\, e^{2x}}{16}
$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 23, page 106
Problem number: 24.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_y]]
```

$$\boxed{y'''' - 6y''' + 9y'' = \sin(3x) + x\,\mathrm{e}^{x}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - 6y''' + 9y'' = 0$$

The characteristic equation is

$$\lambda^4 - 6\lambda^3 + 9\lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = 3$$
$$\lambda_4 = 3$$

Therefore the homogeneous solution is

$$y_h(x) = c_4 x\,\mathrm{e}^{3x} + c_3\mathrm{e}^{3x} + c_2 x + c_1$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= 1 \\ y_2 &= x \\ y_3 &= \mathrm{e}^{3x} \\ y_4 &= x\,\mathrm{e}^{3x} \end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' - 6y''' + 9y'' = \sin(3x) + x\,\mathrm{e}^{x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(3x) + x\,\mathrm{e}^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,\mathrm{e}^{x}, \mathrm{e}^{x}\}, \{\cos(3x), \sin(3x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, x\,\mathrm{e}^{3x}, \mathrm{e}^{3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,\mathrm{e}^{x} + A_2\mathrm{e}^{x} + A_3\cos(3x) + A_4\sin(3x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1\mathrm{e}^{x} + 4A_1 x\,\mathrm{e}^{x} + 4A_2\mathrm{e}^{x} - 162A_3\sin(3x) + 162A_4\cos(3x) = \sin(3x) + x\,\mathrm{e}^{x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{4}, A_2 = -\frac{1}{4}, A_3 = -\frac{1}{162}, A_4 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x\,e^x}{4} - \frac{e^x}{4} - \frac{\cos(3x)}{162}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_4 x\,e^{3x} + c_3 e^{3x} + c_2 x + c_1\right) + \left(\frac{x\,e^x}{4} - \frac{e^x}{4} - \frac{\cos(3x)}{162}\right) \end{aligned}$$

Which simplifies to

$$y = (c_4 x + c_3)\,e^{3x} + c_2 x + c_1 + \frac{x\,e^x}{4} - \frac{e^x}{4} - \frac{\cos(3x)}{162}$$

Summary

The solution(s) found are the following

$$y = (c_4 x + c_3)\,e^{3x} + c_2 x + c_1 + \frac{x\,e^x}{4} - \frac{e^x}{4} - \frac{\cos(3x)}{162} \tag{1}$$

Verification of solutions

$$y = (c_4 x + c_3)\,e^{3x} + c_2 x + c_1 + \frac{x\,e^x}{4} - \frac{e^x}{4} - \frac{\cos(3x)}{162}$$

Verified OK.

ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_3rd_order, _linear, _nonhomogeneous]]`

$$\boxed{y''' - 6y'' + 11y' - 6y = x^2 \mathrm{e}^{2x}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 6y'' + 11y' - 6y = 0$$

The characteristic equation is

$$\lambda^3 - 6\lambda^2 + 11\lambda - 6 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 2$$
$$\lambda_3 = 3$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^x + c_2 e^{2x} + c_3 e^{3x}$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^x$$

$$y_2 = e^{2x}$$

$$y_3 = e^{3x}$$

Now the particular solution to the given ODE is found

$$y''' - 6y'' + 11y' - 6y = x^2 e^{2x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 e^{2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^{2x}, x^2 e^{2x}, e^{2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x, e^{2x}, e^{3x}\}$$

Since e^{2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{2x}, x^2 e^{2x}, e^{2x} x^3\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^{2x} + A_2 x^2 e^{2x} + A_3 e^{2x} x^3$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_2 x\,e^{2x} - 3A_3 e^{2x} x^2 - A_1 e^{2x} + 6A_3 e^{2x} = x^2 e^{2x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -2, A_2 = 0, A_3 = -\frac{1}{3}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2x\,\mathrm{e}^{2x} - \frac{\mathrm{e}^{2x}x^3}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{x} + c_2\mathrm{e}^{2x} + c_3\mathrm{e}^{3x}\right) + \left(-2x\,\mathrm{e}^{2x} - \frac{\mathrm{e}^{2x}x^3}{3}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\mathrm{e}^{x} + c_2\mathrm{e}^{2x} + c_3\mathrm{e}^{3x} - 2x\,\mathrm{e}^{2x} - \frac{\mathrm{e}^{2x}x^3}{3} \tag{1}$$

Verification of solutions

$$y = c_1\mathrm{e}^{x} + c_2\mathrm{e}^{2x} + c_3\mathrm{e}^{3x} - 2x\,\mathrm{e}^{2x} - \frac{\mathrm{e}^{2x}x^3}{3}$$

Verified OK.

14.25.1 Maple step by step solution

Let's solve

$y''' - 6y'' + 11y' - 6y = x^2\mathrm{e}^{2x}$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

- Define new variable $y_3(x)$

  $y_3(x) = y''$

- Isolate for $y_3'(x)$ using original ODE

  $y_3'(x) = x^2 e^{2x} + 6y_3(x) - 11y_2(x) + 6y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = x^2 e^{2x} + 6y_3(x) - 11y_2(x) + 6y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 6 & -11 & 6 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ x^2 e^{2x} \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ x^2 e^{2x} \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 6 & -11 & 6 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = e^x \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{2x} \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[3, \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = e^{3x} \cdot \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

  $\vec{y}(x)=c_1\vec{y}_1+c_2\vec{y}_2+c_3\vec{y}_3+\vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

  $$\phi(x)=\begin{bmatrix} e^{x} & \frac{e^{2x}}{4} & \frac{e^{3x}}{9} \\ e^{x} & \frac{e^{2x}}{2} & \frac{e^{3x}}{3} \\ e^{x} & e^{2x} & e^{3x} \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0)=I$ where I is t

  $\Phi(x)=\phi(x)\cdot\frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

  $$\Phi(x)=\begin{bmatrix} e^{x} & \frac{e^{2x}}{4} & \frac{e^{3x}}{9} \\ e^{x} & \frac{e^{2x}}{2} & \frac{e^{3x}}{3} \\ e^{x} & e^{2x} & e^{3x} \end{bmatrix}\cdot\frac{1}{\begin{bmatrix} 1 & \frac{1}{4} & \frac{1}{9} \\ 1 & \frac{1}{2} & \frac{1}{3} \\ 1 & 1 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

  $$\Phi(x)=\begin{bmatrix} 3e^{x}-3e^{2x}+e^{3x} & -\frac{5e^{x}}{2}+4e^{2x}-\frac{3e^{3x}}{2} & \frac{e^{x}}{2}-e^{2x}+\frac{e^{3x}}{2} \\ 3e^{x}-6e^{2x}+3e^{3x} & -\frac{5e^{x}}{2}+8e^{2x}-\frac{9e^{3x}}{2} & \frac{e^{x}}{2}-2e^{2x}+\frac{3e^{3x}}{2} \\ 3e^{x}-12e^{2x}+9e^{3x} & -\frac{5e^{x}}{2}+16e^{2x}-\frac{27e^{3x}}{2} & \frac{e^{x}}{2}-4e^{2x}+\frac{9e^{3x}}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x)=\Phi(x)\cdot\vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}_p'(x)=\Phi'(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}'(x)=A\cdot\Phi(x)\cdot\vec{v}(x)+\vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A\cdot\Phi(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}'(x)=A\cdot\Phi(x)\cdot\vec{v}(x)+\vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \overrightarrow{v}'(x) = \overrightarrow{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\overrightarrow{v}'(x) = \frac{1}{\Phi(x)} \cdot \overrightarrow{f}(x)$

- Integrate to solve for $\overrightarrow{v}(x)$

  $\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$

- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\overrightarrow{y}_p(x) = \left[\begin{array}{c} \frac{(-x^3-6x)\mathrm{e}^{2x}}{3} - \mathrm{e}^{x} + \mathrm{e}^{3x} \\ \frac{(-2x^3-3x^2-12x-6)\mathrm{e}^{2x}}{3} - \mathrm{e}^{x} + 3\,\mathrm{e}^{3x} \\ \frac{2(-2x^3-6x^2-15x-12)\mathrm{e}^{2x}}{3} - \mathrm{e}^{x} + 9\,\mathrm{e}^{3x} \end{array}\right]$$

- Plug particular solution back into general solution

  $$\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2 + c_3\overrightarrow{y}_3 + \left[\begin{array}{c} \frac{(-x^3-6x)\mathrm{e}^{2x}}{3} - \mathrm{e}^{x} + \mathrm{e}^{3x} \\ \frac{(-2x^3-3x^2-12x-6)\mathrm{e}^{2x}}{3} - \mathrm{e}^{x} + 3\,\mathrm{e}^{3x} \\ \frac{2(-2x^3-6x^2-15x-12)\mathrm{e}^{2x}}{3} - \mathrm{e}^{x} + 9\,\mathrm{e}^{3x} \end{array}\right]$$

- First component of the vector is the solution to the ODE

  $y = \frac{(-4x^3+3c_2-24x)\mathrm{e}^{2x}}{12} + \frac{(c_3+9)\mathrm{e}^{3x}}{9} + \mathrm{e}^{x}(c_1-1)$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 23, page 106
Problem number: 26.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' + 2y' = x^2 + \cos(x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + 2y' = 0$$

The characteristic equation is

$$\lambda^3 + 2\lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = i\sqrt{2}$$
$$\lambda_3 = -i\sqrt{2}$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + e^{-i\sqrt{2}\,x} c_2 + e^{i\sqrt{2}\,x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = e^{-i\sqrt{2}\,x}$$
$$y_3 = e^{i\sqrt{2}\,x}$$

Now the particular solution to the given ODE is found

$$y''' + 2y' = x^2 + \cos(x)$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 + \cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}, \{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{1, e^{i\sqrt{2}\,x}, e^{-i\sqrt{2}\,x}\right\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{\cos(x), \sin(x)\}, \{x, x^2, x^3\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x) + A_3 x + A_4 x^2 + A_5 x^3$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 \sin(x) + A_2 \cos(x) + 6A_5 + 2A_3 + 4A_4 x + 6A_5 x^2 = x^2 + \cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = 1, A_3 = -\frac{1}{2}, A_4 = 0, A_5 = \frac{1}{6}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \sin(x) - \frac{x}{2} + \frac{x^3}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + e^{-i\sqrt{2}\,x}c_2 + e^{i\sqrt{2}\,x}c_3\right) + \left(\sin(x) - \frac{x}{2} + \frac{x^3}{6}\right) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 + e^{-i\sqrt{2}\,x}c_2 + e^{i\sqrt{2}\,x}c_3 + \sin(x) - \frac{x}{2} + \frac{x^3}{6} \tag{1}$$

<u>Verification of solutions</u>

$$y = c_1 + e^{-i\sqrt{2}\,x}c_2 + e^{i\sqrt{2}\,x}c_3 + \sin(x) - \frac{x}{2} + \frac{x^3}{6}$$

Verified OK.

14.26.1 Maple step by step solution

Let's solve

$y''' + 2y' = x^2 + \cos(x)$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$

- Define new variable $y_3(x)$

  $y_3(x) = y''$

- Isolate for $y_3'(x)$ using original ODE

  $y_3'(x) = x^2 + \cos(x) - 2y_2(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = x^2 + \cos(x) - 2y_2(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -2 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ x^2 + \cos(x) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ x^2 + \cos(x) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -2 & 0 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[-I\sqrt{2}, \begin{bmatrix} -\frac{1}{2} \\ \frac{I}{2}\sqrt{2} \\ 1 \end{bmatrix}\right], \left[I\sqrt{2}, \begin{bmatrix} -\frac{1}{2} \\ -\frac{I}{2}\sqrt{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-I\sqrt{2}, \begin{bmatrix} -\frac{1}{2} \\ \frac{I}{2}\sqrt{2} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-I\sqrt{2}\,x} \cdot \begin{bmatrix} -\frac{1}{2} \\ \frac{I}{2}\sqrt{2} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$\left(\cos\left(\sqrt{2}\,x\right) - I\sin\left(\sqrt{2}\,x\right)\right) \cdot \begin{bmatrix} -\frac{1}{2} \\ \frac{I}{2}\sqrt{2} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\frac{\cos\left(\sqrt{2}\,x\right)}{2} + \frac{I\sin\left(\sqrt{2}\,x\right)}{2} \\ \frac{I}{2}\left(\cos\left(\sqrt{2}\,x\right) - I\sin\left(\sqrt{2}\,x\right)\right)\sqrt{2} \\ \cos\left(\sqrt{2}\,x\right) - I\sin\left(\sqrt{2}\,x\right) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x)=\begin{bmatrix} -\frac{\cos\left(\sqrt{2}\,x\right)}{2} \\ \frac{\sqrt{2}\,\sin\left(\sqrt{2}\,x\right)}{2} \\ \cos\left(\sqrt{2}\,x\right) \end{bmatrix}, \vec{y}_3(x)=\begin{bmatrix} \frac{\sin\left(\sqrt{2}\,x\right)}{2} \\ \frac{\sqrt{2}\,\cos\left(\sqrt{2}\,x\right)}{2} \\ -\sin\left(\sqrt{2}\,x\right) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x)=c_1\vec{y}_1+c_2\vec{y}_2(x)+c_3\vec{y}_3(x)+\vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x)=\begin{bmatrix} 1 & -\frac{\cos\left(\sqrt{2}\,x\right)}{2} & \frac{\sin\left(\sqrt{2}\,x\right)}{2} \\ 0 & \frac{\sqrt{2}\,\sin\left(\sqrt{2}\,x\right)}{2} & \frac{\sqrt{2}\,\cos\left(\sqrt{2}\,x\right)}{2} \\ 0 & \cos\left(\sqrt{2}\,x\right) & -\sin\left(\sqrt{2}\,x\right) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0)=I$ where I is t

$\Phi(x)=\phi(x)\cdot\frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x)=\begin{bmatrix} 1 & -\frac{\cos\left(\sqrt{2}\,x\right)}{2} & \frac{\sin\left(\sqrt{2}\,x\right)}{2} \\ 0 & \frac{\sqrt{2}\,\sin\left(\sqrt{2}\,x\right)}{2} & \frac{\sqrt{2}\,\cos\left(\sqrt{2}\,x\right)}{2} \\ 0 & \cos\left(\sqrt{2}\,x\right) & -\sin\left(\sqrt{2}\,x\right) \end{bmatrix}\cdot\frac{1}{\begin{bmatrix} 1 & -\frac{1}{2} & 0 \\ 0 & 0 & \frac{\sqrt{2}}{2} \\ 0 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x)=\begin{bmatrix} 1 & \frac{\sqrt{2}\,\sin\left(\sqrt{2}\,x\right)}{2} & \frac{1}{2}-\frac{\cos\left(\sqrt{2}\,x\right)}{2} \\ 0 & \cos\left(\sqrt{2}\,x\right) & \frac{\sqrt{2}\,\sin\left(\sqrt{2}\,x\right)}{2} \\ 0 & -\sqrt{2}\,\sin\left(\sqrt{2}\,x\right) & \cos\left(\sqrt{2}\,x\right) \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

$\vec{y}_p(x)=\Phi(x)\cdot\vec{v}(x)$

- Take the derivative of the particular solution

  $\overrightarrow{y}'_p(x) = \Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$
- Cancel like terms

  $\Phi(x) \cdot \overrightarrow{v}'(x) = \overrightarrow{f}(x)$
- Multiply by the inverse of the fundamental matrix

  $\overrightarrow{v}'(x) = \frac{1}{\Phi(x)} \cdot \overrightarrow{f}(x)$
- Integrate to solve for $\overrightarrow{v}(x)$

  $\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$
- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$
- Plug in the fundamental matrix and the forcing function and compute

  $$\overrightarrow{y}_p(x) = \begin{bmatrix} \frac{x^3}{6} - \frac{x}{2} - \frac{\sqrt{2}\sin\left(\sqrt{2}\,x\right)}{4} + \sin(x) \\ -\frac{1}{2} + \frac{x^2}{2} + \cos(x) - \frac{\cos\left(\sqrt{2}\,x\right)}{2} \\ \frac{\sqrt{2}\sin\left(\sqrt{2}\,x\right)}{2} - \sin(x) + x \end{bmatrix}$$

- Plug particular solution back into general solution

  $$\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2(x) + c_3\overrightarrow{y}_3(x) + \begin{bmatrix} \frac{x^3}{6} - \frac{x}{2} - \frac{\sqrt{2}\sin\left(\sqrt{2}\,x\right)}{4} + \sin(x) \\ -\frac{1}{2} + \frac{x^2}{2} + \cos(x) - \frac{\cos\left(\sqrt{2}\,x\right)}{2} \\ \frac{\sqrt{2}\sin\left(\sqrt{2}\,x\right)}{2} - \sin(x) + x \end{bmatrix}$$
- First component of the vector is the solution to the ODE

  $y = \frac{\left(2c_3 - \sqrt{2}\right)\sin\left(\sqrt{2}\,x\right)}{4} + \frac{x^3}{6} - \frac{c_2\cos\left(\sqrt{2}\,x\right)}{2} - \frac{x}{2} + c_1 + \sin(x)$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 23, page 106
Problem number: 27.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_high_order, _linear, _nonhomogeneous]]`

$$\boxed{y'''' + 3y'' - y' + 2y = \sin(2x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 3y'' - y' + 2y = 0$$

The characteristic equation is

$$\lambda^4 + 3\lambda^2 - \lambda + 2 = 0$$

The roots of the above equation are

$$\begin{aligned}
\lambda_1 &= \text{RootOf}\left(_Z^4 + 3_Z^2 - _Z + 2, \text{index} = 1\right) \\
\lambda_2 &= \text{RootOf}\left(_Z^4 + 3_Z^2 - _Z + 2, \text{index} = 2\right) \\
\lambda_3 &= \text{RootOf}\left(_Z^4 + 3_Z^2 - _Z + 2, \text{index} = 3\right) \\
\lambda_4 &= \text{RootOf}\left(_Z^4 + 3_Z^2 - _Z + 2, \text{index} = 4\right)
\end{aligned}$$

Therefore the homogeneous solution is

$$y_h(x) = e^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=1)x}c_1+e^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=3)x}c_2+e^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=4)}$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned}
y_1 &= e^{\mathrm{RootOf}(_Z^4+3_Z^2-_Z+2,\mathrm{index}=1)x} \\
y_2 &= e^{\mathrm{RootOf}(_Z^4+3_Z^2-_Z+2,\mathrm{index}=3)x} \\
y_3 &= e^{\mathrm{RootOf}(_Z^4+3_Z^2-_Z+2,\mathrm{index}=4)x} \\
y_4 &= e^{\mathrm{RootOf}(_Z^4+3_Z^2-_Z+2,\mathrm{index}=2)x}
\end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' + 3y'' - y' + 2y = \sin(2x)$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=1)x}, e^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=2)x}, e^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=3)x}, e^{\mathrm{RootOf}(\_Z^4}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(2x) + A_2 \sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$6A_1 \cos(2x) + 6A_2 \sin(2x) + 2A_1 \sin(2x) - 2A_2 \cos(2x) = \sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{20}, A_2 = \frac{3}{20}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\cos(2x)}{20} + \frac{3\sin(2x)}{20}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=1)x} c_1 + \mathrm{e}^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=3)x} c_2 \right. \\ &\quad \left. + \mathrm{e}^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=4)x} c_3 + \mathrm{e}^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=2)x} c_4\right) \\ &\quad + \left(\frac{\cos(2x)}{20} + \frac{3\sin(2x)}{20}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y &= \mathrm{e}^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=1)x} c_1 + \mathrm{e}^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=3)x} c_2 \\ &\quad + \mathrm{e}^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=4)x} c_3 \\ &\quad + \mathrm{e}^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=2)x} c_4 + \frac{\cos(2x)}{20} + \frac{3\sin(2x)}{20} \end{aligned} \tag{1}$$

Verification of solutions

$$\begin{aligned} y &= \mathrm{e}^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=1)x} c_1 + \mathrm{e}^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=3)x} c_2 \\ &\quad + \mathrm{e}^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=4)x} c_3 \\ &\quad + \mathrm{e}^{\mathrm{RootOf}(\_Z^4+3\_Z^2-\_Z+2,\mathrm{index}=2)x} c_4 + \frac{\cos(2x)}{20} + \frac{3\sin(2x)}{20} \end{aligned}$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 23, page 106
Problem number: 30.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_high_order, _missing_y]]`

$$\boxed{y'''' + 2y'' + y' = x^3 - \frac{\cos(2x)}{2}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 2y'' + y' = 0$$

The characteristic equation is

$$\lambda^4 + 2\lambda^2 + \lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$

$$\lambda_2 = -\frac{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}{6} + \frac{4}{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}$$

$$\lambda_3 = \frac{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}{12} - \frac{2}{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(-\frac{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}{6} - \frac{4}{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}\right)}{2}$$

$$\lambda_4 = \frac{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}{12} - \frac{2}{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(-\frac{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}{6} - \frac{4}{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}\right)}{2}$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + \mathrm{e}^{\left(\frac{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}{12} - \frac{2}{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(-\frac{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}{6} - \frac{4}{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}\right)}{2}\right)x} c_2 + \mathrm{e}^{\left(\frac{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}{12} - \frac{2}{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}}$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$

$$y_2 = \mathrm{e}^{\left(\frac{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}{12} - \frac{2}{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(-\frac{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}{6} - \frac{4}{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}\right)}{2}\right)x}$$

$$y_3 = \mathrm{e}^{\left(\frac{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}{12} - \frac{2}{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(-\frac{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}{6} - \frac{4}{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}\right)}{2}\right)x}$$

$$y_4 = \mathrm{e}^{\left(-\frac{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}{6} + \frac{4}{\left(108+12\sqrt{177}\right)^{\frac{1}{3}}}\right)x}$$

Now the particular solution to the given ODE is found

$$y'''' + 2y'' + y' = x^3 - \frac{\cos(2x)}{2}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^3 - \frac{\cos(2x)}{2}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(2x), \sin(2x)\}, \{1, x, x^2, x^3\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{1, e^{\left(-\frac{(108+12\sqrt{177})^{\frac{1}{3}}}{6}+\frac{4}{(108+12\sqrt{177})^{\frac{1}{3}}}\right)x}, e^{\left(\frac{(108+12\sqrt{177})^{\frac{1}{3}}}{12}-\frac{2}{(108+12\sqrt{177})^{\frac{1}{3}}}-\frac{i\sqrt{3}\left(-\frac{(108+12\sqrt{177})^{\frac{1}{3}}}{6}-\frac{4}{(108+12\sqrt{177})^{\frac{1}{3}}}\right)}{2}\right)x}, e^{\left(\frac{(108}{}\right.}\right.$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{\cos(2x), \sin(2x)\}, \{x, x^2, x^3, x^4\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 \cos(2x) + A_2 \sin(2x) + A_3 x + A_4 x^2 + A_5 x^3 + A_6 x^4$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&8A_1 \cos(2x) + 8A_2 \sin(2x) + 24A_6 + 4A_4 + 12A_5 x + 24A_6 x^2 - 2A_1 \sin(2x)\\&+ 2A_2 \cos(2x) + A_3 + 2A_4 x + 3A_5 x^2 + 4A_6 x^3 = x^3 - \frac{\cos(2x)}{2}\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{17}, A_2 = -\frac{1}{68}, A_3 = -54, A_4 = 12, A_5 = -2, A_6 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{\cos(2x)}{17} - \frac{\sin(2x)}{68} - 54x + 12x^2 - 2x^3 + \frac{x^4}{4}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 + e^{\left(\frac{(108+12\sqrt{177})^{\frac{1}{3}}}{12} - \frac{2}{(108+12\sqrt{177})^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(-\frac{(108+12\sqrt{177})^{\frac{1}{3}}}{6} - \frac{4}{(108+12\sqrt{177})^{\frac{1}{3}}}\right)}{2}\right)x} c_2 \right. \\
&\quad + e^{\left(\frac{(108+12\sqrt{177})^{\frac{1}{3}}}{12} - \frac{2}{(108+12\sqrt{177})^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(\frac{(108+12\sqrt{177})^{\frac{1}{3}}}{6} - \frac{4}{(108+12\sqrt{177})^{\frac{1}{3}}}\right)}{2}\right)x} c_3 \\
&\quad \left. + e^{\left(-\frac{(108+12\sqrt{177})^{\frac{1}{3}}}{6} + \frac{4}{(108+12\sqrt{177})^{\frac{1}{3}}}\right)x} c_4 \right) \\
&\quad + \left(-\frac{\cos(2x)}{17} - \frac{\sin(2x)}{68} - 54x + 12x^2 - 2x^3 + \frac{x^4}{4}\right)
\end{aligned}$$

Which simplifies to

$$y = c_1 + e^{\frac{\left(i(108+12\sqrt{3}\sqrt{59})^{\frac{2}{3}}\sqrt{3}+24i\sqrt{3}+(108+12\sqrt{3}\sqrt{59})^{\frac{2}{3}}-24\right)x}{12(108+12\sqrt{3}\sqrt{59})^{\frac{1}{3}}}} c_2 + e^{-\frac{x\left((i\sqrt{3}-1)(108+12\sqrt{3}\sqrt{59})^{\frac{2}{3}}+24i\sqrt{3}+24\right)}{12(108+12\sqrt{3}\sqrt{59})^{\frac{1}{3}}}} c_3 + e^{-\frac{\left((108+12\sqrt{3}\sqrt{59})^{\frac{2}{3}}-24\right)x}{6(108+12\sqrt{3}\sqrt{59})^{\frac{1}{3}}}} c_4 - \frac{\cos(2x)}{17} - \frac{\sin(2x)}{68} - 54x + 12x^2 - 2x^3 + \frac{x^4}{4}$$

Summary
The solution(s) found are the following

$$y = c_1 + e^{\frac{\left(i\left(108+12\sqrt{3}\,\sqrt{59}\right)^{\frac{2}{3}}\sqrt{3}+24i\sqrt{3}+\left(108+12\sqrt{3}\,\sqrt{59}\right)^{\frac{2}{3}}-24\right)x}{12\left(108+12\sqrt{3}\,\sqrt{59}\right)^{\frac{1}{3}}}} c_2 + e^{-\frac{x\left(\left(i\sqrt{3}-1\right)\left(108+12\sqrt{3}\,\sqrt{59}\right)^{\frac{2}{3}}+24i\sqrt{3}+24\right)}{12\left(108+12\sqrt{3}\,\sqrt{59}\right)^{\frac{1}{3}}}} c_3 + e^{-\frac{\left(\left(108+12\sqrt{3}\,\sqrt{59}\right)^{\frac{2}{3}}-24\right)x}{6\left(108+12\sqrt{3}\,\sqrt{59}\right)^{\frac{1}{3}}}} c_4 - \frac{\cos(2x)}{17} - \frac{\sin(2x)}{68} - 54x + 12x^2 - 2x^3 + \frac{x^4}{4} \tag{1}$$

Verification of solutions

$$y = c_1 + e^{\frac{\left(i\left(108+12\sqrt{3}\,\sqrt{59}\right)^{\frac{2}{3}}\sqrt{3}+24i\sqrt{3}+\left(108+12\sqrt{3}\,\sqrt{59}\right)^{\frac{2}{3}}-24\right)x}{12\left(108+12\sqrt{3}\,\sqrt{59}\right)^{\frac{1}{3}}}} c_2 + e^{-\frac{x\left(\left(i\sqrt{3}-1\right)\left(108+12\sqrt{3}\,\sqrt{59}\right)^{\frac{2}{3}}+24i\sqrt{3}+24\right)}{12\left(108+12\sqrt{3}\,\sqrt{59}\right)^{\frac{1}{3}}}} c_3 + e^{-\frac{\left(\left(108+12\sqrt{3}\,\sqrt{59}\right)^{\frac{2}{3}}-24\right)x}{6\left(108+12\sqrt{3}\,\sqrt{59}\right)^{\frac{1}{3}}}} c_4 - \frac{\cos(2x)}{17} - \frac{\sin(2x)}{68} - 54x + 12x^2 - 2x^3 + \frac{x^4}{4}$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 23, page 106
Problem number: 31.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' + 4y'' + 5y' = \mathrm{e}^{-2x} \cos(x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + 4y'' + 5y' = 0$$

The characteristic equation is

$$\lambda^3 + 4\lambda^2 + 5\lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = -2 + i$$
$$\lambda_3 = -2 - i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + e^{(-2+i)x} c_2 + e^{(-2-i)x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned}
y_1 &= 1 \\
y_2 &= e^{(-2+i)x} \\
y_3 &= e^{(-2-i)x}
\end{aligned}$$

Now the particular solution to the given ODE is found

$$y''' + 4y'' + 5y' = e^{-2x} \cos(x)$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)} \, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$\begin{aligned}
W &= \begin{bmatrix} 1 & e^{(-2+i)x} & e^{(-2-i)x} \\ 0 & (-2+i)\, e^{(-2+i)x} & (-2-i)\, e^{(-2-i)x} \\ 0 & (3-4i)\, e^{(-2+i)x} & (3+4i)\, e^{(-2-i)x} \end{bmatrix} \\
|W| &= -10i e^{(-2+i)x} e^{(-2-i)x}
\end{aligned}$$

The determinant simplifies to

$$|W| = -10i\mathrm{e}^{-4x}$$

Now we determine W_i for each U_i.

$$\begin{aligned}W_1(x) &= \det\begin{bmatrix}\mathrm{e}^{(-2+i)x} & \mathrm{e}^{(-2-i)x}\\ (-2+i)\,\mathrm{e}^{(-2+i)x} & (-2-i)\,\mathrm{e}^{(-2-i)x}\end{bmatrix}\\ &= -2i\mathrm{e}^{-4x}\end{aligned}$$

$$\begin{aligned}W_2(x) &= \det\begin{bmatrix}1 & \mathrm{e}^{(-2-i)x}\\ 0 & (-2-i)\,\mathrm{e}^{(-2-i)x}\end{bmatrix}\\ &= (-2-i)\,\mathrm{e}^{(-2-i)x}\end{aligned}$$

$$\begin{aligned}W_3(x) &= \det\begin{bmatrix}1 & \mathrm{e}^{(-2+i)x}\\ 0 & (-2+i)\,\mathrm{e}^{(-2+i)x}\end{bmatrix}\\ &= (-2+i)\,\mathrm{e}^{(-2+i)x}\end{aligned}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned}U_1 &= (-1)^{3-1}\int \frac{F(x)W_1(x)}{aW(x)}\,dx\\ &= (-1)^2\int \frac{\left(\mathrm{e}^{-2x}\cos(x)\right)\left(-2i\mathrm{e}^{-4x}\right)}{(1)\left(-10i\mathrm{e}^{-4x}\right)}\,dx\\ &= \int \frac{-2i\mathrm{e}^{-2x}\cos(x)\,\mathrm{e}^{-4x}}{-10i\mathrm{e}^{-4x}}\,dx\\ &= \int \left(\frac{\mathrm{e}^{-2x}\cos(x)}{5}\right)dx\\ &= -\frac{2\,\mathrm{e}^{-2x}\cos(x)}{25} + \frac{\mathrm{e}^{-2x}\sin(x)}{25}\end{aligned}$$

$$
\begin{aligned}
U_2 &= (-1)^{3-2} \int \frac{F(x)W_2(x)}{aW(x)}\,dx \\
&= (-1)^1 \int \frac{\left(e^{-2x}\cos(x)\right)\left((-2-i)\,e^{(-2-i)x}\right)}{(1)\left(-10i e^{-4x}\right)}\,dx \\
&= -\int \frac{(-2-i)\,e^{-2x}\cos(x)\,e^{(-2-i)x}}{-10i e^{-4x}}\,dx \\
&= -\int \left(\left(\frac{1}{10}-\frac{i}{5}\right)\cos(x)\,e^{-ix}\right) dx \\
&= -\left(\int \left(\frac{1}{10}-\frac{i}{5}\right)\cos(x)\,e^{-ix}dx\right)
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{3-3} \int \frac{F(x)W_3(x)}{aW(x)}\,dx \\
&= (-1)^0 \int \frac{\left(e^{-2x}\cos(x)\right)\left((-2+i)\,e^{(-2+i)x}\right)}{(1)\left(-10i e^{-4x}\right)}\,dx \\
&= \int \frac{(-2+i)\,e^{-2x}\cos(x)\,e^{(-2+i)x}}{-10i e^{-4x}}\,dx \\
&= \int \left(\left(-\frac{1}{10}-\frac{i}{5}\right)\cos(x)\,e^{ix}\right) dx \\
&= -\frac{x}{20}-\frac{ix}{10}-\frac{e^{2ix}}{20}+\frac{i e^{2ix}}{40} \\
&= -\frac{x}{20}-\frac{ix}{10}-\frac{e^{2ix}}{20}+\frac{i e^{2ix}}{40}
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Hence

$$
\begin{aligned}
y_p = &\left(-\frac{2\,e^{-2x}\cos(x)}{25}+\frac{e^{-2x}\sin(x)}{25}\right) \\
&+ \left(-\left(\int \left(\frac{1}{10}-\frac{i}{5}\right)\cos(x)\,e^{-ix}dx\right)\right)\left(e^{(-2+i)x}\right) \\
&+ \left(-\frac{x}{20}-\frac{ix}{10}-\frac{e^{2ix}}{20}+\frac{i e^{2ix}}{40}\right)\left(e^{(-2-i)x}\right)
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = \frac{e^{-2x}\left(\left(-\frac{26}{5}+i-4x\right)\cos(x)+2\left(-\frac{7}{10}+i-4x\right)\sin(x)\right)}{40}
$$

Which simplifies to

$$y_p = \frac{e^{-2x}\left(\left(-\frac{26}{5}+i-4x\right)\cos(x)+2\left(-\frac{7}{10}+i-4x\right)\sin(x)\right)}{40}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + e^{(-2+i)x}c_2 + e^{(-2-i)x}c_3\right) \\ &\quad + \left(\frac{e^{-2x}\left(\left(-\frac{26}{5}+i-4x\right)\cos(x)+2\left(-\frac{7}{10}+i-4x\right)\sin(x)\right)}{40}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y &= c_1 + e^{(-2+i)x}c_2 + e^{(-2-i)x}c_3 \\ &\quad + \frac{e^{-2x}\left(\left(-\frac{26}{5}+i-4x\right)\cos(x)+2\left(-\frac{7}{10}+i-4x\right)\sin(x)\right)}{40} \end{aligned} \tag{1}$$

Verification of solutions

$$y = c_1 + e^{(-2+i)x}c_2 + e^{(-2-i)x}c_3 + \frac{e^{-2x}\left(\left(-\frac{26}{5}+i-4x\right)\cos(x)+2\left(-\frac{7}{10}+i-4x\right)\sin(x)\right)}{40}$$

Verified OK.

14.29.1 Maple step by step solution

Let's solve

$y''' + 4y'' + 5y' = e^{-2x}\cos(x)$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(x)$

    $y_1(x) = y$

  - Define new variable $y_2(x)$

    $y_2(x) = y'$

  - Define new variable $y_3(x)$

$y_3(x) = y''$

- Isolate for $y_3'(x)$ using original ODE

  $y_3'(x) = e^{-2x}\cos(x) - 4y_3(x) - 5y_2(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = e^{-2x}\cos(x) - 4y_3(x) - 5y_2(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -5 & -4 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ e^{-2x}\cos(x) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ e^{-2x}\cos(x) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -5 & -4 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[-2 - I, \begin{bmatrix} \frac{3}{25} - \frac{4\,I}{25} \\ -\frac{2}{5} + \frac{I}{5} \\ 1 \end{bmatrix}\right], \left[-2 + I, \begin{bmatrix} \frac{3}{25} + \frac{4\,I}{25} \\ -\frac{2}{5} - \frac{I}{5} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-2 - \mathrm{I}, \begin{bmatrix} \frac{3}{25} - \frac{4\,\mathrm{I}}{25} \\ -\frac{2}{5} + \frac{\mathrm{I}}{5} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$\mathrm{e}^{(-2-\mathrm{I})x} \cdot \begin{bmatrix} \frac{3}{25} - \frac{4\,\mathrm{I}}{25} \\ -\frac{2}{5} + \frac{\mathrm{I}}{5} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$\mathrm{e}^{-2x} \cdot (\cos(x) - \mathrm{I}\sin(x)) \cdot \begin{bmatrix} \frac{3}{25} - \frac{4\,\mathrm{I}}{25} \\ -\frac{2}{5} + \frac{\mathrm{I}}{5} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\mathrm{e}^{-2x} \cdot \begin{bmatrix} \left(\frac{3}{25} - \frac{4\,\mathrm{I}}{25}\right)(\cos(x) - \mathrm{I}\sin(x)) \\ \left(-\frac{2}{5} + \frac{\mathrm{I}}{5}\right)(\cos(x) - \mathrm{I}\sin(x)) \\ \cos(x) - \mathrm{I}\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = \mathrm{e}^{-2x} \cdot \begin{bmatrix} \frac{3\cos(x)}{25} - \frac{4\sin(x)}{25} \\ -\frac{2\cos(x)}{5} + \frac{\sin(x)}{5} \\ \cos(x) \end{bmatrix}, \vec{y}_3(x) = \mathrm{e}^{-2x} \cdot \begin{bmatrix} -\frac{3\sin(x)}{25} - \frac{4\cos(x)}{25} \\ \frac{2\sin(x)}{5} + \frac{\cos(x)}{5} \\ -\sin(x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} 1 & \mathrm{e}^{-2x}\left(\frac{3\cos(x)}{25} - \frac{4\sin(x)}{25}\right) & \mathrm{e}^{-2x}\left(-\frac{3\sin(x)}{25} - \frac{4\cos(x)}{25}\right) \\ 0 & \mathrm{e}^{-2x}\left(-\frac{2\cos(x)}{5} + \frac{\sin(x)}{5}\right) & \mathrm{e}^{-2x}\left(\frac{2\sin(x)}{5} + \frac{\cos(x)}{5}\right) \\ 0 & \mathrm{e}^{-2x}\cos(x) & -\mathrm{e}^{-2x}\sin(x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} 1 & \mathrm{e}^{-2x}\left(\frac{3\cos(x)}{25} - \frac{4\sin(x)}{25}\right) & \mathrm{e}^{-2x}\left(-\frac{3\sin(x)}{25} - \frac{4\cos(x)}{25}\right) \\ 0 & \mathrm{e}^{-2x}\left(-\frac{2\cos(x)}{5} + \frac{\sin(x)}{5}\right) & \mathrm{e}^{-2x}\left(\frac{2\sin(x)}{5} + \frac{\cos(x)}{5}\right) \\ 0 & \mathrm{e}^{-2x}\cos(x) & -\mathrm{e}^{-2x}\sin(x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & \frac{3}{25} & -\frac{4}{25} \\ 0 & -\frac{2}{5} & \frac{1}{5} \\ 0 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} 1 & \frac{4}{5} + \frac{\mathrm{e}^{-2x}(-3\sin(x)-4\cos(x))}{5} & \frac{1}{5} + \frac{(-\cos(x)-2\sin(x))\mathrm{e}^{-2x}}{5} \\ 0 & \mathrm{e}^{-2x}(\cos(x) + 2\sin(x)) & \mathrm{e}^{-2x}\sin(x) \\ 0 & -5\,\mathrm{e}^{-2x}\sin(x) & \mathrm{e}^{-2x}(-2\sin(x) + \cos(x)) \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

$\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

$\vec{y}'_p(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x)\cdot \vec{v}(x)+\Phi(x)\cdot \vec{v}'(x)=A\cdot \Phi(x)\cdot \vec{v}(x)+\vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A\cdot \Phi(x)\cdot \vec{v}(x)+\Phi(x)\cdot \vec{v}'(x)=A\cdot \Phi(x)\cdot \vec{v}(x)+\vec{f}(x)$

- Cancel like terms

  $\Phi(x)\cdot \vec{v}'(x)=\vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x)=\frac{1}{\Phi(x)}\cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x)=\int_0^x \frac{1}{\Phi(s)}\cdot \vec{f}(s)\,ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x)=\Phi(x)\cdot \left(\int_0^x \frac{1}{\Phi(s)}\cdot \vec{f}(s)\,ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x)=\left[\begin{array}{c}\frac{2}{25}+\frac{((-5x-4)\cos(x)+(-10x-3)\sin(x))\mathrm{e}^{-2x}}{50}\\ \frac{\mathrm{e}^{-2x}\sin(x)x}{2}\\ \frac{\mathrm{e}^{-2x}(\sin(x)+x\cos(x)-2\sin(x)x)}{2}\end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x)=c_1\vec{y}_1+c_2\vec{y}_2(x)+c_3\vec{y}_3(x)+\left[\begin{array}{c}\frac{2}{25}+\frac{((-5x-4)\cos(x)+(-10x-3)\sin(x))\mathrm{e}^{-2x}}{50}\\ \frac{\mathrm{e}^{-2x}\sin(x)x}{2}\\ \frac{\mathrm{e}^{-2x}(\sin(x)+x\cos(x)-2\sin(x)x)}{2}\end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y=\frac{\left((-5x+6c_2-8c_3-4)\cos(x)-10\left(x+\frac{4c_2}{5}+\frac{3c_3}{5}+\frac{3}{10}\right)\sin(x)\right)\mathrm{e}^{-2x}}{50}+c_1+\frac{2}{25}$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 23, page 106
Problem number: 32.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' + y'' - 2y' = e^{-2x} \cos(2x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + y'' - 2y' = 0$$

The characteristic equation is

$$\lambda^3 + \lambda^2 - 2\lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 1$$
$$\lambda_3 = -2$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + c_2 e^{-2x} + c_3 e^x$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= 1 \\
y_2 &= \mathrm{e}^{-2x} \\
y_3 &= \mathrm{e}^{x}
\end{aligned}
$$

Now the particular solution to the given ODE is found

$$
y''' + y'' - 2y' = \mathrm{e}^{-2x} \cos(2x)
$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
\mathrm{e}^{-2x} \cos(2x)
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\mathrm{e}^{-2x} \cos(2x), \mathrm{e}^{-2x} \sin(2x)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{1, \mathrm{e}^{x}, \mathrm{e}^{-2x}\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 \mathrm{e}^{-2x} \cos(2x) + A_2 \mathrm{e}^{-2x} \sin(2x)
$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
\begin{aligned}
&-4A_1 \mathrm{e}^{-2x} \sin(2x) + 20A_1 \mathrm{e}^{-2x} \cos(2x) + 4A_2 \mathrm{e}^{-2x} \cos(2x) + 20A_2 \mathrm{e}^{-2x} \sin(2x) \\
&= \mathrm{e}^{-2x} \cos(2x)
\end{aligned}
$$

Solving for the unknowns by comparing coefficients results in

$$
\left[A_1 = \frac{5}{104}, A_2 = \frac{1}{104}\right]
$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{5\,\mathrm{e}^{-2x}\cos(2x)}{104} + \frac{\mathrm{e}^{-2x}\sin(2x)}{104}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + c_2\mathrm{e}^{-2x} + c_3\mathrm{e}^{x}\right) + \left(\frac{5\,\mathrm{e}^{-2x}\cos(2x)}{104} + \frac{\mathrm{e}^{-2x}\sin(2x)}{104}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + c_2\mathrm{e}^{-2x} + c_3\mathrm{e}^{x} + \frac{5\,\mathrm{e}^{-2x}\cos(2x)}{104} + \frac{\mathrm{e}^{-2x}\sin(2x)}{104} \tag{1}$$

Verification of solutions

$$y = c_1 + c_2\mathrm{e}^{-2x} + c_3\mathrm{e}^{x} + \frac{5\,\mathrm{e}^{-2x}\cos(2x)}{104} + \frac{\mathrm{e}^{-2x}\sin(2x)}{104}$$

Verified OK.

14.30.1 Maple step by step solution

Let's solve

$y''' + y'' - 2y' = \mathrm{e}^{-2x}\cos(2x)$

- Highest derivative means the order of the ODE is 3

  y'''

- ☐ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

$y_3'(x) = \mathrm{e}^{-2x} \cos(2x) - y_3(x) + 2y_2(x)$

Convert linear ODE into a system of first order ODEs

$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = \mathrm{e}^{-2x} \cos(2x) - y_3(x) + 2y_2(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 2 & -1 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ \mathrm{e}^{-2x} \cos(2x) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ \mathrm{e}^{-2x} \cos(2x) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 2 & -1 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2, \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}\right], \left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-2, \left[\begin{array}{c} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{-2x} \cdot \left[\begin{array}{c} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[0, \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = \mathrm{e}^{x} \cdot \left[\begin{array}{c} 1 \\ 1 \\ 1 \end{array}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3 + \vec{y}_p(x)$$

□ Fundamental matrix

  ◦ Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} \frac{e^{-2x}}{4} & 1 & e^{x} \\ -\frac{e^{-2x}}{2} & 0 & e^{x} \\ e^{-2x} & 0 & e^{x} \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

  $$\Phi(x) = \begin{bmatrix} \frac{e^{-2x}}{4} & 1 & e^{x} \\ -\frac{e^{-2x}}{2} & 0 & e^{x} \\ e^{-2x} & 0 & e^{x} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} \frac{1}{4} & 1 & 1 \\ -\frac{1}{2} & 0 & 1 \\ 1 & 0 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

  $$\Phi(x) = \begin{bmatrix} 1 & \frac{(4\,e^{3x}-3\,e^{2x}-1)e^{-2x}}{6} & \frac{(2\,e^{3x}-3\,e^{2x}+1)e^{-2x}}{6} \\ 0 & \frac{(2\,e^{3x}+1)e^{-2x}}{3} & \frac{(e^{3x}-1)e^{-2x}}{3} \\ 0 & \frac{2(e^{3x}-1)e^{-2x}}{3} & \frac{(e^{3x}+2)e^{-2x}}{3} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

$\overrightarrow{v}'(x) = \frac{1}{\Phi(x)} \cdot \overrightarrow{f}(x)$

- Integrate to solve for $\overrightarrow{v}(x)$

  $\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$

- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\overrightarrow{y}_p(x) = \left[\begin{array}{c} \frac{e^{-2x}\left(8\,e^{3x}-13\,e^{2x}+5\cos(2x)+\sin(2x)\right)}{104} \\ -\frac{\left(-2\,e^{3x}+2\cos(2x)+3\sin(2x)\right)e^{-2x}}{26} \\ -\frac{\left(-e^{3x}+\cos(2x)-5\sin(2x)\right)e^{-2x}}{13} \end{array}\right]$$

- Plug particular solution back into general solution

$$\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2 + c_3\overrightarrow{y}_3 + \left[\begin{array}{c} \frac{e^{-2x}\left(8\,e^{3x}-13\,e^{2x}+5\cos(2x)+\sin(2x)\right)}{104} \\ -\frac{\left(-2\,e^{3x}+2\cos(2x)+3\sin(2x)\right)e^{-2x}}{26} \\ -\frac{\left(-e^{3x}+\cos(2x)-5\sin(2x)\right)e^{-2x}}{13} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = \frac{\left(104c_3e^{3x}+8\,e^{3x}+104c_2e^{2x}-13\,e^{2x}+5\cos(2x)+\sin(2x)+26c_1\right)e^{-2x}}{104}$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 23, page 106
Problem number: 33.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' + 2y' = \sin(x)\, x^2}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + 2y' = 0$$

The characteristic equation is

$$\lambda^3 + 2\lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = i\sqrt{2}$$
$$\lambda_3 = -i\sqrt{2}$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + e^{-i\sqrt{2}\,x}c_2 + e^{i\sqrt{2}\,x}c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = e^{-i\sqrt{2}\,x}$$
$$y_3 = e^{i\sqrt{2}\,x}$$

Now the particular solution to the given ODE is found

$$y''' + 2y' = \sin(x)\,x^2$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)\,x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\cos(x), x^2\cos(x), \sin(x)\,x, \sin(x)\,x^2, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{1, e^{i\sqrt{2}\,x}, e^{-i\sqrt{2}\,x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1x\cos(x) + A_2x^2\cos(x) + A_3\sin(x)\,x + A_4\sin(x)\,x^2 + A_5\cos(x) + A_6\sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-A_1\cos(x) - A_1x\sin(x) - 6A_2\sin(x) - 2A_2x\cos(x)\\ &- A_2x^2\sin(x) + A_3\cos(x)\,x - A_3\sin(x) + A_4\cos(x)\,x^2\\ &- 2A_4\sin(x)\,x + 6A_4\cos(x) - A_5\sin(x) + A_6\cos(x) = \sin(x)\,x^2\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = -1, A_3 = -2, A_4 = 0, A_5 = 8, A_6 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -x^2 \cos(x) - 2\sin(x)\, x + 8\cos(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + \mathrm{e}^{-i\sqrt{2}\,x} c_2 + \mathrm{e}^{i\sqrt{2}\,x} c_3\right) + \left(-x^2 \cos(x) - 2\sin(x)\, x + 8\cos(x)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + \mathrm{e}^{-i\sqrt{2}\,x} c_2 + \mathrm{e}^{i\sqrt{2}\,x} c_3 - x^2 \cos(x) - 2\sin(x)\, x + 8\cos(x) \tag{1}$$

Verification of solutions

$$y = c_1 + \mathrm{e}^{-i\sqrt{2}\,x} c_2 + \mathrm{e}^{i\sqrt{2}\,x} c_3 - x^2 \cos(x) - 2\sin(x)\, x + 8\cos(x)$$

Verified OK.

14.31.1 Maple step by step solution

Let's solve

$y''' + 2y' = \sin(x)\, x^2$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

  ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$

- Isolate for $y_3'(x)$ using original ODE

  $y_3'(x) = \sin(x)\, x^2 - 2y_2(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = \sin(x)\, x^2 - 2y_2(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -2 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ \sin(x)\, x^2 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ \sin(x)\, x^2 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -2 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[-\mathrm{I}\sqrt{2}, \begin{bmatrix} -\frac{1}{2} \\ \frac{\mathrm{I}}{2}\sqrt{2} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}\sqrt{2}, \begin{bmatrix} -\frac{1}{2} \\ -\frac{\mathrm{I}}{2}\sqrt{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}\sqrt{2}, \left[\begin{array}{c} -\frac{1}{2} \\ \frac{\mathrm{I}}{2}\sqrt{2} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$\mathrm{e}^{-\mathrm{I}\sqrt{2}\,x} \cdot \left[\begin{array}{c} -\frac{1}{2} \\ \frac{\mathrm{I}}{2}\sqrt{2} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$\left(\cos\left(\sqrt{2}\,x\right) - \mathrm{I}\sin\left(\sqrt{2}\,x\right)\right) \cdot \left[\begin{array}{c} -\frac{1}{2} \\ \frac{\mathrm{I}}{2}\sqrt{2} \\ 1 \end{array}\right]$$

- Simplify expression

$$\left[\begin{array}{c} -\frac{\cos\left(\sqrt{2}\,x\right)}{2} + \frac{\mathrm{I}\sin\left(\sqrt{2}\,x\right)}{2} \\ \frac{\mathrm{I}}{2}\left(\cos\left(\sqrt{2}\,x\right) - \mathrm{I}\sin\left(\sqrt{2}\,x\right)\right)\sqrt{2} \\ \cos\left(\sqrt{2}\,x\right) - \mathrm{I}\sin\left(\sqrt{2}\,x\right) \end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = \begin{bmatrix} -\frac{\cos\left(\sqrt{2}\,x\right)}{2} \\ \frac{\sqrt{2}\,\sin\left(\sqrt{2}\,x\right)}{2} \\ \cos\left(\sqrt{2}\,x\right) \end{bmatrix}, \vec{y}_3(x) = \begin{bmatrix} \frac{\sin\left(\sqrt{2}\,x\right)}{2} \\ \frac{\sqrt{2}\,\cos\left(\sqrt{2}\,x\right)}{2} \\ -\sin\left(\sqrt{2}\,x\right) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} 1 & -\frac{\cos\left(\sqrt{2}\,x\right)}{2} & \frac{\sin\left(\sqrt{2}\,x\right)}{2} \\ 0 & \frac{\sqrt{2}\,\sin\left(\sqrt{2}\,x\right)}{2} & \frac{\sqrt{2}\,\cos\left(\sqrt{2}\,x\right)}{2} \\ 0 & \cos\left(\sqrt{2}\,x\right) & -\sin\left(\sqrt{2}\,x\right) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} 1 & -\frac{\cos\left(\sqrt{2}\,x\right)}{2} & \frac{\sin\left(\sqrt{2}\,x\right)}{2} \\ 0 & \frac{\sqrt{2}\,\sin\left(\sqrt{2}\,x\right)}{2} & \frac{\sqrt{2}\,\cos\left(\sqrt{2}\,x\right)}{2} \\ 0 & \cos\left(\sqrt{2}\,x\right) & -\sin\left(\sqrt{2}\,x\right) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & -\frac{1}{2} & 0 \\ 0 & 0 & \frac{\sqrt{2}}{2} \\ 0 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} 1 & \frac{\sqrt{2}\,\sin\left(\sqrt{2}\,x\right)}{2} & \frac{1}{2} - \frac{\cos\left(\sqrt{2}\,x\right)}{2} \\ 0 & \cos\left(\sqrt{2}\,x\right) & \frac{\sqrt{2}\,\sin\left(\sqrt{2}\,x\right)}{2} \\ 0 & -\sqrt{2}\,\sin\left(\sqrt{2}\,x\right) & \cos\left(\sqrt{2}\,x\right) \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

$\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

$\vec{y}_p'(x) = \Phi'(x)\cdot\vec{v}(x) + \Phi(x)\cdot\vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x)\cdot\vec{v}(x) + \Phi(x)\cdot\vec{v}'(x) = A\cdot\Phi(x)\cdot\vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A\cdot\Phi(x)\cdot\vec{v}(x) + \Phi(x)\cdot\vec{v}'(x) = A\cdot\Phi(x)\cdot\vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x)\cdot\vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)}\cdot\vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)}\cdot\vec{f}(s)\,ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x)\cdot\left(\int_0^x \frac{1}{\Phi(s)}\cdot\vec{f}(s)\,ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \left[\begin{array}{c} -1 - x^2\cos(x) - 2\sin(x)x + 8\cos(x) - 7\cos(\sqrt{2}\,x) \\ \frac{\left(14\sin\left(\sqrt{2}\,x\right)+\sqrt{2}\,(-4x\cos(x)+\sin(x)x^2-10\sin(x))\right)\sqrt{2}}{2\left(1+\sqrt{2}\right)^3\left(\sqrt{2}-1\right)^3} \\ x^2\cos(x) + 6\sin(x)x - 14\cos(x) + 14\cos(\sqrt{2}\,x) \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \left[\begin{array}{c} -1 - x^2\cos(x) - 2\sin(x)x + 8\cos(x) - 7\cos(\sqrt{2}\,x) \\ \frac{\left(14\sin\left(\sqrt{2}\,x\right)+\sqrt{2}\,(-4x\cos(x)+\sin(x)x^2-10\sin(x))\right)\sqrt{2}}{2\left(1+\sqrt{2}\right)^3\left(\sqrt{2}-1\right)^3} \\ x^2\cos(x) + 6\sin(x)x - 14\cos(x) + 14\cos(\sqrt{2}\,x) \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = -1 - x^2\cos(x) - 2\sin(x)x + 8\cos(x) - 7\cos(\sqrt{2}\,x) + \frac{c_3\sin\left(\sqrt{2}\,x\right)}{2} - \frac{c_2\cos\left(\sqrt{2}\,x\right)}{2} + c_1$$

Problem number: 34.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'''' - y = x^2 \cos(x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - y = 0$$

The characteristic equation is

$$\lambda^4 - 1 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = -1$$
$$\lambda_3 = i$$
$$\lambda_4 = -i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} + \mathrm{e}^{-ix} c_3 + \mathrm{e}^{ix} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= \mathrm{e}^{-x} \\ y_2 &= \mathrm{e}^{x} \\ y_3 &= \mathrm{e}^{-ix} \\ y_4 &= \mathrm{e}^{ix} \end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' - y = x^2 \cos(x)$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)} \, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 & y_4 \\ y_1' & y_2' & y_3' & y_4' \\ y_1'' & y_2'' & y_3'' & y_4'' \\ y_1''' & y_2''' & y_3''' & y_4''' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} \mathrm{e}^{-x} & \mathrm{e}^{x} & \mathrm{e}^{-ix} & \mathrm{e}^{ix} \\ -\mathrm{e}^{-x} & \mathrm{e}^{x} & -i\mathrm{e}^{-ix} & i\mathrm{e}^{ix} \\ \mathrm{e}^{-x} & \mathrm{e}^{x} & -\mathrm{e}^{-ix} & -\mathrm{e}^{ix} \\ -\mathrm{e}^{-x} & \mathrm{e}^{x} & i\mathrm{e}^{-ix} & -i\mathrm{e}^{ix} \end{bmatrix}$$

$$|W| = 16i \mathrm{e}^{-x} \mathrm{e}^{x} \mathrm{e}^{-ix} \mathrm{e}^{ix}$$

The determinant simplifies to

$$|W| = 16i$$

Now we determine W_i for each U_i.

$$W_1(x) = \det\begin{bmatrix} e^x & e^{-ix} & e^{ix} \\ e^x & -ie^{-ix} & ie^{ix} \\ e^x & -e^{-ix} & -e^{ix} \end{bmatrix}$$
$$= 4ie^x$$

$$W_2(x) = \det\begin{bmatrix} e^{-x} & e^{-ix} & e^{ix} \\ -e^{-x} & -ie^{-ix} & ie^{ix} \\ e^{-x} & -e^{-ix} & -e^{ix} \end{bmatrix}$$
$$= 4ie^{-x}$$

$$W_3(x) = \det\begin{bmatrix} e^{-x} & e^x & e^{ix} \\ -e^{-x} & e^x & ie^{ix} \\ e^{-x} & e^x & -e^{ix} \end{bmatrix}$$
$$= -4\,e^{ix}$$

$$W_4(x) = \det\begin{bmatrix} e^{-x} & e^x & e^{-ix} \\ -e^{-x} & e^x & -ie^{-ix} \\ e^{-x} & e^x & -e^{-ix} \end{bmatrix}$$
$$= -4\,e^{-ix}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned} U_1 &= (-1)^{4-1}\int \frac{F(x)W_1(x)}{aW(x)}\,dx \\ &= (-1)^3\int \frac{(x^2\cos(x))\,(4ie^x)}{(1)\,(16i)}\,dx \\ &= -\int \frac{4ix^2\cos(x)\,e^x}{16i}\,dx \\ &= -\int \left(\frac{\cos(x)\,e^x x^2}{4}\right)dx \\ &= -\frac{\left(\frac{x^2}{2}-\frac{1}{2}\right)e^x\cos(x)}{4} + \frac{\left(x-\frac{1}{2}x^2-\frac{1}{2}\right)e^x\sin(x)}{4} \end{aligned}$$

$$
\begin{aligned}
U_2 &= (-1)^{4-2} \int \frac{F(x)W_2(x)}{aW(x)}\,dx \\
&= (-1)^2 \int \frac{\left(x^2 \cos(x)\right)\left(4i\mathrm{e}^{-x}\right)}{(1)\,(16i)}\,dx \\
&= \int \frac{4ix^2 \cos(x)\,\mathrm{e}^{-x}}{16i}\,dx \\
&= \int \left(\frac{x^2 \cos(x)\,\mathrm{e}^{-x}}{4}\right) dx \\
&= \frac{\left(-\frac{x^2}{2} + \frac{1}{2}\right)\mathrm{e}^{-x}\cos(x)}{4} - \frac{\left(-\frac{1}{2}x^2 - x - \frac{1}{2}\right)\mathrm{e}^{-x}\sin(x)}{4}
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{4-3} \int \frac{F(x)W_3(x)}{aW(x)}\,dx \\
&= (-1)^1 \int \frac{\left(x^2 \cos(x)\right)\left(-4\,\mathrm{e}^{ix}\right)}{(1)\,(16i)}\,dx \\
&= -\int \frac{-4x^2 \cos(x)\,\mathrm{e}^{ix}}{16i}\,dx \\
&= -\int \left(\frac{ix^2 \cos(x)\,\mathrm{e}^{ix}}{4}\right) dx \\
&= -\frac{ix^3}{24} - \frac{\left(2x^2 + 2ix - 1\right)\mathrm{e}^{2ix}}{32}
\end{aligned}
$$

$$
\begin{aligned}
U_4 &= (-1)^{4-4} \int \frac{F(x)W_4(x)}{aW(x)}\,dx \\
&= (-1)^0 \int \frac{\left(x^2 \cos(x)\right)\left(-4\,\mathrm{e}^{-ix}\right)}{(1)\,(16i)}\,dx \\
&= \int \frac{-4x^2 \cos(x)\,\mathrm{e}^{-ix}}{16i}\,dx \\
&= \int \left(\frac{ix^2 \cos(x)\,\mathrm{e}^{-ix}}{4}\right) dx \\
&= \int \frac{ix^2 \cos(x)\,\mathrm{e}^{-ix}}{4} dx
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4
$$

Hence

$$y_p = \left(-\frac{\left(\frac{x^2}{2}-\frac{1}{2}\right)\mathrm{e}^{x}\cos\left(x\right)}{4}+\frac{\left(x-\frac{1}{2}x^2-\frac{1}{2}\right)\mathrm{e}^{x}\sin\left(x\right)}{4}\right)\left(\mathrm{e}^{-x}\right)$$
$$+\left(\frac{\left(-\frac{x^2}{2}+\frac{1}{2}\right)\mathrm{e}^{-x}\cos\left(x\right)}{4}-\frac{\left(-\frac{1}{2}x^2-x-\frac{1}{2}\right)\mathrm{e}^{-x}\sin\left(x\right)}{4}\right)\left(\mathrm{e}^{x}\right)$$
$$+\left(-\frac{ix^3}{24}-\frac{\left(2x^2+2ix-1\right)\mathrm{e}^{2ix}}{32}\right)\left(\mathrm{e}^{-ix}\right)$$
$$+\left(\int\frac{ix^2\cos\left(x\right)\mathrm{e}^{-ix}}{4}dx\right)\left(\mathrm{e}^{ix}\right)$$

Therefore the particular solution is

$$y_p = \frac{\sin\left(x\right)\left(-8x^3+60x+3i\right)}{96}+\frac{\left(-36x^2+33\right)\cos\left(x\right)}{96}$$

Which simplifies to

$$y_p = \frac{\sin\left(x\right)\left(-8x^3+60x+3i\right)}{96}+\frac{\left(-36x^2+33\right)\cos\left(x\right)}{96}$$

Therefore the general solution is

$$y = y_h + y_p$$
$$= \left(c_1\mathrm{e}^{-x}+c_2\mathrm{e}^{x}+\mathrm{e}^{-ix}c_3+\mathrm{e}^{ix}c_4\right)+\left(\frac{\sin\left(x\right)\left(-8x^3+60x+3i\right)}{96}+\frac{\left(-36x^2+33\right)\cos\left(x\right)}{96}\right)$$

<u>Summary</u>

The solution(s) found are the following

$$y = c_1\mathrm{e}^{-x}+c_2\mathrm{e}^{x}+\mathrm{e}^{-ix}c_3+\mathrm{e}^{ix}c_4+\frac{\sin\left(x\right)\left(-8x^3+60x+3i\right)}{96}+\frac{\left(-36x^2+33\right)\cos\left(x\right)}{96} \tag{1}$$

<u>Verification of solutions</u>

$$y = c_1\mathrm{e}^{-x}+c_2\mathrm{e}^{x}+\mathrm{e}^{-ix}c_3+\mathrm{e}^{ix}c_4+\frac{\sin\left(x\right)\left(-8x^3+60x+3i\right)}{96}+\frac{\left(-36x^2+33\right)\cos\left(x\right)}{96}$$

Verified OK.

14.32.1 Maple step by step solution

Let's solve

$y'''' - y = x^2 \cos(x)$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(x)$

    $y_1(x) = y$

  - Define new variable $y_2(x)$

    $y_2(x) = y'$

  - Define new variable $y_3(x)$

    $y_3(x) = y''$

  - Define new variable $y_4(x)$

    $y_4(x) = y'''$

  - Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = x^2 \cos(x) + y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = x^2 \cos(x) + y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ x^2 \cos(x) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 0 \\ x^2 \cos(x) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} \mathrm{I} \\ -1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{-x} \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-I, \begin{bmatrix} -I \\ -1 \\ I \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-Ix} \cdot \begin{bmatrix} -I \\ -1 \\ I \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(x) - I\sin(x)) \cdot \begin{bmatrix} -I \\ -1 \\ I \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ -\cos(x) + \mathrm{I}\sin(x) \\ \mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ \cos(x) - \mathrm{I}\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\overrightarrow{y}_3(x) = \begin{bmatrix} -\sin(x) \\ -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \overrightarrow{y}_4(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{y}_p($

$\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2 + c_3\overrightarrow{y}_3(x) + c_4\overrightarrow{y}_4(x) + \overrightarrow{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} -\mathrm{e}^{-x} & \mathrm{e}^{x} & -\sin(x) & -\cos(x) \\ \mathrm{e}^{-x} & \mathrm{e}^{x} & -\cos(x) & \sin(x) \\ -\mathrm{e}^{-x} & \mathrm{e}^{x} & \sin(x) & \cos(x) \\ \mathrm{e}^{-x} & \mathrm{e}^{x} & \cos(x) & -\sin(x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} -\mathrm{e}^{-x} & \mathrm{e}^{x} & -\sin(x) & -\cos(x) \\ \mathrm{e}^{-x} & \mathrm{e}^{x} & -\cos(x) & \sin(x) \\ -\mathrm{e}^{-x} & \mathrm{e}^{x} & \sin(x) & \cos(x) \\ \mathrm{e}^{-x} & \mathrm{e}^{x} & \cos(x) & -\sin(x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -1 & 1 & 0 & -1 \\ 1 & 1 & -1 & 0 \\ -1 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} \frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\cos(x)}{2} & -\frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\sin(x)}{2} & \frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\cos(x)}{2} & -\frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\sin(x)}{2} \\ -\frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\sin(x)}{2} & \frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\cos(x)}{2} & -\frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\sin(x)}{2} & \frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\cos(x)}{2} \\ \frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\cos(x)}{2} & -\frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\sin(x)}{2} & \frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\cos(x)}{2} & -\frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\sin(x)}{2} \\ -\frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\sin(x)}{2} & \frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\cos(x)}{2} & -\frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\sin(x)}{2} & \frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\cos(x)}{2} \end{bmatrix}$$

- ☐ Find a particular solution of the system of ODEs using variation of parameters
  - Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

    $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$
  - Take the derivative of the particular solution

    $\vec{y}'_p(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$
  - Substitute particular solution and its derivative into the system of ODEs

    $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
  - The fundamental matrix has columns that are solutions to the homogeneous system so its der

    $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
  - Cancel like terms

    $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$
  - Multiply by the inverse of the fundamental matrix

    $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$
  - Integrate to solve for $\vec{v}(x)$

    $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$
  - Plug $\vec{v}(x)$ into the equation for the particular solution

    $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$
  - Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \begin{bmatrix} -\frac{e^{-x}}{8} + \frac{(-3x^2+2)\cos(x)}{8} + \frac{\sin(x)(-2x^3+15x)}{24} - \frac{e^{x}}{8} \\ \frac{e^{-x}}{8} + \frac{(-2x^3-3x)\cos(x)}{24} + \frac{(x^2+3)\sin(x)}{8} - \frac{e^{x}}{8} \\ -\frac{e^{-x}}{8} + \frac{(-x^2+2)\cos(x)}{8} + \frac{(2x^3+9x)\sin(x)}{24} - \frac{e^{x}}{8} \\ \frac{e^{-x}}{8} + \frac{(2x^3+3x)\cos(x)}{24} + \frac{(3x^2+1)\sin(x)}{8} - \frac{e^{x}}{8} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \begin{bmatrix} -\frac{e^{-x}}{8} + \frac{(-3x^2+2)\cos(x)}{8} + \frac{\sin(x)(-2x^3+15x)}{24} - \frac{e^x}{8} \\ \frac{e^{-x}}{8} + \frac{(-2x^3-3x)\cos(x)}{24} + \frac{(x^2+3)\sin(x)}{8} - \frac{e^x}{8} \\ -\frac{e^{-x}}{8} + \frac{(-x^2+2)\cos(x)}{8} + \frac{(2x^3+9x)\sin(x)}{24} - \frac{e^x}{8} \\ \frac{e^{-x}}{8} + \frac{(2x^3+3x)\cos(x)}{24} + \frac{(3x^2+1)\sin(x)}{8} - \frac{e^x}{8} \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = \frac{(-8c_1-1)e^{-x}}{8} + \frac{(-3x^2-8c_4+2)\cos(x)}{8} + \frac{(-2x^3-24c_3+15x)\sin(x)}{24} + \frac{e^x(8c_2-1)}{8}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + 4y = \sin(x) x}$$

15.1.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 4, f(x) = \sin(x) x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(4)} \\ &= \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2i \\ \lambda_2 &= -2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2i \\ \lambda_2 &= -2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(2x) + c_2 \sin(2x))$$

Or

$$y = c_1 \cos(2x) + c_2 \sin(2x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(2x) + c_2 \sin(2x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)\, x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\cos(x), \sin(x)\, x, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(2x), \sin(2x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x \cos(x) + A_2 \sin(x)\, x + A_3 \cos(x) + A_4 \sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}
&-2A_1 \sin(x) + 3A_1 x \cos(x) + 3A_2 \sin(x)\, x + 2A_2 \cos(x) + 3A_3 \cos(x) + 3A_4 \sin(x) \\
&= \sin(x)\, x
\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{3}, A_3 = -\frac{2}{9}, A_4 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\sin(x)\, x}{3} - \frac{2\cos(x)}{9}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(2x) + c_2 \sin(2x)) + \left(\frac{\sin(x)\, x}{3} - \frac{2\cos(x)}{9}\right)
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \cos(2x) + c_2 \sin(2x) + \frac{\sin(x)\, x}{3} - \frac{2\cos(x)}{9} \tag{1}$$

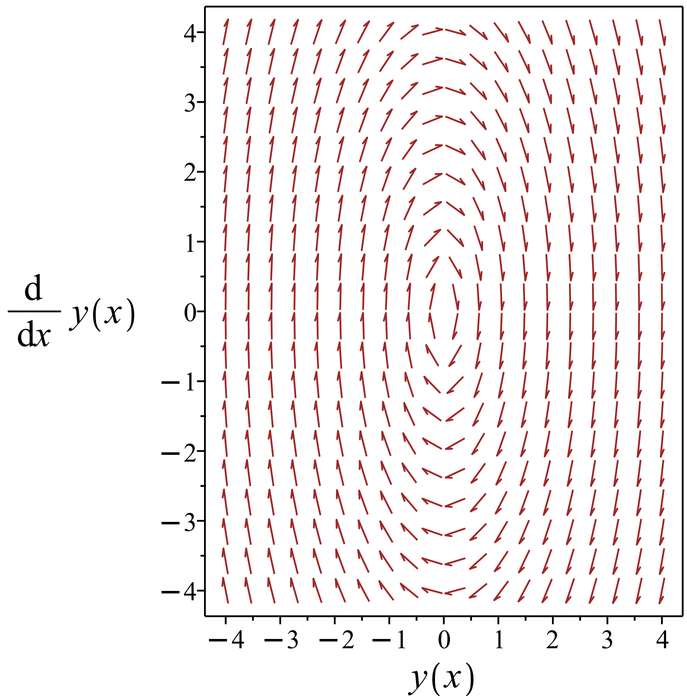

Figure 662: Slope field plot

Verification of solutions

$$y = c_1 \cos(2x) + c_2 \sin(2x) + \frac{\sin(x)\, x}{3} - \frac{2\cos(x)}{9}$$

Verified OK.

15.1.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 516: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(2x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \cos(2x) \int \frac{1}{\cos(2x)^2}\, dx \\
&= \cos(2x) \left(\frac{\tan(2x)}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(2x)) + c_2\left(\cos(2x)\left(\frac{\tan(2x)}{2}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)\,x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\cos(x),\sin(x)\,x,\cos(x),\sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sin(2x)}{2},\cos(2x)\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1x\cos(x)+A_2\sin(x)\,x+A_3\cos(x)+A_4\sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1\sin(x)+3A_1x\cos(x)+3A_2\sin(x)\,x+2A_2\cos(x)+3A_3\cos(x)+3A_4\sin(x) = \sin(x)\,x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1=0, A_2=\frac{1}{3}, A_3=-\frac{2}{9}, A_4=0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\sin(x)\,x}{3}-\frac{2\cos(x)}{9}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\cos(2x)+\frac{c_2\sin(2x)}{2}\right)+\left(\frac{\sin(x)\,x}{3}-\frac{2\cos(x)}{9}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2} + \frac{\sin(x)\, x}{3} - \frac{2\cos(x)}{9} \tag{1}$$

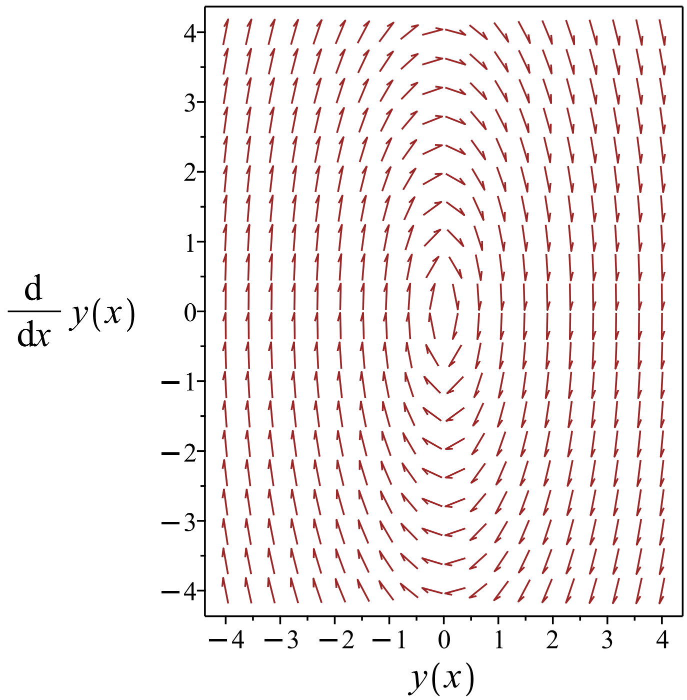

Figure 663: Slope field plot

Verification of solutions

$$y = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2} + \frac{\sin(x)\, x}{3} - \frac{2\cos(x)}{9}$$

Verified OK.

15.1.3 Maple step by step solution

Let's solve

$y'' + 4y = \sin(x)\, x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 + 4 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r = (-2\,\mathrm{I}, 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(2x) + c_2 \sin(2x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \sin(x)\, x\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(2x) & \sin(2x) \\ -2\sin(2x) & 2\cos(2x) \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\cos(2x)\left(\int \sin(2x)\sin(x) x dx\right)}{2} + \frac{\sin(2x)\left(\int \cos(2x)\sin(x) x dx\right)}{2}$

- ○ Compute integrals

  $y_p(x) = \frac{\sin(x) x}{3} - \frac{2\cos(x)}{9}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(2x) + c_2 \sin(2x) + \frac{\sin(x) x}{3} - \frac{2\cos(x)}{9}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + y = x^2 \cos(x)}$$

15.2.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = x^2 \cos(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 \cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x \cos(x), x^2 \cos(x), \sin(x) x, \sin(x) x^2, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x \cos(x), x^2 \cos(x), x^3 \cos(x), x^3 \sin(x), \sin(x) x, \sin(x) x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x \cos(x) + A_2 x^2 \cos(x) + A_3 x^3 \cos(x) + A_4 x^3 \sin(x) + A_5 \sin(x) x + A_6 \sin(x) x^2$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-2A_1 \sin(x) + 2A_2 \cos(x) - 4A_2 x \sin(x) + 6A_3 x \cos(x) - 6A_3 x^2 \sin(x) \\ &+ 6A_4 x \sin(x) + 6A_4 x^2 \cos(x) + 2A_5 \cos(x) + 4A_6 \cos(x) x + 2A_6 \sin(x) = x^2 \cos(x)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{4}, A_3 = 0, A_4 = \frac{1}{6}, A_5 = -\frac{1}{4}, A_6 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2 \cos(x)}{4} + \frac{x^3 \sin(x)}{6} - \frac{\sin(x) x}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + \left(\frac{x^2 \cos(x)}{4} + \frac{x^3 \sin(x)}{6} - \frac{\sin(x) x}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{x^2 \cos(x)}{4} + \frac{x^3 \sin(x)}{6} - \frac{\sin(x) x}{4} \tag{1}$$

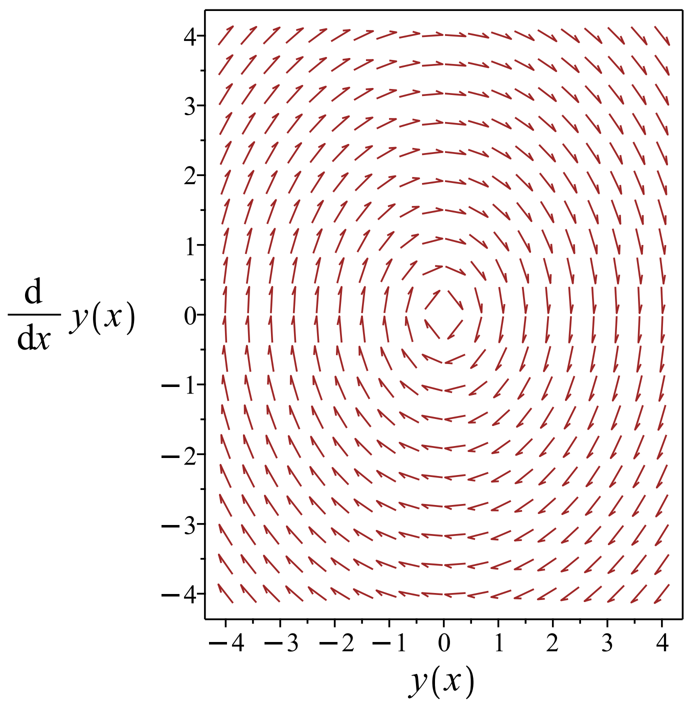

Figure 664: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{x^2 \cos(x)}{4} + \frac{x^3 \sin(x)}{6} - \frac{\sin(x) x}{4}$$

Verified OK.

15.2.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 518: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}
$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\ &= \cos(x)\,(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 \cos (x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x \cos (x), x^2 \cos (x), \sin (x) x, \sin (x) x^2, \cos (x), \sin (x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos (x), \sin (x)\}$$

Since $\cos (x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x \cos (x), x^2 \cos (x), x^3 \cos (x), x^3 \sin (x), \sin (x) x, \sin (x) x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x \cos (x) + A_2 x^2 \cos (x) + A_3 x^3 \cos (x) + A_4 x^3 \sin (x) + A_5 \sin (x) x + A_6 \sin (x) x^2$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned} &-2A_1 \sin (x) + 2A_2 \cos (x) - 4A_2 x \sin (x) + 6A_3 x \cos (x) - 6A_3 x^2 \sin (x) \\ &+ 6A_4 x \sin (x) + 6A_4 x^2 \cos (x) + 2A_5 \cos (x) + 4A_6 \cos (x) x + 2A_6 \sin (x) = x^2 \cos (x) \end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{4}, A_3 = 0, A_4 = \frac{1}{6}, A_5 = -\frac{1}{4}, A_6 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2 \cos (x)}{4} + \frac{x^3 \sin (x)}{6} - \frac{\sin (x) x}{4}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + \left(\frac{x^2 \cos(x)}{4} + \frac{x^3 \sin(x)}{6} - \frac{\sin(x)\, x}{4}\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 \cos(x) + c_2 \sin(x) + \frac{x^2 \cos(x)}{4} + \frac{x^3 \sin(x)}{6} - \frac{\sin(x)\, x}{4} \tag{1}
$$

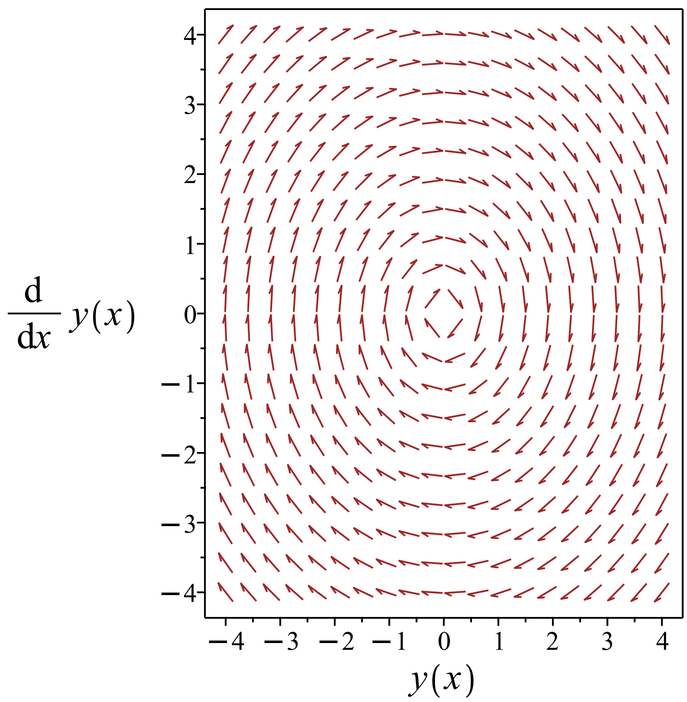

Figure 665: Slope field plot

Verification of solutions

$$
y = c_1 \cos(x) + c_2 \sin(x) + \frac{x^2 \cos(x)}{4} + \frac{x^3 \sin(x)}{6} - \frac{\sin(x)\, x}{4}
$$

Verified OK.

15.2.3 Maple step by step solution

Let's solve

$y'' + y = x^2 \cos(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x^2 \cos(x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$

  - Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{\cos(x) \left(\int \sin(2x) x^2 dx\right)}{2} + \sin(x) \left(\int x^2 \cos(x)^2 dx\right)$$

- Compute integrals

$$y_p(x) = \frac{\cos(x) (2x^2 - 1)}{8} + \frac{(2x^3 - 3x) \sin(x)}{12}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{\cos(x) (2x^2 - 1)}{8} + \frac{(2x^3 - 3x) \sin(x)}{12}$$

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' - y = x^2 \cos(x)}$$

15.3.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = -1, f(x) = x^2 \cos(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)}\\ &= \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +1\\ \lambda_2 &= -1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1\\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(1)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{x} + c_2 \mathrm{e}^{-x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{x} + c_2 \mathrm{e}^{-x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 \cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\cos(x), x^2\cos(x), \sin(x)x, \sin(x)x^2, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\cos(x) + A_2 x^2\cos(x) + A_3\sin(x)x + A_4\sin(x)x^2 + A_5\cos(x) + A_6\sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-2A_1\sin(x) - 2A_1x\cos(x) + 2A_2\cos(x) - 4A_2x\sin(x)\\&- 2A_2x^2\cos(x) - 2A_3\sin(x)x + 2A_3\cos(x) - 2A_4\sin(x)x^2\\&+ 4A_4\cos(x)x + 2A_4\sin(x) - 2A_5\cos(x) - 2A_6\sin(x) = x^2\cos(x)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = -\frac{1}{2}, A_3 = 1, A_4 = 0, A_5 = \frac{1}{2}, A_6 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x^2\cos(x)}{2} + \sin(x)x + \frac{\cos(x)}{2}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\&= \left(c_1e^x + c_2e^{-x}\right) + \left(-\frac{x^2\cos(x)}{2} + \sin(x)x + \frac{\cos(x)}{2}\right)\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^x + c_2 e^{-x} - \frac{x^2 \cos(x)}{2} + \sin(x) x + \frac{\cos(x)}{2} \tag{1}$$

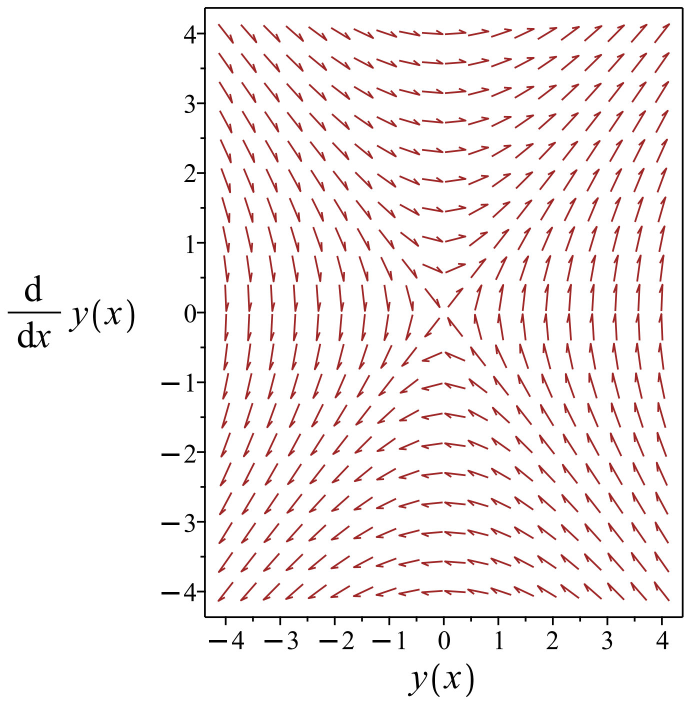

Figure 666: Slope field plot

Verification of solutions

$$y = c_1 e^x + c_2 e^{-x} - \frac{x^2 \cos(x)}{2} + \sin(x) x + \frac{\cos(x)}{2}$$

Verified OK.

15.3.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A &= 1\\ B &= 0\\ C &= -1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r &= \frac{s}{t}\\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s &= 1\\ t &= 1\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 520: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \mathrm{e}^{-x} \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\
&= \mathrm{e}^{-x} \int \frac{1}{\mathrm{e}^{-2x}}\,dx \\
&= \mathrm{e}^{-x}\left(\frac{\mathrm{e}^{2x}}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-x}\right) + c_2\left(\mathrm{e}^{-x}\left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1\mathrm{e}^{-x} + \frac{c_2\mathrm{e}^{x}}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 \cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x \cos(x), x^2 \cos(x), \sin(x) x, \sin(x) x^2, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{e^x}{2}, e^{-x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x \cos(x) + A_2 x^2 \cos(x) + A_3 \sin(x) x + A_4 \sin(x) x^2 + A_5 \cos(x) + A_6 \sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}
&-2A_1 \sin(x) - 2A_1 x \cos(x) + 2A_2 \cos(x) - 4A_2 x \sin(x) \\
&- 2A_2 x^2 \cos(x) - 2A_3 \sin(x) x + 2A_3 \cos(x) - 2A_4 \sin(x) x^2 \\
&+ 4A_4 \cos(x) x + 2A_4 \sin(x) - 2A_5 \cos(x) - 2A_6 \sin(x) = x^2 \cos(x)
\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = -\frac{1}{2}, A_3 = 1, A_4 = 0, A_5 = \frac{1}{2}, A_6 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x^2 \cos(x)}{2} + \sin(x) x + \frac{\cos(x)}{2}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 e^{-x} + \frac{c_2 e^x}{2}\right) + \left(-\frac{x^2 \cos(x)}{2} + \sin(x) x + \frac{\cos(x)}{2}\right)
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-x} + \frac{c_2 e^{x}}{2} - \frac{x^2 \cos(x)}{2} + \sin(x) x + \frac{\cos(x)}{2} \tag{1}$$

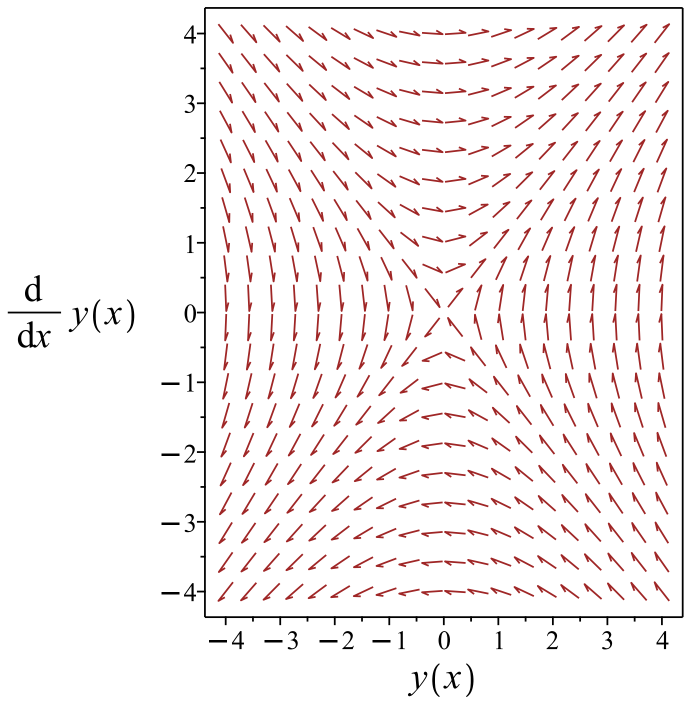

Figure 667: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + \frac{c_2 e^{x}}{2} - \frac{x^2 \cos(x)}{2} + \sin(x) x + \frac{\cos(x)}{2}$$

Verified OK.

15.3.3 Maple step by step solution

Let's solve

$y'' - y = x^2 \cos(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 - 1 = 0$

- Factor the characteristic polynomial

  $(r-1)(r+1) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-x} + c_2 e^{x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = x^2\cos(x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x} & e^{x} \\ -e^{-x} & e^{x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\frac{e^{-x}\left(\int \cos(x)e^{x}x^2 dx\right)}{2} + \frac{e^{x}\left(\int x^2\cos(x)e^{-x}dx\right)}{2}$

  - Compute integrals

    $y_p(x) = -\frac{x^2\cos(x)}{2} + \sin(x)\,x + \frac{\cos(x)}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-x} + c_2 e^{x} - \frac{x^2\cos(x)}{2} + \sin(x)\,x + \frac{\cos(x)}{2}$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 24, page 109
Problem number: 4.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' + 4y' = e^{x} + \sin(x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + 4y' = 0$$

The characteristic equation is

$$\lambda^3 + 4\lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 2i$$
$$\lambda_3 = -2i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + e^{2ix}c_2 + e^{-2ix}c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = e^{2ix}$$
$$y_3 = e^{-2ix}$$

Now the particular solution to the given ODE is found

$$y''' + 4y' = e^x + \sin(x)$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x + \sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}, \{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-2ix}, e^{2ix}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^x + A_2 \cos(x) + A_3 \sin(x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$5A_1 e^x - 3A_2 \sin(x) + 3A_3 \cos(x) = e^x + \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{5}, A_2 = -\frac{1}{3}, A_3 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x}{5} - \frac{\cos(x)}{3}$$

Therefore the general solution is

$$y = y_h + y_p$$
$$= \left(c_1 + e^{2ix}c_2 + e^{-2ix}c_3\right) + \left(\frac{e^x}{5} - \frac{\cos(x)}{3}\right)$$

Summary
The solution(s) found are the following

$$y = c_1 + e^{2ix}c_2 + e^{-2ix}c_3 + \frac{e^x}{5} - \frac{\cos(x)}{3} \tag{1}$$

Verification of solutions

$$y = c_1 + e^{2ix}c_2 + e^{-2ix}c_3 + \frac{e^x}{5} - \frac{\cos(x)}{3}$$

Verified OK.

15.4.1 Maple step by step solution

Let's solve

$y''' + 4y' = e^x + \sin(x)$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = e^x + \sin(x) - 4y_2(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = e^x + \sin(x) - 4y_2(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -4 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ e^x + \sin(x) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ e^x + \sin(x) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -4 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[-2\,\mathrm{I}, \begin{bmatrix} -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right], \left[2\,\mathrm{I}, \begin{bmatrix} -\frac{1}{4} \\ -\frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-2\,\mathrm{I}, \begin{bmatrix} -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$\mathrm{e}^{-2\,\mathrm{I}x} \cdot \begin{bmatrix} -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(2x) - \mathrm{I}\sin(2x)) \cdot \begin{bmatrix} -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\frac{\cos(2x)}{4} + \frac{\mathrm{I}\sin(2x)}{4} \\ \frac{\mathrm{I}}{2}(\cos(2x) - \mathrm{I}\sin(2x)) \\ \cos(2x) - \mathrm{I}\sin(2x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\overrightarrow{y}_2(x) = \begin{bmatrix} -\frac{\cos(2x)}{4} \\ \frac{\sin(2x)}{2} \\ \cos(2x) \end{bmatrix}, \overrightarrow{y}_3(x) = \begin{bmatrix} \frac{\sin(2x)}{4} \\ \frac{\cos(2x)}{2} \\ -\sin(2x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{y}_p($

$$\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2(x) + c_3\overrightarrow{y}_3(x) + \overrightarrow{y}_p(x)$$

☐ Fundamental matrix

  ◦ Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} 1 & -\frac{\cos(2x)}{4} & \frac{\sin(2x)}{4} \\ 0 & \frac{\sin(2x)}{2} & \frac{\cos(2x)}{2} \\ 0 & \cos(2x) & -\sin(2x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$
- Substitute the value of $\phi(x)$ and $\phi(0)$

  $$\Phi(x) = \begin{bmatrix} 1 & -\frac{\cos(2x)}{4} & \frac{\sin(2x)}{4} \\ 0 & \frac{\sin(2x)}{2} & \frac{\cos(2x)}{2} \\ 0 & \cos(2x) & -\sin(2x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & -\frac{1}{4} & 0 \\ 0 & 0 & \frac{1}{2} \\ 0 & 1 & 0 \end{bmatrix}}$$
- Evaluate and simplify to get the fundamental matrix

  $$\Phi(x) = \begin{bmatrix} 1 & \frac{\sin(2x)}{2} & \frac{1}{4} - \frac{\cos(2x)}{4} \\ 0 & \cos(2x) & \frac{\sin(2x)}{2} \\ 0 & -2\sin(2x) & \cos(2x) \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$
- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$
- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\overrightarrow{v}(x)$

  $\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$

- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\overrightarrow{y}_p(x) = \begin{bmatrix} \frac{4\cos(x)^2}{15} + \frac{(-3\sin(x)-5)\cos(x)}{15} + \frac{e^x}{5} - \frac{2}{15} \\ \frac{(-8\cos(x)+5)\sin(x)}{15} - \frac{2\cos(x)^2}{5} + \frac{e^x}{5} + \frac{1}{5} \\ \frac{4\cos(x)\sin(x)}{5} - \frac{16\cos(x)^2}{15} + \frac{e^x}{5} + \frac{\cos(x)}{3} + \frac{8}{15} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2(x) + c_3\overrightarrow{y}_3(x) + \begin{bmatrix} \frac{4\cos(x)^2}{15} + \frac{(-3\sin(x)-5)\cos(x)}{15} + \frac{e^x}{5} - \frac{2}{15} \\ \frac{(-8\cos(x)+5)\sin(x)}{15} - \frac{2\cos(x)^2}{5} + \frac{e^x}{5} + \frac{1}{5} \\ \frac{4\cos(x)\sin(x)}{5} - \frac{16\cos(x)^2}{15} + \frac{e^x}{5} + \frac{\cos(x)}{3} + \frac{8}{15} \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = \frac{(-30c_2+16)\cos(x)^2}{60} + \frac{(-20+(30c_3-12)\sin(x))\cos(x)}{60} + c_1 + \frac{c_2}{4} + \frac{e^x}{5} - \frac{2}{15}$$

Problem number: 5.
ODE order: 5.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_high_order, _missing_y]]`

$$\boxed{y^{(5)} + y'''' = x^2}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y^{(5)} + y'''' = 0$$

The characteristic equation is

$$\lambda^5 + \lambda^4 = 0$$

The roots of the above equation are

$$\lambda_1 = -1$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$
$$\lambda_4 = 0$$
$$\lambda_5 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 + c_3 x + c_4 x^2 + c_5 x^3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = 1$$
$$y_3 = x$$
$$y_4 = x^2$$
$$y_5 = x^3$$

Now the particular solution to the given ODE is found

$$y^{(5)} + y'''' = x^2$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, x^2, x^3, e^{-x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x, x^2, x^3\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2, x^3, x^4\}]$$

Since x^2 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^3, x^4, x^5\}]$$

Since x^3 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^4, x^5, x^6\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_3x^6 + A_2x^5 + A_1x^4$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$360x^2A_3 + 120xA_2 + 720xA_3 + 24A_1 + 120A_2 = x^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{12}, A_2 = -\frac{1}{60}, A_3 = \frac{1}{360}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{360}x^6 - \frac{1}{60}x^5 + \frac{1}{12}x^4$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1e^{-x} + c_2 + c_3x + c_4x^2 + c_5x^3) + \left(\frac{1}{360}x^6 - \frac{1}{60}x^5 + \frac{1}{12}x^4\right) \end{aligned}$$

<u>Summary</u>

The solution(s) found are the following

$$y = c_1e^{-x} + c_2 + c_3x + c_4x^2 + c_5x^3 + \frac{x^6}{360} - \frac{x^5}{60} + \frac{x^4}{12} \tag{1}$$

<u>Verification of solutions</u>

$$y = c_1e^{-x} + c_2 + c_3x + c_4x^2 + c_5x^3 + \frac{x^6}{360} - \frac{x^5}{60} + \frac{x^4}{12}$$

Verified OK.

15.6 problem 6

Internal problem ID [2239]
Internal file name [`OUTPUT/2239_Monday_February_26_2024_09_18_37_AM_42527952/index.tex`]

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 24, page 109
Problem number: 6.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{2y'' + 3y' - 2y = x^2 e^x}$$

15.6.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 2, B = 3, C = -2, f(x) = x^2 e^x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$2y'' + 3y' - 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 2, B = 3, C = -2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$2\lambda^2 e^{\lambda x} + 3\lambda\, e^{\lambda x} - 2\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$2\lambda^2 + 3\lambda - 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 2, B = 3, C = -2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-3}{(2)\,(2)} \pm \frac{1}{(2)\,(2)}\sqrt{3^2 - (4)\,(2)\,(-2)} \\ &= -\frac{3}{4} \pm \frac{5}{4}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{3}{4} + \frac{5}{4} \\ \lambda_2 &= -\frac{3}{4} - \frac{5}{4}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \frac{1}{2} \\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{\left(\frac{1}{2}\right)x} + c_2 e^{(-2)x}\end{aligned}$$

Or

$$y = c_1 e^{\frac{x}{2}} + c_2 e^{-2x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{\frac{x}{2}} + c_2 e^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^x, x^2 e^x, e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^{-2x}, e^{\frac{x}{2}}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,e^x + A_2 x^2 e^x + A_3 e^x$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$7A_1 e^x + 3A_1 x\,e^x + 4A_2 e^x + 14A_2 x\,e^x + 3A_2 x^2 e^x + 3A_3 e^x = x^2 e^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{14}{9}, A_2 = \frac{1}{3}, A_3 = \frac{86}{27}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{14x\,e^x}{9} + \frac{x^2 e^x}{3} + \frac{86\,e^x}{27}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{\frac{x}{2}} + c_2 e^{-2x}\right) + \left(-\frac{14x\,e^x}{9} + \frac{x^2 e^x}{3} + \frac{86\,e^x}{27}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{\frac{x}{2}} + c_2 e^{-2x} - \frac{14x\,e^x}{9} + \frac{x^2 e^x}{3} + \frac{86\,e^x}{27} \tag{1}$$

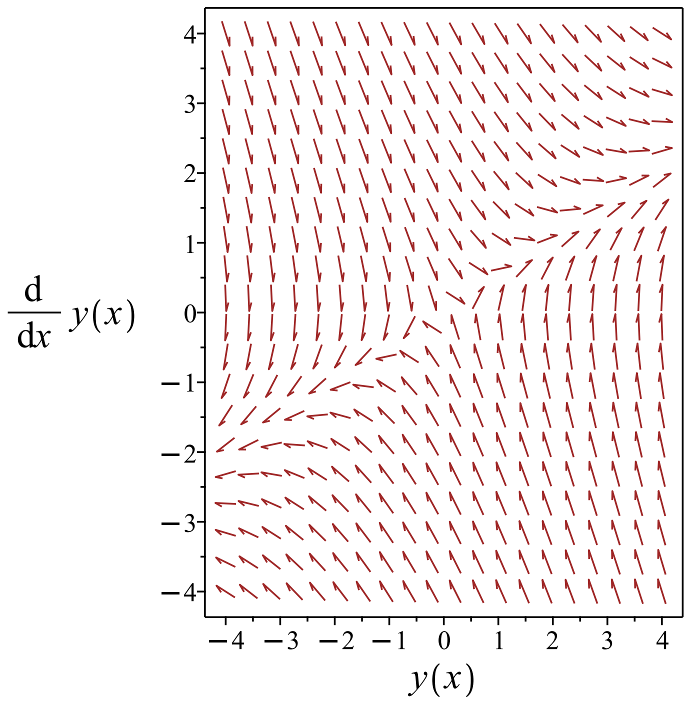

Figure 668: Slope field plot

Verification of solutions

$$y = c_1 e^{\frac{x}{2}} + c_2 e^{-2x} - \frac{14x\,e^x}{9} + \frac{x^2 e^x}{3} + \frac{86\,e^x}{27}$$

Verified OK.

15.6.2 Solving using Kovacic algorithm

Writing the ode as

$$2y'' + 3y' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 2 \\
B &= 3 \\
C &= -2
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{25}{16} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 25 \\
t &= 16
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \frac{25z(x)}{16} \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 523: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{25}{16}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{5x}{4}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{3}{2}\,dx} \\ &= z_1 e^{-\frac{3x}{4}} \\ &= z_1 \left(\mathrm{e}^{-\frac{3x}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{3}{2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{3x}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(\frac{2\,\mathrm{e}^{\frac{5x}{2}}}{5}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-2x}\right) + c_2 \left(\mathrm{e}^{-2x} \left(\frac{2\,\mathrm{e}^{\frac{5x}{2}}}{5}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$2y'' + 3y' - 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-2x} + \frac{2c_2 \mathrm{e}^{\frac{x}{2}}}{5}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 \mathrm{e}^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x \,\mathrm{e}^x, x^2 \mathrm{e}^x, \mathrm{e}^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{2 \,\mathrm{e}^{\frac{x}{2}}}{5}, \mathrm{e}^{-2x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x \,\mathrm{e}^x + A_2 x^2 \mathrm{e}^x + A_3 \mathrm{e}^x$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$7A_1 \mathrm{e}^x + 3A_1 x \,\mathrm{e}^x + 4A_2 \mathrm{e}^x + 14A_2 x \,\mathrm{e}^x + 3A_2 x^2 \mathrm{e}^x + 3A_3 \mathrm{e}^x = x^2 \mathrm{e}^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{14}{9}, A_2 = \frac{1}{3}, A_3 = \frac{86}{27}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{14x \,\mathrm{e}^x}{9} + \frac{x^2 \mathrm{e}^x}{3} + \frac{86 \,\mathrm{e}^x}{27}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-2x} + \frac{2c_2 \mathrm{e}^{\frac{x}{2}}}{5}\right) + \left(-\frac{14x \,\mathrm{e}^x}{9} + \frac{x^2 \mathrm{e}^x}{3} + \frac{86 \,\mathrm{e}^x}{27}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-2x} + \frac{2c_2 e^{\frac{x}{2}}}{5} - \frac{14x\,e^{x}}{9} + \frac{x^2 e^{x}}{3} + \frac{86\,e^{x}}{27} \tag{1}$$

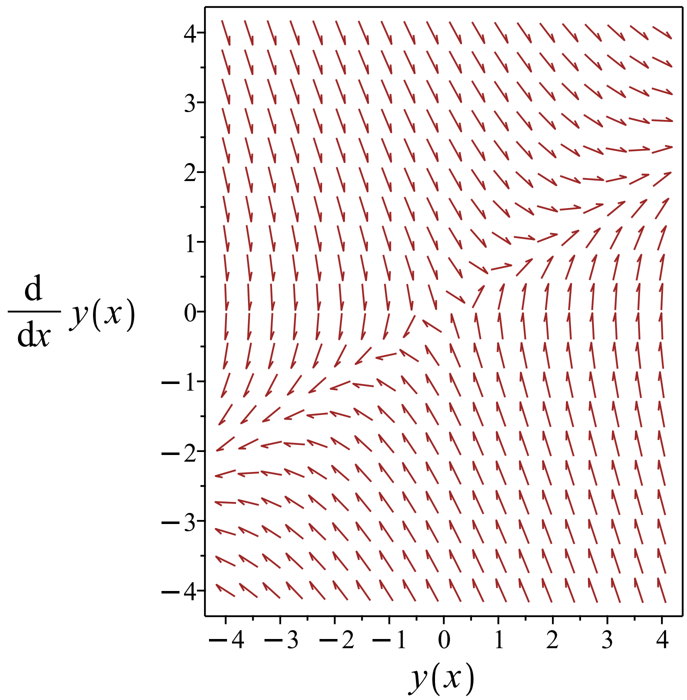

Figure 669: Slope field plot

Verification of solutions

$$y = c_1 e^{-2x} + \frac{2c_2 e^{\frac{x}{2}}}{5} - \frac{14x\,e^{x}}{9} + \frac{x^2 e^{x}}{3} + \frac{86\,e^{x}}{27}$$

Verified OK.

15.6.3 Maple step by step solution

Let's solve

$2y'' + 3y' - 2y = x^2 e^x$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

$y'' = -\frac{3y'}{2} + y + \frac{x^2 e^x}{2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{3y'}{2} - y = \frac{x^2 e^x}{2}$
- Characteristic polynomial of homogeneous ODE

  $r^2 + \frac{3}{2}r - 1 = 0$
- Factor the characteristic polynomial

  $\frac{(r+2)(2r-1)}{2} = 0$
- Roots of the characteristic polynomial

  $r = \left(-2, \frac{1}{2}\right)$
- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-2x}$
- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{\frac{x}{2}}$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-2x} + c_2 e^{\frac{x}{2}} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \frac{x^2 e^x}{2}\right]$
- Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-2x} & e^{\frac{x}{2}} \\ -2e^{-2x} & \frac{e^{\frac{x}{2}}}{2} \end{bmatrix}$
- Compute Wronskian

  $W(y_1(x), y_2(x)) = \frac{5e^{-\frac{3x}{2}}}{2}$
- Substitute functions into equation for $y_p(x)$

  $y_p(x) = \frac{\left(e^{\frac{5x}{2}}\left(\int x^2 e^{\frac{x}{2}}dx\right) - \left(\int x^2 e^{3x}dx\right)\right)e^{-2x}}{5}$
- Compute integrals

$$y_p(x) = \frac{e^x (9x^2-42x+86)}{27}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 e^{-2x} + c_2 e^{\frac{x}{2}} + \frac{e^x (9x^2-42x+86)}{27}$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 24, page 109
Problem number: 8.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' + y' = \sin(x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + y' = 0$$

The characteristic equation is

$$\lambda^3 + \lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = i$$
$$\lambda_3 = -i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + c_2 e^{-ix} + e^{ix} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= 1 \\
y_2 &= \mathrm{e}^{-ix} \\
y_3 &= \mathrm{e}^{ix}
\end{aligned}
$$

Now the particular solution to the given ODE is found

$$
y''' + y' = \sin(x)
$$

Let the particular solution be

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$
U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)}\, dx
$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$
W(x) = \begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}
$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$
\begin{aligned}
W &= \begin{bmatrix} 1 & \mathrm{e}^{-ix} & \mathrm{e}^{ix} \\ 0 & -i\mathrm{e}^{-ix} & i\mathrm{e}^{ix} \\ 0 & -\mathrm{e}^{-ix} & -\mathrm{e}^{ix} \end{bmatrix} \\
|W| &= 2i\mathrm{e}^{-ix}\mathrm{e}^{ix}
\end{aligned}
$$

The determinant simplifies to

$$
|W| = 2i
$$

Now we determine W_i for each U_i.

$$
\begin{aligned}
W_1(x) &= \det \begin{bmatrix} e^{-ix} & e^{ix} \\ -ie^{-ix} & ie^{ix} \end{bmatrix} \\
&= 2i
\end{aligned}
$$

$$
\begin{aligned}
W_2(x) &= \det \begin{bmatrix} 1 & e^{ix} \\ 0 & ie^{ix} \end{bmatrix} \\
&= ie^{ix}
\end{aligned}
$$

$$
\begin{aligned}
W_3(x) &= \det \begin{bmatrix} 1 & e^{-ix} \\ 0 & -ie^{-ix} \end{bmatrix} \\
&= -ie^{-ix}
\end{aligned}
$$

Now we are ready to evaluate each $U_i(x)$.

$$
\begin{aligned}
U_1 &= (-1)^{3-1} \int \frac{F(x)W_1(x)}{aW(x)}\,dx \\
&= (-1)^2 \int \frac{(\sin(x))\,(2i)}{(1)\,(2i)}\,dx \\
&= \int \frac{2i\sin(x)}{2i}\,dx \\
&= \int (\sin(x))\,dx \\
&= -\cos(x)
\end{aligned}
$$

$$
\begin{aligned}
U_2 &= (-1)^{3-2} \int \frac{F(x)W_2(x)}{aW(x)}\,dx \\
&= (-1)^1 \int \frac{(\sin(x))\,(ie^{ix})}{(1)\,(2i)}\,dx \\
&= -\int \frac{i\sin(x)\,e^{ix}}{2i}\,dx \\
&= -\int \left(\frac{e^{ix}\sin(x)}{2}\right)dx \\
&= -\left(\int \frac{e^{ix}\sin(x)}{2}\,dx\right)
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{3-3} \int \frac{F(x) W_3(x)}{a W(x)}\, dx \\
&= (-1)^0 \int \frac{(\sin(x)) \left(-i \mathrm{e}^{-ix}\right)}{(1)\,(2i)}\, dx \\
&= \int \frac{-i \sin(x)\, \mathrm{e}^{-ix}}{2i}\, dx \\
&= \int \left(-\frac{\mathrm{e}^{-ix} \sin(x)}{2}\right) dx \\
&= \int -\frac{\mathrm{e}^{-ix} \sin(x)}{2} dx
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Hence

$$
\begin{aligned}
y_p = {} & (-\cos(x)) \\
& + \left(-\left(\int \frac{\mathrm{e}^{ix} \sin(x)}{2} dx\right)\right) \left(\mathrm{e}^{-ix}\right) \\
& + \left(\int -\frac{\mathrm{e}^{-ix} \sin(x)}{2} dx\right) \left(\mathrm{e}^{ix}\right)
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = -\cos(x) - \frac{\left(\int \mathrm{e}^{ix} \sin(x)\, dx\right) \mathrm{e}^{-ix}}{2} - \frac{\left(\int \mathrm{e}^{-ix} \sin(x)\, dx\right) \mathrm{e}^{ix}}{2}
$$

Which simplifies to

$$
y_p = -\left(\int \sin(x)^2\, dx\right) \sin(x) - \frac{\cos(x) \left(\int \sin(2x)\, dx + 2\right)}{2}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 + c_2 \mathrm{e}^{-ix} + \mathrm{e}^{ix} c_3\right) + \left(-\left(\int \sin(x)^2\, dx\right) \sin(x) - \frac{\cos(x) \left(\int \sin(2x)\, dx + 2\right)}{2}\right)
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = c_1 + c_2 \mathrm{e}^{-ix} + \mathrm{e}^{ix} c_3 - \left(\int \sin(x)^2\, dx\right) \sin(x) - \frac{\cos(x) \left(\int \sin(2x)\, dx + 2\right)}{2} \tag{1}
$$

Verification of solutions

$$y = c_1 + c_2 e^{-ix} + e^{ix} c_3 - \left(\int \sin(x)^2 dx\right) \sin(x) - \frac{\cos(x) \left(\int \sin(2x) dx + 2\right)}{2}$$

Verified OK.

15.7.1 Maple step by step solution

Let's solve

$y''' + y' = \sin(x)$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = \sin(x) - y_2(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = \sin(x) - y_2(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ \sin(x) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \left[\begin{array}{c} 0 \\ 0 \\ \sin \left(x \right) \end{array}\right]$$

- Define the coefficient matrix

$$A = \left[\begin{array}{ccc} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{array}\right]$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]\right], \left[-\mathrm{I}, \left[\begin{array}{c} -1 \\ \mathrm{I} \\ 1 \end{array}\right]\right], \left[\mathrm{I}, \left[\begin{array}{c} -1 \\ -\mathrm{I} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[0, \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \left[\begin{array}{c} -1 \\ \mathrm{I} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$e^{-Ix} \cdot \begin{bmatrix} -1 \\ I \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(x) - I\sin(x)) \cdot \begin{bmatrix} -1 \\ I \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\cos(x) + I\sin(x) \\ I(\cos(x) - I\sin(x)) \\ \cos(x) - I\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_3(x) = \begin{bmatrix} \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \vec{y}_p(x)$$

☐ Fundamental matrix

  - Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} 1 & -\cos(x) & \sin(x) \\ 0 & \sin(x) & \cos(x) \\ 0 & \cos(x) & -\sin(x) \end{bmatrix}$$

  - The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$$

  - Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x)=\begin{bmatrix}1 & -\cos(x) & \sin(x)\\ 0 & \sin(x) & \cos(x)\\ 0 & \cos(x) & -\sin(x)\end{bmatrix}\cdot\frac{1}{\begin{bmatrix}1 & -1 & 0\\ 0 & 0 & 1\\ 0 & 1 & 0\end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x)=\begin{bmatrix}1 & \sin(x) & 1-\cos(x)\\ 0 & \cos(x) & \sin(x)\\ 0 & -\sin(x) & \cos(x)\end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(x)$ and solve for $\overrightarrow{v}(x)$

  $\overrightarrow{y}_p(x)=\Phi(x)\cdot\overrightarrow{v}(x)$

- Take the derivative of the particular solution

  $\overrightarrow{y}'_p(x)=\Phi'(x)\cdot\overrightarrow{v}(x)+\Phi(x)\cdot\overrightarrow{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x)\cdot\overrightarrow{v}(x)+\Phi(x)\cdot\overrightarrow{v}'(x)=A\cdot\Phi(x)\cdot\overrightarrow{v}(x)+\overrightarrow{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A\cdot\Phi(x)\cdot\overrightarrow{v}(x)+\Phi(x)\cdot\overrightarrow{v}'(x)=A\cdot\Phi(x)\cdot\overrightarrow{v}(x)+\overrightarrow{f}(x)$

- Cancel like terms

  $\Phi(x)\cdot\overrightarrow{v}'(x)=\overrightarrow{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\overrightarrow{v}'(x)=\frac{1}{\Phi(x)}\cdot\overrightarrow{f}(x)$

- Integrate to solve for $\overrightarrow{v}(x)$

  $\overrightarrow{v}(x)=\int_0^x \frac{1}{\Phi(s)}\cdot\overrightarrow{f}(s)\,ds$

- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $\overrightarrow{y}_p(x)=\Phi(x)\cdot\left(\int_0^x \frac{1}{\Phi(s)}\cdot\overrightarrow{f}(s)\,ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \begin{bmatrix} 1 - \frac{\sin(x)x}{2} - \cos(x) \\ -\frac{x\cos(x)}{2} + \frac{\sin(x)}{2} \\ \frac{\sin(x)x}{2} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \begin{bmatrix} 1 - \frac{\sin(x)x}{2} - \cos(x) \\ -\frac{x\cos(x)}{2} + \frac{\sin(x)}{2} \\ \frac{\sin(x)x}{2} \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = 1 + (-c_2 - 1)\cos(x) + \frac{(2c_3 - x)\sin(x)}{2} + c_1$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 24, page 109
Problem number: 9.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' - y' = \sin(x) x}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - y' = 0$$

The characteristic equation is

$$\lambda^3 - \lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 1$$
$$\lambda_3 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 + c_3 e^{x}$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= \mathrm{e}^{-x} \\
y_2 &= 1 \\
y_3 &= \mathrm{e}^{x}
\end{aligned}
$$

Now the particular solution to the given ODE is found

$$
y''' - y' = \sin(x)\, x
$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
\sin(x)\, x
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{x\cos(x), \sin(x)\, x, \cos(x), \sin(x)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{1, \mathrm{e}^{x}, \mathrm{e}^{-x}\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 x\cos(x) + A_2\sin(x)\, x + A_3\cos(x) + A_4\sin(x)
$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
\begin{aligned}
&-4A_1\cos(x) + 2A_1 x\sin(x) - 2A_2\cos(x)\, x - 4A_2\sin(x) + 2A_3\sin(x) - 2A_4\cos(x) \\
&= \sin(x)\, x
\end{aligned}
$$

Solving for the unknowns by comparing coefficients results in

$$
\left[A_1 = \frac{1}{2}, A_2 = 0, A_3 = 0, A_4 = -1\right]
$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x \cos(x)}{2} - \sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2 + c_3 e^{x}\right) + \left(\frac{x \cos(x)}{2} - \sin(x)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 + c_3 e^{x} + \frac{x \cos(x)}{2} - \sin(x) \tag{1}$$

Verification of solutions

$$y = c_1 e^{-x} + c_2 + c_3 e^{x} + \frac{x \cos(x)}{2} - \sin(x)$$

Verified OK.

15.8.1 Maple step by step solution

Let's solve

$y''' - y' = \sin(x)\, x$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(x)$

    $y_1(x) = y$

  - Define new variable $y_2(x)$

    $y_2(x) = y'$

  - Define new variable $y_3(x)$

    $y_3(x) = y''$

  - Isolate for $y_3'(x)$ using original ODE

$y_3'(x) = \sin(x)\, x + y_2(x)$

Convert linear ODE into a system of first order ODEs

$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = \sin(x)\, x + y_2(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ \sin(x)\, x \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ \sin(x)\, x \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}$$

- Rewrite the system as

$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = e^{-x} \cdot \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[0, \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = e^{x} \cdot \left[\begin{array}{c} 1 \\ 1 \\ 1 \end{array}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3 + \vec{y}_p(x)$$

□ Fundamental matrix

 ○ Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} e^{-x} & 1 & e^{x} \\ -e^{-x} & 0 & e^{x} \\ e^{-x} & 0 & e^{x} \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$
- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} e^{-x} & 1 & e^{x} \\ -e^{-x} & 0 & e^{x} \\ e^{-x} & 0 & e^{x} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & 1 & 1 \\ -1 & 0 & 1 \\ 1 & 0 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} 1 & -\frac{e^{-x}}{2} + \frac{e^{x}}{2} & \frac{e^{-x}}{2} - 1 + \frac{e^{x}}{2} \\ 0 & \frac{e^{x}}{2} + \frac{e^{-x}}{2} & -\frac{e^{-x}}{2} + \frac{e^{x}}{2} \\ 0 & -\frac{e^{-x}}{2} + \frac{e^{x}}{2} & \frac{e^{x}}{2} + \frac{e^{-x}}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$
- Take the derivative of the particular solution

  $\vec{y}'_p(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$
- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\overrightarrow{v}(x)$

  $\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$

- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\overrightarrow{y}_p(x) = \begin{bmatrix} \frac{x\cos(x)}{2} - \sin(x) + \frac{e^x}{4} - \frac{e^{-x}}{4} \\ \frac{e^x}{4} + \frac{e^{-x}}{4} - \frac{\sin(x)x}{2} - \frac{\cos(x)}{2} \\ -\frac{x\cos(x)}{2} + \frac{e^x}{4} - \frac{e^{-x}}{4} \end{bmatrix}$$

- Plug particular solution back into general solution

  $$\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2 + c_3\overrightarrow{y}_3 + \begin{bmatrix} \frac{x\cos(x)}{2} - \sin(x) + \frac{e^x}{4} - \frac{e^{-x}}{4} \\ \frac{e^x}{4} + \frac{e^{-x}}{4} - \frac{\sin(x)x}{2} - \frac{\cos(x)}{2} \\ -\frac{x\cos(x)}{2} + \frac{e^x}{4} - \frac{e^{-x}}{4} \end{bmatrix}$$

- First component of the vector is the solution to the ODE

  $y = c_1 e^{-x} + c_3 e^x + \frac{x\cos(x)}{2} - \sin(x) + \frac{e^x}{4} - \frac{e^{-x}}{4} + c_2$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 24, page 109
Problem number: 10.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' + 2y'' = x\cos(2x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + 2y'' = 0$$

The characteristic equation is

$$\lambda^3 + 2\lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = -2$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_2 x + c_1 + e^{-2x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned}
y_1 &= 1 \\
y_2 &= x \\
y_3 &= e^{-2x}
\end{aligned}$$

Now the particular solution to the given ODE is found

$$y''' + 2y'' = x \cos(2x)$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x \cos(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x \cos(2x), x \sin(2x), \cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, e^{-2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x \cos(2x) + A_2 x \sin(2x) + A_3 \cos(2x) + A_4 \sin(2x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}
&-12A_1 \cos(2x) + 8A_1 x \sin(2x) - 12A_2 \sin(2x) - 8A_2 x \cos(2x) \\
&+ 8A_3 \sin(2x) - 8A_4 \cos(2x) - 8A_1 \sin(2x) - 8A_1 x \cos(2x) \\
&+ 8A_2 \cos(2x) - 8A_2 x \sin(2x) - 8A_3 \cos(2x) - 8A_4 \sin(2x) = x \cos(2x)
\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{16}, A_2 = -\frac{1}{16}, A_3 = -\frac{1}{16}, A_4 = \frac{3}{32}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\cos(2x)}{16} - \frac{x\sin(2x)}{16} - \frac{\cos(2x)}{16} + \frac{3\sin(2x)}{32}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_2 x + c_1 + \mathrm{e}^{-2x} c_3\right) + \left(-\frac{x\cos(2x)}{16} - \frac{x\sin(2x)}{16} - \frac{\cos(2x)}{16} + \frac{3\sin(2x)}{32}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_2 x + c_1 + \mathrm{e}^{-2x} c_3 - \frac{x\cos(2x)}{16} - \frac{x\sin(2x)}{16} - \frac{\cos(2x)}{16} + \frac{3\sin(2x)}{32} \tag{1}$$

Verification of solutions

$$y = c_2 x + c_1 + \mathrm{e}^{-2x} c_3 - \frac{x\cos(2x)}{16} - \frac{x\sin(2x)}{16} - \frac{\cos(2x)}{16} + \frac{3\sin(2x)}{32}$$

Verified OK.

Problem number: 11.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + 3y' + 2y = x^2 \cos(x)}$$

15.10.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 3, C = 2, f(x) = x^2 \cos(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 3y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A=1, B=3, C=2$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x}+3\lambda\,\mathrm{e}^{\lambda x}+2\,\mathrm{e}^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2+3\lambda+2=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=3, C=2$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{-3}{(2)\,(1)}\pm\frac{1}{(2)\,(1)}\sqrt{3^2-(4)\,(1)\,(2)}\\&=-\frac{3}{2}\pm\frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1&=-\frac{3}{2}+\frac{1}{2}\\\lambda_2&=-\frac{3}{2}-\frac{1}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1&=-1\\\lambda_2&=-2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y&=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}\\y&=c_1e^{(-1)x}+c_2e^{(-2)x}\end{aligned}$$

Or

$$y=c_1\mathrm{e}^{-x}+c_2\mathrm{e}^{-2x}$$

Therefore the homogeneous solution y_h is

$$y_h=c_1\mathrm{e}^{-x}+c_2\mathrm{e}^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 \cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x \cos(x), x^2 \cos(x), \sin(x) x, \sin(x) x^2, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-2x}, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x \cos(x) + A_2 x^2 \cos(x) + A_3 \sin(x) x + A_4 \sin(x) x^2 + A_5 \cos(x) + A_6 \sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}
&6A_2 x \cos(x) + 6A_4 \sin(x) x + 4A_4 \cos(x) x - 3A_5 \sin(x) + 3A_6 \cos(x) \\
&- 2A_1 \sin(x) + 3A_1 \cos(x) - 3A_1 x \sin(x) - 3A_2 x^2 \sin(x) \\
&+ 3A_3 \cos(x) x + 3A_3 \sin(x) + 3A_4 \cos(x) x^2 + 2A_2 \cos(x) \\
&- 4A_2 x \sin(x) + 2A_3 \cos(x) + 2A_4 \sin(x) + A_1 x \cos(x) + A_2 x^2 \cos(x) \\
&+ A_3 \sin(x) x + A_4 \sin(x) x^2 + A_5 \cos(x) + A_6 \sin(x) = x^2 \cos(x)
\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{6}{25}, A_2 = \frac{1}{10}, A_3 = -\frac{17}{25}, A_4 = \frac{3}{10}, A_5 = -\frac{133}{250}, A_6 = \frac{81}{250}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{6x \cos(x)}{25} + \frac{x^2 \cos(x)}{10} - \frac{17 \sin(x) x}{25} + \frac{3 \sin(x) x^2}{10} - \frac{133 \cos(x)}{250} + \frac{81 \sin(x)}{250}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 e^{-x} + c_2 e^{-2x}\right) \\
&\quad + \left(\frac{6x \cos(x)}{25} + \frac{x^2 \cos(x)}{10} - \frac{17 \sin(x) x}{25} + \frac{3 \sin(x) x^2}{10} - \frac{133 \cos(x)}{250} + \frac{81 \sin(x)}{250}\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 e^{-2x} + \frac{6x\cos(x)}{25} + \frac{x^2\cos(x)}{10} - \frac{17\sin(x)x}{25} + \frac{3\sin(x)x^2}{10} - \frac{133\cos(x)}{250} + \frac{81\sin(x)}{250} \tag{1}$$

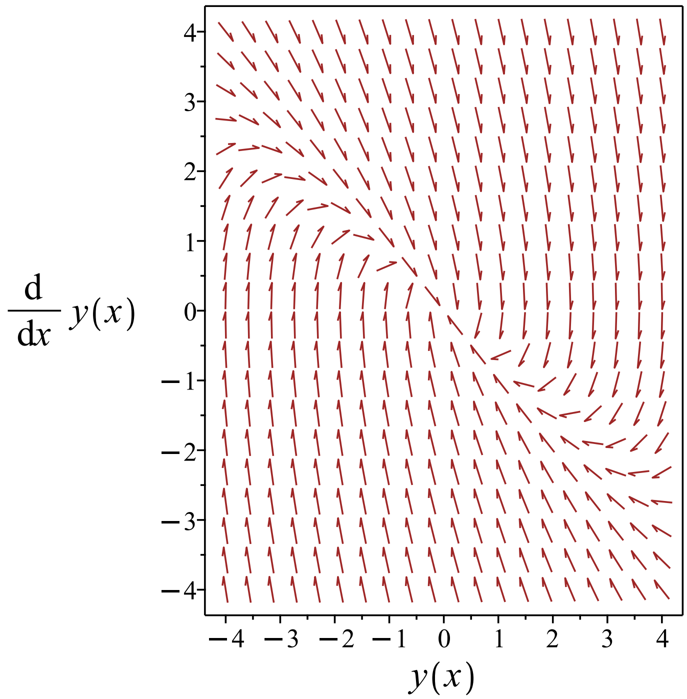

Figure 670: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + c_2 e^{-2x} + \frac{6x\cos(x)}{25} + \frac{x^2\cos(x)}{10} - \frac{17\sin(x)x}{25} + \frac{3\sin(x)x^2}{10} - \frac{133\cos(x)}{250} + \frac{81\sin(x)}{250}$$

Verified OK.

15.10.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 3y' + 2y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 3 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 527: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{3}{1}\,dx} \end{aligned}$$

$$
\begin{aligned}
&= z_1 e^{-\frac{3x}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{3x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-3x}}{(y_1)^2}\, dx \\
&= y_1 (\mathrm{e}^{x})
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-2x}\right) + c_2 \left(\mathrm{e}^{-2x} (\mathrm{e}^{x})\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 3y' + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 \cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x \cos(x), x^2 \cos(x), \sin(x) x, \sin(x) x^2, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-2x}, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x \cos(x) + A_2 x^2 \cos(x) + A_3 \sin(x) x + A_4 \sin(x) x^2 + A_5 \cos(x) + A_6 \sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-3A_5 \sin(x) + 3A_6 \cos(x) - 2A_1 \sin(x) + 2A_3 \cos(x) + 2A_4 \sin(x)\\&+ 3A_1 \cos(x) - 3A_1 x \sin(x) - 3A_2 x^2 \sin(x) + 3A_3 \cos(x) x\\&+ 3A_3 \sin(x) + 3A_4 \cos(x) x^2 + 2A_2 \cos(x) - 4A_2 x \sin(x)\\&+ A_5 \cos(x) + A_6 \sin(x) + A_1 x \cos(x) + A_2 x^2 \cos(x) + A_3 \sin(x) x\\&+ A_4 \sin(x) x^2 + 6A_2 x \cos(x) + 6A_4 \sin(x) x + 4A_4 \cos(x) x = x^2 \cos(x)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{6}{25}, A_2 = \frac{1}{10}, A_3 = -\frac{17}{25}, A_4 = \frac{3}{10}, A_5 = -\frac{133}{250}, A_6 = \frac{81}{250}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{6x \cos(x)}{25} + \frac{x^2 \cos(x)}{10} - \frac{17 \sin(x) x}{25} + \frac{3 \sin(x) x^2}{10} - \frac{133 \cos(x)}{250} + \frac{81 \sin(x)}{250}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\&= \left(c_1 e^{-2x} + c_2 e^{-x}\right)\\&\quad + \left(\frac{6x \cos(x)}{25} + \frac{x^2 \cos(x)}{10} - \frac{17 \sin(x) x}{25} + \frac{3 \sin(x) x^2}{10} - \frac{133 \cos(x)}{250} + \frac{81 \sin(x)}{250}\right)\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-2x} + c_2 e^{-x} + \frac{6x \cos(x)}{25} + \frac{x^2 \cos(x)}{10} - \frac{17 \sin(x) x}{25} + \frac{3 \sin(x) x^2}{10} - \frac{133 \cos(x)}{250} + \frac{81 \sin(x)}{250} \tag{1}$$

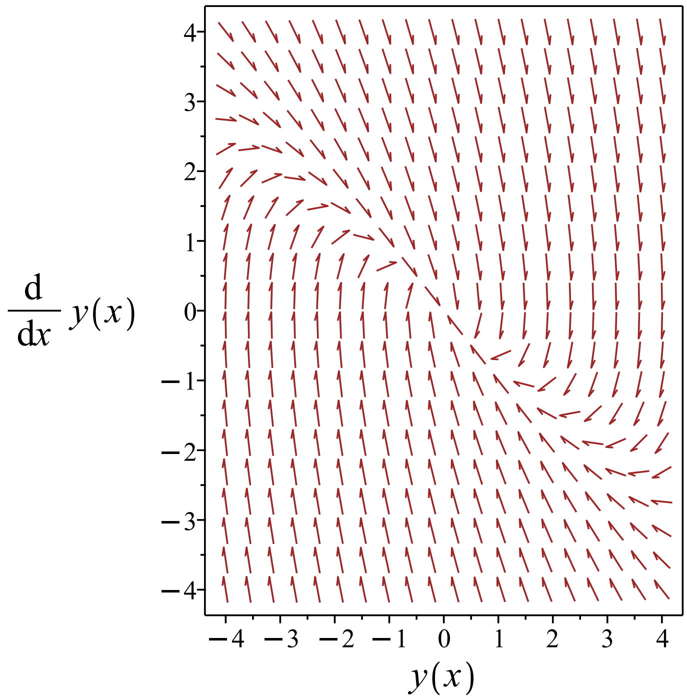

Figure 671: Slope field plot

Verification of solutions

$$y = c_1 e^{-2x} + c_2 e^{-x} + \frac{6x \cos(x)}{25} + \frac{x^2 \cos(x)}{10} - \frac{17 \sin(x) x}{25} + \frac{3 \sin(x) x^2}{10} - \frac{133 \cos(x)}{250} + \frac{81 \sin(x)}{250}$$

Verified OK.

15.10.3 Maple step by step solution

Let's solve

$y'' + 3y' + 2y = x^2 \cos(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 3r + 2 = 0$

- Factor the characteristic polynomial

  $(r + 2)(r + 1) = 0$

- Roots of the characteristic polynomial

  $r = (-2, -1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-2x} + c_2 e^{-x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x^2 \cos(x)\right]$

  ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-2x} & e^{-x} \\ -2\,e^{-2x} & -e^{-x} \end{bmatrix}$

  ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{-3x}$

  ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -e^{-2x}\left(\int e^{2x} \cos(x)\, x^2 dx\right) + e^{-x}\left(\int \cos(x)\, e^x x^2 dx\right)$

- Compute integrals

  $y_p(x) = \frac{(25x^2+60x-133)\cos(x)}{250} + \frac{\sin(x)(75x^2-170x+81)}{250}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-2x} + c_2 e^{-x} + \frac{(25x^2+60x-133)\cos(x)}{250} + \frac{\sin(x)(75x^2-170x+81)}{250}$

Problem number: 12.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' - 4y' + 3y = \sin(x)\, x^2}$$

15.11.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 3, f(x) = \sin(x)\, x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 3y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 3$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 4\lambda\, e^{\lambda x} + 3\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 3 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 3$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-4^2 - (4)(1)(3)}\\ &= 2 \pm 1\end{aligned}$$

Hence

$$\lambda_1 = 2 + 1$$
$$\lambda_2 = 2 - 1$$

Which simplifies to

$$\lambda_1 = 3$$
$$\lambda_2 = 1$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(3)x} + c_2 e^{(1)x}$$

Or

$$y = c_1 e^{3x} + c_2 e^{x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{3x} + c_2 e^{x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)\,x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\cos(x)\,,x^2\cos(x)\,,\sin(x)\,x,\sin(x)\,x^2,\cos(x)\,,\sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x, e^{3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1x\cos(x) + A_2x^2\cos(x) + A_3\sin(x)\,x + A_4\sin(x)\,x^2 + A_5\cos(x) + A_6\sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}
&4A_5\sin(x) - 4A_6\cos(x) - 2A_1\sin(x) + 2A_3\cos(x) + 2A_4\sin(x)\\
&- 4A_1\cos(x) + 4A_1x\sin(x) + 4A_2x^2\sin(x) - 4A_3\cos(x)\,x - 4A_3\sin(x)\\
&- 4A_4\cos(x)\,x^2 + 2A_2\cos(x) - 4A_2x\sin(x) + 2A_1x\cos(x)\\
&+ 2A_2x^2\cos(x) + 2A_3\sin(x)\,x + 2A_4\sin(x)\,x^2 + 2A_5\cos(x)\\
&+ 2A_6\sin(x) + 4A_4\cos(x)\,x - 8A_2x\cos(x) - 8A_4\sin(x)\,x = \sin(x)\,x^2
\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{11}{25}, A_2 = \frac{1}{5}, A_3 = -\frac{2}{25}, A_4 = \frac{1}{10}, A_5 = \frac{28}{125}, A_6 = -\frac{67}{250}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{11x\cos(x)}{25} + \frac{x^2\cos(x)}{5} - \frac{2\sin(x)\,x}{25} + \frac{\sin(x)\,x^2}{10} + \frac{28\cos(x)}{125} - \frac{67\sin(x)}{250}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p\\
&= \left(c_1e^{3x} + c_2e^x\right)\\
&\quad + \left(\frac{11x\cos(x)}{25} + \frac{x^2\cos(x)}{5} - \frac{2\sin(x)\,x}{25} + \frac{\sin(x)\,x^2}{10} + \frac{28\cos(x)}{125} - \frac{67\sin(x)}{250}\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{3x} + c_2 e^{x} + \frac{11x \cos(x)}{25} + \frac{x^2 \cos(x)}{5} - \frac{2 \sin(x) x}{25} + \frac{\sin(x) x^2}{10} + \frac{28 \cos(x)}{125} - \frac{67 \sin(x)}{250} \tag{1}$$

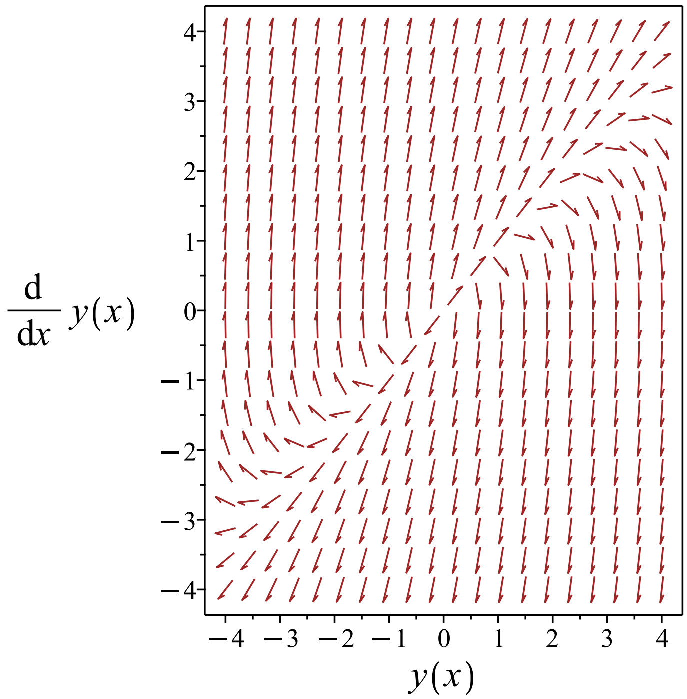

Figure 672: Slope field plot

Verification of solutions

$$y = c_1 e^{3x} + c_2 e^{x} + \frac{11x \cos(x)}{25} + \frac{x^2 \cos(x)}{5} - \frac{2 \sin(x) x}{25} + \frac{\sin(x) x^2}{10} + \frac{28 \cos(x)}{125} - \frac{67 \sin(x)}{250}$$

Verified OK.

15.11.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 529: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-x}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-4}{1} \, dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{2x} \\
&= z_1 \left(\mathrm{e}^{2x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^x
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{4x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\mathrm{e}^{2x}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2 \left(\mathrm{e}^x \left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 4y' + 3y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^x + \frac{c_2 \mathrm{e}^{3x}}{2}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)\, x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\cos(x), x^2\cos(x), \sin(x)\, x, \sin(x)\, x^2, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{e^{3x}}{2}, e^{x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\cos(x) + A_2 x^2\cos(x) + A_3\sin(x)\, x + A_4\sin(x)\, x^2 + A_5\cos(x) + A_6\sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}
&-8A_2 x\cos(x) - 8A_4\sin(x)\, x + 4A_4\cos(x)\, x + 4A_5\sin(x) - 4A_6\cos(x) \\
&- 2A_1\sin(x) + 2A_3\cos(x) + 2A_4\sin(x) - 4A_1\cos(x) + 4A_1 x\sin(x) \\
&+ 4A_2 x^2\sin(x) - 4A_3\cos(x)\, x - 4A_3\sin(x) - 4A_4\cos(x)\, x^2 \\
&+ 2A_2\cos(x) - 4A_2 x\sin(x) + 2A_5\cos(x) + 2A_6\sin(x) + 2A_1 x\cos(x) \\
&+ 2A_2 x^2\cos(x) + 2A_3\sin(x)\, x + 2A_4\sin(x)\, x^2 = \sin(x)\, x^2
\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{11}{25}, A_2 = \frac{1}{5}, A_3 = -\frac{2}{25}, A_4 = \frac{1}{10}, A_5 = \frac{28}{125}, A_6 = -\frac{67}{250}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{11x\cos(x)}{25} + \frac{x^2\cos(x)}{5} - \frac{2\sin(x)\, x}{25} + \frac{\sin(x)\, x^2}{10} + \frac{28\cos(x)}{125} - \frac{67\sin(x)}{250}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \mathrm{e}^{x} + \frac{c_2 \mathrm{e}^{3x}}{2}\right) \\
&\quad + \left(\frac{11x\cos(x)}{25} + \frac{x^2\cos(x)}{5} - \frac{2\sin(x)\,x}{25} + \frac{\sin(x)\,x^2}{10} + \frac{28\cos(x)}{125} - \frac{67\sin(x)}{250}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = c_1 \mathrm{e}^{x} + \frac{c_2 \mathrm{e}^{3x}}{2} + \frac{11x\cos(x)}{25} + \frac{x^2\cos(x)}{5} \\
- \frac{2\sin(x)\,x}{25} + \frac{\sin(x)\,x^2}{10} + \frac{28\cos(x)}{125} - \frac{67\sin(x)}{250}
\end{aligned}
\tag{1}
$$

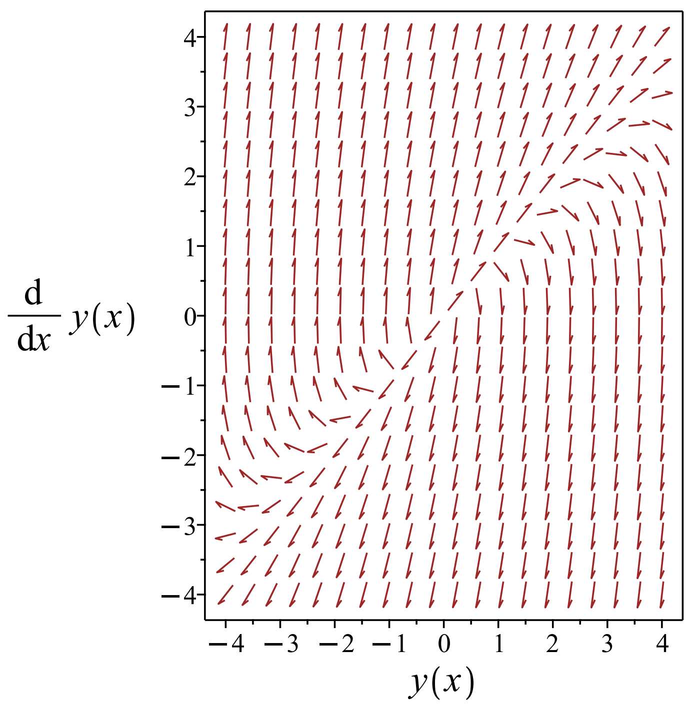

Figure 673: Slope field plot

Verification of solutions

$$y = c_1 e^x + \frac{c_2 e^{3x}}{2} + \frac{11x \cos(x)}{25} + \frac{x^2 \cos(x)}{5} - \frac{2\sin(x)\, x}{25} + \frac{\sin(x)\, x^2}{10} + \frac{28\cos(x)}{125} - \frac{67\sin(x)}{250}$$

Verified OK.

15.11.3 Maple step by step solution

Let's solve

$y'' - 4y' + 3y = \sin(x)\, x^2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 4r + 3 = 0$

- Factor the characteristic polynomial

  $(r-1)(r-3) = 0$

- Roots of the characteristic polynomial

  $r = (1, 3)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^x$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^x + c_2 e^{3x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \sin(x)\, x^2\right]$

- ○ Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^x & e^{3x} \\ e^x & 3\,e^{3x} \end{bmatrix}$$

- Compute Wronskian

  $$W(y_1(x), y_2(x)) = 2\,e^{4x}$$

- Substitute functions into equation for $y_p(x)$

  $$y_p(x) = -\frac{e^x\left(\int x^2 \sin(x) e^{-x} dx\right)}{2} + \frac{e^{3x}\left(\int x^2 e^{-3x} \sin(x) dx\right)}{2}$$

- Compute integrals

  $$y_p(x) = \frac{(25x^2+55x+28)\cos(x)}{125} + \frac{\left(x^2-\frac{4}{5}x-\frac{67}{25}\right)\sin(x)}{10}$$

- Substitute particular solution into general solution to ODE

  $$y = c_1 e^x + c_2 e^{3x} + \frac{(25x^2+55x+28)\cos(x)}{125} + \frac{\left(x^2-\frac{4}{5}x-\frac{67}{25}\right)\sin(x)}{10}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' - y = x \sin(2x)}$$

15.12.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = -1, f(x) = x \sin(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)}\\ &= \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +1\\ \lambda_2 &= -1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1\\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(1)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$y = c_1 e^{x} + c_2 e^{-x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{x} + c_2 e^{-x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x \sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\cos(2x), x\sin(2x), \cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\cos(2x) + A_2 x\sin(2x) + A_3\cos(2x) + A_4\sin(2x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-4A_1\sin(2x) - 5A_1x\cos(2x) + 4A_2\cos(2x)\\&- 5A_2x\sin(2x) - 5A_3\cos(2x) - 5A_4\sin(2x) = x\sin(2x)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = -\frac{1}{5}, A_3 = -\frac{4}{25}, A_4 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\sin(2x)}{5} - \frac{4\cos(2x)}{25}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\&= \left(c_1 e^{x} + c_2 e^{-x}\right) + \left(-\frac{x\sin(2x)}{5} - \frac{4\cos(2x)}{25}\right)\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^x + c_2 e^{-x} - \frac{x \sin(2x)}{5} - \frac{4 \cos(2x)}{25} \tag{1}$$

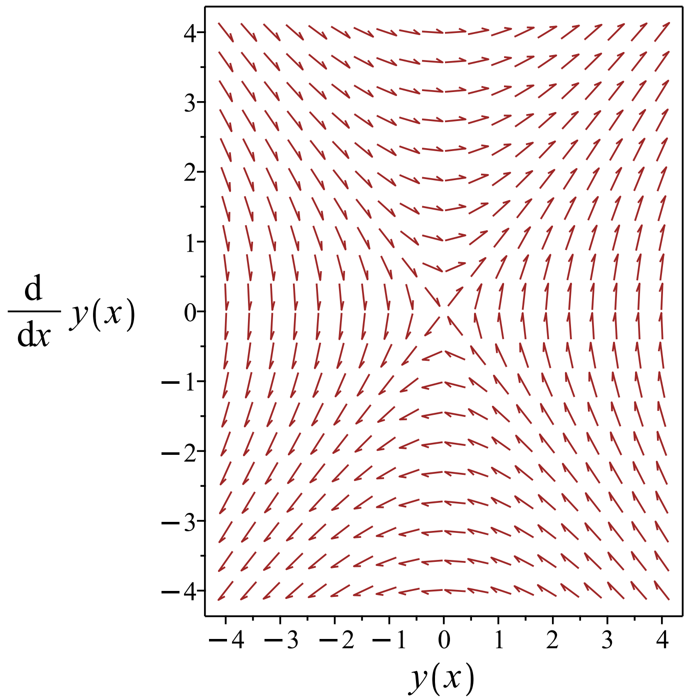

Figure 674: Slope field plot

Verification of solutions

$$y = c_1 e^x + c_2 e^{-x} - \frac{x \sin(2x)}{5} - \frac{4 \cos(2x)}{25}$$

Verified OK.

15.12.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 0 \\
C &= -1
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{1}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 1 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 531: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \mathrm{e}^{-x} \end{aligned}$$

Which simplifies to

$$y_1 = e^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} dx}}{y_1^2} dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2} dx \\
&= e^{-x} \int \frac{1}{e^{-2x}} dx \\
&= e^{-x} \left(\frac{e^{2x}}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(e^{-x}\right) + c_2 \left(e^{-x} \left(\frac{e^{2x}}{2}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{-x} + \frac{c_2 e^{x}}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x \sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x \cos(2x), x \sin(2x), \cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{e^x}{2}, e^{-x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x \cos(2x) + A_2 x \sin(2x) + A_3 \cos(2x) + A_4 \sin(2x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-4A_1 \sin(2x) - 5A_1 x \cos(2x) + 4A_2 \cos(2x)\\ &\quad - 5A_2 x \sin(2x) - 5A_3 \cos(2x) - 5A_4 \sin(2x) = x \sin(2x)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = -\frac{1}{5}, A_3 = -\frac{4}{25}, A_4 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x \sin(2x)}{5} - \frac{4 \cos(2x)}{25}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\ &= \left(c_1 e^{-x} + \frac{c_2 e^x}{2}\right) + \left(-\frac{x \sin(2x)}{5} - \frac{4 \cos(2x)}{25}\right)\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-x} + \frac{c_2 e^x}{2} - \frac{x \sin(2x)}{5} - \frac{4\cos(2x)}{25} \tag{1}$$

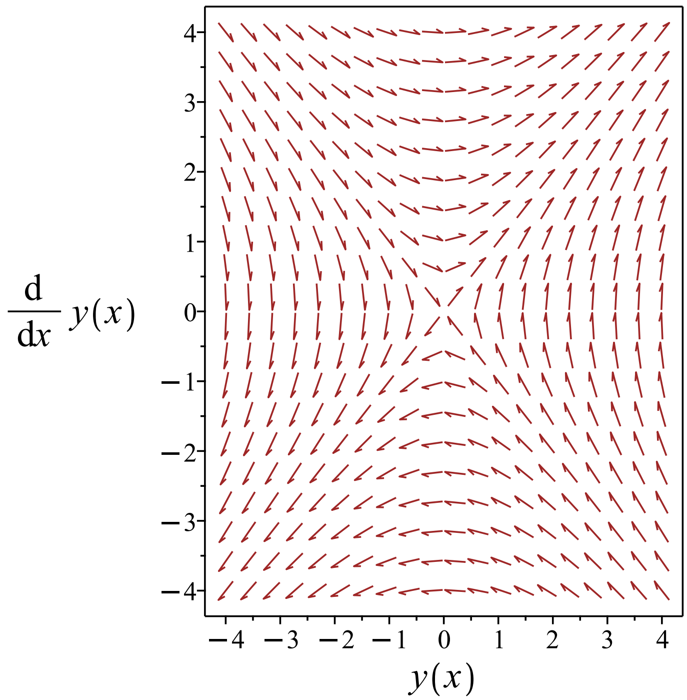

Figure 675: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + \frac{c_2 e^x}{2} - \frac{x \sin(2x)}{5} - \frac{4\cos(2x)}{25}$$

Verified OK.

15.12.3 Maple step by step solution

Let's solve

$y'' - y = x \sin(2x)$

- Highest derivative means the order of the ODE is 2

y''

- Characteristic polynomial of homogeneous ODE

$r^2 - 1 = 0$

- Factor the characteristic polynomial

  $(r-1)(r+1) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x \sin(2x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-x} & \mathrm{e}^{x} \\ -\mathrm{e}^{-x} & \mathrm{e}^{x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\frac{\mathrm{e}^{-x}\left(\int \sin(2x)\mathrm{e}^{x} x dx\right)}{2} + \frac{\mathrm{e}^{x}\left(\int \sin(2x)\mathrm{e}^{-x} x dx\right)}{2}$

  - Compute integrals

    $y_p(x) = -\frac{x \sin(2x)}{5} - \frac{4\cos(2x)}{25}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} - \frac{x \sin(2x)}{5} - \frac{4\cos(2x)}{25}$

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + 2y' = x^3 \sin(2x)}$$

15.13.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 0, f(x) = x^3 \sin(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+2y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=1, B=2, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x}+2\lambda\, e^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2+2\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=2, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{-2}{(2)(1)}\pm\frac{1}{(2)(1)}\sqrt{2^2-(4)(1)(0)}\\&=-1\pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1&=-1+1\\\lambda_2&=-1-1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1&=0\\\lambda_2&=-2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y&=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}\\y&=c_1e^{(0)x}+c_2e^{(-2)x}\end{aligned}$$

Or

$$y = c_1 + c_2 e^{-2x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + c_2 e^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^3 \sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x \cos(2x), x \sin(2x), x^2 \cos(2x), x^3 \cos(2x), x^3 \sin(2x), \sin(2x) x^2, \cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$\begin{aligned} y_p = {} & A_1 x \cos(2x) + A_2 x \sin(2x) + A_3 x^2 \cos(2x) + A_4 x^3 \cos(2x) \\ & + A_5 x^3 \sin(2x) + A_6 \sin(2x) x^2 + A_7 \cos(2x) + A_8 \sin(2x) \end{aligned}$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6, A_7, A_8\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned} & 4A_3 x \cos(2x) + 6A_4 x^2 \cos(2x) + 6A_5 x^2 \sin(2x) + 4A_6 \sin(2x) x \\ & + 6A_4 x \cos(2x) + 6A_5 x \sin(2x) + 8A_6 \cos(2x) x + 2A_3 \cos(2x) \\ & - 8A_3 x \sin(2x) - 12A_4 x^2 \sin(2x) + 12A_5 x^2 \cos(2x) + 2A_6 \sin(2x) \\ & + 2A_1 \cos(2x) - 4A_1 x \sin(2x) + 2A_2 \sin(2x) + 4A_2 x \cos(2x) \\ & - 4A_3 x^2 \sin(2x) - 4A_4 x^3 \sin(2x) + 4A_5 x^3 \cos(2x) + 4A_6 \cos(2x) x^2 \\ & - 4A_7 \cos(2x) - 4A_8 \sin(2x) - 4A_1 x \cos(2x) - 4A_2 x \sin(2x) \\ & - 4A_3 x^2 \cos(2x) - 4A_4 x^3 \cos(2x) - 4A_5 x^3 \sin(2x) - 4A_6 \sin(2x) x^2 \\ & - 4A_1 \sin(2x) + 4A_2 \cos(2x) - 4A_7 \sin(2x) + 4A_8 \cos(2x) = x^3 \sin(2x) \end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{15}{32}, A_2 = \frac{3}{32}, A_3 = -\frac{3}{16}, A_4 = -\frac{1}{8}, A_5 = -\frac{1}{8}, A_6 = \frac{3}{8}, A_7 = 0, A_8 = -\frac{15}{64}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$\begin{aligned} y_p = &\frac{15x\cos(2x)}{32} + \frac{3x\sin(2x)}{32} - \frac{3x^2\cos(2x)}{16} - \frac{x^3\cos(2x)}{8} \\ &- \frac{x^3\sin(2x)}{8} + \frac{3\sin(2x)\,x^2}{8} - \frac{15\sin(2x)}{64} \end{aligned}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + c_2 e^{-2x}\right) + \left(\frac{15x\cos(2x)}{32} + \frac{3x\sin(2x)}{32} - \frac{3x^2\cos(2x)}{16} - \frac{x^3\cos(2x)}{8} \right. \\ &\qquad \left. - \frac{x^3\sin(2x)}{8} + \frac{3\sin(2x)\,x^2}{8} - \frac{15\sin(2x)}{64}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = c_1 + c_2 e^{-2x} &+ \frac{15x\cos(2x)}{32} + \frac{3x\sin(2x)}{32} - \frac{3x^2\cos(2x)}{16} \\ &- \frac{x^3\cos(2x)}{8} - \frac{x^3\sin(2x)}{8} + \frac{3\sin(2x)\,x^2}{8} - \frac{15\sin(2x)}{64} \end{aligned} \tag{1}$$

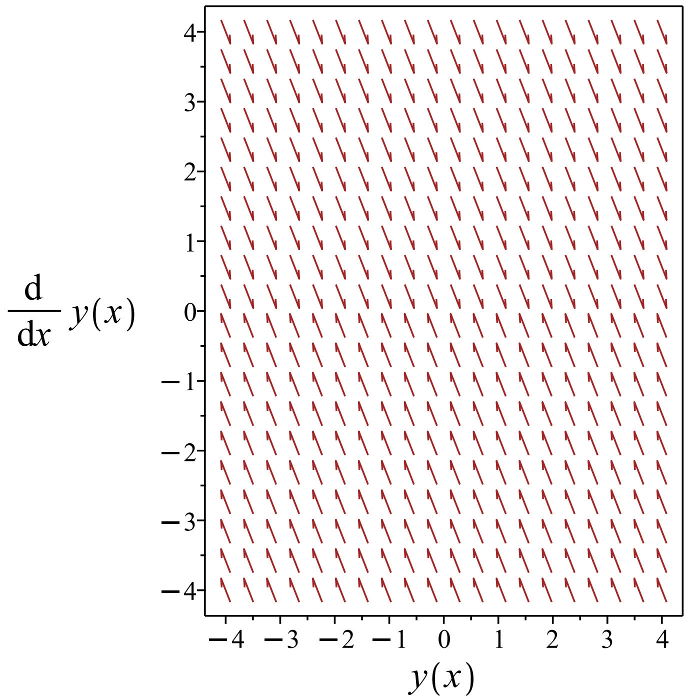

Figure 676: Slope field plot

Verification of solutions

$$y = c_1 + c_2 e^{-2x} + \frac{15x\cos(2x)}{32} + \frac{3x\sin(2x)}{32} - \frac{3x^2\cos(2x)}{16} - \frac{x^3\cos(2x)}{8} - \frac{x^3\sin(2x)}{8} + \frac{3\sin(2x)\,x^2}{8} - \frac{15\sin(2x)}{64}$$

Verified OK.

15.13.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 2y')\,dx = \int x^3\sin(2x)\,dx$$

$$2y + y' = -\frac{x^3\cos(2x)}{2} + \frac{3\sin(2x)\,x^2}{4} - \frac{3\sin(2x)}{8} + \frac{3x\cos(2x)}{4} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= 2\\
q(x) &= \frac{(-4x^3+6x)\cos(2x)}{8}+\frac{3\sin(2x)\,x^2}{4}+c_1-\frac{3\sin(2x)}{8}
\end{aligned}
$$

Hence the ode is

$$
2y+y' = \frac{(-4x^3+6x)\cos(2x)}{8}+\frac{3\sin(2x)\,x^2}{4}+c_1-\frac{3\sin(2x)}{8}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int 2dx}\\
&= e^{2x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{(-4x^3+6x)\cos(2x)}{8}+\frac{3\sin(2x)\,x^2}{4}+c_1-\frac{3\sin(2x)}{8}\right)\\
\frac{d}{dx}(e^{2x}y) &= (e^{2x})\left(\frac{(-4x^3+6x)\cos(2x)}{8}+\frac{3\sin(2x)\,x^2}{4}+c_1-\frac{3\sin(2x)}{8}\right)\\
d(e^{2x}y) &= \left(-\frac{(4x^3\cos(2x)-6\sin(2x)\,x^2-6x\cos(2x)+3\sin(2x)-8c_1)\,e^{2x}}{8}\right)dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
e^{2x}y &= \int -\frac{(4x^3\cos(2x)-6\sin(2x)\,x^2-6x\cos(2x)+3\sin(2x)-8c_1)\,e^{2x}}{8}\,dx\\
e^{2x}y &= -\frac{(4x^3-3x+\frac{3}{2})\,e^{2x}\cos(2x)}{32}+\frac{(-4x^3+6x^2-3x)\,e^{2x}\sin(2x)}{32}+\frac{3(-2x^2+2x-\frac{1}{2})\,e^{2x}\cos(2x)}{32}+
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$
y = e^{-2x}\left(-\frac{(4x^3-3x+\frac{3}{2})\,e^{2x}\cos(2x)}{32}+\frac{(-4x^3+6x^2-3x)\,e^{2x}\sin(2x)}{32}+\frac{3(-2x^2+2x-\frac{1}{2})\,e^{2x}\cos(2x}{32}\right.
$$

which simplifies to

$$
y = \frac{(-8x^3+24x^2+6x-15)\sin(2x)}{64}+\frac{(-4x^3-6x^2+15x)\cos(2x)}{32}+c_2e^{-2x}+\frac{c_1}{2}
$$

Summary

The solution(s) found are the following

$$
y = \frac{(-8x^3+24x^2+6x-15)\sin(2x)}{64}+\frac{(-4x^3-6x^2+15x)\cos(2x)}{32}+c_2e^{-2x}+\frac{c_1}{2} \tag{1}
$$

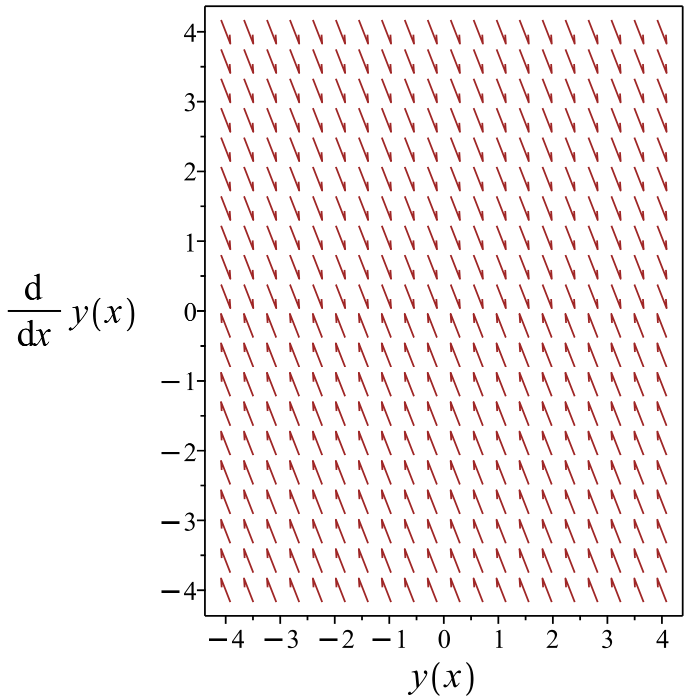

Figure 677: Slope field plot

<u>Verification of solutions</u>

$$y = \frac{(-8x^3 + 24x^2 + 6x - 15)\sin(2x)}{64} + \frac{(-4x^3 - 6x^2 + 15x)\cos(2x)}{32} + c_2 e^{-2x} + \frac{c_1}{2}$$

Verified OK.

15.13.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + 2p(x) - x^3 \sin(2x) = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned}p(x) &= 2\\ q(x) &= x^3 \sin(2x)\end{aligned}$$

Hence the ode is

$$p'(x) + 2p(x) = x^3 \sin(2x)$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int 2dx}\\ &= e^{2x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu p) &= (\mu)\left(x^3 \sin(2x)\right)\\ \frac{d}{dx}\left(e^{2x} p\right) &= \left(e^{2x}\right)\left(x^3 \sin(2x)\right)\\ d\left(e^{2x} p\right) &= \left(x^3 \sin(2x) e^{2x}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{2x} p &= \int x^3 \sin(2x) e^{2x} dx\\ e^{2x} p &= \frac{(-4x^3 + 6x^2 - 3x) e^{2x} \cos(2x)}{16} + \frac{\left(4x^3 - 3x + \frac{3}{2}\right) e^{2x} \sin(2x)}{16} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$p(x) = e^{-2x}\left(\frac{(-4x^3 + 6x^2 - 3x) e^{2x} \cos(2x)}{16} + \frac{\left(4x^3 - 3x + \frac{3}{2}\right) e^{2x} \sin(2x)}{16}\right) + c_1 e^{-2x}$$

which simplifies to

$$p(x) = \frac{(-4x^3 + 6x^2 - 3x) \cos(2x)}{16} + \frac{(8x^3 - 6x + 3) \sin(2x)}{32} + c_1 e^{-2x}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{(-4x^3 + 6x^2 - 3x) \cos(2x)}{16} + \frac{(8x^3 - 6x + 3) \sin(2x)}{32} + c_1 e^{-2x}$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int \frac{x^{3} \sin (2x)}{4}-\frac{x^{3} \cos (2x)}{4}+\frac{3x^{2} \cos (2x)}{8}-\frac{3x \sin (2x)}{16}-\frac{3x \cos (2x)}{16}+\frac{3 \sin (2x)}{32}+c_{1} \mathrm{e}^{-2x} \,\mathrm{d}x \\
&= \frac{3 \sin (2x)\, x^{2}}{8}-\frac{15 \sin (2x)}{64}+\frac{15x \cos (2x)}{32}-\frac{x^{3} \cos (2x)}{8}-\frac{c_{1} \mathrm{e}^{-2x}}{2}+\frac{3x \sin (2x)}{32}-\frac{x^{3} \sin (2x)}{8}-3x^{2}\, \mathrm{c}
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
\begin{aligned}
y = {} & \frac{3 \sin (2x)\, x^{2}}{8}-\frac{15 \sin (2x)}{64}+\frac{15x \cos (2x)}{32}-\frac{x^{3} \cos (2x)}{8} \\
& -\frac{c_{1} \mathrm{e}^{-2x}}{2}+\frac{3x \sin (2x)}{32}-\frac{x^{3} \sin (2x)}{8}-\frac{3x^{2} \cos (2x)}{16}+c_{2}
\end{aligned} \tag{1}
$$

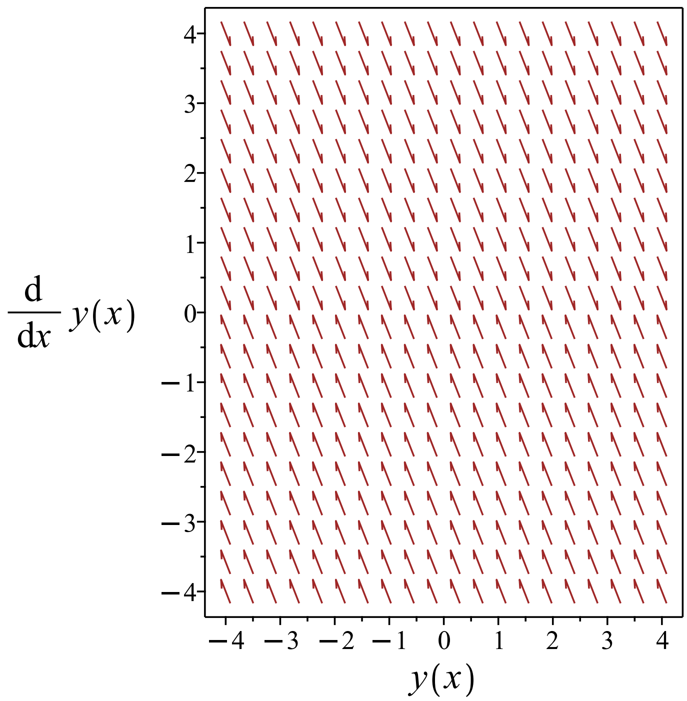

Figure 678: Slope field plot

<u>Verification of solutions</u>

$$
\begin{aligned}
y = {} & \frac{3 \sin (2x)\, x^{2}}{8}-\frac{15 \sin (2x)}{64}+\frac{15x \cos (2x)}{32}-\frac{x^{3} \cos (2x)}{8} \\
& -\frac{c_{1} \mathrm{e}^{-2x}}{2}+\frac{3x \sin (2x)}{32}-\frac{x^{3} \sin (2x)}{8}-\frac{3x^{2} \cos (2x)}{16}+c_{2}
\end{aligned}
$$

Verified OK.

15.13.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + 2y' = x^3 \sin(2x)$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 2y')\,dx = \int x^3 \sin(2x)\,dx$$

$$2y + y' = -\frac{x^3 \cos(2x)}{2} + \frac{3 \sin(2x)\,x^2}{4} - \frac{3 \sin(2x)}{8} + \frac{3x \cos(2x)}{4} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 2$$
$$q(x) = \frac{(-4x^3 + 6x)\cos(2x)}{8} + \frac{3 \sin(2x)\,x^2}{4} + c_1 - \frac{3 \sin(2x)}{8}$$

Hence the ode is

$$2y + y' = \frac{(-4x^3 + 6x)\cos(2x)}{8} + \frac{3 \sin(2x)\,x^2}{4} + c_1 - \frac{3 \sin(2x)}{8}$$

The integrating factor μ is

$$\mu = e^{\int 2dx}$$
$$= e^{2x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{(-4x^3 + 6x)\cos(2x)}{8} + \frac{3 \sin(2x)\,x^2}{4} + c_1 - \frac{3 \sin(2x)}{8}\right)$$
$$\frac{d}{dx}(e^{2x} y) = (e^{2x})\left(\frac{(-4x^3 + 6x)\cos(2x)}{8} + \frac{3 \sin(2x)\,x^2}{4} + c_1 - \frac{3 \sin(2x)}{8}\right)$$
$$d(e^{2x} y) = \left(-\frac{(4x^3 \cos(2x) - 6 \sin(2x)\,x^2 - 6x \cos(2x) + 3 \sin(2x) - 8c_1)\,e^{2x}}{8}\right) dx$$

Integrating gives

$$e^{2x}y = \int -\frac{(4x^3\cos(2x) - 6\sin(2x)x^2 - 6x\cos(2x) + 3\sin(2x) - 8c_1)e^{2x}}{8}\,dx$$

$$e^{2x}y = -\frac{\left(4x^3 - 3x + \frac{3}{2}\right)e^{2x}\cos(2x)}{32} + \frac{(-4x^3 + 6x^2 - 3x)e^{2x}\sin(2x)}{32} + \frac{3\left(-2x^2 + 2x - \frac{1}{2}\right)e^{2x}\cos(2x)}{32} +$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$y = e^{-2x}\left(-\frac{\left(4x^3 - 3x + \frac{3}{2}\right)e^{2x}\cos(2x)}{32} + \frac{(-4x^3 + 6x^2 - 3x)e^{2x}\sin(2x)}{32} + \frac{3\left(-2x^2 + 2x - \frac{1}{2}\right)e^{2x}\cos(2x}{32}\right.$$

which simplifies to

$$y = \frac{(-8x^3 + 24x^2 + 6x - 15)\sin(2x)}{64} + \frac{(-4x^3 - 6x^2 + 15x)\cos(2x)}{32} + c_2e^{-2x} + \frac{c_1}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{(-8x^3 + 24x^2 + 6x - 15)\sin(2x)}{64} + \frac{(-4x^3 - 6x^2 + 15x)\cos(2x)}{32} + c_2e^{-2x} + \frac{c_1}{2} \tag{1}$$

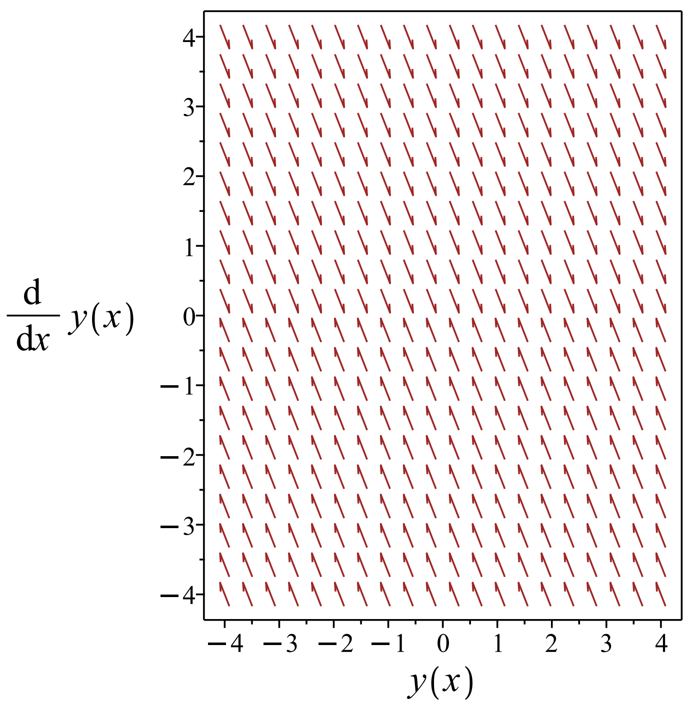

Figure 679: Slope field plot

Verification of solutions

$$y = \frac{(-8x^3 + 24x^2 + 6x - 15)\sin(2x)}{64} + \frac{(-4x^3 - 6x^2 + 15x)\cos(2x)}{32} + c_2 \mathrm{e}^{-2x} + \frac{c_1}{2}$$

Verified OK.

15.13.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 533: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\
&= z_1 e^{-x} \\
&= z_1 \left(\mathrm{e}^{-x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\mathrm{e}^{2x}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-2x}\right) + c_2\left(\mathrm{e}^{-2x}\left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+2y'=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-2x} + \frac{c_2}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^3 \sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\cos(2x), x\sin(2x), x^2\cos(2x), x^3\cos(2x), x^3\sin(2x), \sin(2x)x^2, \cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{1}{2}, \mathrm{e}^{-2x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$\begin{aligned}y_p = {} & A_1x\cos(2x) + A_2x\sin(2x) + A_3x^2\cos(2x) + A_4x^3\cos(2x) \\ & + A_5x^3\sin(2x) + A_6\sin(2x)x^2 + A_7\cos(2x) + A_8\sin(2x)\end{aligned}$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6, A_7, A_8\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-4A_7\sin(2x) + 4A_8\cos(2x) - 4A_1\sin(2x) + 4A_2\cos(2x) + 2A_6\sin(2x) \\ &+ 2A_1\cos(2x) - 4A_1x\sin(2x) + 2A_2\sin(2x) + 4A_2x\cos(2x) \\ &- 4A_3x^2\sin(2x) - 4A_4x^3\sin(2x) + 4A_5x^3\cos(2x) + 4A_6\cos(2x)x^2 \\ &+ 2A_3\cos(2x) - 8A_3x\sin(2x) - 12A_4x^2\sin(2x) + 12A_5x^2\cos(2x) \\ &- 4A_7\cos(2x) - 4A_8\sin(2x) - 4A_1x\cos(2x) - 4A_2x\sin(2x) \\ &- 4A_3x^2\cos(2x) - 4A_4x^3\cos(2x) - 4A_5x^3\sin(2x) - 4A_6\sin(2x)x^2 \\ &+ 6A_4x\cos(2x) + 6A_5x\sin(2x) + 8A_6\cos(2x)x + 4A_3x\cos(2x) \\ &+ 6A_4x^2\cos(2x) + 6A_5x^2\sin(2x) + 4A_6\sin(2x)x = x^3\sin(2x)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{15}{32}, A_2 = \frac{3}{32}, A_3 = -\frac{3}{16}, A_4 = -\frac{1}{8}, A_5 = -\frac{1}{8}, A_6 = \frac{3}{8}, A_7 = 0, A_8 = -\frac{15}{64}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$\begin{aligned} y_p = {} & \frac{15x\cos(2x)}{32} + \frac{3x\sin(2x)}{32} - \frac{3x^2\cos(2x)}{16} - \frac{x^3\cos(2x)}{8} \\ & - \frac{x^3\sin(2x)}{8} + \frac{3\sin(2x)\,x^2}{8} - \frac{15\sin(2x)}{64} \end{aligned}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-2x} + \frac{c_2}{2}\right) + \left(\frac{15x\cos(2x)}{32} + \frac{3x\sin(2x)}{32} - \frac{3x^2\cos(2x)}{16} - \frac{x^3\cos(2x)}{8} \right. \\ & \qquad \left. - \frac{x^3\sin(2x)}{8} + \frac{3\sin(2x)\,x^2}{8} - \frac{15\sin(2x)}{64}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & c_1 e^{-2x} + \frac{c_2}{2} + \frac{15x\cos(2x)}{32} + \frac{3x\sin(2x)}{32} - \frac{3x^2\cos(2x)}{16} \\ & - \frac{x^3\cos(2x)}{8} - \frac{x^3\sin(2x)}{8} + \frac{3\sin(2x)\,x^2}{8} - \frac{15\sin(2x)}{64} \end{aligned} \tag{1}$$

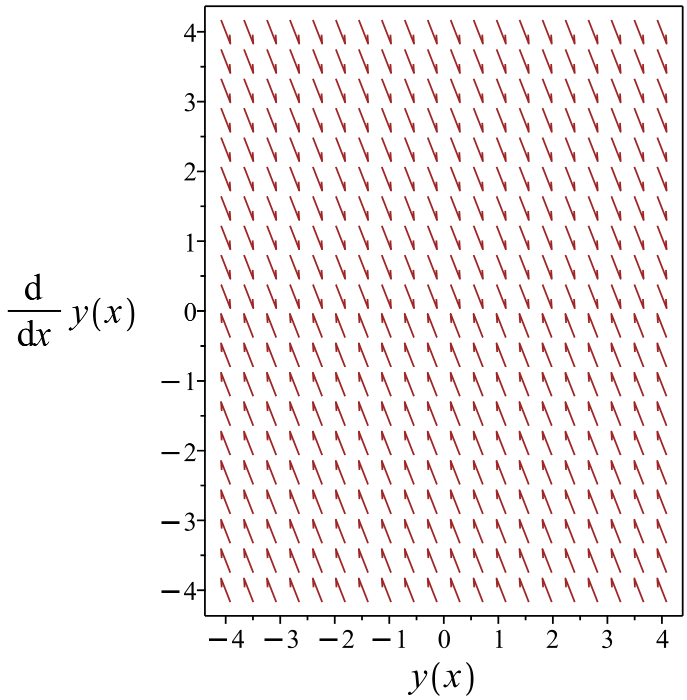

Figure 680: Slope field plot

Verification of solutions

$$y = c_1 e^{-2x} + \frac{c_2}{2} + \frac{15x\cos(2x)}{32} + \frac{3x\sin(2x)}{32} - \frac{3x^2\cos(2x)}{16} - \frac{x^3\cos(2x)}{8} - \frac{x^3\sin(2x)}{8} + \frac{3\sin(2x)\,x^2}{8} - \frac{15\sin(2x)}{64}$$

Verified OK.

15.13.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}p(x) &= 1\\ q(x) &= 2\\ r(x) &= 0\\ s(x) &= x^3 \sin(2x)\end{aligned}$$

Hence

$$\begin{aligned}p''(x) &= 0\\ q'(x) &= 0\end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$2y + y' = \int x^3 \sin(2x)\, dx$$

We now have a first order ode to solve which is

$$2y + y' = -\frac{x^3 \cos(2x)}{2} + \frac{3 \sin(2x)\, x^2}{4} - \frac{3 \sin(2x)}{8} + \frac{3x \cos(2x)}{4} + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= 2\\ q(x) &= \frac{(-4x^3 + 6x)\cos(2x)}{8} + \frac{3 \sin(2x)\, x^2}{4} + c_1 - \frac{3 \sin(2x)}{8}\end{aligned}$$

Hence the ode is

$$2y + y' = \frac{(-4x^3 + 6x)\cos(2x)}{8} + \frac{3\sin(2x)\,x^2}{4} + c_1 - \frac{3\sin(2x)}{8}$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int 2dx}\\ &= \mathrm{e}^{2x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{(-4x^3 + 6x)\cos(2x)}{8} + \frac{3\sin(2x)\,x^2}{4} + c_1 - \frac{3\sin(2x)}{8}\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}(\mathrm{e}^{2x}y) &= (\mathrm{e}^{2x})\left(\frac{(-4x^3 + 6x)\cos(2x)}{8} + \frac{3\sin(2x)\,x^2}{4} + c_1 - \frac{3\sin(2x)}{8}\right)\\ \mathrm{d}(\mathrm{e}^{2x}y) &= \left(-\frac{(4x^3\cos(2x) - 6\sin(2x)\,x^2 - 6x\cos(2x) + 3\sin(2x) - 8c_1)\,\mathrm{e}^{2x}}{8}\right)\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\mathrm{e}^{2x}y &= \int -\frac{(4x^3\cos(2x) - 6\sin(2x)\,x^2 - 6x\cos(2x) + 3\sin(2x) - 8c_1)\,\mathrm{e}^{2x}}{8}\,\mathrm{d}x\\ \mathrm{e}^{2x}y &= -\frac{\left(4x^3 - 3x + \frac{3}{2}\right)\mathrm{e}^{2x}\cos(2x)}{32} + \frac{(-4x^3 + 6x^2 - 3x)\,\mathrm{e}^{2x}\sin(2x)}{32} + \frac{3\left(-2x^2 + 2x - \frac{1}{2}\right)\mathrm{e}^{2x}\cos(2x)}{32} +\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{2x}$ results in

$$y = \mathrm{e}^{-2x}\left(-\frac{\left(4x^3 - 3x + \frac{3}{2}\right)\mathrm{e}^{2x}\cos(2x)}{32} + \frac{(-4x^3 + 6x^2 - 3x)\,\mathrm{e}^{2x}\sin(2x)}{32} + \frac{3\left(-2x^2 + 2x - \frac{1}{2}\right)\mathrm{e}^{2x}\cos(2x}{32}\right.$$

which simplifies to

$$y = \frac{(-8x^3 + 24x^2 + 6x - 15)\sin(2x)}{64} + \frac{(-4x^3 - 6x^2 + 15x)\cos(2x)}{32} + c_2\mathrm{e}^{-2x} + \frac{c_1}{2}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \frac{(-8x^3 + 24x^2 + 6x - 15)\sin(2x)}{64} + \frac{(-4x^3 - 6x^2 + 15x)\cos(2x)}{32} + c_2\mathrm{e}^{-2x} + \frac{c_1}{2} \quad (1)$$

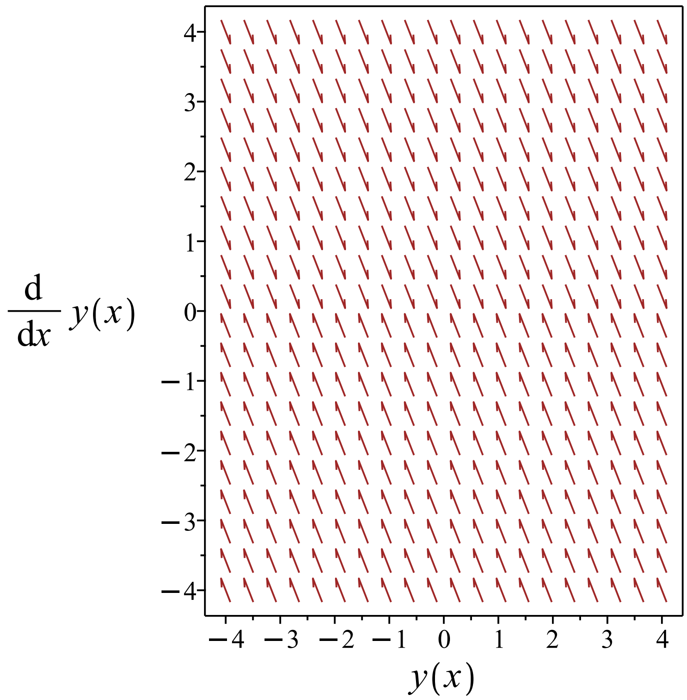

Figure 681: Slope field plot

Verification of solutions

$$y = \frac{(-8x^3 + 24x^2 + 6x - 15)\sin(2x)}{64} + \frac{(-4x^3 - 6x^2 + 15x)\cos(2x)}{32} + c_2 e^{-2x} + \frac{c_1}{2}$$

Verified OK.

15.13.7 Maple step by step solution

Let's solve

$y'' + 2y' = x^3 \sin(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r = 0$

- Factor the characteristic polynomial

  $r(r + 2) = 0$

- Roots of the characteristic polynomial

$r = (-2, 0)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-2x} + c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = x^3 \sin(2x)\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-2x} & 1 \\ -2\,\mathrm{e}^{-2x} & 0 \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2\,\mathrm{e}^{-2x}$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\mathrm{e}^{-2x}\left(\int x^3 \sin(2x)\mathrm{e}^{2x}dx\right)}{2} + \frac{\left(\int x^3 \sin(2x)dx\right)}{2}$

- ○ Compute integrals

  $y_p(x) = \frac{(-8x^3+24x^2+6x-15)\sin(2x)}{64} - \frac{\left(x^2+\frac{3}{2}x-\frac{15}{4}\right)x\cos(2x)}{8}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-2x} + c_2 + \frac{(-8x^3+24x^2+6x-15)\sin(2x)}{64} - \frac{\left(x^2+\frac{3}{2}x-\frac{15}{4}\right)x\cos(2x)}{8}$

$$\boxed{y'' - y' = e^{2x} \sin(x) x}$$

15.14.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -1, C = 0, f(x) = e^{2x} \sin(x) x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -1, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - \lambda \,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -1, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{1}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-1^2 - (4)\,(1)\,(0)}\\ &= \frac{1}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= \frac{1}{2} + \frac{1}{2}\\ \lambda_2 &= \frac{1}{2} - \frac{1}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1\\ \lambda_2 &= 0\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(1)x} + c_2 e^{(0)x}\end{aligned}$$

Or

$$y = c_1 e^x + c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^x + c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{2x} \sin(x) x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x} \cos(x), e^{2x} \sin(x), e^{2x} \cos(x) x, e^{2x} \sin(x) x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^x\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{2x} \cos(x) + A_2 e^{2x} \sin(x) + A_3 e^{2x} \cos(x) x + A_4 e^{2x} \sin(x) x$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned} A_1 e^{2x} \cos(x) - 3A_1 e^{2x} \sin(x) + A_2 e^{2x} \sin(x) + 3A_2 e^{2x} \cos(x) + A_3 e^{2x} \cos(x) x \\ - 3A_3 e^{2x} \sin(x) x + 3A_3 e^{2x} \cos(x) + A_4 e^{2x} \sin(x) x + 3A_4 e^{2x} \cos(x) x \\ + 3A_4 e^{2x} \sin(x) - 2A_3 e^{2x} \sin(x) + 2A_4 e^{2x} \cos(x) = e^{2x} \sin(x) x \end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{17}{50}, A_2 = \frac{3}{25}, A_3 = -\frac{3}{10}, A_4 = \frac{1}{10}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{17 e^{2x} \cos(x)}{50} + \frac{3 e^{2x} \sin(x)}{25} - \frac{3 e^{2x} \cos(x) x}{10} + \frac{e^{2x} \sin(x) x}{10}$$

Therefore the general solution is

$$y = y_h + y_p$$
$$= (c_1 e^x + c_2) + \left(\frac{17\, e^{2x} \cos(x)}{50} + \frac{3\, e^{2x} \sin(x)}{25} - \frac{3\, e^{2x} \cos(x)\, x}{10} + \frac{e^{2x} \sin(x)\, x}{10}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 e^x + c_2 + \frac{17\, e^{2x} \cos(x)}{50} + \frac{3\, e^{2x} \sin(x)}{25} - \frac{3\, e^{2x} \cos(x)\, x}{10} + \frac{e^{2x} \sin(x)\, x}{10} \tag{1}$$

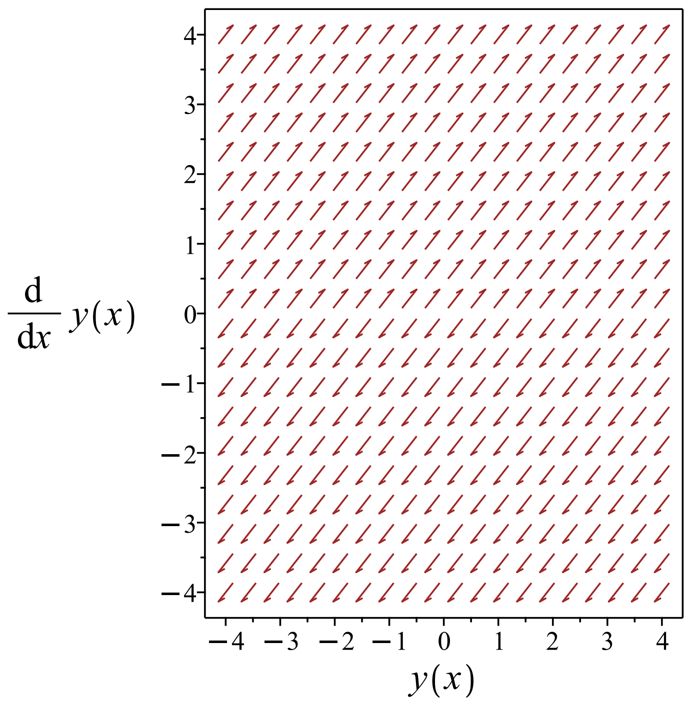

Figure 682: Slope field plot

Verification of solutions

$$y = c_1 e^x + c_2 + \frac{17\, e^{2x} \cos(x)}{50} + \frac{3\, e^{2x} \sin(x)}{25} - \frac{3\, e^{2x} \cos(x)\, x}{10} + \frac{e^{2x} \sin(x)\, x}{10}$$

Verified OK.

15.14.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - y')\, dx = \int e^{2x} \sin(x)\, x dx$$

$$y' - y = \left(-\frac{x}{5} + \frac{4}{25}\right) e^{2x} \cos(x) + \left(\frac{2x}{5} - \frac{3}{25}\right) e^{2x} \sin(x) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -1 \\ q(x) &= \frac{((4-5x)\cos(x) + \sin(x)(10x-3))\, e^{2x}}{25} + c_1 \end{aligned}$$

Hence the ode is

$$y' - y = \frac{((4-5x)\cos(x) + \sin(x)(10x-3))\, e^{2x}}{25} + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-1) dx} \\ &= e^{-x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(\frac{((4-5x)\cos(x) + \sin(x)(10x-3))\, e^{2x}}{25} + c_1\right) \\ \frac{d}{dx}\left(e^{-x} y\right) &= \left(e^{-x}\right)\left(\frac{((4-5x)\cos(x) + \sin(x)(10x-3))\, e^{2x}}{25} + c_1\right) \\ d\left(e^{-x} y\right) &= \left(c_1 e^{-x} - \frac{\left(\left(-\frac{4}{5} + x\right)\cos(x) + \sin(x)\left(\frac{3}{5} - 2x\right)\right) e^{x}}{5}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{-x} y &= \int c_1 e^{-x} - \frac{\left(\left(-\frac{4}{5} + x\right)\cos(x) + \sin(x)\left(\frac{3}{5} - 2x\right)\right) e^{x}}{5}\, dx \\ e^{-x} y &= -c_1 e^{-x} - \frac{e^{x}\cos(x)\, x}{10} + \frac{\left(-\frac{x}{2} + \frac{1}{2}\right) e^{x} \sin(x)}{5} + \frac{2\left(-\frac{x}{2} + \frac{1}{2}\right) e^{x} \cos(x)}{5} + \frac{e^{x}\sin(x)\, x}{5} + \frac{7\cos(x)\, e^{x}}{50} + \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-x}$ results in

$$y = \mathrm{e}^{x}\left(-c_1\mathrm{e}^{-x} - \frac{\mathrm{e}^{x}\cos\left(x\right)x}{10} + \frac{\left(-\frac{x}{2}+\frac{1}{2}\right)\mathrm{e}^{x}\sin\left(x\right)}{5} + \frac{2\left(-\frac{x}{2}+\frac{1}{2}\right)\mathrm{e}^{x}\cos\left(x\right)}{5} + \frac{\mathrm{e}^{x}\sin\left(x\right)x}{5} + \frac{7\cos\left(x\right)\mathrm{e}^{x}}{50}\right.$$

which simplifies to

$$y = \frac{\left(\left(-15x+17\right)\cos\left(x\right)+\sin\left(x\right)\left(5x+6\right)\right)\mathrm{e}^{2x}}{50} + c_2\mathrm{e}^{x} - c_1$$

Summary

The solution(s) found are the following

$$y = \frac{\left(\left(-15x+17\right)\cos\left(x\right)+\sin\left(x\right)\left(5x+6\right)\right)\mathrm{e}^{2x}}{50} + c_2\mathrm{e}^{x} - c_1 \tag{1}$$

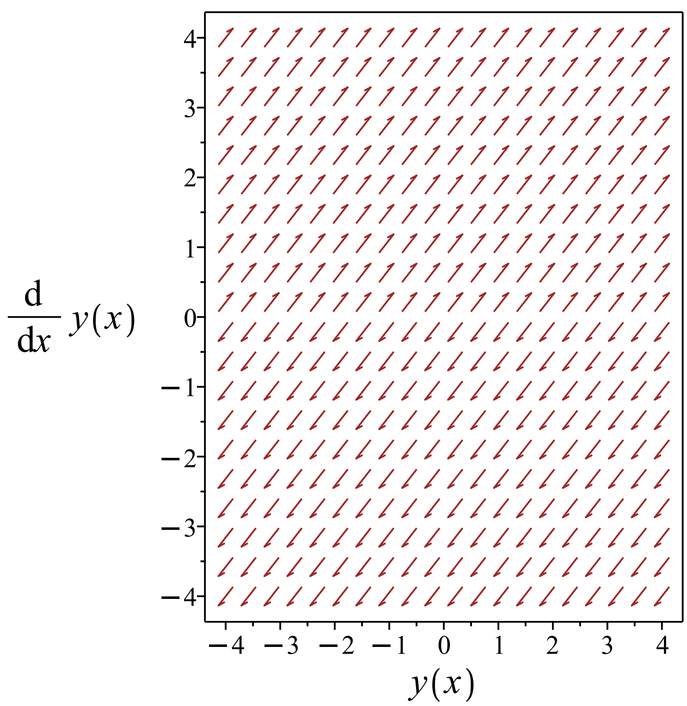

Figure 683: Slope field plot

Verification of solutions

$$y = \frac{\left(\left(-15x+17\right)\cos\left(x\right)+\sin\left(x\right)\left(5x+6\right)\right)\mathrm{e}^{2x}}{50} + c_2\mathrm{e}^{x} - c_1$$

Verified OK.

15.14.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$-p(x) + p'(x) - e^{2x} \sin(x) x = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -1 \\ q(x) &= e^{2x} \sin(x) x \end{aligned}$$

Hence the ode is

$$-p(x) + p'(x) = e^{2x} \sin(x) x$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-1)dx} \\ &= e^{-x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu) \left(e^{2x} \sin(x) x\right) \\ \frac{d}{dx}\left(e^{-x} p\right) &= \left(e^{-x}\right) \left(e^{2x} \sin(x) x\right) \\ d\left(e^{-x} p\right) &= \left(e^{x} \sin(x) x\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{-x} p &= \int e^{x} \sin(x) x \, dx \\ e^{-x} p &= \left(-\frac{x}{2} + \frac{1}{2}\right) e^{x} \cos(x) + \frac{e^{x} \sin(x) x}{2} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-x}$ results in

$$p(x) = \mathrm{e}^{x}\left(\left(-\frac{x}{2}+\frac{1}{2}\right)\mathrm{e}^{x}\cos(x)+\frac{\mathrm{e}^{x}\sin(x)\,x}{2}\right)+c_1\mathrm{e}^{x}$$

which simplifies to

$$p(x) = \frac{\mathrm{e}^{2x}((1-x)\cos(x)+\sin(x)\,x)}{2}+c_1\mathrm{e}^{x}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{\mathrm{e}^{2x}((1-x)\cos(x)+\sin(x)\,x)}{2}+c_1\mathrm{e}^{x}$$

Integrating both sides gives

$$\begin{aligned}y &= \int -\frac{\mathrm{e}^{2x}\cos(x)\,x}{2}+\frac{\mathrm{e}^{2x}\sin(x)\,x}{2}+\frac{\mathrm{e}^{2x}\cos(x)}{2}+c_1\mathrm{e}^{x}\,\mathrm{d}x\\ &= \frac{\mathrm{e}^{2x}\cos(x)}{5}+\frac{\mathrm{e}^{2x}\sin(x)}{10}+\frac{\left(-\frac{x}{5}+\frac{4}{25}\right)\mathrm{e}^{2x}\cos(x)}{2}+\frac{\left(\frac{2x}{5}-\frac{3}{25}\right)\mathrm{e}^{2x}\sin(x)}{2}+c_1\mathrm{e}^{x}-\frac{\left(\frac{2x}{5}-\frac{3}{25}\right)\mathrm{e}^{2x}\cos(x)}{2}\end{aligned}$$

Summary
The solution(s) found are the following

$$\begin{aligned}y = {}&\frac{\mathrm{e}^{2x}\cos(x)}{5}+\frac{\mathrm{e}^{2x}\sin(x)}{10}+\frac{\left(-\frac{x}{5}+\frac{4}{25}\right)\mathrm{e}^{2x}\cos(x)}{2}+\frac{\left(\frac{2x}{5}-\frac{3}{25}\right)\mathrm{e}^{2x}\sin(x)}{2}\\ &+c_1\mathrm{e}^{x}-\frac{\left(\frac{2x}{5}-\frac{3}{25}\right)\mathrm{e}^{2x}\cos(x)}{2}+\frac{\left(-\frac{x}{5}+\frac{4}{25}\right)\mathrm{e}^{2x}\sin(x)}{2}+c_2\end{aligned} \tag{1}$$

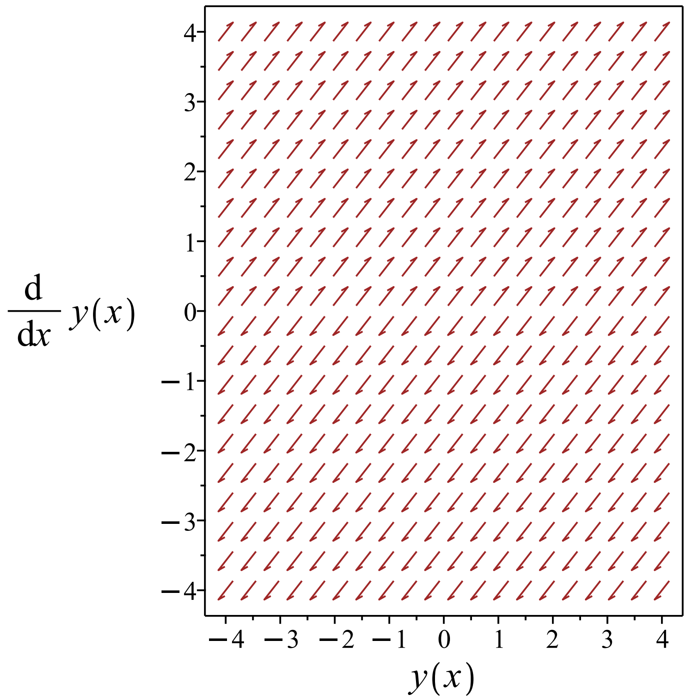

Figure 684: Slope field plot

Verification of solutions

$$y = \frac{e^{2x}\cos(x)}{5} + \frac{e^{2x}\sin(x)}{10} + \frac{\left(-\frac{x}{5}+\frac{4}{25}\right)e^{2x}\cos(x)}{2} + \frac{\left(\frac{2x}{5}-\frac{3}{25}\right)e^{2x}\sin(x)}{2} + c_1 e^{x} - \frac{\left(\frac{2x}{5}-\frac{3}{25}\right)e^{2x}\cos(x)}{2} + \frac{\left(-\frac{x}{5}+\frac{4}{25}\right)e^{2x}\sin(x)}{2} + c_2$$

Verified OK.

15.14.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' - y' = e^{2x}\sin(x)\,x$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - y')\,dx = \int e^{2x}\sin(x)\,x dx$$

$$y' - y = \left(-\frac{x}{5}+\frac{4}{25}\right)e^{2x}\cos(x) + \left(\frac{2x}{5}-\frac{3}{25}\right)e^{2x}\sin(x) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= -1\\ q(x) &= \frac{((4-5x)\cos(x) + \sin(x)(10x-3))\,\mathrm{e}^{2x}}{25} + c_1\end{aligned}$$

Hence the ode is

$$y' - y = \frac{((4-5x)\cos(x) + \sin(x)(10x-3))\,\mathrm{e}^{2x}}{25} + c_1$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int(-1)dx}\\ &= \mathrm{e}^{-x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{((4-5x)\cos(x) + \sin(x)(10x-3))\,\mathrm{e}^{2x}}{25} + c_1\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}(\mathrm{e}^{-x}y) &= (\mathrm{e}^{-x})\left(\frac{((4-5x)\cos(x) + \sin(x)(10x-3))\,\mathrm{e}^{2x}}{25} + c_1\right)\\ \mathrm{d}(\mathrm{e}^{-x}y) &= \left(c_1\mathrm{e}^{-x} - \frac{\left(\left(-\frac{4}{5}+x\right)\cos(x) + \sin(x)\left(\frac{3}{5}-2x\right)\right)\mathrm{e}^{x}}{5}\right)\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\mathrm{e}^{-x}y &= \int c_1\mathrm{e}^{-x} - \frac{\left(\left(-\frac{4}{5}+x\right)\cos(x) + \sin(x)\left(\frac{3}{5}-2x\right)\right)\mathrm{e}^{x}}{5}\,\mathrm{d}x\\ \mathrm{e}^{-x}y &= -c_1\mathrm{e}^{-x} - \frac{\mathrm{e}^{x}\cos(x)\,x}{10} + \frac{\left(-\frac{x}{2}+\frac{1}{2}\right)\mathrm{e}^{x}\sin(x)}{5} + \frac{2\left(-\frac{x}{2}+\frac{1}{2}\right)\mathrm{e}^{x}\cos(x)}{5} + \frac{\mathrm{e}^{x}\sin(x)\,x}{5} + \frac{7\cos(x)\,\mathrm{e}^{x}}{50} +\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-x}$ results in

$$y = \mathrm{e}^{x}\left(-c_1\mathrm{e}^{-x} - \frac{\mathrm{e}^{x}\cos(x)\,x}{10} + \frac{\left(-\frac{x}{2}+\frac{1}{2}\right)\mathrm{e}^{x}\sin(x)}{5} + \frac{2\left(-\frac{x}{2}+\frac{1}{2}\right)\mathrm{e}^{x}\cos(x)}{5} + \frac{\mathrm{e}^{x}\sin(x)\,x}{5} + \frac{7\cos(x)\,\mathrm{e}^{x}}{50}\right.$$

which simplifies to

$$y = \frac{((-15x+17)\cos(x) + \sin(x)(5x+6))\,\mathrm{e}^{2x}}{50} + c_2\mathrm{e}^{x} - c_1$$

Summary

The solution(s) found are the following

$$y = \frac{((-15x+17)\cos(x)+\sin(x)(5x+6))\,e^{2x}}{50}+c_2e^{x}-c_1 \tag{1}$$

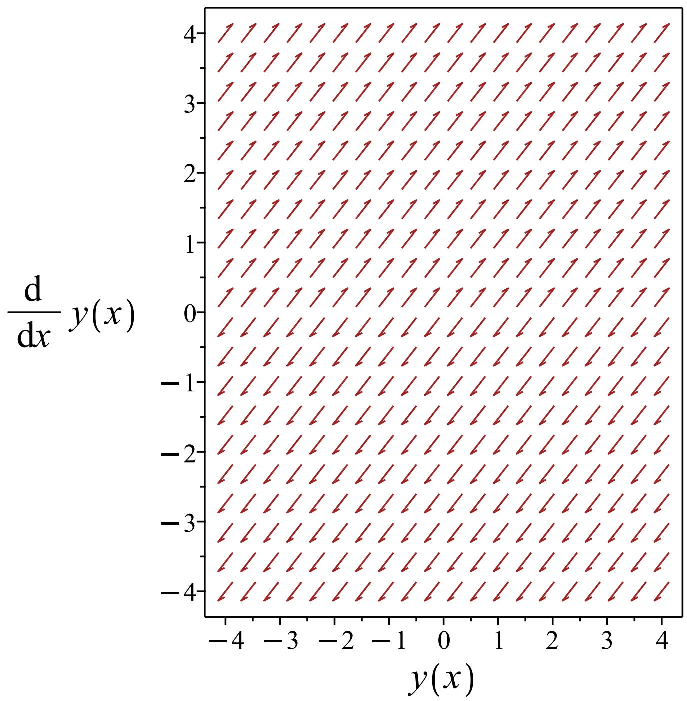

Figure 685: Slope field plot

Verification of solutions

$$y = \frac{((-15x+17)\cos(x)+\sin(x)(5x+6))\,e^{2x}}{50}+c_2e^{x}-c_1$$

Verified OK.

15.14.5 Solving using Kovacic algorithm

Writing the ode as

$$y''-y'=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -1 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 535: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-1}{1}\,dx} \\ &= z_1 e^{\frac{x}{2}} \\ &= z_1 \left(\mathrm{e}^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^x}{(y_1)^2}\,dx \\ &= y_1(\mathrm{e}^x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(1) + c_2(1(\mathrm{e}^x)) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 + c_2\mathrm{e}^x$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\mathrm{e}^{2x} \sin(x)\, x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x}\cos(x), e^{2x}\sin(x), e^{2x}\cos(x)x, e^{2x}\sin(x)x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{2x}\cos(x) + A_2 e^{2x}\sin(x) + A_3 e^{2x}\cos(x)x + A_4 e^{2x}\sin(x)x$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&A_1 e^{2x}\cos(x) - 3A_1 e^{2x}\sin(x) + A_2 e^{2x}\sin(x) + 3A_2 e^{2x}\cos(x) + A_3 e^{2x}\cos(x)x \\ &- 3A_3 e^{2x}\sin(x)x + 3A_3 e^{2x}\cos(x) + A_4 e^{2x}\sin(x)x + 3A_4 e^{2x}\cos(x)x \\ &+ 3A_4 e^{2x}\sin(x) - 2A_3 e^{2x}\sin(x) + 2A_4 e^{2x}\cos(x) = e^{2x}\sin(x)x\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{17}{50}, A_2 = \frac{3}{25}, A_3 = -\frac{3}{10}, A_4 = \frac{1}{10}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{17\,e^{2x}\cos(x)}{50} + \frac{3\,e^{2x}\sin(x)}{25} - \frac{3\,e^{2x}\cos(x)x}{10} + \frac{e^{2x}\sin(x)x}{10}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p \\ &= (c_1 + c_2 e^{x}) + \left(\frac{17\,e^{2x}\cos(x)}{50} + \frac{3\,e^{2x}\sin(x)}{25} - \frac{3\,e^{2x}\cos(x)x}{10} + \frac{e^{2x}\sin(x)x}{10}\right)\end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 + c_2 e^{x} + \frac{17\,e^{2x}\cos(x)}{50} + \frac{3\,e^{2x}\sin(x)}{25} - \frac{3\,e^{2x}\cos(x)x}{10} + \frac{e^{2x}\sin(x)x}{10} \tag{1}$$

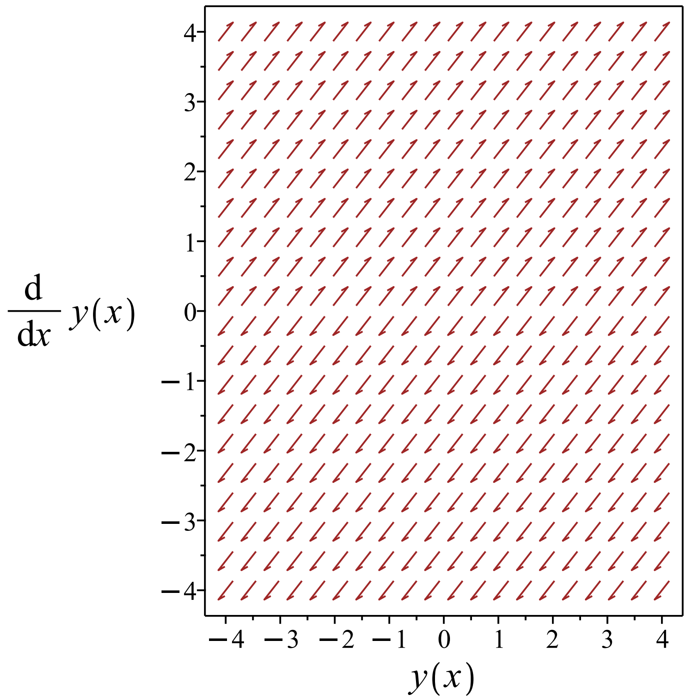

Figure 686: Slope field plot

Verification of solutions

$$y = c_1 + c_2 e^x + \frac{17\,e^{2x}\cos(x)}{50} + \frac{3\,e^{2x}\sin(x)}{25} - \frac{3\,e^{2x}\cos(x)\,x}{10} + \frac{e^{2x}\sin(x)\,x}{10}$$

Verified OK.

15.14.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= -1 \\ r(x) &= 0 \\ s(x) &= e^{2x}\sin(x)\,x \end{aligned}$$

Hence

$$p''(x) = 0$$
$$q'(x) = 0$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$y' - y = \int \mathrm{e}^{2x} \sin(x)\, x\, dx$$

We now have a first order ode to solve which is

$$y' - y = \left(-\frac{x}{5} + \frac{4}{25}\right) \mathrm{e}^{2x} \cos(x) + \left(\frac{2x}{5} - \frac{3}{25}\right) \mathrm{e}^{2x} \sin(x) + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -1$$
$$q(x) = \frac{((4 - 5x)\cos(x) + \sin(x)(10x - 3))\, \mathrm{e}^{2x}}{25} + c_1$$

Hence the ode is

$$y' - y = \frac{((4 - 5x)\cos(x) + \sin(x)(10x - 3))\, \mathrm{e}^{2x}}{25} + c_1$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int (-1) dx}$$
$$= \mathrm{e}^{-x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{((4-5x)\cos(x)+\sin(x)(10x-3))\,e^{2x}}{25}+c_1\right)$$

$$\frac{d}{dx}\left(e^{-x}y\right) = \left(e^{-x}\right)\left(\frac{((4-5x)\cos(x)+\sin(x)(10x-3))\,e^{2x}}{25}+c_1\right)$$

$$d\left(e^{-x}y\right) = \left(c_1e^{-x} - \frac{\left(\left(-\frac{4}{5}+x\right)\cos(x)+\sin(x)\left(\frac{3}{5}-2x\right)\right)e^{x}}{5}\right)dx$$

Integrating gives

$$e^{-x}y = \int c_1e^{-x} - \frac{\left(\left(-\frac{4}{5}+x\right)\cos(x)+\sin(x)\left(\frac{3}{5}-2x\right)\right)e^{x}}{5}\,dx$$

$$e^{-x}y = -c_1e^{-x} - \frac{e^{x}\cos(x)\,x}{10} + \frac{\left(-\frac{x}{2}+\frac{1}{2}\right)e^{x}\sin(x)}{5} + \frac{2\left(-\frac{x}{2}+\frac{1}{2}\right)e^{x}\cos(x)}{5} + \frac{e^{x}\sin(x)\,x}{5} + \frac{7\cos(x)\,e^{x}}{50} +$$

Dividing both sides by the integrating factor $\mu = e^{-x}$ results in

$$y = e^{x}\left(-c_1e^{-x} - \frac{e^{x}\cos(x)\,x}{10} + \frac{\left(-\frac{x}{2}+\frac{1}{2}\right)e^{x}\sin(x)}{5} + \frac{2\left(-\frac{x}{2}+\frac{1}{2}\right)e^{x}\cos(x)}{5} + \frac{e^{x}\sin(x)\,x}{5} + \frac{7\cos(x)\,e^{x}}{50} +\right.$$

which simplifies to

$$y = \frac{((-15x+17)\cos(x)+\sin(x)(5x+6))\,e^{2x}}{50} + c_2e^{x} - c_1$$

Summary
The solution(s) found are the following

$$y = \frac{((-15x+17)\cos(x)+\sin(x)(5x+6))\,e^{2x}}{50} + c_2e^{x} - c_1 \tag{1}$$

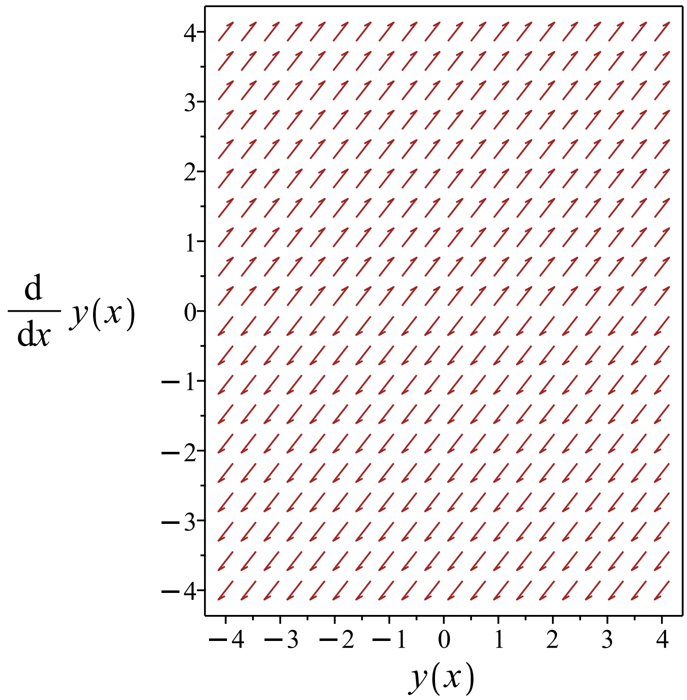

Figure 687: Slope field plot

Verification of solutions

$$y = \frac{((-15x+17)\cos(x) + \sin(x)(5x+6))\, e^{2x}}{50} + c_2 e^{x} - c_1$$

Verified OK.

15.14.7 Maple step by step solution

Let's solve

$-y' + y'' = e^{2x} \sin(x)\, x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - r = 0$

- Factor the characteristic polynomial

  $r(r-1) = 0$

- Roots of the characteristic polynomial

$r = (0, 1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = 1$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 e^x + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = e^{2x} \sin(x) x\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & e^x \\ 0 & e^x \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^x$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\left(\int e^{2x} \sin(x) x dx\right) + e^x \left(\int e^x \sin(x) x dx\right)$

  ◦ Compute integrals

  $y_p(x) = \frac{((-15x+17)\cos(x)+\sin(x)(5x+6))e^{2x}}{50}$

- Substitute particular solution into general solution to ODE

  $y = \frac{((-15x+17)\cos(x)+\sin(x)(5x+6))e^{2x}}{50} + c_2 e^x + c_1$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' - 4y = \mathrm{e}^{2x} \cos(x)\, x}$$

15.15.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = -4, f(x) = \mathrm{e}^{2x} \cos(x)\, x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = -4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 4\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-4)}\\ &= \pm 2\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2\\ \lambda_2 &= -2\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2\\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(2)x} + c_2 e^{(-2)x}\end{aligned}$$

Or

$$y = c_1 e^{2x} + c_2 e^{-2x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{2x} + c_2 e^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{2x} \cos(x) x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x} \cos(x), e^{2x} \sin(x), e^{2x} \cos(x) x, e^{2x} \sin(x) x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-2x}, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{2x} \cos(x) + A_2 e^{2x} \sin(x) + A_3 e^{2x} \cos(x) x + A_4 e^{2x} \sin(x) x$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-A_1 e^{2x} \cos(x) - 4A_1 e^{2x} \sin(x) - A_2 e^{2x} \sin(x) + 4A_2 e^{2x} \cos(x) - A_3 e^{2x} \cos(x) x \\ &- 4A_3 e^{2x} \sin(x) x + 4A_3 e^{2x} \cos(x) - 2A_3 e^{2x} \sin(x) - A_4 e^{2x} \sin(x) x \\ &+ 4A_4 e^{2x} \cos(x) x + 4A_4 e^{2x} \sin(x) + 2A_4 e^{2x} \cos(x) = e^{2x} \cos(x) x\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{76}{289}, A_2 = \frac{2}{289}, A_3 = -\frac{1}{17}, A_4 = \frac{4}{17}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{76 e^{2x} \cos(x)}{289} + \frac{2 e^{2x} \sin(x)}{289} - \frac{e^{2x} \cos(x) x}{17} + \frac{4 e^{2x} \sin(x) x}{17}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p \\ &= (c_1 e^{2x} + c_2 e^{-2x}) + \left(\frac{76 e^{2x} \cos(x)}{289} + \frac{2 e^{2x} \sin(x)}{289} - \frac{e^{2x} \cos(x) x}{17} + \frac{4 e^{2x} \sin(x) x}{17}\right)\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{2x} + c_2 e^{-2x} + \frac{76\, e^{2x} \cos(x)}{289} + \frac{2\, e^{2x} \sin(x)}{289} - \frac{e^{2x} \cos(x)\, x}{17} + \frac{4\, e^{2x} \sin(x)\, x}{17} \tag{1}$$

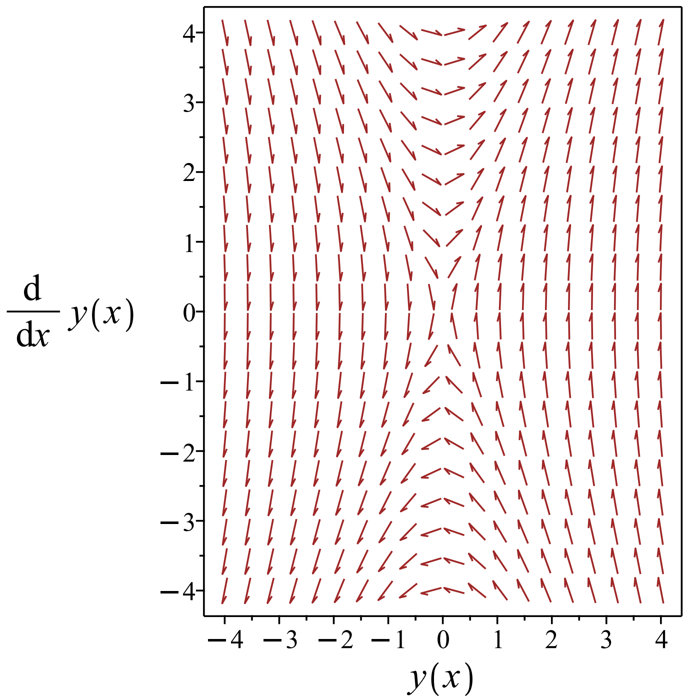

Figure 688: Slope field plot

Verification of solutions

$$y = c_1 e^{2x} + c_2 e^{-2x} + \frac{76\, e^{2x} \cos(x)}{289} + \frac{2\, e^{2x} \sin(x)}{289} - \frac{e^{2x} \cos(x)\, x}{17} + \frac{4\, e^{2x} \sin(x)\, x}{17}$$

Verified OK.

15.15.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= -4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 537: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-2x}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}
$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \mathrm{e}^{-2x}
\end{aligned}
$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \mathrm{e}^{-2x} \int \frac{1}{\mathrm{e}^{-4x}}\, dx \\ &= \mathrm{e}^{-2x} \left(\frac{\mathrm{e}^{4x}}{4}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-2x}\right) + c_2 \left(\mathrm{e}^{-2x} \left(\frac{\mathrm{e}^{4x}}{4}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-2x} + \frac{c_2 \mathrm{e}^{2x}}{4}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
e^{2x} \cos(x) x
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{e^{2x} \cos(x), e^{2x} \sin(x), e^{2x} \cos(x) x, e^{2x} \sin(x) x\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\frac{e^{2x}}{4}, e^{-2x}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 e^{2x} \cos(x) + A_2 e^{2x} \sin(x) + A_3 e^{2x} \cos(x) x + A_4 e^{2x} \sin(x) x
$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
\begin{aligned}
&-A_1 e^{2x} \cos(x) - 4A_1 e^{2x} \sin(x) - A_2 e^{2x} \sin(x) + 4A_2 e^{2x} \cos(x) - A_3 e^{2x} \cos(x) x \\
&- 4A_3 e^{2x} \sin(x) x + 4A_3 e^{2x} \cos(x) - 2A_3 e^{2x} \sin(x) - A_4 e^{2x} \sin(x) x \\
&+ 4A_4 e^{2x} \cos(x) x + 4A_4 e^{2x} \sin(x) + 2A_4 e^{2x} \cos(x) = e^{2x} \cos(x) x
\end{aligned}
$$

Solving for the unknowns by comparing coefficients results in

$$
\left[A_1 = \frac{76}{289}, A_2 = \frac{2}{289}, A_3 = -\frac{1}{17}, A_4 = \frac{4}{17}\right]
$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$
y_p = \frac{76\, e^{2x} \cos(x)}{289} + \frac{2\, e^{2x} \sin(x)}{289} - \frac{e^{2x} \cos(x) x}{17} + \frac{4\, e^{2x} \sin(x) x}{17}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 e^{-2x} + \frac{c_2 e^{2x}}{4}\right) + \left(\frac{76\, e^{2x} \cos(x)}{289} + \frac{2\, e^{2x} \sin(x)}{289} - \frac{e^{2x} \cos(x) x}{17} + \frac{4\, e^{2x} \sin(x) x}{17}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-2x} + \frac{c_2 e^{2x}}{4} + \frac{76\, e^{2x} \cos(x)}{289} + \frac{2\, e^{2x} \sin(x)}{289} - \frac{e^{2x} \cos(x)\, x}{17} + \frac{4\, e^{2x} \sin(x)\, x}{17} \tag{1}$$

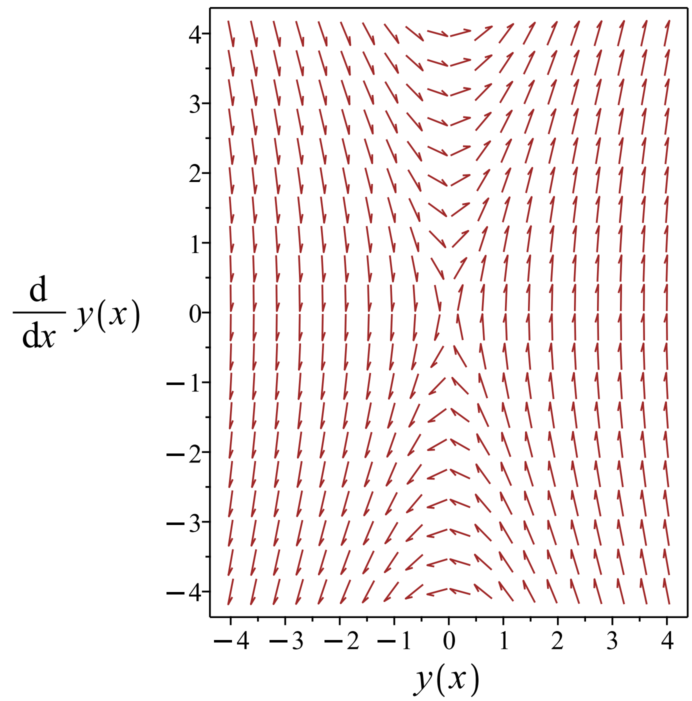

Figure 689: Slope field plot

Verification of solutions

$$y = c_1 e^{-2x} + \frac{c_2 e^{2x}}{4} + \frac{76\, e^{2x} \cos(x)}{289} + \frac{2\, e^{2x} \sin(x)}{289} - \frac{e^{2x} \cos(x)\, x}{17} + \frac{4\, e^{2x} \sin(x)\, x}{17}$$

Verified OK.

$$\boxed{y'' + 2y' = x^2 \sin(x) e^{-x}}$$

15.16.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 0, f(x) = x^2 \sin(x) e^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+2y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=1, B=2, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x}+2\lambda\,\mathrm{e}^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2+2\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=2, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{-2}{(2)\,(1)}\pm\frac{1}{(2)\,(1)}\sqrt{2^2-(4)\,(1)\,(0)}\\&=-1\pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1&=-1+1\\\lambda_2&=-1-1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1&=0\\\lambda_2&=-2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y&=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}\\y&=c_1e^{(0)x}+c_2e^{(-2)x}\end{aligned}$$

Or

$$y = c_1 + c_2 e^{-2x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + c_2 e^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 \sin(x) e^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x) e^{-x}, \sin(x) e^{-x}, x\cos(x) e^{-x}, x^2 \cos(x) e^{-x}, x^2 \sin(x) e^{-x}, \sin(x) x e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$\begin{aligned} y_p = {} & A_1 \cos(x) e^{-x} + A_2 \sin(x) e^{-x} + A_3 x \cos(x) e^{-x} \\ & + A_4 x^2 \cos(x) e^{-x} + A_5 x^2 \sin(x) e^{-x} + A_6 \sin(x) x e^{-x} \end{aligned}$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned} & 2A_4 \cos(x) e^{-x} - 4A_4 x \sin(x) e^{-x} + 2A_5 \sin(x) e^{-x} + 4A_5 x \cos(x) e^{-x} \\ & + 2A_6 \cos(x) e^{-x} - 2A_4 x^2 \cos(x) e^{-x} - 2A_5 x^2 \sin(x) e^{-x} \\ & - 2A_6 \sin(x) x e^{-x} - 2A_3 x \cos(x) e^{-x} - 2A_3 \sin(x) e^{-x} \\ & - 2A_1 \cos(x) e^{-x} - 2A_2 \sin(x) e^{-x} = x^2 \sin(x) e^{-x} \end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{2}, A_3 = -1, A_4 = 0, A_5 = -\frac{1}{2}, A_6 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\sin(x)\,e^{-x}}{2} - x\cos(x)\,e^{-x} - \frac{x^2\sin(x)\,e^{-x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + c_2 e^{-2x}\right) + \left(\frac{\sin(x)\,e^{-x}}{2} - x\cos(x)\,e^{-x} - \frac{x^2\sin(x)\,e^{-x}}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + c_2 e^{-2x} + \frac{\sin(x)\,e^{-x}}{2} - x\cos(x)\,e^{-x} - \frac{x^2\sin(x)\,e^{-x}}{2} \tag{1}$$

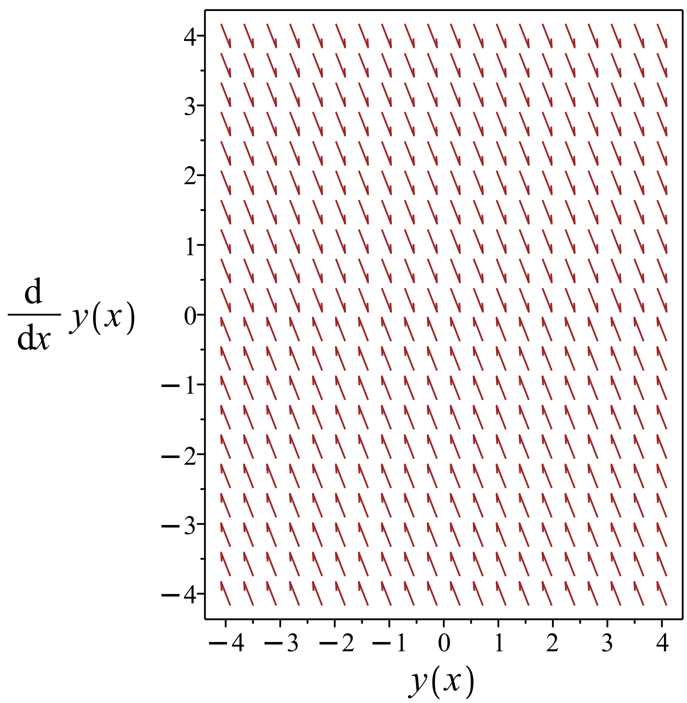

Figure 690: Slope field plot

Verification of solutions

$$y = c_1 + c_2 e^{-2x} + \frac{\sin(x)\,e^{-x}}{2} - x\cos(x)\,e^{-x} - \frac{x^2\sin(x)\,e^{-x}}{2}$$

Verified OK.

15.16.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 2y')\, dx = \int x^2 \sin(x)\, e^{-x} dx$$

$$2y + y' = \left(-\frac{1}{2}x^2 - x - \frac{1}{2}\right) e^{-x} \cos(x) + \left(-\frac{x^2}{2} + \frac{1}{2}\right) e^{-x} \sin(x) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 2 \\ q(x) &= \frac{\left(-(x+1)^2 \cos(x) + (1-x^2)\sin(x)\right) e^{-x}}{2} + c_1 \end{aligned}$$

Hence the ode is

$$2y + y' = \frac{\left(-(x+1)^2 \cos(x) + (1-x^2)\sin(x)\right) e^{-x}}{2} + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 2dx} \\ &= e^{2x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(\frac{\left(-(x+1)^2 \cos(x) + (1-x^2)\sin(x)\right) e^{-x}}{2} + c_1\right) \\ \frac{d}{dx}\left(e^{2x} y\right) &= \left(e^{2x}\right)\left(\frac{\left(-(x+1)^2 \cos(x) + (1-x^2)\sin(x)\right) e^{-x}}{2} + c_1\right) \\ d\left(e^{2x} y\right) &= \left(-\frac{e^{x}\left((x+1)^2 \cos(x) + \sin(x)\, x^2 - 2c_1 e^{x} - \sin(x)\right)}{2}\right) dx \end{aligned}$$

Integrating gives

$$e^{2x} y = \int -\frac{e^{x}\left((x+1)^2 \cos(x) + \sin(x)\, x^2 - 2c_1 e^{x} - \sin(x)\right)}{2}\, dx$$

$$e^{2x} y = -\frac{\left(\frac{x^2}{2} - \frac{1}{2}\right) e^{x} \cos(x)}{2} + \frac{\left(x - \frac{1}{2}x^2 - \frac{1}{2}\right) e^{x} \sin(x)}{2} - \frac{\left(x - \frac{1}{2}x^2 - \frac{1}{2}\right) e^{x} \cos(x)}{2} - \frac{\left(\frac{x^2}{2} - \frac{1}{2}\right) e^{x} \sin(x)}{2}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{2x}$ results in

$$y = \mathrm{e}^{-2x}\left(-\frac{\left(\frac{x^2}{2}-\frac{1}{2}\right)\mathrm{e}^{x}\cos(x)}{2}+\frac{\left(x-\frac{1}{2}x^2-\frac{1}{2}\right)\mathrm{e}^{x}\sin(x)}{2}-\frac{\left(x-\frac{1}{2}x^2-\frac{1}{2}\right)\mathrm{e}^{x}\cos(x)}{2}-\frac{\left(\frac{x^2}{2}-\frac{1}{2}\right)\mathrm{e}^{x}\sin}{2}\right.$$

which simplifies to

$$y = -\frac{\left(-c_1\mathrm{e}^{2x}+\mathrm{e}^{x}\left(2x\cos(x)+\sin(x)\,x^2-\sin(x)\right)-2c_2\right)\mathrm{e}^{-2x}}{2}$$

<u>Summary</u>
The solution(s) found are the following

$$y = -\frac{\left(-c_1\mathrm{e}^{2x}+\mathrm{e}^{x}\left(2x\cos(x)+\sin(x)\,x^2-\sin(x)\right)-2c_2\right)\mathrm{e}^{-2x}}{2} \tag{1}$$

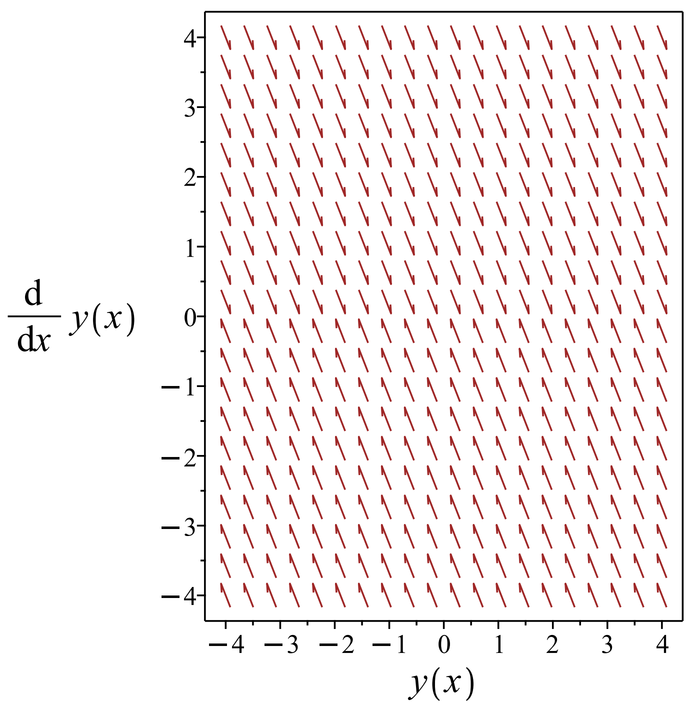

Figure 691: Slope field plot

<u>Verification of solutions</u>

$$y = -\frac{\left(-c_1\mathrm{e}^{2x}+\mathrm{e}^{x}\left(2x\cos(x)+\sin(x)\,x^2-\sin(x)\right)-2c_2\right)\mathrm{e}^{-2x}}{2}$$

Verified OK.

15.16.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + 2p(x) - x^2 \sin(x) e^{-x} = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= 2 \\ q(x) &= x^2 \sin(x) e^{-x} \end{aligned}$$

Hence the ode is

$$p'(x) + 2p(x) = x^2 \sin(x) e^{-x}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 2dx} \\ &= e^{2x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu)\left(x^2 \sin(x) e^{-x}\right) \\ \frac{d}{dx}\left(e^{2x} p\right) &= \left(e^{2x}\right)\left(x^2 \sin(x) e^{-x}\right) \\ d\left(e^{2x} p\right) &= \left(e^{x} \sin(x) x^2\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{2x} p &= \int e^{x} \sin(x) x^2 \, dx \\ e^{2x} p &= \left(x - \frac{1}{2}x^2 - \frac{1}{2}\right) e^{x} \cos(x) + \left(\frac{x^2}{2} - \frac{1}{2}\right) e^{x} \sin(x) + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{2x}$ results in

$$p(x) = \mathrm{e}^{-2x}\left(\left(x - \frac{1}{2}x^2 - \frac{1}{2}\right)\mathrm{e}^{x}\cos(x) + \left(\frac{x^2}{2} - \frac{1}{2}\right)\mathrm{e}^{x}\sin(x)\right) + c_1\mathrm{e}^{-2x}$$

which simplifies to

$$p(x) = -\frac{(((x-1)\cos(x) - (x+1)\sin(x))(x-1)\,\mathrm{e}^{x} - 2c_1)\,\mathrm{e}^{-2x}}{2}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -\frac{(((x-1)\cos(x) - (x+1)\sin(x))(x-1)\,\mathrm{e}^{x} - 2c_1)\,\mathrm{e}^{-2x}}{2}$$

Integrating both sides gives

$$y = \int -\frac{\mathrm{e}^{-2x}(\cos(x)\,\mathrm{e}^{x}x^2 - \mathrm{e}^{x}\sin(x)\,x^2 - 2\,\mathrm{e}^{x}\cos(x)\,x + \cos(x)\,\mathrm{e}^{x} + \sin(x)\,\mathrm{e}^{x} - 2c_1)}{2}\,\mathrm{d}x$$

$$= -\frac{\left(-\frac{x^2}{2} + \frac{1}{2}\right)\mathrm{e}^{-x}\cos(x)}{2} + \frac{\left(-\frac{1}{2}x^2 - x - \frac{1}{2}\right)\mathrm{e}^{-x}\sin(x)}{2} + \frac{\left(-\frac{1}{2}x^2 - x - \frac{1}{2}\right)\mathrm{e}^{-x}\cos(x)}{2} + \frac{\left(-\frac{x^2}{2} + \frac{1}{2}\right)\mathrm{e}}{2}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = &-\frac{\left(-\frac{x^2}{2} + \frac{1}{2}\right)\mathrm{e}^{-x}\cos(x)}{2} + \frac{\left(-\frac{1}{2}x^2 - x - \frac{1}{2}\right)\mathrm{e}^{-x}\sin(x)}{2} \\ &+ \frac{\left(-\frac{1}{2}x^2 - x - \frac{1}{2}\right)\mathrm{e}^{-x}\cos(x)}{2} + \frac{\left(-\frac{x^2}{2} + \frac{1}{2}\right)\mathrm{e}^{-x}\sin(x)}{2} \\ &- \frac{x\cos(x)\,\mathrm{e}^{-x}}{2} - \left(-\frac{x}{2} - \frac{1}{2}\right)\mathrm{e}^{-x}\sin(x) + \frac{\cos(x)\,\mathrm{e}^{-x}}{2} - \frac{c_1\mathrm{e}^{-2x}}{2} + c_2 \end{aligned} \tag{1}$$

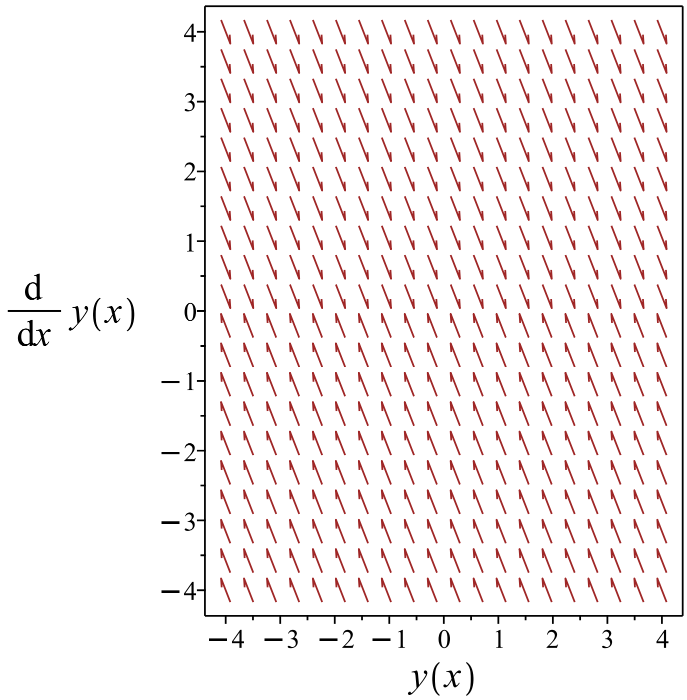

Figure 692: Slope field plot

Verification of solutions

$$y = -\frac{\left(-\frac{x^2}{2}+\frac{1}{2}\right)\mathrm{e}^{-x}\cos(x)}{2} + \frac{\left(-\frac{1}{2}x^2 - x - \frac{1}{2}\right)\mathrm{e}^{-x}\sin(x)}{2} + \frac{\left(-\frac{1}{2}x^2 - x - \frac{1}{2}\right)\mathrm{e}^{-x}\cos(x)}{2} + \frac{\left(-\frac{x^2}{2}+\frac{1}{2}\right)\mathrm{e}^{-x}\sin(x)}{2} - \frac{x\cos(x)\,\mathrm{e}^{-x}}{2} - \left(-\frac{x}{2}-\frac{1}{2}\right)\mathrm{e}^{-x}\sin(x) + \frac{\cos(x)\,\mathrm{e}^{-x}}{2} - \frac{c_1\mathrm{e}^{-2x}}{2} + c_2$$

Verified OK.

15.16.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + 2y' = x^2\sin(x)\,\mathrm{e}^{-x}$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(y''+2y'\right)dx = \int x^2\sin\left(x\right)\mathrm{e}^{-x}dx$$

$$2y+y' = \left(-\frac{1}{2}x^2-x-\frac{1}{2}\right)\mathrm{e}^{-x}\cos\left(x\right)+\left(-\frac{x^2}{2}+\frac{1}{2}\right)\mathrm{e}^{-x}\sin\left(x\right)+c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y = q(x)$$

Where here

$$\begin{aligned}
p(x) &= 2 \\
q(x) &= \frac{\left(-(x+1)^2\cos\left(x\right)+\left(1-x^2\right)\sin\left(x\right)\right)\mathrm{e}^{-x}}{2}+c_1
\end{aligned}$$

Hence the ode is

$$2y+y' = \frac{\left(-(x+1)^2\cos\left(x\right)+\left(1-x^2\right)\sin\left(x\right)\right)\mathrm{e}^{-x}}{2}+c_1$$

The integrating factor μ is

$$\begin{aligned}
\mu &= \mathrm{e}^{\int 2dx} \\
&= \mathrm{e}^{2x}
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{\left(-(x+1)^2\cos\left(x\right)+\left(1-x^2\right)\sin\left(x\right)\right)\mathrm{e}^{-x}}{2}+c_1\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{2x}y\right) &= \left(\mathrm{e}^{2x}\right)\left(\frac{\left(-(x+1)^2\cos\left(x\right)+\left(1-x^2\right)\sin\left(x\right)\right)\mathrm{e}^{-x}}{2}+c_1\right) \\
\mathrm{d}\left(\mathrm{e}^{2x}y\right) &= \left(-\frac{\mathrm{e}^{x}\left((x+1)^2\cos\left(x\right)+\sin\left(x\right)x^2-2c_1\mathrm{e}^{x}-\sin\left(x\right)\right)}{2}\right)\mathrm{d}x
\end{aligned}$$

Integrating gives

$$\begin{aligned}
\mathrm{e}^{2x}y &= \int -\frac{\mathrm{e}^{x}\left((x+1)^2\cos\left(x\right)+\sin\left(x\right)x^2-2c_1\mathrm{e}^{x}-\sin\left(x\right)\right)}{2}\,\mathrm{d}x \\
\mathrm{e}^{2x}y &= -\frac{\left(\frac{x^2}{2}-\frac{1}{2}\right)\mathrm{e}^{x}\cos\left(x\right)}{2}+\frac{\left(x-\frac{1}{2}x^2-\frac{1}{2}\right)\mathrm{e}^{x}\sin\left(x\right)}{2}-\frac{\left(x-\frac{1}{2}x^2-\frac{1}{2}\right)\mathrm{e}^{x}\cos\left(x\right)}{2}-\frac{\left(\frac{x^2}{2}-\frac{1}{2}\right)\mathrm{e}^{x}\sin\left(x\right)}{2}
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{2x}$ results in

$$y = \mathrm{e}^{-2x}\left(-\frac{\left(\frac{x^2}{2}-\frac{1}{2}\right)\mathrm{e}^{x}\cos\left(x\right)}{2}+\frac{\left(x-\frac{1}{2}x^2-\frac{1}{2}\right)\mathrm{e}^{x}\sin\left(x\right)}{2}-\frac{\left(x-\frac{1}{2}x^2-\frac{1}{2}\right)\mathrm{e}^{x}\cos\left(x\right)}{2}-\frac{\left(\frac{x^2}{2}-\frac{1}{2}\right)\mathrm{e}^{x}\sin}{2}\right.$$

which simplifies to

$$y = -\frac{\left(-c_1\mathrm{e}^{2x}+\mathrm{e}^{x}\left(2x\cos\left(x\right)+\sin\left(x\right)x^2-\sin\left(x\right)\right)-2c_2\right)\mathrm{e}^{-2x}}{2}$$

Summary

The solution(s) found are the following

$$y = -\frac{\left(-c_1\mathrm{e}^{2x}+\mathrm{e}^{x}\left(2x\cos\left(x\right)+\sin\left(x\right)x^2-\sin\left(x\right)\right)-2c_2\right)\mathrm{e}^{-2x}}{2} \tag{1}$$

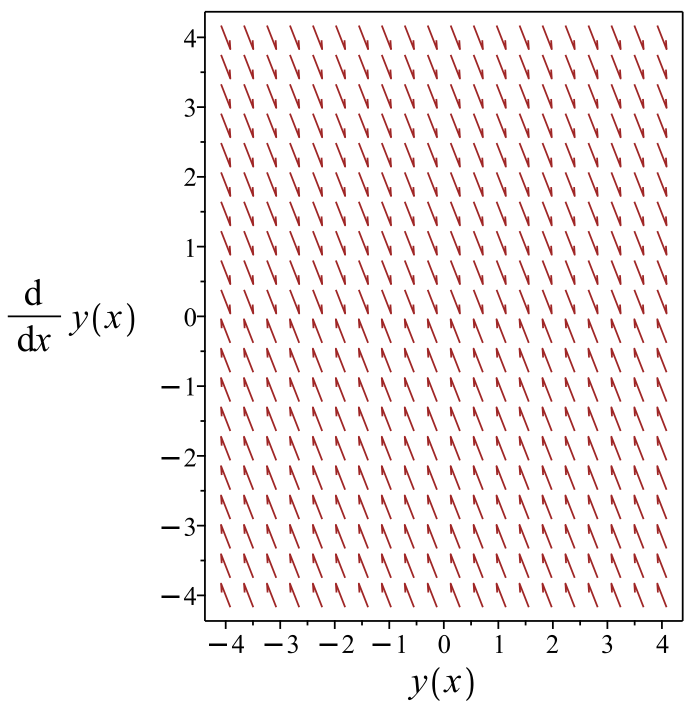

Figure 693: Slope field plot

Verification of solutions

$$y = -\frac{\left(-c_1\mathrm{e}^{2x}+\mathrm{e}^{x}\left(2x\cos\left(x\right)+\sin\left(x\right)x^2-\sin\left(x\right)\right)-2c_2\right)\mathrm{e}^{-2x}}{2}$$

Verified OK.

15.16.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 539: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-x}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{2}{1} \, dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{-x} \\
&= z_1 \left(\mathrm{e}^{-x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{-2x}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\frac{\mathrm{e}^{2x}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-2x}\right) + c_2 \left(\mathrm{e}^{-2x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 2y' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-2x} + \frac{c_2}{2}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 \sin(x) e^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x) e^{-x}, \sin(x) e^{-x}, x \cos(x) e^{-x}, x^2 \cos(x) e^{-x}, x^2 \sin(x) e^{-x}, \sin(x) x e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{1}{2}, e^{-2x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$\begin{aligned}y_p = &A_1 \cos(x) e^{-x} + A_2 \sin(x) e^{-x} + A_3 x \cos(x) e^{-x} \\ &+ A_4 x^2 \cos(x) e^{-x} + A_5 x^2 \sin(x) e^{-x} + A_6 \sin(x) x e^{-x}\end{aligned}$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-2A_4 x^2 \cos(x) e^{-x} - 2A_5 x^2 \sin(x) e^{-x} - 2A_6 \sin(x) x e^{-x} \\ &- 2A_3 x \cos(x) e^{-x} + 2A_4 \cos(x) e^{-x} - 4A_4 x \sin(x) e^{-x} \\ &+ 2A_5 \sin(x) e^{-x} + 4A_5 x \cos(x) e^{-x} + 2A_6 \cos(x) e^{-x} \\ &- 2A_3 \sin(x) e^{-x} - 2A_1 \cos(x) e^{-x} - 2A_2 \sin(x) e^{-x} = x^2 \sin(x) e^{-x}\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{2}, A_3 = -1, A_4 = 0, A_5 = -\frac{1}{2}, A_6 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\sin(x) e^{-x}}{2} - x \cos(x) e^{-x} - \frac{x^2 \sin(x) e^{-x}}{2}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \mathrm{e}^{-2x} + \frac{c_2}{2}\right) + \left(\frac{\sin(x)\,\mathrm{e}^{-x}}{2} - x\cos(x)\,\mathrm{e}^{-x} - \frac{x^2 \sin(x)\,\mathrm{e}^{-x}}{2}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-2x} + \frac{c_2}{2} + \frac{\sin(x)\,\mathrm{e}^{-x}}{2} - x\cos(x)\,\mathrm{e}^{-x} - \frac{x^2 \sin(x)\,\mathrm{e}^{-x}}{2} \tag{1}
$$

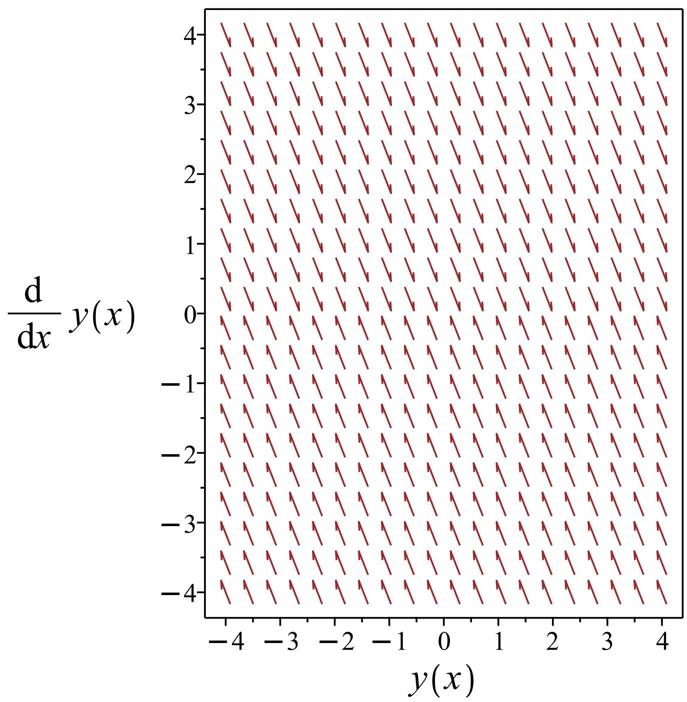

Figure 694: Slope field plot

Verification of solutions

$$
y = c_1 \mathrm{e}^{-2x} + \frac{c_2}{2} + \frac{\sin(x)\,\mathrm{e}^{-x}}{2} - x\cos(x)\,\mathrm{e}^{-x} - \frac{x^2 \sin(x)\,\mathrm{e}^{-x}}{2}
$$

Verified OK.

15.16.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y''+q(x)\,y'+r(x)\,y=s(x)$$

is exact if

$$p''(x)-q'(x)+r(x)=0 \tag{1}$$

For the given ode we have

$$\begin{aligned}p(x)&=1\\q(x)&=2\\r(x)&=0\\s(x)&=x^{2}\sin\left(x\right){\mathrm e}^{-x}\end{aligned}$$

Hence

$$\begin{aligned}p''(x)&=0\\q'(x)&=0\end{aligned}$$

Therefore (1) becomes

$$0-\left(0\right)+\left(0\right)=0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y'+\left(q(x)-p'(x)\right)y\right)'=s(x)$$

Integrating gives

$$p(x)\,y'+\left(q(x)-p'(x)\right)y=\int s(x)\;dx$$

Substituting the above values for p, q, r, s gives

$$2y+y'=\int x^{2}\sin\left(x\right){\mathrm e}^{-x}\,dx$$

We now have a first order ode to solve which is

$$2y+y'=\left(-\frac{1}{2}x^{2}-x-\frac{1}{2}\right){\mathrm e}^{-x}\cos\left(x\right)+\left(-\frac{x^{2}}{2}+\frac{1}{2}\right){\mathrm e}^{-x}\sin\left(x\right)+c_{1}$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= 2\\ q(x) &= \frac{\left(-(x+1)^2 \cos(x) + (1-x^2)\sin(x)\right) e^{-x}}{2} + c_1\end{aligned}$$

Hence the ode is

$$2y + y' = \frac{\left(-(x+1)^2 \cos(x) + (1-x^2)\sin(x)\right) e^{-x}}{2} + c_1$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int 2dx}\\ &= e^{2x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{\left(-(x+1)^2 \cos(x) + (1-x^2)\sin(x)\right) e^{-x}}{2} + c_1\right)\\ \frac{d}{dx}\left(e^{2x} y\right) &= \left(e^{2x}\right)\left(\frac{\left(-(x+1)^2 \cos(x) + (1-x^2)\sin(x)\right) e^{-x}}{2} + c_1\right)\\ d\left(e^{2x} y\right) &= \left(-\frac{e^{x}\left((x+1)^2 \cos(x) + \sin(x)\, x^2 - 2c_1 e^{x} - \sin(x)\right)}{2}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{2x} y &= \int -\frac{e^{x}\left((x+1)^2 \cos(x) + \sin(x)\, x^2 - 2c_1 e^{x} - \sin(x)\right)}{2}\, dx\\ e^{2x} y &= -\frac{\left(\frac{x^2}{2} - \frac{1}{2}\right) e^{x} \cos(x)}{2} + \frac{\left(x - \frac{1}{2}x^2 - \frac{1}{2}\right) e^{x} \sin(x)}{2} - \frac{\left(x - \frac{1}{2}x^2 - \frac{1}{2}\right) e^{x} \cos(x)}{2} - \frac{\left(\frac{x^2}{2} - \frac{1}{2}\right) e^{x} \sin(x)}{2}\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$y = e^{-2x}\left(-\frac{\left(\frac{x^2}{2} - \frac{1}{2}\right) e^{x} \cos(x)}{2} + \frac{\left(x - \frac{1}{2}x^2 - \frac{1}{2}\right) e^{x} \sin(x)}{2} - \frac{\left(x - \frac{1}{2}x^2 - \frac{1}{2}\right) e^{x} \cos(x)}{2} - \frac{\left(\frac{x^2}{2} - \frac{1}{2}\right) e^{x} \sin}{2}\right.$$

which simplifies to

$$y = -\frac{\left(-c_1 e^{2x} + e^x\left(2x\cos(x) + \sin(x)\, x^2 - \sin(x)\right) - 2c_2\right) e^{-2x}}{2}$$

Summary
The solution(s) found are the following

$$y = -\frac{\left(-c_1 e^{2x} + e^x\left(2x\cos(x) + \sin(x)\, x^2 - \sin(x)\right) - 2c_2\right) e^{-2x}}{2} \tag{1}$$

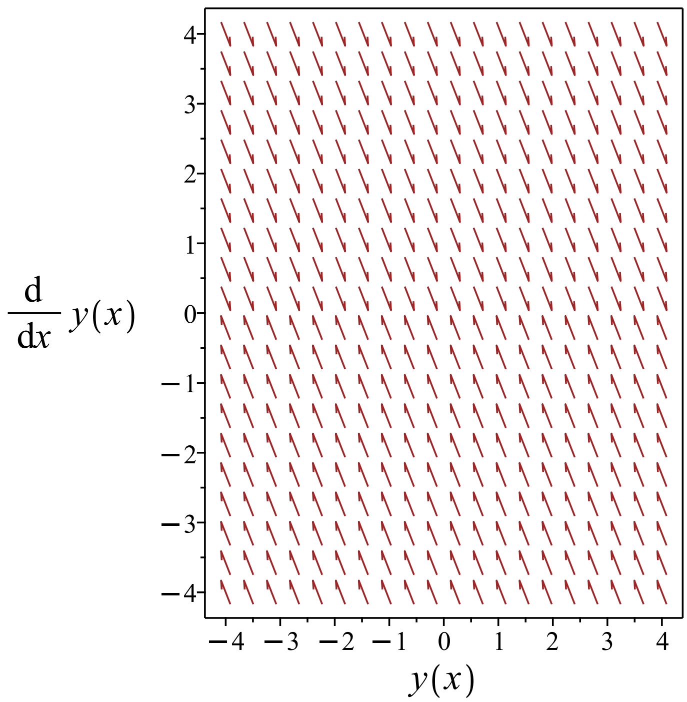

Figure 695: Slope field plot

Verification of solutions

$$y = -\frac{\left(-c_1 e^{2x} + e^x\left(2x\cos(x) + \sin(x)\, x^2 - \sin(x)\right) - 2c_2\right) e^{-2x}}{2}$$

Verified OK.

15.16.7 Maple step by step solution

Let's solve

$y'' + 2y' = x^2 \sin(x) e^{-x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r = 0$

- Factor the characteristic polynomial

  $r(r+2) = 0$

- Roots of the characteristic polynomial

  $r = (-2, 0)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-2x} + c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x^2 \sin(x) e^{-x}\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-2x} & 1 \\ -2e^{-2x} & 0 \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2e^{-2x}$

  ◦ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{\mathrm{e}^{-2x} \left(\int \mathrm{e}^{x} \sin(x) x^2 dx\right)}{2} + \frac{\left(\int x^2 \sin(x) \mathrm{e}^{-x} dx\right)}{2}$$

- Compute integrals

$$y_p(x) = -\frac{\mathrm{e}^{-x} \left(2x \cos(x) + \sin(x) x^2 - \sin(x)\right)}{2}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 \mathrm{e}^{-2x} + c_2 - \frac{\mathrm{e}^{-x} \left(2x \cos(x) + \sin(x) x^2 - \sin(x)\right)}{2}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^2y'' - 4y'x + y = 0}$$

16.1.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 4xrx^{r-1} + x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 4r\,x^r + x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 4r + 1 = 0$$

Or

$$r^2 - 5r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{5}{2} - \frac{\sqrt{21}}{2}$$
$$r_2 = \frac{5}{2} + \frac{\sqrt{21}}{2}$$

Since the roots are real and distinct, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_1 x^{\frac{5}{2} - \frac{\sqrt{21}}{2}} + c_2 x^{\frac{5}{2} + \frac{\sqrt{21}}{2}}$$

Summary

The solution(s) found are the following

$$y = c_1 x^{\frac{5}{2} - \frac{\sqrt{21}}{2}} + c_2 x^{\frac{5}{2} + \frac{\sqrt{21}}{2}} \tag{1}$$

Verification of solutions

$$y = c_1 x^{\frac{5}{2} - \frac{\sqrt{21}}{2}} + c_2 x^{\frac{5}{2} + \frac{\sqrt{21}}{2}}$$

Verified OK.

16.1.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2 y'' - 4y'x + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = -\frac{4}{x}$$
$$q(x) = \frac{1}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int -\frac{4}{x}dx\right)}dx \\
&= \int e^{4\ln(x)}\,dx \\
&= \int x^4 dx \\
&= \frac{x^5}{5}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{1}{x^2}}{x^8} \\
&= \frac{1}{x^{10}}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{x^{10}} = 0$$

But in terms of τ

$$\frac{1}{x^{10}} = \frac{1}{25\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{25\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$25\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$25\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0$$

Simplifying gives

$$25r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$25r(r-1) + 0 + 1 = 0$$

Or

$$25r^2 - 25r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2} - \frac{\sqrt{21}}{10}$$
$$r_2 = \frac{1}{2} + \frac{\sqrt{21}}{10}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{\frac{1}{2}-\frac{\sqrt{21}}{10}} + c_2\tau^{\frac{1}{2}+\frac{\sqrt{21}}{10}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{5}\,\sqrt{x^5}\left(c_1 5^{\frac{\sqrt{21}}{10}} \left(x^5\right)^{-\frac{\sqrt{21}}{10}} + c_2 5^{-\frac{\sqrt{21}}{10}} \left(x^5\right)^{\frac{\sqrt{21}}{10}}\right)}{5}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{5}\,\sqrt{x^5}\left(c_1 5^{\frac{\sqrt{21}}{10}} \left(x^5\right)^{-\frac{\sqrt{21}}{10}} + c_2 5^{-\frac{\sqrt{21}}{10}} \left(x^5\right)^{\frac{\sqrt{21}}{10}}\right)}{5} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{5}\,\sqrt{x^5}\left(c_1 5^{\frac{\sqrt{21}}{10}} \left(x^5\right)^{-\frac{\sqrt{21}}{10}} + c_2 5^{-\frac{\sqrt{21}}{10}} \left(x^5\right)^{\frac{\sqrt{21}}{10}}\right)}{5}$$

Verified OK.

16.1.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2 y'' - 4y'x + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{x} \\ q(x) &= \frac{1}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}
\tau' &= \frac{1}{c}\sqrt{q} \\
&= \frac{\sqrt{\frac{1}{x^2}}}{c} \\
\tau'' &= -\frac{1}{c\sqrt{\frac{1}{x^2}}\, x^3}
\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{1}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{4}{x}\frac{\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= -5c
\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - 5c\left(\frac{d}{d\tau}y(\tau)\right) + c^2 y(\tau) &= 0
\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = \mathrm{e}^{\frac{5c\tau}{2}}\left(c_1 \cosh\left(\frac{c\sqrt{21}\,\tau}{2}\right) + i c_2 \sinh\left(\frac{c\sqrt{21}\,\tau}{2}\right)\right)$$

Now from (6)

$$\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\, dx \\
&= \frac{\int \sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{\frac{1}{x^2}}\, x \ln(x)}{c}
\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = x^{\frac{5}{2}} \left(c_1 \cosh\left(\frac{\sqrt{21}\, \ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\sqrt{21}\, \ln(x)}{2}\right)\right)$$

Summary

The solution(s) found are the following

$$y = x^{\frac{5}{2}} \left(c_1 \cosh\left(\frac{\sqrt{21}\, \ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\sqrt{21}\, \ln(x)}{2}\right)\right) \tag{1}$$

Verification of solutions

$$y = x^{\frac{5}{2}} \left(c_1 \cosh\left(\frac{\sqrt{21}\, \ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\sqrt{21}\, \ln(x)}{2}\right)\right)$$

Verified OK.

16.1.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2 y'' - 4y'x + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = -\frac{4}{x}$$
$$q(x) = \frac{1}{x^2}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{4n}{x^2} + \frac{1}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = \frac{5}{2} + \frac{\sqrt{21}}{2} \tag{6}$$

Substituting this value in (3) gives

$$v''(x) + \left(\frac{5+\sqrt{21}}{x} - \frac{4}{x}\right) v'(x) = 0$$

$$v''(x) + \frac{(1+\sqrt{21})\, v'(x)}{x} = 0 \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(1+\sqrt{21})\, u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{(-1-\sqrt{21})\, u}{x} \end{aligned}$$

Where $f(x) = \frac{-1-\sqrt{21}}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= \frac{-1-\sqrt{21}}{x}\, dx \\ \int \frac{1}{u}\, du &= \int \frac{-1-\sqrt{21}}{x}\, dx \\ \ln(u) &= \left(-1-\sqrt{21}\right) \ln(x) + c_1 \\ u &= \mathrm{e}^{\left(-1-\sqrt{21}\right) \ln(x)+c_1} \\ &= c_1 \mathrm{e}^{\left(-1-\sqrt{21}\right) \ln(x)} \end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1 x^{-\sqrt{21}}}{x}$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= -\frac{\sqrt{21}\, c_1 x^{-\sqrt{21}}}{21} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\, x^n \\
&= \left(-\frac{\sqrt{21}\, c_1 x^{-\sqrt{21}}}{21} + c_2\right) x^{\frac{5}{2}+\frac{\sqrt{21}}{2}} \\
&= -\frac{x^{\frac{5}{2}-\frac{\sqrt{21}}{2}} \left(\sqrt{21}\, c_1 - 21 c_2 x^{\sqrt{21}}\right)}{21}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(-\frac{\sqrt{21}\, c_1 x^{-\sqrt{21}}}{21} + c_2\right) x^{\frac{5}{2}+\frac{\sqrt{21}}{2}} \tag{1}$$

Verification of solutions

$$y = \left(-\frac{\sqrt{21}\, c_1 x^{-\sqrt{21}}}{21} + c_2\right) x^{\frac{5}{2}+\frac{\sqrt{21}}{2}}$$

Verified OK.

16.1.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 4y'x + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -4x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{5}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 5 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{5}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 541: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{5}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 5$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{21}}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{21}}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{5}{x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = 5$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{21}}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{21}}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{5}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2} + \frac{\sqrt{21}}{2}$	$\frac{1}{2} - \frac{\sqrt{21}}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2} + \frac{\sqrt{21}}{2}$	$\frac{1}{2} - \frac{\sqrt{21}}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_\infty^- = \frac{1}{2} - \frac{\sqrt{21}}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= \frac{1}{2} - \frac{\sqrt{21}}{2} - \left(\frac{1}{2} - \frac{\sqrt{21}}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{\frac{1}{2} - \frac{\sqrt{21}}{2}}{x} + (-)\,(0) \\
&= \frac{\frac{1}{2} - \frac{\sqrt{21}}{2}}{x} \\
&= -\frac{\sqrt{21} - 1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{\frac{1}{2} - \frac{\sqrt{21}}{2}}{x}\right)(0) + \left(\left(-\frac{\frac{1}{2} - \frac{\sqrt{21}}{2}}{x^2} \right) + \left(\frac{\frac{1}{2} - \frac{\sqrt{21}}{2}}{x} \right)^2 - \left(\frac{5}{x^2} \right) \right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \frac{\frac{1}{2} - \frac{\sqrt{21}}{2}}{x} dx} \\
&= x^{\frac{1}{2} - \frac{\sqrt{21}}{2}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x}{x^2}\,dx} \\
&= z_1 e^{2\ln(x)} \\
&= z_1 \left(x^2\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x^{\frac{5}{2}-\frac{\sqrt{21}}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{4\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{x^{\sqrt{21}}\sqrt{21}}{21}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{\frac{5}{2}-\frac{\sqrt{21}}{2}}\right) + c_2 \left(x^{\frac{5}{2}-\frac{\sqrt{21}}{2}} \left(\frac{x^{\sqrt{21}}\sqrt{21}}{21}\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x^{\frac{5}{2}-\frac{\sqrt{21}}{2}} + \frac{c_2\sqrt{21}\, x^{\frac{5}{2}+\frac{\sqrt{21}}{2}}}{21} \tag{1}$$

Verification of solutions

$$y = c_1 x^{\frac{5}{2}-\frac{\sqrt{21}}{2}} + \frac{c_2\sqrt{21}\, x^{\frac{5}{2}+\frac{\sqrt{21}}{2}}}{21}$$

Verified OK.

16.1.6 Maple step by step solution

Let's solve

$x^2y'' - 4y'x + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{4y'}{x} - \frac{y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{4y'}{x} + \frac{y}{x^2} = 0$

- Multiply by denominators of the ODE

  $x^2y'' - 4y'x + y = 0$

- Make a change of variables

  $t = \ln(x)$

☐ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

$$x^2\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2}-\frac{\frac{d}{dt}y(t)}{x^2}\right)-4\frac{d}{dt}y(t)+y(t)=0$$

- Simplify

$$\frac{d^2}{dt^2}y(t)-5\frac{d}{dt}y(t)+y(t)=0$$

- Characteristic polynomial of ODE

$$r^2-5r+1=0$$

- Use quadratic formula to solve for r

$$r=\frac{5\pm\left(\sqrt{21}\right)}{2}$$

- Roots of the characteristic polynomial

$$r=\left(\frac{5}{2}-\frac{\sqrt{21}}{2},\frac{5}{2}+\frac{\sqrt{21}}{2}\right)$$

- 1st solution of the ODE

$$y_1(t)=\mathrm{e}^{\left(\frac{5}{2}-\frac{\sqrt{21}}{2}\right)t}$$

- 2nd solution of the ODE

$$y_2(t)=\mathrm{e}^{\left(\frac{5}{2}+\frac{\sqrt{21}}{2}\right)t}$$

- General solution of the ODE

$$y(t)=c_1y_1(t)+c_2y_2(t)$$

- Substitute in solutions

$$y(t)=c_1\mathrm{e}^{\left(\frac{5}{2}-\frac{\sqrt{21}}{2}\right)t}+c_2\mathrm{e}^{\left(\frac{5}{2}+\frac{\sqrt{21}}{2}\right)t}$$

- Change variables back using $t=\ln(x)$

$$y=c_1\mathrm{e}^{\left(\frac{5}{2}-\frac{\sqrt{21}}{2}\right)\ln(x)}+c_2\mathrm{e}^{\left(\frac{5}{2}+\frac{\sqrt{21}}{2}\right)\ln(x)}$$

- Simplify

$$y=x^{\frac{5}{2}}\left(x^{\frac{\sqrt{21}}{2}}c_2+x^{-\frac{\sqrt{21}}{2}}c_1\right)$$

```

$$\boxed{x^2y'' + y'x + 16y = 0}$$

16.2.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + xrx^{r-1} + 16x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + r\,x^r + 16x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + r + 16 = 0$$

Or

$$r^2 + 16 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= -4i \\ r_2 &= 4i \end{aligned}$$

The roots are complex conjugate of each others. Let the roots be

$$\begin{aligned} r_1 &= \alpha + i\beta \\ r_2 &= \alpha - i\beta \end{aligned}$$

Where in this case $\alpha = 0$ and $\beta = -4$. Hence the solution becomes

$$\begin{aligned} y &= c_1 x^{r_1} + c_2 x^{r_2} \\ &= c_1 x^{\alpha + i\beta} + c_2 x^{\alpha - i\beta} \\ &= x^{\alpha}\left(c_1 x^{i\beta} + c_2 x^{-i\beta}\right) \\ &= x^{\alpha}\left(c_1 e^{\ln\left(x^{i\beta}\right)} + c_2 e^{\ln\left(x^{-i\beta}\right)}\right) \\ &= x^{\alpha}\left(c_1 e^{i(\beta \ln x)} + c_2 e^{-i(\beta \ln x)}\right) \end{aligned}$$

Using the values for $\alpha = 0, \beta = -4$, the above becomes

$$y = x^0\left(c_1 e^{-4i\ln(x)} + c_2 e^{4i\ln(x)}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y = c_1 \cos(4\ln(x)) + c_2 \sin(4\ln(x))$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(4\ln(x)) + c_2 \sin(4\ln(x)) \tag{1}$$

Verification of solutions

$$y = c_1 \cos(4\ln(x)) + c_2 \sin(4\ln(x))$$

Verified OK.

16.2.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2y'' + y'x + 16y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= \frac{16}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\ &= \int \mathrm{e}^{-\left(\int \frac{1}{x}dx\right)}dx \\ &= \int e^{-\ln(x)}\, dx \\ &= \int \frac{1}{x}dx \\ &= \ln(x) \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned} q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{16}{x^2}}{\frac{1}{x^2}} \\ &= 16 \end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned} \frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + 16y(\tau) &= 0 \end{aligned}$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = 16$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda\tau} + 16\, e^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 + 16 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 16$ into the above gives

$$\begin{aligned} \lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(16)} \\ &= \pm 4i \end{aligned}$$

Hence

$$\begin{aligned} \lambda_1 &= +4i \\ \lambda_2 &= -4i \end{aligned}$$

Which simplifies to

$$\lambda_1 = 4i$$
$$\lambda_2 = -4i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 4$. Therefore the final solution, when using Euler relation, can be written as

$$y(\tau) = e^{\alpha \tau}(c_1 \cos(\beta \tau) + c_2 \sin(\beta \tau))$$

Which becomes

$$y(\tau) = e^0(c_1 \cos(4\tau) + c_2 \sin(4\tau))$$

Or

$$y(\tau) = c_1 \cos(4\tau) + c_2 \sin(4\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \cos(4 \ln(x)) + c_2 \sin(4 \ln(x))$$

Summary
The solution(s) found are the following

$$y = c_1 \cos(4 \ln(x)) + c_2 \sin(4 \ln(x)) \tag{1}$$

Verification of solutions

$$y = c_1 \cos(4 \ln(x)) + c_2 \sin(4 \ln(x))$$

Verified OK.

16.2.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2y'' + y'x + 16y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= \frac{1}{x} \\
q(x) &= \frac{16}{x^2}
\end{aligned}
$$

Applying change of variables $\tau = g(x)$ to (2) results

$$
\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}
$$

Where τ is the new independent variable, and

$$
p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}
$$

$$
q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}
$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$
\begin{aligned}
\tau' &= \frac{1}{c}\sqrt{q} \\
&= \frac{4\sqrt{\frac{1}{x^2}}}{c} \\
\tau'' &= -\frac{4}{c\sqrt{\frac{1}{x^2}}\,x^3}
\end{aligned} \tag{6}
$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{4}{c\sqrt{\frac{1}{x^2}}\,x^3} + \frac{1}{x}\frac{4\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{4\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= 0
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0
\end{aligned} \tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$\begin{aligned}\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int 4\sqrt{\frac{1}{x^2}}dx}{c} \\ &= \frac{4\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = c_1 \cos(4\ln(x)) + c_2 \sin(4\ln(x))$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(4\ln(x)) + c_2 \sin(4\ln(x)) \tag{1}$$

Verification of solutions

$$y = c_1 \cos(4\ln(x)) + c_2 \sin(4\ln(x))$$

Verified OK.

16.2.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2y'' + y'x + 16y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned}p(x) &= \frac{1}{x} \\ q(x) &= \frac{16}{x^2}\end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n}{x^2} + \frac{16}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 4i \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{8i}{x} + \frac{1}{x}\right) v'(x) &= 0 \\ v''(x) + \frac{(1+8i)\, v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(1+8i)\, u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{(-1-8i)\, u}{x} \end{aligned}$$

Where $f(x) = \frac{-1-8i}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= \frac{-1-8i}{x}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{-1-8i}{x}\,dx \\
\ln(u) &= (-1-8i)\ln(x) + c_1 \\
u &= e^{(-1-8i)\ln(x)+c_1} \\
&= c_1 e^{(-1-8i)\ln(x)}
\end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1 x^{-8i}}{x}$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= \frac{i c_1 x^{-8i}}{8} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\,x^n \\
&= \left(\frac{i c_1 x^{-8i}}{8} + c_2\right) x^{4i} \\
&= x^{4i} c_2 + \frac{i x^{-4i} c_1}{8}
\end{aligned}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \left(\frac{i c_1 x^{-8i}}{8} + c_2\right) x^{4i} \tag{1}$$

<u>Verification of solutions</u>

$$y = \left(\frac{i c_1 x^{-8i}}{8} + c_2\right) x^{4i}$$

Verified OK.

16.2.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + y'x + 16y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= 16 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-65}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -65 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{65}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 543: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{65}{4x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{65}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + 4i \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - 4i
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = -\frac{65}{4x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{65}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + 4i \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - 4i
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{65}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2} + 4i$	$\frac{1}{2} - 4i$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2} + 4i$	$\frac{1}{2} - 4i$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = \frac{1}{2} - 4i$ then

$$
\begin{aligned}
d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= \frac{1}{2} - 4i - \left(\frac{1}{2} - 4i\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{\frac{1}{2} - 4i}{x} + (-)\,(0) \\
&= \frac{\frac{1}{2} - 4i}{x} \\
&= \frac{\frac{1}{2} - 4i}{x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{\frac{1}{2} - 4i}{x}\right)(0) + \left(\left(\frac{-\frac{1}{2} + 4i}{x^2}\right) + \left(\frac{\frac{1}{2} - 4i}{x}\right)^2 - \left(-\frac{65}{4x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \frac{\frac{1}{2} - 4i}{x} dx} \\
&= x^{\frac{1}{2} - 4i}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2}\,dx} \\
&= z_1 e^{-\frac{\ln(x)}{2}} \\
&= z_1 \left(\frac{1}{\sqrt{x}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{-4i}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{i x^{8i}}{8}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{-4i}\right) + c_2 \left(x^{-4i}\left(-\frac{i x^{8i}}{8}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = x^{-4i} c_1 - \frac{i c_2 x^{4i}}{8} \tag{1}
$$

Verification of solutions

$$
y = x^{-4i} c_1 - \frac{i c_2 x^{4i}}{8}
$$

Verified OK.

16.2.6 Maple step by step solution

Let's solve

$x^2 y'' + y'x + 16y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y'}{x} - \frac{16y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + \frac{16y}{x^2} = 0$

- Multiply by denominators of the ODE

  $x^2 y'' + y'x + 16y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $x^2 \left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) + \frac{d}{dt}y(t) + 16y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) + 16y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 + 16 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-64})}{2}$
- Roots of the characteristic polynomial

  $r = (-4\,\mathrm{I}, 4\,\mathrm{I})$
- 1st solution of the ODE

  $y_1(t) = \cos(4t)$
- 2nd solution of the ODE

  $y_2(t) = \sin(4t)$
- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$
- Substitute in solutions

  $y(t) = c_1 \cos(4t) + c_2 \sin(4t)$
- Change variables back using $t = \ln(x)$

  $y = c_1 \cos(4\ln(x)) + c_2 \sin(4\ln(x))$

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{4x^2y'' - 16y'x + 25y = 0}$$

16.3.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$4x^2(r(r-1))x^{r-2} - 16xrx^{r-1} + 25x^r = 0$$

Simplifying gives

$$4r(r-1)\,x^r - 16r\,x^r + 25x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$4r(r-1) - 16r + 25 = 0$$

Or

$$4r^2 - 20r + 25 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{5}{2}$$
$$r_2 = \frac{5}{2}$$

Since the roots are equal, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^r$ and $y_2 = x^r \ln(x)$. Hence

$$y = x^{\frac{5}{2}} c_1 + c_2 x^{\frac{5}{2}} \ln(x)$$

Summary

The solution(s) found are the following

$$y = x^{\frac{5}{2}} c_1 + c_2 x^{\frac{5}{2}} \ln(x) \tag{1}$$

Verification of solutions

$$y = x^{\frac{5}{2}} c_1 + c_2 x^{\frac{5}{2}} \ln(x)$$

Verified OK.

16.3.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$4x^2 y'' - 16y'x + 25y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = -\frac{4}{x}$$
$$q(x) = \frac{25}{4x^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}\tau &= \int e^{-\left(\int p(x)dx\right)}dx \\ &= \int e^{-\left(\int -\frac{4}{x}dx\right)}dx \\ &= \int e^{4\ln(x)}\,dx \\ &= \int x^4 dx \\ &= \frac{x^5}{5}\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{25}{4x^2}}{x^8} \\ &= \frac{25}{4x^{10}}\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{25y(\tau)}{4x^{10}} = 0$$

But in terms of τ

$$\frac{25}{4x^{10}} = \frac{1}{4\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{4\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$4\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0$$

Simplifying gives

$$4r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$4r(r-1) + 0 + 1 = 0$$

Or

$$4r^2 - 4r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2}$$
$$r_2 = \frac{1}{2}$$

Since the roots are equal, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^r$ and $y_2 = \tau^r \ln(\tau)$. Hence

$$y(\tau) = c_1\sqrt{\tau} + c_2\sqrt{\tau}\,\ln(\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{5}\,\sqrt{x^5}\,(c_1 + c_2\ln(x^5) - c_2\ln(5))}{5}$$

Summary
The solution(s) found are the following

$$y = \frac{\sqrt{5}\,\sqrt{x^5}\,(c_1 + c_2 \ln(x^5) - c_2 \ln(5))}{5} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{5}\,\sqrt{x^5}\,(c_1 + c_2 \ln(x^5) - c_2 \ln(5))}{5}$$

Verified OK.

16.3.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$4x^2y'' - 16y'x + 25y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{x} \\ q(x) &= \frac{25}{4x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{5\sqrt{\frac{1}{x^2}}}{2c} \\ \tau'' &= -\frac{5}{2c\sqrt{\frac{1}{x^2}}\,x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{5}{2c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{4}{x}\frac{5\sqrt{\frac{1}{x^2}}}{2c}}{\left(\frac{5\sqrt{\frac{1}{x^2}}}{2c}\right)^2} \\
&= -2c
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - 2c\left(\frac{d}{d\tau}y(\tau)\right) + c^2 y(\tau) &= 0 \qquad (7)
\end{aligned}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = \mathrm{e}^{c\tau} c_1
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \frac{5\sqrt{\frac{1}{x^2}}}{2}dx}{c} \\
&= \frac{5\sqrt{\frac{1}{x^2}}\,x\ln(x)}{2c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = x^{\frac{5}{2}} c_1
$$

Summary
The solution(s) found are the following

$$
y = x^{\frac{5}{2}} c_1 \qquad (1)
$$

Verification of solutions

$$
y = x^{\frac{5}{2}} c_1
$$

Verified OK.

16.3.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$4x^2y'' - 16y'x + 25y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{x} \\ q(x) &= \frac{25}{4x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{4n}{x^2} + \frac{25}{4x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = \frac{5}{2} \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{v'(x)}{x} &= 0 \\ v''(x) + \frac{v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{u}{x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{1}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{1}{x}\,dx \\ \ln(u) &= -\ln(x) + c_1 \\ u &= e^{-\ln(x)+c_1} \\ &= \frac{c_1}{x} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= c_1 \ln(x) + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\,x^n \\ &= (c_1 \ln(x) + c_2)\,x^{\frac{5}{2}} \\ &= (c_1 \ln(x) + c_2)\,x^{\frac{5}{2}} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = (c_1 \ln(x) + c_2)\,x^{\frac{5}{2}} \tag{1}$$

Verification of solutions

$$y = (c_1 \ln(x) + c_2)\,x^{\frac{5}{2}}$$

Verified OK.

16.3.5 Solving using Kovacic algorithm

Writing the ode as

$$4x^2y'' - 16y'x + 25y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -16x \\ C &= 25 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 545: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = -\frac{1}{4x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{1}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-}=\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (-)[\sqrt{r}]_{\infty} \\ &= \frac{1}{2x} + (-)\,(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-16x}{4x^2}\,dx} \\
&= z_1 e^{2\ln(x)} \\
&= z_1\left(x^2\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{\frac{5}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-16x}{4x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{4\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^{\frac{5}{2}}\right) + c_2\left(x^{\frac{5}{2}}(\ln(x))\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = x^{\frac{5}{2}} c_1 + c_2 x^{\frac{5}{2}} \ln(x) \tag{1}
$$

Verification of solutions

$$
y = x^{\frac{5}{2}} c_1 + c_2 x^{\frac{5}{2}} \ln(x)
$$

Verified OK.

16.3.6 Maple step by step solution

Let's solve

$4x^2y'' - 16y'x + 25y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{4y'}{x} - \frac{25y}{4x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{4y'}{x} + \frac{25y}{4x^2} = 0$

- Multiply by denominators of the ODE

  $4x^2y'' - 16y'x + 25y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right)t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $4x^2\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) - 16\frac{d}{dt}y(t) + 25y(t) = 0$

- Simplify

  $4\frac{d^2}{dt^2}y(t) - 20\frac{d}{dt}y(t) + 25y(t) = 0$

- Isolate 2nd derivative

  $\frac{d^2}{dt^2}y(t) = 5\frac{d}{dt}y(t) - \frac{25y(t)}{4}$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dt^2}y(t) - 5\frac{d}{dt}y(t) + \frac{25y(t)}{4} = 0$
- Characteristic polynomial of ODE

  $r^2 - 5r + \frac{25}{4} = 0$
- Factor the characteristic polynomial

  $\frac{(2r-5)^2}{4} = 0$
- Root of the characteristic polynomial

  $r = \frac{5}{2}$
- 1st solution of the ODE

  $y_1(t) = e^{\frac{5t}{2}}$
- Repeated root, multiply $y_1(t)$ by t to ensure linear independence

  $y_2(t) = t\,e^{\frac{5t}{2}}$
- General solution of the ODE

  $y(t) = c_1y_1(t) + c_2y_2(t)$
- Substitute in solutions

  $y(t) = c_1e^{\frac{5t}{2}} + c_2t\,e^{\frac{5t}{2}}$
- Change variables back using $t = \ln(x)$

  $y = x^{\frac{5}{2}}c_1 + c_2x^{\frac{5}{2}}\ln(x)$
- Simplify

  $y = (c_1 + c_2\ln(x))\,x^{\frac{5}{2}}$

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^2y'' + 5y'x + 10y = 0}$$

16.4.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 5xrx^{r-1} + 10x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 5r\,x^r + 10x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 5r + 10 = 0$$

Or

$$r^2 + 4r + 10 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= -2 - i\sqrt{6} \\ r_2 &= -2 + i\sqrt{6} \end{aligned}$$

The roots are complex conjugate of each others. Let the roots be

$$\begin{aligned} r_1 &= \alpha + i\beta \\ r_2 &= \alpha - i\beta \end{aligned}$$

Where in this case $\alpha = -2$ and $\beta = -\sqrt{6}$. Hence the solution becomes

$$\begin{aligned} y &= c_1 x^{r_1} + c_2 x^{r_2} \\ &= c_1 x^{\alpha+i\beta} + c_2 x^{\alpha-i\beta} \\ &= x^{\alpha}\left(c_1 x^{i\beta} + c_2 x^{-i\beta}\right) \\ &= x^{\alpha}\left(c_1 e^{\ln\left(x^{i\beta}\right)} + c_2 e^{\ln\left(x^{-i\beta}\right)}\right) \\ &= x^{\alpha}\left(c_1 e^{i(\beta \ln x)} + c_2 e^{-i(\beta \ln x)}\right) \end{aligned}$$

Using the values for $\alpha = -2, \beta = -\sqrt{6}$, the above becomes

$$y = x^{-2}\left(c_1 e^{-i\sqrt{6}\,\ln(x)} + c_2 e^{i\sqrt{6}\,\ln(x)}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y = \frac{1}{x^2}\left(c_1 \cos\left(\sqrt{6}\,\ln(x)\right) + c_2 \sin\left(\sqrt{6}\,\ln(x)\right)\right)$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 \cos\left(\sqrt{6}\,\ln(x)\right) + c_2 \sin\left(\sqrt{6}\,\ln(x)\right)}{x^2} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \cos\left(\sqrt{6}\,\ln(x)\right) + c_2 \sin\left(\sqrt{6}\,\ln(x)\right)}{x^2}$$

Verified OK.

16.4.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2y'' + 5y'x + 10y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{5}{x} \\ q(x) &= \frac{10}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\ &= \int \mathrm{e}^{-\left(\int \frac{5}{x}dx\right)}dx \\ &= \int e^{-5\ln(x)}\,dx \\ &= \int \frac{1}{x^5}dx \\ &= -\frac{1}{4x^4} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{10}{x^2}}{\frac{1}{x^{10}}} \\
&= 10x^8
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + 10x^8 y(\tau) &= 0
\end{aligned}$$

But in terms of τ

$$10x^8 = \frac{5}{8\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{5y(\tau)}{8\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$8\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 5y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$8\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 5\tau^r = 0$$

Simplifying gives

$$8r(r-1)\,\tau^r + 0\,\tau^r + 5\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$8r(r-1) + 0 + 5 = 0$$

Or

$$8r^2 - 8r + 5 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2} - \frac{i\sqrt{6}}{4}$$
$$r_2 = \frac{1}{2} + \frac{i\sqrt{6}}{4}$$

The roots are complex conjugate of each others. Let the roots be

$$r_1 = \alpha + i\beta$$
$$r_2 = \alpha - i\beta$$

Where in this case $\alpha = \frac{1}{2}$ and $\beta = -\frac{\sqrt{6}}{4}$. Hence the solution becomes

$$\begin{aligned}
y(\tau) &= c_1 \tau^{r_1} + c_2 \tau^{r_2} \\
&= c_1 \tau^{\alpha + i\beta} + c_2 \tau^{\alpha - i\beta} \\
&= \tau^{\alpha}\left(c_1 \tau^{i\beta} + c_2 \tau^{-i\beta}\right) \\
&= \tau^{\alpha}\left(c_1 e^{\ln(\tau^{i\beta})} + c_2 e^{\ln(\tau^{-i\beta})}\right) \\
&= \tau^{\alpha}\left(c_1 e^{i(\beta \ln \tau)} + c_2 e^{-i(\beta \ln \tau)}\right)
\end{aligned}$$

Using the values for $\alpha = \frac{1}{2}, \beta = -\frac{\sqrt{6}}{4}$, the above becomes

$$y(\tau) = \tau^{\frac{1}{2}}\left(c_1 e^{-\frac{i\sqrt{6}\,\ln(\tau)}{4}} + c_2 e^{\frac{i\sqrt{6}\,\ln(\tau)}{4}}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y(\tau) = \sqrt{\tau}\left(c_1 \cos\left(\frac{\sqrt{6}\,\ln(\tau)}{4}\right) + c_2 \sin\left(\frac{\sqrt{6}\,\ln(\tau)}{4}\right)\right)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{-\frac{1}{x^4}}\left(c_1 \cos\left(\frac{\sqrt{6}\left(-2\ln(2)+\ln\left(-\frac{1}{x^4}\right)\right)}{4}\right) + c_2 \sin\left(\frac{\sqrt{6}\left(-2\ln(2)+\ln\left(-\frac{1}{x^4}\right)\right)}{4}\right)\right)}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{-\frac{1}{x^4}}\left(c_1 \cos\left(\frac{\sqrt{6}\left(-2\ln(2)+\ln\left(-\frac{1}{x^4}\right)\right)}{4}\right) + c_2 \sin\left(\frac{\sqrt{6}\left(-2\ln(2)+\ln\left(-\frac{1}{x^4}\right)\right)}{4}\right)\right)}{2} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{-\frac{1}{x^4}}\left(c_1 \cos\left(\frac{\sqrt{6}\left(-2\ln(2)+\ln\left(-\frac{1}{x^4}\right)\right)}{4}\right) + c_2 \sin\left(\frac{\sqrt{6}\left(-2\ln(2)+\ln\left(-\frac{1}{x^4}\right)\right)}{4}\right)\right)}{2}$$

Verified OK.

16.4.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2y'' + 5y'x + 10y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{5}{x} \\ q(x) &= \frac{10}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{10}\,\sqrt{\frac{1}{x^2}}}{c} \end{aligned} \tag{6}$$

$$\tau'' = -\frac{\sqrt{10}}{c\sqrt{\frac{1}{x^2}}\,x^3}$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'\,(x)^2} \\
&= \frac{-\frac{\sqrt{10}}{c\sqrt{\frac{1}{x^2}}\,x^3} + \frac{5}{x}\frac{\sqrt{10}\,\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{10}\,\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= \frac{2c\sqrt{10}}{5}
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{2c\sqrt{10}\left(\frac{d}{d\tau}y(\tau)\right)}{5} + c^2 y(\tau) &= 0
\end{aligned} \tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = e^{-\frac{\sqrt{10}\,c\tau}{5}}\left(c_1 \cos\left(\frac{c\sqrt{15}\,\tau}{5}\right) + c_2 \sin\left(\frac{c\sqrt{15}\,\tau}{5}\right)\right)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{10}\,\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{10}\,\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = \frac{c_1 \cos\left(\sqrt{6}\,\ln(x)\right) + c_2 \sin\left(\sqrt{6}\,\ln(x)\right)}{x^2}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1 \cos\left(\sqrt{6}\,\ln(x)\right) + c_2 \sin\left(\sqrt{6}\,\ln(x)\right)}{x^2} \tag{1}
$$

Verification of solutions

$$y = \frac{c_1 \cos\left(\sqrt{6}\, \ln(x)\right) + c_2 \sin\left(\sqrt{6}\, \ln(x)\right)}{x^2}$$

Verified OK.

16.4.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2 y'' + 5y'x + 10y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = \frac{5}{x}$$
$$q(x) = \frac{10}{x^2}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{5n}{x^2} + \frac{10}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = -2 + i\sqrt{6} \tag{6}$$

Substituting this value in (3) gives

$$v''(x) + \left(\frac{-4 + 2i\sqrt{6}}{x} + \frac{5}{x}\right) v'(x) = 0$$
$$v''(x) + \frac{(2i\sqrt{6} + 1)\, v'(x)}{x} = 0 \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(2i\sqrt{6} + 1)\, u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= \frac{(-2i\sqrt{6} - 1)\, u}{x} \end{aligned}$$

Where $f(x) = \frac{-2i\sqrt{6}-1}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= \frac{-2i\sqrt{6} - 1}{x}\, dx \\ \int \frac{1}{u}\, du &= \int \frac{-2i\sqrt{6} - 1}{x}\, dx \\ \ln(u) &= \left(-2i\sqrt{6} - 1\right) \ln(x) + c_1 \\ u &= \mathrm{e}^{\left(-2i\sqrt{6}-1\right) \ln(x) + c_1} \\ &= c_1 \mathrm{e}^{\left(-2i\sqrt{6}-1\right) \ln(x)} \end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1 x^{-2i\sqrt{6}}}{x}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= \frac{i\sqrt{6}\, c_1 x^{-2i\sqrt{6}}}{12} + c_2 \end{aligned}$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(\frac{i\sqrt{6}\, c_1 x^{-2i\sqrt{6}}}{12} + c_2\right) x^{-2+i\sqrt{6}} \\
&= \frac{\frac{i x^{-i\sqrt{6}} \sqrt{6}\, c_1}{12} + x^{i\sqrt{6}} c_2}{x^2}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \left(\frac{i\sqrt{6}\, c_1 x^{-2i\sqrt{6}}}{12} + c_2\right) x^{-2+i\sqrt{6}} \tag{1}
$$

Verification of solutions

$$
y = \left(\frac{i\sqrt{6}\, c_1 x^{-2i\sqrt{6}}}{12} + c_2\right) x^{-2+i\sqrt{6}}
$$

Verified OK.

16.4.5 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{aligned}
x^2 y'' + 5y'x + 10y &= 0 && (1) \\
Ay'' + By' + Cy &= 0 && (2)
\end{aligned}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x^2 \\
B &= 5x \\
C &= 10
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-25}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -25$$
$$t = 4x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{25}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 547: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{25}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{25}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + i\sqrt{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - i\sqrt{6} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{25}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{25}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + i\sqrt{6} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - i\sqrt{6} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{25}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2} + i\sqrt{6}$	$\frac{1}{2} - i\sqrt{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2} + i\sqrt{6}$	$\frac{1}{2} - i\sqrt{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2} - i\sqrt{6}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= \frac{1}{2} - i\sqrt{6} - \left(\frac{1}{2} - i\sqrt{6}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{\frac{1}{2} - i\sqrt{6}}{x} + (-)(0) \\ &= \frac{\frac{1}{2} - i\sqrt{6}}{x} \\ &= \frac{-2i\sqrt{6} + 1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{\frac{1}{2} - i\sqrt{6}}{x}\right)(0) + \left(\left(-\frac{\frac{1}{2} - i\sqrt{6}}{x^2}\right) + \left(\frac{\frac{1}{2} - i\sqrt{6}}{x}\right)^2 - \left(-\frac{25}{4x^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \frac{\frac{1}{2} - i\sqrt{6}}{x} dx} \\
&= x^{\frac{1}{2} - i\sqrt{6}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{5x}{x^2} \, dx} \\
&= z_1 e^{-\frac{5 \ln(x)}{2}} \\
&= z_1 \left(\frac{1}{x^{\frac{5}{2}}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x^{-2 - i\sqrt{6}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{5x}{x^2}\,dx}}{(y_1)^2}\,dx$$

$$= y_1 \int \frac{e^{-5\ln(x)}}{(y_1)^2}\,dx$$

$$= y_1 \left(-\frac{i x^{2i\sqrt{6}}\sqrt{6}}{12}\right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$

$$= c_1 \left(x^{-2-i\sqrt{6}}\right) + c_2 \left(x^{-2-i\sqrt{6}} \left(-\frac{i x^{2i\sqrt{6}}\sqrt{6}}{12}\right)\right)$$

Summary

The solution(s) found are the following

$$y = c_1 x^{-2-i\sqrt{6}} - \frac{i c_2 \sqrt{6}\, x^{-2+i\sqrt{6}}}{12} \tag{1}$$

Verification of solutions

$$y = c_1 x^{-2-i\sqrt{6}} - \frac{i c_2 \sqrt{6}\, x^{-2+i\sqrt{6}}}{12}$$

Verified OK.

16.4.6 Maple step by step solution

Let's solve

$x^2 y'' + 5y'x + 10y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{5y'}{x} - \frac{10y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' + \frac{5y'}{x} + \frac{10y}{x^2} = 0$

- Multiply by denominators of the ODE

  $x^2 y'' + 5y'x + 10y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $x^2\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) + 5\frac{d}{dt}y(t) + 10y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) + 4\frac{d}{dt}y(t) + 10y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 + 4r + 10 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-4)\pm(\sqrt{-24})}{2}$

- Roots of the characteristic polynomial

  $r = \left(-2 - \mathrm{I}\sqrt{6}, -2 + \mathrm{I}\sqrt{6}\right)$

- 1st solution of the ODE

  $y_1(t) = \mathrm{e}^{-2t}\cos\left(\sqrt{6}\,t\right)$

- 2nd solution of the ODE

  $y_2(t) = \mathrm{e}^{-2t}\sin\left(\sqrt{6}\,t\right)$

- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$

- Substitute in solutions

  $y(t) = c_1 \mathrm{e}^{-2t} \cos\left(\sqrt{6}\, t\right) + c_2 \mathrm{e}^{-2t} \sin\left(\sqrt{6}\, t\right)$

- Change variables back using $t = \ln(x)$

  $y = \frac{c_1 \cos\left(\sqrt{6}\, \ln(x)\right)}{x^2} + \frac{c_2 \sin\left(\sqrt{6}\, \ln(x)\right)}{x^2}$

- Simplify

  $y = \frac{c_1 \cos\left(\sqrt{6}\, \ln(x)\right)}{x^2} + \frac{c_2 \sin\left(\sqrt{6}\, \ln(x)\right)}{x^2}$

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{2x^2y'' - 3y'x - 18y = \ln(x)}$$

16.5.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 2x^2, B = -3x, C = -18, f(x) = \ln(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$2x^2y'' - 3y'x - 18y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$2x^2(r(r-1))x^{r-2} - 3xrx^{r-1} - 18x^r = 0$$

Simplifying gives

$$2r(r-1)\,x^r - 3r\,x^r - 18x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$2r(r-1) - 3r - 18 = 0$$

Or

$$2r^2 - 5r - 18 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -2$$
$$r_2 = \frac{9}{2}$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = \frac{c_1}{x^2} + c_2x^{\frac{9}{2}}$$

Next, we find the particular solution to the ODE

$$2x^2y'' - 3y'x - 18y = \ln(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x^2}$$

$$y_2 = x^{\frac{9}{2}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x^2} & x^{\frac{9}{2}} \\ \frac{d}{dx}\left(\frac{1}{x^2}\right) & \frac{d}{dx}\left(x^{\frac{9}{2}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^2} & x^{\frac{9}{2}} \\ -\frac{2}{x^3} & \frac{9x^{\frac{7}{2}}}{2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^2}\right)\left(\frac{9x^{\frac{7}{2}}}{2}\right) - \left(x^{\frac{9}{2}}\right)\left(-\frac{2}{x^3}\right)$$

Which simplifies to

$$W = \frac{13x^{\frac{3}{2}}}{2}$$

Which simplifies to

$$W = \frac{13x^{\frac{3}{2}}}{2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^{\frac{9}{2}} \ln(x)}{13x^{\frac{7}{2}}} \, dx$$

Which simplifies to

$$u_1 = -\int \frac{x \ln(x)}{13} dx$$

Hence

$$u_1 = -\frac{\ln(x)\, x^2}{26} + \frac{x^2}{52}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\ln(x)}{x^2}}{13x^{\frac{7}{2}}}\, dx$$

Which simplifies to

$$u_2 = \int \frac{\ln(x)}{13x^{\frac{11}{2}}} dx$$

Hence

$$u_2 = -\frac{2\ln(x)}{117x^{\frac{9}{2}}} - \frac{4}{1053x^{\frac{9}{2}}}$$

Which simplifies to

$$u_1 = -\frac{x^2(2\ln(x) - 1)}{52}$$

$$u_2 = \frac{-\frac{2\ln(x)}{117} - \frac{4}{1053}}{x^{\frac{9}{2}}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\ln(x)}{18} + \frac{5}{324}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= -\frac{\ln(x)}{18} + \frac{5}{324} + \frac{c_1}{x^2} + c_2 x^{\frac{9}{2}} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{\ln(x)}{18} + \frac{5}{324} + \frac{c_1}{x^2} + c_2 x^{\frac{9}{2}} \tag{1}$$

Verification of solutions

$$y = -\frac{\ln(x)}{18} + \frac{5}{324} + \frac{c_1}{x^2} + c_2 x^{\frac{9}{2}}$$

Verified OK.

16.5.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$2x^2y'' - 3y'x - 18y = 0$$

In normal form the ode

$$2x^2y'' - 3y'x - 18y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{3}{2x} \\ q(x) &= -\frac{9}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$
\begin{aligned}
\tau &= \int e^{-\left(\int p(x)dx\right)} dx \\
&= \int e^{-\left(\int -\frac{3}{2x} dx\right)} dx \\
&= \int e^{\frac{3\ln(x)}{2}} dx \\
&= \int x^{\frac{3}{2}} dx \\
&= \frac{2x^{\frac{5}{2}}}{5}
\end{aligned} \tag{6}
$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{-\frac{9}{x^2}}{x^3} \\
&= -\frac{9}{x^5}
\end{aligned} \tag{7}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - \frac{9y(\tau)}{x^5} &= 0
\end{aligned}
$$

But in terms of τ

$$
-\frac{9}{x^5} = -\frac{36}{25\tau^2}
$$

Hence the above ode becomes

$$
\frac{d^2}{d\tau^2}y(\tau) - \frac{36y(\tau)}{25\tau^2} = 0
$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$
25\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 - 36y(\tau) = 0
$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$
25\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} - 36\tau^r = 0
$$

Simplifying gives

$$25r(r-1)\,\tau^r + 0\,\tau^r - 36\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$25r(r-1) + 0 - 36 = 0$$

Or

$$25r^2 - 25r - 36 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -\frac{4}{5}$$
$$r_2 = \frac{9}{5}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = \frac{c_1}{\tau^{\frac{4}{5}}} + c_2 \tau^{\frac{9}{5}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\left(4c_2 2^{\frac{3}{5}} x^5 \left(x^{\frac{5}{2}}\right)^{\frac{3}{5}} + 25c_1 5^{\frac{3}{5}}\right) 10^{\frac{1}{5}}}{50 \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{\left(4c_2 2^{\frac{3}{5}} x^5 \left(x^{\frac{5}{2}}\right)^{\frac{3}{5}} + 25c_1 5^{\frac{3}{5}}\right) 10^{\frac{1}{5}}}{50 \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}$$

$$y_2 = \frac{x^5}{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}} & \frac{x^5}{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}} \\ \frac{d}{dx}\left(\frac{1}{\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}\right) & \frac{d}{dx}\left(\frac{x^5}{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}} & \frac{x^5}{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}} \\ -\frac{2x^{\frac{3}{2}}}{\left(x^{\frac{5}{2}}\right)^{\frac{9}{5}}} & -\frac{x^{\frac{13}{2}}}{2\left(x^{\frac{5}{2}}\right)^{\frac{6}{5}}} + \frac{5x^4}{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}\right)\left(-\frac{x^{\frac{13}{2}}}{2\left(x^{\frac{5}{2}}\right)^{\frac{6}{5}}} + \frac{5x^4}{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}\right) - \left(\frac{x^5}{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}\right)\left(-\frac{2x^{\frac{3}{2}}}{\left(x^{\frac{5}{2}}\right)^{\frac{9}{5}}}\right)$$

Which simplifies to

$$W = \frac{13x^{\frac{3}{2}}}{2}$$

Which simplifies to

$$W = \frac{13x^{\frac{3}{2}}}{2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x^5 \ln(x)}{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}}{13x^{\frac{7}{2}}}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{x^{\frac{3}{2}} \ln(x)}{13 \left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}} dx$$

Hence

$$u_1 = -\frac{\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}} (2\ln(x) - 1)}{52}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\ln(x)}{\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}}{13x^{\frac{7}{2}}}\, dx$$

Which simplifies to

$$u_2 = \int \frac{\ln(x)}{13 \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}} x^{\frac{7}{2}}} dx$$

Hence

$$u_2 = \int_0^x \frac{\ln(\alpha)}{13 \left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \alpha^{\frac{7}{2}}} d\alpha$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\ln(x)}{26} + \frac{1}{52} + \frac{\left(\int_0^x \frac{\ln(\alpha)}{13\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \alpha^{\frac{7}{2}}} d\alpha\right) x^5}{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}$$

Which simplifies to

$$y_p(x) = -\frac{\ln(x)}{26} + \frac{1}{52} + \frac{\left(\int_0^x \frac{\ln(\alpha)}{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \alpha^{\frac{7}{2}}} d\alpha\right) x^5}{13\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{\left(4c_2 2^{\frac{3}{5}} x^5 \left(x^{\frac{5}{2}}\right)^{\frac{3}{5}} + 25c_1 5^{\frac{3}{5}}\right) 10^{\frac{1}{5}}}{50\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}\right) + \left(-\frac{\ln(x)}{26} + \frac{1}{52} + \frac{\left(\int_0^x \frac{\ln(\alpha)}{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \alpha^{\frac{7}{2}}} d\alpha\right) x^5}{13\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(4c_2 2^{\frac{3}{5}} x^5 \left(x^{\frac{5}{2}}\right)^{\frac{3}{5}} + 25c_1 5^{\frac{3}{5}}\right) 10^{\frac{1}{5}}}{50\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}} - \frac{\ln(x)}{26} + \frac{1}{52} + \frac{\left(\int_0^x \frac{\ln(\alpha)}{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \alpha^{\frac{7}{2}}} d\alpha\right) x^5}{13\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}} \tag{1}$$

Verification of solutions

$$y = \frac{\left(4c_2 2^{\frac{3}{5}} x^5 \left(x^{\frac{5}{2}}\right)^{\frac{3}{5}} + 25c_1 5^{\frac{3}{5}}\right) 10^{\frac{1}{5}}}{50\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}} - \frac{\ln(x)}{26} + \frac{1}{52} + \frac{\left(\int_0^x \frac{\ln(\alpha)}{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \alpha^{\frac{7}{2}}} d\alpha\right) x^5}{13\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}$$

Verified OK.

16.5.3 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 2x^2, B = -3x, C = -18, f(x) = \ln(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$2x^2y'' - 3y'x - 18y = 0$$

In normal form the ode

$$2x^2y'' - 3y'x - 18y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{3}{2x} \\ q(x) &= -\frac{9}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{3n}{2x^2} - \frac{9}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = \frac{9}{2} \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{15v'(x)}{2x} &= 0 \\ v''(x) + \frac{15v'(x)}{2x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{15u(x)}{2x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{15u}{2x} \end{aligned}$$

Where $f(x) = -\frac{15}{2x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{15}{2x}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{15}{2x}\, dx \\ \ln(u) &= -\frac{15\ln(x)}{2} + c_1 \\ u &= \mathrm{e}^{-\frac{15\ln(x)}{2} + c_1} \\ &= \frac{c_1}{x^{\frac{15}{2}}} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= -\frac{2c_1}{13x^{\frac{13}{2}}} + c_2 \end{aligned}$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(-\frac{2c_1}{13x^{\frac{13}{2}}} + c_2\right) x^{\frac{9}{2}} \\
&= \frac{13c_2 x^{\frac{13}{2}} - 2c_1}{13x^2}
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
2x^2 y'' - 3y'x - 18y = \ln(x)
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \frac{1}{x^2} \\
y_2 &= x^{\frac{9}{2}}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix} \frac{1}{x^2} & x^{\frac{9}{2}} \\ \frac{d}{dx}\left(\frac{1}{x^2}\right) & \frac{d}{dx}\left(x^{\frac{9}{2}}\right) \end{vmatrix}
$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^2} & x^{\frac{9}{2}} \\ -\frac{2}{x^3} & \frac{9x^{\frac{7}{2}}}{2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^2}\right)\left(\frac{9x^{\frac{7}{2}}}{2}\right) - \left(x^{\frac{9}{2}}\right)\left(-\frac{2}{x^3}\right)$$

Which simplifies to

$$W = \frac{13x^{\frac{3}{2}}}{2}$$

Which simplifies to

$$W = \frac{13x^{\frac{3}{2}}}{2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^{\frac{9}{2}} \ln (x)}{13x^{\frac{7}{2}}} \, dx$$

Which simplifies to

$$u_1 = -\int \frac{x \ln (x)}{13} dx$$

Hence

$$u_1 = -\frac{\ln (x) \, x^2}{26} + \frac{x^2}{52}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\ln(x)}{x^2}}{13x^{\frac{7}{2}}} \, dx$$

Which simplifies to

$$u_2 = \int \frac{\ln (x)}{13x^{\frac{11}{2}}} dx$$

Hence

$$u_2 = -\frac{2 \ln (x)}{117x^{\frac{9}{2}}} - \frac{4}{1053x^{\frac{9}{2}}}$$

Which simplifies to

$$u_1 = -\frac{x^2(2\ln(x) - 1)}{52}$$

$$u_2 = \frac{-\frac{2\ln(x)}{117} - \frac{4}{1053}}{x^{\frac{9}{2}}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\ln(x)}{18} + \frac{5}{324}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(-\frac{2c_1}{13x^{\frac{13}{2}}} + c_2\right)x^{\frac{9}{2}}\right) + \left(-\frac{\ln(x)}{18} + \frac{5}{324}\right) \\ &= -\frac{\ln(x)}{18} + \frac{5}{324} + \left(-\frac{2c_1}{13x^{\frac{13}{2}}} + c_2\right)x^{\frac{9}{2}} \end{aligned}$$

Which simplifies to

$$y = -\frac{\ln(x)}{18} + \frac{5}{324} + \left(-\frac{2c_1}{13x^{\frac{13}{2}}} + c_2\right)x^{\frac{9}{2}}$$

Summary

The solution(s) found are the following

$$y = -\frac{\ln(x)}{18} + \frac{5}{324} + \left(-\frac{2c_1}{13x^{\frac{13}{2}}} + c_2\right)x^{\frac{9}{2}} \tag{1}$$

Verification of solutions

$$y = -\frac{\ln(x)}{18} + \frac{5}{324} + \left(-\frac{2c_1}{13x^{\frac{13}{2}}} + c_2\right)x^{\frac{9}{2}}$$

Verified OK.

16.5.4 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{align*}
2x^2y'' - 3y'x - 18y &= 0 \tag{1} \\
Ay'' + By' + Cy &= 0 \tag{2}
\end{align*}
$$

Comparing (1) and (2) shows that

$$
\begin{align*}
A &= 2x^2 \\
B &= -3x \tag{3} \\
C &= -18
\end{align*}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A}\,dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \tag{4}
$$

Where r is given by

$$
\begin{align*}
r &= \frac{s}{t} \tag{5} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{align*}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{165}{16x^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{align*}
s &= 165 \\
t &= 16x^2
\end{align*}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{165}{16x^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\,dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 549: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{165}{16x^2}
$$

For the pole at $x=0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b=\frac{165}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2}+\sqrt{1+4b} = \frac{15}{4} \\
\alpha_c^- &= \frac{1}{2}-\sqrt{1+4b} = -\frac{11}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{165}{16x^2}
$$

Since the $\gcd(s,t)=1$. This gives $b=\frac{165}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b} = \frac{15}{4} \\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b} = -\frac{11}{4}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{165}{16x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{15}{4}$	$-\frac{11}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{15}{4}$	$-\frac{11}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = -\frac{11}{4}$ then

$$\begin{aligned} d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\ &= -\frac{11}{4} - \left(-\frac{11}{4}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\ &= -\frac{11}{4x} + (-)\,(0) \\ &= -\frac{11}{4x} \\ &= -\frac{11}{4x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{11}{4x}\right)(0) + \left(\left(\frac{11}{4x^2}\right) + \left(-\frac{11}{4x}\right)^2 - \left(\frac{165}{16x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int -\frac{11}{4x} dx} \\ &= \frac{1}{x^{\frac{11}{4}}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3x}{2x^2}\,dx} \\
&= z_1 e^{\frac{3\ln(x)}{4}} \\
&= z_1 \left(x^{\frac{3}{4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x^2}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3x}{2x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{3\ln(x)}{2}}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{2x^{\frac{13}{2}}}{13}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x^2}\right) + c_2 \left(\frac{1}{x^2}\left(\frac{2x^{\frac{13}{2}}}{13}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$2x^2y'' - 3y'x - 18y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_1}{x^2} + \frac{2c_2x^{\frac{9}{2}}}{13}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x^2}$$

$$y_2 = \frac{2x^{\frac{9}{2}}}{13}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{2x^{\frac{9}{2}}}{13} \\ \frac{d}{dx}\left(\frac{1}{x^2}\right) & \frac{d}{dx}\left(\frac{2x^{\frac{9}{2}}}{13}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{2x^{\frac{9}{2}}}{13} \\ -\frac{2}{x^3} & \frac{9x^{\frac{7}{2}}}{13} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^2}\right)\left(\frac{9x^{\frac{7}{2}}}{13}\right) - \left(\frac{2x^{\frac{9}{2}}}{13}\right)\left(-\frac{2}{x^3}\right)$$

Which simplifies to

$$W = x^{\frac{3}{2}}$$

Which simplifies to

$$W = x^{\frac{3}{2}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{2x^{\frac{9}{2}}\ln(x)}{13}}{2x^{\frac{7}{2}}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{x\ln(x)}{13}dx$$

Hence

$$u_1 = -\frac{\ln(x)\,x^2}{26} + \frac{x^2}{52}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\ln(x)}{x^2}}{2x^{\frac{7}{2}}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{\ln(x)}{2x^{\frac{11}{2}}}dx$$

Hence

$$u_2 = -\frac{\ln(x)}{9x^{\frac{9}{2}}} - \frac{2}{81x^{\frac{9}{2}}}$$

Which simplifies to

$$u_1 = -\frac{x^2(2\ln(x) - 1)}{52}$$

$$u_2 = \frac{-9\ln(x) - 2}{81x^{\frac{9}{2}}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\ln(x)}{18} + \frac{5}{324}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x^2} + \frac{2c_2x^{\frac{9}{2}}}{13}\right) + \left(-\frac{\ln(x)}{18} + \frac{5}{324}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x^2} + \frac{2c_2x^{\frac{9}{2}}}{13} - \frac{\ln(x)}{18} + \frac{5}{324} \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x^2} + \frac{2c_2x^{\frac{9}{2}}}{13} - \frac{\ln(x)}{18} + \frac{5}{324}$$

Verified OK.

Section: Exercise 25, page 112
Problem number: 6.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{2x^2y'' - 3y'x + 2y = \ln(x^2)}$$

16.6.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 2x^2, B = -3x, C = 2, f(x) = \ln(x^2)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$2x^2y'' - 3y'x + 2y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$2x^2(r(r-1))x^{r-2} - 3xrx^{r-1} + 2x^r = 0$$

Simplifying gives

$$2r(r-1)\,x^r - 3r\,x^r + 2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$2r(r-1) - 3r + 2 = 0$$

Or

$$2r^2 - 5r + 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= 2 \\ r_2 &= \frac{1}{2} \end{aligned}$$

Since the roots are real and distinct, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_1 x^2 + \sqrt{x}\, c_2$$

Next, we find the particular solution to the ODE

$$2x^2 y'' - 3y'x + 2y = \ln\left(x^2\right)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= x^2 \\ y_2 &= \sqrt{x} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & \sqrt{x} \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(\sqrt{x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & \sqrt{x} \\ 2x & \frac{1}{2\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = (x^2)\left(\frac{1}{2\sqrt{x}}\right) - (\sqrt{x})(2x)$$

Which simplifies to

$$W = -\frac{3x^{\frac{3}{2}}}{2}$$

Which simplifies to

$$W = -\frac{3x^{\frac{3}{2}}}{2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sqrt{x}\,\ln(x^2)}{-3x^{\frac{7}{2}}}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{\ln(x^2)}{3x^3}\,dx$$

Hence

$$u_1 = -\frac{\ln(x^2)}{6x^2} - \frac{1}{6x^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2 \ln(x^2)}{-3x^{\frac{7}{2}}}dx$$

Which simplifies to

$$u_2 = \int -\frac{\ln(x^2)}{3x^{\frac{3}{2}}}dx$$

Hence

$$u_2 = \frac{2\ln(x^2)}{3\sqrt{x}} + \frac{8}{3\sqrt{x}}$$

Which simplifies to

$$u_1 = \frac{-1 - \ln(x^2)}{6x^2}$$

$$u_2 = \frac{\frac{2\ln(x^2)}{3} + \frac{8}{3}}{\sqrt{x}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{5}{2} + \frac{\ln(x^2)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \frac{5}{2} + \frac{\ln(x^2)}{2} + c_1x^2 + \sqrt{x}\, c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{5}{2} + \frac{\ln(x^2)}{2} + c_1x^2 + \sqrt{x}\, c_2 \tag{1}$$

Verification of solutions

$$y = \frac{5}{2} + \frac{\ln(x^2)}{2} + c_1x^2 + \sqrt{x}\, c_2$$

Verified OK.

16.6.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$2x^2y'' - 3y'x + 2y = 0$$

In normal form the ode

$$2x^2y'' - 3y'x + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{3}{2x} \\ q(x) &= \frac{1}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$
\begin{aligned}
\tau &= \int e^{-\left(\int p(x)dx\right)} dx \\
&= \int e^{-\left(\int -\frac{3}{2x}dx\right)} dx \\
&= \int e^{\frac{3\ln(x)}{2}} dx \\
&= \int x^{\frac{3}{2}} dx \\
&= \frac{2x^{\frac{5}{2}}}{5}
\end{aligned} \tag{6}
$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{1}{x^2}}{x^3} \\
&= \frac{1}{x^5}
\end{aligned} \tag{7}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{x^5} &= 0
\end{aligned}
$$

But in terms of τ

$$
\frac{1}{x^5} = \frac{4}{25\tau^2}
$$

Hence the above ode becomes

$$
\frac{d^2}{d\tau^2}y(\tau) + \frac{4y(\tau)}{25\tau^2} = 0
$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$
25\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 4y(\tau) = 0
$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$
25\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 4\tau^r = 0
$$

Simplifying gives

$$25r(r-1)\,\tau^r + 0\,\tau^r + 4\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$25r(r-1) + 0 + 4 = 0$$

Or

$$25r^2 - 25r + 4 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{5}$$
$$r_2 = \frac{4}{5}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1 \tau^{\frac{1}{5}} + c_2 \tau^{\frac{4}{5}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 2^{\frac{1}{5}} 5^{\frac{4}{5}} \left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}{5} + \frac{c_2 2^{\frac{4}{5}} 5^{\frac{1}{5}} \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}{5}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 2^{\frac{1}{5}} 5^{\frac{4}{5}} \left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}{5} + \frac{c_2 2^{\frac{4}{5}} 5^{\frac{1}{5}} \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}{5}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}$$

$$y_2 = \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(x^{\frac{5}{2}}\right)^{\frac{1}{5}} & \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}} \\ \frac{d}{dx}\left(\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}\right) & \frac{d}{dx}\left(\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(x^{\frac{5}{2}}\right)^{\frac{1}{5}} & \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}} \\ \frac{x^{\frac{3}{2}}}{2\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}} & \frac{2x^{\frac{3}{2}}}{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}} \end{vmatrix}$$

Therefore

$$W = \left(\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}\right)\left(\frac{2x^{\frac{3}{2}}}{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}\right) - \left(\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}\right)\left(\frac{x^{\frac{3}{2}}}{2\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}\right)$$

Which simplifies to

$$W = \frac{3x^{\frac{3}{2}}}{2}$$

Which simplifies to

$$W = \frac{3x^{\frac{3}{2}}}{2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}} \ln\left(x^2\right)}{3x^{\frac{7}{2}}}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}} \ln\left(x^2\right)}{3x^{\frac{7}{2}}} dx$$

Hence

$$u_1 = -\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \ln\left(\alpha^2\right)}{3\alpha^{\frac{7}{2}}} d\alpha\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}} \ln\left(x^2\right)}{3x^{\frac{7}{2}}}\, dx$$

Which simplifies to

$$u_2 = \int \frac{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}} \ln\left(x^2\right)}{3x^{\frac{7}{2}}} dx$$

Hence

$$u_2 = \int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{1}{5}} \ln\left(\alpha^2\right)}{3\alpha^{\frac{7}{2}}} d\alpha$$

Which simplifies to

$$u_1 = -\frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \ln(\alpha^2)}{\alpha^{\frac{7}{2}}} d\alpha\right)}{3}$$

$$u_2 = \frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{1}{5}} \ln(\alpha^2)}{\alpha^{\frac{7}{2}}} d\alpha\right)}{3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \ln(\alpha^2)}{\alpha^{\frac{7}{2}}} d\alpha\right)\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}{3} + \frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{1}{5}} \ln(\alpha^2)}{\alpha^{\frac{7}{2}}} d\alpha\right)\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 2^{\frac{1}{5}} 5^{\frac{4}{5}} \left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}{5} + \frac{c_2 2^{\frac{4}{5}} 5^{\frac{1}{5}} \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}{5}\right) \\ &\quad + \left(-\frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \ln(\alpha^2)}{\alpha^{\frac{7}{2}}} d\alpha\right)\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}{3} + \frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{1}{5}} \ln(\alpha^2)}{\alpha^{\frac{7}{2}}} d\alpha\right)\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}{3}\right) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$\begin{aligned} y = {} & \frac{c_1 2^{\frac{1}{5}} 5^{\frac{4}{5}} \left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}{5} + \frac{c_2 2^{\frac{4}{5}} 5^{\frac{1}{5}} \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}{5} \\ & - \frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \ln(\alpha^2)}{\alpha^{\frac{7}{2}}} d\alpha\right)\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}{3} + \frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{1}{5}} \ln(\alpha^2)}{\alpha^{\frac{7}{2}}} d\alpha\right)\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}{3} \end{aligned} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 2^{\frac{1}{5}} 5^{\frac{4}{5}} \left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}{5} + \frac{c_2 2^{\frac{4}{5}} 5^{\frac{1}{5}} \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}{5} - \frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \ln(\alpha^2)}{\alpha^{\frac{7}{2}}} d\alpha\right) \left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}{3} + \frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{1}{5}} \ln(\alpha^2)}{\alpha^{\frac{7}{2}}} d\alpha\right) \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}{3}$$

Verified OK.

16.6.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 2x^2, B = -3x, C = 2, f(x) = \ln(x^2)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$2x^2y'' - 3y'x + 2y = 0$$

In normal form the ode

$$2x^2y'' - 3y'x + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = -\frac{3}{2x}$$
$$q(x) = \frac{1}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}\tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{1}{c\sqrt{\frac{1}{x^2}}\,x^3}\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{1}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{3}{2x}\frac{\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= -\frac{5c}{2}\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) - \frac{5c\left(\frac{d}{d\tau}y(\tau)\right)}{2} + c^2 y(\tau) &= 0\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = \mathrm{e}^{\frac{5c\tau}{4}}\left(c_1\cosh\left(\frac{3c\tau}{4}\right) + ic_2\sinh\left(\frac{3c\tau}{4}\right)\right)$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = x^{\frac{5}{4}}\left(c_1\cosh\left(\frac{3\ln(x)}{4}\right) + ic_2\sinh\left(\frac{3\ln(x)}{4}\right)\right)
$$

Now the particular solution to this ODE is found

$$
2x^2y'' - 3y'x + 2y = \ln\left(x^2\right)
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1y_1 + u_2y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \left(x^{\frac{5}{2}}\right)^{\frac{1}{5}} \\
y_2 &= \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(x^{\frac{5}{2}}\right)^{\frac{1}{5}} & \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}} \\ \frac{d}{dx}\left(\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}\right) & \frac{d}{dx}\left(\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(x^{\frac{5}{2}}\right)^{\frac{1}{5}} & \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}} \\ \frac{x^{\frac{3}{2}}}{2\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}} & \frac{2x^{\frac{3}{2}}}{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}} \end{vmatrix}$$

Therefore

$$W = \left(\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}\right)\left(\frac{2x^{\frac{3}{2}}}{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}\right) - \left(\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}\right)\left(\frac{x^{\frac{3}{2}}}{2\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}\right)$$

Which simplifies to

$$W = \frac{3x^{\frac{3}{2}}}{2}$$

Which simplifies to

$$W = \frac{3x^{\frac{3}{2}}}{2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}} \ln\left(x^2\right)}{3x^{\frac{7}{2}}}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}} \ln\left(x^2\right)}{3x^{\frac{7}{2}}} dx$$

Hence

$$u_1 = -\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \ln\left(\alpha^2\right)}{3\alpha^{\frac{7}{2}}} d\alpha\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}} \ln\left(x^2\right)}{3x^{\frac{7}{2}}} dx$$

Which simplifies to

$$u_2 = \int \frac{\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}} \ln\left(x^2\right)}{3x^{\frac{7}{2}}} dx$$

Hence

$$u_2 = \int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{1}{5}} \ln\left(\alpha^2\right)}{3\alpha^{\frac{7}{2}}} d\alpha$$

Which simplifies to

$$u_1 = -\frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \ln(\alpha^2)}{\alpha^{\frac{7}{2}}} d\alpha\right)}{3}$$

$$u_2 = \frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{1}{5}} \ln(\alpha^2)}{\alpha^{\frac{7}{2}}} d\alpha\right)}{3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \ln(\alpha^2)}{\alpha^{\frac{7}{2}}} d\alpha\right) \left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}{3} + \frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{1}{5}} \ln(\alpha^2)}{\alpha^{\frac{7}{2}}} d\alpha\right) \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}{3}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(x^{\frac{5}{4}}\left(c_1 \cosh\left(\frac{3\ln(x)}{4}\right) + i c_2 \sinh\left(\frac{3\ln(x)}{4}\right)\right)\right) \\
&\quad + \left(-\frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}}\ln(\alpha^2)}{\alpha^{\frac{7}{2}}}d\alpha\right)\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}{3} + \frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{1}{5}}\ln(\alpha^2)}{\alpha^{\frac{7}{2}}}d\alpha\right)\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}{3}\right) \\
&= -\frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}}\ln(\alpha^2)}{\alpha^{\frac{7}{2}}}d\alpha\right)\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}{3} + \frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{1}{5}}\ln(\alpha^2)}{\alpha^{\frac{7}{2}}}d\alpha\right)\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}{3} \\
&\quad + x^{\frac{5}{4}}\left(c_1 \cosh\left(\frac{3\ln(x)}{4}\right) + i c_2 \sinh\left(\frac{3\ln(x)}{4}\right)\right)
\end{aligned}
$$

Which simplifies to

$$
\begin{aligned}
y &= i x^{\frac{5}{4}} \sinh\left(\frac{3\ln(x)}{4}\right) c_2 + x^{\frac{5}{4}} \cosh\left(\frac{3\ln(x)}{4}\right) c_1 \\
&\quad + \frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{1}{5}}\ln(\alpha^2)}{\alpha^{\frac{7}{2}}}d\alpha\right)\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}{3} - \frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}}\ln(\alpha^2)}{\alpha^{\frac{7}{2}}}d\alpha\right)\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}{3}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= i x^{\frac{5}{4}} \sinh\left(\frac{3\ln(x)}{4}\right) c_2 + x^{\frac{5}{4}} \cosh\left(\frac{3\ln(x)}{4}\right) c_1 \\
&\quad + \frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{1}{5}}\ln(\alpha^2)}{\alpha^{\frac{7}{2}}}d\alpha\right)\left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}{3} - \frac{\left(\int_0^x \frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}}\ln(\alpha^2)}{\alpha^{\frac{7}{2}}}d\alpha\right)\left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}{3}
\end{aligned} \tag{1}
$$

Verification of solutions

$$
y = i x^{\frac{5}{4}} \sinh\left(\frac{3 \ln\left(x\right)}{4}\right) c_{2}+x^{\frac{5}{4}} \cosh\left(\frac{3 \ln\left(x\right)}{4}\right) c_{1} \\
+\frac{\left(\int_{0}^{x}\frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{1}{5}} \ln\left(\alpha^{2}\right)}{\alpha^{\frac{7}{2}}}d\alpha\right) \left(x^{\frac{5}{2}}\right)^{\frac{4}{5}}}{3}-\frac{\left(\int_{0}^{x}\frac{\left(\alpha^{\frac{5}{2}}\right)^{\frac{4}{5}} \ln\left(\alpha^{2}\right)}{\alpha^{\frac{7}{2}}}d\alpha\right) \left(x^{\frac{5}{2}}\right)^{\frac{1}{5}}}{3}
$$

Verified OK.

16.6.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$
A y''(x) + B y'(x) + C y(x) = f(x)
$$

Where $A = 2x^{2}, B = -3x, C = 2, f(x) = \ln\left(x^{2}\right)$. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. Solving for y_h from

$$
2x^{2}y''-3y'x+2y = 0
$$

In normal form the ode

$$
2x^{2}y''-3y'x+2y = 0 \tag{1}
$$

Becomes

$$
y''+p(x) y'+q(x) y = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= -\frac{3}{2x} \\
q(x) &= \frac{1}{x^{2}}
\end{aligned}
$$

Applying change of variables on the depndent variable $y = v(x) x^{n}$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$
v''(x)+\left(\frac{2n}{x}+p\right) v'(x)+\left(\frac{n(n-1)}{x^{2}}+\frac{np}{x}+q\right) v(x) = 0 \tag{3}
$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{3n}{2x^2} + \frac{1}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 2 \tag{6}$$

Substituting this value in (3) gives

$$v''(x) + \frac{5v'(x)}{2x} = 0$$
$$v''(x) + \frac{5v'(x)}{2x} = 0 \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{5u(x)}{2x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{5u}{2x} \end{aligned}$$

Where $f(x) = -\frac{5}{2x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{5}{2x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{5}{2x}\,dx \\ \ln(u) &= -\frac{5\ln(x)}{2} + c_1 \\ u &= e^{-\frac{5\ln(x)}{2} + c_1} \\ &= \frac{c_1}{x^{\frac{5}{2}}} \end{aligned}$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= -\frac{2c_1}{3x^{\frac{3}{2}}} + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(-\frac{2c_1}{3x^{\frac{3}{2}}} + c_2\right) x^2 \\
&= c_2 x^2 - \frac{2\sqrt{x}\, c_1}{3}
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
2x^2y'' - 3y'x + 2y = \ln\left(x^2\right)
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x^2 \\
y_2 &= \sqrt{x}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & \sqrt{x} \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(\sqrt{x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & \sqrt{x} \\ 2x & \frac{1}{2\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = (x^2)\left(\frac{1}{2\sqrt{x}}\right) - (\sqrt{x})\,(2x)$$

Which simplifies to

$$W = -\frac{3x^{\frac{3}{2}}}{2}$$

Which simplifies to

$$W = -\frac{3x^{\frac{3}{2}}}{2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sqrt{x}\,\ln(x^2)}{-3x^{\frac{7}{2}}}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{\ln(x^2)}{3x^3}dx$$

Hence

$$u_1 = -\frac{\ln(x^2)}{6x^2} - \frac{1}{6x^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2\ln(x^2)}{-3x^{\frac{7}{2}}}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{\ln(x^2)}{3x^{\frac{3}{2}}} dx$$

Hence

$$u_2 = \frac{2\ln(x^2)}{3\sqrt{x}} + \frac{8}{3\sqrt{x}}$$

Which simplifies to

$$u_1 = \frac{-1 - \ln(x^2)}{6x^2}$$

$$u_2 = \frac{\frac{2\ln(x^2)}{3} + \frac{8}{3}}{\sqrt{x}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{5}{2} + \frac{\ln(x^2)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(-\frac{2c_1}{3x^{\frac{3}{2}}} + c_2\right)x^2\right) + \left(\frac{5}{2} + \frac{\ln(x^2)}{2}\right) \\ &= \frac{5}{2} + \frac{\ln(x^2)}{2} + \left(-\frac{2c_1}{3x^{\frac{3}{2}}} + c_2\right)x^2 \end{aligned}$$

Which simplifies to

$$y = c_2x^2 - \frac{2\sqrt{x}\,c_1}{3} + \frac{\ln(x^2)}{2} + \frac{5}{2}$$

Summary

The solution(s) found are the following

$$y = c_2x^2 - \frac{2\sqrt{x}\,c_1}{3} + \frac{\ln(x^2)}{2} + \frac{5}{2} \tag{1}$$

Verification of solutions

$$y = c_2x^2 - \frac{2\sqrt{x}\,c_1}{3} + \frac{\ln(x^2)}{2} + \frac{5}{2}$$

Verified OK.

16.6.5 Solving using Kovacic algorithm

Writing the ode as

$$2x^2y'' - 3y'x + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2 \\ B &= -3x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{5}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 5 \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{5}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 550: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{5}{16x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{5}{16x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{5}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{5}{16x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = -\frac{1}{4}$ then

$$\begin{aligned}
d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= -\frac{1}{4} - \left(-\frac{1}{4}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{4x} + (-)\,(0) \\
&= -\frac{1}{4x} \\
&= -\frac{1}{4x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(-\frac{1}{4x}\right)(0) + \left(\left(\frac{1}{4x^2}\right) + \left(-\frac{1}{4x}\right)^2 - \left(\frac{5}{16x^2}\right) \right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int -\frac{1}{4x} dx} \\
&= \frac{1}{x^{\frac{1}{4}}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3x}{2x^2}\,dx} \\
&= z_1 e^{\frac{3\ln(x)}{4}} \\
&= z_1\left(x^{\frac{3}{4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \sqrt{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3x}{2x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{3\ln(x)}{2}}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{2x^{\frac{3}{2}}}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\sqrt{x}\right) + c_2\left(\sqrt{x}\left(\frac{2x^{\frac{3}{2}}}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$2x^2y'' - 3y'x + 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \sqrt{x}\, c_1 + \frac{2c_2x^2}{3}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sqrt{x}$$
$$y_2 = \frac{2x^2}{3}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{x} & \frac{2x^2}{3} \\ \frac{d}{dx}\left(\sqrt{x}\right) & \frac{d}{dx}\left(\frac{2x^2}{3}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{x} & \frac{2x^2}{3} \\ \frac{1}{2\sqrt{x}} & \frac{4x}{3} \end{vmatrix}$$

Therefore

$$W = (\sqrt{x})\left(\frac{4x}{3}\right) - \left(\frac{2x^2}{3}\right)\left(\frac{1}{2\sqrt{x}}\right)$$

Which simplifies to

$$W = x^{\frac{3}{2}}$$

Which simplifies to

$$W = x^{\frac{3}{2}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{2x^2 \ln(x^2)}{3}}{2x^{\frac{7}{2}}}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\ln(x^2)}{3x^{\frac{3}{2}}} dx$$

Hence

$$u_1 = \frac{2\ln(x^2)}{3\sqrt{x}} + \frac{8}{3\sqrt{x}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sqrt{x}\, \ln(x^2)}{2x^{\frac{7}{2}}}\, dx$$

Which simplifies to

$$u_2 = \int \frac{\ln(x^2)}{2x^3} dx$$

Hence

$$u_2 = -\frac{\ln(x^2)}{4x^2} - \frac{1}{4x^2}$$

Which simplifies to

$$u_1 = \frac{\frac{2\ln(x^2)}{3} + \frac{8}{3}}{\sqrt{x}}$$

$$u_2 = \frac{-1 - \ln(x^2)}{4x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{5}{2} + \frac{\ln(x^2)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\sqrt{x}\, c_1 + \frac{2c_2x^2}{3}\right) + \left(\frac{5}{2} + \frac{\ln(x^2)}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \sqrt{x}\, c_1 + \frac{2c_2x^2}{3} + \frac{5}{2} + \frac{\ln(x^2)}{2} \tag{1}$$

Verification of solutions

$$y = \sqrt{x}\, c_1 + \frac{2c_2x^2}{3} + \frac{5}{2} + \frac{\ln(x^2)}{2}$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 25, page 112
Problem number: 7.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - 3y'x + 4y = x^3}$$

16.7.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -3x, C = 4, f(x) = x^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 3y'x + 4y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 3xrx^{r-1} + 4x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 3r\,x^r + 4x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 3r + 4 = 0$$

Or

$$r^2 - 4r + 4 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= 2 \\ r_2 &= 2 \end{aligned}$$

Since the roots are equal, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^r$ and $y_2 = x^r \ln(x)$. Hence

$$y = c_1x^2 + c_2 \ln(x)\,x^2$$

Next, we find the particular solution to the ODE

$$x^2y'' - 3y'x + 4y = x^3$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= x^2 \\ y_2 &= \ln(x)\,x^2 \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & \ln(x)\, x^2 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(\ln(x)\, x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & \ln(x)\, x^2 \\ 2x & x + 2x\ln(x) \end{vmatrix}$$

Therefore

$$W = (x^2)(x + 2x\ln(x)) - (\ln(x)\, x^2)(2x)$$

Which simplifies to

$$W = x^3$$

Which simplifies to

$$W = x^3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^5 \ln(x)}{x^5}\, dx$$

Which simplifies to

$$u_1 = -\int \ln(x)\, dx$$

Hence

$$u_1 = -x\ln(x) + x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^5}{x^5}\, dx$$

Which simplifies to

$$u_2 = \int 1 dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (-x \ln(x) + x)\, x^2 + x^3 \ln(x)$$

Which simplifies to

$$y_p(x) = x^3$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= x^2(c_2 \ln(x) + c_1 + x) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = x^2(c_2 \ln(x) + c_1 + x) \tag{1}$$

Verification of solutions

$$y = x^2(c_2 \ln(x) + c_1 + x)$$

Verified OK.

16.7.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 3y'x + 4y = 0$$

In normal form the ode

$$x^2y'' - 3y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{3}{x} \\ q(x) &= \frac{4}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'\left(x\right)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'\left(x\right)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\, \tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}\tau &= \int e^{-\left(\int p(x)dx\right)}dx \\ &= \int e^{-\left(\int -\frac{3}{x}dx\right)}dx \\ &= \int e^{3\ln(x)}\,dx \\ &= \int x^3 dx \\ &= \frac{x^4}{4} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned} q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{4}{x^2}}{x^6} \\ &= \frac{4}{x^8} \end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned} \frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + \frac{4y(\tau)}{x^8} &= 0 \end{aligned}$$

But in terms of τ

$$\frac{4}{x^8} = \frac{1}{4\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{4\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$4\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0$$

Simplifying gives

$$4r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$4r(r-1) + 0 + 1 = 0$$

Or

$$4r^2 - 4r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2}$$
$$r_2 = \frac{1}{2}$$

Since the roots are equal, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^r$ and $y_2 = \tau^r \ln(\tau)$. Hence

$$y(\tau) = c_1\sqrt{\tau} + c_2\sqrt{\tau}\,\ln(\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{(-2c_2 \ln(2) + c_2 \ln(x^4) + c_1)\sqrt{x^4}}{2}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{(-2c_2 \ln(2) + c_2 \ln(x^4) + c_1)\sqrt{x^4}}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sqrt{x^4}$$

$$y_2 = -\ln(2)\sqrt{x^4} + \frac{\ln(x^4)\sqrt{x^4}}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{x^4} & -\ln(2)\sqrt{x^4} + \frac{\ln(x^4)\sqrt{x^4}}{2} \\ \frac{d}{dx}\left(\sqrt{x^4}\right) & \frac{d}{dx}\left(-\ln(2)\sqrt{x^4} + \frac{\ln(x^4)\sqrt{x^4}}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{x^4} & -\ln(2)\sqrt{x^4} + \frac{\ln(x^4)\sqrt{x^4}}{2} \\ \frac{2x^3}{\sqrt{x^4}} & -\frac{2\ln(2)x^3}{\sqrt{x^4}} + \frac{2\sqrt{x^4}}{x} + \frac{\ln(x^4)x^3}{\sqrt{x^4}} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{x^4}\right)\left(-\frac{2\ln(2)x^3}{\sqrt{x^4}} + \frac{2\sqrt{x^4}}{x} + \frac{\ln(x^4)x^3}{\sqrt{x^4}}\right) - \left(-\ln(2)\sqrt{x^4} + \frac{\ln(x^4)\sqrt{x^4}}{2}\right)\left(\frac{2x^3}{\sqrt{x^4}}\right)$$

Which simplifies to

$$W = 2x^3$$

Which simplifies to

$$W = 2x^3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(-\ln(2)\sqrt{x^4} + \frac{\ln(x^4)\sqrt{x^4}}{2}\right)x^3}{2x^5}\,dx$$

Which simplifies for $0 < x$ to

$$u_1 = -\int \left(\ln(x) - \frac{\ln(2)}{2}\right) dx$$

Hence

$$u_1 = \frac{x(\ln(2) - 2\ln(x) + 2)}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sqrt{x^4}\,x^3}{2x^5}\,dx$$

Which simplifies for $0 < x$ to

$$u_2 = \int \frac{1}{2} dx$$

Hence

$$u_2 = \frac{x}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x(\ln(2) - 2\ln(x) + 2)\sqrt{x^4}}{2} + \frac{x\left(-\ln(2)\sqrt{x^4} + \frac{\ln(x^4)\sqrt{x^4}}{2}\right)}{2}$$

Which simplifies to

$$y_p(x) = x^3$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{(-2c_2\ln(2) + c_2\ln(x^4) + c_1)\sqrt{x^4}}{2}\right) + (x^3) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{\left(-2c_2 \ln(2) + c_2 \ln(x^4) + c_1\right)\sqrt{x^4}}{2} + x^3 \tag{1}$$

Verification of solutions

$$y = \frac{\left(-2c_2 \ln(2) + c_2 \ln(x^4) + c_1\right)\sqrt{x^4}}{2} + x^3$$

Verified OK. `{0 < x}`

16.7.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -3x, C = 4, f(x) = x^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 3y'x + 4y = 0$$

In normal form the ode

$$x^2y'' - 3y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = -\frac{3}{x}$$
$$q(x) = \frac{4}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}\tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{2\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{2}{c\sqrt{\frac{1}{x^2}}\,x^3}\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{2}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{3}{x}\frac{2\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{2\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= -2c\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) - 2c\left(\frac{d}{d\tau}y(\tau)\right) + c^2 y(\tau) &= 0\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = e^{c\tau} c_1$$

Now from (6)

$$\begin{aligned}\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int 2\sqrt{\frac{1}{x^2}}dx}{c} \\ &= \frac{2\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = c_1 x^2$$

Now the particular solution to this ODE is found

$$x^2 y'' - 3y'x + 4y = x^3$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \sqrt{x^4} \\ y_2 &= -\ln(2)\sqrt{x^4} + \frac{\ln(x^4)\sqrt{x^4}}{2} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{x^4} & -\ln(2)\sqrt{x^4} + \frac{\ln(x^4)\sqrt{x^4}}{2} \\ \frac{d}{dx}\left(\sqrt{x^4}\right) & \frac{d}{dx}\left(-\ln(2)\sqrt{x^4} + \frac{\ln(x^4)\sqrt{x^4}}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{x^4} & -\ln(2)\sqrt{x^4} + \frac{\ln(x^4)\sqrt{x^4}}{2} \\ \frac{2x^3}{\sqrt{x^4}} & -\frac{2\ln(2)x^3}{\sqrt{x^4}} + \frac{2\sqrt{x^4}}{x} + \frac{\ln(x^4)x^3}{\sqrt{x^4}} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{x^4}\right)\left(-\frac{2\ln(2)\,x^3}{\sqrt{x^4}} + \frac{2\sqrt{x^4}}{x} + \frac{\ln(x^4)\,x^3}{\sqrt{x^4}}\right) - \left(-\ln(2)\sqrt{x^4} + \frac{\ln(x^4)\sqrt{x^4}}{2}\right)\left(\frac{2x^3}{\sqrt{x^4}}\right)$$

Which simplifies to

$$W = 2x^3$$

Which simplifies to

$$W = 2x^3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(-\ln(2)\sqrt{x^4} + \frac{\ln(x^4)\sqrt{x^4}}{2}\right)x^3}{2x^5}\,dx$$

Which simplifies for $0 < x$ to

$$u_1 = -\int \left(\ln(x) - \frac{\ln(2)}{2}\right) dx$$

Hence

$$u_1 = \frac{x(\ln(2) - 2\ln(x) + 2)}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sqrt{x^4}\,x^3}{2x^5}\,dx$$

Which simplifies for $0 < x$ to

$$u_2 = \int \frac{1}{2}dx$$

Hence

$$u_2 = \frac{x}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x(\ln (2) - 2 \ln (x) + 2) \sqrt{x^4}}{2} + \frac{x\left(-\ln (2) \sqrt{x^4} + \frac{\ln(x^4) \sqrt{x^4}}{2}\right)}{2}$$

Which simplifies to

$$y_p(x) = x^3$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 x^2) + (x^3) \\ &= c_1 x^2 + x^3 \end{aligned}$$

Which simplifies to

$$y = x^2(x + c_1)$$

Summary

The solution(s) found are the following

$$y = x^2(x + c_1) \tag{1}$$

Verification of solutions

$$y = x^2(x + c_1)$$

Verified OK. `{0 < x}`

16.7.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -3x, C = 4, f(x) = x^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 3y'x + 4y = 0$$

In normal form the ode

$$x^2y'' - 3y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{3}{x} \\ q(x) &= \frac{4}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{3n}{x^2} + \frac{4}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 2 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{v'(x)}{x} &= 0 \\ v''(x) + \frac{v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{u}{x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{1}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{1}{x}\,dx \\ \ln(u) &= -\ln(x) + c_1 \\ u &= e^{-\ln(x) + c_1} \\ &= \frac{c_1}{x} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= c_1 \ln(x) + c_2 \end{aligned}$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= (c_1 \ln(x) + c_2)\, x^2 \\
&= (c_1 \ln(x) + c_2)\, x^2
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
x^2y'' - 3y'x + 4y = x^3
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1y_1 + u_2y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x^2 \\
y_2 &= \ln(x)\, x^2
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix} x^2 & \ln(x)\, x^2 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(\ln(x)\, x^2) \end{vmatrix}
$$

Which gives

$$W = \begin{vmatrix} x^2 & \ln(x)\, x^2 \\ 2x & x + 2x\ln(x) \end{vmatrix}$$

Therefore

$$W = (x^2)\,(x + 2x\ln(x)) - (\ln(x)\, x^2)\,(2x)$$

Which simplifies to

$$W = x^3$$

Which simplifies to

$$W = x^3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^5 \ln(x)}{x^5}\, dx$$

Which simplifies to

$$u_1 = -\int \ln(x)\, dx$$

Hence

$$u_1 = -x(\ln(x) - 1)$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^5}{x^5}\, dx$$

Which simplifies to

$$u_2 = \int 1 dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -x^3(\ln(x) - 1) + x^3 \ln(x)$$

Which simplifies to

$$y_p(x) = x^3$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left((c_1 \ln(x) + c_2) x^2\right) + \left(x^3\right) \\ &= x^3 + (c_1 \ln(x) + c_2) x^2 \end{aligned}$$

Which simplifies to

$$y = x^2(c_1 \ln(x) + c_2 + x)$$

Summary
The solution(s) found are the following

$$y = x^2(c_1 \ln(x) + c_2 + x) \tag{1}$$

Verification of solutions

$$y = x^2(c_1 \ln(x) + c_2 + x)$$

Verified OK. `{0 < x}`

16.7.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' - 3y'x + 4y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -3x \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 551: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\,(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-3x}{x^2} \, dx} \\ &= z_1 e^{\frac{3 \ln(x)}{2}} \\ &= z_1 \left(x^{\frac{3}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^2$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{3\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^2\right) + c_2\left(x^2(\ln(x))\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
x^2 y'' - 3y'x + 4y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 x^2 + c_2 \ln(x)\, x^2
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x^2 \\
y_2 &= \ln(x)\, x^2
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & \ln(x)\, x^2 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(\ln(x)\, x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & \ln(x)\, x^2 \\ 2x & x + 2x\ln(x) \end{vmatrix}$$

Therefore

$$W = (x^2)(x + 2x\ln(x)) - (\ln(x)\, x^2)(2x)$$

Which simplifies to

$$W = x^3$$

Which simplifies to

$$W = x^3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^5 \ln(x)}{x^5}\, dx$$

Which simplifies to

$$u_1 = -\int \ln(x)\, dx$$

Hence

$$u_1 = -x(\ln(x) - 1)$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^5}{x^5}\, dx$$

Which simplifies to

$$u_2 = \int 1 dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -x^3(\ln(x) - 1) + x^3 \ln(x)$$

Which simplifies to

$$y_p(x) = x^3$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x^2 + c_2 \ln(x)\, x^2\right) + \left(x^3\right) \end{aligned}$$

Which simplifies to

$$y = x^2(c_1 + c_2 \ln(x)) + x^3$$

Summary
The solution(s) found are the following

$$y = x^2(c_1 + c_2 \ln(x)) + x^3 \tag{1}$$

Verification of solutions

$$y = x^2(c_1 + c_2 \ln(x)) + x^3$$

Verified OK. `{0 < x}`

$$\boxed{x^2y'' + 3y'x + y = 1 - x}$$

16.8.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 3x, C = 1, f(x) = 1 - x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 3y'x + y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 3xrx^{r-1} + x^r = 0$$

Simplifying gives

$$r(r-1)\, x^r + 3r\, x^r + x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 3r + 1 = 0$$

Or

$$r^2 + 2r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -1$$
$$r_2 = -1$$

Since the roots are equal, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^r$ and $y_2 = x^r \ln(x)$. Hence

$$y = \frac{c_1}{x} + \frac{c_2 \ln(x)}{x}$$

Next, we find the particular solution to the ODE

$$x^2y'' + 3y'x + y = 1 - x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = \frac{\ln(x)}{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & \frac{\ln(x)}{x} \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(\frac{\ln(x)}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & \frac{\ln(x)}{x} \\ -\frac{1}{x^2} & \frac{1}{x^2} - \frac{\ln(x)}{x^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)\left(\frac{1}{x^2} - \frac{\ln(x)}{x^2}\right) - \left(\frac{\ln(x)}{x}\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = \frac{1}{x^3}$$

Which simplifies to

$$W = \frac{1}{x^3}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\ln(x)(1-x)}{x}}{\frac{1}{x}} dx$$

Which simplifies to

$$u_1 = -\int \ln(x)(1-x)\,dx$$

Hence

$$u_1 = \frac{\ln(x)\,x^2}{2} - \frac{x^2}{4} - x\ln(x) + x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{1-x}{x}}{\frac{1}{x}} dx$$

Which simplifies to

$$u_2 = \int (1-x)\,dx$$

Hence

$$u_2 = x - \frac{1}{2}x^2$$

Which simplifies to

$$u_1 = \frac{(2x^2 - 4x)\ln(x)}{4} - \frac{x^2}{4} + x$$

$$u_2 = x - \frac{1}{2}x^2$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\frac{(2x^2-4x)\ln(x)}{4} - \frac{x^2}{4} + x}{x} + \frac{\left(x - \frac{1}{2}x^2\right)\ln(x)}{x}$$

Which simplifies to

$$y_p(x) = -\frac{x}{4} + 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= -\frac{x}{4} + 1 + \frac{c_1}{x} + \frac{c_2 \ln(x)}{x} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{x}{4} + 1 + \frac{c_1}{x} + \frac{c_2 \ln(x)}{x} \tag{1}$$

Verification of solutions

$$y = -\frac{x}{4} + 1 + \frac{c_1}{x} + \frac{c_2 \ln(x)}{x}$$

Verified OK.

16.8.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + 3y'x + y = 0$$

In normal form the ode

$$x^2y'' + 3y'x + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned}
p(x) &= \frac{3}{x} \\
q(x) &= \frac{1}{x^2}
\end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\, \tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int e^{-\left(\int p(x) dx\right)} dx \\
&= \int e^{-\left(\int \frac{3}{x} dx\right)} dx \\
&= \int e^{-3\ln(x)}\, dx \\
&= \int \frac{1}{x^3} dx \\
&= -\frac{1}{2x^2}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{1}{x^2}}{\frac{1}{x^6}} \\
&= x^4
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + x^4 y(\tau) &= 0
\end{aligned}
$$

But in terms of τ

$$
x^4 = \frac{1}{4\tau^2}
$$

Hence the above ode becomes

$$
\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{4\tau^2} = 0
$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$
4\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + y(\tau) = 0
$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$
4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0
$$

Simplifying gives

$$
4r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0
$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$
4r(r-1) + 0 + 1 = 0
$$

Or

$$
4r^2 - 4r + 1 = 0 \tag{1}
$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$
\begin{aligned}
r_1 &= \frac{1}{2} \\
r_2 &= \frac{1}{2}
\end{aligned}
$$

Since the roots are equal, then the general solution is

$$
y(\tau) = c_1 y_1 + c_2 y_2
$$

Where $y_1 = \tau^r$ and $y_2 = \tau^r \ln(\tau)$. Hence

$$y(\tau) = c_1\sqrt{\tau} + c_2\sqrt{\tau}\,\ln(\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\left(c_1 - c_2\ln(2) + c_2\ln\left(-\frac{1}{x^2}\right)\right)}{2}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\left(c_1 - c_2\ln(2) + c_2\ln\left(-\frac{1}{x^2}\right)\right)}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sqrt{-\frac{1}{x^2}}$$

$$y_2 = -\frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln(2)}{2} + \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{-\frac{1}{x^2}} & -\frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln\left(-\frac{1}{x^2}\right)}{2} \\ \frac{d}{dx}\left(\sqrt{-\frac{1}{x^2}}\right) & \frac{d}{dx}\left(-\frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln\left(-\frac{1}{x^2}\right)}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{-\frac{1}{x^2}} & -\frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln\left(-\frac{1}{x^2}\right)}{2} \\ \frac{1}{\sqrt{-\frac{1}{x^2}}\,x^3} & -\frac{\sqrt{2}\ln(2)}{2\sqrt{-\frac{1}{x^2}}\,x^3} + \frac{\sqrt{2}\ln\left(-\frac{1}{x^2}\right)}{2\sqrt{-\frac{1}{x^2}}\,x^3} - \frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}}{x} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{-\frac{1}{x^2}}\right)\left(-\frac{\sqrt{2}\ln(2)}{2\sqrt{-\frac{1}{x^2}}\,x^3} + \frac{\sqrt{2}\ln\left(-\frac{1}{x^2}\right)}{2\sqrt{-\frac{1}{x^2}}\,x^3} - \frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}}{x}\right) - \left(-\frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln\left(-\frac{1}{x^2}\right)}{2}\right)\left(\frac{1}{\sqrt{-\frac{1}{x^2}}\,x^3}\right)$$

Which simplifies to

$$W = \frac{\sqrt{2}}{x^3}$$

Which simplifies to

$$W = \frac{\sqrt{2}}{x^3}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(-\frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln\left(-\frac{1}{x^2}\right)}{2}\right)(1-x)}{\frac{\sqrt{2}}{x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\sqrt{-\frac{1}{x^2}}\,\left(\ln(2) - \ln\left(-\frac{1}{x^2}\right)\right)(x-1)\,x}{2} dx$$

Hence

$$u_1 = -\frac{\sqrt{-\frac{1}{x^2}}\,x\left(x - \frac{1}{2}x^2\right)\ln\left(-\frac{1}{x^2}\right)}{2} - \frac{\sqrt{-\frac{1}{x^2}}\,x^3\ln(2)}{4} + \frac{\sqrt{-\frac{1}{x^2}}\,x^2\ln(2)}{2} + \frac{\sqrt{-\frac{1}{x^2}}\,x^3}{4} - \sqrt{-\frac{1}{x^2}}\,x^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sqrt{-\frac{1}{x^2}}\,(1-x)}{\frac{\sqrt{2}}{x}} dx$$

Which simplifies to

$$u_2 = \int -\frac{\sqrt{-\frac{1}{x^2}}\,(x-1)\,x\sqrt{2}}{2} dx$$

Hence

$$u_2 = -\frac{x^2(-2+x)\sqrt{-\frac{1}{x^2}}\,\sqrt{2}}{4}$$

Which simplifies to

$$u_1 = -\frac{\left((2-x)\ln\left(-\frac{1}{x^2}\right) + (-2+x)\ln(2) - x + 4\right)x^2\sqrt{-\frac{1}{x^2}}}{4}$$

$$u_2 = -\frac{x^2(-2+x)\sqrt{-\frac{1}{x^2}}\,\sqrt{2}}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{(2-x)\ln\left(-\frac{1}{x^2}\right)}{4} + \frac{(-2+x)\ln(2)}{4} - \frac{x}{4} + 1 - \frac{x^2(-2+x)\sqrt{-\frac{1}{x^2}}\,\sqrt{2}\left(-\frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln\left(-\frac{1}{x^2}\right)}{2}\right)}{4}$$

Which simplifies to

$$y_p(x) = -\frac{x}{4} + 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\left(c_1 - c_2 \ln(2) + c_2 \ln\left(-\frac{1}{x^2}\right)\right)}{2}\right) + \left(-\frac{x}{4} + 1\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\left(c_1 - c_2 \ln(2) + c_2 \ln\left(-\frac{1}{x^2}\right)\right)}{2} - \frac{x}{4} + 1 \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\left(c_1 - c_2 \ln(2) + c_2 \ln\left(-\frac{1}{x^2}\right)\right)}{2} - \frac{x}{4} + 1$$

Verified OK.

16.8.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 3x, C = 1, f(x) = 1 - x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 3y'x + y = 0$$

In normal form the ode

$$x^2y'' + 3y'x + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{3}{x} \\ q(x) &= \frac{1}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{1}{c\sqrt{\frac{1}{x^2}}\, x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{1}{c\sqrt{\frac{1}{x^2}}\, x^3} + \frac{3}{x}\frac{\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= 2c \end{aligned}$$

Therefore ode (3) now becomes

$$y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2} y(\tau) + 2c\left(\frac{d}{d\tau} y(\tau)\right) + c^2 y(\tau) = 0 \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = \mathrm{e}^{-c\tau} c_1$$

Now from (6)

$$\begin{aligned}\tau &= \int \frac{1}{c}\sqrt{q}\, dx \\ &= \frac{\int \sqrt{\frac{1}{x^2}}dx}{c} \\ &= \frac{\sqrt{\frac{1}{x^2}}\, x \ln(x)}{c}\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = \frac{c_1}{x}$$

Now the particular solution to this ODE is found

$$x^2 y'' + 3y'x + y = 1 - x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sqrt{-\frac{1}{x^2}}$$
$$y_2 = -\frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln\left(-\frac{1}{x^2}\right)}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{-\frac{1}{x^2}} & -\frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln(2)}{2} + \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{2} \\ \frac{d}{dx}\left(\sqrt{-\frac{1}{x^2}}\right) & \frac{d}{dx}\left(-\frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln(2)}{2} + \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{-\frac{1}{x^2}} & -\frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln(2)}{2} + \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{2} \\ \frac{1}{\sqrt{-\frac{1}{x^2}}\,x^3} & -\frac{\sqrt{2}\,\ln(2)}{2\sqrt{-\frac{1}{x^2}}\,x^3} + \frac{\sqrt{2}\,\ln\left(-\frac{1}{x^2}\right)}{2\sqrt{-\frac{1}{x^2}}\,x^3} - \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}}{x} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{-\frac{1}{x^2}}\right)\left(-\frac{\sqrt{2}\,\ln(2)}{2\sqrt{-\frac{1}{x^2}}\,x^3} + \frac{\sqrt{2}\,\ln\left(-\frac{1}{x^2}\right)}{2\sqrt{-\frac{1}{x^2}}\,x^3} - \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}}{x}\right) - \left(-\frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln(2)}{2} + \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{2}\right)\left(\frac{1}{\sqrt{-\frac{1}{x^2}}\,x^3}\right)$$

Which simplifies to

$$W = \frac{\sqrt{2}}{x^3}$$

Which simplifies to

$$W = \frac{\sqrt{2}}{x^3}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(-\frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln(2)}{2} + \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{2}\right)(1-x)}{\frac{\sqrt{2}}{x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\sqrt{-\frac{1}{x^2}}\,\left(\ln\left(2\right) - \ln\left(-\frac{1}{x^2}\right)\right)(x-1)\,x}{2}dx$$

Hence

$$u_1 = -\frac{\sqrt{-\frac{1}{x^2}}\,x\left(x - \frac{1}{2}x^2\right)\ln\left(-\frac{1}{x^2}\right)}{2} - \frac{\sqrt{-\frac{1}{x^2}}\,x^3\ln\left(2\right)}{4} + \frac{\sqrt{-\frac{1}{x^2}}\,x^2\ln\left(2\right)}{2} + \frac{\sqrt{-\frac{1}{x^2}}\,x^3}{4} - \sqrt{-\frac{1}{x^2}}\,x^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sqrt{-\frac{1}{x^2}}\,(1-x)}{\frac{\sqrt{2}}{x}}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{\sqrt{-\frac{1}{x^2}}\,(x-1)\,x\sqrt{2}}{2}dx$$

Hence

$$u_2 = -\frac{x^2(-2+x)\,\sqrt{-\frac{1}{x^2}}\,\sqrt{2}}{4}$$

Which simplifies to

$$u_1 = -\frac{\left((2-x)\ln\left(-\frac{1}{x^2}\right) + (-2+x)\ln\left(2\right) - x + 4\right)x^2\sqrt{-\frac{1}{x^2}}}{4}$$

$$u_2 = -\frac{x^2(-2+x)\,\sqrt{-\frac{1}{x^2}}\,\sqrt{2}}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{(2-x)\ln\left(-\frac{1}{x^2}\right)}{4} + \frac{(-2+x)\ln(2)}{4} - \frac{x}{4} + 1 - \frac{x^2(-2+x)\sqrt{-\frac{1}{x^2}}\,\sqrt{2}\left(-\frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\,\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{2}\right)}{4}$$

Which simplifies to

$$y_p(x) = -\frac{x}{4} + 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x}\right) + \left(-\frac{x}{4} + 1\right) \\ &= -\frac{x}{4} + 1 + \frac{c_1}{x} \end{aligned}$$

Which simplifies to

$$y = -\frac{x}{4} + 1 + \frac{c_1}{x}$$

Summary

The solution(s) found are the following

$$y = -\frac{x}{4} + 1 + \frac{c_1}{x} \tag{1}$$

Verification of solutions

$$y = -\frac{x}{4} + 1 + \frac{c_1}{x}$$

Verified OK.

16.8.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 3x, C = 1, f(x) = 1 - x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 3y'x + y = 0$$

In normal form the ode

$$x^2y'' + 3y'x + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{3}{x} \\ q(x) &= \frac{1}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{3n}{x^2} + \frac{1}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = -1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{v'(x)}{x} &= 0 \\ v''(x) + \frac{v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{u}{x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{1}{x}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{1}{x}\, dx \\ \ln(u) &= -\ln(x) + c_1 \\ u &= \mathrm{e}^{-\ln(x)+c_1} \\ &= \frac{c_1}{x} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= c_1 \ln(x) + c_2 \end{aligned}$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \frac{c_1 \ln(x) + c_2}{x} \\
&= \frac{c_1 \ln(x) + c_2}{x}
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
x^2 y'' + 3y'x + y = 1 - x
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \frac{1}{x} \\
y_2 &= \frac{\ln(x)}{x}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix} \frac{1}{x} & \frac{\ln(x)}{x} \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(\frac{\ln(x)}{x}\right) \end{vmatrix}
$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & \frac{\ln(x)}{x} \\ -\frac{1}{x^2} & \frac{1}{x^2} - \frac{\ln(x)}{x^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)\left(\frac{1}{x^2} - \frac{\ln(x)}{x^2}\right) - \left(\frac{\ln(x)}{x}\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = \frac{1}{x^3}$$

Which simplifies to

$$W = \frac{1}{x^3}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\ln(x)(1-x)}{x}}{\frac{1}{x}}\,dx$$

Which simplifies to

$$u_1 = -\int \ln(x)\,(1-x)\,dx$$

Hence

$$u_1 = \frac{\ln(x)\,x^2}{2} - \frac{x^2}{4} - x\ln(x) + x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{1-x}{x}}{\frac{1}{x}}\,dx$$

Which simplifies to

$$u_2 = \int (1-x)\,dx$$

Hence

$$u_2 = x - \frac{1}{2}x^2$$

Which simplifies to

$$u_1 = \frac{(2x^2 - 4x)\ln(x)}{4} - \frac{x^2}{4} + x$$

$$u_2 = x - \frac{1}{2}x^2$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\frac{(2x^2-4x)\ln(x)}{4} - \frac{x^2}{4} + x}{x} + \frac{\left(x - \frac{1}{2}x^2\right)\ln(x)}{x}$$

Which simplifies to

$$y_p(x) = -\frac{x}{4} + 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 \ln(x) + c_2}{x}\right) + \left(-\frac{x}{4} + 1\right) \\ &= -\frac{x}{4} + 1 + \frac{c_1 \ln(x) + c_2}{x} \end{aligned}$$

Which simplifies to

$$y = -\frac{x}{4} + 1 + \frac{c_1 \ln(x) + c_2}{x}$$

Summary
The solution(s) found are the following

$$y = -\frac{x}{4} + 1 + \frac{c_1 \ln(x) + c_2}{x} \tag{1}$$

Verification of solutions

$$y = -\frac{x}{4} + 1 + \frac{c_1 \ln(x) + c_2}{x}$$

Verified OK.

16.8.5 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$
\begin{aligned}
\int (x^2y'' + 3y'x + y)\, dx &= \int (1 - x)\, dx \\
y'x^2 + yx &= x - \frac{1}{2}x^2 + c_1
\end{aligned}
$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
y' + p(x)y = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= \frac{1}{x} \\
q(x) &= \frac{-x^2 + 2c_1 + 2x}{2x^2}
\end{aligned}
$$

Hence the ode is

$$
y' + \frac{y}{x} = \frac{-x^2 + 2c_1 + 2x}{2x^2}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int \frac{1}{x}dx} \\
&= x
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{-x^2 + 2c_1 + 2x}{2x^2}\right) \\
\frac{d}{dx}(yx) &= (x)\left(\frac{-x^2 + 2c_1 + 2x}{2x^2}\right) \\
d(yx) &= \left(\frac{-x^2 + 2c_1 + 2x}{2x}\right) dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
yx &= \int \frac{-x^2 + 2c_1 + 2x}{2x}\, dx \\
yx &= x - \frac{x^2}{4} + c_1 \ln(x) + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$y = \frac{x - \frac{x^2}{4} + c_1 \ln(x)}{x} + \frac{c_2}{x}$$

which simplifies to

$$y = \frac{c_1 \ln(x) - \frac{x^2}{4} + c_2 + x}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 \ln(x) - \frac{x^2}{4} + c_2 + x}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \ln(x) - \frac{x^2}{4} + c_2 + x}{x}$$

Verified OK.

16.8.6 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$x^2 y'' + 3y'x + y = 1 - x$$

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2 y'' + 3y'x + y)\, dx = \int (1 - x)\, dx$$
$$y'x^2 + yx = x - \frac{1}{2}x^2 + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{-x^2 + 2c_1 + 2x}{2x^2}$$

Hence the ode is

$$y' + \frac{y}{x} = \frac{-x^2 + 2c_1 + 2x}{2x^2}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{1}{x} dx} \\ &= x\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{-x^2 + 2c_1 + 2x}{2x^2}\right) \\ \frac{d}{dx}(yx) &= (x)\left(\frac{-x^2 + 2c_1 + 2x}{2x^2}\right) \\ d(yx) &= \left(\frac{-x^2 + 2c_1 + 2x}{2x}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}yx &= \int \frac{-x^2 + 2c_1 + 2x}{2x} dx \\ yx &= x - \frac{x^2}{4} + c_1 \ln(x) + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$y = \frac{x - \frac{x^2}{4} + c_1 \ln(x)}{x} + \frac{c_2}{x}$$

which simplifies to

$$y = \frac{c_1 \ln(x) - \frac{x^2}{4} + c_2 + x}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 \ln(x) - \frac{x^2}{4} + c_2 + x}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \ln(x) - \frac{x^2}{4} + c_2 + x}{x}$$

Verified OK.

16.8.7 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + 3y'x + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 3x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 552: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = -\frac{1}{4x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{1}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = \frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_{\infty}^{-} - (\alpha_{c_1}^{-}) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} + (-)(0) \\
&= \frac{1}{2x} \\
&= \frac{1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right) \right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \frac{1}{2x} dx} \\
&= \sqrt{x}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3x}{x^2}\,dx} \\
&= z_1 e^{-\frac{3\ln(x)}{2}} \\
&= z_1 \left(\frac{1}{x^{\frac{3}{2}}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-3\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x}\right) + c_2 \left(\frac{1}{x}(\ln(x))\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2 y'' + 3y'x + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_1}{x} + \frac{c_2 \ln(x)}{x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = \frac{\ln(x)}{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & \frac{\ln(x)}{x} \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(\frac{\ln(x)}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & \frac{\ln(x)}{x} \\ -\frac{1}{x^2} & \frac{1}{x^2} - \frac{\ln(x)}{x^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)\left(\frac{1}{x^2} - \frac{\ln(x)}{x^2}\right) - \left(\frac{\ln(x)}{x}\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = \frac{1}{x^3}$$

Which simplifies to

$$W = \frac{1}{x^3}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\ln(x)(1-x)}{x}}{\frac{1}{x}} dx$$

Which simplifies to

$$u_1 = -\int \ln(x)(1-x)\, dx$$

Hence

$$u_1 = \frac{\ln(x)\, x^2}{2} - \frac{x^2}{4} - x\ln(x) + x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{1-x}{x}}{\frac{1}{x}} dx$$

Which simplifies to

$$u_2 = \int (1-x)\, dx$$

Hence

$$u_2 = x - \frac{1}{2}x^2$$

Which simplifies to

$$u_1 = \frac{(2x^2 - 4x)\ln(x)}{4} - \frac{x^2}{4} + x$$

$$u_2 = x - \frac{1}{2}x^2$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\frac{(2x^2-4x)\ln(x)}{4} - \frac{x^2}{4} + x}{x} + \frac{\left(x - \frac{1}{2}x^2\right)\ln(x)}{x}$$

Which simplifies to

$$y_p(x) = -\frac{x}{4} + 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x} + \frac{c_2 \ln(x)}{x}\right) + \left(-\frac{x}{4} + 1\right) \end{aligned}$$

Which simplifies to

$$y = \frac{c_1 + c_2 \ln(x)}{x} - \frac{x}{4} + 1$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 + c_2 \ln(x)}{x} - \frac{x}{4} + 1 \tag{1}$$

Verification of solutions

$$y = \frac{c_1 + c_2 \ln(x)}{x} - \frac{x}{4} + 1$$

Verified OK.

16.8.8 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}
p(x) &= x^2 \\
q(x) &= 3x \\
r(x) &= 1 \\
s(x) &= 1-x
\end{aligned}$$

Hence

$$\begin{aligned}
p''(x) &= 2 \\
q'(x) &= 3
\end{aligned}$$

Therefore (1) becomes

$$2-(3)+(1)=0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$y'x^2 + yx = \int 1 - x\, dx$$

We now have a first order ode to solve which is

$$y'x^2 + yx = -\frac{1}{2}x^2 + c_1 + x$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}
p(x) &= \frac{1}{x} \\
q(x) &= \frac{-x^2 + 2c_1 + 2x}{2x^2}
\end{aligned}$$

Hence the ode is

$$y' + \frac{y}{x} = \frac{-x^2 + 2c_1 + 2x}{2x^2}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{1}{x}dx}\\ &= x\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{-x^2 + 2c_1 + 2x}{2x^2}\right)\\ \frac{d}{dx}(yx) &= (x)\left(\frac{-x^2 + 2c_1 + 2x}{2x^2}\right)\\ d(yx) &= \left(\frac{-x^2 + 2c_1 + 2x}{2x}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}yx &= \int \frac{-x^2 + 2c_1 + 2x}{2x} dx\\ yx &= x - \frac{x^2}{4} + c_1 \ln(x) + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$y = \frac{x - \frac{x^2}{4} + c_1 \ln(x)}{x} + \frac{c_2}{x}$$

which simplifies to

$$y = \frac{c_1 \ln(x) - \frac{x^2}{4} + c_2 + x}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 \ln(x) - \frac{x^2}{4} + c_2 + x}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \ln(x) - \frac{x^2}{4} + c_2 + x}{x}$$

Verified OK.

The type(s) of ODE detected by this program : **"higher_order_ODE_non_constant_coefficients_of_type_Euler"**

Maple gives the following as the ode type

```
[[_3rd_order, _exact, _linear, _nonhomogeneous]]
```

$$\boxed{x^3y''' + 2x^2y'' - y'x + y = \frac{1}{x}}$$

This is higher order nonhomogeneous Euler type ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous Euler ODE And y_p is a particular solution to the nonhomogeneous Euler ODE. y_h is the solution to

$$x^3y''' + 2x^2y'' - y'x + y = 0$$

This is Euler ODE of higher order. Let $y = x^\lambda$. Hence

$$\begin{aligned}
y' &= \lambda\, x^{\lambda-1} \\
y'' &= \lambda(\lambda-1)\, x^{\lambda-2} \\
y''' &= \lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3}
\end{aligned}$$

Substituting these back into

$$x^3y''' + 2x^2y'' - y'x + y = \frac{1}{x}$$

gives

$$-x\lambda\, x^{\lambda-1} + 2x^2\lambda(\lambda-1)\, x^{\lambda-2} + x^3\lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} + x^\lambda = 0$$

Which simplifies to

$$-\lambda\, x^\lambda + 2\lambda(\lambda-1)\, x^\lambda + \lambda(\lambda-1)\,(\lambda-2)\, x^\lambda + x^\lambda = 0$$

And since $x^\lambda \neq 0$ then dividing through by x^λ, the above becomes

$$-\lambda + 2\lambda(\lambda-1) + \lambda(\lambda-1)\,(\lambda-2) + 1 = 0$$

Simplifying gives the characteristic equation as

$$(\lambda+1)\,(\lambda-1)^2 = 0$$

Solving the above gives the following roots

$$\lambda_1 = -1$$
$$\lambda_2 = 1$$
$$\lambda_3 = 1$$

This table summarises the result

root	multiplicity	type of root
-1	1	real root
1	2	real root

The solution is generated by going over the above table. For each real root λ of multiplicity one generates a c_1x^λ basis solution. Each real root of multiplicty two, generates c_1x^λ and $c_2x^\lambda \ln(x)$ basis solutions. Each real root of multiplicty three, generates c_1x^λ and $c_2x^\lambda \ln(x)$ and $c_3x^\lambda \ln(x)^2$ basis solutions, and so on. Each complex root $\alpha \pm i\beta$ of multiplicity one generates $x^\alpha(c_1\cos(\beta\ln(x)) + c_2\sin(\beta\ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity two generates $\ln(x)\, x^\alpha(c_1\cos(\beta\ln(x)) + c_2\sin(\beta\ln(x)))$ basis solutions. And each complex root $\alpha\pm i\beta$ of multiplicity three generates $\ln(x)^2\, x^\alpha(c_1\cos(\beta\ln(x)) + c_2$ basis solutions. And so on. Using the above show that the solution is

$$y = \frac{c_1}{x} + c_2x + \ln(x)\, c_3x$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= \frac{1}{x} \\
y_2 &= x \\
y_3 &= x \ln(x)
\end{aligned}
$$

Now the particular solution to the given ODE is found

$$
x^3 y''' + 2x^2 y'' - y'x + y = \frac{1}{x}
$$

Let the particular solution be

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$
U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)} \, dx
$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$
W(x) = \begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}
$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$
\begin{aligned}
W &= \begin{bmatrix} \frac{1}{x} & x & x \ln(x) \\ -\frac{1}{x^2} & 1 & \ln(x) + 1 \\ \frac{2}{x^3} & 0 & \frac{1}{x} \end{bmatrix} \\
|W| &= \frac{4}{x^2}
\end{aligned}
$$

The determinant simplifies to

$$|W| = \frac{4}{x^2}$$

Now we determine W_i for each U_i.

$$\begin{aligned} W_1(x) &= \det \begin{bmatrix} x & x\ln(x) \\ 1 & \ln(x)+1 \end{bmatrix} \\ &= x \end{aligned}$$

$$\begin{aligned} W_2(x) &= \det \begin{bmatrix} \frac{1}{x} & x\ln(x) \\ -\frac{1}{x^2} & \ln(x)+1 \end{bmatrix} \\ &= \frac{2\ln(x)+1}{x} \end{aligned}$$

$$\begin{aligned} W_3(x) &= \det \begin{bmatrix} \frac{1}{x} & x \\ -\frac{1}{x^2} & 1 \end{bmatrix} \\ &= \frac{2}{x} \end{aligned}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned} U_1 &= (-1)^{3-1} \int \frac{F(x)W_1(x)}{aW(x)}\,dx \\ &= (-1)^2 \int \frac{\left(\frac{1}{x}\right)(x)}{(x^3)\left(\frac{4}{x^2}\right)}\,dx \\ &= \int \frac{1}{4x}\,dx \\ &= \int \left(\frac{1}{4x}\right)\,dx \\ &= \frac{\ln(x)}{4} \end{aligned}$$

$$
\begin{aligned}
U_2 &= (-1)^{3-2} \int \frac{F(x) W_2(x)}{a W(x)}\, dx \\
&= (-1)^1 \int \frac{\left(\frac{1}{x}\right)\left(\frac{2\ln(x)+1}{x}\right)}{(x^3)\left(\frac{4}{x^2}\right)}\, dx \\
&= -\int \frac{\frac{2\ln(x)+1}{x^2}}{4x}\, dx \\
&= -\int \left(\frac{2\ln(x)+1}{4x^3}\right) dx \\
&= \frac{\ln(x)}{4x^2} + \frac{1}{4x^2}
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{3-3} \int \frac{F(x) W_3(x)}{a W(x)}\, dx \\
&= (-1)^0 \int \frac{\left(\frac{1}{x}\right)\left(\frac{2}{x}\right)}{(x^3)\left(\frac{4}{x^2}\right)}\, dx \\
&= \int \frac{\frac{2}{x^2}}{4x}\, dx \\
&= \int \left(\frac{1}{2x^3}\right) dx \\
&= -\frac{1}{4x^2}
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Hence

$$
\begin{aligned}
y_p = {} & \left(\frac{\ln(x)}{4}\right)\left(\frac{1}{x}\right) \\
& + \left(\frac{\ln(x)}{4x^2} + \frac{1}{4x^2}\right)(x) \\
& + \left(-\frac{1}{4x^2}\right)(x \ln(x))
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = \frac{\ln(x) + 1}{4x}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\frac{c_1}{x} + c_2 x + \ln(x)\, c_3 x\right) + \left(\frac{\ln(x) + 1}{4x}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1}{x} + c_2 x + \ln(x)\, c_3 x + \frac{\ln(x) + 1}{4x} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1}{x} + c_2 x + \ln(x)\, c_3 x + \frac{\ln(x) + 1}{4x}
$$

Verified OK.

Section: Exercise 25, page 112
Problem number: 10.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_1", "second_order_change_of_variable_on_y_method_2", "linear_second_order_ode_solved_by_an_integrating_factor", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - 2y'x + 2y = 4x + \sin(\ln(x))}$$

16.10.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -2x, C = 2, f(x) = 4x + \sin(\ln(x))$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 2y'x + 2y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 2xrx^{r-1} + 2x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 2r\,x^r + 2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 2r + 2 = 0$$

Or

$$r^2 - 3r + 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = 1$$
$$r_2 = 2$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_2x^2 + c_1x$$

Next, we find the particular solution to the ODE

$$x^2y'' - 2y'x + 2y = 4x + \sin(\ln(x))$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = x^2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & x^2 \\ \frac{d}{dx}(x) & \frac{d}{dx}(x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & x^2 \\ 1 & 2x \end{vmatrix}$$

Therefore

$$W = (x)(2x) - (x^2)(1)$$

Which simplifies to

$$W = x^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^2(4x + \sin(\ln(x)))}{x^4}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{4x + \sin(\ln(x))}{x^2} dx$$

Hence

$$u_1 = -4\ln(x) - \frac{-\frac{1}{2} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{2} - \tan\left(\frac{\ln(x)}{2}\right)}{\left(1 + \tan\left(\frac{\ln(x)}{2}\right)^2\right) x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(4x + \sin(\ln(x)))}{x^4}\, dx$$

Which simplifies to

$$u_2 = \int \frac{4x + \sin(\ln(x))}{x^3} dx$$

Hence

$$u_2 = -\frac{4}{x} + \frac{-\frac{1}{5} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{5} - \frac{4\tan\left(\frac{\ln(x)}{2}\right)}{5}}{\left(1 + \tan\left(\frac{\ln(x)}{2}\right)^2\right) x^2}$$

Which simplifies to

$$u_1 = \frac{-8x\ln(x) + \sin(\ln(x)) + \cos(\ln(x))}{2x}$$

$$u_2 = \frac{-\frac{\cos(\ln(x))}{5} - \frac{2\sin(\ln(x))}{5} - 4x}{x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\sin(\ln(x))}{10} - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} - 4x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \frac{\sin(\ln(x))}{10} - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} - 4x + c_2x^2 + c_1x \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\sin(\ln(x))}{10} - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} - 4x + c_2x^2 + c_1x \tag{1}$$

Verification of solutions

$$y = \frac{\sin(\ln(x))}{10} - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} - 4x + c_2x^2 + c_1x$$

Verified OK.

16.10.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)$$

Where $p(x) = -\frac{2}{x}$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int -\frac{2}{x}\,dx} \\ &= \frac{1}{x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= \frac{4x + \sin(\ln(x))}{x^3} \\ \left(\frac{y}{x}\right)'' &= \frac{4x + \sin(\ln(x))}{x^3} \end{aligned}$$

Integrating once gives

$$\left(\frac{y}{x}\right)' = \frac{-\frac{\cos(\ln(x))}{5} - \frac{2\sin(\ln(x))}{5} - 4x}{x^2} + c_1$$

Integrating again gives

$$\left(\frac{y}{x}\right) = \frac{\frac{\sin(\ln(x))}{10} + c_1x^2 - 4x\ln(x) + \frac{3\cos(\ln(x))}{10}}{x} + c_2$$

Hence the solution is

$$y = \frac{\frac{\frac{\sin(\ln(x))}{10} + c_1x^2 - 4x\ln(x) + \frac{3\cos(\ln(x))}{10}}{x} + c_2}{\frac{1}{x}}$$

Or

$$y = c_1x^2 + c_2x - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} + \frac{\sin(\ln(x))}{10}$$

Summary

The solution(s) found are the following

$$y = c_1x^2 + c_2x - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} + \frac{\sin(\ln(x))}{10} \tag{1}$$

Verification of solutions

$$y = c_1x^2 + c_2x - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} + \frac{\sin(\ln(x))}{10}$$

Verified OK.

16.10.3 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 2y'x + 2y = 0$$

In normal form the ode

$$x^2y'' - 2y'x + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= \frac{2}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int e^{-\left(\int p(x)dx\right)}dx \\ &= \int e^{-\left(\int -\frac{2}{x}dx\right)}dx \\ &= \int e^{2\ln(x)}\,dx \\ &= \int x^2dx \\ &= \frac{x^3}{3} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{2}{x^2}}{x^4} \\
&= \frac{2}{x^6}
\end{aligned} \tag{7}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{x^6} &= 0
\end{aligned}
$$

But in terms of τ

$$
\frac{2}{x^6} = \frac{2}{9\tau^2}
$$

Hence the above ode becomes

$$
\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{9\tau^2} = 0
$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$
9\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 2y(\tau) = 0
$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$
9\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 2\tau^r = 0
$$

Simplifying gives

$$
9r(r-1)\,\tau^r + 0\,\tau^r + 2\tau^r = 0
$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$
9r(r-1) + 0 + 2 = 0
$$

Or

$$
9r^2 - 9r + 2 = 0 \tag{1}
$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{3}$$
$$r_2 = \frac{2}{3}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1 \tau^{\frac{1}{3}} + c_2 \tau^{\frac{2}{3}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 3^{\frac{2}{3}} (x^3)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} (x^3)^{\frac{2}{3}}}{3}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 3^{\frac{2}{3}} (x^3)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} (x^3)^{\frac{2}{3}}}{3}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = (x^3)^{\frac{1}{3}}$$
$$y_2 = (x^3)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^3)^{\frac{1}{3}} & (x^3)^{\frac{2}{3}} \\ \frac{d}{dx}\left((x^3)^{\frac{1}{3}}\right) & \frac{d}{dx}\left((x^3)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^3)^{\frac{1}{3}} & (x^3)^{\frac{2}{3}} \\ \frac{x^2}{(x^3)^{\frac{2}{3}}} & \frac{2x^2}{(x^3)^{\frac{1}{3}}} \end{vmatrix}$$

Therefore

$$W = \left((x^3)^{\frac{1}{3}}\right)\left(\frac{2x^2}{(x^3)^{\frac{1}{3}}}\right) - \left((x^3)^{\frac{2}{3}}\right)\left(\frac{x^2}{(x^3)^{\frac{2}{3}}}\right)$$

Which simplifies to

$$W = x^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^3)^{\frac{2}{3}}\,(4x + \sin(\ln(x)))}{x^4}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^3)^{\frac{2}{3}}\,(4x + \sin(\ln(x)))}{x^4}dx$$

Hence

$$u_1 = \mathit{undefined}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^3)^{\frac{1}{3}}\,(4x + \sin(\ln(x)))}{x^4}\,dx$$

Which simplifies to

$$u_2 = \int \frac{\left(x^3\right)^{\frac{1}{3}} \left(4x + \sin\left(\ln\left(x\right)\right)\right)}{x^4} dx$$

Hence

$$u_2 = \mathit{undefined}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \text{undefined} \left(x^3\right)^{\frac{1}{3}} + \text{undefined} \left(x^3\right)^{\frac{2}{3}}$$

Which simplifies to

$$y_p(x) = \left(x^3\right)^{\frac{1}{3}} \left(\left(x^3\right)^{\frac{1}{3}} + 1\right) \text{undefined}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 3^{\frac{2}{3}} \left(x^3\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} \left(x^3\right)^{\frac{2}{3}}}{3}\right) + \left(\left(x^3\right)^{\frac{1}{3}} \left(\left(x^3\right)^{\frac{1}{3}} + 1\right) \text{undefined}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 3^{\frac{2}{3}} \left(x^3\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} \left(x^3\right)^{\frac{2}{3}}}{3} + \left(x^3\right)^{\frac{1}{3}} \left(\left(x^3\right)^{\frac{1}{3}} + 1\right) \text{undefined} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 3^{\frac{2}{3}} \left(x^3\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} \left(x^3\right)^{\frac{2}{3}}}{3} + \left(x^3\right)^{\frac{1}{3}} \left(\left(x^3\right)^{\frac{1}{3}} + 1\right) \text{undefined}$$

Verified OK.

16.10.4 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -2x, C = 2, f(x) = 4x + \sin(\ln(x))$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 2y'x + 2y = 0$$

In normal form the ode

$$x^2y'' - 2y'x + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned}
p(x) &= -\frac{2}{x} \\
q(x) &= \frac{2}{x^2}
\end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}
\tau' &= \frac{1}{c}\sqrt{q} \\
&= \frac{\sqrt{2}\,\sqrt{\frac{1}{x^2}}}{c} \qquad (6) \\
\tau'' &= -\frac{\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\,x^3}
\end{aligned}$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{2}{x}\frac{\sqrt{2}\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{2}\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= -\frac{3c\sqrt{2}}{2}
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - \frac{3c\sqrt{2}\left(\frac{d}{d\tau}y(\tau)\right)}{2} + c^2 y(\tau) &= 0 \qquad (7)
\end{aligned}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = \mathrm{e}^{\frac{3\sqrt{2}\,c\tau}{4}}\left(c_1 \cosh\left(\frac{\sqrt{2}\,c\tau}{4}\right) + ic_2 \sinh\left(\frac{\sqrt{2}\,c\tau}{4}\right)\right)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{2}\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{2}\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = x^{\frac{3}{2}}\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)
$$

Now the particular solution to this ODE is found

$$
x^2y'' - 2y'x + 2y = 4x + \sin(\ln(x))
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(x^3\right)^{\frac{1}{3}}$$
$$y_2 = \left(x^3\right)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(x^3\right)^{\frac{1}{3}} & \left(x^3\right)^{\frac{2}{3}} \\ \frac{d}{dx}\left(\left(x^3\right)^{\frac{1}{3}}\right) & \frac{d}{dx}\left(\left(x^3\right)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(x^3\right)^{\frac{1}{3}} & \left(x^3\right)^{\frac{2}{3}} \\ \frac{x^2}{\left(x^3\right)^{\frac{2}{3}}} & \frac{2x^2}{\left(x^3\right)^{\frac{1}{3}}} \end{vmatrix}$$

Therefore

$$W = \left(\left(x^3\right)^{\frac{1}{3}}\right)\left(\frac{2x^2}{\left(x^3\right)^{\frac{1}{3}}}\right) - \left(\left(x^3\right)^{\frac{2}{3}}\right)\left(\frac{x^2}{\left(x^3\right)^{\frac{2}{3}}}\right)$$

Which simplifies to

$$W = x^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^3)^{\frac{2}{3}} (4x + \sin(\ln(x)))}{x^4} \, dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^3)^{\frac{2}{3}} (4x + \sin(\ln(x)))}{x^4} dx$$

Hence

$$u_1 = \mathit{undefined}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^3)^{\frac{1}{3}} (4x + \sin(\ln(x)))}{x^4} \, dx$$

Which simplifies to

$$u_2 = \int \frac{(x^3)^{\frac{1}{3}} (4x + \sin(\ln(x)))}{x^4} dx$$

Hence

$$u_2 = \mathit{undefined}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \text{undefined}\,(x^3)^{\frac{1}{3}} + \text{undefined}\,(x^3)^{\frac{2}{3}}$$

Which simplifies to

$$y_p(x) = (x^3)^{\frac{1}{3}} \left((x^3)^{\frac{1}{3}} + 1\right) \text{undefined}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(x^{\frac{3}{2}}\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)\right) + \left(\left(x^3\right)^{\frac{1}{3}}\left(\left(x^3\right)^{\frac{1}{3}} + 1\right) \text{undefined}\right) \\
&= \left(x^3\right)^{\frac{1}{3}}\left(\left(x^3\right)^{\frac{1}{3}} + 1\right) \text{undefined} + x^{\frac{3}{2}}\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)
\end{aligned}
$$

Which simplifies to

$$
y = \left(x^3\right)^{\frac{1}{3}}\left(\left(x^3\right)^{\frac{1}{3}} + 1\right) \text{undefined} + x^{\frac{3}{2}}\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)
$$

Summary

The solution(s) found are the following

$$
y = \left(x^3\right)^{\frac{1}{3}}\left(\left(x^3\right)^{\frac{1}{3}} + 1\right) \text{undefined} + x^{\frac{3}{2}}\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x)}{2}\right)\right) \tag{1}
$$

Verification of solutions

$$
y = \left(x^3\right)^{\frac{1}{3}}\left(\left(x^3\right)^{\frac{1}{3}} + 1\right) \text{undefined} + x^{\frac{3}{2}}\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)
$$

Verified OK.

16.10.5 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' - 2y'x + 2y = 0
$$

In normal form the given ode is written as

$$
y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= -\frac{2}{x} \\
q(x) &= \frac{2}{x^2}
\end{aligned}
$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{2}{x^2} - \frac{\left(-\frac{2}{x}\right)'}{2} - \frac{\left(-\frac{2}{x}\right)^2}{4} \\
&= \frac{2}{x^2} - \frac{\left(\frac{2}{x^2}\right)}{2} - \frac{\left(\frac{4}{x^2}\right)}{4} \\
&= \frac{2}{x^2} - \left(\frac{1}{x^2}\right) - \frac{1}{x^2} \\
&= 0
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\, z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{-\frac{2}{x}}{2}} \\
&= x
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\, x \tag{4}
$$

Applying this change of variable to the original ode results in

$$
x^3 v''(x) = 4x + \sin(\ln(x))
$$

Which is now solved for $v(x)$ Simplyfing the ode gives

$$
v''(x) = \frac{4x + \sin(\ln(x))}{x^3}
$$

Integrating once gives

$$v'(x) = -\frac{4}{x} + \frac{-\frac{1}{5} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{5} - \frac{4\tan\left(\frac{\ln(x)}{2}\right)}{5}}{\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)x^2} + c_1$$

Integrating again gives

$$v(x) = \frac{\frac{3}{10} - \frac{3\tan\left(\frac{\ln(x)}{2}\right)^2}{10} + \frac{\tan\left(\frac{\ln(x)}{2}\right)}{5}}{\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)x} - 4\ln(x) + c_1 x + c_2$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= \left(\frac{\frac{3}{10} - \frac{3\tan\left(\frac{\ln(x)}{2}\right)^2}{10} + \frac{\tan\left(\frac{\ln(x)}{2}\right)}{5}}{\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)x} - 4\ln(x) + c_1 x + c_2\right)(z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = x$$

Hence (7) becomes

$$y = \left(\frac{\frac{3}{10} - \frac{3\tan\left(\frac{\ln(x)}{2}\right)^2}{10} + \frac{\tan\left(\frac{\ln(x)}{2}\right)}{5}}{\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)x} - 4\ln(x) + c_1 x + c_2\right)x$$

Therefore the homogeneous solution y_h is

$$y_h = \left(\frac{\frac{3}{10} - \frac{3\tan\left(\frac{\ln(x)}{2}\right)^2}{10} + \frac{\tan\left(\frac{\ln(x)}{2}\right)}{5}}{\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)x} - 4\ln(x) + c_1 x + c_2\right)x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = (x^3)^{\frac{1}{3}}$$

$$y_2 = (x^3)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^3)^{\frac{1}{3}} & (x^3)^{\frac{2}{3}} \\ \frac{d}{dx}\left((x^3)^{\frac{1}{3}}\right) & \frac{d}{dx}\left((x^3)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^3)^{\frac{1}{3}} & (x^3)^{\frac{2}{3}} \\ \frac{x^2}{(x^3)^{\frac{2}{3}}} & \frac{2x^2}{(x^3)^{\frac{1}{3}}} \end{vmatrix}$$

Therefore

$$W = \left((x^3)^{\frac{1}{3}}\right)\left(\frac{2x^2}{(x^3)^{\frac{1}{3}}}\right) - \left((x^3)^{\frac{2}{3}}\right)\left(\frac{x^2}{(x^3)^{\frac{2}{3}}}\right)$$

Which simplifies to

$$W = x^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(x^3\right)^{\frac{2}{3}} \left(4x + \sin\left(\ln\left(x\right)\right)\right)}{x^4} dx$$

Which simplifies to

$$u_1 = -\int \frac{\left(x^3\right)^{\frac{2}{3}} \left(4x + \sin\left(\ln\left(x\right)\right)\right)}{x^4} dx$$

Hence

$$u_1 = undefined$$

And Eq. (3) becomes

$$u_2 = \int \frac{\left(x^3\right)^{\frac{1}{3}} \left(4x + \sin\left(\ln\left(x\right)\right)\right)}{x^4} dx$$

Which simplifies to

$$u_2 = \int \frac{\left(x^3\right)^{\frac{1}{3}} \left(4x + \sin\left(\ln\left(x\right)\right)\right)}{x^4} dx$$

Hence

$$u_2 = undefined$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \text{undefined} \left(x^3\right)^{\frac{1}{3}} + \text{undefined} \left(x^3\right)^{\frac{2}{3}}$$

Which simplifies to

$$y_p(x) = \left(x^3\right)^{\frac{1}{3}} \left(\left(x^3\right)^{\frac{1}{3}} + 1\right) \text{undefined}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(\frac{\frac{3}{10} - \frac{3\tan\left(\frac{\ln(x)}{2}\right)^2}{10} + \frac{\tan\left(\frac{\ln(x)}{2}\right)}{5}}{\left(1 + \tan\left(\frac{\ln(x)}{2}\right)^2\right) x} - 4\ln\left(x\right) + c_1 x + c_2\right) x\right) \\ &\quad + \left(\left(x^3\right)^{\frac{1}{3}} \left(\left(x^3\right)^{\frac{1}{3}} + 1\right) \text{undefined}\right) \end{aligned}$$

Which simplifies to

$$y = c_1x^2 + c_2x - 4x \ln(x) + \frac{3\cos(\ln(x))}{10} + \frac{\sin(\ln(x))}{10} + (x^3)^{\frac{1}{3}} \left((x^3)^{\frac{1}{3}} + 1\right) \text{undefined}$$

Summary

The solution(s) found are the following

$$y = c_1x^2 + c_2x - 4x \ln(x) + \frac{3\cos(\ln(x))}{10} + \frac{\sin(\ln(x))}{10} + (x^3)^{\frac{1}{3}} \left((x^3)^{\frac{1}{3}} + 1\right) \text{undefined} \tag{1}$$

Verification of solutions

$$y = c_1x^2 + c_2x - 4x \ln(x) + \frac{3\cos(\ln(x))}{10} + \frac{\sin(\ln(x))}{10} + (x^3)^{\frac{1}{3}} \left((x^3)^{\frac{1}{3}} + 1\right) \text{undefined}$$

Verified OK.

16.10.6 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -2x, C = 2, f(x) = 4x + \sin(\ln(x))$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 2y'x + 2y = 0$$

In normal form the ode

$$x^2y'' - 2y'x + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= -\frac{2}{x} \\
q(x) &= \frac{2}{x^2}
\end{aligned}
$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$
v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}
$$

Let the coefficient of $v(x)$ above be zero. Hence

$$
\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}
$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$
\frac{n(n-1)}{x^2} - \frac{2n}{x^2} + \frac{2}{x^2} = 0 \tag{5}
$$

Solving (5) for n gives

$$
n = 2 \tag{6}
$$

Substituting this value in (3) gives

$$
\begin{aligned}
v''(x) + \frac{2v'(x)}{x} &= 0 \\
v''(x) + \frac{2v'(x)}{x} &= 0
\end{aligned} \tag{7}
$$

Using the substitution

$$
u(x) = v'(x)
$$

Then (7) becomes

$$
u'(x) + \frac{2u(x)}{x} = 0 \tag{8}
$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{2u}{x} \end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{2}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{2}{x}\,dx \\ \ln(u) &= -2\ln(x) + c_1 \\ u &= \mathrm{e}^{-2\ln(x)+c_1} \\ &= \frac{c_1}{x^2} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= -\frac{c_1}{x} + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\,x^n \\ &= \left(-\frac{c_1}{x} + c_2\right)x^2 \\ &= x(c_2 x - c_1) \end{aligned}$$

Now the particular solution to this ODE is found

$$x^2 y'' - 2y'x + 2y = 4x + \sin(\ln(x))$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = x^2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & x^2 \\ \frac{d}{dx}(x) & \frac{d}{dx}(x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & x^2 \\ 1 & 2x \end{vmatrix}$$

Therefore

$$W = (x)(2x) - (x^2)(1)$$

Which simplifies to

$$W = x^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^2(4x + \sin(\ln(x)))}{x^4}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{4x + \sin(\ln(x))}{x^2} dx$$

Hence

$$u_1 = -4\ln(x) - \frac{-\frac{1}{2} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{2} - \tan\left(\frac{\ln(x)}{2}\right)}{\left(1 + \tan\left(\frac{\ln(x)}{2}\right)^2\right) x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(4x + \sin(\ln(x)))}{x^4} dx$$

Which simplifies to

$$u_2 = \int \frac{4x + \sin(\ln(x))}{x^3} dx$$

Hence

$$u_2 = -\frac{4}{x} + \frac{-\frac{1}{5} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{5} - \frac{4\tan\left(\frac{\ln(x)}{2}\right)}{5}}{\left(1 + \tan\left(\frac{\ln(x)}{2}\right)^2\right) x^2}$$

Which simplifies to

$$u_1 = \frac{-8x\ln(x) + \sin(\ln(x)) + \cos(\ln(x))}{2x}$$
$$u_2 = \frac{-\frac{\cos(\ln(x))}{5} - \frac{2\sin(\ln(x))}{5} - 4x}{x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\sin(\ln(x))}{10} - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} - 4x$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\left(-\frac{c_1}{x} + c_2\right) x^2\right) + \left(\frac{\sin(\ln(x))}{10} - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} - 4x\right) \\
&= \frac{\sin(\ln(x))}{10} - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} - 4x + \left(-\frac{c_1}{x} + c_2\right) x^2
\end{aligned}
$$

Which simplifies to

$$
y = c_2x^2 - 4x\ln(x) - c_1x + \frac{\sin(\ln(x))}{10} + \frac{3\cos(\ln(x))}{10} - 4x
$$

Summary

The solution(s) found are the following

$$
y = c_2x^2 - 4x\ln(x) - c_1x + \frac{\sin(\ln(x))}{10} + \frac{3\cos(\ln(x))}{10} - 4x \tag{1}
$$

Verification of solutions

$$
y = c_2x^2 - 4x\ln(x) - c_1x + \frac{\sin(\ln(x))}{10} + \frac{3\cos(\ln(x))}{10} - 4x
$$

Verified OK.

16.10.7 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$
Ay'' + By' + Cy = F(x)
$$

This method reduces the order ode the ODE by one by applying the transformation

$$
y = Bv
$$

This results in

$$
\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}
$$

And now the original ode becomes

$$\begin{aligned}A(v''B+2v'B'+B''v)+B(B'v+v'B)+CBv&=0\\ ABv''+\left(2AB'+B^2\right)v'+\left(AB''+BB'+CB\right)v&=0\end{aligned}\tag{1}$$

If the term $AB''+BB'+CB$ is zero, then this method works and can be used to solve

$$ABv''+\left(2AB'+B^2\right)v'=0$$

By Using $u=v'$ which reduces the order of the above ode to one. The new ode is

$$ABu'+\left(2AB'+B^2\right)u=0$$

The above ode is first order ode which is solved for u. Now a new ode $v'=u$ is solved for v as first order ode. Then the final solution is obtain from $y=Bv$.

This method works only if the term $AB''+BB'+CB$ is zero. The given ODE shows that

$$\begin{aligned}A&=x^2\\ B&=-2x\\ C&=2\\ F&=4x+\sin\left(\ln\left(x\right)\right)\end{aligned}$$

The above shows that for this ode

$$\begin{aligned}AB''+BB'+CB&=\left(x^2\right)(0)+(-2x)(-2)+(2)(-2x)\\ &=0\end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$-2x^3v''+(0)\,v'=0$$

Now by applying $v'=u$ the above becomes

$$-2x^3u'(x)=0$$

Which is now solved for u. Integrating both sides gives

$$\begin{aligned}u(x)&=\int 0\,\mathrm{d}x\\ &=c_1\end{aligned}$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= c_1
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int c_1 \, \mathrm{d}x \\
&= c_1 x + c_2
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= Bv \\
&= (-2x)\left(c_1 x + c_2\right) \\
&= -2x(c_1 x + c_2)
\end{aligned}
$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x \\
y_2 &= x^2
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix} x & x^2 \\ \frac{d}{dx}(x) & \frac{d}{dx}(x^2) \end{vmatrix}
$$

Which gives

$$W = \begin{vmatrix} x & x^2 \\ 1 & 2x \end{vmatrix}$$

Therefore

$$W = (x)(2x) - (x^2)(1)$$

Which simplifies to

$$W = x^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^2(4x + \sin(\ln(x)))}{x^4} dx$$

Which simplifies to

$$u_1 = -\int \frac{4x + \sin(\ln(x))}{x^2} dx$$

Hence

$$u_1 = -4\ln(x) - \frac{-\frac{1}{2} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{2} - \tan\left(\frac{\ln(x)}{2}\right)}{\left(1 + \tan\left(\frac{\ln(x)}{2}\right)^2\right) x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(4x + \sin(\ln(x)))}{x^4} dx$$

Which simplifies to

$$u_2 = \int \frac{4x + \sin(\ln(x))}{x^3} dx$$

Hence

$$u_2 = -\frac{4}{x} + \frac{-\frac{1}{5} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{5} - \frac{4\tan\left(\frac{\ln(x)}{2}\right)}{5}}{\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)x^2}$$

Which simplifies to

$$u_1 = \frac{-8x\ln(x) + \sin(\ln(x)) + \cos(\ln(x))}{2x}$$
$$u_2 = \frac{-\frac{\cos(\ln(x))}{5} - \frac{2\sin(\ln(x))}{5} - 4x}{x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\sin(\ln(x))}{10} - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} - 4x$$

Hence the complete solution is

$$\begin{aligned} y(x) &= y_h + y_p \\ &= (-2x(c_1x + c_2)) + \left(\frac{\sin(\ln(x))}{10} - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} - 4x\right) \\ &= -2c_1x^2 - 4x\ln(x) - 2c_2x + \frac{\sin(\ln(x))}{10} + \frac{3\cos(\ln(x))}{10} - 4x \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -2c_1x^2 - 4x\ln(x) - 2c_2x + \frac{\sin(\ln(x))}{10} + \frac{3\cos(\ln(x))}{10} - 4x \tag{1}$$

Verification of solutions

$$y = -2c_1x^2 - 4x\ln(x) - 2c_2x + \frac{\sin(\ln(x))}{10} + \frac{3\cos(\ln(x))}{10} - 4x$$

Verified OK.

16.10.8 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 2y'x + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 554: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{\ln(x)} \\
&= z_1(x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2}\, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{2\ln(x)}}{(y_1)^2} \, dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x) + c_2(x(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2 y'' - 2y'x + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_2 x^2 + c_1 x
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = x^2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & x^2 \\ \frac{d}{dx}(x) & \frac{d}{dx}(x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & x^2 \\ 1 & 2x \end{vmatrix}$$

Therefore

$$W = (x)(2x) - (x^2)(1)$$

Which simplifies to

$$W = x^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^2(4x + \sin(\ln(x)))}{x^4} \, dx$$

Which simplifies to

$$u_1 = -\int \frac{4x + \sin(\ln(x))}{x^2} dx$$

Hence

$$u_1 = -4\ln(x) - \frac{-\frac{1}{2} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{2} - \tan\left(\frac{\ln(x)}{2}\right)}{\left(1 + \tan\left(\frac{\ln(x)}{2}\right)^2\right) x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(4x + \sin(\ln(x)))}{x^4} \, dx$$

Which simplifies to

$$u_2 = \int \frac{4x + \sin(\ln(x))}{x^3} dx$$

Hence

$$u_2 = -\frac{4}{x} + \frac{-\frac{1}{5} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{5} - \frac{4\tan\left(\frac{\ln(x)}{2}\right)}{5}}{\left(1 + \tan\left(\frac{\ln(x)}{2}\right)^2\right) x^2}$$

Which simplifies to

$$u_1 = \frac{-8x\ln(x) + \sin(\ln(x)) + \cos(\ln(x))}{2x}$$
$$u_2 = \frac{-\frac{\cos(\ln(x))}{5} - \frac{2\sin(\ln(x))}{5} - 4x}{x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\sin(\ln(x))}{10} - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} - 4x$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_2x^2 + c_1x) + \left(\frac{\sin(\ln(x))}{10} - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} - 4x\right)
\end{aligned}
$$

Which simplifies to

$$
y = x(c_2x + c_1) + \frac{\sin(\ln(x))}{10} - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} - 4x
$$

Summary

The solution(s) found are the following

$$
y = x(c_2x + c_1) + \frac{\sin(\ln(x))}{10} - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} - 4x \tag{1}
$$

Verification of solutions

$$
y = x(c_2x + c_1) + \frac{\sin(\ln(x))}{10} - 4x\ln(x) + \frac{3\cos(\ln(x))}{10} - 4x
$$

```

$$\boxed{x^2y'' - y'x + 2y = \ln(x)\,x^2}$$

16.11.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -x, C = 2, f(x) = \ln(x)\,x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - y'x + 2y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - xrx^{r-1} + 2x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - r\,x^r + 2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - r + 2 = 0$$

Or

$$r^2 - 2r + 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= 1 - i \\ r_2 &= 1 + i \end{aligned}$$

The roots are complex conjugate of each others. Let the roots be

$$\begin{aligned} r_1 &= \alpha + i\beta \\ r_2 &= \alpha - i\beta \end{aligned}$$

Where in this case $\alpha = 1$ and $\beta = -1$. Hence the solution becomes

$$\begin{aligned} y &= c_1 x^{r_1} + c_2 x^{r_2} \\ &= c_1 x^{\alpha + i\beta} + c_2 x^{\alpha - i\beta} \\ &= x^\alpha \left(c_1 x^{i\beta} + c_2 x^{-i\beta}\right) \\ &= x^\alpha \left(c_1 e^{\ln\left(x^{i\beta}\right)} + c_2 e^{\ln\left(x^{-i\beta}\right)}\right) \\ &= x^\alpha \left(c_1 e^{i(\beta \ln x)} + c_2 e^{-i(\beta \ln x)}\right) \end{aligned}$$

Using the values for $\alpha = 1, \beta = -1$, the above becomes

$$y = x^1 \left(c_1 e^{-i\ln(x)} + c_2 e^{i\ln(x)}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y = x(c_1 \cos(\ln(x)) + c_2 \sin(\ln(x)))$$

Next, we find the particular solution to the ODE

$$x^2y'' - y'x + 2y = \ln(x)\, x^2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \cos(\ln(x))\, x \\ y_2 &= -\sin(\ln(x))\, x \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(\ln(x))\, x & -\sin(\ln(x))\, x \\ \frac{d}{dx}(\cos(\ln(x))\, x) & \frac{d}{dx}(-\sin(\ln(x))\, x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(\ln(x))\, x & -\sin(\ln(x))\, x \\ -\sin(\ln(x)) + \cos(\ln(x)) & -\sin(\ln(x)) - \cos(\ln(x)) \end{vmatrix}$$

Therefore

$$\begin{aligned} W = {} & (\cos(\ln(x))\, x)\,(-\sin(\ln(x)) - \cos(\ln(x))) \\ & - (-\sin(\ln(x))\, x)\,(-\sin(\ln(x)) + \cos(\ln(x))) \end{aligned}$$

Which simplifies to

$$W = -\sin(\ln(x))^2 x - \cos(\ln(x))^2 x$$

Which simplifies to

$$W = -x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\sin(\ln(x))\, x^3 \ln(x)}{-x^3} dx$$

Which simplifies to

$$u_1 = -\int \sin(\ln(x)) \ln(x)\, dx$$

Hence

$$u_1 = -\left(-\frac{\ln(x)}{2} + \frac{1}{2}\right) x \cos(\ln(x)) - \frac{\sin(\ln(x)) \ln(x)\, x}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(\ln(x))\, x^3 \ln(x)}{-x^3} dx$$

Which simplifies to

$$u_2 = \int -\cos(\ln(x)) \ln(x)\, dx$$

Hence

$$u_2 = -\frac{\ln(x)\cos(\ln(x))\, x}{2} + \left(-\frac{\ln(x)}{2} + \frac{1}{2}\right) x \sin(\ln(x))$$

Which simplifies to

$$u_1 = \left(-\frac{(\sin(\ln(x)) - \cos(\ln(x))) \ln(x)}{2} - \frac{\cos(\ln(x))}{2}\right) x$$

$$u_2 = -\frac{((\ln(x) - 1)\sin(\ln(x)) + \cos(\ln(x)) \ln(x))\, x}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{(\sin(\ln(x)) - \cos(\ln(x)))\ln(x)}{2} - \frac{\cos(\ln(x))}{2}\right)x^2\cos(\ln(x)) + \frac{((\ln(x)-1)\sin(\ln(x)) + \cos(\ln(x))\ln(x))\,x^2\sin(\ln(x))}{2}$$

Which simplifies to

$$y_p(x) = \frac{(\ln(x)-1)\,x^2}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \sin(\ln(x))\,c_2 x + \cos(\ln(x))\,c_1 x - \frac{x^2}{2} + \frac{\ln(x)\,x^2}{2} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \sin(\ln(x))\,c_2 x + \cos(\ln(x))\,c_1 x - \frac{x^2}{2} + \frac{\ln(x)\,x^2}{2} \tag{1}$$

Verification of solutions

$$y = \sin(\ln(x))\,c_2 x + \cos(\ln(x))\,c_1 x - \frac{x^2}{2} + \frac{\ln(x)\,x^2}{2}$$

Verified OK.

16.11.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - y'x + 2y = 0$$

In normal form the ode

$$x^2y'' - y'x + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned}p(x) &= -\frac{1}{x}\\ q(x) &= \frac{2}{x^2}\end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}\tau &= \int e^{-\left(\int p(x)dx\right)}dx\\ &= \int e^{-\left(\int -\frac{1}{x}dx\right)}dx\\ &= \int e^{\ln(x)}\,dx\\ &= \int x dx\\ &= \frac{x^2}{2}\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}q_1(\tau) &= \frac{q(x)}{\tau'(x)^2}\\ &= \frac{\frac{2}{x^2}}{x^2}\\ &= \frac{2}{x^4}\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{x^4} = 0$$

But in terms of τ

$$\frac{2}{x^4} = \frac{1}{2\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{2\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$2\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$2\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0$$

Simplifying gives

$$2r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$2r(r-1) + 0 + 1 = 0$$

Or

$$2r^2 - 2r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2} - \frac{i}{2}$$
$$r_2 = \frac{1}{2} + \frac{i}{2}$$

The roots are complex conjugate of each others. Let the roots be

$$r_1 = \alpha + i\beta$$
$$r_2 = \alpha - i\beta$$

Where in this case $\alpha = \frac{1}{2}$ and $\beta = -\frac{1}{2}$. Hence the solution becomes

$$\begin{aligned}
y(\tau) &= c_1 \tau^{r_1} + c_2 \tau^{r_2} \\
&= c_1 \tau^{\alpha + i\beta} + c_2 \tau^{\alpha - i\beta} \\
&= \tau^{\alpha}\left(c_1 \tau^{i\beta} + c_2 \tau^{-i\beta}\right) \\
&= \tau^{\alpha}\left(c_1 e^{\ln(\tau^{i\beta})} + c_2 e^{\ln(\tau^{-i\beta})}\right) \\
&= \tau^{\alpha}\left(c_1 e^{i(\beta \ln \tau)} + c_2 e^{-i(\beta \ln \tau)}\right)
\end{aligned}$$

Using the values for $\alpha = \frac{1}{2}, \beta = -\frac{1}{2}$, the above becomes

$$y(\tau) = \tau^{\frac{1}{2}}\left(c_1 e^{-\frac{i \ln(\tau)}{2}} + c_2 e^{\frac{i \ln(\tau)}{2}}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y(\tau) = \sqrt{\tau}\left(c_1 \cos\left(\frac{\ln(\tau)}{2}\right) + c_2 \sin\left(\frac{\ln(\tau)}{2}\right)\right)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{2}\, x\left(c_1 \cos\left(\ln(x) - \frac{\ln(2)}{2}\right) + c_2 \sin\left(\ln(x) - \frac{\ln(2)}{2}\right)\right)}{2}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{\sqrt{2}\, x\left(c_1 \cos\left(\ln(x) - \frac{\ln(2)}{2}\right) + c_2 \sin\left(\ln(x) - \frac{\ln(2)}{2}\right)\right)}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \frac{\sqrt{2}\, x \cos(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\, x \sin(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2} \\
y_2 &= \frac{\sqrt{2}\, x \sin(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\, x \cos(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix}
\frac{\sqrt{2}\, x \cos(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\, x \sin(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2} & \frac{\sqrt{2}\, x \sin(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\, x \cos(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2} \\
\frac{d}{dx}\left(\frac{\sqrt{2}\, x \cos(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\, x \sin(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2}\right) & \frac{d}{dx}\left(\frac{\sqrt{2}\, x \sin(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\, x \cos(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2}\right)
\end{vmatrix}
$$

Which gives

$$
W = \begin{vmatrix}
\frac{\sqrt{2}\, x \cos(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\, x \sin(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2} \\
\frac{\sqrt{2}\, \cos(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\, \sin(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\, \sin(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\, \cos(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2} \quad \frac{\sqrt{2}\, \sin(\ln(x)) \cos(}{2}
\end{vmatrix}
$$

Therefore

$$W = \left(\frac{\sqrt{2}\, x \cos\left(\ln\left(x\right)\right) \cos\left(\frac{\ln\left(2\right)}{2}\right)}{2} + \frac{\sqrt{2}\, x \sin\left(\ln\left(x\right)\right) \sin\left(\frac{\ln\left(2\right)}{2}\right)}{2}\right) \left(\frac{\sqrt{2}\, \sin\left(\ln\left(x\right)\right) \cos\left(\frac{\ln\left(2\right)}{2}\right)}{2} + \frac{\sqrt{2}\, \cos\left(\ln\left(x\right)\right) \cos\left(\frac{\ln\left(2\right)}{2}\right)}{2} - \frac{\sqrt{2}\, \cos\left(\ln\left(x\right)\right) \sin\left(\frac{\ln\left(2\right)}{2}\right)}{2} + \frac{\sqrt{2}\, \sin\left(\ln\left(x\right)\right) \sin\left(\frac{\ln\left(2\right)}{2}\right)}{2}\right) - \left(\frac{\sqrt{2}\, x \sin\left(\ln\left(x\right)\right) \cos\left(\frac{\ln\left(2\right)}{2}\right)}{2} - \frac{\sqrt{2}\, x \cos\left(\ln\left(x\right)\right) \sin\left(\frac{\ln\left(2\right)}{2}\right)}{2}\right) \left(\frac{\sqrt{2}\, \cos\left(\ln\left(x\right)\right) \cos\left(\frac{\ln\left(2\right)}{2}\right)}{2} - \frac{\sqrt{2}\, \sin\left(\ln\left(x\right)\right) \cos\left(\frac{\ln\left(2\right)}{2}\right)}{2} + \frac{\sqrt{2}\, \sin\left(\ln\left(x\right)\right) \sin\left(\frac{\ln\left(2\right)}{2}\right)}{2} + \frac{\sqrt{2}\, \cos\left(\ln\left(x\right)\right) \sin\left(\frac{\ln\left(2\right)}{2}\right)}{2}\right)$$

Which simplifies to

$$W = \frac{x \cos\left(\ln\left(x\right)\right)^{2} \cos\left(\frac{\ln\left(2\right)}{2}\right)^{2}}{2} + \frac{x \sin\left(\ln\left(x\right)\right)^{2} \sin\left(\frac{\ln\left(2\right)}{2}\right)^{2}}{2} + \frac{x \sin\left(\ln\left(x\right)\right)^{2} \cos\left(\frac{\ln\left(2\right)}{2}\right)^{2}}{2} + \frac{x \cos\left(\ln\left(x\right)\right)^{2} \sin\left(\frac{\ln\left(2\right)}{2}\right)^{2}}{2}$$

Which simplifies to

$$W = \frac{x}{2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(\frac{\sqrt{2}\, x \sin\left(\ln\left(x\right)\right) \cos\left(\frac{\ln\left(2\right)}{2}\right)}{2} - \frac{\sqrt{2}\, x \cos\left(\ln\left(x\right)\right) \sin\left(\frac{\ln\left(2\right)}{2}\right)}{2}\right) \ln\left(x\right) x^{2}}{\frac{x^{3}}{2}} dx$$

Which simplifies to

$$u_1 = -\int \sqrt{2}\left(\sin\left(\ln\left(x\right)\right)\cos\left(\frac{\ln\left(2\right)}{2}\right) - \cos\left(\ln\left(x\right)\right)\sin\left(\frac{\ln\left(2\right)}{2}\right)\right)\ln\left(x\right)dx$$

Hence

$$u_1 = -\frac{\left(-\frac{\sqrt{2}\,\cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\,\sin\left(\frac{\ln(2)}{2}\right)}{2}\right)x\ln\left(x\right) + \left(\sqrt{2}\,\cos\left(\frac{\ln(2)}{2}\right) - \sqrt{2}\,\sin\left(\frac{\ln(2)}{2}\right)\right)x\ln\left(x\right)\tan\left(\frac{\ln(x)}{2}\right) + \left(\cdots\right.}{1\cdots}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\left(\frac{\sqrt{2}\,x\cos(\ln(x))\cos\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\,x\sin(\ln(x))\sin\left(\frac{\ln(2)}{2}\right)}{2}\right)\ln\left(x\right)x^2}{\frac{x^3}{2}}dx$$

Which simplifies to

$$u_2 = \int \sqrt{2}\left(\cos\left(\ln\left(x\right)\right)\cos\left(\frac{\ln\left(2\right)}{2}\right) + \sin\left(\ln\left(x\right)\right)\sin\left(\frac{\ln\left(2\right)}{2}\right)\right)\ln\left(x\right)dx$$

Hence

$$u_2 = \frac{\left(\frac{\sqrt{2}\,\cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\,\sin\left(\frac{\ln(2)}{2}\right)}{2}\right)x\ln\left(x\right) + \left(\sqrt{2}\,\cos\left(\frac{\ln(2)}{2}\right) + \sqrt{2}\,\sin\left(\frac{\ln(2)}{2}\right)\right)x\ln\left(x\right)\tan\left(\frac{\ln(x)}{2}\right) + \left(-\frac{\sqrt{2}\,c\cdots}{}\right.}{1+\cdots}$$

Which simplifies to

$$u_1 = \frac{\left(\left(\cos\left(\ln\left(x\right)\right)\left(\ln\left(x\right)-1\right) - \sin\left(\ln\left(x\right)\right)\ln\left(x\right)\right)\cos\left(\frac{\ln(2)}{2}\right) + \left(\left(\ln\left(x\right)-1\right)\sin\left(\ln\left(x\right)\right) + \cos\left(\ln\left(x\right)\right)\ln\left(x\right)\right)\cdots}{2}$$

$$u_2 = \frac{\left(\left(\left(\ln\left(x\right)-1\right)\sin\left(\ln\left(x\right)\right) + \cos\left(\ln\left(x\right)\right)\ln\left(x\right)\right)\cos\left(\frac{\ln(2)}{2}\right) - \sin\left(\frac{\ln(2)}{2}\right)\left(\cos\left(\ln\left(x\right)\right)\left(\ln\left(x\right)-1\right) - \sin\left(\ln\cdots\right.\right.}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\left(\left(\cos\left(\ln\left(x\right)\right)\left(\ln\left(x\right)-1\right)-\sin\left(\ln\left(x\right)\right)\ln\left(x\right)\right)\cos\left(\frac{\ln(2)}{2}\right)+\left(\left(\ln\left(x\right)-1\right)\sin\left(\ln\left(x\right)\right)+\cos\left(\ln\left(x\right)\right)\ln\left(x\right)\right)\right.}{2} + \frac{\left(\left(\left(\ln\left(x\right)-1\right)\sin\left(\ln\left(x\right)\right)+\cos\left(\ln\left(x\right)\right)\ln\left(x\right)\right)\cos\left(\frac{\ln(2)}{2}\right)-\sin\left(\frac{\ln(2)}{2}\right)\left(\cos\left(\ln\left(x\right)\right)\left(\ln\left(x\right)-1\right)-\sin\left(\right.\right.\right.}{2}$$

Which simplifies to

$$y_p(x) = \frac{\left(\ln\left(x\right)-1\right)x^2}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{\sqrt{2}\,x\left(c_1\cos\left(\ln\left(x\right)-\frac{\ln(2)}{2}\right)+c_2\sin\left(\ln\left(x\right)-\frac{\ln(2)}{2}\right)\right)}{2}\right)+\left(\frac{\left(\ln\left(x\right)-1\right)x^2}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{2}\,x\left(c_1\cos\left(\ln\left(x\right)-\frac{\ln(2)}{2}\right)+c_2\sin\left(\ln\left(x\right)-\frac{\ln(2)}{2}\right)\right)}{2}+\frac{\left(\ln\left(x\right)-1\right)x^2}{2} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{2}\,x\left(c_1\cos\left(\ln\left(x\right)-\frac{\ln(2)}{2}\right)+c_2\sin\left(\ln\left(x\right)-\frac{\ln(2)}{2}\right)\right)}{2}+\frac{\left(\ln\left(x\right)-1\right)x^2}{2}$$

Verified OK.

16.11.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -x, C = 2, f(x) = \ln(x)\, x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - y'x + 2y = 0$$

In normal form the ode

$$x^2y'' - y'x + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= \frac{2}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{2}\,\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\, x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{1}{x}\frac{\sqrt{2}\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{2}\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= -c\sqrt{2}
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - c\sqrt{2}\left(\frac{d}{d\tau}y(\tau)\right) + c^2 y(\tau) &= 0
\end{aligned}
\tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = \mathrm{e}^{\frac{\sqrt{2}\,c\tau}{2}}\left(c_1\cos\left(\frac{\sqrt{2}\,c\tau}{2}\right) + c_2\sin\left(\frac{\sqrt{2}\,c\tau}{2}\right)\right)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{2}\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{2}\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = x(c_1\cos(\ln(x)) + c_2\sin(\ln(x)))
$$

Now the particular solution to this ODE is found

$$
x^2y'' - y'x + 2y = \ln(x)\,x^2
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{\sqrt{2}\, x \cos\left(\ln\left(x\right)\right) \cos\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\, x \sin\left(\ln\left(x\right)\right) \sin\left(\frac{\ln(2)}{2}\right)}{2}$$

$$y_2 = \frac{\sqrt{2}\, x \sin\left(\ln\left(x\right)\right) \cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\, x \cos\left(\ln\left(x\right)\right) \sin\left(\frac{\ln(2)}{2}\right)}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{\sqrt{2}\, x \cos(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\, x \sin(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2} & \frac{\sqrt{2}\, x \sin(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\, x \cos(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2} \\ \frac{d}{dx}\left(\frac{\sqrt{2}\, x \cos(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\, x \sin(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2}\right) & \frac{d}{dx}\left(\frac{\sqrt{2}\, x \sin(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\, x \cos(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{\sqrt{2}\, x \cos(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\, x \sin(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2} \\ \frac{\sqrt{2}\, \cos(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\, \sin(\ln(x)) \cos\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\, \sin(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\, \cos(\ln(x)) \sin\left(\frac{\ln(2)}{2}\right)}{2} \quad \frac{\sqrt{2}\, \sin(\ln(x)) \cos\left(\right.}{2}$$

Therefore

$$W = \left(\frac{\sqrt{2}\,x\cos(\ln(x))\cos\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\,x\sin(\ln(x))\sin\left(\frac{\ln(2)}{2}\right)}{2}\right)\left(\frac{\sqrt{2}\,\sin(\ln(x))\cos\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\,\cos(\ln(x))\cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\,\cos(\ln(x))\sin\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\,\sin(\ln(x))\sin\left(\frac{\ln(2)}{2}\right)}{2}\right) - \left(\frac{\sqrt{2}\,x\sin(\ln(x))\cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\,x\cos(\ln(x))\sin\left(\frac{\ln(2)}{2}\right)}{2}\right)\left(\frac{\sqrt{2}\,\cos(\ln(x))\cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\,\sin(\ln(x))\cos\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\,\sin(\ln(x))\sin\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\,\cos(\ln(x))\sin\left(\frac{\ln(2)}{2}\right)}{2}\right)$$

Which simplifies to

$$W = \frac{x\cos(\ln(x))^2\cos\left(\frac{\ln(2)}{2}\right)^2}{2} + \frac{x\sin(\ln(x))^2\sin\left(\frac{\ln(2)}{2}\right)^2}{2} + \frac{x\sin(\ln(x))^2\cos\left(\frac{\ln(2)}{2}\right)^2}{2} + \frac{x\cos(\ln(x))^2\sin\left(\frac{\ln(2)}{2}\right)^2}{2}$$

Which simplifies to

$$W = \frac{x}{2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(\frac{\sqrt{2}\,x\sin(\ln(x))\cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\,x\cos(\ln(x))\sin\left(\frac{\ln(2)}{2}\right)}{2}\right)\ln(x)\,x^2}{\frac{x^3}{2}}\,dx$$

Which simplifies to

$$u_1 = -\int \sqrt{2}\left(\sin(\ln(x))\cos\left(\frac{\ln(2)}{2}\right) - \cos(\ln(x))\sin\left(\frac{\ln(2)}{2}\right)\right)\ln(x)\,dx$$

Hence

$$u_1 = -\frac{\left(-\frac{\sqrt{2}\,\cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\,\sin\left(\frac{\ln(2)}{2}\right)}{2}\right) x\ln(x) + \left(\sqrt{2}\,\cos\left(\frac{\ln(2)}{2}\right) - \sqrt{2}\,\sin\left(\frac{\ln(2)}{2}\right)\right) x\ln(x)\tan\left(\frac{\ln(x)}{2}\right) + \left(\sqrt{\ }\right.}{1}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\left(\frac{\sqrt{2}\,x\cos(\ln(x))\cos\left(\frac{\ln(2)}{2}\right)}{2} + \frac{\sqrt{2}\,x\sin(\ln(x))\sin\left(\frac{\ln(2)}{2}\right)}{2}\right)\ln(x)\,x^2}{\frac{x^3}{2}}\,dx$$

Which simplifies to

$$u_2 = \int \sqrt{2}\left(\cos(\ln(x))\cos\left(\frac{\ln(2)}{2}\right) + \sin(\ln(x))\sin\left(\frac{\ln(2)}{2}\right)\right)\ln(x)\,dx$$

Hence

$$u_2 = \frac{\left(\frac{\sqrt{2}\,\cos\left(\frac{\ln(2)}{2}\right)}{2} - \frac{\sqrt{2}\,\sin\left(\frac{\ln(2)}{2}\right)}{2}\right) x\ln(x) + \left(\sqrt{2}\,\cos\left(\frac{\ln(2)}{2}\right) + \sqrt{2}\,\sin\left(\frac{\ln(2)}{2}\right)\right) x\ln(x)\tan\left(\frac{\ln(x)}{2}\right) + \left(-\frac{\sqrt{2}\,c}{}\right.}{1+}$$

Which simplifies to

$$u_1 = \frac{\left((\cos(\ln(x))(\ln(x)-1) - \sin(\ln(x))\ln(x))\cos\left(\frac{\ln(2)}{2}\right) + ((\ln(x)-1)\sin(\ln(x)) + \cos(\ln(x))\ln(x))\right.}{2}$$

$$u_2 = \frac{\left(((\ln(x)-1)\sin(\ln(x)) + \cos(\ln(x))\ln(x))\cos\left(\frac{\ln(2)}{2}\right) - \sin\left(\frac{\ln(2)}{2}\right)(\cos(\ln(x))(\ln(x)-1) - \sin(\ln\right.}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\left(\left(\cos(\ln(x))(\ln(x)-1) - \sin(\ln(x))\ln(x)\right)\cos\left(\frac{\ln(2)}{2}\right) + \left((\ln(x)-1)\sin(\ln(x)) + \cos(\ln(x))\ln(x)\right)\right.}{2} + \frac{\left(\left((\ln(x)-1)\sin(\ln(x)) + \cos(\ln(x))\ln(x)\right)\cos\left(\frac{\ln(2)}{2}\right) - \sin\left(\frac{\ln(2)}{2}\right)\left(\cos(\ln(x))(\ln(x)-1) - \sin(\right.\right.}{2}$$

Which simplifies to

$$y_p(x) = \frac{(\ln(x)-1)\,x^2}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (x(c_1\cos(\ln(x)) + c_2\sin(\ln(x)))) + \left(\frac{(\ln(x)-1)\,x^2}{2}\right) \\ &= \frac{(\ln(x)-1)\,x^2}{2} + x(c_1\cos(\ln(x)) + c_2\sin(\ln(x))) \end{aligned}$$

Which simplifies to

$$y = \sin(\ln(x))\,c_2x + \cos(\ln(x))\,c_1x - \frac{x^2}{2} + \frac{\ln(x)\,x^2}{2}$$

Summary

The solution(s) found are the following

$$y = \sin(\ln(x))\,c_2x + \cos(\ln(x))\,c_1x - \frac{x^2}{2} + \frac{\ln(x)\,x^2}{2} \tag{1}$$

Verification of solutions

$$y = \sin(\ln(x))\,c_2x + \cos(\ln(x))\,c_1x - \frac{x^2}{2} + \frac{\ln(x)\,x^2}{2}$$

Verified OK.

16.11.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -x, C = 2, f(x) = \ln(x)\,x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - y'x + 2y = 0$$

In normal form the ode

$$x^2y'' - y'x + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= \frac{2}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right)v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right)v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{n}{x^2} + \frac{2}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 1 + i \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{2+2i}{x} - \frac{1}{x}\right) v'(x) &= 0 \\ v''(x) + \frac{(1+2i)\, v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(1+2i)\, u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{(-1-2i)\, u}{x} \end{aligned}$$

Where $f(x) = \frac{-1-2i}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= \frac{-1-2i}{x}\, dx \\ \int \frac{1}{u}\, du &= \int \frac{-1-2i}{x}\, dx \\ \ln(u) &= (-1-2i)\ln(x) + c_1 \\ u &= \mathrm{e}^{(-1-2i)\ln(x)+c_1} \\ &= c_1 \mathrm{e}^{(-1-2i)\ln(x)} \end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1 x^{-2i}}{x}$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= \frac{i c_1 x^{-2i}}{2} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\,x^n \\
&= \left(\frac{i c_1 x^{-2i}}{2} + c_2\right) x^{1+i} \\
&= x^{1+i} c_2 + \frac{i x^{1-i} c_1}{2}
\end{aligned}$$

Now the particular solution to this ODE is found

$$x^2 y'' - y' x + 2y = \ln(x)\, x^2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= x\, x^{-i} \\
y_2 &= x\, x^{i}
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x\,x^{-i} & x\,x^{i} \\ \frac{d}{dx}(x\,x^{-i}) & \frac{d}{dx}(x\,x^{i}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x\,x^{-i} & x\,x^{i} \\ x^{-i} - ix^{-i} & x^{i} + ix^{i} \end{vmatrix}$$

Therefore

$$W = (x\,x^{-i})\,(x^{i} + ix^{i}) - (x\,x^{i})\,(x^{-i} - ix^{-i})$$

Which simplifies to

$$W = 2ix$$

Which simplifies to

$$W = 2ix$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^3 x^i \ln(x)}{2ix^3}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{ix^i \ln(x)}{2}dx$$

Hence

$$u_1 = \frac{x^{1+i}(-1 + (1+i)\ln(x))}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^3 x^{-i} \ln(x)}{2ix^3}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{ix^{-i} \ln(x)}{2}dx$$

Hence

$$u_2 = -\frac{(1+(-1+i)\ln(x))\, x^{1-i}}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x^{1+i}(-1+(1+i)\ln(x))\, x\, x^{-i}}{4} - \frac{(1+(-1+i)\ln(x))\, x^{1-i} x\, x^{i}}{4}$$

Which simplifies to

$$y_p(x) = \frac{(\ln(x)-1)\, x^2}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(\frac{i c_1 x^{-2i}}{2} + c_2\right) x^{1+i}\right) + \left(\frac{(\ln(x)-1)\, x^2}{2}\right) \\ &= \frac{(\ln(x)-1)\, x^2}{2} + \left(\frac{i c_1 x^{-2i}}{2} + c_2\right) x^{1+i} \end{aligned}$$

Which simplifies to

$$y = \frac{i x^{1-i} c_1}{2} + x^{1+i} c_2 + \frac{(\ln(x)-1)\, x^2}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{i x^{1-i} c_1}{2} + x^{1+i} c_2 + \frac{(\ln(x)-1)\, x^2}{2} \tag{1}$$

Verification of solutions

$$y = \frac{i x^{1-i} c_1}{2} + x^{1+i} c_2 + \frac{(\ln(x)-1)\, x^2}{2}$$

Verified OK.

16.11.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - y'x + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-5}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -5 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{5}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 555: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{5}{4x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + i \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - i
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = -\frac{5}{4x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{5}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + i \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - i
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{5}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2} + i$	$\frac{1}{2} - i$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2} + i$	$\frac{1}{2} - i$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = \frac{1}{2} - i$ then

$$\begin{aligned} d &= \alpha_{\infty}^{-} - (\alpha_{c_1}^{-}) \\ &= \frac{1}{2} - i - \left(\frac{1}{2} - i\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\ &= \frac{\frac{1}{2} - i}{x} + (-)(0) \\ &= \frac{\frac{1}{2} - i}{x} \\ &= \frac{\frac{1}{2} - i}{x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{\frac{1}{2} - i}{x}\right)(0) + \left(\left(\frac{-\frac{1}{2} + i}{x^2}\right) + \left(\frac{\frac{1}{2} - i}{x}\right)^2 - \left(-\frac{5}{4x^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \frac{\frac{1}{2} - i}{x} dx} \\ &= x^{\frac{1}{2} - i} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x}{x^2}\,dx} \\
&= z_1 e^{\frac{\ln(x)}{2}} \\
&= z_1\left(\sqrt{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{1-i}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{i x^{2i}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^{1-i}\right) + c_2\left(x^{1-i}\left(-\frac{i x^{2i}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' - y'x + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = x^{1-i} c_1 - \frac{i c_2 x^{1+i}}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^{1-i}$$
$$y_2 = -\frac{i x^{1+i}}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^{1-i} & -\frac{i x^{1+i}}{2} \\ \frac{d}{dx}\left(x^{1-i}\right) & \frac{d}{dx}\left(-\frac{i x^{1+i}}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^{1-i} & -\frac{i x^{1+i}}{2} \\ \frac{(1-i) x^{1-i}}{x} & \frac{\left(\frac{1}{2}-\frac{i}{2}\right) x^{1+i}}{x} \end{vmatrix}$$

Therefore

$$W = \left(x^{1-i}\right)\left(\frac{\left(\frac{1}{2}-\frac{i}{2}\right)x^{1+i}}{x}\right) - \left(-\frac{i x^{1+i}}{2}\right)\left(\frac{(1-i)\,x^{1-i}}{x}\right)$$

Which simplifies to

$$W = \frac{x^{1-i}x^{1+i}}{x}$$

Which simplifies to

$$W = x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{i x^{1+i}\ln(x)x^2}{2}}{x^3}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{i x^{i}\ln(x)}{2}dx$$

Hence

$$u_1 = \frac{x^{1+i}(-1+(1+i)\ln(x))}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^{1-i}\ln(x)\,x^2}{x^3}\,dx$$

Which simplifies to

$$u_2 = \int x^{-i}\ln(x)\,dx$$

Hence

$$u_2 = \frac{(-i+(1+i)\ln(x))\,x^{1-i}}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x^{1+i}(-1+(1+i)\ln(x))\,x^{1-i}}{4} - \frac{i(-i+(1+i)\ln(x))\,x^{1-i}x^{1+i}}{4}$$

Which simplifies to

$$y_p(x) = \frac{(\ln (x) - 1) x^2}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(x^{1-i} c_1 - \frac{i c_2 x^{1+i}}{2}\right) + \left(\frac{(\ln (x) - 1) x^2}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = x^{1-i} c_1 - \frac{i c_2 x^{1+i}}{2} + \frac{(\ln (x) - 1) x^2}{2} \tag{1}$$

Verification of solutions

$$y = x^{1-i} c_1 - \frac{i c_2 x^{1+i}}{2} + \frac{(\ln (x) - 1) x^2}{2}$$

Verified OK.

$$\boxed{x^2y'' + 4y'x + 3y = \ln(x)(x-1)}$$

16.12.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 4x, C = 3, f(x) = \ln(x)(x-1)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 4y'x + 3y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 4xrx^{r-1} + 3x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 4r\,x^r + 3x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 4r + 3 = 0$$

Or

$$r^2 + 3r + 3 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= -\frac{i\sqrt{3}}{2} - \frac{3}{2} \\ r_2 &= \frac{i\sqrt{3}}{2} - \frac{3}{2} \end{aligned}$$

The roots are complex conjugate of each others. Let the roots be

$$\begin{aligned} r_1 &= \alpha + i\beta \\ r_2 &= \alpha - i\beta \end{aligned}$$

Where in this case $\alpha = -\frac{3}{2}$ and $\beta = -\frac{\sqrt{3}}{2}$. Hence the solution becomes

$$\begin{aligned} y &= c_1 x^{r_1} + c_2 x^{r_2} \\ &= c_1 x^{\alpha+i\beta} + c_2 x^{\alpha-i\beta} \\ &= x^\alpha \left(c_1 x^{i\beta} + c_2 x^{-i\beta}\right) \\ &= x^\alpha \left(c_1 e^{\ln(x^{i\beta})} + c_2 e^{\ln(x^{-i\beta})}\right) \\ &= x^\alpha \left(c_1 e^{i(\beta \ln x)} + c_2 e^{-i(\beta \ln x)}\right) \end{aligned}$$

Using the values for $\alpha = -\frac{3}{2}, \beta = -\frac{\sqrt{3}}{2}$, the above becomes

$$y = x^{-\frac{3}{2}} \left(c_1 e^{-\frac{i\sqrt{3}\,\ln(x)}{2}} + c_2 e^{\frac{i\sqrt{3}\,\ln(x)}{2}}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y = \frac{1}{x^{\frac{3}{2}}} \left(c_1 \cos \left(\frac{\sqrt{3}\, \ln(x)}{2} \right) + c_2 \sin \left(\frac{\sqrt{3}\, \ln(x)}{2} \right) \right)$$

Next, we find the particular solution to the ODE

$$x^2 y'' + 4y'x + 3y = \ln(x)\,(x - 1)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{x^{\frac{3}{2}}}$$

$$y_2 = -\frac{\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{x^{\frac{3}{2}}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{x^{\frac{3}{2}}} & -\frac{\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{x^{\frac{3}{2}}} \\ \frac{d}{dx}\left(\frac{\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{x^{\frac{3}{2}}}\right) & \frac{d}{dx}\left(-\frac{\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{x^{\frac{3}{2}}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{x^{\frac{3}{2}}} & -\frac{\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{x^{\frac{3}{2}}} \\ -\frac{3\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{2x^{\frac{5}{2}}} - \frac{\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{2x^{\frac{5}{2}}} & \frac{3\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{2x^{\frac{5}{2}}} - \frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{2x^{\frac{5}{2}}} \end{vmatrix}$$

Therefore

$$W = \left(\frac{\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{x^{\frac{3}{2}}}\right)\left(\frac{3\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{2x^{\frac{5}{2}}} - \frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{2x^{\frac{5}{2}}}\right) - \left(-\frac{\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{x^{\frac{3}{2}}}\right)\left(-\frac{3\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{2x^{\frac{5}{2}}} - \frac{\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{2x^{\frac{5}{2}}}\right)$$

Which simplifies to

$$W = -\frac{\sqrt{3}\left(\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)^2 + \sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)^2\right)}{2x^4}$$

Which simplifies to

$$W = -\frac{\sqrt{3}}{2x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)\ln(x)(x-1)}{x^{\frac{3}{2}}}}{-\frac{\sqrt{3}}{2x^2}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{2\sqrt{x}\,\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)\ln(x)\,(x-1)\,\sqrt{3}}{3}dx$$

Hence

$$u_1 = \frac{\left(\left(\left(x-\frac{7}{3}\right)\ln(x) - \frac{5x}{7} + \frac{7}{3}\right)\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right) - 5\left(\left(x-\frac{7}{5}\right)\ln(x) - \frac{11x}{35} + \frac{7}{15}\right)\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)\right)x^{\frac{3}{2}}\sqrt{3}}{21}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)\ln(x)(x-1)}{x^{\frac{3}{2}}}}{-\frac{\sqrt{3}}{2x^2}}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{2\sqrt{x}\,\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)\ln\left(x\right)\left(x-1\right)\sqrt{3}}{3}dx$$

Hence

$$u_2 = -\frac{\left(\left((5x-7)\ln\left(x\right)-\frac{11x}{7}+\frac{7}{3}\right)\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)+\left(\left(x-\frac{7}{3}\right)\ln\left(x\right)-\frac{5x}{7}+\frac{7}{3}\right)\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)\right)x^{\frac{3}{2}}\sqrt{3}}{21}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\left(\left(\left(x-\frac{7}{3}\right)\ln\left(x\right)-\frac{5x}{7}+\frac{7}{3}\right)\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)-5\left(\left(x-\frac{7}{5}\right)\ln\left(x\right)-\frac{11x}{35}+\frac{7}{15}\right)\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)\right)\sqrt{3}\,\cos\left(\frac{\sqrt{3}\right.}{21} + \frac{\left(\left((5x-7)\ln\left(x\right)-\frac{11x}{7}+\frac{7}{3}\right)\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)+\left(\left(x-\frac{7}{3}\right)\ln\left(x\right)-\frac{5x}{7}+\frac{7}{3}\right)\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)\right)\sqrt{3}\,\sin\left(\frac{\sqrt{3}\right.}{21}$$

Which simplifies to

$$y_p(x) = \frac{1}{3} + \frac{(3x-7)\ln\left(x\right)}{21} - \frac{5x}{49}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \frac{1}{3} + \frac{(3x-7)\ln\left(x\right)}{21} - \frac{5x}{49} + \frac{c_1\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)+c_2\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{x^{\frac{3}{2}}} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{3} + \frac{(3x-7)\ln\left(x\right)}{21} - \frac{5x}{49} + \frac{c_1\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)+c_2\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{x^{\frac{3}{2}}} \tag{1}$$

Verification of solutions

$$y=\frac{1}{3}+\frac{(3x-7)\ln(x)}{21}-\frac{5x}{49}+\frac{c_1\cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)+c_2\sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{x^{\frac{3}{2}}}$$

Verified OK.

16.12.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$x^2y''+4y'x+3y=0$$

In normal form the ode

$$x^2y''+4y'x+3y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$p(x)=\frac{4}{x}$$
$$q(x)=\frac{3}{x^2}$$

Applying change of variables $\tau=g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau)+p_1\left(\frac{d}{d\tau}y(\tau)\right)+q_1y(\tau)=0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau)=\frac{\tau''(x)+p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau)=\frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\
&= \int \mathrm{e}^{-\left(\int \frac{4}{x}dx\right)} dx \\
&= \int e^{-4\ln(x)}\, dx \\
&= \int \frac{1}{x^4} dx \\
&= -\frac{1}{3x^3} \qquad (6)
\end{aligned}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{3}{x^2}}{\frac{1}{x^8}} \\
&= 3x^6 \qquad (7)
\end{aligned}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + 3x^6 y(\tau) &= 0
\end{aligned}$$

But in terms of τ

$$3x^6 = \frac{1}{3\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{3\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$3\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$3\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0$$

Simplifying gives

$$3r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$3r(r-1) + 0 + 1 = 0$$

Or

$$3r^2 - 3r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2} - \frac{i\sqrt{3}}{6}$$
$$r_2 = \frac{1}{2} + \frac{i\sqrt{3}}{6}$$

The roots are complex conjugate of each others. Let the roots be

$$r_1 = \alpha + i\beta$$
$$r_2 = \alpha - i\beta$$

Where in this case $\alpha = \frac{1}{2}$ and $\beta = -\frac{\sqrt{3}}{6}$. Hence the solution becomes

$$\begin{aligned} y(\tau) &= c_1\tau^{r_1} + c_2\tau^{r_2} \\ &= c_1\tau^{\alpha+i\beta} + c_2\tau^{\alpha-i\beta} \\ &= \tau^\alpha\left(c_1\tau^{i\beta} + c_2\tau^{-i\beta}\right) \\ &= \tau^\alpha\left(c_1e^{\ln(\tau^{i\beta})} + c_2e^{\ln(\tau^{-i\beta})}\right) \\ &= \tau^\alpha\left(c_1e^{i(\beta\ln\tau)} + c_2e^{-i(\beta\ln\tau)}\right) \end{aligned}$$

Using the values for $\alpha = \frac{1}{2}, \beta = -\frac{\sqrt{3}}{6}$, the above becomes

$$y(\tau) = \tau^{\frac{1}{2}}\left(c_1e^{-\frac{i\sqrt{3}\,\ln(\tau)}{6}} + c_2e^{\frac{i\sqrt{3}\,\ln(\tau)}{6}}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y(\tau) = \sqrt{\tau}\left(c_1 \cos\left(\frac{\sqrt{3}\,\ln(\tau)}{6}\right) + c_2 \sin\left(\frac{\sqrt{3}\,\ln(\tau)}{6}\right)\right)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\left(c_1 \cos\left(\frac{\sqrt{3}\left(-\ln(3)+\ln\left(-\frac{1}{x^3}\right)\right)}{6}\right) + c_2 \sin\left(\frac{\sqrt{3}\left(-\ln(3)+\ln\left(-\frac{1}{x^3}\right)\right)}{6}\right)\right)\sqrt{3}\,\sqrt{-\frac{1}{x^3}}}{3}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{\left(c_1 \cos\left(\frac{\sqrt{3}\left(-\ln(3)+\ln\left(-\frac{1}{x^3}\right)\right)}{6}\right) + c_2 \sin\left(\frac{\sqrt{3}\left(-\ln(3)+\ln\left(-\frac{1}{x^3}\right)\right)}{6}\right)\right)\sqrt{3}\,\sqrt{-\frac{1}{x^3}}}{3}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3}$$

$$y_2 = -\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)}{3}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} & -\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}}{\ldots}\right.}{\ldots} \\ \frac{d}{dx}\left(\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3}\right) & \frac{d}{dx}\left(-\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\ldots\right.}{\ldots}\right.\end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{\ldots} \\ \frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2\sqrt{-\frac{1}{x^3}}\,x^4} + \frac{\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2x} + \frac{\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2\sqrt{-\frac{1}{x^3}}\,x^4} - \frac{\sqrt{\ldots}}{\ldots} \end{vmatrix}$$

Therefore

$$W = \left(\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3}\right)\left(-\frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2\sqrt{-\frac{1}{x^3}}\,x^4} - \frac{\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2x} + \frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)}{2\sqrt{-\frac{1}{x^3}}\,x^4} - \frac{\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)}{2x}\right) - \left(-\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)}{3}\right)\left(\frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2\sqrt{-\frac{1}{x^3}}\,x^4} + \frac{\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2x} + \frac{\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2\sqrt{-\frac{1}{x^3}}\,x^4} - \frac{\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2x}\right)$$

Which simplifies to

$$W = \frac{\sqrt{3}\left(\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)^2\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)^2 + \cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)^2\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)^2 + \cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)^2\sin\left(\frac{\sqrt{3}\,\ln(-}{6}\right.}{6x^4}$$

Which simplifies to

$$W = \frac{\sqrt{3}}{6x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(-\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)}{3}\right)\ln(x)\,(x-1)}{\frac{\sqrt{3}}{6x^2}}dx$$

Which simplifies to

$$u_1 = -\int -2\sqrt{-\frac{1}{x^3}}\left(-\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) + \cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\right)\ln(x)\,(x-1)\,x^2dx$$

Hence

$$u_1 = -\left(\int_0^x -2\sqrt{-\frac{1}{\alpha^3}}\left(-\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) + \cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\right)\ln(\alpha)\,(\alpha-1)\,\alpha^2d\alpha\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\left(\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3}\right)\ln(x)\,(x-1)}{\frac{\sqrt{3}}{6x^2}}dx$$

Which simplifies to

$$u_2 = \int 2\sqrt{-\frac{1}{x^3}}\left(\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) + \sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\right)\ln(x)(x-1)\,x^2 dx$$

Hence

$$u_2 = \int_0^x 2\sqrt{-\frac{1}{\alpha^3}}\left(\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) + \sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\right)\ln(\alpha)(\alpha-1)\,\alpha^2 d\alpha$$

Which simplifies to

$$u_1 = -2\left(\int_0^x \left(\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) - \cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\right)\sqrt{-\frac{1}{\alpha^3}}\,\ln(\alpha)(\alpha-1)\,\alpha^2 d\alpha\right)$$

$$u_2 = 2\left(\int_0^x \sqrt{-\frac{1}{\alpha^3}}\left(\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) + \sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\right)\ln(\alpha)(\alpha-1)\,\alpha^2 d\alpha\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2\left(\int_0^x \left(\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) - \cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\right)\sqrt{-\frac{1}{\alpha^3}}\,\ln(\alpha)\,(\alpha - 1)\,\alpha^2 d\alpha\right)\left(\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3}\right) + 2\left(\int_0^x \sqrt{-\frac{1}{\alpha^3}}\left(\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) + \sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\right)\ln(\alpha)\,(\alpha - 1)\,\alpha^2 d\alpha\right)\left(-\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)}{3}\right)$$

Which simplifies to

$$y_p(x) = -\frac{2\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\left(\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\left(\int_0^x \left(\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) - \cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right.\right.\right.\right.}{}$$

Therefore the general solution is

$$y = y_h + y_p$$

$$= \left(\frac{\left(c_1 \cos\left(\frac{\sqrt{3}\left(-\ln(3)+\ln\left(-\frac{1}{x^3}\right)\right)}{6}\right) + c_2 \sin\left(\frac{\sqrt{3}\left(-\ln(3)+\ln\left(-\frac{1}{x^3}\right)\right)}{6}\right)\right)\sqrt{3}\sqrt{-\frac{1}{x^3}}}{3} \right)$$

$$+ \left(-\frac{2\sqrt{3}\sqrt{-\frac{1}{x^3}}\left(\cos\left(\frac{\sqrt{3}\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\ln(3)}{6}\right)\left(\int_0^x \left(\sin\left(\frac{\sqrt{3}\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\ln(3)}{6}\right) - \cos\left(\frac{\sqrt{3}\ln(\right.\right.\right.\right.}{}\right.$$

Summary

The solution(s) found are the following

$$y = \frac{\left(c_1 \cos\left(\frac{\sqrt{3}\left(-\ln(3)+\ln\left(-\frac{1}{x^3}\right)\right)}{6}\right) + c_2 \sin\left(\frac{\sqrt{3}\left(-\ln(3)+\ln\left(-\frac{1}{x^3}\right)\right)}{6}\right)\right)\sqrt{3}\sqrt{-\frac{1}{x^3}}}{3} \quad (1)$$

$$- \frac{2\sqrt{3}\sqrt{-\frac{1}{x^3}}\left(\cos\left(\frac{\sqrt{3}\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\ln(3)}{6}\right)\left(\int_0^x \left(\sin\left(\frac{\sqrt{3}\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\ln(3)}{6}\right) - \cos\left(\frac{\sqrt{3}\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right.\right.\right.\right.}{}$$

Verification of solutions

$$y = \frac{\left(c_1 \cos\left(\frac{\sqrt{3}\left(-\ln(3)+\ln\left(-\frac{1}{x^3}\right)\right)}{6}\right) + c_2 \sin\left(\frac{\sqrt{3}\left(-\ln(3)+\ln\left(-\frac{1}{x^3}\right)\right)}{6}\right)\right)\sqrt{3}\sqrt{-\frac{1}{x^3}}}{3}$$

$$- \frac{2\sqrt{3}\sqrt{-\frac{1}{x^3}}\left(\cos\left(\frac{\sqrt{3}\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\ln(3)}{6}\right)\left(\int_0^x \left(\sin\left(\frac{\sqrt{3}\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\ln(3)}{6}\right) - \cos\left(\frac{\sqrt{3}\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right.\right.\right.\right.}{}$$

Verified OK.

16.12.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 4x, C = 3, f(x) = \ln(x)(x-1)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 4y'x + 3y = 0$$

In normal form the ode

$$x^2y'' + 4y'x + 3y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{4}{x} \\ q(x) &= \frac{3}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{3}\,\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{\sqrt{3}}{c\sqrt{\frac{1}{x^2}}\, x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{\sqrt{3}}{c\sqrt{\frac{1}{x^2}}\, x^3} + \frac{4}{x}\frac{\sqrt{3}\,\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{3}\,\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= c\sqrt{3} \end{aligned}$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2} y(\tau) + c\sqrt{3}\left(\frac{d}{d\tau} y(\tau)\right) + c^2 y(\tau) &= 0
\end{aligned}
\tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = \mathrm{e}^{-\frac{\sqrt{3}\,c\tau}{2}} \left(c_1 \cos\left(\frac{c\tau}{2}\right) + c_2 \sin\left(\frac{c\tau}{2}\right)\right)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\, dx \\
&= \frac{\int \sqrt{3}\sqrt{\frac{1}{x^2}} dx}{c} \\
&= \frac{\sqrt{3}\sqrt{\frac{1}{x^2}}\, x \ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = \frac{c_1 \cos\left(\frac{\sqrt{3}\ln(x)}{2}\right) + c_2 \sin\left(\frac{\sqrt{3}\ln(x)}{2}\right)}{x^{\frac{3}{2}}}
$$

Now the particular solution to this ODE is found

$$
x^2 y'' + 4y'x + 3y = \ln(x)(x - 1)
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3}$$

$$y_2 = -\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)}{3}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} & -\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\cdots\right.}{} \\ \frac{d}{dx}\left(\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3}\right) & \frac{d}{dx}\left(-\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\cdots\right.}{}\right. \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} \cdots \\ \frac{\sqrt{3}\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2\sqrt{-\frac{1}{x^3}}\,x^4} + \frac{\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2x} + \frac{\sqrt{3}\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2\sqrt{-\frac{1}{x^3}}\,x^4} - \cdots \end{vmatrix}$$

Therefore

$$W = \left(\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3}\right)\left(-\frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2\sqrt{-\frac{1}{x^3}}\,x^4} - \frac{\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2x} + \frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)}{2\sqrt{-\frac{1}{x^3}}\,x^4} - \frac{\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)}{2x}\right) - \left(-\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)}{3}\right)\left(\frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2\sqrt{-\frac{1}{x^3}}\,x^4} + \frac{\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2x} + \frac{\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2\sqrt{-\frac{1}{x^3}}\,x^4} - \frac{\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{2x}\right)$$

Which simplifies to

$$W = \frac{\sqrt{3}\left(\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)^2\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)^2 + \cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)^2\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)^2 + \cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)^2\sin\left(\frac{\sqrt{3}\,\ln\left(-\right.}{6}\right.}{6x^4}$$

Which simplifies to

$$W = \frac{\sqrt{3}}{6x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(-\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)}{3}\right)\ln(x)(x-1)}{\frac{\sqrt{3}}{6x^2}}dx$$

Which simplifies to

$$u_1 = -\int -2\sqrt{-\frac{1}{x^3}}\left(-\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) + \cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\right)\ln(x)(x-1)\,x^2 dx$$

Hence

$$u_1 = -\left(\int_0^x -2\sqrt{-\frac{1}{\alpha^3}}\left(-\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) + \cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\right)\ln(\alpha)(\alpha-1)\,\alpha^2 d\alpha\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\left(\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3}\right)\ln(x)(x-1)}{\frac{\sqrt{3}}{6x^2}}dx$$

Which simplifies to

$$u_2 = \int 2\sqrt{-\frac{1}{x^3}}\, \left(\cos\left(\frac{\sqrt{3}\, \ln\left(-\frac{1}{x^3}\right)}{6}\right) \cos\left(\frac{\sqrt{3}\, \ln\left(3\right)}{6}\right) + \sin\left(\frac{\sqrt{3}\, \ln\left(-\frac{1}{x^3}\right)}{6}\right) \sin\left(\frac{\sqrt{3}\, \ln\left(3\right)}{6}\right)\right) \ln\left(x\right) \left(x-1\right) x^2 dx$$

Hence

$$u_2 = \int_0^x 2\sqrt{-\frac{1}{\alpha^3}}\, \left(\cos\left(\frac{\sqrt{3}\, \ln\left(-\frac{1}{\alpha^3}\right)}{6}\right) \cos\left(\frac{\sqrt{3}\, \ln\left(3\right)}{6}\right) + \sin\left(\frac{\sqrt{3}\, \ln\left(-\frac{1}{\alpha^3}\right)}{6}\right) \sin\left(\frac{\sqrt{3}\, \ln\left(3\right)}{6}\right)\right) \ln\left(\alpha\right) \left(\alpha-1\right) \alpha^2 d\alpha$$

Which simplifies to

$$u_1 = -2\left(\int_0^x \left(\sin\left(\frac{\sqrt{3}\, \ln\left(-\frac{1}{\alpha^3}\right)}{6}\right) \cos\left(\frac{\sqrt{3}\, \ln\left(3\right)}{6}\right) - \cos\left(\frac{\sqrt{3}\, \ln\left(-\frac{1}{\alpha^3}\right)}{6}\right) \sin\left(\frac{\sqrt{3}\, \ln\left(3\right)}{6}\right)\right) \sqrt{-\frac{1}{\alpha^3}}\, \ln\left(\alpha\right) \left(\alpha-1\right) \alpha^2 d\alpha\right)$$

$$u_2 = 2\left(\int_0^x \sqrt{-\frac{1}{\alpha^3}}\, \left(\cos\left(\frac{\sqrt{3}\, \ln\left(-\frac{1}{\alpha^3}\right)}{6}\right) \cos\left(\frac{\sqrt{3}\, \ln\left(3\right)}{6}\right) + \sin\left(\frac{\sqrt{3}\, \ln\left(-\frac{1}{\alpha^3}\right)}{6}\right) \sin\left(\frac{\sqrt{3}\, \ln\left(3\right)}{6}\right)\right) \ln\left(\alpha\right) \left(\alpha-1\right) \alpha^2 d\alpha\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2\left(\int_0^x \left(\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) - \cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\right)\sqrt{-\frac{1}{\alpha^3}}\,\ln(\alpha)\,(\alpha - 1)\,\alpha^2 d\alpha\right)\left(\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3}\right) + 2\left(\int_0^x \sqrt{-\frac{1}{\alpha^3}}\left(\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) + \sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\right)\ln(\alpha)\,(\alpha - 1)\,\alpha^2 d\alpha\right)\left(-\frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)}{3} + \frac{\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\,\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)}{3}\right)$$

Which simplifies to

$$y_p(x) = -\frac{2\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\left(\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\left(\int_0^x \left(\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) - \cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right.\right.\right.\right.}{}$$

Therefore the general solution is

$$y = y_h + y_p$$

$$= \left(\frac{c_1 \cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right) + c_2 \sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{x^{\frac{3}{2}}}\right)$$

$$+ \left(-\frac{2\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\left(\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\left(\int_0^x \left(\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) - \cos\left(\frac{\sqrt{3}\,\ln\left(\right.}{}\right.\right.\right.\right.}{}\right.$$

$$= -\frac{2\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\left(\cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{x^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right)\left(\int_0^x \left(\sin\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right)}{6}\right)\cos\left(\frac{\sqrt{3}\,\ln(3)}{6}\right) - \cos\left(\frac{\sqrt{3}\,\ln\left(-\frac{1}{\alpha^3}\right.}{6}\right.\right.\right.\right.}{}$$

$$+ \frac{c_1 \cos\left(\frac{\sqrt{3}\,\ln(x)}{2}\right) + c_2 \sin\left(\frac{\sqrt{3}\,\ln(x)}{2}\right)}{x^{\frac{3}{2}}}$$

Which simplifies to

$$y = -\frac{2x^{\frac{3}{2}}\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\left(\int_0^x -\sqrt{-\frac{1}{\alpha^3}}\,\ln(\alpha)(\alpha-1)\,\alpha^2 \sin\left(\frac{\sqrt{3}\left(-\ln\left(-\frac{1}{\alpha^3}\right)+\ln(3)\right)}{6}\right)d\alpha\right)\cos\left(\frac{\sqrt{3}\left(-\ln(3)+\ln\left(-\frac{1}{x^3}\right)\right)}{6}\right.}{}$$

Summary

The solution(s) found are the following

$$y = -\frac{2x^{\frac{3}{2}}\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\left(\int_0^x -\sqrt{-\frac{1}{\alpha^3}}\,\ln(\alpha)(\alpha-1)\,\alpha^2 \sin\left(\frac{\sqrt{3}\left(-\ln\left(-\frac{1}{\alpha^3}\right)+\ln(3)\right)}{6}\right)d\alpha\right)\cos\left(\frac{\sqrt{3}\left(-\ln(3)+\ln\left(-\frac{1}{x^3}\right)\right)}{6}\right.}{} \tag{1}$$

Verification of solutions

$$y = -\frac{2x^{\frac{3}{2}}\sqrt{3}\,\sqrt{-\frac{1}{x^3}}\left(\int_0^x -\sqrt{-\frac{1}{\alpha^3}}\,\ln(\alpha)(\alpha-1)\,\alpha^2 \sin\left(\frac{\sqrt{3}\left(-\ln\left(-\frac{1}{\alpha^3}\right)+\ln(3)\right)}{6}\right)d\alpha\right)\cos\left(\frac{\sqrt{3}\left(-\ln(3)+\ln\left(-\frac{1}{x^3}\right)\right)}{6}\right.}{}$$

Verified OK.

16.12.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 4x, C = 3, f(x) = \ln(x)(x-1)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 4y'x + 3y = 0$$

In normal form the ode

$$x^2y'' + 4y'x + 3y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{4}{x} \\ q(x) &= \frac{3}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{4n}{x^2} + \frac{3}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = \frac{i\sqrt{3}}{2} - \frac{3}{2} \tag{6}$$

Substituting this value in (3) gives

$$v''(x) + \left(\frac{i\sqrt{3}-3}{x} + \frac{4}{x}\right) v'(x) = 0$$
$$v''(x) + \frac{\left(1+i\sqrt{3}\right) v'(x)}{x} = 0 \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{\left(1+i\sqrt{3}\right) u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{\left(-i\sqrt{3}-1\right) u}{x} \end{aligned}$$

Where $f(x) = \frac{-i\sqrt{3}-1}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= \frac{-i\sqrt{3}-1}{x}\, dx \\ \int \frac{1}{u}\, du &= \int \frac{-i\sqrt{3}-1}{x}\, dx \\ \ln(u) &= \left(-i\sqrt{3}-1\right)\ln(x) + c_1 \\ u &= \mathrm{e}^{\left(-i\sqrt{3}-1\right)\ln(x)+c_1} \\ &= c_1 \mathrm{e}^{\left(-i\sqrt{3}-1\right)\ln(x)} \end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1 x^{-i\sqrt{3}}}{x}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= \frac{i\sqrt{3}\, c_1 x^{-i\sqrt{3}}}{3} + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\, x^n \\ &= \left(\frac{i\sqrt{3}\, c_1 x^{-i\sqrt{3}}}{3} + c_2\right) x^{\frac{i\sqrt{3}}{2} - \frac{3}{2}} \\ &= \frac{x^{-\frac{i\sqrt{3}}{2} - \frac{3}{2}} \left(i\sqrt{3}\, c_1 + 3 c_2 x^{i\sqrt{3}}\right)}{3} \end{aligned}$$

Now the particular solution to this ODE is found

$$x^2 y'' + 4y' x + 3y = \ln(x)\,(x - 1)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{x^{\frac{i\sqrt{3}}{2}}}{x^{\frac{3}{2}}}$$

$$y_2 = \frac{x^{\frac{i\sqrt{3}}{2}} x^{-i\sqrt{3}}}{x^{\frac{3}{2}}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{x^{\frac{i\sqrt{3}}{2}}}{x^{\frac{3}{2}}} & \frac{x^{\frac{i\sqrt{3}}{2}} x^{-i\sqrt{3}}}{x^{\frac{3}{2}}} \\ \frac{d}{dx}\left(\frac{x^{\frac{i\sqrt{3}}{2}}}{x^{\frac{3}{2}}}\right) & \frac{d}{dx}\left(\frac{x^{\frac{i\sqrt{3}}{2}} x^{-i\sqrt{3}}}{x^{\frac{3}{2}}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{x^{\frac{i\sqrt{3}}{2}}}{x^{\frac{3}{2}}} & \frac{x^{\frac{i\sqrt{3}}{2}} x^{-i\sqrt{3}}}{x^{\frac{3}{2}}} \\ \frac{i x^{\frac{i\sqrt{3}}{2}} \sqrt{3}}{2x^{\frac{5}{2}}} - \frac{3x^{\frac{i\sqrt{3}}{2}}}{2x^{\frac{5}{2}}} & -\frac{i x^{\frac{i\sqrt{3}}{2}} \sqrt{3}\, x^{-i\sqrt{3}}}{2x^{\frac{5}{2}}} - \frac{3x^{\frac{i\sqrt{3}}{2}} x^{-i\sqrt{3}}}{2x^{\frac{5}{2}}} \end{vmatrix}$$

Therefore

$$W = \left(\frac{x^{\frac{i\sqrt{3}}{2}}}{x^{\frac{3}{2}}}\right)\left(-\frac{i x^{\frac{i\sqrt{3}}{2}} \sqrt{3}\, x^{-i\sqrt{3}}}{2x^{\frac{5}{2}}} - \frac{3x^{\frac{i\sqrt{3}}{2}} x^{-i\sqrt{3}}}{2x^{\frac{5}{2}}}\right) - \left(\frac{x^{\frac{i\sqrt{3}}{2}} x^{-i\sqrt{3}}}{x^{\frac{3}{2}}}\right)\left(\frac{i x^{\frac{i\sqrt{3}}{2}} \sqrt{3}}{2x^{\frac{5}{2}}} - \frac{3x^{\frac{i\sqrt{3}}{2}}}{2x^{\frac{5}{2}}}\right)$$

Which simplifies to

$$W = -\frac{i x^{i\sqrt{3}} \sqrt{3}\, x^{-i\sqrt{3}}}{x^4}$$

Which simplifies to

$$W = -\frac{i\sqrt{3}}{x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x^{\frac{i\sqrt{3}}{2}} x^{-i\sqrt{3}} \ln(x)(x-1)}{x^{\frac{3}{2}}}}{-\frac{i\sqrt{3}}{x^2}}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{i \ln(x) \sqrt{3}\, x^{\frac{1}{2}-\frac{i\sqrt{3}}{2}} (x-1)}{3} dx$$

Hence

$$u_1 = -\frac{5x^{\frac{3}{2}-\frac{i\sqrt{3}}{2}} \left(-\frac{7}{5} + i\left(\left(x-\frac{7}{5}\right)\ln(x) - \frac{11x}{35} + \frac{7}{15}\right)\sqrt{3} + \frac{(7-3x)\ln(x)}{5} + \frac{3x}{7}\right)}{42}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{x^{\frac{i\sqrt{3}}{2}} \ln(x)(x-1)}{x^{\frac{3}{2}}}}{-\frac{i\sqrt{3}}{x^2}} dx$$

Which simplifies to

$$u_2 = \int \frac{i \ln(x) \sqrt{3}\, x^{\frac{1}{2}+\frac{i\sqrt{3}}{2}} (x-1)}{3} dx$$

Hence

$$u_2 = \frac{5x^{\frac{3}{2}+\frac{i\sqrt{3}}{2}} \left(\frac{7}{5} + i\left(\left(x-\frac{7}{5}\right)\ln(x) - \frac{11x}{35} + \frac{7}{15}\right)\sqrt{3} + \frac{(3x-7)\ln(x)}{5} - \frac{3x}{7}\right)}{42}$$

Which simplifies to

$$u_1 = \frac{5\left(\frac{7}{5} - i\left(\left(x-\frac{7}{5}\right)\ln(x) - \frac{11x}{35} + \frac{7}{15}\right)\sqrt{3} - \frac{(7-3x)\ln(x)}{5} - \frac{3x}{7}\right) x^{\frac{3}{2}} x^{-\frac{i\sqrt{3}}{2}}}{42}$$

$$u_2 = \frac{5x^{\frac{3}{2}+\frac{i\sqrt{3}}{2}} \left(\frac{7}{5} + i\left(\left(x-\frac{7}{5}\right)\ln(x) - \frac{11x}{35} + \frac{7}{15}\right)\sqrt{3} + \frac{(3x-7)\ln(x)}{5} - \frac{3x}{7}\right)}{42}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{5\left(\frac{7}{5} - i\left(\left(x-\frac{7}{5}\right)\ln(x) - \frac{11x}{35} + \frac{7}{15}\right)\sqrt{3} - \frac{(7-3x)\ln(x)}{5} - \frac{3x}{7}\right) x^{-\frac{i\sqrt{3}}{2}} x^{\frac{i\sqrt{3}}{2}}}{42} + \frac{5x^{\frac{3}{2}+\frac{i\sqrt{3}}{2}} \left(\frac{7}{5} + i\left(\left(x-\frac{7}{5}\right)\ln(x) - \frac{11x}{35} + \frac{7}{15}\right)\sqrt{3} + \frac{(3x-7)\ln(x)}{5} - \frac{3x}{7}\right) x^{\frac{i\sqrt{3}}{2}} x^{-i\sqrt{3}}}{42x^{\frac{3}{2}}}$$

Which simplifies to

$$y_p(x) = \frac{1}{3} + \frac{(3x-7)\ln(x)}{21} - \frac{5x}{49}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(\frac{i\sqrt{3}\,c_1 x^{-i\sqrt{3}}}{3} + c_2\right) x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}\right) + \left(\frac{1}{3} + \frac{(3x-7)\ln(x)}{21} - \frac{5x}{49}\right) \\ &= \frac{1}{3} + \frac{(3x-7)\ln(x)}{21} - \frac{5x}{49} + \left(\frac{i\sqrt{3}\,c_1 x^{-i\sqrt{3}}}{3} + c_2\right) x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}} \end{aligned}$$

Which simplifies to

$$y = \frac{1}{3} + \frac{(3x-7)\ln(x)}{21} - \frac{5x}{49} + \left(\frac{i\sqrt{3}\,c_1 x^{-i\sqrt{3}}}{3} + c_2\right) x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}$$

Summary
The solution(s) found are the following

$$y = \frac{1}{3} + \frac{(3x-7)\ln(x)}{21} - \frac{5x}{49} + \left(\frac{i\sqrt{3}\,c_1 x^{-i\sqrt{3}}}{3} + c_2\right) x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}} \tag{1}$$

Verification of solutions

$$y = \frac{1}{3} + \frac{(3x-7)\ln(x)}{21} - \frac{5x}{49} + \left(\frac{i\sqrt{3}\,c_1 x^{-i\sqrt{3}}}{3} + c_2\right) x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}$$

Verified OK.

16.12.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + 4y'x + 3y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x^2 \\
B &= 4x \\
C &= 3
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A}\,dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-1}{x^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -1 \\
t &= x^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(-\frac{1}{x^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\,dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 556: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b=-1$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2}+\frac{i\sqrt{3}}{2} \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}-\frac{i\sqrt{3}}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty=0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r=\frac{s}{t}=-\frac{1}{x^2}
$$

Since the $\gcd(s,t)=1$. This gives $b=-1$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2}+\frac{i\sqrt{3}}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}-\frac{i\sqrt{3}}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=-\frac{1}{x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}+\frac{i\sqrt{3}}{2}$	$\frac{1}{2}-\frac{i\sqrt{3}}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}+\frac{i\sqrt{3}}{2}$	$\frac{1}{2}-\frac{i\sqrt{3}}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = \frac{1}{2} - \frac{i\sqrt{3}}{2}$ then

$$
\begin{aligned}
d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= \frac{1}{2} - \frac{i\sqrt{3}}{2} - \left(\frac{1}{2} - \frac{i\sqrt{3}}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_{\infty}
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{\frac{1}{2} - \frac{i\sqrt{3}}{2}}{x} + (-)\,(0) \\
&= \frac{\frac{1}{2} - \frac{i\sqrt{3}}{2}}{x} \\
&= \frac{1 - i\sqrt{3}}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{\frac{1}{2} - \frac{i\sqrt{3}}{2}}{x}\right)(0) + \left(\left(-\frac{\frac{1}{2} - \frac{i\sqrt{3}}{2}}{x^2}\right) + \left(\frac{\frac{1}{2} - \frac{i\sqrt{3}}{2}}{x}\right)^2 - \left(-\frac{1}{x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \frac{\frac{1}{2} - \frac{i\sqrt{3}}{2}}{x} dx} \\
&= x^{\frac{1}{2} - \frac{i\sqrt{3}}{2}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4x}{x^2}\,dx} \\
&= z_1 e^{-2\ln(x)} \\
&= z_1\left(\frac{1}{x^2}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-4\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{i x^{i\sqrt{3}}\sqrt{3}}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}}\right) + c_2\left(x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}}\left(-\frac{i x^{i\sqrt{3}}\sqrt{3}}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$x^2y''+4y'x+3y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}} - \frac{i c_2 \sqrt{3}\, x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}}{3}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}}$$

$$y_2 = -\frac{i\sqrt{3}\, x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}}{3}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}} & -\frac{i\sqrt{3}\, x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}}{3} \\ \frac{d}{dx}\left(x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}}\right) & \frac{d}{dx}\left(-\frac{i\sqrt{3}\, x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}}{3}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}} & -\frac{i\sqrt{3}\, x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}}{3} \\ \frac{x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}}\left(-\frac{i\sqrt{3}}{2}-\frac{3}{2}\right)}{x} & -\frac{i\sqrt{3}\, x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}\left(\frac{i\sqrt{3}}{2}-\frac{3}{2}\right)}{3x} \end{vmatrix}$$

Therefore

$$\begin{aligned} W &= \left(x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}}\right)\left(-\frac{i\sqrt{3}\, x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}\left(\frac{i\sqrt{3}}{2}-\frac{3}{2}\right)}{3x}\right) \\ &\quad - \left(-\frac{i\sqrt{3}\, x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}}{3}\right)\left(\frac{x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}}\left(-\frac{i\sqrt{3}}{2}-\frac{3}{2}\right)}{x}\right) \end{aligned}$$

Which simplifies to

$$W = \frac{x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}}\, x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}}{x}$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{i\sqrt{3}\, x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}} \ln(x)(x-1)}{3}}{\frac{1}{x^2}}\, dx$$

Which simplifies to

$$u_1 = -\int -\frac{i \ln(x)\sqrt{3}\, x^{\frac{1}{2}+\frac{i\sqrt{3}}{2}}(x-1)}{3} dx$$

Hence

$$u_1 = -\frac{5\left(-\frac{7}{5} - i\left(\left(x-\frac{7}{5}\right)\ln(x) - \frac{11x}{35} + \frac{7}{15}\right)\sqrt{3} - \frac{(3x-7)\ln(x)}{5} + \frac{3x}{7}\right) x^{\frac{3}{2}} x^{\frac{i\sqrt{3}}{2}}}{42}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}} \ln\left(x\right) \left(x-1\right)}{\frac{1}{x^2}} \, dx$$

Which simplifies to

$$u_2 = \int \ln\left(x\right) x^{\frac{1}{2}-\frac{i\sqrt{3}}{2}} \left(x-1\right) dx$$

Hence

$$u_2 = \frac{x^{\frac{3}{2}-\frac{i\sqrt{3}}{2}} \left(\frac{7}{3}+i\left(\left(x-\frac{7}{3}\right)\ln\left(x\right)-\frac{5x}{7}+\frac{7}{3}\right)\sqrt{3}+\left(5x-7\right)\ln\left(x\right)-\frac{11x}{7}\right)}{14}$$

Which simplifies to

$$u_1 = \frac{5x^{\frac{3}{2}+\frac{i\sqrt{3}}{2}} \left(\frac{7}{5}+i\left(\left(x-\frac{7}{5}\right)\ln\left(x\right)-\frac{11x}{35}+\frac{7}{15}\right)\sqrt{3}+\frac{\left(3x-7\right)\ln\left(x\right)}{5}-\frac{3x}{7}\right)}{42}$$

$$u_2 = \frac{x^{\frac{3}{2}-\frac{i\sqrt{3}}{2}} \left(\frac{7}{3}+i\left(\left(x-\frac{7}{3}\right)\ln\left(x\right)-\frac{5x}{7}+\frac{7}{3}\right)\sqrt{3}+\left(5x-7\right)\ln\left(x\right)-\frac{11x}{7}\right)}{14}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{5x^{\frac{3}{2}+\frac{i\sqrt{3}}{2}} \left(\frac{7}{5}+i\left(\left(x-\frac{7}{5}\right)\ln\left(x\right)-\frac{11x}{35}+\frac{7}{15}\right)\sqrt{3}+\frac{\left(3x-7\right)\ln\left(x\right)}{5}-\frac{3x}{7}\right) x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}}}{42} - \frac{i x^{\frac{3}{2}-\frac{i\sqrt{3}}{2}} \left(\frac{7}{3}+i\left(\left(x-\frac{7}{3}\right)\ln\left(x\right)-\frac{5x}{7}+\frac{7}{3}\right)\sqrt{3}+\left(5x-7\right)\ln\left(x\right)-\frac{11x}{7}\right)\sqrt{3}\, x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}}{42}$$

Which simplifies to

$$y_p(x) = \frac{1}{3}+\frac{\left(3x-7\right)\ln\left(x\right)}{21}-\frac{5x}{49}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}} - \frac{i c_2 \sqrt{3}\, x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}}{3}\right) + \left(\frac{1}{3}+\frac{\left(3x-7\right)\ln\left(x\right)}{21}-\frac{5x}{49}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}} - \frac{i c_2 \sqrt{3}\, x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}}{3} + \frac{1}{3} + \frac{(3x-7)\ln(x)}{21} - \frac{5x}{49} \tag{1}$$

Verification of solutions

$$y = c_1 x^{-\frac{i\sqrt{3}}{2}-\frac{3}{2}} - \frac{i c_2 \sqrt{3}\, x^{\frac{i\sqrt{3}}{2}-\frac{3}{2}}}{3} + \frac{1}{3} + \frac{(3x-7)\ln(x)}{21} - \frac{5x}{49}$$

Verified OK.

Maple gives the following as the ode type

```
[[_3rd_order, _with_linear_symmetries]]
```

$$\boxed{4x^3y''' + 8x^2y'' - y'x + y = x + \ln(x)}$$

This is higher order nonhomogeneous Euler type ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous Euler ODE And y_p is a particular solution to the nonhomogeneous Euler ODE. y_h is the solution to

$$4x^3y''' + 8x^2y'' - y'x + y = 0$$

This is Euler ODE of higher order. Let $y = x^\lambda$. Hence

$$\begin{aligned}
y' &= \lambda\, x^{\lambda-1} \\
y'' &= \lambda(\lambda-1)\, x^{\lambda-2} \\
y''' &= \lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3}
\end{aligned}$$

Substituting these back into

$$4x^3y''' + 8x^2y'' - y'x + y = x + \ln(x)$$

gives

$$-x\lambda\, x^{\lambda-1}+8x^{2}\lambda(\lambda-1)\, x^{\lambda-2}+4x^{3}\lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3}+x^{\lambda}=0$$

Which simplifies to

$$-\lambda\, x^{\lambda}+8\lambda(\lambda-1)\, x^{\lambda}+4\lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda}+x^{\lambda}=0$$

And since $x^{\lambda}\neq 0$ then dividing through by x^{λ}, the above becomes

$$-\lambda+8\lambda(\lambda-1)+4\lambda(\lambda-1)\,(\lambda-2)+1=0$$

Simplifying gives the characteristic equation as

$$4\lambda^{3}-4\lambda^{2}-\lambda+1=0$$

Solving the above gives the following roots

$$\lambda_1 = 1$$
$$\lambda_2 = -\frac{1}{2}$$
$$\lambda_3 = \frac{1}{2}$$

This table summarises the result

root	multiplicity	type of root
1	1	real root
$-\frac{1}{2}$	1	real root
$\frac{1}{2}$	1	real root

The solution is generated by going over the above table. For each real root λ of multiplicity one generates a $c_1 x^{\lambda}$ basis solution. Each real root of multiplicty two, generates $c_1 x^{\lambda}$ and $c_2 x^{\lambda}\ln(x)$ basis solutions. Each real root of multiplicty three, generates $c_1 x^{\lambda}$ and $c_2 x^{\lambda}\ln(x)$ and $c_3 x^{\lambda}\ln(x)^{2}$ basis solutions, and so on. Each complex root $\alpha\pm i\beta$ of multiplicity one generates $x^{\alpha}(c_1\cos(\beta\ln(x))+c_2\sin(\beta\ln(x)))$ basis solutions. And each complex root $\alpha\pm i\beta$ of multiplicity two generates $\ln(x)\, x^{\alpha}(c_1\cos(\beta\ln(x))+c_2\sin(\beta\ln(x)))$ basis solutions. And each complex root $\alpha\pm i\beta$ of multiplicity three generates $\ln(x)^{2} x^{\alpha}(c_1\cos(\beta\ln(x))+c_2$ basis solutions. And so on. Using the above show that the solution is

$$y = c_1 x+\frac{c_2}{\sqrt{x}}+\sqrt{x}\, c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= x \\
y_2 &= \frac{1}{\sqrt{x}} \\
y_3 &= \sqrt{x}
\end{aligned}
$$

Now the particular solution to the given ODE is found

$$
4x^3y''' + 8x^2y'' - y'x + y = x + \ln(x)
$$

Let the particular solution be

$$
y_p = U_1y_1 + U_2y_2 + U_3y_3
$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$
U_i = (-1)^{n-i} \int \frac{F(x)W_i(x)}{aW(x)}\,dx
$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$
W(x) = \begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}
$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$
\begin{aligned}
W &= \begin{bmatrix} x & \frac{1}{\sqrt{x}} & \sqrt{x} \\ 1 & -\frac{1}{2x^{\frac{3}{2}}} & \frac{1}{2\sqrt{x}} \\ 0 & \frac{3}{4x^{\frac{5}{2}}} & -\frac{1}{4x^{\frac{3}{2}}} \end{bmatrix} \\
|W| &= \frac{3}{4x^2}
\end{aligned}
$$

The determinant simplifies to

$$|W| = \frac{3}{4x^2}$$

Now we determine W_i for each U_i.

$$\begin{aligned} W_1(x) &= \det \begin{bmatrix} \frac{1}{\sqrt{x}} & \sqrt{x} \\ -\frac{1}{2x^{\frac{3}{2}}} & \frac{1}{2\sqrt{x}} \end{bmatrix} \\ &= \frac{1}{x} \end{aligned}$$

$$\begin{aligned} W_2(x) &= \det \begin{bmatrix} x & \sqrt{x} \\ 1 & \frac{1}{2\sqrt{x}} \end{bmatrix} \\ &= -\frac{\sqrt{x}}{2} \end{aligned}$$

$$\begin{aligned} W_3(x) &= \det \begin{bmatrix} x & \frac{1}{\sqrt{x}} \\ 1 & -\frac{1}{2x^{\frac{3}{2}}} \end{bmatrix} \\ &= -\frac{3}{2\sqrt{x}} \end{aligned}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned} U_1 &= (-1)^{3-1} \int \frac{F(x)W_1(x)}{aW(x)}\, dx \\ &= (-1)^2 \int \frac{(x + \ln(x))\left(\frac{1}{x}\right)}{(4x^3)\left(\frac{3}{4x^2}\right)}\, dx \\ &= \int \frac{\frac{x+\ln(x)}{x}}{3x}\, dx \\ &= \int \left(\frac{x + \ln(x)}{3x^2}\right) dx \\ &= \frac{\ln(x)}{3} - \frac{\ln(x)}{3x} - \frac{1}{3x} \end{aligned}$$

$$
\begin{aligned}
U_2 &= (-1)^{3-2} \int \frac{F(x) W_2(x)}{a W(x)}\, dx \\
&= (-1)^{1} \int \frac{(x+\ln(x))\left(-\frac{\sqrt{x}}{2}\right)}{(4x^3)\left(\frac{3}{4x^2}\right)}\, dx \\
&= -\int \frac{-\frac{(x+\ln(x))\sqrt{x}}{2}}{3x}\, dx \\
&= -\int \left(-\frac{x+\ln(x)}{6\sqrt{x}}\right) dx \\
&= \frac{x^{\frac{3}{2}}}{9} + \frac{\ln(x)\sqrt{x}}{3} - \frac{2\sqrt{x}}{3}
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{3-3} \int \frac{F(x) W_3(x)}{a W(x)}\, dx \\
&= (-1)^{0} \int \frac{(x+\ln(x))\left(-\frac{3}{2\sqrt{x}}\right)}{(4x^3)\left(\frac{3}{4x^2}\right)}\, dx \\
&= \int \frac{-\frac{3(x+\ln(x))}{2\sqrt{x}}}{3x}\, dx \\
&= \int \left(-\frac{x+\ln(x)}{2x^{\frac{3}{2}}}\right) dx \\
&= -\sqrt{x} + \frac{\ln(x)}{\sqrt{x}} + \frac{2}{\sqrt{x}}
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Hence

$$
\begin{aligned}
y_p = {} & \left(\frac{\ln(x)}{3} - \frac{\ln(x)}{3x} - \frac{1}{3x}\right)(x) \\
& + \left(\frac{x^{\frac{3}{2}}}{9} + \frac{\ln(x)\sqrt{x}}{3} - \frac{2\sqrt{x}}{3}\right)\left(\frac{1}{\sqrt{x}}\right) \\
& + \left(-\sqrt{x} + \frac{\ln(x)}{\sqrt{x}} + \frac{2}{\sqrt{x}}\right)(\sqrt{x})
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = \frac{x\ln(x)}{3} + \ln(x) + 1 - \frac{8x}{9}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 x + \frac{c_2}{\sqrt{x}} + \sqrt{x}\, c_3\right) + \left(\frac{x \ln(x)}{3} + \ln(x) + 1 - \frac{8x}{9}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x + \frac{c_2}{\sqrt{x}} + \sqrt{x}\, c_3 + \frac{x \ln(x)}{3} + \ln(x) + 1 - \frac{8x}{9} \tag{1}
$$

Verification of solutions

$$
y = c_1 x + \frac{c_2}{\sqrt{x}} + \sqrt{x}\, c_3 + \frac{x \ln(x)}{3} + \ln(x) + 1 - \frac{8x}{9}
$$

Verified OK.

The type(s) of ODE detected by this program : **"higher_order_ODE_non_constant_coefficients_of_type_Euler"**

Maple gives the following as the ode type

```
[[_3rd_order, _with_linear_symmetries]]
```

$$\boxed{3x^3y''' + 4x^2y'' - 10y'x + 10y = \frac{4}{x^2}}$$

This is higher order nonhomogeneous Euler type ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous Euler ODE And y_p is a particular solution to the nonhomogeneous Euler ODE. y_h is the solution to

$$3x^3y''' + 4x^2y'' - 10y'x + 10y = 0$$

This is Euler ODE of higher order. Let $y = x^\lambda$. Hence

$$\begin{aligned} y' &= \lambda\, x^{\lambda-1} \\ y'' &= \lambda(\lambda-1)\, x^{\lambda-2} \\ y''' &= \lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} \end{aligned}$$

Substituting these back into

$$3x^3y''' + 4x^2y'' - 10y'x + 10y = \frac{4}{x^2}$$

gives

$$-10x\lambda\, x^{\lambda-1} + 4x^2\lambda(\lambda-1)\, x^{\lambda-2} + 3x^3\lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} + 10x^\lambda = 0$$

Which simplifies to

$$-10\lambda\, x^\lambda + 4\lambda(\lambda-1)\, x^\lambda + 3\lambda(\lambda-1)\,(\lambda-2)\, x^\lambda + 10x^\lambda = 0$$

And since $x^\lambda \neq 0$ then dividing through by x^λ, the above becomes

$$-10\lambda + 4\lambda(\lambda-1) + 3\lambda(\lambda-1)\,(\lambda-2) + 10 = 0$$

Simplifying gives the characteristic equation as

$$3\lambda^3 - 5\lambda^2 - 8\lambda + 10 = 0$$

Solving the above gives the following roots

$$\lambda_1 = 1$$
$$\lambda_2 = \frac{1}{3} - \frac{\sqrt{31}}{3}$$
$$\lambda_3 = \frac{1}{3} + \frac{\sqrt{31}}{3}$$

This table summarises the result

root	multiplicity	type of root
1	1	real root
$\frac{1}{3} - \frac{\sqrt{31}}{3}$	1	real root
$\frac{1}{3} + \frac{\sqrt{31}}{3}$	1	real root

The solution is generated by going over the above table. For each real root λ of multiplicity one generates a $c_1 x^\lambda$ basis solution. Each real root of multiplicty two, generates $c_1 x^\lambda$ and $c_2 x^\lambda \ln(x)$ basis solutions. Each real root of multiplicty three, generates $c_1 x^\lambda$ and $c_2 x^\lambda \ln(x)$ and $c_3 x^\lambda \ln(x)^2$ basis solutions, and so on. Each complex root $\alpha \pm i\beta$ of multiplicity one generates $x^\alpha (c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity two generates $\ln(x)\, x^\alpha (c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity three generates $\ln(x)^2\, x^\alpha (c_1 \cos(\beta \ln(x)) + c_2$ basis solutions. And so on. Using the above show that the solution is

$$
y = c_1 x + c_2 x^{\frac{1}{3}-\frac{\sqrt{31}}{3}} + c_3 x^{\frac{1}{3}+\frac{\sqrt{31}}{3}}
$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= x \\
y_2 &= x^{\frac{1}{3}-\frac{\sqrt{31}}{3}} \\
y_3 &= x^{\frac{1}{3}+\frac{\sqrt{31}}{3}}
\end{aligned}
$$

Now the particular solution to the given ODE is found

$$
3x^3 y''' + 4x^2 y'' - 10y'x + 10y = \frac{4}{x^2}
$$

Let the particular solution be

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$
U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)}\, dx
$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$
W(x) = \begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}
$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$
W = \begin{bmatrix} x & x^{\frac{1}{3}-\frac{\sqrt{31}}{3}} & x^{\frac{1}{3}+\frac{\sqrt{31}}{3}} \\ 1 & -\frac{x^{-\frac{2}{3}-\frac{\sqrt{31}}{3}}\left(-1+\sqrt{31}\right)}{3} & \frac{x^{-\frac{2}{3}+\frac{\sqrt{31}}{3}}\left(1+\sqrt{31}\right)}{3} \\ 0 & \frac{x^{-\frac{5}{3}-\frac{\sqrt{31}}{3}}\left(-1+\sqrt{31}\right)\left(2+\sqrt{31}\right)}{9} & \frac{x^{-\frac{5}{3}+\frac{\sqrt{31}}{3}}\left(-2+\sqrt{31}\right)\left(1+\sqrt{31}\right)}{9} \end{bmatrix}
$$

$$
|W| = -\frac{10x\, x^{-\frac{2}{3}-\frac{\sqrt{31}}{3}} x^{-\frac{5}{3}+\frac{\sqrt{31}}{3}} \sqrt{31}}{9} + \frac{20x\, x^{-\frac{2}{3}-\frac{\sqrt{31}}{3}} x^{-\frac{5}{3}+\frac{\sqrt{31}}{3}}}{9} - \frac{10x\, x^{-\frac{5}{3}-\frac{\sqrt{31}}{3}} x^{-\frac{2}{3}+\frac{\sqrt{31}}{3}} \sqrt{31}}{9} - \frac{20x\, x^{-\frac{5}{3}-\frac{\sqrt{31}}{3}} x^{-}}{9}
$$

The determinant simplifies to

$$|W| = -\frac{2\sqrt{31}}{x^{\frac{4}{3}}}$$

Now we determine W_i for each U_i.

$$\begin{aligned} W_1(x) &= \det \begin{bmatrix} x^{\frac{1}{3}-\frac{\sqrt{31}}{3}} & x^{\frac{1}{3}+\frac{\sqrt{31}}{3}} \\ -\frac{x^{-\frac{2}{3}-\frac{\sqrt{31}}{3}}\left(-1+\sqrt{31}\right)}{3} & \frac{x^{-\frac{2}{3}+\frac{\sqrt{31}}{3}}\left(1+\sqrt{31}\right)}{3} \end{bmatrix} \\ &= \frac{2\sqrt{31}}{3x^{\frac{1}{3}}} \end{aligned}$$

$$\begin{aligned} W_2(x) &= \det \begin{bmatrix} x & x^{\frac{1}{3}+\frac{\sqrt{31}}{3}} \\ 1 & \frac{x^{-\frac{2}{3}+\frac{\sqrt{31}}{3}}\left(1+\sqrt{31}\right)}{3} \end{bmatrix} \\ &= \frac{\left(-2+\sqrt{31}\right) x^{\frac{1}{3}+\frac{\sqrt{31}}{3}}}{3} \end{aligned}$$

$$\begin{aligned} W_3(x) &= \det \begin{bmatrix} x & x^{\frac{1}{3}-\frac{\sqrt{31}}{3}} \\ 1 & -\frac{x^{-\frac{2}{3}-\frac{\sqrt{31}}{3}}\left(-1+\sqrt{31}\right)}{3} \end{bmatrix} \\ &= -\frac{\left(2+\sqrt{31}\right) x^{\frac{1}{3}-\frac{\sqrt{31}}{3}}}{3} \end{aligned}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned} U_1 &= (-1)^{3-1} \int \frac{F(x)W_1(x)}{aW(x)}\, dx \\ &= (-1)^2 \int \frac{\left(\frac{4}{x^2}\right)\left(\frac{2\sqrt{31}}{3x^{\frac{1}{3}}}\right)}{(3x^3)\left(-\frac{2\sqrt{31}}{x^{\frac{4}{3}}}\right)}\, dx \\ &= \int \frac{\frac{8\sqrt{31}}{3x^{\frac{7}{3}}}}{-6x^{\frac{5}{3}}\sqrt{31}}\, dx \\ &= \int \left(-\frac{4}{9x^4}\right) dx \\ &= \frac{4}{27x^3} \end{aligned}$$

$$
\begin{aligned}
U_2 &= (-1)^{3-2} \int \frac{F(x) W_2(x)}{a W(x)}\, dx \\
&= (-1)^1 \int \frac{\left(\frac{4}{x^2}\right)\left(\frac{\left(-2+\sqrt{31}\right) x^{\frac{1}{3}+\frac{\sqrt{31}}{3}}}{3}\right)}{\left(3x^3\right)\left(-\frac{2\sqrt{31}}{x^{\frac{4}{3}}}\right)}\, dx \\
&= -\int \frac{\frac{4\left(-2+\sqrt{31}\right) x^{\frac{1}{3}+\frac{\sqrt{31}}{3}}}{3x^2}}{-6x^{\frac{5}{3}}\sqrt{31}}\, dx \\
&= -\int \left(-\frac{2\sqrt{31}\, x^{-\frac{10}{3}+\frac{\sqrt{31}}{3}}\left(-2+\sqrt{31}\right)}{279}\right) dx \\
&= -\frac{x^{-\frac{7}{3}+\frac{\sqrt{31}}{3}}\sqrt{31}\left(-2+\sqrt{31}\right)\left(7+\sqrt{31}\right)}{837}
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{3-3} \int \frac{F(x) W_3(x)}{a W(x)}\, dx \\
&= (-1)^0 \int \frac{\left(\frac{4}{x^2}\right)\left(-\frac{\left(2+\sqrt{31}\right) x^{\frac{1}{3}-\frac{\sqrt{31}}{3}}}{3}\right)}{\left(3x^3\right)\left(-\frac{2\sqrt{31}}{x^{\frac{4}{3}}}\right)}\, dx \\
&= \int \frac{-\frac{4\left(2+\sqrt{31}\right) x^{\frac{1}{3}-\frac{\sqrt{31}}{3}}}{3x^2}}{-6x^{\frac{5}{3}}\sqrt{31}}\, dx \\
&= \int \left(\frac{2\sqrt{31}\, x^{-\frac{10}{3}-\frac{\sqrt{31}}{3}}\left(2+\sqrt{31}\right)}{279}\right) dx \\
&= \frac{x^{-\frac{7}{3}-\frac{\sqrt{31}}{3}}\sqrt{31}\left(-7+\sqrt{31}\right)\left(2+\sqrt{31}\right)}{837}
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Hence

$$
\begin{aligned}
y_p = &\left(\frac{4}{27x^3}\right)(x) \\
&+ \left(-\frac{x^{-\frac{7}{3}+\frac{\sqrt{31}}{3}}\sqrt{31}\left(-2+\sqrt{31}\right)\left(7+\sqrt{31}\right)}{837}\right)\left(x^{\frac{1}{3}-\frac{\sqrt{31}}{3}}\right) \\
&+ \left(\frac{x^{-\frac{7}{3}-\frac{\sqrt{31}}{3}}\sqrt{31}\left(-7+\sqrt{31}\right)\left(2+\sqrt{31}\right)}{837}\right)\left(x^{\frac{1}{3}+\frac{\sqrt{31}}{3}}\right)
\end{aligned}
$$

Therefore the particular solution is

$$y_p = -\frac{2}{9x^2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x + c_2 x^{\frac{1}{3}-\frac{\sqrt{31}}{3}} + c_3 x^{\frac{1}{3}+\frac{\sqrt{31}}{3}}\right) + \left(-\frac{2}{9x^2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x + c_2 x^{\frac{1}{3}-\frac{\sqrt{31}}{3}} + c_3 x^{\frac{1}{3}+\frac{\sqrt{31}}{3}} - \frac{2}{9x^2} \tag{1}$$

Verification of solutions

$$y = c_1 x + c_2 x^{\frac{1}{3}-\frac{\sqrt{31}}{3}} + c_3 x^{\frac{1}{3}+\frac{\sqrt{31}}{3}} - \frac{2}{9x^2}$$

Verified OK.

The type(s) of ODE detected by this program : **"higher_order_ODE_non_constant_coefficients_of_type_Euler"**

Maple gives the following as the ode type

```
[[_high_order, _exact, _linear, _nonhomogeneous]]
```

$$\boxed{x^4y'''' + 7x^3y''' + 9x^2y'' - 6xy' - 6y = \cos(\ln(x))}$$

This is higher order nonhomogeneous Euler type ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous Euler ODE And y_p is a particular solution to the nonhomogeneous Euler ODE. y_h is the solution to

$$x^4y'''' + 7x^3y''' + 9x^2y'' - 6xy' - 6y = 0$$

This is Euler ODE of higher order. Let $y = x^\lambda$. Hence

$$\begin{aligned}
y' &= \lambda\, x^{\lambda-1} \\
y'' &= \lambda(\lambda-1)\, x^{\lambda-2} \\
y''' &= \lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} \\
y'''' &= \lambda(\lambda-1)\,(\lambda-2)\,(\lambda-3)\, x^{\lambda-4}
\end{aligned}$$

Substituting these back into

$$x^4y'''' + 7x^3y''' + 9x^2y'' - 6xy' - 6y = \cos(\ln(x))$$

gives

$$
\begin{aligned}
&-6x\lambda\, x^{\lambda-1} + 9x^2\lambda(\lambda-1)\, x^{\lambda-2} + 7x^3\lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} \\
&+ x^4\lambda(\lambda-1)\,(\lambda-2)\,(\lambda-3)\, x^{\lambda-4} - 6x^\lambda = 0
\end{aligned}
$$

Which simplifies to

$$
-6\lambda\, x^\lambda + 9\lambda(\lambda-1)\, x^\lambda + 7\lambda(\lambda-1)\,(\lambda-2)\, x^\lambda + \lambda(\lambda-1)\,(\lambda-2)\,(\lambda-3)\, x^\lambda - 6x^\lambda = 0
$$

And since $x^\lambda \neq 0$ then dividing through by x^λ, the above becomes

$$
-6\lambda + 9\lambda(\lambda-1) + 7\lambda(\lambda-1)\,(\lambda-2) + \lambda(\lambda-1)\,(\lambda-2)\,(\lambda-3) - 6 = 0
$$

Simplifying gives the characteristic equation as

$$
\lambda^4 + \lambda^3 - \lambda^2 - 7\lambda - 6 = 0
$$

Solving the above gives the following roots

$$
\begin{aligned}
\lambda_1 &= 2 \\
\lambda_2 &= -1 \\
\lambda_3 &= -1 - i\sqrt{2} \\
\lambda_4 &= -1 + i\sqrt{2}
\end{aligned}
$$

This table summarises the result

root	multiplicity	type of root
-1	1	real root
2	1	real root
$-1 \pm \sqrt{2}i$	1	complex conjugate root

The solution is generated by going over the above table. For each real root λ of multiplicity one generates a $c_1 x^\lambda$ basis solution. Each real root of multiplicty two, generates $c_1 x^\lambda$ and $c_2 x^\lambda \ln(x)$ basis solutions. Each real root of multiplicty three, generates $c_1 x^\lambda$ and $c_2 x^\lambda \ln(x)$ and $c_3 x^\lambda \ln(x)^2$ basis solutions, and so on. Each complex root $\alpha \pm i\beta$ of multiplicity one generates $x^\alpha (c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity two generates $\ln(x)\, x^\alpha (c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity three generates $\ln(x)^2\, x^\alpha (c_1 \cos(\beta \ln(x)) + c_2$ basis solutions. And so on. Using the above show that the solution is

$$
y = \frac{c_1}{x} + c_2 x^2 + \frac{c_3 \cos\left(\sqrt{2}\, \ln\left(x \right)\right) + c_4 \sin\left(\sqrt{2}\, \ln\left(x \right)\right)}{x}
$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{align*}
y_1 &= \frac{1}{x} \\
y_2 &= x^2 \\
y_3 &= \frac{\cos\left(\sqrt{2}\, \ln\left(x \right)\right)}{x} \\
y_4 &= \frac{\sin\left(\sqrt{2}\, \ln\left(x \right)\right)}{x}
\end{align*}
$$

Now the particular solution to the given ODE is found

$$
x^4 y'''' + 7x^3 y''' + 9x^2 y'' - 6x y' - 6y = \cos\left(\ln\left(x \right)\right)
$$

Let the particular solution be

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4
$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$
U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)} \, dx
$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$
W(x) = \begin{vmatrix} y_1 & y_2 & y_3 & y_4 \\ y_1' & y_2' & y_3' & y_4' \\ y_1'' & y_2'' & y_3'' & y_4'' \\ y_1''' & y_2''' & y_3''' & y_4''' \end{vmatrix}
$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} \frac{1}{x} & x^2 & \frac{\cos\left(\sqrt{2}\,\ln(x)\right)}{x} & \frac{\sin\left(\sqrt{2}\,\ln(x)\right)}{x} \\ -\frac{1}{x^2} & 2x & \frac{-\cos\left(\sqrt{2}\,\ln(x)\right)-\sqrt{2}\,\sin\left(\sqrt{2}\,\ln(x)\right)}{x^2} & \frac{-\sin\left(\sqrt{2}\,\ln(x)\right)+\sqrt{2}\,\cos\left(\sqrt{2}\,\ln(x)\right)}{x^2} \\ \frac{2}{x^3} & 2 & \frac{3\sqrt{2}\,\sin\left(\sqrt{2}\,\ln(x)\right)}{x^3} & -\frac{3\sqrt{2}\,\cos\left(\sqrt{2}\,\ln(x)\right)}{x^3} \\ -\frac{6}{x^4} & 0 & \frac{-9\sqrt{2}\,\sin\left(\sqrt{2}\,\ln(x)\right)+6\cos\left(\sqrt{2}\,\ln(x)\right)}{x^4} & \frac{9\sqrt{2}\,\cos\left(\sqrt{2}\,\ln(x)\right)+6\sin\left(\sqrt{2}\,\ln(x)\right)}{x^4} \end{bmatrix}$$

$$|W| = \frac{66\sqrt{2}\left(\cos\left(\sqrt{2}\,\ln\left(x\right)\right)^2+\sin\left(\sqrt{2}\,\ln\left(x\right)\right)^2\right)}{x^7}$$

The determinant simplifies to

$$|W| = \frac{66\sqrt{2}}{x^7}$$

Now we determine W_i for each U_i.

$$W_1(x) = \det\begin{bmatrix} x^2 & \frac{\cos\left(\sqrt{2}\,\ln(x)\right)}{x} & \frac{\sin\left(\sqrt{2}\,\ln(x)\right)}{x} \\ 2x & \frac{-\cos\left(\sqrt{2}\,\ln(x)\right)-\sqrt{2}\,\sin\left(\sqrt{2}\,\ln(x)\right)}{x^2} & \frac{-\sin\left(\sqrt{2}\,\ln(x)\right)+\sqrt{2}\,\cos\left(\sqrt{2}\,\ln(x)\right)}{x^2} \\ 2 & \frac{3\sqrt{2}\,\sin\left(\sqrt{2}\,\ln(x)\right)}{x^3} & -\frac{3\sqrt{2}\,\cos\left(\sqrt{2}\,\ln(x)\right)}{x^3} \end{bmatrix}$$
$$= \frac{11\sqrt{2}}{x^3}$$

$$W_2(x) = \det\begin{bmatrix} \frac{1}{x} & \frac{\cos\left(\sqrt{2}\,\ln(x)\right)}{x} & \frac{\sin\left(\sqrt{2}\,\ln(x)\right)}{x} \\ -\frac{1}{x^2} & \frac{-\cos\left(\sqrt{2}\,\ln(x)\right)-\sqrt{2}\,\sin\left(\sqrt{2}\,\ln(x)\right)}{x^2} & \frac{-\sin\left(\sqrt{2}\,\ln(x)\right)+\sqrt{2}\,\cos\left(\sqrt{2}\,\ln(x)\right)}{x^2} \\ \frac{2}{x^3} & \frac{3\sqrt{2}\,\sin\left(\sqrt{2}\,\ln(x)\right)}{x^3} & -\frac{3\sqrt{2}\,\cos\left(\sqrt{2}\,\ln(x)\right)}{x^3} \end{bmatrix}$$
$$= \frac{2\sqrt{2}}{x^6}$$

$$W_3(x) = \det \begin{bmatrix} \frac{1}{x} & x^2 & \frac{\sin\left(\sqrt{2}\ln(x)\right)}{x} \\ -\frac{1}{x^2} & 2x & \frac{-\sin\left(\sqrt{2}\ln(x)\right)+\sqrt{2}\cos\left(\sqrt{2}\ln(x)\right)}{x^2} \\ \frac{2}{x^3} & 2 & -\frac{3\sqrt{2}\cos\left(\sqrt{2}\ln(x)\right)}{x^3} \end{bmatrix}$$

$$= \frac{-9\sqrt{2}\cos\left(\sqrt{2}\ln(x)\right) - 6\sin\left(\sqrt{2}\ln(x)\right)}{x^3}$$

$$W_4(x) = \det \begin{bmatrix} \frac{1}{x} & x^2 & \frac{\cos\left(\sqrt{2}\ln(x)\right)}{x} \\ -\frac{1}{x^2} & 2x & \frac{-\cos\left(\sqrt{2}\ln(x)\right)-\sqrt{2}\sin\left(\sqrt{2}\ln(x)\right)}{x^2} \\ \frac{2}{x^3} & 2 & \frac{3\sqrt{2}\sin\left(\sqrt{2}\ln(x)\right)}{x^3} \end{bmatrix}$$

$$= \frac{9\sqrt{2}\sin\left(\sqrt{2}\ln(x)\right) - 6\cos\left(\sqrt{2}\ln(x)\right)}{x^3}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned} U_1 &= (-1)^{4-1}\int \frac{F(x)W_1(x)}{aW(x)}\,dx \\ &= (-1)^3 \int \frac{(\cos(\ln(x)))\left(\frac{11\sqrt{2}}{x^3}\right)}{(x^4)\left(\frac{66\sqrt{2}}{x^7}\right)}\,dx \\ &= -\int \frac{\frac{11\cos(\ln(x))\sqrt{2}}{x^3}}{\frac{66\sqrt{2}}{x^3}}\,dx \\ &= -\int \left(\frac{\cos(\ln(x))}{6}\right)dx \\ &= -\frac{\cos(\ln(x))\,x}{12} - \frac{\sin(\ln(x))\,x}{12} \end{aligned}$$

$$
\begin{aligned}
U_2 &= (-1)^{4-2} \int \frac{F(x)W_2(x)}{aW(x)}\,dx \\
&= (-1)^2 \int \frac{(\cos(\ln(x)))\left(\frac{2\sqrt{2}}{x^6}\right)}{(x^4)\left(\frac{66\sqrt{2}}{x^7}\right)}\,dx \\
&= \int \frac{\frac{2\cos(\ln(x))\sqrt{2}}{x^6}}{\frac{66\sqrt{2}}{x^3}}\,dx \\
&= \int \left(\frac{\cos(\ln(x))}{33x^3}\right)\,dx \\
&= \frac{-\frac{2}{165} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)^2}{165} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)}{165}}{\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)x^2}
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{4-3} \int \frac{F(x)W_3(x)}{aW(x)}\,dx \\
&= (-1)^1 \int \frac{(\cos(\ln(x)))\left(\frac{-9\sqrt{2}\,\cos\left(\sqrt{2}\,\ln(x)\right)-6\sin\left(\sqrt{2}\,\ln(x)\right)}{x^3}\right)}{(x^4)\left(\frac{66\sqrt{2}}{x^7}\right)}\,dx \\
&= -\int \frac{\frac{\cos(\ln(x))\left(-9\sqrt{2}\,\cos\left(\sqrt{2}\,\ln(x)\right)-6\sin\left(\sqrt{2}\,\ln(x)\right)\right)}{x^3}}{\frac{66\sqrt{2}}{x^3}}\,dx \\
&= -\int \left(\frac{\cos(\ln(x))\left(-9\sqrt{2}\,\cos\left(\sqrt{2}\,\ln(x)\right)-6\sin\left(\sqrt{2}\,\ln(x)\right)\right)\sqrt{2}}{132}\right)\,dx \\
&= -\left(\int \frac{\cos(\ln(x))\left(-9\sqrt{2}\,\cos\left(\sqrt{2}\,\ln(x)\right)-6\sin\left(\sqrt{2}\,\ln(x)\right)\right)\sqrt{2}}{132}dx\right)
\end{aligned}
$$

$$
\begin{aligned}
U_4 &= (-1)^{4-4} \int \frac{F(x) W_4(x)}{a W(x)}\, dx \\
&= (-1)^0 \int \frac{(\cos(\ln(x))) \left(\frac{9\sqrt{2}\, \sin\left(\sqrt{2}\, \ln(x)\right) - 6\cos\left(\sqrt{2}\, \ln(x)\right)}{x^3}\right)}{(x^4)\left(\frac{66\sqrt{2}}{x^7}\right)}\, dx \\
&= \int \frac{\frac{\cos(\ln(x))\left(9\sqrt{2}\, \sin\left(\sqrt{2}\, \ln(x)\right) - 6\cos\left(\sqrt{2}\, \ln(x)\right)\right)}{x^3}}{\frac{66\sqrt{2}}{x^3}}\, dx \\
&= \int \left(\frac{\cos(\ln(x))\left(3\sqrt{2}\, \sin\left(\sqrt{2}\, \ln(x)\right) - 2\cos\left(\sqrt{2}\, \ln(x)\right)\right)\sqrt{2}}{44}\right) dx \\
&= \int \frac{\cos(\ln(x))\left(3\sqrt{2}\, \sin\left(\sqrt{2}\, \ln(x)\right) - 2\cos\left(\sqrt{2}\, \ln(x)\right)\right)\sqrt{2}}{44} dx
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4
$$

Hence

$$
\begin{aligned}
y_p = &\left(-\frac{\cos(\ln(x))\, x}{12} - \frac{\sin(\ln(x))\, x}{12}\right)\left(\frac{1}{x}\right) \\
&+ \left(\frac{-\frac{2}{165} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)^2}{165} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)}{165}}{\left(1 + \tan\left(\frac{\ln(x)}{2}\right)^2\right) x^2}\right)(x^2) \\
&+ \left(-\left(\int \frac{\cos(\ln(x))\left(-9\sqrt{2}\, \cos\left(\sqrt{2}\, \ln(x)\right) - 6\sin\left(\sqrt{2}\, \ln(x)\right)\right)\sqrt{2}}{132} dx\right)\right)\left(\frac{\cos\left(\sqrt{2}\, \ln(x)\right)}{x}\right) \\
&+ \left(\int \frac{\cos(\ln(x))\left(3\sqrt{2}\, \sin\left(\sqrt{2}\, \ln(x)\right) - 2\cos\left(\sqrt{2}\, \ln(x)\right)\right)\sqrt{2}}{44} dx\right)\left(\frac{\sin\left(\sqrt{2}\, \ln(x)\right)}{x}\right)
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = \frac{5\sqrt{2}\left(\int \cos(\ln(x))\left(3\sqrt{2}\, \cos\left(\sqrt{2}\, \ln(x)\right) + 2\sin\left(\sqrt{2}\, \ln(x)\right)\right) dx\right)\cos\left(\sqrt{2}\, \ln(x)\right) + 5\sqrt{2}\left(\int \cos(\ln(x)\right.}{220}
$$

Therefore the general solution is

$$
y = y_h + y_p
$$

$$= \left(\frac{c_1}{x} + c_2 x^2 + \frac{c_3 \cos\left(\sqrt{2}\, \ln(x)\right) + c_4 \sin\left(\sqrt{2}\, \ln(x)\right)}{x}\right)$$

$$+ \left(\frac{5\sqrt{2}\left(\int \cos(\ln(x)) \left(3\sqrt{2}\, \cos\left(\sqrt{2}\, \ln(x)\right) + 2\sin\left(\sqrt{2}\, \ln(x)\right)\right) dx\right) \cos\left(\sqrt{2}\, \ln(x)\right) + 5\sqrt{2}\left(\int \cos(\ln\right.}{2}\right.$$

Which simplifies to

$$y = \frac{c_2 x^3 + c_4 \sin\left(\sqrt{2}\, \ln(x)\right) + c_3 \cos\left(\sqrt{2}\, \ln(x)\right) + c_1}{x}$$
$$+ \frac{5\sqrt{2}\left(\int \cos(\ln(x)) \left(3\sqrt{2}\, \cos\left(\sqrt{2}\, \ln(x)\right) + 2\sin\left(\sqrt{2}\, \ln(x)\right)\right) dx\right) \cos\left(\sqrt{2}\, \ln(x)\right) + 5\sqrt{2}\left(\int \cos(\ln(x\right.}{220x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_2 x^3 + c_4 \sin\left(\sqrt{2}\, \ln(x)\right) + c_3 \cos\left(\sqrt{2}\, \ln(x)\right) + c_1}{x} \tag{1}$$
$$+ \frac{5\sqrt{2}\left(\int \cos(\ln(x)) \left(3\sqrt{2}\, \cos\left(\sqrt{2}\, \ln(x)\right) + 2\sin\left(\sqrt{2}\, \ln(x)\right)\right) dx\right) \cos\left(\sqrt{2}\, \ln(x)\right) + 5\sqrt{2}\left(\int \cos(\ln(x\right.}{220x}$$

Verification of solutions

$$y = \frac{c_2 x^3 + c_4 \sin\left(\sqrt{2}\, \ln(x)\right) + c_3 \cos\left(\sqrt{2}\, \ln(x)\right) + c_1}{x}$$
$$+ \frac{5\sqrt{2}\left(\int \cos(\ln(x)) \left(3\sqrt{2}\, \cos\left(\sqrt{2}\, \ln(x)\right) + 2\sin\left(\sqrt{2}\, \ln(x)\right)\right) dx\right) \cos\left(\sqrt{2}\, \ln(x)\right) + 5\sqrt{2}\left(\int \cos(\ln(x\right.}{220x}$$

Verified OK.

The type(s) of ODE detected by this program : **"higher_order_ODE_non_constant_coefficients_of_type_Euler"**

Maple gives the following as the ode type

```
[[_3rd_order, _linear, _nonhomogeneous]]
```

$$\boxed{x^3y''' - 2x^2y'' - xy' + 4y = \sin(\ln(x))}$$

This is higher order nonhomogeneous Euler type ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous Euler ODE And y_p is a particular solution to the nonhomogeneous Euler ODE. y_h is the solution to

$$x^3y''' - 2x^2y'' - xy' + 4y = 0$$

This is Euler ODE of higher order. Let $y = x^\lambda$. Hence

$$\begin{aligned}
y' &= \lambda\, x^{\lambda-1} \\
y'' &= \lambda(\lambda-1)\, x^{\lambda-2} \\
y''' &= \lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3}
\end{aligned}$$

Substituting these back into

$$x^3y''' - 2x^2y'' - xy' + 4y = \sin(\ln(x))$$

gives

$$-x\lambda\, x^{\lambda-1} - 2x^2\lambda(\lambda-1)\, x^{\lambda-2} + x^3\lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} + 4x^\lambda = 0$$

Which simplifies to

$$-\lambda\, x^\lambda - 2\lambda(\lambda-1)\, x^\lambda + \lambda(\lambda-1)\,(\lambda-2)\, x^\lambda + 4x^\lambda = 0$$

And since $x^\lambda \neq 0$ then dividing through by x^λ, the above becomes

$$-\lambda - 2\lambda(\lambda-1) + \lambda(\lambda-1)\,(\lambda-2) + 4 = 0$$

Simplifying gives the characteristic equation as

$$\lambda^3 - 5\lambda^2 + 3\lambda + 4 = 0$$

Solving the above gives the following roots

$$\lambda_1 = 4$$
$$\lambda_2 = \frac{\sqrt{5}}{2} + \frac{1}{2}$$
$$\lambda_3 = -\frac{\sqrt{5}}{2} + \frac{1}{2}$$

This table summarises the result

root	multiplicity	type of root
4	1	real root
$-\frac{\sqrt{5}}{2} + \frac{1}{2}$	1	real root
$\frac{\sqrt{5}}{2} + \frac{1}{2}$	1	real root

The solution is generated by going over the above table. For each real root λ of multiplicity one generates a $c_1 x^\lambda$ basis solution. Each real root of multiplicty two, generates $c_1 x^\lambda$ and $c_2 x^\lambda \ln(x)$ basis solutions. Each real root of multiplicty three, generates $c_1 x^\lambda$ and $c_2 x^\lambda \ln(x)$ and $c_3 x^\lambda \ln(x)^2$ basis solutions, and so on. Each complex root $\alpha \pm i\beta$ of multiplicity one generates $x^\alpha(c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity two generates $\ln(x)\, x^\alpha(c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity three generates $\ln(x)^2\, x^\alpha(c_1 \cos(\beta \ln(x)) + c_2$ basis solutions. And so on. Using the above show that the solution is

$$y = c_1 x^4 + c_2 x^{-\frac{\sqrt{5}}{2}+\frac{1}{2}} + c_3 x^{\frac{\sqrt{5}}{2}+\frac{1}{2}}$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= x^4 \\
y_2 &= x^{-\frac{\sqrt{5}}{2}+\frac{1}{2}} \\
y_3 &= x^{\frac{\sqrt{5}}{2}+\frac{1}{2}}
\end{aligned}
$$

Now the particular solution to the given ODE is found

$$
x^3y''' - 2x^2y'' - xy' + 4y = \sin(\ln(x))
$$

Let the particular solution be

$$
y_p = U_1y_1 + U_2y_2 + U_3y_3
$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$
U_i = (-1)^{n-i}\int \frac{F(x)W_i(x)}{aW(x)}\,dx
$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$
W(x) = \begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}
$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$
W = \begin{bmatrix} x^4 & x^{-\frac{\sqrt{5}}{2}+\frac{1}{2}} & x^{\frac{\sqrt{5}}{2}+\frac{1}{2}} \\ 4x^3 & -\frac{x^{-\frac{1}{2}-\frac{\sqrt{5}}{2}}\left(\sqrt{5}-1\right)}{2} & \frac{x^{-\frac{1}{2}+\frac{\sqrt{5}}{2}}\left(\sqrt{5}+1\right)}{2} \\ 12x^2 & x^{-\frac{3}{2}-\frac{\sqrt{5}}{2}} & x^{-\frac{3}{2}+\frac{\sqrt{5}}{2}} \end{bmatrix}
$$

$$
|W| = -\frac{x^4x^{-\frac{1}{2}-\frac{\sqrt{5}}{2}}x^{-\frac{3}{2}+\frac{\sqrt{5}}{2}}\sqrt{5}}{2} + \frac{x^4x^{-\frac{1}{2}-\frac{\sqrt{5}}{2}}x^{-\frac{3}{2}+\frac{\sqrt{5}}{2}}}{2} - \frac{x^4x^{-\frac{1}{2}+\frac{\sqrt{5}}{2}}x^{-\frac{3}{2}-\frac{\sqrt{5}}{2}}\sqrt{5}}{2} - \frac{x^4x^{-\frac{1}{2}+\frac{\sqrt{5}}{2}}x^{-\frac{3}{2}-\frac{\sqrt{5}}{2}}}{2} + 4x^{\frac{\sqrt{5}}{2}+}
$$

The determinant simplifies to

$$|W| = 11x^2\sqrt{5}$$

Now we determine W_i for each U_i.

$$\begin{aligned}
W_1(x) &= \det \begin{bmatrix} x^{-\frac{\sqrt{5}}{2}+\frac{1}{2}} & x^{\frac{\sqrt{5}}{2}+\frac{1}{2}} \\ -\frac{x^{-\frac{1}{2}-\frac{\sqrt{5}}{2}}\left(\sqrt{5}-1\right)}{2} & \frac{x^{-\frac{1}{2}+\frac{\sqrt{5}}{2}}\left(\sqrt{5}+1\right)}{2} \end{bmatrix} \\
&= \sqrt{5}
\end{aligned}$$

$$\begin{aligned}
W_2(x) &= \det \begin{bmatrix} x^4 & x^{\frac{\sqrt{5}}{2}+\frac{1}{2}} \\ 4x^3 & \frac{x^{-\frac{1}{2}+\frac{\sqrt{5}}{2}}\left(\sqrt{5}+1\right)}{2} \end{bmatrix} \\
&= \frac{\left(\sqrt{5}-7\right) x^{\frac{7}{2}+\frac{\sqrt{5}}{2}}}{2}
\end{aligned}$$

$$\begin{aligned}
W_3(x) &= \det \begin{bmatrix} x^4 & x^{-\frac{\sqrt{5}}{2}+\frac{1}{2}} \\ 4x^3 & -\frac{x^{-\frac{1}{2}-\frac{\sqrt{5}}{2}}\left(\sqrt{5}-1\right)}{2} \end{bmatrix} \\
&= -\frac{\left(7+\sqrt{5}\right) x^{\frac{7}{2}-\frac{\sqrt{5}}{2}}}{2}
\end{aligned}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned}
U_1 &= (-1)^{3-1} \int \frac{F(x)W_1(x)}{aW(x)}\, dx \\
&= (-1)^2 \int \frac{\left(\sin\left(\ln\left(x\right)\right)\right)\left(\sqrt{5}\right)}{\left(x^3\right)\left(11x^2\sqrt{5}\right)}\, dx \\
&= \int \frac{\sin\left(\ln\left(x\right)\right)\sqrt{5}}{11x^5\sqrt{5}}\, dx \\
&= \int \left(\frac{\sin\left(\ln\left(x\right)\right)}{11x^5}\right) dx \\
&= \frac{\left(-\frac{1}{374}+\frac{2i}{187}\right) x^{i}}{x^4} + \frac{\left(-\frac{1}{374}-\frac{2i}{187}\right) x^{-i}}{x^4}
\end{aligned}$$

$$
\begin{aligned}
U_2 &= (-1)^{3-2} \int \frac{F(x) W_2(x)}{a W(x)}\, dx \\
&= (-1)^1 \int \frac{(\sin(\ln(x))) \left(\frac{\left(\sqrt{5}-7\right) x^{\frac{7}{2}+\frac{\sqrt{5}}{2}}}{2}\right)}{(x^3)\left(11 x^2 \sqrt{5}\right)}\, dx \\
&= -\int \frac{\frac{\sin(\ln(x))\left(\sqrt{5}-7\right) x^{\frac{7}{2}+\frac{\sqrt{5}}{2}}}{2}}{11 x^5 \sqrt{5}}\, dx \\
&= -\int \left(\frac{x^{-\frac{3}{2}+\frac{\sqrt{5}}{2}} \sqrt{5}\, \sin(\ln(x)) \left(\sqrt{5}-7\right)}{110}\right) dx \\
&= -\frac{i\sqrt{5}\left(\sqrt{5}-7\right)\left(i\sqrt{5}+5i-2\sqrt{5}\right) x\, x^{-\frac{3}{2}+\frac{\sqrt{5}}{2}} x^{i}}{2200} - \frac{i\sqrt{5}\left(\sqrt{5}-7\right)\left(i\sqrt{5}+5i+2\sqrt{5}\right) x\, x^{-\frac{3}{2}+\frac{\sqrt{5}}{2}} x^{-i}}{2200} \\
&= -\frac{i\sqrt{5}\left(\sqrt{5}-7\right)\left(i\sqrt{5}+5i-2\sqrt{5}\right) x\, x^{-\frac{3}{2}+\frac{\sqrt{5}}{2}} x^{i}}{2200} - \frac{i\sqrt{5}\left(\sqrt{5}-7\right)\left(i\sqrt{5}+5i+2\sqrt{5}\right) x\, x^{-\frac{3}{2}+\frac{\sqrt{5}}{2}} x^{-i}}{2200}
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{3-3} \int \frac{F(x) W_3(x)}{a W(x)}\, dx \\
&= (-1)^0 \int \frac{(\sin(\ln(x))) \left(-\frac{\left(7+\sqrt{5}\right) x^{\frac{7}{2}-\frac{\sqrt{5}}{2}}}{2}\right)}{(x^3)\left(11 x^2 \sqrt{5}\right)}\, dx \\
&= \int \frac{-\frac{\sin(\ln(x))\left(7+\sqrt{5}\right) x^{\frac{7}{2}-\frac{\sqrt{5}}{2}}}{2}}{11 x^5 \sqrt{5}}\, dx \\
&= \int \left(-\frac{x^{-\frac{3}{2}-\frac{\sqrt{5}}{2}} \sqrt{5}\, \sin(\ln(x)) \left(7+\sqrt{5}\right)}{110}\right) dx \\
&= \frac{i\sqrt{5}\left(7+\sqrt{5}\right)\left(i\sqrt{5}-5i-2\sqrt{5}\right) x\, x^{-\frac{3}{2}-\frac{\sqrt{5}}{2}} x^{i}}{2200} + \frac{i\sqrt{5}\left(7+\sqrt{5}\right)\left(i\sqrt{5}-5i+2\sqrt{5}\right) x\, x^{-\frac{3}{2}-\frac{\sqrt{5}}{2}} x^{-i}}{2200} \\
&= \frac{i\sqrt{5}\left(7+\sqrt{5}\right)\left(i\sqrt{5}-5i-2\sqrt{5}\right) x\, x^{-\frac{3}{2}-\frac{\sqrt{5}}{2}} x^{i}}{2200} + \frac{i\sqrt{5}\left(7+\sqrt{5}\right)\left(i\sqrt{5}-5i+2\sqrt{5}\right) x\, x^{-\frac{3}{2}-\frac{\sqrt{5}}{2}} x^{-i}}{2200}
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Hence

$$y_p = \left(\frac{\left(-\frac{1}{374}+\frac{2i}{187}\right)x^{i}}{x^{4}}+\frac{\left(-\frac{1}{374}-\frac{2i}{187}\right)x^{-i}}{x^{4}}\right)\left(x^{4}\right)$$
$$+\left(-\frac{i\sqrt{5}\left(\sqrt{5}-7\right)\left(i\sqrt{5}+5i-2\sqrt{5}\right)x\,x^{-\frac{3}{2}+\frac{\sqrt{5}}{2}}x^{i}}{2200}-\frac{i\sqrt{5}\left(\sqrt{5}-7\right)\left(i\sqrt{5}+5i+2\sqrt{5}\right)x\,x^{-\frac{3}{2}+\frac{\sqrt{5}}{2}}x^{-i}}{2200}\right)$$
$$+\left(\frac{i\sqrt{5}\left(7+\sqrt{5}\right)\left(i\sqrt{5}-5i-2\sqrt{5}\right)x\,x^{-\frac{3}{2}-\frac{\sqrt{5}}{2}}x^{i}}{2200}+\frac{i\sqrt{5}\left(7+\sqrt{5}\right)\left(i\sqrt{5}-5i+2\sqrt{5}\right)x\,x^{-\frac{3}{2}-\frac{\sqrt{5}}{2}}x^{-i}}{2200}\right)\left(x\right.$$

Therefore the particular solution is

$$y_p = -\frac{9\left(\left(\frac{2}{9}+i\right)x^{2i}+\frac{2}{9}-i\right)x^{-i}}{170}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x^4 + c_2 x^{-\frac{\sqrt{5}}{2}+\frac{1}{2}} + c_3 x^{\frac{\sqrt{5}}{2}+\frac{1}{2}}\right) + \left(-\frac{9\left(\left(\frac{2}{9}+i\right)x^{2i}+\frac{2}{9}-i\right)x^{-i}}{170}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x^4 + c_2 x^{-\frac{\sqrt{5}}{2}+\frac{1}{2}} + c_3 x^{\frac{\sqrt{5}}{2}+\frac{1}{2}} - \frac{9\left(\left(\frac{2}{9}+i\right)x^{2i}+\frac{2}{9}-i\right)x^{-i}}{170} \tag{1}$$

Verification of solutions

$$y = c_1 x^4 + c_2 x^{-\frac{\sqrt{5}}{2}+\frac{1}{2}} + c_3 x^{\frac{\sqrt{5}}{2}+\frac{1}{2}} - \frac{9\left(\left(\frac{2}{9}+i\right)x^{2i}+\frac{2}{9}-i\right)x^{-i}}{170}$$

Verified OK.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = x(t) + \cos(t)$$
$$y'(t) = -y(t) + 4t$$

17.1.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \cos(t) \\ 4t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} e^{t} & 0 \\ 0 & e^{-t} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} e^{t} & 0 \\ 0 & e^{-t} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} e^{t} c_1 \\ e^{-t} c_2 \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t) \, dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} e^{-t} & 0 \\ 0 & e^{t} \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} e^{t} & 0 \\ 0 & e^{-t} \end{bmatrix} \int \begin{bmatrix} e^{-t} & 0 \\ 0 & e^{t} \end{bmatrix} \begin{bmatrix} \cos(t) \\ 4t \end{bmatrix} dt \\ &= \begin{bmatrix} e^{t} & 0 \\ 0 & e^{-t} \end{bmatrix} \begin{bmatrix} -\frac{e^{-t}(\cos(t) - \sin(t))}{2} \\ 4(t-1)\, e^{t} \end{bmatrix} \\ &= \begin{bmatrix} -\frac{\cos(t)}{2} + \frac{\sin(t)}{2} \\ 4t - 4 \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$\begin{aligned} \vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\ &= \begin{bmatrix} e^{t} c_1 - \frac{\cos(t)}{2} + \frac{\sin(t)}{2} \\ e^{-t} c_2 + 4t - 4 \end{bmatrix} \end{aligned}$$

17.1.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \cos(t) \\ 4t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & 0 \\ 0 & -1-\lambda \end{bmatrix}\right) = 0$$

Since the matrix A is triangular matrix, then the determinant is the product of the elements along the diagonal. Therefore the above becomes

$$(1-\lambda)(-1-\lambda) = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -1$$
$$\lambda_2 = 1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
1	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} - (-1) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 2 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2 & 0 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 0\}$

Hence the solution is

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = t \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

Let $t=1$ the eigenvector becomes

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 0 & 0 \\ 0 & -2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 0 & 0 & 0 \\ 0 & -2 & 0 \end{array}\right]$$

Since the current pivot $A(1,2)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 1 and row 2 gives

$$\left[\begin{array}{cc|c} 0 & -2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 0 & -2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_1\}$ and the leading variables are $\{v_2\}$. Let $v_1 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_2 = 0\}$

Hence the solution is

$$\begin{bmatrix} t \\ 0 \end{bmatrix} = \begin{bmatrix} t \\ 0 \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ 0 \end{bmatrix} = t \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-1	1	1	No	$\begin{bmatrix} 0 \\ 1 \end{bmatrix}$
1	1	1	No	$\begin{bmatrix} 1 \\ 0 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{-t} \\ &= \begin{bmatrix} 0 \\ 1 \end{bmatrix} e^{-t} \end{aligned}$$

Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_2(t) &= \vec{v}_2 e^{t} \\ &= \begin{bmatrix} 1 \\ 0 \end{bmatrix} e^{t} \end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} 0 \\ \mathrm{e}^{-t} \end{bmatrix} + c_2 \begin{bmatrix} \mathrm{e}^{t} \\ 0 \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} 0 & \mathrm{e}^{t} \\ \mathrm{e}^{-t} & 0 \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} 0 & \mathrm{e}^{t} \\ \mathrm{e}^{-t} & 0 \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} 0 & \mathrm{e}^{t} \\ \mathrm{e}^{-t} & 0 \end{bmatrix} \int \begin{bmatrix} 0 & \mathrm{e}^{t} \\ \mathrm{e}^{-t} & 0 \end{bmatrix} \begin{bmatrix} \cos(t) \\ 4t \end{bmatrix} dt \\
&= \begin{bmatrix} 0 & \mathrm{e}^{t} \\ \mathrm{e}^{-t} & 0 \end{bmatrix} \int \begin{bmatrix} 4\,\mathrm{e}^{t} t \\ \mathrm{e}^{-t} \cos(t) \end{bmatrix} dt \\
&= \begin{bmatrix} 0 & \mathrm{e}^{t} \\ \mathrm{e}^{-t} & 0 \end{bmatrix} \begin{bmatrix} 4(t-1)\,\mathrm{e}^{t} \\ -\frac{\mathrm{e}^{-t}(\cos(t)-\sin(t))}{2} \end{bmatrix} \\
&= \begin{bmatrix} -\frac{\cos(t)}{2} + \frac{\sin(t)}{2} \\ 4t - 4 \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} 0 \\ c_1 \mathrm{e}^{-t} \end{bmatrix} + \begin{bmatrix} c_2 \mathrm{e}^{t} \\ 0 \end{bmatrix} + \begin{bmatrix} -\frac{\cos(t)}{2} + \frac{\sin(t)}{2} \\ 4t - 4 \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_2 \mathrm{e}^{t} - \frac{\cos(t)}{2} + \frac{\sin(t)}{2} \\ c_1 \mathrm{e}^{-t} + 4t - 4 \end{bmatrix}$$

17.1.3 Maple step by step solution

Let's solve

$[x'(t) = x(t) + \cos(t), y'(t) = -y(t) + 4t]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} \cos(t) \\ 4t \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} \cos(t) \\ 4t \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} \cos(t) \\ 4t \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$$

- Rewrite the system as

  $\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t) + \overrightarrow{f}$
- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

  $\left[\left[-1, \begin{bmatrix} 0 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 0 \end{bmatrix}\right]\right]$
- Consider eigenpair

  $\left[-1, \begin{bmatrix} 0 \\ 1 \end{bmatrix}\right]$
- Solution to homogeneous system from eigenpair

  $\overrightarrow{x}_1 = \mathrm{e}^{-t} \cdot \begin{bmatrix} 0 \\ 1 \end{bmatrix}$
- Consider eigenpair

  $\left[1, \begin{bmatrix} 1 \\ 0 \end{bmatrix}\right]$
- Solution to homogeneous system from eigenpair

  $\overrightarrow{x}_2 = \mathrm{e}^{t} \cdot \begin{bmatrix} 1 \\ 0 \end{bmatrix}$
- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{x}_p($

  $\overrightarrow{x}(t) = c_1 \overrightarrow{x}_1 + c_2 \overrightarrow{x}_2 + \overrightarrow{x}_p(t)$

□ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

  $\phi(t) = \begin{bmatrix} 0 & \mathrm{e}^{t} \\ \mathrm{e}^{-t} & 0 \end{bmatrix}$
- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

  $\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$
- Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} 0 & e^{t} \\ e^{-t} & 0 \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} e^{t} & 0 \\ 0 & e^{-t} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

$$\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$$

- Take the derivative of the particular solution

$$\vec{x}'_p(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$$

- Substitute particular solution and its derivative into the system of ODEs

$$\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$$A \cdot \Phi(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$$

- Cancel like terms

$$\Phi(t) \cdot \vec{v}'(t) = \vec{f}(t)$$

- Multiply by the inverse of the fundamental matrix

$$\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$$

- Integrate to solve for $\vec{v}(t)$

$$\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\,ds$$

- Plug $\vec{v}(t)$ into the equation for the particular solution

$$\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\,ds\right)$$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{x}_p(t) = \begin{bmatrix} \frac{e^{t}}{2} - \frac{\cos(t)}{2} + \frac{\sin(t)}{2} \\ 4\,e^{-t} + 4t - 4 \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \left[\begin{array}{c} \frac{e^t}{2} - \frac{\cos(t)}{2} + \frac{\sin(t)}{2} \\ 4\,e^{-t} + 4t - 4 \end{array}\right]$$

- Substitute in vector of dependent variables

$$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} c_2 e^t + \frac{e^t}{2} - \frac{\cos(t)}{2} + \frac{\sin(t)}{2} \\ (c_1 + 4)\,e^{-t} + 4t - 4 \end{array}\right]$$

- Solution to the system of ODEs

$$\left\{x(t) = c_2 e^t + \frac{e^t}{2} - \frac{\cos(t)}{2} + \frac{\sin(t)}{2}, y(t) = (c_1 + 4)\,e^{-t} + 4t - 4\right\}$$

✓ Solution by Maple

Time used: 0.031 (sec). Leaf size: 32

```
dsolve([diff(x(t),t)-x(t)=cos(t),diff(y(t),t)+y(t)=4*t],singsol=all)
```

$$x(t) = -\frac{\cos(t)}{2} + \frac{\sin(t)}{2} + c_1 e^t$$
$$y(t) = 4t - 4 + c_2 e^{-t}$$

✓ Solution by Mathematica

Time used: 0.076 (sec). Leaf size: 39

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 26, page 115
Problem number: 2.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 3t^2 - 5x(t) \\
y'(t) &= -y(t) + \mathrm{e}^{3t}
\end{aligned}
$$

17.2.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -5 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 3t^2 \\ \mathrm{e}^{3t} \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} e^{-5t} & 0 \\ 0 & e^{-t} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} e^{-5t} & 0 \\ 0 & e^{-t} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} e^{-5t}c_1 \\ e^{-t}c_2 \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} e^{5t} & 0 \\ 0 & e^{t} \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} e^{-5t} & 0 \\ 0 & e^{-t} \end{bmatrix} \int \begin{bmatrix} e^{5t} & 0 \\ 0 & e^{t} \end{bmatrix} \begin{bmatrix} 3t^2 \\ e^{3t} \end{bmatrix} dt \\ &= \begin{bmatrix} e^{-5t} & 0 \\ 0 & e^{-t} \end{bmatrix} \begin{bmatrix} \frac{3(25t^2-10t+2)e^{5t}}{125} \\ \frac{e^{4t}}{4} \end{bmatrix} \\ &= \begin{bmatrix} \frac{3}{5}t^2 - \frac{6}{25}t + \frac{6}{125} \\ \frac{e^{3t}}{4} \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$\begin{aligned} \vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\ &= \begin{bmatrix} e^{-5t}c_1 + \frac{3t^2}{5} - \frac{6t}{25} + \frac{6}{125} \\ e^{-t}c_2 + \frac{e^{3t}}{4} \end{bmatrix} \end{aligned}$$

17.2.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -5 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 3t^2 \\ e^{3t} \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} -5 & 0 \\ 0 & -1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -5-\lambda & 0 \\ 0 & -1-\lambda \end{bmatrix}\right) = 0$$

Since the matrix A is triangular matrix, then the determinant is the product of the elements along the diagonal. Therefore the above becomes

$$(-5-\lambda)(-1-\lambda) = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -1$$
$$\lambda_2 = -5$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
-5	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -5$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -5 & 0 \\ 0 & -1 \end{bmatrix} - (-5) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 0 & 0 \\ 0 & 4 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 0 & 0 & 0 \\ 0 & 4 & 0 \end{array}\right]$$

Since the current pivot $A(1, 2)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 1 and row 2 gives

$$\left[\begin{array}{cc|c} 0 & 4 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 0 & 4 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_1\}$ and the leading variables are $\{v_2\}$. Let $v_1 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_2 = 0\}$

Hence the solution is

$$\begin{bmatrix} t \\ 0 \end{bmatrix} = \begin{bmatrix} t \\ 0 \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ 0 \end{bmatrix} = t \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -5 & 0 \\ 0 & -1 \end{bmatrix} - (-1) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -4 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -4 & 0 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -4 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 0\}$

Hence the solution is

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = t \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-1	1	1	No	$\begin{bmatrix} 0 \\ 1 \end{bmatrix}$
-5	1	1	No	$\begin{bmatrix} 1 \\ 0 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{-t} \\ &= \begin{bmatrix} 0 \\ 1 \end{bmatrix} e^{-t} \end{aligned}$$

Since eigenvalue -5 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_2(t) &= \vec{v}_2 e^{-5t} \\ &= \begin{bmatrix} 1 \\ 0 \end{bmatrix} e^{-5t} \end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} 0 \\ e^{-t} \end{bmatrix} + c_2 \begin{bmatrix} e^{-5t} \\ 0 \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} 0 & e^{-5t} \\ e^{-t} & 0 \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t) \, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} 0 & e^{t} \\ e^{5t} & 0 \end{bmatrix}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} 0 & e^{-5t} \\ e^{-t} & 0 \end{bmatrix} \int \begin{bmatrix} 0 & e^{t} \\ e^{5t} & 0 \end{bmatrix} \begin{bmatrix} 3t^2 \\ e^{3t} \end{bmatrix} dt \\ &= \begin{bmatrix} 0 & e^{-5t} \\ e^{-t} & 0 \end{bmatrix} \int \begin{bmatrix} e^{4t} \\ 3\,e^{5t} t^2 \end{bmatrix} dt \\ &= \begin{bmatrix} 0 & e^{-5t} \\ e^{-t} & 0 \end{bmatrix} \begin{bmatrix} \frac{e^{4t}}{4} \\ \frac{3(25t^2 - 10t + 2)\,e^{5t}}{125} \end{bmatrix} \\ &= \begin{bmatrix} \frac{3}{5}t^2 - \frac{6}{25}t + \frac{6}{125} \\ \frac{e^{3t}}{4} \end{bmatrix} \end{aligned}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} 0 \\ c_1 e^{-t} \end{bmatrix} + \begin{bmatrix} c_2 e^{-5t} \\ 0 \end{bmatrix} + \begin{bmatrix} \frac{3}{5}t^2 - \frac{6}{25}t + \frac{6}{125} \\ \frac{e^{3t}}{4} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_2 e^{-5t} + \frac{3t^2}{5} - \frac{6t}{25} + \frac{6}{125} \\ c_1 e^{-t} + \frac{e^{3t}}{4} \end{bmatrix}$$

17.2.3 Maple step by step solution

Let's solve

$$\left[x'(t) = 3t^2 - 5x(t), y'(t) = -y(t) + (e^t)^3\right]$$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} -5 & 0 \\ 0 & -1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 3t^2 \\ (e^t)^3 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} -5 & 0 \\ 0 & -1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 3t^2 \\ (e^t)^3 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} 3t^2 \\ (e^t)^3 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} -5 & 0 \\ 0 & -1 \end{bmatrix}$$

- Rewrite the system as

  $\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$
- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

  $\left[\left[-5, \begin{bmatrix} 1 \\ 0 \end{bmatrix}\right], \left[-1, \begin{bmatrix} 0 \\ 1 \end{bmatrix}\right]\right]$
- Consider eigenpair

  $\left[-5, \begin{bmatrix} 1 \\ 0 \end{bmatrix}\right]$
- Solution to homogeneous system from eigenpair

  $\vec{x}_1 = e^{-5t} \cdot \begin{bmatrix} 1 \\ 0 \end{bmatrix}$
- Consider eigenpair

  $\left[-1, \begin{bmatrix} 0 \\ 1 \end{bmatrix}\right]$
- Solution to homogeneous system from eigenpair

  $\vec{x}_2 = e^{-t} \cdot \begin{bmatrix} 0 \\ 1 \end{bmatrix}$
- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

  $\vec{x}(t) = c_1 \vec{x}_1 + c_2 \vec{x}_2 + \vec{x}_p(t)$

□ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

  $\phi(t) = \begin{bmatrix} e^{-5t} & 0 \\ 0 & e^{-t} \end{bmatrix}$
- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

  $\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$
- Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} e^{-5t} & 0 \\ 0 & e^{-t} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} e^{-5t} & 0 \\ 0 & e^{-t} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

$\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$

- Take the derivative of the particular solution

$\vec{x}'_p(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

$\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$A \cdot \Phi(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$

- Cancel like terms

$\Phi(t) \cdot \vec{v}'(t) = \vec{f}(t)$

- Multiply by the inverse of the fundamental matrix

$\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$

- Integrate to solve for $\vec{v}(t)$

$\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

$\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{x}_p(t) = \begin{bmatrix} \frac{3t^2}{5} - \frac{6\,e^{-5t}}{125} - \frac{6t}{25} + \frac{6}{125} \\ \frac{e^{3t}}{4} - \frac{e^{-t}}{4} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \left[\begin{array}{c} \frac{3t^2}{5} - \frac{6\,\mathrm{e}^{-5t}}{125} - \frac{6t}{25} + \frac{6}{125} \\ \frac{\mathrm{e}^{3t}}{4} - \frac{\mathrm{e}^{-t}}{4} \end{array}\right]$$

- Substitute in vector of dependent variables

$$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} c_1\mathrm{e}^{-5t} + \frac{3t^2}{5} - \frac{6\,\mathrm{e}^{-5t}}{125} - \frac{6t}{25} + \frac{6}{125} \\ c_2\mathrm{e}^{-t} + \frac{\mathrm{e}^{3t}}{4} - \frac{\mathrm{e}^{-t}}{4} \end{array}\right]$$

- Solution to the system of ODEs

$$\left\{x(t) = c_1\mathrm{e}^{-5t} + \frac{3t^2}{5} - \frac{6\,\mathrm{e}^{-5t}}{125} - \frac{6t}{25} + \frac{6}{125}, y(t) = c_2\mathrm{e}^{-t} + \frac{\mathrm{e}^{3t}}{4} - \frac{\mathrm{e}^{-t}}{4}\right\}$$

✓ Solution by Maple

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 26, page 115
Problem number: 3.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= -2x(t) + 3t \\
y'(t) &= x(t) - \frac{3t}{2} - \frac{y(t)}{2} + \cos(t)^2 - \frac{1}{2}
\end{aligned}
$$

17.3.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -2 & 0 \\ 1 & -\frac{1}{2} \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 3t \\ -\frac{3t}{2} + \cos(t)^2 - \frac{1}{2} \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} e^{-2t} & 0 \\ \frac{2\,e^{-\frac{t}{2}}}{3} - \frac{2\,e^{-2t}}{3} & e^{-\frac{t}{2}} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} e^{-2t} & 0 \\ \frac{2\,e^{-\frac{t}{2}}}{3} - \frac{2\,e^{-2t}}{3} & e^{-\frac{t}{2}} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} e^{-2t} c_1 \\ \left(\frac{2\,e^{-\frac{t}{2}}}{3} - \frac{2\,e^{-2t}}{3}\right) c_1 + e^{-\frac{t}{2}} c_2 \end{bmatrix} \\
&= \begin{bmatrix} e^{-2t} c_1 \\ \frac{(2c_1+3c_2)e^{-\frac{t}{2}}}{3} - \frac{2\,e^{-2t} c_1}{3} \end{bmatrix}
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\, dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \begin{bmatrix} e^{2t} & 0 \\ -\frac{2\left(e^{\frac{3t}{2}}-1\right)e^{\frac{t}{2}}}{3} & e^{\frac{t}{2}} \end{bmatrix}
\end{aligned}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} e^{-2t} & 0 \\ \frac{2\,e^{-\frac{t}{2}}}{3} - \frac{2\,e^{-2t}}{3} & e^{-\frac{t}{2}} \end{bmatrix} \int \begin{bmatrix} e^{2t} & 0 \\ -\frac{2\left(e^{\frac{3t}{2}}-1\right)e^{\frac{t}{2}}}{3} & e^{\frac{t}{2}} \end{bmatrix} \begin{bmatrix} 3t \\ -\frac{3t}{2} + \cos(t)^2 - \frac{1}{2} \end{bmatrix} dt \\
&= \begin{bmatrix} e^{-2t} & 0 \\ \frac{2\,e^{-\frac{t}{2}}}{3} - \frac{2\,e^{-2t}}{3} & e^{-\frac{t}{2}} \end{bmatrix} \begin{bmatrix} \frac{3(2t-1)e^{2t}}{4} \\ \frac{(-34+17t+\cos(2t)+4\sin(2t))e^{\frac{t}{2}}}{17} + \frac{(-2t+1)e^{2t}}{2} \end{bmatrix} \\
&= \begin{bmatrix} \frac{3t}{2} - \frac{3}{4} \\ \frac{\cos(2t)}{17} + \frac{4\sin(2t)}{17} - \frac{3}{2} \end{bmatrix}
\end{aligned}$$

Hence the complete solution is

$$
\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
&= \begin{bmatrix} \mathrm{e}^{-2t} c_1 + \frac{3t}{2} - \frac{3}{4} \\ \frac{(2c_1+3c_2)\mathrm{e}^{-\frac{t}{2}}}{3} - \frac{2\,\mathrm{e}^{-2t} c_1}{3} + \frac{\cos(2t)}{17} + \frac{4\sin(2t)}{17} - \frac{3}{2} \end{bmatrix}
\end{aligned}
$$

17.3.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -2 & 0 \\ 1 & -\frac{1}{2} \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 3t \\ -\frac{3t}{2} + \cos(t)^2 - \frac{1}{2} \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$
\det(A - \lambda I) = 0
$$

Expanding gives

$$
\det\left(\begin{bmatrix} -2 & 0 \\ 1 & -\frac{1}{2} \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0
$$

Therefore

$$
\det\left(\begin{bmatrix} -2-\lambda & 0 \\ 1 & -\frac{1}{2}-\lambda \end{bmatrix}\right) = 0
$$

Since the matrix A is triangular matrix, then the determinant is the product of the elements along the diagonal. Therefore the above becomes

$$(-2-\lambda)(-\frac{1}{2}-\lambda)=0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -\frac{1}{2}$$
$$\lambda_2 = -2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-2	1	real eigenvalue
$-\frac{1}{2}$	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A-\lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -2 & 0 \\ 1 & -\frac{1}{2} \end{bmatrix} - (-2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 0 & 0 \\ 1 & \frac{3}{2} \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 0 & 0 & 0 \\ 1 & \frac{3}{2} & 0 \end{array}\right]$$

Since the current pivot $A(1,1)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 1 and row 2 gives

$$\left[\begin{array}{cc|c} 1 & \frac{3}{2} & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & \frac{3}{2} \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{3t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{3t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{3t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{3t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{3t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{3t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -3 \\ 2 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = -\frac{1}{2}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -2 & 0 \\ 1 & -\frac{1}{2} \end{bmatrix} - \left(-\frac{1}{2}\right) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -\frac{3}{2} & 0 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -\frac{3}{2} & 0 & 0 \\ 1 & 0 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{2R_1}{3} \implies \left[\begin{array}{cc|c} -\frac{3}{2} & 0 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -\frac{3}{2} & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 0\}$

Hence the solution is

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = t \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
$-\frac{1}{2}$	1	1	No	$\begin{bmatrix} 0 \\ 1 \end{bmatrix}$
-2	1	1	No	$\begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue $-\frac{1}{2}$ is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^{-\frac{t}{2}} \\
&= \begin{bmatrix} 0 \\ 1 \end{bmatrix} e^{-\frac{t}{2}}
\end{aligned}
$$

Since eigenvalue -2 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_2(t) &= \vec{v}_2 e^{-2t} \\
&= \begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix} e^{-2t}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)
$$

Which is written as

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} 0 \\ \mathrm{e}^{-\frac{t}{2}} \end{bmatrix} + c_2 \begin{bmatrix} -\frac{3\,\mathrm{e}^{-2t}}{2} \\ \mathrm{e}^{-2t} \end{bmatrix}
$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$
\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}
$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$
\Phi(t) = \begin{bmatrix} 0 & -\frac{3\,\mathrm{e}^{-2t}}{2} \\ \mathrm{e}^{-\frac{t}{2}} & \mathrm{e}^{-2t} \end{bmatrix}
$$

The particular solution is then given by

$$
\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt
$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{2\,e^{\frac{t}{2}}}{3} & e^{\frac{t}{2}} \\ -\frac{2\,e^{2t}}{3} & 0 \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} 0 & -\frac{3\,e^{-2t}}{2} \\ e^{-\frac{t}{2}} & e^{-2t} \end{bmatrix} \int \begin{bmatrix} \frac{2\,e^{\frac{t}{2}}}{3} & e^{\frac{t}{2}} \\ -\frac{2\,e^{2t}}{3} & 0 \end{bmatrix} \begin{bmatrix} 3t \\ -\frac{3t}{2} + \cos(t)^2 - \frac{1}{2} \end{bmatrix} dt \\
&= \begin{bmatrix} 0 & -\frac{3\,e^{-2t}}{2} \\ e^{-\frac{t}{2}} & e^{-2t} \end{bmatrix} \int \begin{bmatrix} \frac{e^{\frac{t}{2}}\left(2\cos(t)^2+t-1\right)}{2} \\ -2\,e^{2t}t \end{bmatrix} dt \\
&= \begin{bmatrix} 0 & -\frac{3\,e^{-2t}}{2} \\ e^{-\frac{t}{2}} & e^{-2t} \end{bmatrix} \begin{bmatrix} \frac{(-34+17t+\cos(2t)+4\sin(2t))e^{\frac{t}{2}}}{17} \\ -\frac{(2t-1)e^{2t}}{2} \end{bmatrix} \\
&= \begin{bmatrix} \frac{3t}{2} - \frac{3}{4} \\ \frac{\cos(2t)}{17} + \frac{4\sin(2t)}{17} - \frac{3}{2} \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} &= \begin{bmatrix} 0 \\ c_1 e^{-\frac{t}{2}} \end{bmatrix} + \begin{bmatrix} -\frac{3c_2 e^{-2t}}{2} \\ c_2 e^{-2t} \end{bmatrix} + \begin{bmatrix} \frac{3t}{2} - \frac{3}{4} \\ \frac{\cos(2t)}{17} + \frac{4\sin(2t)}{17} - \frac{3}{2} \end{bmatrix}
\end{aligned}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{3c_2 e^{-2t}}{2} + \frac{3t}{2} - \frac{3}{4} \\ c_1 e^{-\frac{t}{2}} + c_2 e^{-2t} + \frac{\cos(2t)}{17} + \frac{4\sin(2t)}{17} - \frac{3}{2} \end{bmatrix}$$

17.3.3 Maple step by step solution

Let's solve

$\left[x'(t) = -2x(t) + 3t, y'(t) = x(t) - \frac{3t}{2} - \frac{y(t)}{2} + \cos(t)^2 - \frac{1}{2}\right]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} -2 & 0 \\ 1 & -\frac{1}{2} \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 3t \\ -\frac{3t}{2} + \cos(t)^2 - \frac{1}{2} \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} -2 & 0 \\ 1 & -\frac{1}{2} \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 3t \\ -\frac{3t}{2} + \cos(t)^2 - \frac{1}{2} \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} 3t \\ -\frac{3t}{2} + \cos(t)^2 - \frac{1}{2} \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} -2 & 0 \\ 1 & -\frac{1}{2} \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2, \begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix}\right], \left[-\frac{1}{2}, \begin{bmatrix} 0 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-2, \begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^{-2t} \cdot \begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[-\frac{1}{2}, \begin{bmatrix} 0 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = e^{-\frac{t}{2}} \cdot \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

$$\vec{x}(t) = c_1 \vec{x}_1 + c_2 \vec{x}_2 + \vec{x}_p(t)$$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(t) = \begin{bmatrix} -\frac{3\,e^{-2t}}{2} & 0 \\ e^{-2t} & e^{-\frac{t}{2}} \end{bmatrix}$$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$$\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$$

- Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} -\frac{3\,e^{-2t}}{2} & 0 \\ e^{-2t} & e^{-\frac{t}{2}} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -\frac{3}{2} & 0 \\ 1 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} e^{-2t} & 0 \\ \frac{2\,e^{-\frac{t}{2}}}{3} - \frac{2\,e^{-2t}}{3} & e^{-\frac{t}{2}} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

$$\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$$

- Take the derivative of the particular solution

$$\vec{x}_p'(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$$

- Substitute particular solution and its derivative into the system of ODEs

$$\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A\cdot\Phi(t)\cdot\vec{v}(t)+\Phi(t)\cdot\vec{v}'(t)=A\cdot\Phi(t)\cdot\vec{v}(t)+\vec{f}(t)$

- Cancel like terms

  $\Phi(t)\cdot\vec{v}'(t)=\vec{f}(t)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(t)=\frac{1}{\Phi(t)}\cdot\vec{f}(t)$

- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t)=\int_0^t\frac{1}{\Phi(s)}\cdot\vec{f}(s)\,ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t)=\Phi(t)\cdot\left(\int_0^t\frac{1}{\Phi(s)}\cdot\vec{f}(s)\,ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\vec{x}_p(t)=\left[\begin{array}{c}\frac{3\,\mathrm{e}^{-2t}}{4}+\frac{3t}{2}-\frac{3}{4}\\ \frac{33\,\mathrm{e}^{-\frac{t}{2}}}{17}-\frac{\mathrm{e}^{-2t}}{2}-\frac{3}{2}+\frac{\cos(2t)}{17}+\frac{4\sin(2t)}{17}\end{array}\right]$$

- Plug particular solution back into general solution

  $$\vec{x}(t)=c_1\vec{x}_1+c_2\vec{x}_2+\left[\begin{array}{c}\frac{3\,\mathrm{e}^{-2t}}{4}+\frac{3t}{2}-\frac{3}{4}\\ \frac{33\,\mathrm{e}^{-\frac{t}{2}}}{17}-\frac{\mathrm{e}^{-2t}}{2}-\frac{3}{2}+\frac{\cos(2t)}{17}+\frac{4\sin(2t)}{17}\end{array}\right]$$

- Substitute in vector of dependent variables

  $$\left[\begin{array}{c}x(t)\\ y(t)\end{array}\right]=\left[\begin{array}{c}\frac{(-6c_1+3)\mathrm{e}^{-2t}}{4}+\frac{3t}{2}-\frac{3}{4}\\ c_1\mathrm{e}^{-2t}+c_2\mathrm{e}^{-\frac{t}{2}}+\frac{33\,\mathrm{e}^{-\frac{t}{2}}}{17}-\frac{\mathrm{e}^{-2t}}{2}-\frac{3}{2}+\frac{\cos(2t)}{17}+\frac{4\sin(2t)}{17}\end{array}\right]$$

- Solution to the system of ODEs

  $$\left\{x(t)=\frac{(-6c_1+3)\mathrm{e}^{-2t}}{4}+\frac{3t}{2}-\frac{3}{4},y(t)=c_1\mathrm{e}^{-2t}+c_2\mathrm{e}^{-\frac{t}{2}}+\frac{33\,\mathrm{e}^{-\frac{t}{2}}}{17}-\frac{\mathrm{e}^{-2t}}{2}-\frac{3}{2}+\frac{\cos(2t)}{17}+\frac{4\sin(2t)}{17}\right\}$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= -y(t) + x(t) + 2\sin(t) \\
y'(t) &= 4y(t) - 4x(t) - 2\sin(t)
\end{aligned}
$$

17.4.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & -1 \\ -4 & 4 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 2\sin(t) \\ -2\sin(t) \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{4}{5} + \frac{e^{5t}}{5} & -\frac{e^{5t}}{5} + \frac{1}{5} \\ -\frac{4\,e^{5t}}{5} + \frac{4}{5} & \frac{1}{5} + \frac{4\,e^{5t}}{5} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} \frac{4}{5} + \frac{e^{5t}}{5} & -\frac{e^{5t}}{5} + \frac{1}{5} \\ -\frac{4\,e^{5t}}{5} + \frac{4}{5} & \frac{1}{5} + \frac{4\,e^{5t}}{5} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} \left(\frac{4}{5} + \frac{e^{5t}}{5}\right) c_1 + \left(-\frac{e^{5t}}{5} + \frac{1}{5}\right) c_2 \\ \left(-\frac{4\,e^{5t}}{5} + \frac{4}{5}\right) c_1 + \left(\frac{1}{5} + \frac{4\,e^{5t}}{5}\right) c_2 \end{bmatrix} \\ &= \begin{bmatrix} \frac{e^{5t}(-c_2+c_1)}{5} + \frac{4c_1}{5} + \frac{c_2}{5} \\ \frac{(-4c_1+4c_2)e^{5t}}{5} + \frac{4c_1}{5} + \frac{c_2}{5} \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\, dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} \frac{e^{-5t}}{5} + \frac{4}{5} & \frac{1}{5} - \frac{e^{-5t}}{5} \\ \frac{4}{5} - \frac{4\,e^{-5t}}{5} & \frac{4\,e^{-5t}}{5} + \frac{1}{5} \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} \frac{4}{5} + \frac{e^{5t}}{5} & -\frac{e^{5t}}{5} + \frac{1}{5} \\ -\frac{4\,e^{5t}}{5} + \frac{4}{5} & \frac{1}{5} + \frac{4\,e^{5t}}{5} \end{bmatrix} \int \begin{bmatrix} \frac{e^{-5t}}{5} + \frac{4}{5} & \frac{1}{5} - \frac{e^{-5t}}{5} \\ \frac{4}{5} - \frac{4\,e^{-5t}}{5} & \frac{4\,e^{-5t}}{5} + \frac{1}{5} \end{bmatrix} \begin{bmatrix} 2\sin(t) \\ -2\sin(t) \end{bmatrix} dt \\ &= \begin{bmatrix} \frac{4}{5} + \frac{e^{5t}}{5} & -\frac{e^{5t}}{5} + \frac{1}{5} \\ -\frac{4\,e^{5t}}{5} + \frac{4}{5} & \frac{1}{5} + \frac{4\,e^{5t}}{5} \end{bmatrix} \begin{bmatrix} \frac{2(-\cos(t)-5\sin(t))e^{-5t}}{65} - \frac{6\cos(t)}{5} \\ \frac{8(\cos(t)+5\sin(t))e^{-5t}}{65} - \frac{6\cos(t)}{5} \end{bmatrix} \\ &= \begin{bmatrix} -\frac{16\cos(t)}{13} - \frac{2\sin(t)}{13} \\ -\frac{14\cos(t)}{13} + \frac{8\sin(t)}{13} \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$= \begin{bmatrix} \frac{e^{5t}(-c_2+c_1)}{5} + \frac{4c_1}{5} + \frac{c_2}{5} - \frac{16\cos(t)}{13} - \frac{2\sin(t)}{13} \\ \frac{4(c_2-c_1)e^{5t}}{5} + \frac{4c_1}{5} + \frac{c_2}{5} - \frac{14\cos(t)}{13} + \frac{8\sin(t)}{13} \end{bmatrix}$$

17.4.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & -1 \\ -4 & 4 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 2\sin(t) \\ -2\sin(t) \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & -1 \\ -4 & 4 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & -1 \\ -4 & 4-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 5\lambda = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 5$$
$$\lambda_2 = 0$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
0	1	real eigenvalue
5	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 0$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & -1 \\ -4 & 4 \end{bmatrix} - (0)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 1 & -1 \\ -4 & 4 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 & -1 & 0 \\ -4 & 4 & 0 \end{array}\right]$$

$$R_2 = R_2 + 4R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & -1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 5$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & -1 \\ -4 & 4 \end{bmatrix} - (5) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -4 & -1 \\ -4 & -1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -4 & -1 & 0 \\ -4 & -1 & 0 \end{array} \right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} -4 & -1 & 0 \\ 0 & 0 & 0 \end{array} \right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -4 & -1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{t}{4}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 4 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
5	1	1	No	$\begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}$
0	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 5 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_1(t) = \vec{v}_1 e^{5t}$$
$$= \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix} e^{5t}$$

Since eigenvalue 0 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{0}$$
$$= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{0}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\frac{e^{5t}}{4} \\ e^{5t} \end{bmatrix} + c_2 \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -\frac{e^{5t}}{4} & 1 \\ e^{5t} & 1 \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t) \, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{4 e^{-5t}}{5} & \frac{4 e^{-5t}}{5} \\ \frac{4}{5} & \frac{1}{5} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} -\frac{e^{5t}}{4} & 1 \\ e^{5t} & 1 \end{bmatrix} \int \begin{bmatrix} -\frac{4\,e^{-5t}}{5} & \frac{4\,e^{-5t}}{5} \\ \frac{4}{5} & \frac{1}{5} \end{bmatrix} \begin{bmatrix} 2\sin(t) \\ -2\sin(t) \end{bmatrix} dt$$

$$= \begin{bmatrix} -\frac{e^{5t}}{4} & 1 \\ e^{5t} & 1 \end{bmatrix} \int \begin{bmatrix} -\frac{16\sin(t)e^{-5t}}{5} \\ \frac{6\sin(t)}{5} \end{bmatrix} dt$$

$$= \begin{bmatrix} -\frac{e^{5t}}{4} & 1 \\ e^{5t} & 1 \end{bmatrix} \begin{bmatrix} \frac{8(\cos(t)+5\sin(t))e^{-5t}}{65} \\ -\frac{6\cos(t)}{5} \end{bmatrix}$$

$$= \begin{bmatrix} -\frac{16\cos(t)}{13} - \frac{2\sin(t)}{13} \\ -\frac{14\cos(t)}{13} + \frac{8\sin(t)}{13} \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{c_1 e^{5t}}{4} \\ c_1 e^{5t} \end{bmatrix} + \begin{bmatrix} c_2 \\ c_2 \end{bmatrix} + \begin{bmatrix} -\frac{16\cos(t)}{13} - \frac{2\sin(t)}{13} \\ -\frac{14\cos(t)}{13} + \frac{8\sin(t)}{13} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{c_1 e^{5t}}{4} + c_2 - \frac{16\cos(t)}{13} - \frac{2\sin(t)}{13} \\ c_1 e^{5t} + c_2 - \frac{14\cos(t)}{13} + \frac{8\sin(t)}{13} \end{bmatrix}$$

17.4.3 Maple step by step solution

Let's solve

$[x'(t) = -y(t) + x(t) + 2\sin(t), y'(t) = 4y(t) - 4x(t) - 2\sin(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & -1 \\ -4 & 4 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 2\sin(t) \\ -2\sin(t) \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & -1 \\ -4 & 4 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 2\sin(t) \\ -2\sin(t) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} 2\sin(t) \\ -2\sin(t) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & -1 \\ -4 & 4 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right], \left[5, \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[5, \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = e^{5t} \cdot \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{x}_p($

  $\overrightarrow{x}(t) = c_1\overrightarrow{x}_1 + c_2\overrightarrow{x}_2 + \overrightarrow{x}_p(t)$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

  $$\phi(t) = \begin{bmatrix} 1 & -\frac{e^{5t}}{4} \\ 1 & e^{5t} \end{bmatrix}$$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

  $\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(t)$ and $\phi(0)$

  $$\Phi(t) = \begin{bmatrix} 1 & -\frac{e^{5t}}{4} \\ 1 & e^{5t} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & -\frac{1}{4} \\ 1 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

  $$\Phi(t) = \begin{bmatrix} \frac{4}{5} + \frac{e^{5t}}{5} & -\frac{e^{5t}}{5} + \frac{1}{5} \\ -\frac{4\,e^{5t}}{5} + \frac{4}{5} & \frac{1}{5} + \frac{4\,e^{5t}}{5} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

  $\overrightarrow{x}_p(t) = \Phi(t) \cdot \overrightarrow{v}(t)$

- Take the derivative of the particular solution

  $\overrightarrow{x}'_p(t) = \Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- Cancel like terms

  $\Phi(t) \cdot \overrightarrow{v}'(t) = \overrightarrow{f}(t)$

- Multiply by the inverse of the fundamental matrix

$\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$

- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\vec{x}_p(t) = \left[\begin{array}{c} \frac{6}{5} - \frac{16\cos(t)}{13} + \frac{2\,e^{5t}}{65} - \frac{2\sin(t)}{13} \\ \frac{6}{5} - \frac{14\cos(t)}{13} - \frac{8\,e^{5t}}{65} + \frac{8\sin(t)}{13} \end{array}\right]$$

- Plug particular solution back into general solution

  $$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \left[\begin{array}{c} \frac{6}{5} - \frac{16\cos(t)}{13} + \frac{2\,e^{5t}}{65} - \frac{2\sin(t)}{13} \\ \frac{6}{5} - \frac{14\cos(t)}{13} - \frac{8\,e^{5t}}{65} + \frac{8\sin(t)}{13} \end{array}\right]$$

- Substitute in vector of dependent variables

  $$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} -\frac{c_2 e^{5t}}{4} + \frac{6}{5} - \frac{16\cos(t)}{13} + \frac{2\,e^{5t}}{65} - \frac{2\sin(t)}{13} + c_1 \\ c_2 e^{5t} + \frac{6}{5} - \frac{14\cos(t)}{13} - \frac{8\,e^{5t}}{65} + \frac{8\sin(t)}{13} + c_1 \end{array}\right]$$

- Solution to the system of ODEs

  $$\left\{x(t) = -\frac{c_2 e^{5t}}{4} + \frac{6}{5} - \frac{16\cos(t)}{13} + \frac{2\,e^{5t}}{65} - \frac{2\sin(t)}{13} + c_1, y(t) = c_2 e^{5t} + \frac{6}{5} - \frac{14\cos(t)}{13} - \frac{8\,e^{5t}}{65} + \frac{8\sin(t)}{13} + c_1\right\}$$

Section: Exercise 26, page 115
Problem number: 5.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = -\frac{3x(t)}{2} + \frac{y(t)}{2} + \frac{e^t}{2}$$
$$y'(t) = \frac{5x(t)}{3} - \frac{y(t)}{3} - \frac{2t}{3}$$

17.5.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -\frac{3}{2} & \frac{1}{2} \\ \frac{5}{3} & -\frac{1}{3} \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \frac{e^t}{2} \\ -\frac{2t}{3} \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{\left(3\,e^{\frac{13t}{6}}+10\right)e^{-2t}}{13} & \frac{3\left(e^{\frac{13t}{6}}-1\right)e^{-2t}}{13} \\ \frac{10\left(e^{\frac{13t}{6}}-1\right)e^{-2t}}{13} & \frac{\left(10\,e^{\frac{13t}{6}}+3\right)e^{-2t}}{13} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} \frac{\left(3\,e^{\frac{13t}{6}}+10\right)e^{-2t}}{13} & \frac{3\left(e^{\frac{13t}{6}}-1\right)e^{-2t}}{13} \\ \frac{10\left(e^{\frac{13t}{6}}-1\right)e^{-2t}}{13} & \frac{\left(10\,e^{\frac{13t}{6}}+3\right)e^{-2t}}{13} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} \frac{\left(3\,e^{\frac{13t}{6}}+10\right)e^{-2t}c_1}{13} + \frac{3\left(e^{\frac{13t}{6}}-1\right)e^{-2t}c_2}{13} \\ \frac{10\left(e^{\frac{13t}{6}}-1\right)e^{-2t}c_1}{13} + \frac{\left(10\,e^{\frac{13t}{6}}+3\right)e^{-2t}c_2}{13} \end{bmatrix} \\ &= \begin{bmatrix} \frac{3\left((c_1+c_2)e^{\frac{13t}{6}}+\frac{10c_1}{3}-c_2\right)e^{-2t}}{13} \\ \frac{10\,e^{-2t}\left((c_1+c_2)e^{\frac{13t}{6}}-c_1+\frac{3c_2}{10}\right)}{13} \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned} e^{-At} &= \left(e^{At}\right)^{-1} \\ &= \begin{bmatrix} \frac{10\,e^{2t}}{13} + \frac{3\,e^{-\frac{t}{6}}}{13} & -\frac{3\,e^{2t}}{13} + \frac{3\,e^{-\frac{t}{6}}}{13} \\ -\frac{10\,e^{2t}}{13} + \frac{10\,e^{-\frac{t}{6}}}{13} & \frac{3\,e^{2t}}{13} + \frac{10\,e^{-\frac{t}{6}}}{13} \end{bmatrix} \end{aligned}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} \frac{\left(3\,e^{\frac{13t}{6}}+10\right)e^{-2t}}{13} & \frac{3\left(e^{\frac{13t}{6}}-1\right)e^{-2t}}{13} \\ \frac{10\left(e^{\frac{13t}{6}}-1\right)e^{-2t}}{13} & \frac{\left(10\,e^{\frac{13t}{6}}+3\right)e^{-2t}}{13} \end{bmatrix} \int \begin{bmatrix} \frac{10\,e^{2t}}{13}+\frac{3\,e^{-\frac{t}{6}}}{13} & -\frac{3\,e^{2t}}{13}+\frac{3\,e^{-\frac{t}{6}}}{13} \\ -\frac{10\,e^{2t}}{13}+\frac{10\,e^{-\frac{t}{6}}}{13} & \frac{3\,e^{2t}}{13}+\frac{10\,e^{-\frac{t}{6}}}{13} \end{bmatrix} \begin{bmatrix} \frac{e^t}{2} \\ -\frac{2t}{3} \end{bmatrix} dt$$

$$= \begin{bmatrix} \frac{\left(3\,e^{\frac{13t}{6}}+10\right)e^{-2t}}{13} & \frac{3\left(e^{\frac{13t}{6}}-1\right)e^{-2t}}{13} \\ \frac{10\left(e^{\frac{13t}{6}}-1\right)e^{-2t}}{13} & \frac{\left(10\,e^{\frac{13t}{6}}+3\right)e^{-2t}}{13} \end{bmatrix} \begin{bmatrix} \frac{12(6+t)e^{-\frac{t}{6}}}{13}+\frac{9\,e^{\frac{5t}{6}}}{65}+\frac{(2t-1)e^{2t}}{26}+\frac{5\,e^{3t}}{39} \\ \frac{40(6+t)e^{-\frac{t}{6}}}{13}+\frac{6\,e^{\frac{5t}{6}}}{13}+\frac{(-2t+1)e^{2t}}{26}-\frac{5\,e^{3t}}{39} \end{bmatrix}$$

$$= \begin{bmatrix} t+\frac{11}{2}+\frac{4\,e^t}{15} \\ 3t+\frac{37}{2}+\frac{e^t}{3} \end{bmatrix}$$

Hence the complete solution is

$$\begin{aligned} \vec{x}(t) &= \vec{x}_h(t)+\vec{x}_p(t) \\ &= \begin{bmatrix} \frac{e^{-2t}\left(3(c_1+c_2)e^{\frac{13t}{6}}+13\,e^{2t}t+10c_1-3c_2+\frac{143\,e^{2t}}{2}+\frac{52\,e^{3t}}{15}\right)}{13} \\ \frac{e^{-2t}\left(10(c_1+c_2)e^{\frac{13t}{6}}+39\,e^{2t}t-10c_1+3c_2+\frac{481\,e^{2t}}{2}+\frac{13\,e^{3t}}{3}\right)}{13} \end{bmatrix} \end{aligned}$$

17.5.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)+\vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -\frac{3}{2} & \frac{1}{2} \\ \frac{5}{3} & -\frac{1}{3} \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \frac{e^t}{2} \\ -\frac{2t}{3} \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t)+\vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t)+\vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A-\lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix}-\frac{3}{2} & \frac{1}{2}\\ \frac{5}{3} & -\frac{1}{3}\end{bmatrix} - \lambda\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix}-\frac{3}{2}-\lambda & \frac{1}{2}\\ \frac{5}{3} & -\frac{1}{3}-\lambda\end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + \frac{11}{6}\lambda - \frac{1}{3} = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -2$$
$$\lambda_2 = \frac{1}{6}$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-2	1	real eigenvalue
$\frac{1}{6}$	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix}-\frac{3}{2} & \frac{1}{2}\\ \frac{5}{3} & -\frac{1}{3}\end{bmatrix} - (-2)\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}\right)\begin{bmatrix}v_1\\ v_2\end{bmatrix} = \begin{bmatrix}0\\ 0\end{bmatrix}$$
$$\begin{bmatrix}\frac{1}{2} & \frac{1}{2}\\ \frac{5}{3} & \frac{5}{3}\end{bmatrix}\begin{bmatrix}v_1\\ v_2\end{bmatrix} = \begin{bmatrix}0\\ 0\end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c}\frac{1}{2} & \frac{1}{2} & 0\\ \frac{5}{3} & \frac{5}{3} & 0\end{array}\right]$$

$$R_2 = R_2 - \frac{10R_1}{3} \Longrightarrow \left[\begin{array}{cc|c} \frac{1}{2} & \frac{1}{2} & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} \frac{1}{2} & \frac{1}{2} \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = \frac{1}{6}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -\frac{3}{2} & \frac{1}{2} \\ \frac{5}{3} & -\frac{1}{3} \end{bmatrix} - \left(\frac{1}{6}\right) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -\frac{5}{3} & \frac{1}{2} \\ \frac{5}{3} & -\frac{1}{2} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -\frac{5}{3} & \frac{1}{2} & 0 \\ \frac{5}{3} & -\frac{1}{2} & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} -\frac{5}{3} & \frac{1}{2} & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -\frac{5}{3} & \frac{1}{2} \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{3t}{10}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{3t}{10} \\ t \end{bmatrix} = \begin{bmatrix} \frac{3t}{10} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{3t}{10} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{3}{10} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{3t}{10} \\ t \end{bmatrix} = \begin{bmatrix} \frac{3}{10} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{3t}{10} \\ t \end{bmatrix} = \begin{bmatrix} 3 \\ 10 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
-2	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$
$\frac{1}{6}$	1	1	No	$\begin{bmatrix} \frac{3}{10} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -2 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^{-2t} \\ &= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{-2t}\end{aligned}$$

Since eigenvalue $\frac{1}{6}$ is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{\frac{t}{6}} \\ &= \begin{bmatrix} \frac{3}{10} \\ 1 \end{bmatrix} e^{\frac{t}{6}}\end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\mathrm{e}^{-2t} \\ \mathrm{e}^{-2t} \end{bmatrix} + c_2 \begin{bmatrix} \frac{3\,\mathrm{e}^{\frac{t}{6}}}{10} \\ \mathrm{e}^{\frac{t}{6}} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -\mathrm{e}^{-2t} & \frac{3\,\mathrm{e}^{\frac{t}{6}}}{10} \\ \mathrm{e}^{-2t} & \mathrm{e}^{\frac{t}{6}} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t) \, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{10\,\mathrm{e}^{2t}}{13} & \frac{3\,\mathrm{e}^{2t}}{13} \\ \frac{10\,\mathrm{e}^{-\frac{t}{6}}}{13} & \frac{10\,\mathrm{e}^{-\frac{t}{6}}}{13} \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} -\mathrm{e}^{-2t} & \frac{3\,\mathrm{e}^{\frac{t}{6}}}{10} \\ \mathrm{e}^{-2t} & \mathrm{e}^{\frac{t}{6}} \end{bmatrix} \int \begin{bmatrix} -\frac{10\,\mathrm{e}^{2t}}{13} & \frac{3\,\mathrm{e}^{2t}}{13} \\ \frac{10\,\mathrm{e}^{-\frac{t}{6}}}{13} & \frac{10\,\mathrm{e}^{-\frac{t}{6}}}{13} \end{bmatrix} \begin{bmatrix} \frac{\mathrm{e}^{t}}{2} \\ -\frac{2t}{3} \end{bmatrix} dt \\
&= \begin{bmatrix} -\mathrm{e}^{-2t} & \frac{3\,\mathrm{e}^{\frac{t}{6}}}{10} \\ \mathrm{e}^{-2t} & \mathrm{e}^{\frac{t}{6}} \end{bmatrix} \int \begin{bmatrix} -\frac{5\,\mathrm{e}^{3t}}{13} - \frac{2\,\mathrm{e}^{2t}t}{13} \\ \frac{5\,\mathrm{e}^{\frac{5t}{6}}}{13} - \frac{20t\,\mathrm{e}^{-\frac{t}{6}}}{39} \end{bmatrix} dt \\
&= \begin{bmatrix} -\mathrm{e}^{-2t} & \frac{3\,\mathrm{e}^{\frac{t}{6}}}{10} \\ \mathrm{e}^{-2t} & \mathrm{e}^{\frac{t}{6}} \end{bmatrix} \begin{bmatrix} \frac{(-6t+3)\mathrm{e}^{2t}}{78} - \frac{5\,\mathrm{e}^{3t}}{39} \\ \frac{40(6+t)\mathrm{e}^{-\frac{t}{6}}}{13} + \frac{6\,\mathrm{e}^{\frac{5t}{6}}}{13} \end{bmatrix} \\
&= \begin{bmatrix} t + \frac{11}{2} + \frac{4\,\mathrm{e}^{t}}{15} \\ 3t + \frac{37}{2} + \frac{\mathrm{e}^{t}}{3} \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} &= \begin{bmatrix} -c_1\mathrm{e}^{-2t} \\ c_1\mathrm{e}^{-2t} \end{bmatrix} + \begin{bmatrix} \frac{3c_2\mathrm{e}^{\frac{t}{6}}}{10} \\ c_2\mathrm{e}^{\frac{t}{6}} \end{bmatrix} + \begin{bmatrix} t + \frac{11}{2} + \frac{4\,\mathrm{e}^{t}}{15} \\ 3t + \frac{37}{2} + \frac{\mathrm{e}^{t}}{3} \end{bmatrix}
\end{aligned}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{\left(8\,\mathrm{e}^{3t} + 9c_2\mathrm{e}^{\frac{13t}{6}} + 30\,\mathrm{e}^{2t}t + 165\,\mathrm{e}^{2t} - 30c_1\right)\mathrm{e}^{-2t}}{30} \\ \frac{\left(2\,\mathrm{e}^{3t} + 6c_2\mathrm{e}^{\frac{13t}{6}} + 18\,\mathrm{e}^{2t}t + 111\,\mathrm{e}^{2t} + 6c_1\right)\mathrm{e}^{-2t}}{6} \end{bmatrix}$$

17.5.3 Maple step by step solution

Let's solve

$$\left[x'(t) = -\frac{3x(t)}{2} + \frac{y(t)}{2} + \frac{e^t}{2}, y'(t) = \frac{5x(t)}{3} - \frac{y(t)}{3} - \frac{2t}{3}\right]$$

- Define vector

$$\vec{x}(t) = \left[\begin{array}{c} x(t) \\ y(t) \end{array}\right]$$

- Convert system into a vector equation

$$\vec{x}'(t) = \left[\begin{array}{cc} -\frac{3}{2} & \frac{1}{2} \\ \frac{5}{3} & -\frac{1}{3} \end{array}\right] \cdot \vec{x}(t) + \left[\begin{array}{c} \frac{e^t}{2} \\ -\frac{2t}{3} \end{array}\right]$$

- System to solve

$$\vec{x}'(t) = \left[\begin{array}{cc} -\frac{3}{2} & \frac{1}{2} \\ \frac{5}{3} & -\frac{1}{3} \end{array}\right] \cdot \vec{x}(t) + \left[\begin{array}{c} \frac{e^t}{2} \\ -\frac{2t}{3} \end{array}\right]$$

- Define the forcing function

$$\vec{f}(t) = \left[\begin{array}{c} \frac{e^t}{2} \\ -\frac{2t}{3} \end{array}\right]$$

- Define the coefficient matrix

$$A = \left[\begin{array}{cc} -\frac{3}{2} & \frac{1}{2} \\ \frac{5}{3} & -\frac{1}{3} \end{array}\right]$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2, \left[\begin{array}{c} -1 \\ 1 \end{array}\right]\right], \left[\frac{1}{6}, \left[\begin{array}{c} \frac{3}{10} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-2, \left[\begin{array}{c} -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = e^{-2t} \cdot \left[\begin{array}{c} -1 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[\frac{1}{6}, \left[\begin{array}{c} \frac{3}{10} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = e^{\frac{t}{6}} \cdot \left[\begin{array}{c} \frac{3}{10} \\ 1 \end{array}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

$\vec{x}(t) = c_1 \vec{x}_1 + c_2 \vec{x}_2 + \vec{x}_p(t)$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(t) = \left[\begin{array}{cc} -e^{-2t} & \frac{3 e^{\frac{t}{6}}}{10} \\ e^{-2t} & e^{\frac{t}{6}} \end{array}\right]$$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \left[\begin{array}{cc} -e^{-2t} & \frac{3 e^{\frac{t}{6}}}{10} \\ e^{-2t} & e^{\frac{t}{6}} \end{array}\right] \cdot \frac{1}{\left[\begin{array}{cc} -1 & \frac{3}{10} \\ 1 & 1 \end{array}\right]}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \left[\begin{array}{cc} \frac{\left(3 e^{\frac{13t}{6}} + 10\right) e^{-2t}}{13} & \frac{3\left(e^{\frac{13t}{6}} - 1\right) e^{-2t}}{13} \\ \frac{10\left(e^{\frac{13t}{6}} - 1\right) e^{-2t}}{13} & \frac{\left(10 e^{\frac{13t}{6}} + 3\right) e^{-2t}}{13} \end{array}\right]$$

- ☐ Find a particular solution of the system of ODEs using variation of parameters
  - Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

    $\overrightarrow{x}_p(t) = \Phi(t) \cdot \overrightarrow{v}(t)$
  - Take the derivative of the particular solution

    $\overrightarrow{x}_p'(t) = \Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t)$
  - Substitute particular solution and its derivative into the system of ODEs

    $\Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$
  - The fundamental matrix has columns that are solutions to the homogeneous system so its der

    $A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$
  - Cancel like terms

    $\Phi(t) \cdot \overrightarrow{v}'(t) = \overrightarrow{f}(t)$
  - Multiply by the inverse of the fundamental matrix

    $\overrightarrow{v}'(t) = \frac{1}{\Phi(t)} \cdot \overrightarrow{f}(t)$
  - Integrate to solve for $\overrightarrow{v}(t)$

    $\overrightarrow{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$
  - Plug $\overrightarrow{v}(t)$ into the equation for the particular solution

    $\overrightarrow{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$
  - Plug in the fundamental matrix and the forcing function and compute

    $$\overrightarrow{x}_p(t) = \left[\begin{array}{c} \frac{\left(104\,\mathrm{e}^{3t}-2214\,\mathrm{e}^{\frac{13t}{6}}+390\,\mathrm{e}^{2t}t+2145\,\mathrm{e}^{2t}-35\right)\mathrm{e}^{-2t}}{390} \\ \frac{\left(26\,\mathrm{e}^{3t}-1476\,\mathrm{e}^{\frac{13t}{6}}+234\,\mathrm{e}^{2t}t+1443\,\mathrm{e}^{2t}+7\right)\mathrm{e}^{-2t}}{78} \end{array}\right]$$
- Plug particular solution back into general solution

  $$\overrightarrow{x}(t) = c_1\overrightarrow{x}_1 + c_2\overrightarrow{x}_2 + \left[\begin{array}{c} \frac{\left(104\,\mathrm{e}^{3t}-2214\,\mathrm{e}^{\frac{13t}{6}}+390\,\mathrm{e}^{2t}t+2145\,\mathrm{e}^{2t}-35\right)\mathrm{e}^{-2t}}{390} \\ \frac{\left(26\,\mathrm{e}^{3t}-1476\,\mathrm{e}^{\frac{13t}{6}}+234\,\mathrm{e}^{2t}t+1443\,\mathrm{e}^{2t}+7\right)\mathrm{e}^{-2t}}{78} \end{array}\right]$$
- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{\left(104\,e^{3t}+117c_2 e^{\frac{13t}{6}}-2214\,e^{\frac{13t}{6}}+390\,e^{2t}t+2145\,e^{2t}-390c_1-35\right)e^{-2t}}{390} \\ \frac{\left(26\,e^{3t}+78c_2 e^{\frac{13t}{6}}-1476\,e^{\frac{13t}{6}}+234\,e^{2t}t+1443\,e^{2t}+78c_1+7\right)e^{-2t}}{78} \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = \frac{\left(104\,e^{3t}+117c_2 e^{\frac{13t}{6}}-2214\,e^{\frac{13t}{6}}+390\,e^{2t}t+2145\,e^{2t}-390c_1-35\right)e^{-2t}}{390}, y(t) = \frac{\left(26\,e^{3t}+78c_2 e^{\frac{13t}{6}}-1476\,e^{\frac{13t}{6}}+234\,e^{2t}t\right.}{78}\right.$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 26, page 115
Problem number: 6.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
0 &= -5y'(t) + 3x'(t) + 5y(t) + 5t \\
0 &= -3x'(t) + 5y'(t) + 2x(t)
\end{aligned}
$$

The system is

$$5y'(t) - 3x'(t) = 5y(t) + 5t \tag{1}$$

$$3x'(t) - 5y'(t) = 2x(t) \tag{2}$$

Since the left side is the same, this implies

$$
\begin{aligned}
5y(t) + 5t &= 2x(t) \\
y(t) &= \frac{2x(t)}{5} - t
\end{aligned} \tag{3}
$$

Taking derivative of the above w.r.t. t gives

$$y'(t) = \frac{2x'(t)}{5} - 1 \tag{4}$$

Substituting (3,4) in (1) to eliminate $y(t), y'(t)$ gives

$$
\begin{aligned}
-x'(t) - 5 &= 2x(t) \\
x'(t) &= -2x(t) - 5
\end{aligned} \tag{5}
$$

Which is now solved for $x(t)$. Integrating both sides gives

$$
\begin{aligned}
\int \frac{1}{-2x - 5} dx &= \int dt \\
-\frac{\ln(-2x - 5)}{2} &= t + c_1
\end{aligned}
$$

Raising both side to exponential gives

$$\frac{1}{\sqrt{-2x-5}} = e^{t+c_1}$$

Which simplifies to

$$\frac{1}{\sqrt{-2x-5}} = c_2 e^{t}$$

Given now that we have the solution

$$x(t) = -\frac{e^{-2t}}{2c_2^2} - \frac{5}{2} \tag{6}$$

Then substituting (6) into (3) gives

$$y(t) = -\frac{\left(5t\, c_2^2 e^{2t} + 5c_2^2 e^{2t} + 1\right) e^{-2t}}{5c_2^2} \tag{7}$$

✓ Solution by Maple

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 3x(t) \\
y'(t) &= 2x(t) + 3y(t) \\
z'(t) &= 3y(t) - 2z(t)
\end{aligned}
$$

17.7.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 3 & 0 & 0 \\ 2 & 3 & 0 \\ 0 & 3 & -2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} e^{3t} & 0 & 0 \\ 2t\,e^{3t} & e^{3t} & 0 \\ \frac{(30t-6)e^{-2t}e^{5t}}{25} + \frac{6\,e^{-2t}}{25} & \frac{3(e^{5t}-1)e^{-2t}}{5} & e^{-2t} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} e^{3t} & 0 & 0 \\ 2t\,e^{3t} & e^{3t} & 0 \\ \frac{(30t-6)e^{-2t}e^{5t}}{25} + \frac{6\,e^{-2t}}{25} & \frac{3(e^{5t}-1)e^{-2t}}{5} & e^{-2t} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ c_3 \end{bmatrix} \\
&= \begin{bmatrix} e^{3t}c_1 \\ 2t\,e^{3t}c_1 + e^{3t}c_2 \\ \left(\frac{(30t-6)e^{-2t}e^{5t}}{25} + \frac{6\,e^{-2t}}{25}\right)c_1 + \frac{3(e^{5t}-1)e^{-2t}c_2}{5} + e^{-2t}c_3 \end{bmatrix} \\
&= \begin{bmatrix} e^{3t}c_1 \\ e^{3t}(2c_1t + c_2) \\ \frac{e^{-2t}(3(2(5t-1)c_1+5c_2)e^{5t}+6c_1-15c_2+25c_3)}{25} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

17.7.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 3 & 0 & 0 \\ 2 & 3 & 0 \\ 0 & 3 & -2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 3 & 0 & 0 \\ 2 & 3 & 0 \\ 0 & 3 & -2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix}3-\lambda & 0 & 0\\ 2 & 3-\lambda & 0\\ 0 & 3 & -2-\lambda\end{bmatrix}\right) = 0$$

Since the matrix A is triangular matrix, then the determinant is the product of the elements along the diagonal. Therefore the above becomes

$$(3-\lambda)(3-\lambda)(-2-\lambda) = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 3$$
$$\lambda_2 = -2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-2	1	real eigenvalue
3	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix}3 & 0 & 0\\ 2 & 3 & 0\\ 0 & 3 & -2\end{bmatrix} - (-2)\begin{bmatrix}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{bmatrix}\right)\begin{bmatrix}v_1\\ v_2\\ v_3\end{bmatrix} = \begin{bmatrix}0\\ 0\\ 0\end{bmatrix}$$

$$\begin{bmatrix}5 & 0 & 0\\ 2 & 5 & 0\\ 0 & 3 & 0\end{bmatrix}\begin{bmatrix}v_1\\ v_2\\ v_3\end{bmatrix} = \begin{bmatrix}0\\ 0\\ 0\end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c}5 & 0 & 0 & 0\\ 2 & 5 & 0 & 0\\ 0 & 3 & 0 & 0\end{array}\right]$$

$$R_2 = R_2 - \frac{2R_1}{5} \Longrightarrow \left[\begin{array}{ccc|c} 5 & 0 & 0 & 0 \\ 0 & 5 & 0 & 0 \\ 0 & 3 & 0 & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{3R_2}{5} \Longrightarrow \left[\begin{array}{ccc|c} 5 & 0 & 0 & 0 \\ 0 & 5 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 5 & 0 & 0 \\ 0 & 5 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 0, v_2 = 0\}$

Hence the solution is

$$\begin{bmatrix} 0 \\ 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 0 \\ 0 \\ t \end{bmatrix} = t \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 0 \\ 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & 0 & 0 \\ 2 & 3 & 0 \\ 0 & 3 & -2 \end{bmatrix} - (3) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 0 & 0 & 0 \\ 2 & 0 & 0 \\ 0 & 3 & -5 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 0 & 0 & 0 & 0 \\ 2 & 0 & 0 & 0 \\ 0 & 3 & -5 & 0 \end{array}\right]$$

Since the current pivot $A(1,1)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 1 and row 2 gives

$$\left[\begin{array}{ccc|c} 2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 3 & -5 & 0 \end{array}\right]$$

Since the current pivot $A(2,2)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 2 and row 3 gives

$$\left[\begin{array}{ccc|c} 2 & 0 & 0 & 0 \\ 0 & 3 & -5 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & 0 & 0 \\ 0 & 3 & -5 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = 0, v_2 = \frac{5t}{3}\right\}$

Hence the solution is

$$\begin{bmatrix} 0 \\ \frac{5t}{3} \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ \frac{5t}{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 0 \\ \frac{5t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} 0 \\ \frac{5}{3} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 0 \\ \frac{5t}{3} \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ \frac{5}{3} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} 0 \\ \frac{5t}{3} \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 5 \\ 3 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity algebraic m	multiplicity geometric k	defective?	eigenvectors
3	2	1	Yes	$\begin{bmatrix} 0 \\ \frac{5}{3} \\ 1 \end{bmatrix}$
-2	1	1	No	$\begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. eigenvalue 3 is real and repated eigenvalue of multiplicity 2.There are two possible cases that can happen. This is illustrated in this diagram

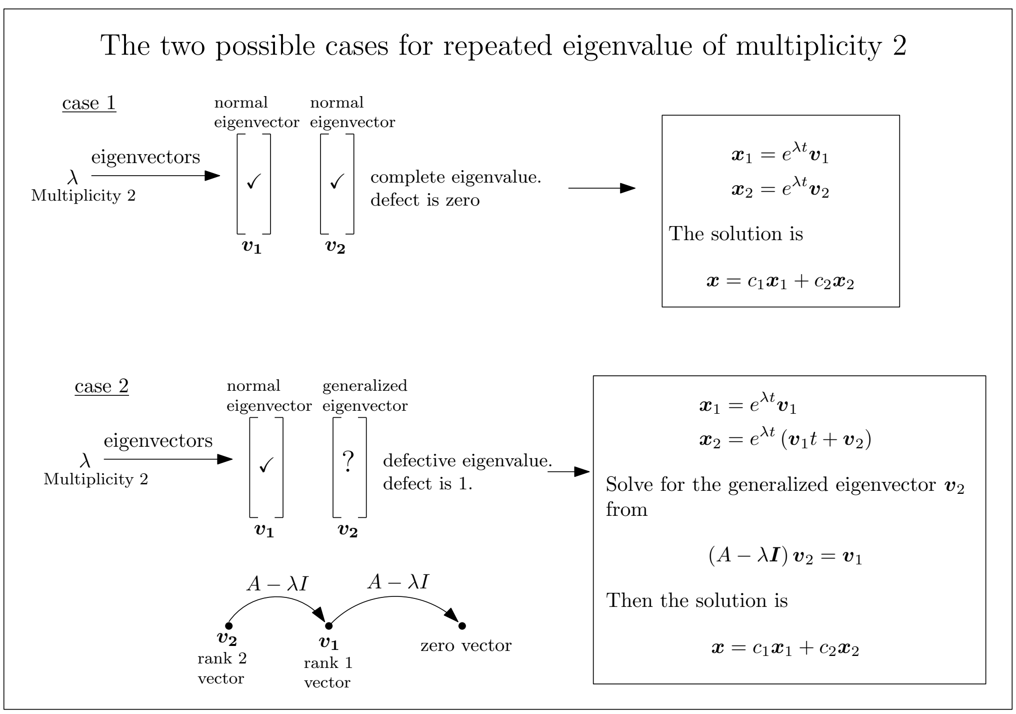

Figure 696: Possible case for repeated λ of multiplicity 2

This eigenvalue has algebraic multiplicity of 2, and geometric multiplicity 1, therefore this is defective eigenvalue. The defect is 1. This falls into case 2 shown above. We need to generate the missing additonal generalized eigevector $\vec{v}_2$ by solving

$$(A - \lambda I)\,\vec{v}_2 = \vec{v}_1$$

Where $\vec{v}_1$ is the normal (rank 1) eigenvector found above. Hence we need to solve

$$\left(\begin{bmatrix} 3 & 0 & 0 \\ 2 & 3 & 0 \\ 0 & 3 & -2 \end{bmatrix} - (3)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ \frac{5}{3} \\ 1 \end{bmatrix}$$

$$\begin{bmatrix} 0 & 0 & 0 \\ 2 & 0 & 0 \\ 0 & 3 & -5 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ \frac{5}{3} \\ 1 \end{bmatrix}$$

Solving for $\vec{v}_2$ gives

$$\vec{v}_2 = \begin{bmatrix} \frac{5}{6} \\ 2 \\ 1 \end{bmatrix}$$

We have found two generalized eigenvectors for eigenvalue 3. Therefore the two basis solution associated with this eigenvalue are

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{\lambda t} \\ &= \begin{bmatrix} 0 \\ \frac{5}{3} \\ 1 \end{bmatrix} \mathrm{e}^{3t} \\ &= \begin{bmatrix} 0 \\ \frac{5\,\mathrm{e}^{3t}}{3} \\ \mathrm{e}^{3t} \end{bmatrix} \end{aligned}$$

And

$$
\begin{aligned}
\vec{x}_2(t) &= (\vec{v}_1 t + \vec{v}_2)\, e^{\lambda t} \\
&= \left(\left[\begin{array}{c} 0 \\ \frac{5}{3} \\ 1 \end{array}\right] t + \left[\begin{array}{c} \frac{5}{6} \\ 2 \\ 1 \end{array}\right]\right) \mathrm{e}^{3t} \\
&= \left[\begin{array}{c} \frac{5\,\mathrm{e}^{3t}}{6} \\ \frac{\mathrm{e}^{3t}(5t+6)}{3} \\ \mathrm{e}^{3t}(t+1) \end{array}\right]
\end{aligned}
$$

Since eigenvalue -2 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_3(t) &= \vec{v}_3 e^{-2t} \\
&= \left[\begin{array}{c} 0 \\ 0 \\ 1 \end{array}\right] e^{-2t}
\end{aligned}
$$

Therefore the final solution is

$$
\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t) + c_3 \vec{x}_3(t)
$$

Which is written as

$$
\left[\begin{array}{c} x(t) \\ y(t) \\ z(t) \end{array}\right] = c_1 \left[\begin{array}{c} 0 \\ \frac{5\,\mathrm{e}^{3t}}{3} \\ \mathrm{e}^{3t} \end{array}\right] + c_2 \left[\begin{array}{c} \frac{5\,\mathrm{e}^{3t}}{6} \\ \mathrm{e}^{3t}\left(\frac{5t}{3}+2\right) \\ \mathrm{e}^{3t}(t+1) \end{array}\right] + c_3 \left[\begin{array}{c} 0 \\ 0 \\ \mathrm{e}^{-2t} \end{array}\right]
$$

Which becomes

$$
\left[\begin{array}{c} x(t) \\ y(t) \\ z(t) \end{array}\right] = \left[\begin{array}{c} \frac{5 c_2 \mathrm{e}^{3t}}{6} \\ \frac{((5t+6)c_2+5c_1)\mathrm{e}^{3t}}{3} \\ (((t+1)\, c_2 + c_1)\, \mathrm{e}^{5t} + c_3)\, \mathrm{e}^{-2t} \end{array}\right]
$$

17.7.3 Maple step by step solution

Let's solve

$[x'(t) = 3x(t), y'(t) = 2x(t) + 3y(t), z'(t) = 3y(t) - 2z(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 3 & 0 & 0 \\ 2 & 3 & 0 \\ 0 & 3 & -2 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 3 & 0 & 0 \\ 2 & 3 & 0 \\ 0 & 3 & -2 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 3 & 0 & 0 \\ 2 & 3 & 0 \\ 0 & 3 & -2 \end{bmatrix}$$

- Rewrite the system as

$\vec{x}'(t) = A \cdot \vec{x}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2, \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} 0 \\ \frac{5}{3} \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-2, \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^{-2t} \cdot \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[3, \begin{bmatrix} 0 \\ \frac{5}{3} \\ 1 \end{bmatrix}\right]$$

- First solution from eigenvalue 3

$$\vec{x}_2(t) = \mathrm{e}^{3t} \cdot \begin{bmatrix} 0 \\ \frac{5}{3} \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\vec{p}$ is to be solved for, $\lambda = 3$ is the eigenvalue, and

$$\vec{x}_3(t) = \mathrm{e}^{\lambda t}\left(t\vec{v} + \vec{p}\right)$$

- Note that the t multiplying $\vec{v}$ makes this solution linearly independent to the 1st solution obtai
- Substitute $\vec{x}_3(t)$ into the homogeneous system

$$\lambda\,\mathrm{e}^{\lambda t}\left(t\vec{v} + \vec{p}\right) + \mathrm{e}^{\lambda t}\vec{v} = \left(\mathrm{e}^{\lambda t}A\right) \cdot \left(t\vec{v} + \vec{p}\right)$$

- Use the fact that $\vec{v}$ is an eigenvector of A

$$\lambda\,\mathrm{e}^{\lambda t}\left(t\vec{v} + \vec{p}\right) + \mathrm{e}^{\lambda t}\vec{v} = \mathrm{e}^{\lambda t}\left(\lambda t\vec{v} + A \cdot \vec{p}\right)$$

- Simplify equation

$$\lambda\vec{p} + \vec{v} = A \cdot \vec{p}$$

- Make use of the identity matrix I

$$(\lambda \cdot I) \cdot \vec{p} + \vec{v} = A \cdot \vec{p}$$

- Condition $\vec{p}$ must meet for $\vec{x}_3(t)$ to be a solution to the homogeneous system

$(A-\lambda\cdot I)\cdot\vec{p}=\vec{v}$

- Choose $\vec{p}$ to use in the second solution to the homogeneous system from eigenvalue 3

$$\left(\begin{bmatrix}3&0&0\\2&3&0\\0&3&-2\end{bmatrix}-3\cdot\begin{bmatrix}1&0&0\\0&1&0\\0&0&1\end{bmatrix}\right)\cdot\vec{p}=\begin{bmatrix}0\\\frac{5}{3}\\1\end{bmatrix}$$

- Choice of $\vec{p}$

$$\vec{p}=\begin{bmatrix}0\\0\\0\end{bmatrix}$$

- Second solution from eigenvalue 3

$$\vec{x}_3(t)=\mathrm{e}^{3t}\cdot\left(t\cdot\begin{bmatrix}0\\\frac{5}{3}\\1\end{bmatrix}+\begin{bmatrix}0\\0\\0\end{bmatrix}\right)$$

- General solution to the system of ODEs

$\vec{x}=c_1\vec{x}_1+c_2\vec{x}_2(t)+c_3\vec{x}_3(t)$

- Substitute solutions into the general solution

$$\vec{x}=c_1\mathrm{e}^{-2t}\cdot\begin{bmatrix}0\\0\\1\end{bmatrix}+c_2\mathrm{e}^{3t}\cdot\begin{bmatrix}0\\\frac{5}{3}\\1\end{bmatrix}+c_3\mathrm{e}^{3t}\cdot\left(t\cdot\begin{bmatrix}0\\\frac{5}{3}\\1\end{bmatrix}+\begin{bmatrix}0\\0\\0\end{bmatrix}\right)$$

- Substitute in vector of dependent variables

$$\begin{bmatrix}x(t)\\y(t)\\z(t)\end{bmatrix}=\begin{bmatrix}0\\\frac{5\,\mathrm{e}^{3t}(tc_3+c_2)}{3}\\\mathrm{e}^{-2t}\left((tc_3+c_2)\,\mathrm{e}^{5t}+c_1\right)\end{bmatrix}$$

- Solution to the system of ODEs

$\left\{x(t)=0, y(t)=\frac{5\,\mathrm{e}^{3t}(tc_3+c_2)}{3}, z(t)=\mathrm{e}^{-2t}\left((tc_3+c_2)\,\mathrm{e}^{5t}+c_1\right)\right\}$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_quadrature", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _quadrature]]
```

$$\boxed{y'' = \cos(t)}$$

18.1.1 Solving as second order ode quadrature ode

Integrating once gives

$$y' = \sin(t) + c_1$$

Integrating again gives

$$y = -\cos(t) + c_1 x + c_2$$

Summary
The solution(s) found are the following

$$y = -\cos(t) + c_1 t + c_2 \tag{1}$$

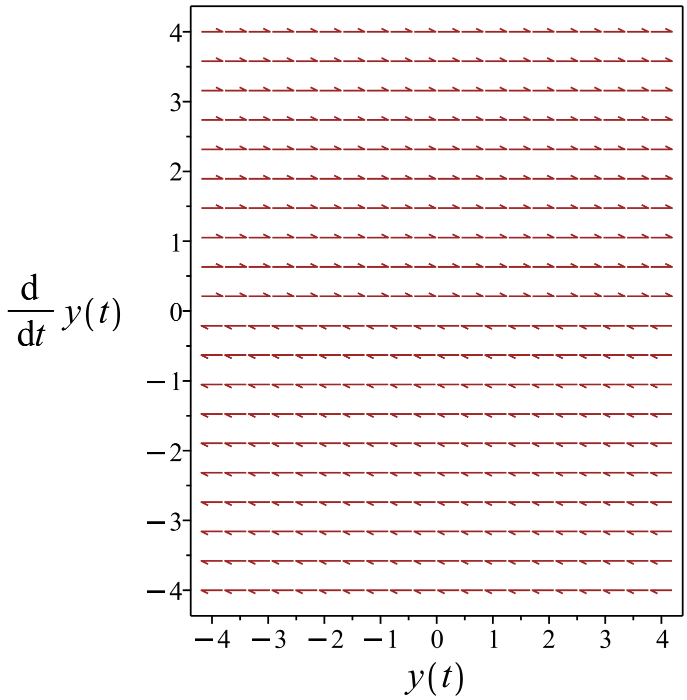

Figure 697: Slope field plot

Verification of solutions

$$y = -\cos(t) + c_1 t + c_2$$

Verified OK.

18.1.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(t) + By'(t) + Cy(t) = f(t)$$

Where $A = 1, B = 0, C = 0, f(t) = \cos(t)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(t) + By'(t) + Cy(t) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(t) + By'(t) + Cy(t) = f(t)$. y_h is the solution to

$$y'' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(t) + By'(t) + Cy(t) = 0$$

Where in the above $A = 1, B = 0, C = 0$. Let the solution be $y = e^{\lambda t}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda t} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda t}$ gives

$$\lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(0)^2 - (4)(1)(0)} \\ &= 0\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 0$. Therefore the solution is

$$y = c_1 1 + c_2 t \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_2 t + c_1$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(t)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(t), \sin(t)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, t\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(t) + A_2 \sin(t)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 \cos(t) - A_2 \sin(t) = \cos(t)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1, A_2 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\cos(t)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 t + c_1) + (-\cos(t)) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_2 t + c_1 - \cos(t) \tag{1}$$

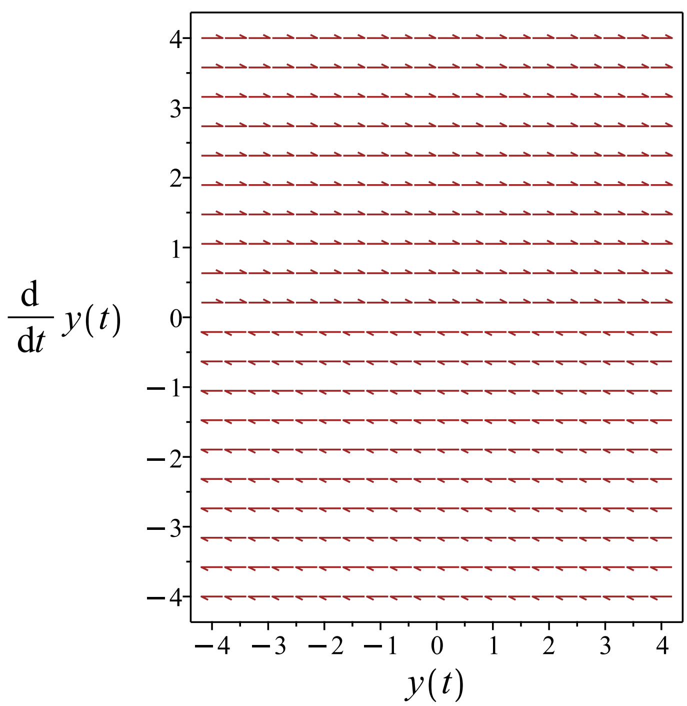

Figure 698: Slope field plot

Verification of solutions

$$y = c_2 t + c_1 - \cos(t)$$

Verified OK.

18.1.3 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t t gives

$$\int y'' dt = \int \cos(t)\, dt$$
$$y' = \sin(t) + c_1$$

Which is now solved for y. Integrating both sides gives

$$y = \int \sin(t) + c_1 \, \mathrm{d}t$$
$$= -\cos(t) + c_1 t + c_2$$

Summary
The solution(s) found are the following

$$y = -\cos(t) + c_1 t + c_2 \tag{1}$$

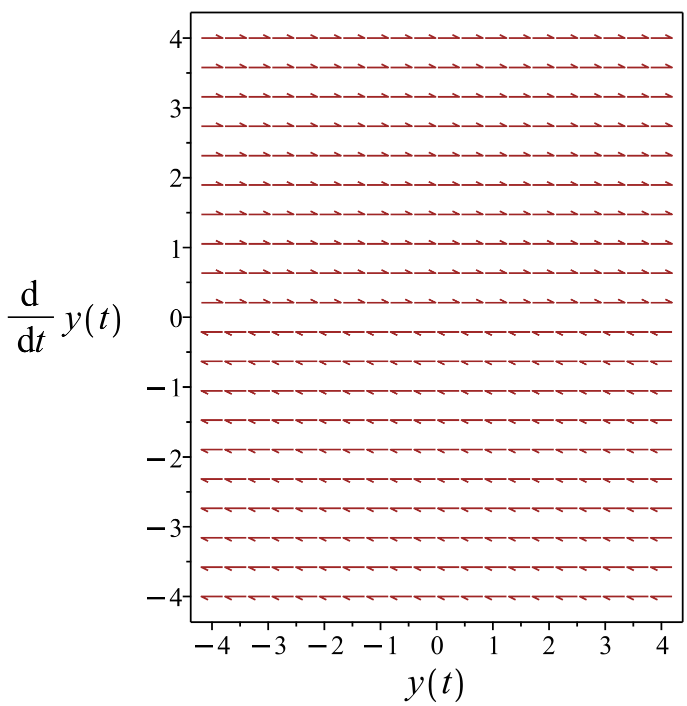

Figure 699: Slope field plot

Verification of solutions

$$y = -\cos(t) + c_1 t + c_2$$

Verified OK.

18.1.4 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(t) = y'$$

Then

$$p'(t) = y''$$

Hence the ode becomes

$$p'(t) - \cos(t) = 0$$

Which is now solve for $p(t)$ as first order ode. Integrating both sides gives

$$\begin{aligned} p(t) &= \int \cos(t)\, \mathrm{d}t \\ &= \sin(t) + c_1 \end{aligned}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \sin(t) + c_1$$

Integrating both sides gives

$$\begin{aligned} y &= \int \sin(t) + c_1\, \mathrm{d}t \\ &= -\cos(t) + c_1 t + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = -\cos(t) + c_1 t + c_2 \tag{1}$$

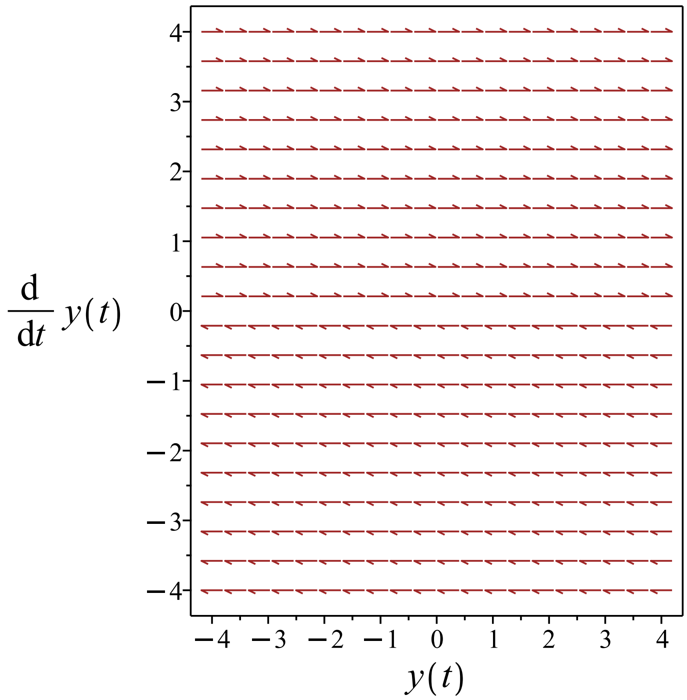

Figure 700: Slope field plot

Verification of solutions

$$y = -\cos(t) + c_1 t + c_2$$

Verified OK.

18.1.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A} \, dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 567: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of t, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(t) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dt}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= 1 \end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dt}}{y_1^2} \, dt$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2} \, dt \\ &= 1 \int \frac{1}{1} \, dt \\ &= 1(t) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(1) + c_2(1(t)) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(t) + By'(t) + Cy(t) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(t) + By'(t) + Cy(t) = f(t)$. y_h is the solution to

$$y'' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_2 t + c_1$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(t)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(t), \sin(t)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, t\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(t) + A_2 \sin(t)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 \cos(t) - A_2 \sin(t) = \cos(t)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1, A_2 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\cos(t)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 t + c_1) + (-\cos(t)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_2 t + c_1 - \cos(t) \tag{1}$$

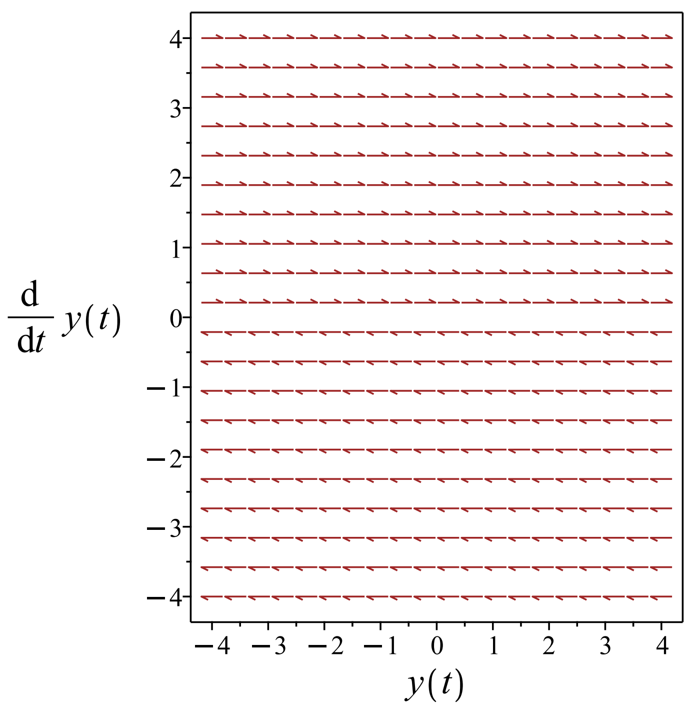

Figure 701: Slope field plot

Verification of solutions

$$y = c_2 t + c_1 - \cos(t)$$

Verified OK.

18.1.6 Solving as exact linear second order ode ode

An ode of the form

$$p(t)\, y'' + q(t)\, y' + r(t)\, y = s(t)$$

is exact if

$$p''(t) - q'(t) + r(t) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 0 \\ r(x) &= 0 \\ s(x) &= \cos(t) \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(t)\, y' + (q(t) - p'(t))\, y)' = s(x)$$

Integrating gives

$$p(t)\, y' + (q(t) - p'(t))\, y = \int s(t)\, dt$$

Substituting the above values for p, q, r, s gives

$$y' = \int \cos(t)\, dt$$

We now have a first order ode to solve which is

$$y' = \sin(t) + c_1$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int \sin(t) + c_1 \, \mathrm{d}t \\
&= -\cos(t) + c_1 t + c_2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = -\cos(t) + c_1 t + c_2 \tag{1}
$$

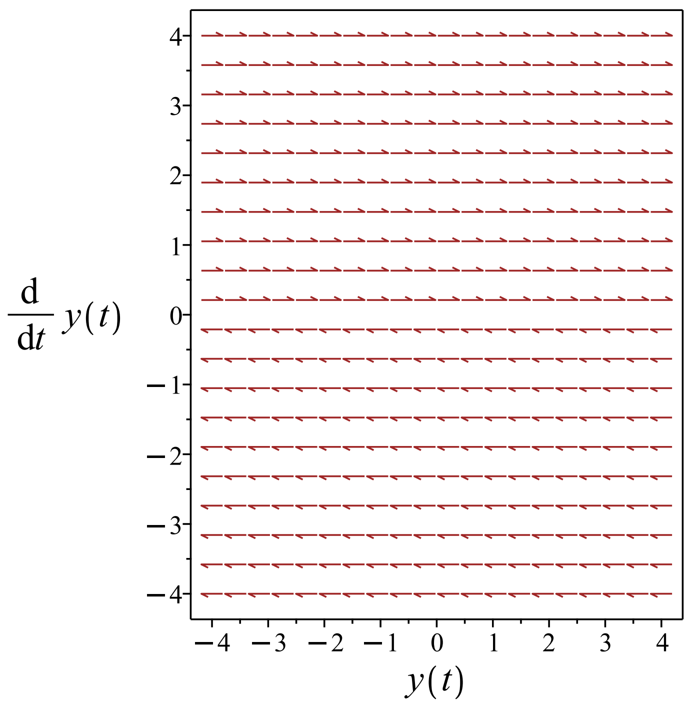

Figure 702: Slope field plot

Verification of solutions

$$
y = -\cos(t) + c_1 t + c_2
$$

Verified OK.

18.1.7 Maple step by step solution

Let's solve

$y'' = \cos(t)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{0})}{2}$

- Roots of the characteristic polynomial

  $r = 0$

- 1st solution of the homogeneous ODE

  $y_1(t) = 1$

- Repeated root, multiply $y_1(t)$ by t to ensure linear independence

  $y_2(t) = t$

- General solution of the ODE

  $y = c_1 y_1(t) + c_2 y_2(t) + y_p(t)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 t + y_p(t)$

□ Find a particular solution $y_p(t)$ of the ODE

  - Use variation of parameters to find y_p here $f(t)$ is the forcing function

    $\left[y_p(t) = -y_1(t) \left(\int \frac{y_2(t) f(t)}{W(y_1(t), y_2(t))} dt\right) + y_2(t) \left(\int \frac{y_1(t) f(t)}{W(y_1(t), y_2(t))} dt\right), f(t) = \cos(t)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(t), y_2(t)) = \begin{bmatrix} 1 & t \\ 0 & 1 \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(t), y_2(t)) = 1$

  - Substitute functions into equation for $y_p(t)$

$y_p(t) = -\left(\int t \cos(t)\, dt\right) + t\left(\int \cos(t)\, dt\right)$

- Compute integrals

  $y_p(t) = -\cos(t)$

- Substitute particular solution into general solution to ODE

  $y = c_2 t + c_1 - \cos(t)$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - k^2 y = 0}$$

18.2.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(t) + By'(t) + Cy(t) = 0$$

Where in the above $A = 1, B = 0, C = -k^2$. Let the solution be $y = e^{\lambda t}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda t} - k^2 e^{\lambda t} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda t}$ gives

$$-k^2 + \lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -k^2$ into the above gives

$$\lambda_{1,2} = \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-k^2)}$$
$$= \pm\sqrt{k^2}$$

Hence

$$\lambda_1 = +\sqrt{k^2}$$
$$\lambda_2 = -\sqrt{k^2}$$

Which simplifies to

$$\lambda_1 = \sqrt{k^2}$$
$$\lambda_2 = -\sqrt{k^2}$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 t} + c_2 e^{\lambda_2 t}$$
$$y = c_1 e^{\left(\sqrt{k^2}\right)t} + c_2 e^{\left(-\sqrt{k^2}\right)t}$$

Or

$$y = c_1 \mathrm{e}^{\sqrt{k^2}\, t} + c_2 \mathrm{e}^{-\sqrt{k^2}\, t}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{\sqrt{k^2}\, t} + c_2 \mathrm{e}^{-\sqrt{k^2}\, t} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{\sqrt{k^2}\, t} + c_2 \mathrm{e}^{-\sqrt{k^2}\, t}$$

Verified OK.

18.2.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' - k^2y'y = 0$$

Integrating the above w.r.t t gives

$$\int (y'y'' - k^2y'y)\,dt = 0$$
$$\frac{y'^2}{2} - \frac{k^2y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{k^2y^2 + 2c_1} \tag{1}$$
$$y' = -\sqrt{k^2y^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

<u>Solving equation (1)</u>

Integrating both sides gives

$$\int \frac{1}{\sqrt{k^2y^2 + 2c_1}}dy = \int dt$$
$$\frac{\ln\left(\frac{k^2y}{\sqrt{k^2}} + \sqrt{k^2y^2 + 2c_1}\right)}{\sqrt{k^2}} = t + c_2$$

Raising both side to exponential gives

$$\mathrm{e}^{\frac{\ln\left(\frac{k^2y}{\sqrt{k^2}} + \sqrt{k^2y^2+2c_1}\right)}{\sqrt{k^2}}} = \mathrm{e}^{t+c_2}$$

Which simplifies to

$$\left(ky\,\mathrm{csgn}(k) + \sqrt{k^2y^2 + 2c_1}\right)^{\frac{1}{\sqrt{k^2}}} = c_3\mathrm{e}^t$$

Simplifying the solution $y = \frac{\mathrm{csgn}(k)\left((c_3\mathrm{e}^t)^{\mathrm{csgn}(k)k} - 2(c_3\mathrm{e}^t)^{-\mathrm{csgn}(k)k}c_1\right)}{2k}$ to $y = \frac{(c_3\mathrm{e}^t)^k - 2(c_3\mathrm{e}^t)^{-k}c_1}{2k}$

<u>Solving equation (2)</u>

Integrating both sides gives

$$\int -\frac{1}{\sqrt{k^2y^2+2c_1}}dy = \int dt$$
$$-\frac{\ln\left(\frac{k^2y}{\sqrt{k^2}}+\sqrt{k^2y^2+2c_1}\right)}{\sqrt{k^2}} = t+c_4$$

Raising both side to exponential gives

$$\mathrm{e}^{-\frac{\ln\left(\frac{k^2y}{\sqrt{k^2}}+\sqrt{k^2y^2+2c_1}\right)}{\sqrt{k^2}}} = \mathrm{e}^{t+c_4}$$

Which simplifies to

$$\left(ky\,\mathrm{csgn}\left(k\right)+\sqrt{k^2y^2+2c_1}\right)^{-\frac{\mathrm{csgn}(k)}{k}} = c_5\mathrm{e}^t$$

Simplifying the solution $y = -\frac{\mathrm{csgn}(k)\left(2\left(c_5\mathrm{e}^t\right)^{\mathrm{csgn}(k)k}c_1-\left(c_5\mathrm{e}^t\right)^{-\mathrm{csgn}(k)k}\right)}{2k}$ to $y = -\frac{2\left(c_5\mathrm{e}^t\right)^kc_1-\left(c_5\mathrm{e}^t\right)^{-k}}{2k}$

Summary

The solution(s) found are the following

$$y = \frac{\left(c_3\mathrm{e}^t\right)^k-2\left(c_3\mathrm{e}^t\right)^{-k}c_1}{2k} \tag{1}$$
$$y = -\frac{2\left(c_5\mathrm{e}^t\right)^kc_1-\left(c_5\mathrm{e}^t\right)^{-k}}{2k} \tag{2}$$

Verification of solutions

$$y = \frac{\left(c_3\mathrm{e}^t\right)^k-2\left(c_3\mathrm{e}^t\right)^{-k}c_1}{2k}$$

Verified OK.

$$y = -\frac{2\left(c_5\mathrm{e}^t\right)^kc_1-\left(c_5\mathrm{e}^t\right)^{-k}}{2k}$$

Verified OK.

18.2.3 Solving using Kovacic algorithm

Writing the ode as

$$y''-k^2y = 0 \tag{1}$$
$$Ay''+By'+Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= -k^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A} \, dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{k^2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= k^2 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(k^2\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t) \, e^{-\int \frac{B}{2A} \, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 569: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = k^2$ is not a function of t, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(t) = \mathrm{e}^{\sqrt{k^2}\, t}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dt}
$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \mathrm{e}^{\sqrt{k^2}\, t}
\end{aligned}
$$

Which simplifies to

$$y_1 = e^{\sqrt{k^2}\, t}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{y_1^2}\, dt$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dt \\
&= e^{\sqrt{k^2}\, t} \int \frac{1}{e^{2\sqrt{k^2}\, t}}\, dt \\
&= e^{\sqrt{k^2}\, t} \left(-\frac{\operatorname{csgn}(k)\, e^{-2\operatorname{csgn}(k) k t}}{2k}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(e^{\sqrt{k^2}\, t}\right) + c_2 \left(e^{\sqrt{k^2}\, t} \left(-\frac{\operatorname{csgn}(k)\, e^{-2\operatorname{csgn}(k) k t}}{2k}\right)\right)
\end{aligned}$$

Summary

The solution(s) found are th

Simplifying the solution $y = c_1 e^{\sqrt{k^2}\, t} - \frac{c_2 \operatorname{csgn}(k) e^{-\operatorname{csgn}(k) k t}}{2k}$ to $y = c_1 e^{\sqrt{k^2}\, t} - \frac{c_2 e^{-kt}}{2k}$

Verification of solutions

$$y = c_1 e^{\sqrt{k^2}\, t} - \frac{c_2 e^{-kt}}{2k}$$

Verified OK.

18.3.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ax''(t) + Bx'(t) + Cx(t) = 0$$

Where in the above $A = 1, B = 0, C = k^2$. Let the solution be $x = e^{\lambda t}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda t} + k^2 \mathrm{e}^{\lambda t} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda t}$ gives

$$k^2 + \lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = k^2$ into the above gives

$$\lambda_{1,2} = \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(k^2)}$$
$$= \pm\sqrt{-k^2}$$

Hence

$$\lambda_1 = +\sqrt{-k^2}$$
$$\lambda_2 = -\sqrt{-k^2}$$

Which simplifies to

$$\lambda_1 = \sqrt{-k^2}$$
$$\lambda_2 = -\sqrt{-k^2}$$

Since roots are real and distinct, then the solution is

$$x = c_1 e^{\lambda_1 t} + c_2 e^{\lambda_2 t}$$
$$x = c_1 e^{\left(\sqrt{-k^2}\right)t} + c_2 e^{\left(-\sqrt{-k^2}\right)t}$$

Or

$$x = c_1 \mathrm{e}^{\sqrt{-k^2}\, t} + c_2 \mathrm{e}^{-\sqrt{-k^2}\, t}$$

<u>Summary</u>
The solution(s) found are the following

$$x = c_1 \mathrm{e}^{\sqrt{-k^2}\, t} + c_2 \mathrm{e}^{-\sqrt{-k^2}\, t} \tag{1}$$

<u>Verification of solutions</u>

$$x = c_1 \mathrm{e}^{\sqrt{-k^2}\, t} + c_2 \mathrm{e}^{-\sqrt{-k^2}\, t}$$

Verified OK.

18.3.2 Solving as second order ode can be made integrable ode

Multiplying the ode by x' gives

$$x'x'' + k^2x'x = 0$$

Integrating the above w.r.t t gives

$$\int (x'x'' + k^2x'x)\, dt = 0$$
$$\frac{x'^2}{2} + \frac{k^2x^2}{2} = c_2$$

Which is now solved for x. Solving the given ode for x' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$x' = \sqrt{-k^2x^2 + 2c_1} \tag{1}$$
$$x' = -\sqrt{-k^2x^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-k^2x^2 + 2c_1}} dx = \int dt$$
$$\frac{\arctan\left(\frac{\sqrt{k^2}\, x}{\sqrt{-k^2x^2+2c_1}}\right)}{\sqrt{k^2}} = t + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-k^2x^2 + 2c_1}} dx = \int dt$$
$$-\frac{\arctan\left(\frac{\sqrt{k^2}\, x}{\sqrt{-k^2x^2+2c_1}}\right)}{\sqrt{k^2}} = t + c_3$$

Summary
The solution(s) found are the following

$$\frac{\arctan\left(\frac{\sqrt{k^2}\,x}{\sqrt{-k^2x^2+2c_1}}\right)}{\sqrt{k^2}} = t + c_2 \tag{1}$$

$$-\frac{\arctan\left(\frac{\sqrt{k^2}\,x}{\sqrt{-k^2x^2+2c_1}}\right)}{\sqrt{k^2}} = t + c_3 \tag{2}$$

Verification of solutions

$$\frac{\arctan\left(\frac{\sqrt{k^2}\,x}{\sqrt{-k^2x^2+2c_1}}\right)}{\sqrt{k^2}} = t + c_2$$

Verified OK.

$$-\frac{\arctan\left(\frac{\sqrt{k^2}\,x}{\sqrt{-k^2x^2+2c_1}}\right)}{\sqrt{k^2}} = t + c_3$$

Verified OK.

18.3.3 Solving using Kovacic algorithm

Writing the ode as

$$x'' + k^2x = 0 \tag{1}$$

$$Ax'' + Bx' + Cx = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= k^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = xe^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-k^2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -k^2 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(-k^2\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then x is found using the inverse transformation

$$x = z(t) \, e^{-\int \frac{B}{2A} \, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 571: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -k^2$ is not a function of t, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(t) = \mathrm{e}^{\sqrt{-k^2}\, t}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in x is found from

$$x_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dt}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} x_1 &= z_1 \\ &= \mathrm{e}^{\sqrt{-k^2}\, t} \end{aligned}$$

Which simplifies to

$$x_1 = \mathrm{e}^{\sqrt{-k^2}\, t}$$

The second solution x_2 to the original ode is found using reduction of order

$$x_2 = x_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{x_1^2}\, dt$$

Since $B = 0$ then the above becomes

$$\begin{aligned} x_2 &= x_1 \int \frac{1}{x_1^2}\, dt \\ &= \mathrm{e}^{\sqrt{-k^2}\, t} \int \frac{1}{\mathrm{e}^{2\sqrt{-k^2}\, t}}\, dt \\ &= \mathrm{e}^{\sqrt{-k^2}\, t} \left(\frac{\sqrt{-k^2}\, \mathrm{e}^{-2\sqrt{-k^2}\, t}}{2k^2} \right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
x &= c_1x_1 + c_2x_2 \\
&= c_1\left(\mathrm{e}^{\sqrt{-k^2}\, t}\right) + c_2\left(\mathrm{e}^{\sqrt{-k^2}\, t}\left(\frac{\sqrt{-k^2}\, \mathrm{e}^{-2\sqrt{-k^2}\, t}}{2k^2}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
x = c_1\mathrm{e}^{\sqrt{-k^2}\, t} + \frac{c_2\sqrt{-k^2}\, \mathrm{e}^{-\sqrt{-k^2}\, t}}{2k^2} \tag{1}
$$

Verification of solutions

$$
x = c_1\mathrm{e}^{\sqrt{-k^2}\, t} + \frac{c_2\sqrt{-k^2}\, \mathrm{e}^{-\sqrt{-k^2}\, t}}{2k^2}
$$

Verified OK.

18.3.4 Maple step by step solution

Let's solve

$x'' + k^2x = 0$

- Highest derivative means the order of the ODE is 2

  x''

- Characteristic polynomial of ODE

  $k^2 + r^2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0\pm\left(\sqrt{-4k^2}\right)}{2}$

- Roots of the characteristic polynomial

  $r = \left(\sqrt{-k^2}, -\sqrt{-k^2}\right)$

- 1st solution of the ODE

  $x_1(t) = \mathrm{e}^{\sqrt{-k^2}\, t}$

- 2nd solution of the ODE

  $x_2(t) = \mathrm{e}^{-\sqrt{-k^2}\, t}$

- General solution of the ODE

  $x = c_1x_1(t) + c_2x_2(t)$

- Substitute in solutions

  $x = c_1 e^{\sqrt{-k^2}\, t} + c_2 e^{-\sqrt{-k^2}\, t}$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 4.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1]]
```

$$\boxed{y^3 y'' = -4}$$

18.4.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$y^3 p(y) \left(\frac{d}{dy} p(y)\right) = -4$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$\begin{aligned}
p' &= F(y,p)\\
&= f(y)g(p)\\
&= -\frac{4}{y^3 p}
\end{aligned}$$

Where $f(y) = -\frac{4}{y^3}$ and $g(p) = \frac{1}{p}$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{\frac{1}{p}}\,dp &= -\frac{4}{y^3}\,dy\\
\int \frac{1}{\frac{1}{p}}\,dp &= \int -\frac{4}{y^3}\,dy\\
\frac{p^2}{2} &= \frac{2}{y^2} + c_1
\end{aligned}$$

The solution is

$$\frac{p(y)^2}{2} - \frac{2}{y^2} - c_1 = 0$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$\frac{y'^2}{2} - \frac{2}{y^2} - c_1 = 0$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{\sqrt{2c_1 y^2 + 4}}{y} \tag{1}$$

$$y' = -\frac{\sqrt{2c_1 y^2 + 4}}{y} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\begin{aligned}
\int \frac{y}{\sqrt{2c_1 y^2 + 4}}dy &= \int dx\\
\frac{c_1 y^2 + 2}{c_1\sqrt{2c_1 y^2 + 4}} &= x + c_2
\end{aligned}$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{y}{\sqrt{2c_1y^2+4}}dy = \int dx$$
$$-\frac{c_1y^2+2}{c_1\sqrt{2c_1y^2+4}} = x + c_3$$

Summary

The solution(s) found are the following

$$\frac{c_1y^2+2}{c_1\sqrt{2c_1y^2+4}} = x + c_2 \tag{1}$$
$$-\frac{c_1y^2+2}{c_1\sqrt{2c_1y^2+4}} = x + c_3 \tag{2}$$

Verification of solutions

$$\frac{c_1y^2+2}{c_1\sqrt{2c_1y^2+4}} = x + c_2$$

Verified OK.

$$-\frac{c_1y^2+2}{c_1\sqrt{2c_1y^2+4}} = x + c_3$$

Verified OK.

18.4.2 Maple step by step solution

Let's solve

$y^3y'' = -4$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x) = y'$

- Compute y''

  $u'(x) = y''$

- Use chain rule on the lhs

$y'\left(\frac{d}{dy}u(y)\right) = y''$

- Substitute in the definition of u

$u(y)\left(\frac{d}{dy}u(y)\right) = y''$

- Make substitutions $y' = u(y), y'' = u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

$y^3 u(y)\left(\frac{d}{dy}u(y)\right) = -4$

- Separate variables

$u(y)\left(\frac{d}{dy}u(y)\right) = -\frac{4}{y^3}$

- Integrate both sides with respect to y

$\int u(y)\left(\frac{d}{dy}u(y)\right)dy = \int -\frac{4}{y^3}dy + c_1$

- Evaluate integral

$\frac{u(y)^2}{2} = \frac{2}{y^2} + c_1$

- Solve for $u(y)$

$\left\{u(y) = \frac{\sqrt{2c_1y^2+4}}{y}, u(y) = -\frac{\sqrt{2c_1y^2+4}}{y}\right\}$

- Solve 1st ODE for $u(y)$

$u(y) = \frac{\sqrt{2c_1y^2+4}}{y}$

- Revert to original variables with substitution $u(y) = y', y = y$

$y' = \frac{\sqrt{2c_1y^2+4}}{y}$

- Separate variables

$\frac{yy'}{\sqrt{2c_1y^2+4}} = 1$

- Integrate both sides with respect to x

$\int \frac{yy'}{\sqrt{2c_1y^2+4}}dx = \int 1dx + c_2$

- Evaluate integral

$\frac{\sqrt{2c_1y^2+4}}{2c_1} = x + c_2$

- Solve for y

$\left\{y = \frac{\sqrt{2}\sqrt{c_1(c_1^2c_2^2+2c_1^2c_2x+c_1^2x^2-1)}}{c_1}, y = -\frac{\sqrt{2}\sqrt{c_1(c_1^2c_2^2+2c_1^2c_2x+c_1^2x^2-1)}}{c_1}\right\}$

- Solve 2nd ODE for $u(y)$

  $$u(y) = -\frac{\sqrt{2c_1y^2+4}}{y}$$

- Revert to original variables with substitution $u(y) = y', y = y$

  $$y' = -\frac{\sqrt{2c_1y^2+4}}{y}$$

- Separate variables

  $$\frac{yy'}{\sqrt{2c_1y^2+4}} = -1$$

- Integrate both sides with respect to x

  $$\int \frac{yy'}{\sqrt{2c_1y^2+4}}dx = \int (-1)\, dx + c_2$$

- Evaluate integral

  $$\frac{\sqrt{2c_1y^2+4}}{2c_1} = -x + c_2$$

- Solve for y

  $$\left\{y = \frac{\sqrt{2}\,\sqrt{c_1\,(c_1^2c_2^2-2c_1^2c_2x+c_1^2x^2-1)}}{c_1}, y = -\frac{\sqrt{2}\,\sqrt{c_1\,(c_1^2c_2^2-2c_1^2c_2x+c_1^2x^2-1)}}{c_1}\right\}$$

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1]]
```

$$\boxed{x'' - \frac{k^2}{x^2} = 0}$$

18.5.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable x an independent variable. Using

$$x' = p(x)$$

Then

$$\begin{aligned} x'' &= \frac{dp}{dt} \\ &= \frac{dx}{dt}\frac{dp}{dx} \\ &= p\frac{dp}{dx} \end{aligned}$$

Hence the ode becomes

$$p(x)\left(\frac{d}{dx}p(x)\right)x^2 = k^2$$

Which is now solved as first order ode for $p(x)$. In canonical form the ODE is

$$\begin{aligned} p' &= F(x, p) \\ &= f(x)g(p) \\ &= \frac{k^2}{p\,x^2} \end{aligned}$$

Where $f(x) = \frac{k^2}{x^2}$ and $g(p) = \frac{1}{p}$. Integrating both sides gives

$$\frac{1}{\frac{1}{p}}\,dp = \frac{k^2}{x^2}\,dx$$

$$\int \frac{1}{\frac{1}{p}}\,dp = \int \frac{k^2}{x^2}\,dx$$

$$\frac{p^2}{2} = -\frac{k^2}{x} + c_1$$

The solution is

$$\frac{p(x)^2}{2} + \frac{k^2}{x} - c_1 = 0$$

For solution (1) found earlier, since $p = x'$ then we now have a new first order ode to solve which is

$$\frac{x'^2}{2} + \frac{k^2}{x} - c_1 = 0$$

Solving the given ode for x' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$x' = \frac{\sqrt{2}\,\sqrt{x\,(c_1 x - k^2)}}{x} \tag{1}$$

$$x' = -\frac{\sqrt{2}\,\sqrt{x\,(c_1 x - k^2)}}{x} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{x\sqrt{2}}{2\sqrt{x\,(c_1 x - k^2)}}dx = \int dt$$

$$\frac{\sqrt{2}\,\sqrt{x^2 c_1 - k^2 x}}{2c_1} + \frac{\sqrt{2}\,k^2 \ln\left(\frac{-\frac{k^2}{2}+c_1 x}{\sqrt{c_1}} + \sqrt{x^2 c_1 - k^2 x}\right)}{4c_1^{\frac{3}{2}}} = t + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{x\sqrt{2}}{2\sqrt{x\left(c_1 x-k^2\right)}}dx = \int dt$$

$$-\frac{\sqrt{2}\,\sqrt{x^2 c_1-k^2 x}}{2c_1}-\frac{\sqrt{2}\,k^2 \ln\left(\frac{-\frac{k^2}{2}+c_1 x}{\sqrt{c_1}}+\sqrt{x^2 c_1-k^2 x}\right)}{4c_1^{\frac{3}{2}}} = t+c_3$$

Summary

The solution(s) found are the following

$$\frac{\sqrt{2}\,\sqrt{x^2 c_1-k^2 x}}{2c_1}+\frac{\sqrt{2}\,k^2 \ln\left(\frac{-\frac{k^2}{2}+c_1 x}{\sqrt{c_1}}+\sqrt{x^2 c_1-k^2 x}\right)}{4c_1^{\frac{3}{2}}} = t+c_2 \tag{1}$$

$$-\frac{\sqrt{2}\,\sqrt{x^2 c_1-k^2 x}}{2c_1}-\frac{\sqrt{2}\,k^2 \ln\left(\frac{-\frac{k^2}{2}+c_1 x}{\sqrt{c_1}}+\sqrt{x^2 c_1-k^2 x}\right)}{4c_1^{\frac{3}{2}}} = t+c_3 \tag{2}$$

Verification of solutions

$$\frac{\sqrt{2}\,\sqrt{x^2 c_1-k^2 x}}{2c_1}+\frac{\sqrt{2}\,k^2 \ln\left(\frac{-\frac{k^2}{2}+c_1 x}{\sqrt{c_1}}+\sqrt{x^2 c_1-k^2 x}\right)}{4c_1^{\frac{3}{2}}} = t+c_2$$

Verified OK.

$$-\frac{\sqrt{2}\,\sqrt{x^2 c_1-k^2 x}}{2c_1}-\frac{\sqrt{2}\,k^2 \ln\left(\frac{-\frac{k^2}{2}+c_1 x}{\sqrt{c_1}}+\sqrt{x^2 c_1-k^2 x}\right)}{4c_1^{\frac{3}{2}}} = t+c_3$$

Verified OK.

18.5.2 Maple step by step solution

Let's solve

$x''x^2 = k^2$

- Highest derivative means the order of the ODE is 2

  x''

- Define new dependent variable u

  $u(t) = x'$

- Compute x''

  $u'(t) = x''$

- Use chain rule on the lhs

  $x'\left(\frac{d}{dx}u(x)\right) = x''$

- Substitute in the definition of u

  $u(x)\left(\frac{d}{dx}u(x)\right) = x''$

- Make substitutions $x' = u(x), x'' = u(x)\left(\frac{d}{dx}u(x)\right)$ to reduce order of ODE

  $u(x)\left(\frac{d}{dx}u(x)\right)x^2 = k^2$

- Separate variables

  $u(x)\left(\frac{d}{dx}u(x)\right) = \frac{k^2}{x^2}$

- Integrate both sides with respect to x

  $\int u(x)\left(\frac{d}{dx}u(x)\right)dx = \int \frac{k^2}{x^2}dx + c_1$

- Evaluate integral

  $\frac{u(x)^2}{2} = -\frac{k^2}{x} + c_1$

- Solve for $u(x)$

  $\left\{u(x) = \frac{\sqrt{2}\,\sqrt{x(c_1x-k^2)}}{x}, u(x) = -\frac{\sqrt{2}\,\sqrt{x(c_1x-k^2)}}{x}\right\}$

- Solve 1st ODE for $u(x)$

  $u(x) = \frac{\sqrt{2}\,\sqrt{x(c_1x-k^2)}}{x}$

- Revert to original variables with substitution $u(x) = x', x = x$

  $x' = \frac{\sqrt{2}\,\sqrt{x(c_1x-k^2)}}{x}$

- Separate variables

$$\frac{x' x}{\sqrt{x(c_1 x - k^2)}} = \sqrt{2}$$

- Integrate both sides with respect to t

$$\int \frac{x' x}{\sqrt{x(c_1 x - k^2)}} dt = \int \sqrt{2} dt + c_2$$

- Evaluate integral

$$\frac{\sqrt{x^2 c_1 - k^2 x}}{c_1} + \frac{k^2 \ln\left(\frac{-\frac{k^2}{2} + c_1 x}{\sqrt{c_1}} + \sqrt{x^2 c_1 - k^2 x}\right)}{2 c_1^{\frac{3}{2}}} = \sqrt{2}\, t + c_2$$

- Solve for x

$$\left\{ \frac{4 c_1 \left(e^{RootOf\left(-64 \left(e^{\_Z}\right)^2 \sqrt{2}\, c_1^{\frac{5}{2}} \_Z k^2 t - 64 \left(e^{\_Z}\right)^2 c_1^{\frac{5}{2}} c_2 \_Z k^2 + 128 \left(e^{\_Z}\right)^2 \sqrt{2}\, c_1^4 c_2 t + 16 \left(e^{\_Z}\right)^2 c_1 \_Z^2 k^4 + 64 \left(e^{\_Z}\right)^2 c_1^4 c_2^2 + 128 \left(e^{\_Z}\right)^2 c_1^4 t^2 - k^8 \right.}\right.}{8\, e^{RootOf\left(-64 \left(e^{\_Z}\right)^2 \sqrt{2}\, c_1^{\frac{5}{2}} \_Z k^2 t - 64 \left(e^{\_Z}\right)^2 c \right.}} \right.$$

- Solve 2nd ODE for $u(x)$

$$u(x) = -\frac{\sqrt{2}\, \sqrt{x(c_1 x - k^2)}}{x}$$

- Revert to original variables with substitution $u(x) = x', x = x$

$$x' = -\frac{\sqrt{2}\, \sqrt{x(c_1 x - k^2)}}{x}$$

- Separate variables

$$\frac{x' x}{\sqrt{x(c_1 x - k^2)}} = -\sqrt{2}$$

- Integrate both sides with respect to t

$$\int \frac{x' x}{\sqrt{x(c_1 x - k^2)}} dt = \int -\sqrt{2} dt + c_2$$

- Evaluate integral

$$\frac{\sqrt{x^2 c_1 - k^2 x}}{c_1} + \frac{k^2 \ln\left(\frac{-\frac{k^2}{2} + c_1 x}{\sqrt{c_1}} + \sqrt{x^2 c_1 - k^2 x}\right)}{2 c_1^{\frac{3}{2}}} = -\sqrt{2}\, t + c_2$$

- Solve for x

$$\left\{ \frac{4 c_1 \left(e^{RootOf\left(-64 \left(e^{\_Z}\right)^2 \sqrt{2}\, c_1^{\frac{5}{2}} \_Z k^2 t + 64 \left(e^{\_Z}\right)^2 c_1^{\frac{5}{2}} c_2 \_Z k^2 + 128 \left(e^{\_Z}\right)^2 \sqrt{2}\, c_1^4 c_2 t - 16 \left(e^{\_Z}\right)^2 c_1 \_Z^2 k^4 - 64 \left(e^{\_Z}\right)^2 c_1^4 c_2^2 - 128 \left(e^{\_Z}\right)^2 c_1^4 t^2 + k^8 \right.}\right.}{8\, e^{RootOf\left(-64 \left(e^{\_Z}\right)^2 \sqrt{2}\, c_1^{\frac{5}{2}} \_Z k^2 t + 64 \left(e^{\_Z}\right)^2 c \right.}} \right.$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 6.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_quadrature", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _quadrature]]
```

$$\boxed{xy'' = x^2 + 1}$$

Simplyfing the ode gives

$$y'' = \frac{x^2 + 1}{x}$$

18.6.1 Solving as second order ode quadrature ode

Integrating once gives

$$y' = \frac{x^2}{2} + \ln(x) + c_1$$

Integrating again gives

$$y = \frac{x^3}{6} + x\ln(x) - x + c_1x + c_2$$

Summary

The solution(s) found are the following

$$y = \frac{x^3}{6} + x\ln(x) - x + c_1x + c_2 \tag{1}$$

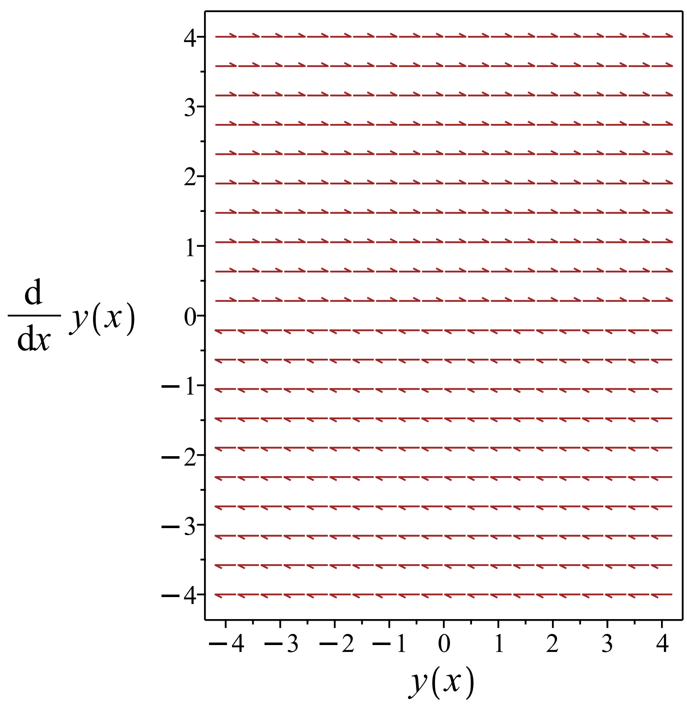

Figure 703: Slope field plot

Verification of solutions

$$y = \frac{x^3}{6} + x\ln(x) - x + c_1x + c_2$$

Verified OK.

18.6.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 0, f(x) = x + \frac{1}{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(0)^2 - (4)(1)(0)} \\ &= 0\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 0$. Therefore the solution is

$$y = c_1 1 + c_2 x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_2 x + c_1$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= 1 \\ y_2 &= x \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & x \\ \frac{d}{dx}(1) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & x \\ 0 & 1 \end{vmatrix}$$

Therefore

$$W = (1)(1) - (x)(0)$$

Which simplifies to

$$W = 1$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x\left(x + \frac{1}{x}\right)}{1}\, dx$$

Which simplifies to

$$u_1 = -\int \left(x^2 + 1\right) dx$$

Hence

$$u_1 = -\frac{1}{3}x^3 - x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x + \frac{1}{x}}{1}\, dx$$

Which simplifies to

$$u_2 = \int \left(x + \frac{1}{x}\right) dx$$

Hence

$$u_2 = \frac{x^2}{2} + \ln(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^3}{3} - x + \left(\frac{x^2}{2} + \ln(x)\right) x$$

Which simplifies to

$$y_p(x) = \frac{x(x^2 + 6\ln(x) - 6)}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 x + c_1) + \left(\frac{x(x^2 + 6\ln(x) - 6)}{6}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_2 x + c_1 + \frac{x(x^2 + 6\ln(x) - 6)}{6} \tag{1}$$

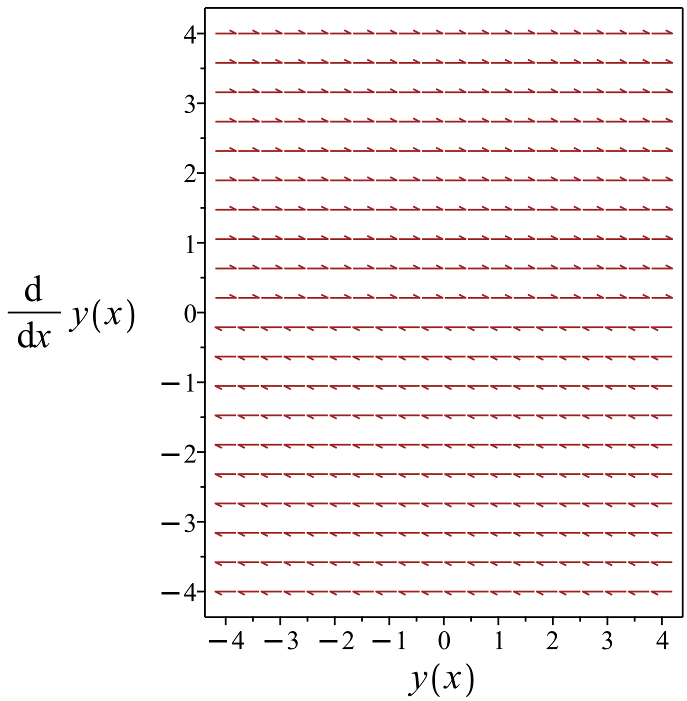

Figure 704: Slope field plot

Verification of solutions

$$y = c_2 x + c_1 + \frac{x(x^2 + 6\ln(x) - 6)}{6}$$

Verified OK.

18.6.3 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int y'' dx = \int \left(x + \frac{1}{x}\right) dx$$

$$y' = \frac{x^2}{2} + \ln(x) + c_1$$

Which is now solved for y. Integrating both sides gives

$$
\begin{aligned}
y &= \int \ln(x) + \frac{x^2}{2} + c_1 \, \mathrm{d}x \\
&= \frac{x^3}{6} + x\ln(x) - x + c_1 x + c_2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{x^3}{6} + x\ln(x) - x + c_1 x + c_2 \tag{1}
$$

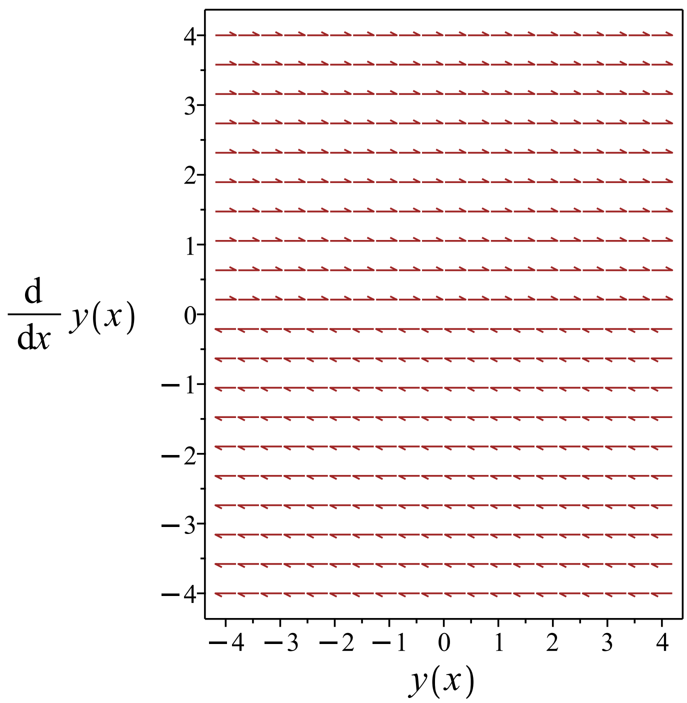

Figure 705: Slope field plot

Verification of solutions

$$
y = \frac{x^3}{6} + x\ln(x) - x + c_1 x + c_2
$$

Verified OK.

18.6.4 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - x - \frac{1}{x} = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\begin{aligned} p(x) &= \int \frac{x^2+1}{x}\, \mathrm{d}x \\ &= \ln(x) + \frac{x^2}{2} + c_1 \end{aligned}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \ln(x) + \frac{x^2}{2} + c_1$$

Integrating both sides gives

$$\begin{aligned} y &= \int \ln(x) + \frac{x^2}{2} + c_1\, \mathrm{d}x \\ &= \frac{x^3}{6} + x\ln(x) - x + c_1 x + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{x^3}{6} + x\ln(x) - x + c_1 x + c_2 \tag{1}$$

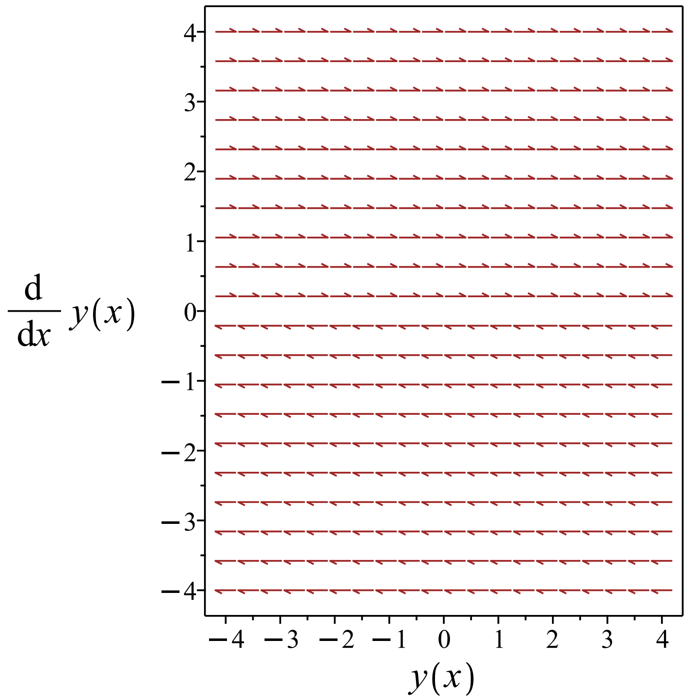

Figure 706: Slope field plot

Verification of solutions

$$y = \frac{x^3}{6} + x \ln(x) - x + c_1 x + c_2$$

Verified OK.

18.6.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 575: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= 1 \end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= 1 \int \frac{1}{1}\,dx \\ &= 1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2(1(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
y'' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_2 x + c_1
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= 1 \\
y_2 &= x
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & x \\ \frac{d}{dx}(1) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & x \\ 0 & 1 \end{vmatrix}$$

Therefore

$$W = (1)(1) - (x)(0)$$

Which simplifies to

$$W = 1$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x\left(x + \frac{1}{x}\right)}{1} \, dx$$

Which simplifies to

$$u_1 = -\int \left(x^2 + 1\right) dx$$

Hence

$$u_1 = -\frac{1}{3}x^3 - x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x + \frac{1}{x}}{1} \, dx$$

Which simplifies to

$$u_2 = \int \left(x + \frac{1}{x}\right) dx$$

Hence

$$u_2 = \frac{x^2}{2} + \ln(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^3}{3} - x + \left(\frac{x^2}{2} + \ln(x)\right) x$$

Which simplifies to

$$y_p(x) = \frac{x(x^2 + 6\ln(x) - 6)}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 x + c_1) + \left(\frac{x(x^2 + 6\ln(x) - 6)}{6}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_2 x + c_1 + \frac{x(x^2 + 6\ln(x) - 6)}{6} \tag{1}$$

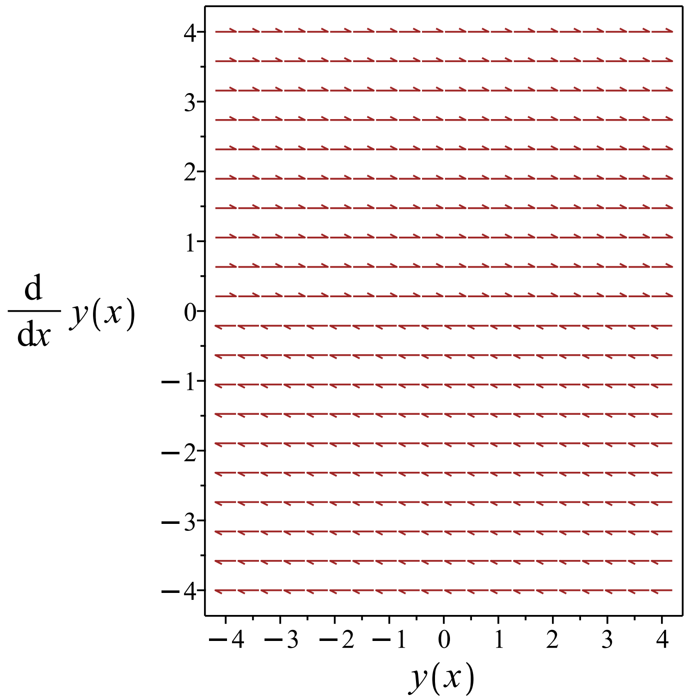

Figure 707: Slope field plot

Verification of solutions

$$y = c_2x + c_1 + \frac{x(x^2 + 6\ln(x) - 6)}{6}$$

Verified OK.

18.6.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 0 \\ r(x) &= 0 \\ s(x) &= x + \frac{1}{x} \end{aligned}$$

Hence

$$p''(x) = 0$$
$$q'(x) = 0$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$y' = \int x + \frac{1}{x}\, dx$$

We now have a first order ode to solve which is

$$y' = \ln(x) + \frac{x^2}{2} + c_1$$

Integrating both sides gives

$$\begin{aligned} y &= \int \ln(x) + \frac{x^2}{2} + c_1 \,\mathrm{d}x \\ &= \frac{x^3}{6} + x\ln(x) - x + c_1 x + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{x^3}{6} + x\ln(x) - x + c_1 x + c_2 \tag{1}$$

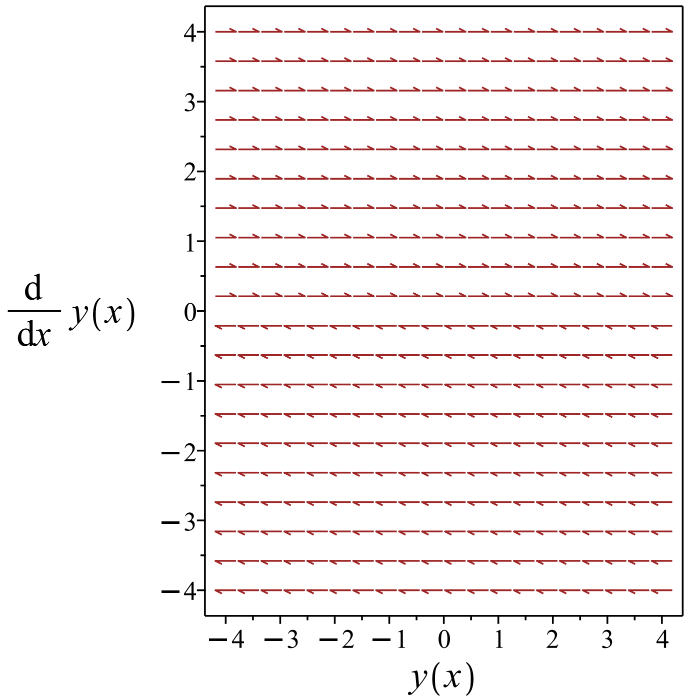

Figure 708: Slope field plot

Verification of solutions

$$y = \frac{x^3}{6} + x \ln(x) - x + c_1 x + c_2$$

Verified OK.

18.6.7 Maple step by step solution

Let's solve

$y'' = x + \frac{1}{x}$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{x^2+1}{x}$

- Characteristic polynomial of homogeneous ODE

  $r^2 = 0$

- Use quadratic formula to solve for r

$r = \frac{0 \pm \left(\sqrt{0}\right)}{2}$

- Roots of the characteristic polynomial

  $r = 0$

- 1st solution of the homogeneous ODE

  $y_1(x) = 1$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 x + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \frac{x^2+1}{x}\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & x \\ 0 & 1 \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 1$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\left(\int (x^2+1)\, dx\right) + x\left(\int \frac{x^2+1}{x} dx\right)$

  ◦ Compute integrals

  $y_p(x) = \frac{x(x^2 + 6\ln(x) - 6)}{6}$

- Substitute particular solution into general solution to ODE

  $y = c_2 x + c_1 + \frac{x(x^2 + 6\ln(x) - 6)}{6}$

$$\boxed{(1-x)\, y'' - y' = 0}$$

18.7.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int ((1-x)\, y'' - y')\, dx = 0$$
$$-(x-1)\, y' = c_1$$

Which is now solved for y. Integrating both sides gives

$$
\begin{aligned}
y &= \int -\frac{c_1}{x-1}\,\mathrm{d}x \\
&= -c_1 \ln(x-1) + c_2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = -c_1 \ln(x-1) + c_2 \tag{1}
$$

Verification of solutions

$$
y = -c_1 \ln(x-1) + c_2
$$

Verified OK.

18.7.2 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$
p(x) = y'
$$

Then

$$
p'(x) = y''
$$

Hence the ode becomes

$$
(1-x)\,p'(x) - p(x) = 0
$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$
\begin{aligned}
p' &= F(x,p) \\
&= f(x)g(p) \\
&= -\frac{p}{x-1}
\end{aligned}
$$

Where $f(x) = -\frac{1}{x-1}$ and $g(p) = p$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{p}\,dp &= -\frac{1}{x-1}\,dx \\
\int \frac{1}{p}\,dp &= \int -\frac{1}{x-1}\,dx \\
\ln(p) &= -\ln(x-1) + c_1 \\
p &= \mathrm{e}^{-\ln(x-1)+c_1} \\
&= \frac{c_1}{x-1}
\end{aligned}
$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{c_1}{x-1}$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{c_1}{x-1}\, \mathrm{d}x \\ &= c_1 \ln(x-1) + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \ln(x-1) + c_2 \tag{1}$$

Verification of solutions

$$y = c_1 \ln(x-1) + c_2$$

Verified OK.

18.7.3 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + \left(2AB' + B^2\right) v' + \left(AB'' + BB' + CB\right) v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right) v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$AB u' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned}
A &= 1 - x \\
B &= -1 \\
C &= 0 \\
F &= 0
\end{aligned}$$

The above shows that for this ode

$$\begin{aligned}
AB'' + BB' + CB &= (1 - x)(0) + (-1)(0) + (0)(-1) \\
&= 0
\end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$x - 1v'' + (1) v' = 0$$

Now by applying $v' = u$ the above becomes

$$(x - 1) u'(x) + u(x) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x, u) \\
&= f(x) g(u) \\
&= -\frac{u}{x - 1}
\end{aligned}$$

Where $f(x) = -\frac{1}{x-1}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u} \, du &= -\frac{1}{x - 1} \, dx \\
\int \frac{1}{u} \, du &= \int -\frac{1}{x - 1} \, dx \\
\ln(u) &= -\ln(x - 1) + c_1 \\
u &= e^{-\ln(x-1)+c_1} \\
&= \frac{c_1}{x - 1}
\end{aligned}$$

The ode for v now becomes

$$\begin{aligned}v' &= u \\ &= \frac{c_1}{x-1}\end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned}v(x) &= \int \frac{c_1}{x-1}\, \mathrm{d}x \\ &= c_1 \ln(x-1) + c_2\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y(x) &= Bv \\ &= (-1)\left(c_1 \ln(x-1) + c_2\right) \\ &= -c_1 \ln(x-1) - c_2\end{aligned}$$

Summary

The solution(s) found are the following

$$y = -c_1 \ln(x-1) - c_2 \tag{1}$$

Verification of solutions

$$y = -c_1 \ln(x-1) - c_2$$

Verified OK.

18.7.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$(1-x)\, y'' - y' = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\begin{aligned}\int \left((1-x)\, y'' - y'\right) dx &= 0 \\ -(x-1)\, y' &= c_1\end{aligned}$$

Which is now solved for y. Integrating both sides gives

$$\begin{aligned}y &= \int -\frac{c_1}{x-1}\, \mathrm{d}x \\ &= -c_1 \ln(x-1) + c_2\end{aligned}$$

Summary
The solution(s) found are the following

$$y = -c_1 \ln (x-1) + c_2 \tag{1}$$

Verification of solutions

$$y = -c_1 \ln (x-1) + c_2$$

Verified OK.

18.7.5 Solving using Kovacic algorithm

Writing the ode as

$$(1-x) y'' - y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1-x \\ B &= -1 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4(x-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4(x-1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4\,(x-1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 577: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x-1)^2$. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4(x-1)^2}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4(x-1)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4(x-1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+}\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x-2} + (-)\,(0) \\ &= \frac{1}{2x-2} \\ &= \frac{1}{2x-2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2x-2}\right)(0) + \left(\left(-\frac{1}{2\,(x-1)^2}\right) + \left(\frac{1}{2x-2}\right)^2 - \left(-\frac{1}{4\,(x-1)^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \frac{1}{2x-2} dx} \\
&= \sqrt{x-1}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-1}{1-x} \, dx} \\
&= z_1 e^{-\frac{\ln(1-x)}{2}} \\
&= z_1 \left(\frac{1}{\sqrt{1-x}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{x-1}}{\sqrt{1-x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{1-x} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\ln(1-x)}}{(y_1)^2} \, dx \\
&= y_1 (\ln (x-1))
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\sqrt{x-1}}{\sqrt{1-x}} \right) + c_2 \left(\frac{\sqrt{x-1}}{\sqrt{1-x}} (\ln (x-1)) \right)
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 \sqrt{x-1}}{\sqrt{1-x}} + \frac{c_2 \sqrt{x-1}\, \ln (x-1)}{\sqrt{1-x}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \sqrt{x-1}}{\sqrt{1-x}} + \frac{c_2 \sqrt{x-1}\, \ln (x-1)}{\sqrt{1-x}}$$

Verified OK.

18.7.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1-x \\ q(x) &= -1 \\ r(x) &= 0 \\ s(x) &= 0 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$(1-x)\,y' = c_1$$

We now have a first order ode to solve which is

$$(1-x)\,y' = c_1$$

Integrating both sides gives

$$\begin{aligned} y &= \int -\frac{c_1}{x-1}\,\mathrm{d}x \\ &= -c_1 \ln(x-1) + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = -c_1 \ln(x-1) + c_2 \tag{1}$$

Verification of solutions

$$y = -c_1 \ln(x-1) + c_2$$

Verified OK.

18.7.7 Maple step by step solution

Let's solve

$(1-x)\,y'' - y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y'}{x-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x-1} = 0$

□ Check to see if $x_0 = 1$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{1}{x-1}, P_3(x) = 0\right]$

  ◦ $(x-1) \cdot P_2(x)$ is analytic at $x = 1$

$$\left((x-1)\cdot P_2(x)\right)\Big|_{x=1} = 1$$

- $(x-1)^2 \cdot P_3(x)$ is analytic at $x=1$

$$\left((x-1)^2\cdot P_3(x)\right)\Big|_{x=1} = 0$$

- $x=1$is a regular singular point

Check to see if $x_0 = 1$ is a regular singular point

$x_0 = 1$

- Multiply by denominators

$y''(x-1) + y' = 0$

- Change variables using $x = u+1$ so that the regular singular point is at $u = 0$

$$u\left(\frac{d^2}{du^2}y(u)\right) + \frac{d}{du}y(u) = 0$$

- Assume series solution for $y(u)$

$$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

□ Rewrite DE with series expansions

- Convert $\frac{d}{du}y(u)$ to series expansion

$$\frac{d}{du}y(u) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1}$$

- Shift index using $k->k+1$

$$\frac{d}{du}y(u) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,u^{k+r}$$

- Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

$$u\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-1}$$

- Shift index using $k->k+1$

$$u\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\,u^{k+r}$$

Rewrite DE with series expansions

$$\sum_{k=-1}^{\infty} a_{k+1}(k+1+r)^2\,u^{k+r} = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r = 0$

- Each term in the series must be 0, giving the recursion relation

$a_{k+1}(k+1)^2 = 0$

- Recursion relation that defines series solution to ODE

$a_{k+1} = 0$

- Recursion relation for $r = 0$

$a_{k+1} = 0$

- Solution for $r = 0$

$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = 0\right]$

- Revert the change of variables $u = x - 1$

$\left[y = \sum_{k=0}^{\infty} a_k (x-1)^k, a_{k+1} = 0\right]$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{(x^2+1)\,y''+2x(y'+1)=0}$$

18.8.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left((x^2+1)\,y''+2xy'\right)dx=\int -2x dx$$
$$(x^2+1)\,y'=-x^2+c_1$$

Which is now solved for y. Integrating both sides gives

$$y=\int \frac{-x^2+c_1}{x^2+1}\,\mathrm{d}x$$
$$=-x+(c_1+1)\arctan(x)+c_2$$

Summary
The solution(s) found are the following

$$y = -x + (c_1 + 1)\arctan(x) + c_2 \tag{1}$$

Verification of solutions

$$y = -x + (c_1 + 1)\arctan(x) + c_2$$

Verified OK.

18.8.2 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$(x^2 + 1)\,p'(x) + 2xp(x) + 2x = 0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned} p' &= F(x,p) \\ &= f(x)g(p) \\ &= \frac{x(-2p-2)}{x^2+1} \end{aligned}$$

Where $f(x) = \frac{x}{x^2+1}$ and $g(p) = -2p - 2$. Integrating both sides gives

$$\begin{aligned} \frac{1}{-2p-2}\,dp &= \frac{x}{x^2+1}\,dx \\ \int \frac{1}{-2p-2}\,dp &= \int \frac{x}{x^2+1}\,dx \\ -\frac{\ln(p+1)}{2} &= \frac{\ln(x^2+1)}{2} + c_1 \end{aligned}$$

Raising both side to exponential gives

$$\frac{1}{\sqrt{p+1}} = \mathrm{e}^{\frac{\ln(x^2+1)}{2} + c_1}$$

Which simplifies to

$$\frac{1}{\sqrt{p+1}} = c_2\sqrt{x^2+1}$$

Which simplifies to

$$p(x) = -\frac{\left(c_2^2 \mathrm{e}^{2c_1}(x^2+1)-1\right)\mathrm{e}^{-2c_1}}{c_2^2\,(x^2+1)}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -\frac{\left(c_2^2 \mathrm{e}^{2c_1}(x^2+1)-1\right)\mathrm{e}^{-2c_1}}{c_2^2\,(x^2+1)}$$

Integrating both sides gives

$$\begin{aligned} y &= \int -\frac{\left(\mathrm{e}^{2c_1} c_2^2 x^2 + c_2^2 \mathrm{e}^{2c_1} - 1\right)\mathrm{e}^{-2c_1}}{c_2^2\,(x^2+1)}\,\mathrm{d}x \\ &= -\frac{\mathrm{e}^{-2c_1}\left(c_2^2 \mathrm{e}^{2c_1} x - \arctan(x)\right)}{c_2^2} + c_3 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{\mathrm{e}^{-2c_1}\left(c_2^2 \mathrm{e}^{2c_1} x - \arctan(x)\right)}{c_2^2} + c_3 \tag{1}$$

Verification of solutions

$$y = -\frac{\mathrm{e}^{-2c_1}\left(c_2^2 \mathrm{e}^{2c_1} x - \arctan(x)\right)}{c_2^2} + c_3$$

Verified OK.

18.8.3 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$\left(x^2+1\right) y'' + 2xy' = -2x$$

Integrating both sides of the ODE w.r.t x gives

$$\begin{aligned} \int \left(\left(x^2+1\right) y'' + 2xy'\right) dx &= \int -2x dx \\ \left(x^2+1\right) y' &= -x^2 + c_1 \end{aligned}$$

Which is now solved for y. Integrating both sides gives

$$
\begin{aligned}
y &= \int \frac{-x^2 + c_1}{x^2 + 1}\, \mathrm{d}x \\
&= -x + (c_1 + 1) \arctan(x) + c_2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = -x + (c_1 + 1) \arctan(x) + c_2 \tag{1}
$$

Verification of solutions

$$
y = -x + (c_1 + 1) \arctan(x) + c_2
$$

Verified OK.

18.8.4 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{aligned}
(x^2 + 1)\, y'' + 2xy' &= 0 && (1) \\
Ay'' + By' + Cy &= 0 && (2)
\end{aligned}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x^2 + 1 \\
B &= 2x \\
C &= 0
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{(x^2+1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 1$$
$$t = (x^2+1)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{1}{(x^2+1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 579: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4(x-i)^2} - \frac{1}{4(x+i)^2} - \frac{i}{4(x-i)} + \frac{i}{4x+4i}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{1}{(x^2+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$-i$	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x-2i} + \frac{1}{2x+2i} + (-)(0) \\
&= \frac{1}{2x-2i} + \frac{1}{2x+2i} \\
&= \frac{x}{x^2+1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x-2i} + \frac{1}{2x+2i}\right)(0) + \left(\left(-\frac{1}{2(x-i)^2} - \frac{1}{2(x+i)^2}\right) + \left(\frac{1}{2x-2i} + \frac{1}{2x+2i}\right)^2 - \left(\frac{1}{(x^2+1)^2}\right.\right.$$

$$0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \left(\frac{1}{2x-2i} + \frac{1}{2x+2i}\right) dx} \\ &= \sqrt{x^2+1} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2x}{x^2+1} \, dx} \\ &= z_1 e^{-\frac{\ln(x^2+1)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x^2+1}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2x}{x^2+1} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-\ln(x^2+1)}}{(y_1)^2} \, dx \\ &= y_1(\arctan(x)) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1(1) + c_2(1(\arctan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
(x^2 + 1)\, y'' + 2xy' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 + c_2 \arctan(x)
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1y_1 + u_2y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= 1 \\
y_2 &= \arctan(x)
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & \arctan(x) \\ \frac{d}{dx}(1) & \frac{d}{dx}(\arctan(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & \arctan(x) \\ 0 & \frac{1}{x^2+1} \end{vmatrix}$$

Therefore

$$W = (1)\left(\frac{1}{x^2+1}\right) - (\arctan(x))(0)$$

Which simplifies to

$$W = \frac{1}{x^2+1}$$

Which simplifies to

$$W = \frac{1}{x^2+1}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-2\arctan(x)\, x}{1}\, dx$$

Which simplifies to

$$u_1 = -\int -2\arctan(x)\, x dx$$

Hence

$$u_1 = \arctan(x)\, x^2 - x + \arctan(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{-2x}{1}\, dx$$

Which simplifies to

$$u_2 = \int -2x dx$$

Hence

$$u_2 = -x^2$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -x + \arctan(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 + c_2 \arctan(x)) + (-x + \arctan(x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + c_2 \arctan(x) - x + \arctan(x) \tag{1}$$

Verification of solutions

$$y = c_1 + c_2 \arctan(x) - x + \arctan(x)$$

Verified OK.

18.8.5 Solving as exact linear second order ode ode

An ode of the form

$$p(x) y'' + q(x) y' + r(x) y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x^2 + 1 \\ q(x) &= 2x \\ r(x) &= 0 \\ s(x) &= -2x \end{aligned}$$

Hence

$$
\begin{aligned}
p''(x) &= 2 \\
q'(x) &= 2
\end{aligned}
$$

Therefore (1) becomes

$$
2 - (2) + (0) = 0
$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$
(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)
$$

Integrating gives

$$
p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\; dx
$$

Substituting the above values for p, q, r, s gives

$$
\left(x^2 + 1\right) y' = \int -2x\, dx
$$

We now have a first order ode to solve which is

$$
\left(x^2 + 1\right) y' = -x^2 + c_1
$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int \frac{-x^2 + c_1}{x^2 + 1}\, \mathrm{d}x \\
&= -x + (c_1 + 1) \arctan(x) + c_2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = -x + (c_1 + 1) \arctan(x) + c_2 \tag{1}
$$

Verification of solutions

$$
y = -x + (c_1 + 1) \arctan(x) + c_2
$$

Verified OK.

18.8.6 Maple step by step solution

Let's solve

$(x^2+1)\,y''+2xy'=-2x$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u=y'$ to reduce order of ODE

  $(x^2+1)\,u'(x)+2xu(x)=-2x$

- Integrate both sides with respect to x

  $\int \left((x^2+1)\,u'(x)+2xu(x)\right)dx=\int -2xdx+c_1$

- Evaluate integral

  $(x^2+1)\,u(x)=-x^2+c_1$

- Solve for $u(x)$

  $u(x)=\frac{-x^2+c_1}{x^2+1}$

- Solve 1st ODE for $u(x)$

  $u(x)=\frac{-x^2+c_1}{x^2+1}$

- Make substitution $u=y'$

  $y'=\frac{-x^2+c_1}{x^2+1}$

- Integrate both sides to solve for y

  $\int y'dx=\int \frac{-x^2+c_1}{x^2+1}dx+c_2$

- Compute integrals

  $y=-x+(c_1+1)\arctan(x)+c_2$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 9.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_missing_y"**

Maple gives the following as the ode type

`[[_2nd_order, _missing_x]]`

$$\boxed{y'' - {y'}^3 - y' = 0}$$

18.9.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + \left(-p(x)^2 - 1\right) p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{p\,(p^2+1)} dp = \int dx$$
$$-\frac{\ln\left(p^2+1\right)}{2} + \ln\left(p\right) = x + c_1$$

Raising both side to exponential gives

$$e^{-\frac{\ln(p^2+1)}{2}+\ln(p)} = e^{x+c_1}$$

Which simplifies to

$$\frac{p}{\sqrt{p^2+1}} = c_2 e^x$$

Since $p = y'$ then the new first order ode to solve is

$$y' = c_2 e^x \sqrt{-\frac{1}{c_2^2 e^{2x} - 1}}$$

Integrating both sides gives

$$\begin{aligned} y &= \int c_2 e^x \sqrt{-\frac{1}{c_2^2 e^{2x} - 1}}\, dx \\ &= \frac{c_2 \sqrt{-\frac{1}{c_2^2 e^{2x}-1}}\, \sqrt{c_2^2 e^{2x} - 1}\, \ln\left(\frac{c_2^2 e^x + \sqrt{c_2^2 e^{2x}-1}\,\sqrt{c_2^2}}{\sqrt{c_2^2}}\right)}{\sqrt{c_2^2}} + c_3 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_2 \sqrt{-\frac{1}{c_2^2 e^{2x}-1}}\, \sqrt{c_2^2 e^{2x} - 1}\, \ln\left(\frac{c_2^2 e^x + \sqrt{c_2^2 e^{2x}-1}\,\sqrt{c_2^2}}{\sqrt{c_2^2}}\right)}{\sqrt{c_2^2}} + c_3 \tag{1}$$

Verification of solutions

$$y = \frac{c_2 \sqrt{-\frac{1}{c_2^2 e^{2x}-1}}\, \sqrt{c_2^2 e^{2x} - 1}\, \ln\left(\frac{c_2^2 e^x + \sqrt{c_2^2 e^{2x}-1}\,\sqrt{c_2^2}}{\sqrt{c_2^2}}\right)}{\sqrt{c_2^2}} + c_3$$

Verified OK.

18.9.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right)+\left(-p(y)^{2}-1\right)p(y)=0$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$\begin{aligned} \int \frac{1}{p^{2}+1}dp &= y+c_{1} \\ \arctan\left(p\right) &= y+c_{1} \end{aligned}$$

Solving for p gives these solutions

$$p_{1}=\tan\left(y+c_{1}\right)$$

For solution (1) found earlier, since $p=y'$ then we now have a new first order ode to solve which is

$$y'=\tan\left(y+c_{1}\right)$$

Integrating both sides gives

$$\begin{aligned} \int \frac{1}{\tan\left(y+c_{1}\right)}dy &= \int dx \\ -\frac{\ln\left(1+\tan\left(y+c_{1}\right)^{2}\right)}{2}+\ln\left(\tan\left(y+c_{1}\right)\right) &= x+c_{2} \end{aligned}$$

Raising both side to exponential gives

$$\mathrm{e}^{-\frac{\ln\left(1+\tan\left(y+c_{1}\right)^{2}\right)}{2}+\ln\left(\tan\left(y+c_{1}\right)\right)}=\mathrm{e}^{x+c_{2}}$$

Which simplifies to

$$\operatorname{csgn}\left(\sec\left(y+c_{1}\right)\right)\sin\left(y+c_{1}\right)=c_{3}\mathrm{e}^{x}$$

Simplifying the solution $y = \operatorname{RootOf}(-\operatorname{csgn}(\sec(\_Z + c_1))\sin(\_Z + c_1) + c_3 e^x)$ to $y = \operatorname{RootOf}(-\sin(\_Z + c_1) + c_3 e^x)$

Summary

The solution(s) found are the following

$$y = \operatorname{RootOf}(-\sin(\_Z + c_1) + c_3 e^x)$$

Verification of solutions

$$y = \operatorname{RootOf}(-\sin(\_Z + c_1) + c_3 e^x)$$

Verified OK.

18.9.3 Maple step by step solution

Let's solve

$y'' + (-y'^2 - 1) y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) + (-u(x)^2 - 1) u(x) = 0$

- Separate variables

  $\frac{u'(x)}{(-u(x)^2-1)u(x)} = -1$

- Integrate both sides with respect to x

  $\int \frac{u'(x)}{(-u(x)^2-1)u(x)} dx = \int (-1) dx + c_1$

- Evaluate integral

  $\frac{\ln(u(x)^2+1)}{2} - \ln(u(x)) = -x + c_1$

- Solve for $u(x)$

  $\left\{u(x) = \frac{1}{\sqrt{e^{-2x+2c_1}-1}}, u(x) = -\frac{1}{\sqrt{e^{-2x+2c_1}-1}}\right\}$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 10.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{xy'' - y' = -x}$$

18.10.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (xy'' - y')\,dx = \int -x dx$$

$$xy' - 2y = -\frac{x^2}{2} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= \frac{-x^2 + 2c_1}{2x} \end{aligned}$$

Hence the ode is

$$y' - \frac{2y}{x} = \frac{-x^2 + 2c_1}{2x}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int -\frac{2}{x}dx} \\ &= \frac{1}{x^2} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(\frac{-x^2 + 2c_1}{2x}\right) \\ \frac{d}{dx}\left(\frac{y}{x^2}\right) &= \left(\frac{1}{x^2}\right)\left(\frac{-x^2 + 2c_1}{2x}\right) \\ d\left(\frac{y}{x^2}\right) &= \left(\frac{-x^2 + 2c_1}{2x^3}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} \frac{y}{x^2} &= \int \frac{-x^2 + 2c_1}{2x^3} dx \\ \frac{y}{x^2} &= -\frac{c_1}{2x^2} - \frac{\ln(x)}{2} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$y = x^2\left(-\frac{c_1}{2x^2} - \frac{\ln(x)}{2}\right) + c_2x^2$$

which simplifies to

$$y = -\frac{\ln(x)\,x^2}{2} + c_2x^2 - \frac{c_1}{2}$$

Summary
The solution(s) found are the following

$$y = -\frac{\ln(x)\, x^2}{2} + c_2 x^2 - \frac{c_1}{2} \tag{1}$$

Verification of solutions

$$y = -\frac{\ln(x)\, x^2}{2} + c_2 x^2 - \frac{c_1}{2}$$

Verified OK.

18.10.2 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x)\, x + x - p(x) = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$p(x) = -\frac{1}{x}$$
$$q(x) = -1$$

Hence the ode is

$$p'(x) - \frac{p(x)}{x} = -1$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{x} dx}$$
$$= \frac{1}{x}$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu p) &= (\mu)(-1) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{p}{x}\right) &= \left(\frac{1}{x}\right)(-1) \\
\mathrm{d}\left(\frac{p}{x}\right) &= \left(-\frac{1}{x}\right) \mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\frac{p}{x} &= \int -\frac{1}{x} \,\mathrm{d}x \\
\frac{p}{x} &= -\ln(x) + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$
p(x) = -x\ln(x) + c_1 x
$$

which simplifies to

$$
p(x) = x(-\ln(x) + c_1)
$$

Since $p = y'$ then the new first order ode to solve is

$$
y' = x(-\ln(x) + c_1)
$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int -x(\ln(x) - c_1)\,\mathrm{d}x \\
&= -\frac{\ln(x)\,x^2}{2} + \frac{x^2}{4} + \frac{c_1 x^2}{2} + c_2
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = -\frac{\ln(x)\,x^2}{2} + \frac{x^2}{4} + \frac{c_1 x^2}{2} + c_2 \tag{1}
$$

Verification of solutions

$$
y = -\frac{\ln(x)\,x^2}{2} + \frac{x^2}{4} + \frac{c_1 x^2}{2} + c_2
$$

Verified OK.

18.10.3 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv = 0 \\ ABv'' + \left(2AB' + B^2\right)v' + \left(AB'' + BB' + CB\right)v = 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right)v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right)u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned} A &= x \\ B &= -1 \\ C &= 0 \\ F &= -x \end{aligned}$$

The above shows that for this ode

$$\begin{aligned} AB'' + BB' + CB &= (x)(0) + (-1)(0) + (0)(-1) \\ &= 0 \end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$-xv'' + (1)\, v' = 0$$

Now by applying $v' = u$ the above becomes

$$-xu'(x) + u(x) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{u}{x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= \frac{1}{x}\, dx \\ \int \frac{1}{u}\, du &= \int \frac{1}{x}\, dx \\ \ln(u) &= \ln(x) + c_1 \\ u &= e^{\ln(x)+c_1} \\ &= c_1 x \end{aligned}$$

The ode for v now becomes

$$\begin{aligned} v' &= u \\ &= c_1 x \end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned} v(x) &= \int c_1 x \,\mathrm{d}x \\ &= \frac{c_1 x^2}{2} + c_2 \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= Bv \\ &= (-1)\left(\frac{c_1 x^2}{2} + c_2\right) \\ &= -\frac{c_1 x^2}{2} - c_2 \end{aligned}$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = -1$$
$$y_2 = x^2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} -1 & x^2 \\ \frac{d}{dx}(-1) & \frac{d}{dx}(x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} -1 & x^2 \\ 0 & 2x \end{vmatrix}$$

Therefore

$$W = (-1)(2x) - (x^2)(0)$$

Which simplifies to

$$W = -2x$$

Which simplifies to

$$W = -2x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-x^3}{-2x^2}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{x}{2}dx$$

Hence

$$u_1 = -\frac{x^2}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x}{-2x^2}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{1}{2x}dx$$

Hence

$$u_2 = -\frac{\ln(x)}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x^2}{4} - \frac{\ln(x)\,x^2}{2}$$

Which simplifies to

$$y_p(x) = -\frac{x^2(-1 + 2\ln(x))}{4}$$

Hence the complete solution is

$$\begin{aligned}
y(x) &= y_h + y_p \\
&= \left(-\frac{c_1 x^2}{2} - c_2\right) + \left(-\frac{x^2(-1 + 2\ln(x))}{4}\right) \\
&= -\frac{\ln(x)\, x^2}{2} + \frac{(1 - 2c_1)\, x^2}{4} - c_2
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{\ln(x)\, x^2}{2} + \frac{(1 - 2c_1)\, x^2}{4} - c_2 \tag{1}$$

Verification of solutions

$$y = -\frac{\ln(x)\, x^2}{2} + \frac{(1 - 2c_1)\, x^2}{4} - c_2$$

Verified OK.

18.10.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$xy'' - y' = -x$$

Integrating both sides of the ODE w.r.t x gives

$$\begin{aligned}
\int (xy'' - y')\, dx &= \int -x dx \\
xy' - 2y &= -\frac{x^2}{2} + c_1
\end{aligned}$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}
p(x) &= -\frac{2}{x} \\
q(x) &= \frac{-x^2 + 2c_1}{2x}
\end{aligned}$$

Hence the ode is

$$y' - \frac{2y}{x} = \frac{-x^2 + 2c_1}{2x}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{2}{x}dx} \\ &= \frac{1}{x^2}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{-x^2 + 2c_1}{2x}\right) \\ \frac{d}{dx}\left(\frac{y}{x^2}\right) &= \left(\frac{1}{x^2}\right)\left(\frac{-x^2 + 2c_1}{2x}\right) \\ d\left(\frac{y}{x^2}\right) &= \left(\frac{-x^2 + 2c_1}{2x^3}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{y}{x^2} &= \int \frac{-x^2 + 2c_1}{2x^3} dx \\ \frac{y}{x^2} &= -\frac{c_1}{2x^2} - \frac{\ln(x)}{2} + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$y = x^2\left(-\frac{c_1}{2x^2} - \frac{\ln(x)}{2}\right) + c_2 x^2$$

which simplifies to

$$y = -\frac{\ln(x)\, x^2}{2} + c_2 x^2 - \frac{c_1}{2}$$

Summary

The solution(s) found are the following

$$y = -\frac{\ln(x)\, x^2}{2} + c_2 x^2 - \frac{c_1}{2} \tag{1}$$

Verification of solutions

$$y = -\frac{\ln(x)\, x^2}{2} + c_2 x^2 - \frac{c_1}{2}$$

Verified OK.

18.10.5 Solving using Kovacic algorithm

Writing the ode as

$$xy'' - y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= -1 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 582: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{3}{4x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{3}{4x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{3}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{2x} + (-)(0) \\
&= -\frac{1}{2x} \\
&= -\frac{1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(-\frac{1}{2x}\right)^2 - \left(\frac{3}{4x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int -\frac{1}{2x} dx} \\
&= \frac{1}{\sqrt{x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-1}{x}\,dx} \\
&= z_1 e^{\frac{\ln(x)}{2}} \\
&= z_1\left(\sqrt{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = 1
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{x^2}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2\left(1\left(\frac{x^2}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
xy'' - y' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 + \frac{c_2 x^2}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = 1$$
$$y_2 = \frac{x^2}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & \frac{x^2}{2} \\ \frac{d}{dx}(1) & \frac{d}{dx}\left(\frac{x^2}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & \frac{x^2}{2} \\ 0 & x \end{vmatrix}$$

Therefore

$$W = (1)\,(x) - \left(\frac{x^2}{2}\right)(0)$$

Which simplifies to

$$W = x$$

Which simplifies to

$$W = x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{x^3}{2}}{x^2}\, dx$$

Which simplifies to

$$u_1 = -\int -\frac{x}{2} dx$$

Hence

$$u_1 = \frac{x^2}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{-x}{x^2}\, dx$$

Which simplifies to

$$u_2 = \int -\frac{1}{x} dx$$

Hence

$$u_2 = -\ln(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x^2}{4} - \frac{\ln(x)\,x^2}{2}$$

Which simplifies to

$$y_p(x) = -\frac{x^2(-1+2\ln(x))}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + \frac{c_2 x^2}{2}\right) + \left(-\frac{x^2(-1+2\ln(x))}{4}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 + \frac{c_2 x^2}{2} - \frac{x^2(-1+2\ln(x))}{4} \tag{1}$$

Verification of solutions

$$y = c_1 + \frac{c_2 x^2}{2} - \frac{x^2(-1+2\ln(x))}{4}$$

Verified OK.

18.10.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x \\ q(x) &= -1 \\ r(x) &= 0 \\ s(x) &= -x \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0-(0)+(0)=0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y'+(q(x)-p'(x))\,y)'=s(x)$$

Integrating gives

$$p(x)\,y'+(q(x)-p'(x))\,y=\int s(x)\;dx$$

Substituting the above values for p,q,r,s gives

$$xy'-2y=\int -x\,dx$$

We now have a first order ode to solve which is

$$xy'-2y=-\frac{x^2}{2}+c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$\begin{aligned}p(x)&=-\frac{2}{x}\\ q(x)&=\frac{-x^2+2c_1}{2x}\end{aligned}$$

Hence the ode is

$$y'-\frac{2y}{x}=\frac{-x^2+2c_1}{2x}$$

The integrating factor μ is

$$\begin{aligned}\mu&=\mathrm{e}^{\int -\frac{2}{x}dx}\\ &=\frac{1}{x^2}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y)&=(\mu)\left(\frac{-x^2+2c_1}{2x}\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{x^2}\right)&=\left(\frac{1}{x^2}\right)\left(\frac{-x^2+2c_1}{2x}\right)\\ \mathrm{d}\left(\frac{y}{x^2}\right)&=\left(\frac{-x^2+2c_1}{2x^3}\right)\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\frac{y}{x^2} = \int \frac{-x^2+2c_1}{2x^3}\, \mathrm{d}x$$
$$\frac{y}{x^2} = -\frac{c_1}{2x^2} - \frac{\ln(x)}{2} + c_2$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$y = x^2\left(-\frac{c_1}{2x^2} - \frac{\ln(x)}{2}\right) + c_2 x^2$$

which simplifies to

$$y = -\frac{\ln(x)\, x^2}{2} + c_2 x^2 - \frac{c_1}{2}$$

Summary

The solution(s) found are the following

$$y = -\frac{\ln(x)\, x^2}{2} + c_2 x^2 - \frac{c_1}{2} \tag{1}$$

Verification of solutions

$$y = -\frac{\ln(x)\, x^2}{2} + c_2 x^2 - \frac{c_1}{2}$$

Verified OK.

18.10.7 Maple step by step solution

Let's solve

$y''x - y' = -x$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x)\, x - u(x) = -x$

- Isolate the derivative

  $u'(x) = -1 + \frac{u(x)}{x}$

- Group terms with $u(x)$ on the lhs of the ODE and the rest on the rhs of the ODE

$u'(x) - \frac{u(x)}{x} = -1$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(u'(x) - \frac{u(x)}{x}\right) = -\mu(x)$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,u(x))$

  $\mu(x)\left(u'(x) - \frac{u(x)}{x}\right) = \mu'(x)\,u(x) + \mu(x)\,u'(x)$
- Isolate $\mu'(x)$

  $\mu'(x) = -\frac{\mu(x)}{x}$
- Solve to find the integrating factor

  $\mu(x) = \frac{1}{x}$
- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,u(x))\right) dx = \int -\mu(x)\,dx + c_1$
- Evaluate the integral on the lhs

  $\mu(x)\,u(x) = \int -\mu(x)\,dx + c_1$
- Solve for $u(x)$

  $u(x) = \frac{\int -\mu(x)dx + c_1}{\mu(x)}$
- Substitute $\mu(x) = \frac{1}{x}$

  $u(x) = x\left(\int -\frac{1}{x}dx + c_1\right)$
- Evaluate the integrals on the rhs

  $u(x) = x(-\ln(x) + c_1)$
- Solve 1st ODE for $u(x)$

  $u(x) = x(-\ln(x) + c_1)$
- Make substitution $u = y'$

  $y' = x(-\ln(x) + c_1)$
- Integrate both sides to solve for y

  $\int y' dx = \int x(-\ln(x) + c_1)\,dx + c_2$
- Compute integrals

  $y = -\frac{\ln(x)x^2}{2} + \frac{x^2}{4} + \frac{c_1 x^2}{2} + c_2$

The type(s) of ODE detected by this program : **"kovacic", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{x'' + x't = t^3}$$

18.11.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable x. Let

$$p(t) = x'$$

Then

$$p'(t) = x''$$

Hence the ode becomes

$$p'(t) + p(t)\,t - t^3 = 0$$

Which is now solve for $p(t)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(t) + p(t)p(t) = q(t)$$

Where here

$$\begin{aligned} p(t) &= t \\ q(t) &= t^3 \end{aligned}$$

Hence the ode is

$$p'(t) + p(t)\,t = t^3$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int t dt} \\ &= \mathrm{e}^{\frac{t^2}{2}} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}t}(\mu p) &= (\mu)\left(t^3\right) \\ \frac{\mathrm{d}}{\mathrm{d}t}\left(\mathrm{e}^{\frac{t^2}{2}} p\right) &= \left(\mathrm{e}^{\frac{t^2}{2}}\right)\left(t^3\right) \\ \mathrm{d}\left(\mathrm{e}^{\frac{t^2}{2}} p\right) &= \left(t^3 \mathrm{e}^{\frac{t^2}{2}}\right) \mathrm{d}t \end{aligned}$$

Integrating gives

$$\begin{aligned} \mathrm{e}^{\frac{t^2}{2}} p &= \int t^3 \mathrm{e}^{\frac{t^2}{2}} \,\mathrm{d}t \\ \mathrm{e}^{\frac{t^2}{2}} p &= \left(t^2 - 2\right) \mathrm{e}^{\frac{t^2}{2}} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\frac{t^2}{2}}$ results in

$$p(t) = \mathrm{e}^{-\frac{t^2}{2}} \left(t^2 - 2\right) \mathrm{e}^{\frac{t^2}{2}} + c_1 \mathrm{e}^{-\frac{t^2}{2}}$$

which simplifies to

$$p(t) = t^2 - 2 + c_1 \mathrm{e}^{-\frac{t^2}{2}}$$

Since $p = x'$ then the new first order ode to solve is

$$x' = t^2 - 2 + c_1 \mathrm{e}^{-\frac{t^2}{2}}$$

Integrating both sides gives

$$\begin{aligned} x &= \int t^2 - 2 + c_1 \mathrm{e}^{-\frac{t^2}{2}} \,\mathrm{d}t \\ &= -2t + \frac{t^3}{3} + \frac{c_1 \sqrt{\pi}\, \sqrt{2}\, \operatorname{erf}\left(\frac{\sqrt{2}\, t}{2}\right)}{2} + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$x = -2t + \frac{t^3}{3} + \frac{c_1 \sqrt{\pi}\, \sqrt{2}\, \operatorname{erf}\left(\frac{\sqrt{2}\, t}{2}\right)}{2} + c_2 \tag{1}$$

Verification of solutions

$$x = -2t + \frac{t^3}{3} + \frac{c_1 \sqrt{\pi}\, \sqrt{2}\, \operatorname{erf}\left(\frac{\sqrt{2}\, t}{2}\right)}{2} + c_2$$

Verified OK.

18.11.2 Solving using Kovacic algorithm

Writing the ode as

$$x'' + x't = 0 \tag{1}$$

$$Ax'' + Bx' + Cx = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= t \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = x e^{\int \frac{B}{2A}\, dt}$$

Then (2) becomes

$$z''(t) = r z(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^2 + 2}{4} \tag{6}$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= t^2 + 2 \\
t &= 4
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(t) = \left(\frac{t^2}{4} + \frac{1}{2}\right) z(t) \tag{7}
$$

Equation (7) is now solved. After finding $z(t)$ then x is found using the inverse transformation

$$
x = z(t)\, e^{-\int \frac{B}{2A}\, dt}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 584: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 2 \\
&= -2
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{1} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{t}{2} + \frac{1}{2t} - \frac{1}{4t^3} + \frac{1}{4t^5} - \frac{5}{16t^7} + \frac{7}{16t^9} - \frac{21}{32t^{11}} + \frac{33}{32t^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i t^i \\ &= \frac{t}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{t^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{t^2+2}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{t^2}{4} + \frac{1}{2}\right) + (0) \\
&= \frac{t^2}{4} + \frac{1}{2}
\end{aligned}
$$

We see that the coefficient of the term $\frac{1}{t}$ in the quotient is $\frac{1}{2}$. Now b can be found.

$$
\begin{aligned}
b &= \left(\frac{1}{2}\right) - (0) \\
&= \frac{1}{2}
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{t}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{1}{2}}{\frac{1}{2}} - 1\right) &&= 0 \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{1}{2}}{\frac{1}{2}} - 1\right) &&= -1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{t^2}{4} + \frac{1}{2}
$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{t}{2}$	0	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 0$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{t}{2}\right) \\ &= \frac{t}{2} \\ &= \frac{t}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{t}{2}\right)(0) + \left(\left(\frac{1}{2}\right) + \left(\frac{t}{2}\right)^2 - \left(\frac{t^2}{4} + \frac{1}{2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= p e^{\int \omega \, dt} \\ &= e^{\int \frac{t}{2} dt} \\ &= e^{\frac{t^2}{4}} \end{aligned}$$

The first solution to the original ode in x is found from

$$
\begin{aligned}
x_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\
&= z_1 e^{-\int \frac{1}{2}\frac{t}{1}\,dt} \\
&= z_1 e^{-\frac{t^2}{4}} \\
&= z_1 \left(\mathrm{e}^{-\frac{t^2}{4}}\right)
\end{aligned}
$$

Which simplifies to

$$
x_1 = 1
$$

The second solution x_2 to the original ode is found using reduction of order

$$
x_2 = x_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{x_1^2}\,dt
$$

Substituting gives

$$
\begin{aligned}
x_2 &= x_1 \int \frac{e^{\int -\frac{t}{1}\,dt}}{(x_1)^2}\,dt \\
&= x_1 \int \frac{e^{-\frac{t^2}{2}}}{(x_1)^2}\,dt \\
&= x_1 \left(\frac{\sqrt{\pi}\,\sqrt{2}\,\operatorname{erf}\left(\frac{\sqrt{2}\,t}{2}\right)}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
x &= c_1 x_1 + c_2 x_2 \\
&= c_1(1) + c_2 \left(1 \left(\frac{\sqrt{\pi}\,\sqrt{2}\,\operatorname{erf}\left(\frac{\sqrt{2}\,t}{2}\right)}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
x = x_h + x_p
$$

Where x_h is the solution to the homogeneous ODE $Ax''(t)+Bx'(t)+Cx(t)=0$, and x_p is a particular solution to the nonhomogeneous ODE $Ax''(t)+Bx'(t)+Cx(t)=f(t)$. x_h is the solution to

$$x''+x't=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$x_h = c_1 + \frac{c_2\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{\sqrt{2}\,t}{2}\right)}{2}$$

The particular solution x_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on t as well. Let

$$x_p(t) = u_1x_1 + u_2x_2 \tag{1}$$

Where u_1, u_2 to be determined, and x_1, x_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$x_1 = 1$$

$$x_2 = \frac{\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{\sqrt{2}\,t}{2}\right)}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{x_2 f(t)}{aW(t)} \tag{2}$$

$$u_2 = \int \frac{x_1 f(t)}{aW(t)} \tag{3}$$

Where $W(t)$ is the Wronskian and a is the coefficient in front of x'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} x_1 & x_2 \\ x_1' & x_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & \frac{\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{\sqrt{2}\,t}{2}\right)}{2} \\ \frac{d}{dt}(1) & \frac{d}{dt}\left(\frac{\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{\sqrt{2}\,t}{2}\right)}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & \frac{\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{\sqrt{2}\,t}{2}\right)}{2} \\ 0 & \mathrm{e}^{-\frac{t^2}{2}} \end{vmatrix}$$

Therefore

$$W = (1)\left(\mathrm{e}^{-\frac{t^2}{2}}\right) - \left(\frac{\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{\sqrt{2}\,t}{2}\right)}{2}\right)(0)$$

Which simplifies to

$$W = \mathrm{e}^{-\frac{t^2}{2}}$$

Which simplifies to

$$W = \mathrm{e}^{-\frac{t^2}{2}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{\sqrt{2}\,t}{2}\right)t^3}{2}}{\mathrm{e}^{-\frac{t^2}{2}}}\,dt$$

Which simplifies to

$$u_1 = -\int \frac{\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{\sqrt{2}\,t}{2}\right)t^3\mathrm{e}^{\frac{t^2}{2}}}{2}dt$$

Hence

$$u_1 = -\sqrt{\pi}\left(2\,\mathrm{erf}\left(\frac{\sqrt{2}\,t}{2}\right)\sqrt{2}\left(\frac{t^2\mathrm{e}^{\frac{t^2}{2}}}{4} - \frac{\mathrm{e}^{\frac{t^2}{2}}}{2}\right) - \frac{2\sqrt{2}\left(\frac{t^3\sqrt{2}}{12} - \frac{\sqrt{2}\,t}{2}\right)}{\sqrt{\pi}}\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{t^3}{\mathrm{e}^{-\frac{t^2}{2}}}\,dt$$

Which simplifies to

$$u_2 = \int t^3\mathrm{e}^{\frac{t^2}{2}}\,dt$$

Hence

$$u_2 = \left(t^2-2\right) \mathrm{e}^{\frac{t^2}{2}}$$

Which simplifies to

$$u_1 = \frac{\left(-3\sqrt{\pi}\, \mathrm{erf}\left(\frac{\sqrt{2}\, t}{2}\right) \left(t^2-2\right) \mathrm{e}^{\frac{t^2}{2}} + \sqrt{2}\, t(t^2-6)\right) \sqrt{2}}{6}$$

$$u_2 = \left(t^2-2\right) \mathrm{e}^{\frac{t^2}{2}}$$

Therefore the particular solution, from equation (1) is

$$x_p(t) = \frac{\left(-3\sqrt{\pi}\, \mathrm{erf}\left(\frac{\sqrt{2}\, t}{2}\right) \left(t^2-2\right) \mathrm{e}^{\frac{t^2}{2}} + \sqrt{2}\, t(t^2-6)\right) \sqrt{2}}{6} + \frac{\left(t^2-2\right) \mathrm{e}^{\frac{t^2}{2}} \sqrt{\pi}\, \sqrt{2}\, \mathrm{erf}\left(\frac{\sqrt{2}\, t}{2}\right)}{2}$$

Which simplifies to

$$x_p(t) = \frac{1}{3}t^3 - 2t$$

Therefore the general solution is

$$\begin{aligned} x &= x_h + x_p \\ &= \left(c_1 + \frac{c_2\sqrt{\pi}\, \sqrt{2}\, \mathrm{erf}\left(\frac{\sqrt{2}\, t}{2}\right)}{2}\right) + \left(\frac{1}{3}t^3 - 2t\right) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$x = c_1 + \frac{c_2\sqrt{\pi}\, \sqrt{2}\, \mathrm{erf}\left(\frac{\sqrt{2}\, t}{2}\right)}{2} + \frac{t^3}{3} - 2t \tag{1}$$

<u>Verification of solutions</u>

$$x = c_1 + \frac{c_2\sqrt{\pi}\, \sqrt{2}\, \mathrm{erf}\left(\frac{\sqrt{2}\, t}{2}\right)}{2} + \frac{t^3}{3} - 2t$$

Verified OK.

18.11.3 Maple step by step solution

Let's solve

$x'' + x't = t^3$

- Highest derivative means the order of the ODE is 2

  x''

- Make substitution $u = x'$ to reduce order of ODE

  $u'(t) + u(t)\, t = t^3$

- Isolate the derivative

  $u'(t) = -u(t)\, t + t^3$

- Group terms with $u(t)$ on the lhs of the ODE and the rest on the rhs of the ODE

  $u'(t) + u(t)\, t = t^3$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\, (u'(t) + u(t)\, t) = \mu(t)\, t^3$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, u(t))$

  $\mu(t)\, (u'(t) + u(t)\, t) = \mu'(t)\, u(t) + \mu(t)\, u'(t)$

- Isolate $\mu'(t)$

  $\mu'(t) = \mu(t)\, t$

- Solve to find the integrating factor

  $\mu(t) = \mathrm{e}^{\frac{t^2}{2}}$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\, u(t))\right) dt = \int \mu(t)\, t^3 dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\, u(t) = \int \mu(t)\, t^3 dt + c_1$

- Solve for $u(t)$

  $u(t) = \frac{\int \mu(t) t^3 dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = \mathrm{e}^{\frac{t^2}{2}}$

  $u(t) = \frac{\int t^3 \mathrm{e}^{\frac{t^2}{2}} dt + c_1}{\mathrm{e}^{\frac{t^2}{2}}}$

- Evaluate the integrals on the rhs

$$u(t) = \frac{(t^2-2)\,e^{\frac{t^2}{2}} + c_1}{e^{\frac{t^2}{2}}}$$

- Simplify

$$u(t) = t^2 - 2 + c_1 e^{-\frac{t^2}{2}}$$

- Solve 1st ODE for $u(t)$

$$u(t) = t^2 - 2 + c_1 e^{-\frac{t^2}{2}}$$

- Make substitution $u = x'$

$$x' = t^2 - 2 + c_1 e^{-\frac{t^2}{2}}$$

- Integrate both sides to solve for x

$$\int x' dt = \int \left(t^2 - 2 + c_1 e^{-\frac{t^2}{2}}\right) dt + c_2$$

- Compute integrals

$$x = -2t + \frac{t^3}{3} + \frac{c_1 \sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{\sqrt{2}\,t}{2}\right)}{2} + c_2$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 12.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{x^2y'' - xy' = 1}$$

18.12.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -x, C = 0, f(x) = 1$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - xy' = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - xrx^{r-1} + 0 = 0$$

Simplifying gives

$$r(r-1)\,x^r - r\,x^r + 0 = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - r + 0 = 0$$

Or

$$r^2 - 2r = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = 0$$
$$r_2 = 2$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_2x^2 + c_1$$

Next, we find the particular solution to the ODE

$$x^2y'' - xy' = 1$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = 1$$
$$y_2 = x^2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & x^2 \\ \frac{d}{dx}(1) & \frac{d}{dx}(x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & x^2 \\ 0 & 2x \end{vmatrix}$$

Therefore

$$W = (1)(2x) - (x^2)(0)$$

Which simplifies to

$$W = 2x$$

Which simplifies to

$$W = 2x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^2}{2x^3} \, dx$$

Which simplifies to

$$u_1 = -\int \frac{1}{2x} dx$$

Hence

$$u_1 = -\frac{\ln(x)}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{1}{2x^3}\, dx$$

Which simplifies to

$$u_2 = \int \frac{1}{2x^3} dx$$

Hence

$$u_2 = -\frac{1}{4x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\ln(x)}{2} - \frac{1}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= -\frac{\ln(x)}{2} - \frac{1}{4} + c_2 x^2 + c_1 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = -\frac{\ln(x)}{2} - \frac{1}{4} + c_2 x^2 + c_1 \tag{1}$$

Verification of solutions

$$y = -\frac{\ln(x)}{2} - \frac{1}{4} + c_2 x^2 + c_1$$

Verified OK.

18.12.2 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$x^2 p'(x) - x p(x) - 1 = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= \frac{1}{x^2}
\end{aligned}$$

Hence the ode is

$$p'(x) - \frac{p(x)}{x} = \frac{1}{x^2}$$

The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int -\frac{1}{x}dx} \\
&= \frac{1}{x}
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dx}(\mu p) &= (\mu)\left(\frac{1}{x^2}\right) \\
\frac{d}{dx}\left(\frac{p}{x}\right) &= \left(\frac{1}{x}\right)\left(\frac{1}{x^2}\right) \\
d\left(\frac{p}{x}\right) &= \frac{1}{x^3}\,dx
\end{aligned}$$

Integrating gives

$$\frac{p}{x} = \int \frac{1}{x^3}\, dx$$
$$\frac{p}{x} = -\frac{1}{2x^2} + c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$p(x) = -\frac{1}{2x} + c_1 x$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -\frac{1}{2x} + c_1 x$$

Integrating both sides gives

$$y = \int \frac{2c_1x^2 - 1}{2x}\, dx$$
$$= \frac{c_1 x^2}{2} - \frac{\ln(x)}{2} + c_2$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 x^2}{2} - \frac{\ln(x)}{2} + c_2 \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x^2}{2} - \frac{\ln(x)}{2} + c_2$$

Verified OK.

18.12.3 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - xy' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$A = x^2$$
$$B = -x \tag{3}$$
$$C = 0$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 586: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2x} + (-)(0) \\ &= -\frac{1}{2x} \\ &= -\frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(-\frac{1}{2x}\right)^2 - \left(\frac{3}{4x^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int -\frac{1}{2x} dx} \\ &= \frac{1}{\sqrt{x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x}{x^2}\,dx} \\
&= z_1 e^{\frac{\ln(x)}{2}} \\
&= z_1\left(\sqrt{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = 1
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{x^2}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2\left(1\left(\frac{x^2}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' - xy' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 + \frac{c_2 x^2}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = 1$$
$$y_2 = \frac{x^2}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & \frac{x^2}{2} \\ \frac{d}{dx}(1) & \frac{d}{dx}\left(\frac{x^2}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & \frac{x^2}{2} \\ 0 & x \end{vmatrix}$$

Therefore

$$W = (1)(x) - \left(\frac{x^2}{2}\right)(0)$$

Which simplifies to

$$W = x$$

Which simplifies to

$$W = x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x^2}{2}}{x^3} dx$$

Which simplifies to

$$u_1 = -\int \frac{1}{2x} dx$$

Hence

$$u_1 = -\frac{\ln(x)}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{1}{x^3} dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x^3} dx$$

Hence

$$u_2 = -\frac{1}{2x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\ln(x)}{2} - \frac{1}{4}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 + \frac{c_2 x^2}{2}\right) + \left(-\frac{\ln(x)}{2} - \frac{1}{4}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 + \frac{c_2 x^2}{2} - \frac{\ln(x)}{2} - \frac{1}{4} \tag{1}
$$

Verification of solutions

$$
y = c_1 + \frac{c_2 x^2}{2} - \frac{\ln(x)}{2} - \frac{1}{4}
$$

Verified OK.

18.12.4 Maple step by step solution

Let's solve

$x^2 y'' - x y' = 1$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $x^2 u'(x) - x u(x) = 1$

- Isolate the derivative

  $u'(x) = \frac{u(x)}{x} + \frac{1}{x^2}$

- Group terms with $u(x)$ on the lhs of the ODE and the rest on the rhs of the ODE

  $u'(x) - \frac{u(x)}{x} = \frac{1}{x^2}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(u'(x) - \frac{u(x)}{x}\right) = \frac{\mu(x)}{x^2}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,u(x))$

  $\mu(x)\left(u'(x) - \frac{u(x)}{x}\right) = \mu'(x)\,u(x) + \mu(x)\,u'(x)$

- Isolate $\mu'(x)$

$\mu'(x) = -\frac{\mu(x)}{x}$

- Solve to find the integrating factor

$\mu(x) = \frac{1}{x}$

- Integrate both sides with respect to x

$\int \left(\frac{d}{dx}(\mu(x)\, u(x))\right) dx = \int \frac{\mu(x)}{x^2} dx + c_1$

- Evaluate the integral on the lhs

$\mu(x)\, u(x) = \int \frac{\mu(x)}{x^2} dx + c_1$

- Solve for $u(x)$

$u(x) = \frac{\int \frac{\mu(x)}{x^2} dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \frac{1}{x}$

$u(x) = x\left(\int \frac{1}{x^3} dx + c_1\right)$

- Evaluate the integrals on the rhs

$u(x) = x\left(-\frac{1}{2x^2} + c_1\right)$

- Solve 1st ODE for $u(x)$

$u(x) = x\left(-\frac{1}{2x^2} + c_1\right)$

- Make substitution $u = y'$

$y' = x\left(-\frac{1}{2x^2} + c_1\right)$

- Integrate both sides to solve for y

$\int y' dx = \int x\left(-\frac{1}{2x^2} + c_1\right) dx + c_2$

- Compute integrals

$y = \frac{c_1 x^2}{2} - \frac{\ln(x)}{2} + c_2$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 13.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_xy]]
```

$$\boxed{y'' - {y'}^2 = 1}$$

18.13.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - 1 - p(x)^2 = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{p^2 + 1} dp = x + c_1$$
$$\arctan(p) = x + c_1$$

Solving for p gives these solutions

$$p_1 = \tan(x + c_1)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \tan(x + c_1)$$

Integrating both sides gives

$$\begin{aligned} y &= \int \tan(x + c_1)\, \mathrm{d}x \\ &= \frac{\ln\left(1 + \tan(x + c_1)^2\right)}{2} + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{\ln\left(1 + \tan(x + c_1)^2\right)}{2} + c_2 \tag{1}$$

Verification of solutions

$$y = \frac{\ln\left(1 + \tan(x + c_1)^2\right)}{2} + c_2$$

Verified OK.

18.13.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right) - p(y)^2 = 1$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$\int \frac{p}{p^2+1}dp = \int dy$$
$$\frac{\ln(p^2+1)}{2} = y + c_1$$

Raising both side to exponential gives

$$\sqrt{p^2+1} = \mathrm{e}^{y+c_1}$$

Which simplifies to

$$\sqrt{p^2+1} = c_2\mathrm{e}^{y}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = \mathrm{RootOf}\left(\_Z^2 - c_2^2\mathrm{e}^{2y} + 1\right)$$

Integrating both sides gives

$$\int \frac{1}{\mathrm{RootOf}\left(\_Z^2 - c_2^2\mathrm{e}^{2y} + 1\right)}dy = \int dx$$
$$\int^y \frac{1}{\mathrm{RootOf}\left(\_Z^2 - c_2^2\mathrm{e}^{2\_a} + 1\right)}d\_a = x + c_3$$

Summary

The solution(s) found are the following

$$\int^y \frac{1}{\mathrm{RootOf}\left(\_Z^2 - c_2^2\mathrm{e}^{2\_a} + 1\right)}d\_a = x + c_3 \tag{1}$$

Verification of solutions

$$\int^y \frac{1}{\mathrm{RootOf}\left(\_Z^2 - c_2^2\mathrm{e}^{2\_a} + 1\right)}d\_a = x + c_3$$

Verified OK.

18.13.3 Maple step by step solution

Let's solve

$y'' - y'^2 = 1$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) - u(x)^2 = 1$

- Separate variables

  $\frac{u'(x)}{u(x)^2+1} = 1$

- Integrate both sides with respect to x

  $\int \frac{u'(x)}{u(x)^2+1} dx = \int 1 dx + c_1$

- Evaluate integral

  $\arctan(u(x)) = x + c_1$

- Solve for $u(x)$

  $u(x) = \tan(x + c_1)$

- Solve 1st ODE for $u(x)$

  $u(x) = \tan(x + c_1)$

- Make substitution $u = y'$

  $y' = \tan(x + c_1)$

- Integrate both sides to solve for y

  $\int y' dx = \int \tan(x + c_1) dx + c_2$

- Compute integrals

  $y = \frac{\ln\left(1+\tan(x+c_1)^2\right)}{2} + c_2$

The type(s) of ODE detected by this program : **"kovacic", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{(-x^2+1)\, y''+x y'=1}$$

18.14.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x)=y'$$

Then

$$p'(x)=y''$$

Hence the ode becomes

$$(-x^2+1)\, p'(x)+x p(x)-1=0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x)+p(x)p(x)=q(x)$$

Where here

$$p(x) = -\frac{x}{x^2 - 1}$$
$$q(x) = -\frac{1}{x^2 - 1}$$

Hence the ode is

$$p'(x) - \frac{xp(x)}{x^2 - 1} = -\frac{1}{x^2 - 1}$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{x}{x^2-1}dx} \\ &= \mathrm{e}^{-\frac{\ln(x-1)}{2} - \frac{\ln(x+1)}{2}}\end{aligned}$$

Which simplifies to

$$\mu = \frac{1}{\sqrt{x-1}\,\sqrt{x+1}}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu p) &= (\mu)\left(-\frac{1}{x^2-1}\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{p}{\sqrt{x-1}\,\sqrt{x+1}}\right) &= \left(\frac{1}{\sqrt{x-1}\,\sqrt{x+1}}\right)\left(-\frac{1}{x^2-1}\right) \\ \mathrm{d}\left(\frac{p}{\sqrt{x-1}\,\sqrt{x+1}}\right) &= \left(-\frac{1}{(x^2-1)\sqrt{x-1}\,\sqrt{x+1}}\right)\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{p}{\sqrt{x-1}\,\sqrt{x+1}} &= \int -\frac{1}{(x^2-1)\sqrt{x-1}\,\sqrt{x+1}}\,\mathrm{d}x \\ \frac{p}{\sqrt{x-1}\,\sqrt{x+1}} &= \frac{\sqrt{x-1}\,\sqrt{x+1}\,x}{x^2-1} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{\sqrt{x-1}\,\sqrt{x+1}}$ results in

$$p(x) = \frac{(x-1)(x+1)\,x}{x^2-1} + c_1\sqrt{x-1}\,\sqrt{x+1}$$

which simplifies to

$$p(x) = x + c_1\sqrt{x-1}\,\sqrt{x+1}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = x + c_1\sqrt{x-1}\,\sqrt{x+1}$$

Integrating both sides gives

$$\begin{aligned}y &= \int x + c_1\sqrt{x-1}\,\sqrt{x+1}\,\mathrm{d}x\\ &= \frac{x^2}{2} + c_1\left(\frac{\sqrt{x-1}\,(x+1)^{\frac{3}{2}}}{2} - \frac{\sqrt{x-1}\,\sqrt{x+1}}{2} - \frac{\sqrt{(x-1)(x+1)}\,\ln\left(x+\sqrt{x^2-1}\right)}{2\sqrt{x+1}\,\sqrt{x-1}}\right) + c_2\end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{x^2}{2} + c_1\left(\frac{\sqrt{x-1}\,(x+1)^{\frac{3}{2}}}{2} - \frac{\sqrt{x-1}\,\sqrt{x+1}}{2} - \frac{\sqrt{(x-1)(x+1)}\,\ln\left(x+\sqrt{x^2-1}\right)}{2\sqrt{x+1}\,\sqrt{x-1}}\right) + c_2 \tag{1}$$

Verification of solutions

$$y = \frac{x^2}{2} + c_1\left(\frac{\sqrt{x-1}\,(x+1)^{\frac{3}{2}}}{2} - \frac{\sqrt{x-1}\,\sqrt{x+1}}{2} - \frac{\sqrt{(x-1)(x+1)}\,\ln\left(x+\sqrt{x^2-1}\right)}{2\sqrt{x+1}\,\sqrt{x-1}}\right) + c_2$$

Verified OK.

18.14.2 Solving using Kovacic algorithm

Writing the ode as

$$\left(-x^2+1\right)y'' + xy' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A &= -x^2+1\\ B &= x\\ C &= 0\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3x^2 + 2}{4(x^2 - 1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3x^2 + 2 \\ t &= 4(x^2 - 1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3x^2 + 2}{4(x^2 - 1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 589: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2-1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{5}{16(x+1)^2} + \frac{5}{16(x-1)^2} - \frac{1}{16(x+1)} + \frac{1}{16x-16}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}\end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3x^2+2}{4(x^2-1)^2}$$

Since the gcd$(s,t)=1$. This gives $b=\frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{3}{2}\\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=-\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{3x^2+2}{4\left(x^2-1\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
1	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
-1	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=-\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}+\alpha_{c_2}^{-}\right)\\
&= -\frac{1}{2}-\left(-\frac{1}{2}\right)\\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{4\left(x-1\right)} - \frac{1}{4\left(x+1\right)} + (-)\left(0\right) \\
&= -\frac{1}{4\left(x-1\right)} - \frac{1}{4\left(x+1\right)} \\
&= -\frac{x}{2x^2-2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{4\left(x-1\right)} - \frac{1}{4\left(x+1\right)}\right)(0) + \left(\left(\frac{1}{4\left(x-1\right)^2} + \frac{1}{4\left(x+1\right)^2}\right) + \left(-\frac{1}{4\left(x-1\right)} - \frac{1}{4\left(x+1\right)}\right)^2 - \left(\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{4(x-1)} - \frac{1}{4(x+1)}\right) dx} \\
&= \frac{1}{\left(x-1\right)^{\frac{1}{4}} \left(x+1\right)^{\frac{1}{4}}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{x}{-x^2+1} \, dx} \\
&= z_1 e^{\frac{\ln(x-1)}{4} + \frac{\ln(x+1)}{4}} \\
&= z_1 \left(\left(x-1\right)^{\frac{1}{4}} \left(x+1\right)^{\frac{1}{4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{(x-1)^{\frac{1}{4}} (x+1)^{\frac{1}{4}}}{(x^2-1)^{\frac{1}{4}}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{-x^2+1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{\frac{\ln(x-1)}{2}+\frac{\ln(x+1)}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(\frac{x\sqrt{x^2-1}}{2} - \frac{\ln\left(x+\sqrt{x^2-1}\right)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{(x-1)^{\frac{1}{4}} (x+1)^{\frac{1}{4}}}{(x^2-1)^{\frac{1}{4}}}\right) + c_2 \left(\frac{(x-1)^{\frac{1}{4}} (x+1)^{\frac{1}{4}}}{(x^2-1)^{\frac{1}{4}}} \left(\frac{x\sqrt{x^2-1}}{2} - \frac{\ln\left(x+\sqrt{x^2-1}\right)}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$\left(-x^2+1\right) y'' + xy' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_1 (x-1)^{\frac{1}{4}} (x+1)^{\frac{1}{4}}}{(x^2-1)^{\frac{1}{4}}} - \frac{c_2 (x-1)^{\frac{1}{4}} (x+1)^{\frac{1}{4}} \left(-x\sqrt{x^2-1}+\ln\left(x+\sqrt{x^2-1}\right)\right)}{2\left(x^2-1\right)^{\frac{1}{4}}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{(x-1)^{\frac{1}{4}} (x+1)^{\frac{1}{4}}}{(x^2-1)^{\frac{1}{4}}}$$

$$y_2 = -\frac{(x-1)^{\frac{1}{4}} (x+1)^{\frac{1}{4}} \left(-x\sqrt{x^2-1} + \ln\left(x+\sqrt{x^2-1}\right)\right)}{2\,(x^2-1)^{\frac{1}{4}}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{(x-1)^{\frac{1}{4}}(x+1)^{\frac{1}{4}}}{(x^2-1)^{\frac{1}{4}}} & -\frac{(x-1)^{\frac{1}{4}}(x+1)^{\frac{1}{4}}\left(-x\sqrt{x^2-1}+\ln\left(x+\sqrt{x^2-1}\right)\right)}{2(x^2-1)^{\frac{1}{4}}} \\ \frac{d}{dx}\left(\frac{(x-1)^{\frac{1}{4}}(x+1)^{\frac{1}{4}}}{(x^2-1)^{\frac{1}{4}}}\right) & \frac{d}{dx}\left(-\frac{(x-1)^{\frac{1}{4}}(x+1)^{\frac{1}{4}}\left(-x\sqrt{x^2-1}+\ln\left(x+\sqrt{x^2-1}\right)\right)}{2(x^2-1)^{\frac{1}{4}}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{(x-1)^{\frac{1}{4}}(x+1)^{\frac{1}{4}}}{(x^2-1)^{\frac{1}{4}}} \\ -\frac{(x-1)^{\frac{1}{4}}(x+1)^{\frac{1}{4}}x}{2(x^2-1)^{\frac{5}{4}}} + \frac{(x+1)^{\frac{1}{4}}}{4(x^2-1)^{\frac{1}{4}}(x-1)^{\frac{3}{4}}} + \frac{(x-1)^{\frac{1}{4}}}{4(x^2-1)^{\frac{1}{4}}(x+1)^{\frac{3}{4}}} & -\frac{(x+1)^{\frac{1}{4}}\left(-x\sqrt{x^2-1}+\ln\left(x+\sqrt{x^2-1}\right)\right)}{8(x-1)^{\frac{3}{4}}(x^2-1)^{\frac{1}{4}}} - \frac{(x-1)^{\frac{1}{4}}\left(-x\sqrt{x^2-1}+\right.}{8(x+1)^{\frac{3}{4}}(x} \end{vmatrix}$$

Therefore

$$
\begin{aligned}
W &= \left(\frac{(x-1)^{\frac{1}{4}} (x+1)^{\frac{1}{4}}}{(x^2-1)^{\frac{1}{4}}}\right) \left(-\frac{(x+1)^{\frac{1}{4}} \left(-x\sqrt{x^2-1}+\ln\left(x+\sqrt{x^2-1}\right)\right)}{8\,(x-1)^{\frac{3}{4}} (x^2-1)^{\frac{1}{4}}} \right. \\
&\quad - \frac{(x-1)^{\frac{1}{4}} \left(-x\sqrt{x^2-1}+\ln\left(x+\sqrt{x^2-1}\right)\right)}{8\,(x+1)^{\frac{3}{4}} (x^2-1)^{\frac{1}{4}}} \\
&\quad - \frac{(x-1)^{\frac{1}{4}} (x+1)^{\frac{1}{4}} \left(-\sqrt{x^2-1}-\frac{x^2}{\sqrt{x^2-1}}+\frac{1+\frac{x}{\sqrt{x^2-1}}}{x+\sqrt{x^2-1}}\right)}{2\,(x^2-1)^{\frac{1}{4}}} \\
&\quad \left. + \frac{(x-1)^{\frac{1}{4}} (x+1)^{\frac{1}{4}} \left(-x\sqrt{x^2-1}+\ln\left(x+\sqrt{x^2-1}\right)\right) x}{4\,(x^2-1)^{\frac{5}{4}}}\right) \\
&\quad - \left(-\frac{(x-1)^{\frac{1}{4}} (x+1)^{\frac{1}{4}} \left(-x\sqrt{x^2-1}+\ln\left(x+\sqrt{x^2-1}\right)\right)}{2\,(x^2-1)^{\frac{1}{4}}}\right) \left(-\frac{(x-1)^{\frac{1}{4}} (x+1)^{\frac{1}{4}}\, x}{2\,(x^2-1)^{\frac{5}{4}}} \right. \\
&\quad \left. + \frac{(x+1)^{\frac{1}{4}}}{4\,(x^2-1)^{\frac{1}{4}} (x-1)^{\frac{3}{4}}} + \frac{(x-1)^{\frac{1}{4}}}{4\,(x^2-1)^{\frac{1}{4}} (x+1)^{\frac{3}{4}}}\right)
\end{aligned}
$$

Which simplifies to

$$
W = \sqrt{x-1}\,\sqrt{x+1}
$$

Which simplifies to

$$
W = \sqrt{x-1}\,\sqrt{x+1}
$$

Therefore Eq. (2) becomes

$$
u_1 = -\int \frac{-\frac{(x-1)^{\frac{1}{4}} (x+1)^{\frac{1}{4}} \left(-x\sqrt{x^2-1}+\ln\left(x+\sqrt{x^2-1}\right)\right)}{2(x^2-1)^{\frac{1}{4}}}}{(-x^2+1)\sqrt{x-1}\,\sqrt{x+1}}\, dx
$$

Which simplifies to

$$
u_1 = -\int \frac{-x\sqrt{x^2-1}+\ln\left(x+\sqrt{x^2-1}\right)}{2\,(x-1)^{\frac{1}{4}} (x+1)^{\frac{1}{4}} (x^2-1)^{\frac{5}{4}}} dx
$$

Hence

$$u_1 = -\left(\int_0^x \frac{-\alpha\sqrt{\alpha^2-1}+\ln\left(\alpha+\sqrt{\alpha^2-1}\right)}{2\left(\alpha-1\right)^{\frac{1}{4}}\left(\alpha+1\right)^{\frac{1}{4}}\left(\alpha^2-1\right)^{\frac{5}{4}}}d\alpha\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{(x-1)^{\frac{1}{4}}(x+1)^{\frac{1}{4}}}{(x^2-1)^{\frac{1}{4}}}}{\left(-x^2+1\right)\sqrt{x-1}\,\sqrt{x+1}}dx$$

Which simplifies to

$$u_2 = \int -\frac{1}{\left(x-1\right)^{\frac{1}{4}}\left(x+1\right)^{\frac{1}{4}}\left(x^2-1\right)^{\frac{5}{4}}}dx$$

Hence

$$u_2 = \frac{\left(x-1\right)^{\frac{3}{4}}\left(x+1\right)^{\frac{3}{4}}x}{\left(x^2-1\right)^{\frac{5}{4}}}$$

Which simplifies to

$$u_1 = \frac{\left(\int_0^x \frac{\alpha\sqrt{\alpha^2-1}-\ln\left(\alpha+\sqrt{\alpha^2-1}\right)}{(\alpha-1)^{\frac{1}{4}}(\alpha+1)^{\frac{1}{4}}(\alpha^2-1)^{\frac{5}{4}}}d\alpha\right)}{2}$$

$$u_2 = \frac{\left(x-1\right)^{\frac{3}{4}}\left(x+1\right)^{\frac{3}{4}}x}{\left(x^2-1\right)^{\frac{5}{4}}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\left(\int_0^x \frac{\alpha\sqrt{\alpha^2-1}-\ln\left(\alpha+\sqrt{\alpha^2-1}\right)}{(\alpha-1)^{\frac{1}{4}}(\alpha+1)^{\frac{1}{4}}(\alpha^2-1)^{\frac{5}{4}}}d\alpha\right)\left(x-1\right)^{\frac{1}{4}}\left(x+1\right)^{\frac{1}{4}}}{2\left(x^2-1\right)^{\frac{1}{4}}} - \frac{\left(x-1\right)\left(x+1\right)x\left(-x\sqrt{x^2-1}+\ln\left(x+\sqrt{x^2-1}\right)\right)}{2\left(x^2-1\right)^{\frac{3}{2}}}$$

Which simplifies to

$$y_p(x) = \frac{\left(\int_0^x \frac{\alpha\sqrt{\alpha^2-1}-\ln\left(\alpha+\sqrt{\alpha^2-1}\right)}{(\alpha-1)^{\frac{1}{4}}(\alpha+1)^{\frac{1}{4}}(\alpha^2-1)^{\frac{5}{4}}}d\alpha\right)\left(x-1\right)^{\frac{1}{4}}\left(x+1\right)^{\frac{1}{4}}\left(x^2-1\right)^{\frac{1}{4}}+x^2\sqrt{x^2-1}-\ln\left(x+\sqrt{x^2-1}\right)x}{2\sqrt{x^2-1}}$$

Therefore the general solution is

$$y = y_h + y_p$$

$$= \left(\frac{c_1(x-1)^{\frac{1}{4}}(x+1)^{\frac{1}{4}}}{(x^2-1)^{\frac{1}{4}}} - \frac{c_2(x-1)^{\frac{1}{4}}(x+1)^{\frac{1}{4}}\left(-x\sqrt{x^2-1}+\ln\left(x+\sqrt{x^2-1}\right)\right)}{2\left(x^2-1\right)^{\frac{1}{4}}}\right)$$

$$+ \left(\frac{\left(\int_0^x \frac{\alpha\sqrt{\alpha^2-1}-\ln\left(\alpha+\sqrt{\alpha^2-1}\right)}{(\alpha-1)^{\frac{1}{4}}(\alpha+1)^{\frac{1}{4}}(\alpha^2-1)^{\frac{5}{4}}}d\alpha\right)(x-1)^{\frac{1}{4}}(x+1)^{\frac{1}{4}}(x^2-1)^{\frac{1}{4}} + x^2\sqrt{x^2-1} - \ln\left(x+\sqrt{x^2-1}\right)x}{2\sqrt{x^2-1}}\right)$$

Which simplifies to

$$y = \frac{(x+1)^{\frac{1}{4}}(x-1)^{\frac{1}{4}}\left(\sqrt{x^2-1}\,c_2x - \ln\left(x+\sqrt{x^2-1}\right)c_2 + 2c_1\right)}{2\left(x^2-1\right)^{\frac{1}{4}}}$$
$$+ \frac{\left(\int_0^x \frac{\alpha\sqrt{\alpha^2-1}-\ln\left(\alpha+\sqrt{\alpha^2-1}\right)}{(\alpha-1)^{\frac{1}{4}}(\alpha+1)^{\frac{1}{4}}(\alpha^2-1)^{\frac{5}{4}}}d\alpha\right)(x-1)^{\frac{1}{4}}(x+1)^{\frac{1}{4}}(x^2-1)^{\frac{1}{4}} + x^2\sqrt{x^2-1} - \ln\left(x+\sqrt{x^2-1}\right)x}{2\sqrt{x^2-1}}$$

Summary

The solution(s) found are the following

$$y = \frac{(x+1)^{\frac{1}{4}}(x-1)^{\frac{1}{4}}\left(\sqrt{x^2-1}\,c_2x - \ln\left(x+\sqrt{x^2-1}\right)c_2 + 2c_1\right)}{2\left(x^2-1\right)^{\frac{1}{4}}} \tag{1}$$
$$+ \frac{\left(\int_0^x \frac{\alpha\sqrt{\alpha^2-1}-\ln\left(\alpha+\sqrt{\alpha^2-1}\right)}{(\alpha-1)^{\frac{1}{4}}(\alpha+1)^{\frac{1}{4}}(\alpha^2-1)^{\frac{5}{4}}}d\alpha\right)(x-1)^{\frac{1}{4}}(x+1)^{\frac{1}{4}}(x^2-1)^{\frac{1}{4}} + x^2\sqrt{x^2-1} - \ln\left(x+\sqrt{x^2-1}\right)x}{2\sqrt{x^2-1}}$$

Verification of solutions

$$y = \frac{(x+1)^{\frac{1}{4}}(x-1)^{\frac{1}{4}}\left(\sqrt{x^2-1}\,c_2x - \ln\left(x+\sqrt{x^2-1}\right)c_2 + 2c_1\right)}{2\left(x^2-1\right)^{\frac{1}{4}}}$$
$$+ \frac{\left(\int_0^x \frac{\alpha\sqrt{\alpha^2-1}-\ln\left(\alpha+\sqrt{\alpha^2-1}\right)}{(\alpha-1)^{\frac{1}{4}}(\alpha+1)^{\frac{1}{4}}(\alpha^2-1)^{\frac{5}{4}}}d\alpha\right)(x-1)^{\frac{1}{4}}(x+1)^{\frac{1}{4}}(x^2-1)^{\frac{1}{4}} + x^2\sqrt{x^2-1} - \ln\left(x+\sqrt{x^2-1}\right)x}{2\sqrt{x^2-1}}$$

Verified OK.

18.14.3 Maple step by step solution

Let's solve

$(-x^2+1)\,y''+xy'=1$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u=y'$ to reduce order of ODE

  $(-x^2+1)\,u'(x)+xu(x)=1$

- Isolate the derivative

  $u'(x)=\frac{xu(x)}{x^2-1}-\frac{1}{x^2-1}$

- Group terms with $u(x)$ on the lhs of the ODE and the rest on the rhs of the ODE

  $u'(x)-\frac{xu(x)}{x^2-1}=-\frac{1}{x^2-1}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(u'(x)-\frac{xu(x)}{x^2-1}\right)=-\frac{\mu(x)}{x^2-1}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,u(x))$

  $\mu(x)\left(u'(x)-\frac{xu(x)}{x^2-1}\right)=\mu'(x)\,u(x)+\mu(x)\,u'(x)$

- Isolate $\mu'(x)$

  $\mu'(x)=-\frac{\mu(x)x}{x^2-1}$

- Solve to find the integrating factor

  $\mu(x)=\frac{1}{\sqrt{x-1}\,\sqrt{x+1}}$

- Integrate both sides with respect to x

  $\int\left(\frac{d}{dx}(\mu(x)\,u(x))\right)dx=\int-\frac{\mu(x)}{x^2-1}dx+c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,u(x)=\int-\frac{\mu(x)}{x^2-1}dx+c_1$

- Solve for $u(x)$

  $u(x)=\frac{\int-\frac{\mu(x)}{x^2-1}dx+c_1}{\mu(x)}$

- Substitute $\mu(x)=\frac{1}{\sqrt{x-1}\,\sqrt{x+1}}$

  $u(x)=\sqrt{x-1}\,\sqrt{x+1}\left(\int-\frac{1}{(x^2-1)\sqrt{x-1}\,\sqrt{x+1}}dx+c_1\right)$

- Evaluate the integrals on the rhs

$$u(x) = \sqrt{x-1}\,\sqrt{x+1}\left(\frac{\sqrt{x-1}\,\sqrt{x+1}\,x}{x^2-1}+c_1\right)$$

- Simplify

$$u(x) = \frac{\sqrt{x-1}\,\sqrt{x+1}\,(\sqrt{x-1}\,\sqrt{x+1}\,x+c_1(x^2-1))}{x^2-1}$$

- Solve 1st ODE for $u(x)$

$$u(x) = \frac{\sqrt{x-1}\,\sqrt{x+1}\,(\sqrt{x-1}\,\sqrt{x+1}\,x+c_1(x^2-1))}{x^2-1}$$

- Make substitution $u = y'$

$$y' = \frac{\sqrt{x-1}\,\sqrt{x+1}\,(\sqrt{x-1}\,\sqrt{x+1}\,x+c_1(x^2-1))}{x^2-1}$$

- Integrate both sides to solve for y

$$\int y'dx = \int \frac{\sqrt{x-1}\,\sqrt{x+1}\,(\sqrt{x-1}\,\sqrt{x+1}\,x+c_1(x^2-1))}{x^2-1}dx + c_2$$

- Compute integrals

$$y = \frac{x^2}{2} + c_1\left(\frac{\sqrt{x-1}\,(x+1)^{\frac{3}{2}}}{2} - \frac{\sqrt{x-1}\,\sqrt{x+1}}{2} - \frac{\sqrt{(x-1)(x+1)}\,\ln\left(x+\sqrt{x^2-1}\right)}{2\sqrt{x+1}\,\sqrt{x-1}}\right) + c_2$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 15.
ODE order: 2.
ODE degree: 2.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - \sqrt{1 + y'^2} = 0}$$

18.15.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - \sqrt{1 + p(x)^2} = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{\sqrt{p^2 + 1}} dp = x + c_1$$
$$\operatorname{arcsinh}(p) = x + c_1$$

Solving for p gives these solutions

$$p_1 = \sinh(x + c_1)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \sinh(x + c_1)$$

Integrating both sides gives

$$\begin{aligned} y &= \int \sinh(x + c_1)\, \mathrm{d}x \\ &= \cosh(x + c_1) + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \cosh(x + c_1) + c_2 \tag{1}$$

Verification of solutions

$$y = \cosh(x + c_1) + c_2$$

Verified OK.

18.15.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right) = \sqrt{1 + p(y)^2}$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$\int \frac{p}{\sqrt{p^2+1}}dp = \int dy$$
$$\sqrt{1+p(y)^2} = y + c_1$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$\sqrt{1+y'^2} = y + c_1$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-1+c_1^2+2yc_1+y^2} \tag{1}$$
$$y' = -\sqrt{-1+c_1^2+2yc_1+y^2} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{c_1^2+2c_1y+y^2-1}}dy = \int dx$$
$$\ln\left(y+c_1+\sqrt{c_1^2+2c_1y+y^2-1}\right) = x + c_2$$

Raising both side to exponential gives

$$y+c_1+\sqrt{c_1^2+2c_1y+y^2-1} = e^{x+c_2}$$

Which simplifies to

$$y+c_1+\sqrt{(y+c_1+1)(y+c_1-1)} = c_3e^x$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{c_1^2+2c_1y+y^2-1}}dy = \int dx$$
$$-\ln\left(y+c_1+\sqrt{c_1^2+2c_1y+y^2-1}\right) = x + c_4$$

Raising both side to exponential gives

$$\frac{1}{y + c_1 + \sqrt{c_1^2 + 2c_1 y + y^2 - 1}} = \mathrm{e}^{x + c_4}$$

Which simplifies to

$$\frac{1}{y + c_1 + \sqrt{(y + c_1 + 1)(y + c_1 - 1)}} = c_5 \mathrm{e}^{x}$$

Summary
The solution(s) found are the following

$$y = \frac{(c_3^2 \mathrm{e}^{2x} - 2\,\mathrm{e}^{x} c_1 c_3 + 1)\,\mathrm{e}^{-x}}{2c_3} \tag{1}$$

$$y = -\frac{(-c_5^2 \mathrm{e}^{2x} + 2c_1 c_5 \mathrm{e}^{x} - 1)\,\mathrm{e}^{-x}}{2c_5} \tag{2}$$

Verification of solutions

$$y = \frac{(c_3^2 \mathrm{e}^{2x} - 2\,\mathrm{e}^{x} c_1 c_3 + 1)\,\mathrm{e}^{-x}}{2c_3}$$

Verified OK.

$$y = -\frac{(-c_5^2 \mathrm{e}^{2x} + 2c_1 c_5 \mathrm{e}^{x} - 1)\,\mathrm{e}^{-x}}{2c_5}$$

Verified OK.

18.15.3 Maple step by step solution

Let's solve

$y'' = \sqrt{1 + y'^2}$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) = \sqrt{u(x)^2 + 1}$

- Separate variables

  $\frac{u'(x)}{\sqrt{u(x)^2+1}} = 1$

- Integrate both sides with respect to x

$$\int \frac{u'(x)}{\sqrt{u(x)^2+1}}dx = \int 1dx + c_1$$

- Evaluate integral

$$\operatorname{arcsinh}(u(x)) = x + c_1$$

- Solve for $u(x)$

$$u(x) = \sinh(x + c_1)$$

- Solve 1st ODE for $u(x)$

$$u(x) = \sinh(x + c_1)$$

- Make substitution $u = y'$

$$y' = \sinh(x + c_1)$$

- Integrate both sides to solve for y

$$\int y'dx = \int \sinh(x + c_1)\, dx + c_2$$

- Compute integrals

$$y = \cosh(x + c_1) + c_2$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 16.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_missing_y", "second_order_nonlinear_solved_by_mainardi_lioville_method"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], _Liouville, [_2nd_order, _reducible,
    _mu_xy]]
```

$$\boxed{y'' - {y'}^2 - y' = 0}$$

18.16.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + (-p(x) - 1)\, p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{p\left(p+1\right)}dp = \int dx$$
$$-\ln\left(p+1\right)+\ln\left(p\right) = x+c_1$$

Raising both side to exponential gives

$$\mathrm{e}^{-\ln(p+1)+\ln(p)} = \mathrm{e}^{x+c_1}$$

Which simplifies to

$$\frac{p}{p+1} = c_2\mathrm{e}^x$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -\frac{c_2\mathrm{e}^x}{-1+c_2\mathrm{e}^x}$$

Integrating both sides gives

$$y = \int -\frac{c_2\mathrm{e}^x}{-1+c_2\mathrm{e}^x}\,\mathrm{d}x$$
$$= -\ln\left(-1+c_2\mathrm{e}^x\right)+c_3$$

Summary

The solution(s) found are the following

$$y = -\ln\left(-1+c_2\mathrm{e}^x\right)+c_3 \tag{1}$$

Verification of solutions

$$y = -\ln\left(-1+c_2\mathrm{e}^x\right)+c_3$$

Verified OK.

18.16.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$
\begin{aligned}
y'' &= \frac{dp}{dx} \\
&= \frac{dy}{dx}\frac{dp}{dy} \\
&= p\frac{dp}{dy}
\end{aligned}
$$

Hence the ode becomes

$$
p(y)\left(\frac{d}{dy}p(y)\right) + (-p(y) - 1)\, p(y) = 0
$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$
\begin{aligned}
\int \frac{1}{p+1}dp &= \int dy \\
\ln(p+1) &= y + c_1
\end{aligned}
$$

Raising both side to exponential gives

$$
p + 1 = \mathrm{e}^{y+c_1}
$$

Which simplifies to

$$
p + 1 = c_2 \mathrm{e}^{y}
$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$
y' = c_2 \mathrm{e}^{y} - 1
$$

Integrating both sides gives

$$
\begin{aligned}
\int \frac{1}{c_2 \mathrm{e}^{y} - 1}dy &= \int dx \\
\ln(c_2 \mathrm{e}^{y} - 1) - \ln(\mathrm{e}^{y}) &= x + c_3
\end{aligned}
$$

Raising both side to exponential gives

$$
\mathrm{e}^{\ln(c_2 \mathrm{e}^{y} - 1) - \ln(\mathrm{e}^{y})} = \mathrm{e}^{x+c_3}
$$

Which simplifies to

$$
c_2 - \mathrm{e}^{-y} = c_4 \mathrm{e}^{x}
$$

Summary
The solution(s) found are the following

$$y = -\ln\left(-c_4 e^x + c_2\right) \tag{1}$$

Verification of solutions

$$y = -\ln\left(-c_4 e^x + c_2\right)$$

Verified OK.

18.16.3 Solving as second order nonlinear solved by mainardi lioville method ode

The ode has the Liouville form given by

$$y'' + f(x)y' + g(y)y'^2 = 0 \tag{1A}$$

Where in this problem

$$\begin{aligned} f(x) &= -1 \\ g(y) &= -1 \end{aligned}$$

Dividing through by y' then Eq (1A) becomes

$$\frac{y''}{y'} + f + gy' = 0 \tag{2A}$$

But the first term in Eq (2A) can be written as

$$\frac{y''}{y'} = \frac{d}{dx}\ln\left(y'\right) \tag{3A}$$

And the last term in Eq (2A) can be written as

$$\begin{aligned} g\frac{dy}{dx} &= \left(\frac{d}{dy}\int g dy\right)\frac{dy}{dx} \\ &= \frac{d}{dx}\int g dy \end{aligned} \tag{4A}$$

Substituting (3A,4A) back into (2A) gives

$$\frac{d}{dx}\ln\left(y'\right) + \frac{d}{dx}\int g dy = -f \tag{5A}$$

Integrating the above w.r.t. x gives

$$\ln\left(y'\right) + \int g dy = -\int f dx + c_1$$

Where c_1 is arbitrary constant. Taking the exponential of the above gives

$$y' = c_2 e^{\int -g dy} e^{\int -f dx} \tag{6A}$$

Where c_2 is a new arbitrary constant. But since $g = -1$ and $f = -1$, then

$$\begin{aligned}\int -g dy &= \int 1 dy \\ &= y \\ \int -f dx &= \int 1 dx \\ &= x\end{aligned}$$

Substituting the above into Eq(6A) gives

$$y' = c_2 e^y e^x$$

Which is now solved as first order separable ode. In canonical form the ODE is

$$\begin{aligned}y' &= F(x, y) \\ &= f(x) g(y) \\ &= c_2 e^y e^x\end{aligned}$$

Where $f(x) = c_2 e^x$ and $g(y) = e^y$. Integrating both sides gives

$$\begin{aligned}\frac{1}{e^y}\, dy &= c_2 e^x\, dx \\ \int \frac{1}{e^y}\, dy &= \int c_2 e^x\, dx \\ -e^{-y} &= c_2 e^x + c_3\end{aligned}$$

The solution is

$$-e^{-y} - c_2 e^x - c_3 = 0$$

Summary

The solution(s) found are the following

$$-e^{-y} - c_2 e^x - c_3 = 0 \tag{1}$$

Verification of solutions

$$-e^{-y} - c_2 e^x - c_3 = 0$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 17.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_integrable_as_is", "second_order_ode_missing_x", "exact nonlinear second order ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _exact, _nonlinear],
  _Lagerstrom, [_2nd_order, _reducible, _mu_x_y1], [_2nd_order,
   _reducible, _mu_xy]]
```

$$\boxed{y'' - yy' = 0}$$

18.17.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - yy')\, dx = 0$$
$$-\frac{y^2}{2} + y' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{1}{\frac{y^2}{2}+c_1}dy = x+c_2$$
$$\frac{\sqrt{2}\,\arctan\left(\frac{y\sqrt{2}}{2\sqrt{c_1}}\right)}{\sqrt{c_1}} = x+c_2$$

Solving for y gives these solutions

$$y_1 = \tan\left(\frac{\sqrt{c_1}\,(x+c_2)\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Summary

The solution(s) found are the following

$$y = \tan\left(\frac{\sqrt{c_1}\,(x+c_2)\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2} \tag{1}$$

Verification of solutions

$$y = \tan\left(\frac{\sqrt{c_1}\,(x+c_2)\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Verified OK.

18.17.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right) - yp(y) = 0$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$\begin{aligned} p(y) &= \int y \, \mathrm{d}y \\ &= \frac{y^2}{2} + c_1 \end{aligned}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = \frac{y^2}{2} + c_1$$

Integrating both sides gives

$$\begin{aligned} \int \frac{1}{\frac{y^2}{2} + c_1} dy &= x + c_2 \\ \frac{\sqrt{2}\, \arctan\left(\frac{y\sqrt{2}}{2\sqrt{c_1}}\right)}{\sqrt{c_1}} &= x + c_2 \end{aligned}$$

Solving for y gives these solutions

$$y_1 = \tan\left(\frac{\sqrt{c_1}\,(x + c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Summary

The solution(s) found are the following

$$y = \tan\left(\frac{\sqrt{c_1}\,(x + c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2} \tag{1}$$

Verification of solutions

$$y = \tan\left(\frac{\sqrt{c_1}\,(x + c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Verified OK.

18.17.3 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' - yy' = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - yy')\, dx = 0$$
$$-\frac{y^2}{2} + y' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{1}{\frac{y^2}{2} + c_1} dy = x + c_2$$
$$\frac{\sqrt{2}\, \arctan\left(\frac{y\sqrt{2}}{2\sqrt{c_1}}\right)}{\sqrt{c_1}} = x + c_2$$

Solving for y gives these solutions

$$y_1 = \tan\left(\frac{\sqrt{c_1}\,(x + c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Summary

The solution(s) found are the following

$$y = \tan\left(\frac{\sqrt{c_1}\,(x + c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2} \tag{1}$$

Verification of solutions

$$y = \tan\left(\frac{\sqrt{c_1}\,(x + c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Verified OK.

18.17.4 Solving as exact nonlinear second order ode ode

An exact non-linear second order ode has the form

$$a_2(x, y, y')\, y'' + a_1(x, y, y')\, y' + a_0(x, y, y') = 0$$

Where the following conditions are satisfied

$$\frac{\partial a_2}{\partial y} = \frac{\partial a_1}{\partial y'}$$
$$\frac{\partial a_2}{\partial x} = \frac{\partial a_0}{\partial y'}$$
$$\frac{\partial a_1}{\partial x} = \frac{\partial a_0}{\partial y}$$

Looking at the the ode given we see that

$$a_2 = 1$$
$$a_1 = -y$$
$$a_0 = 0$$

Applying the conditions to the above shows this is a nonlinear exact second order ode. Therefore it can be reduced to first order ode given by

$$\int a_2\, dy' + \int a_1\, dy + \int a_0\, dx = c_1$$
$$\int 1\, dy' + \int -y\, dy + \int 0\, dx = c_1$$

Which results in

$$-\frac{y^2}{2} + y' = c_1$$

Which is now solved Integrating both sides gives

$$\int \frac{1}{\frac{y^2}{2} + c_1} dy = x + c_2$$
$$\frac{\sqrt{2}\, \arctan\left(\frac{y\sqrt{2}}{2\sqrt{c_1}}\right)}{\sqrt{c_1}} = x + c_2$$

Solving for y gives these solutions

$$y_1 = \tan\left(\frac{\sqrt{c_1}\,(x + c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Summary
The solution(s) found are the following

$$y = \tan\left(\frac{\sqrt{c_1}\,(x+c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2} \tag{1}$$

Verification of solutions

$$y = \tan\left(\frac{\sqrt{c_1}\,(x+c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Verified OK.

18.17.5 Maple step by step solution

Let's solve

$y'' - yy' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x) = y'$

- Compute y''

  $u'(x) = y''$

- Use chain rule on the lhs

  $y'\left(\frac{d}{dy}u(y)\right) = y''$

- Substitute in the definition of u

  $u(y)\left(\frac{d}{dy}u(y)\right) = y''$

- Make substitutions $y' = u(y)\,, y'' = u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

  $u(y)\left(\frac{d}{dy}u(y)\right) - yu(y) = 0$

- Separate variables

  $\frac{d}{dy}u(y) = y$

- Integrate both sides with respect to y

  $\int\left(\frac{d}{dy}u(y)\right)dy = \int y dy + c_1$

- Evaluate integral

  $u(y) = \frac{y^2}{2} + c_1$
- Solve for $u(y)$

  $u(y) = \frac{y^2}{2} + c_1$
- Solve 1st ODE for $u(y)$

  $u(y) = \frac{y^2}{2} + c_1$
- Revert to original variables with substitution $u(y) = y', y = y$

  $y' = \frac{y^2}{2} + c_1$
- Separate variables

  $\frac{y'}{\frac{y^2}{2}+c_1} = 1$
- Integrate both sides with respect to x

  $\int \frac{y'}{\frac{y^2}{2}+c_1}dx = \int 1dx + c_2$
- Evaluate integral

  $\frac{\sqrt{2}\,\arctan\left(\frac{y\sqrt{2}}{2\sqrt{c_1}}\right)}{\sqrt{c_1}} = x + c_2$
- Solve for y

  $y = \tan\left(\frac{\sqrt{c_1}\,(x+c_2)\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 18.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y], [_2nd_order, _reducible, _mu_y_y1]]
```

$$\boxed{\left(x^2+1\right) y''+y'^2=-1}$$

18.18.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x)=y'$$

Then

$$p'(x)=y''$$

Hence the ode becomes

$$\left(x^2+1\right) p'(x)+1+p(x)^2=0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned}
p' &= F(x,p)\\
&= f(x)g(p)\\
&= \frac{-p^2-1}{x^2+1}
\end{aligned}$$

Where $f(x) = \frac{1}{x^2+1}$ and $g(p) = -p^2 - 1$. Integrating both sides gives

$$\frac{1}{-p^2-1}\,dp = \frac{1}{x^2+1}\,dx$$
$$\int \frac{1}{-p^2-1}\,dp = \int \frac{1}{x^2+1}\,dx$$
$$-\arctan(p) = \arctan(x) + c_1$$

The solution is

$$-\arctan(p(x)) - \arctan(x) - c_1 = 0$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$-\arctan(y') - \arctan(x) - c_1 = 0$$

Integrating both sides gives

$$\begin{aligned} y &= \int -\tan(\arctan(x) + c_1)\,\mathrm{d}x \\ &= \frac{i\mathrm{e}^{4ic_1}x}{(\mathrm{e}^{2ic_1}-1)^2} - \frac{4\,\mathrm{e}^{2ic_1}\ln\left((-\mathrm{e}^{2ic_1}+1)\,x + i\mathrm{e}^{2ic_1} + i\right)}{(\mathrm{e}^{2ic_1}-1)^2} - \frac{ix}{(\mathrm{e}^{2ic_1}-1)^2} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{i\mathrm{e}^{4ic_1}x}{(\mathrm{e}^{2ic_1}-1)^2} - \frac{4\,\mathrm{e}^{2ic_1}\ln\left((-\mathrm{e}^{2ic_1}+1)\,x + i\mathrm{e}^{2ic_1} + i\right)}{(\mathrm{e}^{2ic_1}-1)^2} - \frac{ix}{(\mathrm{e}^{2ic_1}-1)^2} + c_2 \tag{1}$$

Verification of solutions

$$y = \frac{i\mathrm{e}^{4ic_1}x}{(\mathrm{e}^{2ic_1}-1)^2} - \frac{4\,\mathrm{e}^{2ic_1}\ln\left((-\mathrm{e}^{2ic_1}+1)\,x + i\mathrm{e}^{2ic_1} + i\right)}{(\mathrm{e}^{2ic_1}-1)^2} - \frac{ix}{(\mathrm{e}^{2ic_1}-1)^2} + c_2$$

Verified OK.

18.18.2 Maple step by step solution

Let's solve

$(x^2+1)\,y''+y'^2=-1$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u=y'$ to reduce order of ODE

  $(x^2+1)\,u'(x)+u(x)^2=-1$

- Separate variables

  $\frac{u'(x)}{-u(x)^2-1}=\frac{1}{x^2+1}$

- Integrate both sides with respect to x

  $\int \frac{u'(x)}{-u(x)^2-1}dx=\int \frac{1}{x^2+1}dx+c_1$

- Evaluate integral

  $-\arctan(u(x))=\arctan(x)+c_1$

- Solve for $u(x)$

  $u(x)=-\tan(\arctan(x)+c_1)$

- Solve 1st ODE for $u(x)$

  $u(x)=-\tan(\arctan(x)+c_1)$

- Make substitution $u=y'$

  $y'=-\tan(\arctan(x)+c_1)$

- Integrate both sides to solve for y

  $\int y'dx=\int -\tan(\arctan(x)+c_1)\,dx+c_2$

- Compute integrals

  $y=\frac{\mathrm{I}\,\mathrm{e}^{4\,\mathrm{I}c_1}x}{(\mathrm{e}^{2\,\mathrm{I}c_1}-1)^2}-\frac{4\,\mathrm{e}^{2\,\mathrm{I}c_1}\ln((-\mathrm{e}^{2\,\mathrm{I}c_1}+1)x+\mathrm{I}\,\mathrm{e}^{2\,\mathrm{I}c_1}+\mathrm{I})}{(\mathrm{e}^{2\,\mathrm{I}c_1}-1)^2}-\frac{\mathrm{I}x}{(\mathrm{e}^{2\,\mathrm{I}c_1}-1)^2}+c_2$

Section: Exercise 35, page 157
Problem number: 19.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_integrable_as_is", "second_order_ode_missing_x", "exact nonlinear second order ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _exact, _nonlinear],
   _Lagerstrom, [_2nd_order, _reducible, _mu_x_y1], [_2nd_order,
    _reducible, _mu_xy]]
```

$$\boxed{y'' + yy' = 0}$$

18.19.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + yy')\,dx = 0$$
$$\frac{y^2}{2} + y' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{1}{-\frac{y^2}{2} + c_1} dy = x + c_2$$

$$\frac{\sqrt{2}\, \operatorname{arctanh}\left(\frac{y\sqrt{2}}{2\sqrt{c_1}}\right)}{\sqrt{c_1}} = x + c_2$$

Solving for y gives these solutions

$$y_1 = \tanh\left(\frac{\sqrt{c_1}\,(x + c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Summary

The solution(s) found are the following

$$y = \tanh\left(\frac{\sqrt{c_1}\,(x + c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2} \tag{1}$$

Verification of solutions

$$y = \tanh\left(\frac{\sqrt{c_1}\,(x + c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Verified OK.

18.19.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right) + yp(y) = 0$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$\begin{aligned} p(y) &= \int -y \, \mathrm{d}y \\ &= -\frac{y^2}{2} + c_1 \end{aligned}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = -\frac{y^2}{2} + c_1$$

Integrating both sides gives

$$\begin{aligned} \int \frac{1}{-\frac{y^2}{2} + c_1} dy &= x + c_2 \\ \frac{\sqrt{2}\, \operatorname{arctanh}\left(\frac{y\sqrt{2}}{2\sqrt{c_1}}\right)}{\sqrt{c_1}} &= x + c_2 \end{aligned}$$

Solving for y gives these solutions

$$y_1 = \tanh\left(\frac{\sqrt{c_1}\,(x + c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Summary

The solution(s) found are the following

$$y = \tanh\left(\frac{\sqrt{c_1}\,(x + c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2} \tag{1}$$

Verification of solutions

$$y = \tanh\left(\frac{\sqrt{c_1}\,(x + c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Verified OK.

18.19.3 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + yy' = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + yy')\, dx = 0$$

$$\frac{y^2}{2} + y' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{1}{-\frac{y^2}{2} + c_1} dy = x + c_2$$

$$\frac{\sqrt{2}\, \operatorname{arctanh}\left(\frac{y\sqrt{2}}{2\sqrt{c_1}}\right)}{\sqrt{c_1}} = x + c_2$$

Solving for y gives these solutions

$$y_1 = \tanh\left(\frac{\sqrt{c_1}\,(x + c_2)\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Summary

The solution(s) found are the following

$$y = \tanh\left(\frac{\sqrt{c_1}\,(x + c_2)\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2} \tag{1}$$

Verification of solutions

$$y = \tanh\left(\frac{\sqrt{c_1}\,(x + c_2)\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Verified OK.

18.19.4 Solving as exact nonlinear second order ode ode

An exact non-linear second order ode has the form

$$a_2(x, y, y')\, y'' + a_1(x, y, y')\, y' + a_0(x, y, y') = 0$$

Where the following conditions are satisfied

$$\begin{aligned}\frac{\partial a_2}{\partial y} &= \frac{\partial a_1}{\partial y'}\\ \frac{\partial a_2}{\partial x} &= \frac{\partial a_0}{\partial y'}\\ \frac{\partial a_1}{\partial x} &= \frac{\partial a_0}{\partial y}\end{aligned}$$

Looking at the the ode given we see that

$$\begin{aligned}a_2 &= 1\\ a_1 &= y\\ a_0 &= 0\end{aligned}$$

Applying the conditions to the above shows this is a nonlinear exact second order ode. Therefore it can be reduced to first order ode given by

$$\begin{aligned}\int a_2\, dy' + \int a_1\, dy + \int a_0\, dx &= c_1\\ \int 1\, dy' + \int y\, dy + \int 0\, dx &= c_1\end{aligned}$$

Which results in

$$\frac{y^2}{2} + y' = c_1$$

Which is now solved Integrating both sides gives

$$\begin{aligned}\int \frac{1}{-\frac{y^2}{2} + c_1} dy &= x + c_2\\ \frac{\sqrt{2}\, \operatorname{arctanh}\left(\frac{y\sqrt{2}}{2\sqrt{c_1}}\right)}{\sqrt{c_1}} &= x + c_2\end{aligned}$$

Solving for y gives these solutions

$$y_1 = \tanh\left(\frac{\sqrt{c_1}\,(x + c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Summary
The solution(s) found are the following

$$y = \tanh\left(\frac{\sqrt{c_1}\,(x+c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2} \tag{1}$$

Verification of solutions

$$y = \tanh\left(\frac{\sqrt{c_1}\,(x+c_2)\,\sqrt{2}}{2}\right)\sqrt{c_1}\,\sqrt{2}$$

Verified OK.

18.19.5 Maple step by step solution

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 20.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], _Liouville, [_2nd_order, _reducible,
    _mu_xy]]
```

$$\boxed{y'' + 2y'^2 = 0}$$

18.20.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + 2p(x)^2 = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int -\frac{1}{2p^2}dp = x + c_1$$
$$\frac{1}{2p} = x + c_1$$

Solving for p gives these solutions

$$p_1 = \frac{1}{2x + 2c_1}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{1}{2x + 2c_1}$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{1}{2x + 2c_1}\, \mathrm{d}x \\ &= \frac{\ln(x + c_1)}{2} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\ln(x + c_1)}{2} + c_2 \tag{1}$$

Verification of solutions

$$y = \frac{\ln(x + c_1)}{2} + c_2$$

Verified OK.

18.20.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right)+2p(y)^2=0$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$\int -\frac{1}{2p}dp = \int dy$$
$$-\frac{\ln(p)}{2} = y + c_1$$

Raising both side to exponential gives

$$\frac{1}{\sqrt{p}} = \mathrm{e}^{y+c_1}$$

Which simplifies to

$$\frac{1}{\sqrt{p}} = c_2\mathrm{e}^{y}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = \frac{\mathrm{e}^{-2y}}{c_2^2}$$

Integrating both sides gives

$$\int c_2^2\mathrm{e}^{2y}dy = x + c_3$$
$$\frac{c_2^2\mathrm{e}^{2y}}{2} = x + c_3$$

Solving for y gives these solutions

$$y_1 = \frac{\ln\left(\frac{2c_3+2x}{c_2^2}\right)}{2}$$

Summary
The solution(s) found are the following

$$y = \frac{\ln\left(\frac{2c_3+2x}{c_2^2}\right)}{2} \tag{1}$$

Verification of solutions

$$y = \frac{\ln\left(\frac{2c_3+2x}{c_2^2}\right)}{2}$$

Verified OK.

18.20.3 Maple step by step solution

Let's solve

$y'' + 2y'^2 = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) + 2u(x)^2 = 0$

- Separate variables

  $\frac{u'(x)}{u(x)^2} = -2$

- Integrate both sides with respect to x

  $\int \frac{u'(x)}{u(x)^2}dx = \int (-2)\,dx + c_1$

- Evaluate integral

  $-\frac{1}{u(x)} = -2x + c_1$

- Solve for $u(x)$

  $u(x) = -\frac{1}{-2x+c_1}$

- Solve 1st ODE for $u(x)$

  $u(x) = -\frac{1}{-2x+c_1}$

- Make substitution $u = y'$

  $y' = -\frac{1}{-2x+c_1}$

- Integrate both sides to solve for y

  $\int y'dx = \int -\frac{1}{-2x+c_1}dx + c_2$

- Compute integrals

  $y = \frac{\ln(-2x+c_1)}{2} + c_2$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 21.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_integrable_as_is", "second_order_ode_missing_x", "exact nonlinear second order ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _exact, _nonlinear],
   _Liouville, [_2nd_order, _reducible, _mu_x_y1], [_2nd_order,
   _reducible, _mu_xy]]
```

$$\boxed{yy'' + {y'}^2 = 0}$$

18.21.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(yy'' + {y'}^2\right) dx = 0$$
$$yy' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{y}{c_1} dy = x + c_2$$
$$\frac{y^2}{2c_1} = x + c_2$$

Solving for y gives these solutions

$$
\begin{aligned}
y_1 &= \sqrt{2c_1c_2 + 2c_1x} \\
y_2 &= -\sqrt{2c_1c_2 + 2c_1x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \sqrt{2c_1c_2 + 2c_1x} \tag{1}
$$

$$
y = -\sqrt{2c_1c_2 + 2c_1x} \tag{2}
$$

Verification of solutions

$$
y = \sqrt{2c_1c_2 + 2c_1x}
$$

Verified OK.

$$
y = -\sqrt{2c_1c_2 + 2c_1x}
$$

Verified OK.

18.21.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$
y' = p(y)
$$

Then

$$
\begin{aligned}
y'' &= \frac{dp}{dx} \\
&= \frac{dy}{dx}\frac{dp}{dy} \\
&= p\frac{dp}{dy}
\end{aligned}
$$

Hence the ode becomes

$$
yp(y)\left(\frac{d}{dy}p(y)\right) + p(y)^2 = 0
$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$
\begin{aligned}
p' &= F(y, p) \\
&= f(y)g(p) \\
&= -\frac{p}{y}
\end{aligned}
$$

Where $f(y) = -\frac{1}{y}$ and $g(p) = p$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{p} dp &= -\frac{1}{y} dy \\
\int \frac{1}{p} dp &= \int -\frac{1}{y} dy \\
\ln(p) &= -\ln(y) + c_1 \\
p &= e^{-\ln(y)+c_1} \\
&= \frac{c_1}{y}
\end{aligned}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = \frac{c_1}{y}$$

Integrating both sides gives

$$\begin{aligned}
\int \frac{y}{c_1} dy &= x + c_2 \\
\frac{y^2}{2c_1} &= x + c_2
\end{aligned}$$

Solving for y gives these solutions

$$\begin{aligned}
y_1 &= \sqrt{2c_1c_2 + 2c_1x} \\
y_2 &= -\sqrt{2c_1c_2 + 2c_1x}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \sqrt{2c_1c_2 + 2c_1x} \tag{1}$$

$$y = -\sqrt{2c_1c_2 + 2c_1x} \tag{2}$$

Verification of solutions

$$y = \sqrt{2c_1c_2 + 2c_1x}$$

Verified OK.

$$y = -\sqrt{2c_1c_2 + 2c_1x}$$

Verified OK.

18.21.3 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$yy'' + y'^2 = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(yy'' + y'^2\right) dx = 0$$
$$yy' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{y}{c_1} dy = x + c_2$$
$$\frac{y^2}{2c_1} = x + c_2$$

Solving for y gives these solutions

$$y_1 = \sqrt{2c_1c_2 + 2c_1x}$$
$$y_2 = -\sqrt{2c_1c_2 + 2c_1x}$$

Summary

The solution(s) found are the following

$$y = \sqrt{2c_1c_2 + 2c_1x} \tag{1}$$
$$y = -\sqrt{2c_1c_2 + 2c_1x} \tag{2}$$

Verification of solutions

$$y = \sqrt{2c_1c_2 + 2c_1x}$$

Verified OK.

$$y = -\sqrt{2c_1c_2 + 2c_1x}$$

Verified OK.

18.21.4 Solving as exact nonlinear second order ode ode

An exact non-linear second order ode has the form

$$a_2(x,y,y')\,y'' + a_1(x,y,y')\,y' + a_0(x,y,y') = 0$$

Where the following conditions are satisfied

$$\begin{aligned}\frac{\partial a_2}{\partial y} &= \frac{\partial a_1}{\partial y'}\\ \frac{\partial a_2}{\partial x} &= \frac{\partial a_0}{\partial y'}\\ \frac{\partial a_1}{\partial x} &= \frac{\partial a_0}{\partial y}\end{aligned}$$

Looking at the the ode given we see that

$$\begin{aligned}a_2 &= y\\ a_1 &= y'\\ a_0 &= 0\end{aligned}$$

Applying the conditions to the above shows this is a nonlinear exact second order ode. Therefore it can be reduced to first order ode given by

$$\begin{aligned}\int a_2\,dy' + \int a_1\,dy + \int a_0\,dx &= c_1\\ \int y\,dy' + \int y'\,dy + \int 0\,dx &= c_1\end{aligned}$$

Which results in

$$2yy' = c_1$$

Which is now solved Integrating both sides gives

$$\begin{aligned}\int \frac{2y}{c_1} dy &= x + c_2\\ \frac{y^2}{c_1} &= x + c_2\end{aligned}$$

Solving for y gives these solutions

$$\begin{aligned}y_1 &= \sqrt{c_1c_2 + c_1x}\\ y_2 &= -\sqrt{c_1c_2 + c_1x}\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \sqrt{c_1 c_2 + c_1 x} \tag{1}$$
$$y = -\sqrt{c_1 c_2 + c_1 x} \tag{2}$$

Verification of solutions

$$y = \sqrt{c_1 c_2 + c_1 x}$$

Verified OK.

$$y = -\sqrt{c_1 c_2 + c_1 x}$$

Verified OK.

18.21.5 Maple step by step solution

Let's solve

$y y'' + y'^2 = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x) = y'$

- Compute y''

  $u'(x) = y''$

- Use chain rule on the lhs

  $y' \left(\frac{d}{dy} u(y)\right) = y''$

- Substitute in the definition of u

  $u(y) \left(\frac{d}{dy} u(y)\right) = y''$

- Make substitutions $y' = u(y)\,, y'' = u(y) \left(\frac{d}{dy} u(y)\right)$ to reduce order of ODE

  $y u(y) \left(\frac{d}{dy} u(y)\right) + u(y)^2 = 0$

- Separate variables

  $\frac{\frac{d}{dy} u(y)}{u(y)} = -\frac{1}{y}$

- Integrate both sides with respect to y

$\int \frac{\frac{d}{dy}u(y)}{u(y)}dy = \int -\frac{1}{y}dy + c_1$

- Evaluate integral

  $\ln(u(y)) = -\ln(y) + c_1$

- Solve for $u(y)$

  $u(y) = \frac{e^{c_1}}{y}$

- Solve 1st ODE for $u(y)$

  $u(y) = \frac{e^{c_1}}{y}$

- Revert to original variables with substitution $u(y) = y', y = y$

  $y' = \frac{e^{c_1}}{y}$

- Separate variables

  $yy' = e^{c_1}$

- Integrate both sides with respect to x

  $\int yy'dx = \int e^{c_1}dx + c_2$

- Evaluate integral

  $\frac{y^2}{2} = e^{c_1}x + c_2$

- Solve for y

  $\left\{y = \sqrt{2\,e^{c_1}x + 2c_2}, y = -\sqrt{2\,e^{c_1}x + 2c_2}\right\}$

18.22 problem 22

Internal problem ID [2294]
Internal file name [`OUTPUT/2294_Tuesday_February_27_2024_08_24_11_AM_88302303/index.tex`]

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 22.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1]]
```

$$\boxed{yy'' - y'^2 = -1}$$

18.22.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$yp(y)\left(\frac{d}{dy}p(y)\right) - p(y)^2 = -1$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$
\begin{aligned}
p' &= F(y, p) \\
&= f(y)g(p) \\
&= \frac{p^2 - 1}{yp}
\end{aligned}
$$

Where $f(y) = \frac{1}{y}$ and $g(p) = \frac{p^2-1}{p}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{p^2-1}{p}}\,dp &= \frac{1}{y}\,dy \\
\int \frac{1}{\frac{p^2-1}{p}}\,dp &= \int \frac{1}{y}\,dy \\
\frac{\ln(p-1)}{2} + \frac{\ln(p+1)}{2} &= \ln(y) + c_1
\end{aligned}
$$

The above can be written as

$$
\begin{aligned}
\left(\frac{1}{2}\right)(\ln(p-1) + \ln(p+1)) &= \ln(y) + 2c_1 \\
\ln(p-1) + \ln(p+1) &= (2)(\ln(y) + 2c_1) \\
&= 2\ln(y) + 4c_1
\end{aligned}
$$

Raising both side to exponential gives

$$
e^{\ln(p-1)+\ln(p+1)} = e^{2\ln(y)+2c_1}
$$

Which simplifies to

$$
\begin{aligned}
p^2 - 1 &= 2c_1 y^2 \\
&= c_2 y^2
\end{aligned}
$$

The solution is

$$
p(y)^2 - 1 = c_2 y^2
$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$
-1 + {y'}^2 = c_2 y^2
$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{c_2 y^2 + 1} \tag{1}$$

$$y' = -\sqrt{c_2 y^2 + 1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{c_2 y^2 + 1}} dy = \int dx$$

$$\frac{\ln\left(y\sqrt{c_2} + \sqrt{c_2 y^2 + 1}\right)}{\sqrt{c_2}} = x + c_3$$

Raising both side to exponential gives

$$e^{\frac{\ln\left(y\sqrt{c_2} + \sqrt{c_2 y^2 + 1}\right)}{\sqrt{c_2}}} = e^{x + c_3}$$

Which simplifies to

$$\left(y\sqrt{c_2} + \sqrt{c_2 y^2 + 1}\right)^{\frac{1}{\sqrt{c_2}}} = c_4 e^x$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{c_2 y^2 + 1}} dy = \int dx$$

$$-\frac{\ln\left(y\sqrt{c_2} + \sqrt{c_2 y^2 + 1}\right)}{\sqrt{c_2}} = x + c_5$$

Raising both side to exponential gives

$$e^{-\frac{\ln\left(y\sqrt{c_2} + \sqrt{c_2 y^2 + 1}\right)}{\sqrt{c_2}}} = e^{x + c_5}$$

Which simplifies to

$$\left(y\sqrt{c_2} + \sqrt{c_2 y^2 + 1}\right)^{-\frac{1}{\sqrt{c_2}}} = c_6 e^x$$

Summary

The solution(s) found are the following

$$y = \frac{\left(\left(c_4 \mathrm{e}^{x}\right)^{2\sqrt{c_2}}-1\right)\left(c_4 \mathrm{e}^{x}\right)^{-\sqrt{c_2}}}{2\sqrt{c_2}} \tag{1}$$

$$y = \frac{\left(\left(c_6 \mathrm{e}^{x}\right)^{-2\sqrt{c_2}}-1\right)\left(c_6 \mathrm{e}^{x}\right)^{\sqrt{c_2}}}{2\sqrt{c_2}} \tag{2}$$

Verification of solutions

$$y = \frac{\left(\left(c_4 \mathrm{e}^{x}\right)^{2\sqrt{c_2}}-1\right)\left(c_4 \mathrm{e}^{x}\right)^{-\sqrt{c_2}}}{2\sqrt{c_2}}$$

Verified OK.

$$y = \frac{\left(\left(c_6 \mathrm{e}^{x}\right)^{-2\sqrt{c_2}}-1\right)\left(c_6 \mathrm{e}^{x}\right)^{\sqrt{c_2}}}{2\sqrt{c_2}}$$

Verified OK.

18.22.2 Maple step by step solution

Let's solve

$y y'' - y'^2 = -1$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x) = y'$

- Compute y''

  $u'(x) = y''$

- Use chain rule on the lhs

  $y'\left(\frac{d}{dy}u(y)\right) = y''$

- Substitute in the definition of u

  $u(y)\left(\frac{d}{dy}u(y)\right) = y''$

- Make substitutions $y' = u(y)\,, y'' = u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

$$yu(y)\left(\frac{d}{dy}u(y)\right)-u(y)^2=-1$$

- Separate variables

$$\frac{\left(\frac{d}{dy}u(y)\right)u(y)}{u(y)^2-1}=\frac{1}{y}$$

- Integrate both sides with respect to y

$$\int\frac{\left(\frac{d}{dy}u(y)\right)u(y)}{u(y)^2-1}dy=\int\frac{1}{y}dy+c_1$$

- Evaluate integral

$$\frac{\ln(-1+u(y))}{2}+\frac{\ln(u(y)+1)}{2}=\ln(y)+c_1$$

- Solve for $u(y)$

$$\left\{u(y)=-\frac{e^{2c_1}\left(-1+\sqrt{(e^{c_1})^2y^2+1}\right)}{(e^{c_1})^2}-1, u(y)=\frac{e^{2c_1}\left(1+\sqrt{(e^{c_1})^2y^2+1}\right)}{(e^{c_1})^2}-1\right\}$$

- Solve 1st ODE for $u(y)$

$$u(y)=-\frac{e^{2c_1}\left(-1+\sqrt{(e^{c_1})^2y^2+1}\right)}{(e^{c_1})^2}-1$$

- Revert to original variables with substitution $u(y)=y', y=y$

$$y'=-\frac{e^{2c_1}\left(-1+\sqrt{(e^{c_1})^2y^2+1}\right)}{(e^{c_1})^2}-1$$

- Separate variables

$$\frac{y'}{-\frac{e^{2c_1}\left(-1+\sqrt{(e^{c_1})^2y^2+1}\right)}{(e^{c_1})^2}-1}=1$$

- Integrate both sides with respect to x

$$\int\frac{y'}{-\frac{e^{2c_1}\left(-1+\sqrt{(e^{c_1})^2y^2+1}\right)}{(e^{c_1})^2}-1}dx=\int 1dx+c_2$$

- Evaluate integral

$$-\left(\mathrm{e}^{c_1}\right)^2 \left(-\frac{\arctan\left(\frac{\mathrm{e}^{4c_1} y}{\sqrt{\mathrm{e}^{2c_1}\mathrm{e}^{4c_1}}}\right)}{\sqrt{\mathrm{e}^{2c_1}\mathrm{e}^{4c_1}}} + \frac{\mathrm{e}^{2c_1}\arctan\left(\frac{\mathrm{e}^{4c_1} y}{\sqrt{\mathrm{e}^{2c_1}\mathrm{e}^{4c_1}}}\right)}{\left(\mathrm{e}^{c_1}\right)^2\sqrt{\mathrm{e}^{2c_1}\mathrm{e}^{4c_1}}} - \frac{\mathrm{e}^{2c_1}\left(\frac{-\sqrt{\left(\mathrm{e}^{c_1}\right)^2\left(y-\sqrt{-\mathrm{e}^{6c_1}}\,\mathrm{e}^{-4c_1}\right)^2+2\left(\mathrm{e}^{c_1}\right)^2\sqrt{-\mathrm{e}^{6c_1}}\,\mathrm{e}^{-4c_1}\left(y-\sqrt{\right.}}}{}\right.}{}\right.$$

- Solve for y

$$y = -\frac{\left(\left(\mathrm{e}^{c_1}\right)^2-\left(\mathrm{e}^{-\mathrm{e}^{c_1}c_2-\mathrm{e}^{c_1}x+c_1}\right)^2\right)\mathrm{e}^{-3c_1+\mathrm{e}^{c_1}c_2+\mathrm{e}^{c_1}x}}{2}$$

- Solve 2nd ODE for $u(y)$

$$u(y) = \frac{\mathrm{e}^{2c_1}\left(1+\sqrt{\left(\mathrm{e}^{c_1}\right)^2 y^2+1}\right)}{\left(\mathrm{e}^{c_1}\right)^2} - 1$$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = \frac{\mathrm{e}^{2c_1}\left(1+\sqrt{\left(\mathrm{e}^{c_1}\right)^2 y^2+1}\right)}{\left(\mathrm{e}^{c_1}\right)^2} - 1$$

- Separate variables

$$\frac{y'}{\frac{\mathrm{e}^{2c_1}\left(1+\sqrt{\left(\mathrm{e}^{c_1}\right)^2 y^2+1}\right)}{\left(\mathrm{e}^{c_1}\right)^2}-1} = 1$$

- Integrate both sides with respect to x

$$\int \frac{y'}{\frac{\mathrm{e}^{2c_1}\left(1+\sqrt{\left(\mathrm{e}^{c_1}\right)^2 y^2+1}\right)}{\left(\mathrm{e}^{c_1}\right)^2}-1} dx = \int 1 dx + c_2$$

- Evaluate integral

$$(e^{c_1})^2 \left(-\frac{e^{2c_1}\arctan\left(\frac{e^{4c_1} y}{\sqrt{e^{2c_1} e^{4c_1}}}\right)}{(e^{c_1})^2\sqrt{e^{2c_1}e^{4c_1}}} + \frac{\arctan\left(\frac{e^{4c_1} y}{\sqrt{e^{2c_1} e^{4c_1}}}\right)}{\sqrt{e^{2c_1}e^{4c_1}}} - \frac{e^{2c_1}\left(\frac{-\sqrt{(e^{c_1})^2\left(y-\sqrt{-e^{6c_1}}\, e^{-4c_1}\right)^2+2(e^{c_1})^2\sqrt{-e^{6c_1}}\, e^{-4c_1}\left(y-\sqrt{-\right.}}}{}\right.}{}\right.$$

- Solve for y

$$y = \frac{\left(\left(e^{c_1}+e^{c_1}c_2+e^{c_1}x\right)^2-(e^{c_1})^2\right)e^{-3c_1-e^{c_1}c_2-e^{c_1}x}}{2}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - y = 0}$$

18.23.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)} \\
&= \pm 1
\end{aligned}$$

Hence

$$\begin{aligned}
\lambda_1 &= +1 \\
\lambda_2 &= -1
\end{aligned}$$

Which simplifies to

$$\begin{aligned}
\lambda_1 &= 1 \\
\lambda_2 &= -1
\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}
y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\
y &= c_1 e^{(1)x} + c_2 e^{(-1)x}
\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{x} + c_2 \mathrm{e}^{-x}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{x} + c_2 \mathrm{e}^{-x} \tag{1}$$

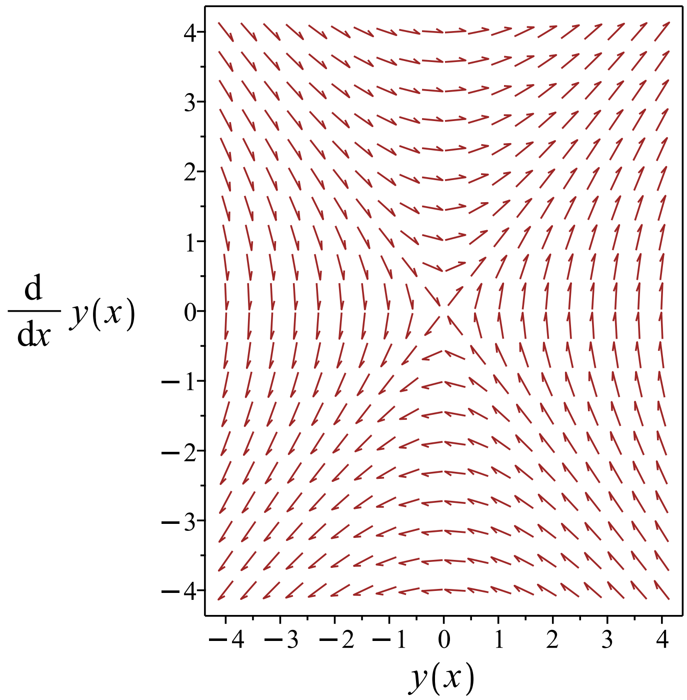

Figure 709: Slope field plot

Verification of solutions

$$y = c_1 e^x + c_2 e^{-x}$$

Verified OK.

18.23.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' - yy' = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' - yy')\,dx = 0$$
$$\frac{y'^2}{2} - \frac{y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{y^2 + 2c_1} \tag{1}$$
$$y' = -\sqrt{y^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{y^2+2c_1}}dy = \int dx$$
$$\ln\left(y+\sqrt{y^2+2c_1}\right) = x + c_2$$

Raising both side to exponential gives

$$y+\sqrt{y^2+2c_1} = e^{x+c_2}$$

Which simplifies to

$$y+\sqrt{y^2+2c_1} = c_3 e^{x}$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{y^2+2c_1}}dy = \int dx$$
$$-\ln\left(y+\sqrt{y^2+2c_1}\right) = x + c_4$$

Raising both side to exponential gives

$$\frac{1}{y+\sqrt{y^2+2c_1}} = e^{x+c_4}$$

Which simplifies to

$$\frac{1}{y+\sqrt{y^2+2c_1}} = c_5 e^{x}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(c_3^2 e^{2x} - 2c_1\right) e^{-x}}{2c_3} \tag{1}$$
$$y = -\frac{\left(2c_1 c_5^2 e^{2x} - 1\right) e^{-x}}{2c_5} \tag{2}$$

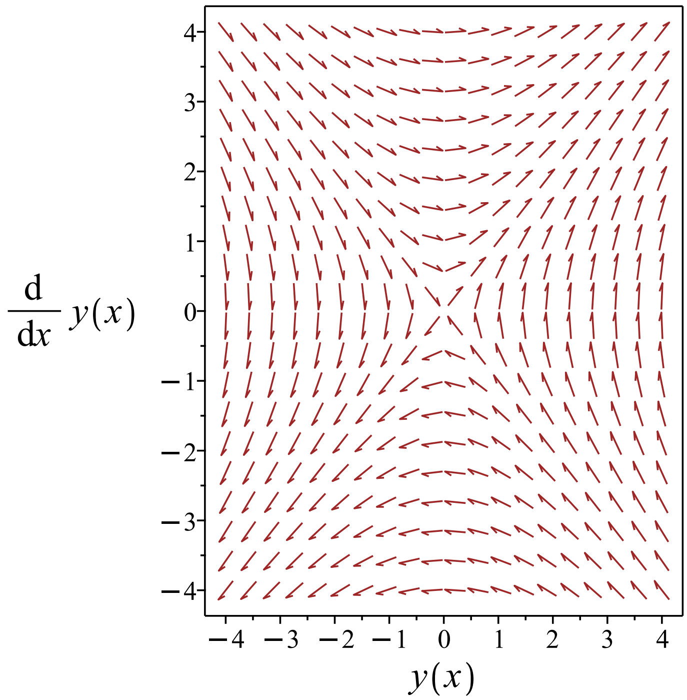

Figure 710: Slope field plot

Verification of solutions

$$y = \frac{(c_3^2 e^{2x} - 2c_1) e^{-x}}{2c_3}$$

Verified OK.

$$y = -\frac{(2c_1 c_5^2 e^{2x} - 1) e^{-x}}{2c_5}$$

Verified OK.

18.23.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 599: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \mathrm{e}^{-x} \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \mathrm{e}^{-x} \int \frac{1}{\mathrm{e}^{-2x}}\, dx \\
&= \mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{x}}{2} \tag{1}$$

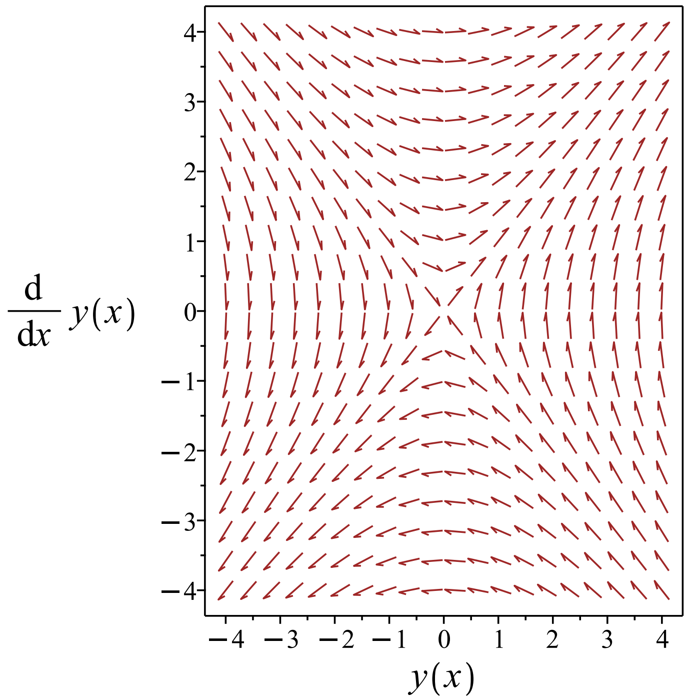

Figure 711: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + \frac{c_2 e^x}{2}$$

Verified OK.

18.23.4 Maple step by step solution

Let's solve

$y'' - y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 1 = 0$

- Factor the characteristic polynomial

  $(r - 1)(r + 1) = 0$

- Roots of the characteristic polynomial

$$r = (-1, 1)$$

- 1st solution of the ODE

$$y_1(x) = e^{-x}$$

- 2nd solution of the ODE

$$y_2(x) = e^{x}$$

- General solution of the ODE

$$y = c_1 y_1(x) + c_2 y_2(x)$$

- Substitute in solutions

$$y = c_1 e^{-x} + c_2 e^{x}$$

Problem number: 24.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_integrable_as_is", "second_order_ode_missing_x", "exact nonlinear second order ode", "second_order_nonlinear_solved_by_mainardi_lioville_method"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _exact, _nonlinear],
  _Liouville, [_2nd_order, _reducible, _mu_x_y1], [_2nd_order,
  _reducible, _mu_xy]]
```

$$\boxed{yy'' + {y'}^2 - yy' = 0}$$

18.24.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (yy'' + (y' - y)\,y')\,dx = 0$$
$$-\frac{y^2}{2} + yy' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{2y}{y^2 + 2c_1} dy = \int dx$$
$$\ln\left(y^2 + 2c_1\right) = x + c_2$$

Raising both side to exponential gives

$$y^2 + 2c_1 = \mathrm{e}^{x+c_2}$$

Which simplifies to

$$y^2 + 2c_1 = c_3 \mathrm{e}^{x}$$

Summary

The solution(s) found are the following

$$y = \mathrm{RootOf}\left(\_Z^2 - c_3 \mathrm{e}^{x} + 2c_1\right) \tag{1}$$

Verification of solutions

$$y = \mathrm{RootOf}\left(\_Z^2 - c_3 \mathrm{e}^{x} + 2c_1\right)$$

Verified OK.

18.24.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$y p(y) \left(\frac{d}{dy}p(y)\right) + \left(p(y) - y\right) p(y) = 0$$

Which is now solved as first order ode for $p(y)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dy}p(y) + p(y)p(y) = q(y)$$

Where here

$$\begin{aligned} p(y) &= \frac{1}{y} \\ q(y) &= 1 \end{aligned}$$

Hence the ode is

$$\frac{d}{dy}p(y) + \frac{p(y)}{y} = 1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int \frac{1}{y}dy} \\ &= y \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}y}(\mu p) &= \mu \\ \frac{\mathrm{d}}{\mathrm{d}y}(yp) &= y \\ \mathrm{d}(yp) &= y\mathrm{d}y \end{aligned}$$

Integrating gives

$$\begin{aligned} yp &= \int y \, \mathrm{d}y \\ yp &= \frac{y^2}{2} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = y$ results in

$$p(y) = \frac{y}{2} + \frac{c_1}{y}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = \frac{y}{2} + \frac{c_1}{y}$$

Integrating both sides gives

$$\int \frac{2y}{y^2 + 2c_1} dy = \int dx$$
$$\ln(y^2 + 2c_1) = x + c_2$$

Raising both side to exponential gives

$$y^2 + 2c_1 = e^{x+c_2}$$

Which simplifies to

$$y^2 + 2c_1 = c_3 e^x$$

Summary

The solution(s) found are the following

$$y = \text{RootOf}\left(\_Z^2 - c_3 e^x + 2c_1\right) \tag{1}$$

Verification of solutions

$$y = \text{RootOf}\left(\_Z^2 - c_3 e^x + 2c_1\right)$$

Verified OK.

18.24.3 Solving as second order nonlinear solved by mainardi lioville method ode

The ode has the Liouville form given by

$$y'' + f(x)y' + g(y)y'^2 = 0 \tag{1A}$$

Where in this problem

$$f(x) = -1$$
$$g(y) = \frac{1}{y}$$

Dividing through by y' then Eq (1A) becomes

$$\frac{y''}{y'} + f + gy' = 0 \tag{2A}$$

But the first term in Eq (2A) can be written as

$$\frac{y''}{y'} = \frac{d}{dx} \ln (y') \tag{3A}$$

And the last term in Eq (2A) can be written as

$$\begin{aligned} g\frac{dy}{dx} &= \left(\frac{d}{dy} \int g dy\right) \frac{dy}{dx} \\ &= \frac{d}{dx} \int g dy \end{aligned} \tag{4A}$$

Substituting (3A,4A) back into (2A) gives

$$\frac{d}{dx} \ln (y') + \frac{d}{dx} \int g dy = -f \tag{5A}$$

Integrating the above w.r.t. x gives

$$\ln (y') + \int g dy = -\int f dx + c_1$$

Where c_1 is arbitrary constant. Taking the exponential of the above gives

$$y' = c_2 e^{\int -g dy} e^{\int -f dx} \tag{6A}$$

Where c_2 is a new arbitrary constant. But since $g = \frac{1}{y}$ and $f = -1$, then

$$\begin{aligned} \int -g dy &= \int -\frac{1}{y} dy \\ &= -\ln (y) \\ \int -f dx &= \int 1 dx \\ &= x \end{aligned}$$

Substituting the above into Eq(6A) gives

$$y' = \frac{c_2 \mathrm{e}^x}{y}$$

Which is now solved as first order separable ode. In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= f(x) g(y) \\ &= \frac{c_2 \mathrm{e}^x}{y} \end{aligned}$$

Where $f(x) = c_2 e^x$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y}}\,dy = c_2 e^x\,dx$$

$$\int \frac{1}{\frac{1}{y}}\,dy = \int c_2 e^x\,dx$$

$$\frac{y^2}{2} = c_2 e^x + c_3$$

The solution is

$$\frac{y^2}{2} - c_2 e^x - c_3 = 0$$

Summary
The solution(s) found are the following

$$\frac{y^2}{2} - c_2 e^x - c_3 = 0 \tag{1}$$

Verification of solutions

$$\frac{y^2}{2} - c_2 e^x - c_3 = 0$$

Verified OK.

18.24.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$yy'' + (y' - y)\,y' = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int (yy'' + (y' - y)\,y')\,dx = 0$$

$$-\frac{y^2}{2} + yy' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{2y}{y^2 + 2c_1}dy = \int dx$$

$$\ln\left(y^2 + 2c_1\right) = x + c_2$$

Raising both side to exponential gives

$$y^2 + 2c_1 = e^{x+c_2}$$

Which simplifies to

$$y^2 + 2c_1 = c_3 e^x$$

Summary
The solution(s) found are the following

$$y = \operatorname{RootOf}\left(\_Z^2 - c_3 e^x + 2c_1\right) \tag{1}$$

Verification of solutions

$$y = \operatorname{RootOf}\left(\_Z^2 - c_3 e^x + 2c_1\right)$$

Verified OK.

18.24.5 Solving as exact nonlinear second order ode ode

An exact non-linear second order ode has the form

$$a_2(x, y, y')\, y'' + a_1(x, y, y')\, y' + a_0(x, y, y') = 0$$

Where the following conditions are satisfied

$$\frac{\partial a_2}{\partial y} = \frac{\partial a_1}{\partial y'}$$
$$\frac{\partial a_2}{\partial x} = \frac{\partial a_0}{\partial y'}$$
$$\frac{\partial a_1}{\partial x} = \frac{\partial a_0}{\partial y}$$

Looking at the the ode given we see that

$$\begin{aligned} a_2 &= y \\ a_1 &= y' - y \\ a_0 &= 0 \end{aligned}$$

Applying the conditions to the above shows this is a nonlinear exact second order ode. Therefore it can be reduced to first order ode given by

$$\int a_2\, dy' + \int a_1\, dy + \int a_0\, dx = c_1$$
$$\int y\, dy' + \int y' - y\, dy + \int 0\, dx = c_1$$

Which results in

$$2yy' - \frac{y^2}{2} = c_1$$

Which is now solved Integrating both sides gives

$$\int \frac{4y}{y^2 + 2c_1} dy = \int dx$$
$$2\ln\left(y^2 + 2c_1\right) = x + c_2$$

Raising both side to exponential gives

$$\left(y^2 + 2c_1\right)^2 = e^{x+c_2}$$

Which simplifies to

$$\left(y^2 + 2c_1\right)^2 = c_3 e^x$$

Summary

The solution(s) found are the following

$$y = \text{RootOf}\left(\_Z^2 - \sqrt{c_3 e^x} + 2c_1\right) \tag{1}$$

Verification of solutions

$$y = \text{RootOf}\left(\_Z^2 - \sqrt{c_3 e^x} + 2c_1\right)$$

Verified OK.

18.24.6 Maple step by step solution

Let's solve

$yy'' + (y' - y)\, y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x) = y'$

- Compute y''

  $u'(x) = y''$

- Use chain rule on the lhs

$y'\left(\frac{d}{dy}u(y)\right) = y''$

- Substitute in the definition of u

$u(y)\left(\frac{d}{dy}u(y)\right) = y''$

- Make substitutions $y' = u(y), y'' = u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

$yu(y)\left(\frac{d}{dy}u(y)\right) + (u(y) - y)\,u(y) = 0$

- Isolate the derivative

$\frac{d}{dy}u(y) = 1 - \frac{u(y)}{y}$

- Group terms with $u(y)$ on the lhs of the ODE and the rest on the rhs of the ODE

$\frac{d}{dy}u(y) + \frac{u(y)}{y} = 1$

- The ODE is linear; multiply by an integrating factor $\mu(y)$

$\mu(y)\left(\frac{d}{dy}u(y) + \frac{u(y)}{y}\right) = \mu(y)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dy}(\mu(y)\,u(y))$

$\mu(y)\left(\frac{d}{dy}u(y) + \frac{u(y)}{y}\right) = \left(\frac{d}{dy}\mu(y)\right)u(y) + \mu(y)\left(\frac{d}{dy}u(y)\right)$

- Isolate $\frac{d}{dy}\mu(y)$

$\frac{d}{dy}\mu(y) = \frac{\mu(y)}{y}$

- Solve to find the integrating factor

$\mu(y) = y$

- Integrate both sides with respect to y

$\int \left(\frac{d}{dy}(\mu(y)\,u(y))\right)dy = \int \mu(y)\,dy + c_1$

- Evaluate the integral on the lhs

$\mu(y)\,u(y) = \int \mu(y)\,dy + c_1$

- Solve for $u(y)$

$u(y) = \frac{\int \mu(y)dy + c_1}{\mu(y)}$

- Substitute $\mu(y) = y$

$u(y) = \frac{\int y dy + c_1}{y}$

- Evaluate the integrals on the rhs

$$u(y) = \frac{\frac{y^2}{2}+c_1}{y}$$

- Simplify

$$u(y) = \frac{y^2+2c_1}{2y}$$

- Solve 1st ODE for $u(y)$

$$u(y) = \frac{y^2+2c_1}{2y}$$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = \frac{y^2+2c_1}{2y}$$

- Separate variables

$$\frac{y'y}{y^2+2c_1} = \frac{1}{2}$$

- Integrate both sides with respect to x

$$\int \frac{y'y}{y^2+2c_1}dx = \int \frac{1}{2}dx + c_2$$

- Evaluate integral

$$\frac{\ln(y^2+2c_1)}{2} = \frac{x}{2} + c_2$$

- Solve for y

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 25.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], _Liouville, [_2nd_order, _reducible,
    _mu_x_y1], [_2nd_order, _reducible, _mu_xy]]
```

$$\boxed{2yy'' - {y'}^2 = 0}$$

18.25.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$2yp(y)\left(\frac{d}{dy}p(y)\right) - p(y)^2 = 0$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$\begin{aligned}
p' &= F(y,p) \\
&= f(y)g(p) \\
&= \frac{p}{2y}
\end{aligned}$$

Where $f(y) = \frac{1}{2y}$ and $g(p) = p$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{p}\,dp &= \frac{1}{2y}\,dy \\
\int \frac{1}{p}\,dp &= \int \frac{1}{2y}\,dy \\
\ln(p) &= \frac{\ln(y)}{2} + c_1 \\
p &= \mathrm{e}^{\frac{\ln(y)}{2}+c_1} \\
&= c_1\sqrt{y}
\end{aligned}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = c_1\sqrt{y}$$

Integrating both sides gives

$$\begin{aligned}
\int \frac{1}{c_1\sqrt{y}}dy &= \int dx \\
\frac{2\sqrt{y}}{c_1} &= x + c_2
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{1}{4}c_1^2c_2^2 + \frac{1}{2}c_1^2c_2x + \frac{1}{4}c_1^2x^2 \tag{1}$$

Verification of solutions

$$y = \frac{1}{4}c_1^2c_2^2 + \frac{1}{2}c_1^2c_2x + \frac{1}{4}c_1^2x^2$$

Verified OK.

18.25.2 Maple step by step solution

Let's solve

$2yy'' - y'^2 = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x) = y'$

- Compute y''

  $u'(x) = y''$

- Use chain rule on the lhs

  $y'\left(\frac{d}{dy}u(y)\right) = y''$

- Substitute in the definition of u

  $u(y)\left(\frac{d}{dy}u(y)\right) = y''$

- Make substitutions $y' = u(y)\,, y'' = u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

  $2yu(y)\left(\frac{d}{dy}u(y)\right) - u(y)^2 = 0$

- Separate variables

  $\frac{\frac{d}{dy}u(y)}{u(y)} = \frac{1}{2y}$

- Integrate both sides with respect to y

  $\int \frac{\frac{d}{dy}u(y)}{u(y)}dy = \int \frac{1}{2y}dy + c_1$

- Evaluate integral

  $\ln(u(y)) = \frac{\ln(y)}{2} + c_1$

- Solve for $u(y)$

  $\left\{u(y) = \frac{\sqrt{e^{-2c_1}y}}{e^{-2c_1}}, u(y) = -\frac{\sqrt{e^{-2c_1}y}}{e^{-2c_1}}\right\}$

- Solve 1st ODE for $u(y)$

  $u(y) = \frac{\sqrt{e^{-2c_1}y}}{e^{-2c_1}}$

- Revert to original variables with substitution $u(y) = y', y = y$

  $y' = \frac{\sqrt{e^{-2c_1}y}}{e^{-2c_1}}$

- Separate variables

  $\frac{y'}{\sqrt{e^{-2c_1} y}} = \frac{1}{e^{-2c_1}}$
- Integrate both sides with respect to x

  $\int \frac{y'}{\sqrt{e^{-2c_1} y}} dx = \int \frac{1}{e^{-2c_1}} dx + c_2$
- Evaluate integral

  $\frac{2\sqrt{e^{-2c_1} y}}{e^{-2c_1}} = \frac{x}{e^{-2c_1}} + c_2$
- Solve for y

  $y = \frac{c_2^2 (e^{-2c_1})^2 + 2c_2 e^{-2c_1} x + x^2}{4\,e^{-2c_1}}$
- Solve 2nd ODE for $u(y)$

  $u(y) = -\frac{\sqrt{e^{-2c_1} y}}{e^{-2c_1}}$
- Revert to original variables with substitution $u(y) = y', y = y$

  $y' = -\frac{\sqrt{e^{-2c_1} y}}{e^{-2c_1}}$
- Separate variables

  $\frac{y'}{\sqrt{e^{-2c_1} y}} = -\frac{1}{e^{-2c_1}}$
- Integrate both sides with respect to x

  $\int \frac{y'}{\sqrt{e^{-2c_1} y}} dx = \int -\frac{1}{e^{-2c_1}} dx + c_2$
- Evaluate integral

  $\frac{2\sqrt{e^{-2c_1} y}}{e^{-2c_1}} = -\frac{x}{e^{-2c_1}} + c_2$
- Solve for y

  $y = \frac{c_2^2 (e^{-2c_1})^2 - 2c_2 e^{-2c_1} x + x^2}{4\,e^{-2c_1}}$

18.26 problem 26

Internal problem ID [2298]
Internal file name [`OUTPUT/2298_Tuesday_February_27_2024_08_24_14_AM_17887916/index.tex`]

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 26.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_xy]]
```

$$\boxed{y'' + 2{y'}^2 = 2}$$

18.26.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + 2p(x)^2 - 2 = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{-2p^2+2}dp = x + c_1$$
$$\frac{\operatorname{arctanh}(p)}{2} = x + c_1$$

Solving for p gives these solutions

$$p_1 = \tanh(2x + 2c_1)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \tanh(2x + 2c_1)$$

Integrating both sides gives

$$\begin{aligned} y &= \int \tanh(2x + 2c_1)\, \mathrm{d}x \\ &= \frac{\ln(\cosh(2x + 2c_1))}{2} + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{\ln(\cosh(2x + 2c_1))}{2} + c_2 \tag{1}$$

Verification of solutions

$$y = \frac{\ln(\cosh(2x + 2c_1))}{2} + c_2$$

Verified OK.

18.26.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right) + 2p(y)^2 = 2$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$\int -\frac{p}{2\left(p^2-1\right)}dp = \int dy$$
$$-\frac{\ln\left(p-1\right)}{4}-\frac{\ln\left(p+1\right)}{4} = y+c_1$$

The above can be written as

$$\left(-\frac{1}{4}\right)\left(\ln\left(p-1\right)+\ln\left(p+1\right)\right) = y+c_1$$
$$\ln\left(p-1\right)+\ln\left(p+1\right) = \left(-4\right)\left(y+c_1\right)$$
$$= -4y-4c_1$$

Raising both side to exponential gives

$$\mathrm{e}^{\ln(p-1)+\ln(p+1)} = -4c_1\mathrm{e}^{-4y}$$

Which simplifies to

$$p^2-1 = c_2\mathrm{e}^{-4y}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = \operatorname{RootOf}\left(\_Z^2-c_2\mathrm{e}^{-4y}-1\right)$$

Integrating both sides gives

$$\int \frac{1}{\operatorname{RootOf}\left(\_Z^2-c_2\mathrm{e}^{-4y}-1\right)}dy = \int dx$$
$$\int^y \frac{1}{\operatorname{RootOf}\left(\_Z^2-c_2\mathrm{e}^{-4\_a}-1\right)}d\_a = x+c_3$$

Summary

The solution(s) found are the following

$$\int^y \frac{1}{\operatorname{RootOf}\left(\_Z^2-c_2\mathrm{e}^{-4\_a}-1\right)}d\_a = x+c_3 \tag{1}$$

Verification of solutions

$$\int^y \frac{1}{\operatorname{RootOf}\left(\_Z^2-c_2\mathrm{e}^{-4\_a}-1\right)}d\_a = x+c_3$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 27.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + y' - y'^3 = 0}$$

18.27.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + \left(1 - p(x)^2\right) p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{p\left(p^2 - 1\right)} dp = \int dx$$

$$\frac{\ln\left(p + 1\right)}{2} + \frac{\ln\left(p - 1\right)}{2} - \ln\left(p\right) = x + c_1$$

Raising both side to exponential gives

$$e^{\frac{\ln(p+1)}{2}+\frac{\ln(p-1)}{2}-\ln(p)} = e^{x+c_1}$$

Which simplifies to

$$\frac{\sqrt{p+1}\,\sqrt{p-1}}{p} = c_2 e^x$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -\frac{\sqrt{1-c_2^2 e^{2x}}-1}{\sqrt{1-c_2^2 e^{2x}}} + 1$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{1}{\sqrt{1-c_2^2 e^{2x}}}\, dx \\ &= -\operatorname{arctanh}\left(\frac{1}{\sqrt{1-c_2^2 e^{2x}}}\right) + c_3 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = -\operatorname{arctanh}\left(\frac{1}{\sqrt{1-c_2^2 e^{2x}}}\right) + c_3 \tag{1}$$

Verification of solutions

$$y = -\operatorname{arctanh}\left(\frac{1}{\sqrt{1-c_2^2 e^{2x}}}\right) + c_3$$

Verified OK.

18.27.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$
\begin{aligned}
y'' &= \frac{dp}{dx} \\
&= \frac{dy}{dx}\frac{dp}{dy} \\
&= p\frac{dp}{dy}
\end{aligned}
$$

Hence the ode becomes

$$
p(y)\left(\frac{d}{dy}p(y)\right) + \left(1 - p(y)^2\right)p(y) = 0
$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$
\begin{aligned}
\int \frac{1}{p^2 - 1}dp &= y + c_1 \\
-\operatorname{arctanh}(p) &= y + c_1
\end{aligned}
$$

Solving for p gives these solutions

$$
p_1 = -\tanh(y + c_1)
$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$
y' = -\tanh(y + c_1)
$$

Integrating both sides gives

$$
\begin{aligned}
\int -\frac{1}{\tanh(y + c_1)}dy &= \int dx \\
\frac{\ln(\tanh(y + c_1) + 1)}{2} + \frac{\ln(-1 + \tanh(y + c_1))}{2} - \ln(\tanh(y + c_1)) &= x + c_2
\end{aligned}
$$

Raising both side to exponential gives

$$
e^{\frac{\ln(\tanh(y+c_1)+1)}{2} + \frac{\ln(-1+\tanh(y+c_1))}{2} - \ln(\tanh(y+c_1))} = e^{x+c_2}
$$

Which simplifies to

$$
\frac{\sqrt{\tanh(y + c_1) + 1}\,\sqrt{-1 + \tanh(y + c_1)}}{\tanh(y + c_1)} = c_3 e^x
$$

Summary
The solution(s) found are the following

$$y = -c_1 + \operatorname{arctanh}\left(\frac{\sqrt{-c_3^2 e^{2x}+1}-1}{\sqrt{-c_3^2 e^{2x}+1}}-1\right) \tag{1}$$

Verification of solutions

$$y = -c_1 + \operatorname{arctanh}\left(\frac{\sqrt{-c_3^2 e^{2x}+1}-1}{\sqrt{-c_3^2 e^{2x}+1}}-1\right)$$

Verified OK.

18.27.3 Maple step by step solution

Let's solve

$y'' + \left(1-y'^2\right) y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) + \left(1-u(x)^2\right) u(x) = 0$

- Separate variables

  $\frac{u'(x)}{\left(1-u(x)^2\right)u(x)} = -1$

- Integrate both sides with respect to x

  $\int \frac{u'(x)}{\left(1-u(x)^2\right)u(x)} dx = \int (-1) dx + c_1$

- Evaluate integral

  $-\frac{\ln(u(x)+1)}{2} - \frac{\ln(-1+u(x))}{2} + \ln(u(x)) = -x + c_1$

- Solve for $u(x)$

  $\left\{u(x) = \frac{\sqrt{\left(e^{-2x+2c_1}-1\right)e^{-2x+2c_1}}}{e^{-2x+2c_1}-1}, u(x) = -\frac{\sqrt{\left(e^{-2x+2c_1}-1\right)e^{-2x+2c_1}}}{e^{-2x+2c_1}-1}\right\}$

- Solve 1st ODE for $u(x)$

  $u(x) = \frac{\sqrt{\left(e^{-2x+2c_1}-1\right)e^{-2x+2c_1}}}{e^{-2x+2c_1}-1}$

- Make substitution $u = y'$

$$y' = \frac{\sqrt{\left(e^{-2x+2c_1}-1\right)e^{-2x+2c_1}}}{e^{-2x+2c_1}-1}$$

- Integrate both sides to solve for y

$$\int y'dx = \int \frac{\sqrt{\left(e^{-2x+2c_1}-1\right)e^{-2x+2c_1}}}{e^{-2x+2c_1}-1}dx + c_2$$

- Compute integrals

$$y = -\frac{\sqrt{\left(e^{-2x+2c_1}-1\right)^2-1+e^{-2x+2c_1}}}{2} - \frac{\ln\left(-\frac{1}{2}+e^{-2x+2c_1}+\sqrt{\left(e^{-2x+2c_1}-1\right)^2-1+e^{-2x+2c_1}}\right)}{4} + \frac{\sqrt{\left(e^{-2x+2c_1}\right)^2-e^{-2x+2c_1}}}{2} -$$

- Solve 2nd ODE for $u(x)$

$$u(x) = -\frac{\sqrt{\left(e^{-2x+2c_1}-1\right)e^{-2x+2c_1}}}{e^{-2x+2c_1}-1}$$

- Make substitution $u = y'$

$$y' = -\frac{\sqrt{\left(e^{-2x+2c_1}-1\right)e^{-2x+2c_1}}}{e^{-2x+2c_1}-1}$$

- Integrate both sides to solve for y

$$\int y'dx = \int -\frac{\sqrt{\left(e^{-2x+2c_1}-1\right)e^{-2x+2c_1}}}{e^{-2x+2c_1}-1}dx + c_2$$

- Compute integrals

$$y = \frac{\sqrt{\left(e^{-2x+2c_1}-1\right)^2-1+e^{-2x+2c_1}}}{2} + \frac{\ln\left(-\frac{1}{2}+e^{-2x+2c_1}+\sqrt{\left(e^{-2x+2c_1}-1\right)^2-1+e^{-2x+2c_1}}\right)}{4} - \frac{\sqrt{\left(e^{-2x+2c_1}\right)^2-e^{-2x+2c_1}}}{2} + \frac{\ln}{}$$

Section: Exercise 35, page 157
Problem number: 28.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], _Liouville, [_2nd_order, _reducible,
    _mu_x_y1], [_2nd_order, _reducible, _mu_xy]]
```

$$\boxed{(y+1)\,y''-3{y'}^2=0}$$

18.28.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y'=p(y)$$

Then

$$\begin{aligned}y''&=\frac{dp}{dx}\\&=\frac{dy}{dx}\frac{dp}{dy}\\&=p\frac{dp}{dy}\end{aligned}$$

Hence the ode becomes

$$(y+1)\,p(y)\left(\frac{d}{dy}p(y)\right)-3p(y)^2=0$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$\begin{aligned} p' &= F(y,p) \\ &= f(y)g(p) \\ &= \frac{3p}{y+1} \end{aligned}$$

Where $f(y) = \frac{3}{y+1}$ and $g(p) = p$. Integrating both sides gives

$$\begin{aligned} \frac{1}{p}\,dp &= \frac{3}{y+1}\,dy \\ \int \frac{1}{p}\,dp &= \int \frac{3}{y+1}\,dy \\ \ln(p) &= 3\ln(y+1) + c_1 \\ p &= e^{3\ln(y+1)+c_1} \\ &= c_1(y+1)^3 \end{aligned}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = c_1(y+1)^3$$

Integrating both sides gives

$$\begin{aligned} \int \frac{1}{c_1(y+1)^3}dy &= x + c_2 \\ -\frac{1}{2c_1(y+1)^2} &= x + c_2 \end{aligned}$$

Solving for y gives these solutions

$$\begin{aligned} y_1 &= -\frac{\sqrt{-2c_1c_2 - 2c_1x} - 1}{\sqrt{-2c_1c_2 - 2c_1x}} \\ y_2 &= -\frac{\sqrt{-2c_1c_2 - 2c_1x} + 1}{\sqrt{-2c_1c_2 - 2c_1x}} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{\sqrt{-2c_1c_2 - 2c_1x} - 1}{\sqrt{-2c_1c_2 - 2c_1x}} \tag{1}$$

$$y = -\frac{\sqrt{-2c_1c_2 - 2c_1x} + 1}{\sqrt{-2c_1c_2 - 2c_1x}} \tag{2}$$

Verification of solutions

$$y = -\frac{\sqrt{-2c_1c_2 - 2c_1x} - 1}{\sqrt{-2c_1c_2 - 2c_1x}}$$

Verified OK.

$$y = -\frac{\sqrt{-2c_1c_2 - 2c_1x} + 1}{\sqrt{-2c_1c_2 - 2c_1x}}$$

Verified OK.

18.28.2 Maple step by step solution

Let's solve

$(y+1)\,y'' - 3y'^2 = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x) = y'$

- Compute y''

  $u'(x) = y''$

- Use chain rule on the lhs

  $y'\left(\frac{d}{dy}u(y)\right) = y''$

- Substitute in the definition of u

  $u(y)\left(\frac{d}{dy}u(y)\right) = y''$

- Make substitutions $y' = u(y)\,, y'' = u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

  $(y+1)\,u(y)\left(\frac{d}{dy}u(y)\right) - 3u(y)^2 = 0$

- Separate variables

  $\frac{\frac{d}{dy}u(y)}{u(y)} = \frac{3}{y+1}$

- Integrate both sides with respect to y

  $\int \frac{\frac{d}{dy}u(y)}{u(y)}dy = \int \frac{3}{y+1}dy + c_1$

- Evaluate integral

$$\ln(u(y)) = 3\ln(y+1) + c_1$$

- Solve for $u(y)$

$$u(y) = e^{c_1}(y+1)^3$$

- Solve 1st ODE for $u(y)$

$$u(y) = e^{c_1}(y+1)^3$$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = e^{c_1}(y+1)^3$$

- Separate variables

$$\frac{y'}{(y+1)^3} = e^{c_1}$$

- Integrate both sides with respect to x

$$\int \frac{y'}{(y+1)^3}dx = \int e^{c_1}dx + c_2$$

- Evaluate integral

$$-\frac{1}{2(y+1)^2} = e^{c_1}x + c_2$$

- Solve for y

$$\left\{y = -\frac{\sqrt{-2\,e^{c_1}x-2c_2}-1}{\sqrt{-2\,e^{c_1}x-2c_2}}, y = -\frac{\sqrt{-2\,e^{c_1}x-2c_2}+1}{\sqrt{-2\,e^{c_1}x-2c_2}}\right\}$$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_quadrature", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _quadrature]]
```

$$\boxed{y'' = \sec(x)\tan(x)}$$

With initial conditions

$$\left[y(0) = \frac{\pi}{4}, y'(0) = 1\right]$$

18.29.1 Solving as second order ode quadrature ode

Integrating once gives

$$y' = \sec(x) + c_1$$

Integrating again gives

$$y = \ln(\sec(x) + \tan(x)) + c_1 x + c_2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \ln(\sec(x) + \tan(x)) + c_1 x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{\pi}{4}$ and $x = 0$ in the above gives

$$\frac{\pi}{4} = c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{\sec(x)\tan(x) + 1 + \tan(x)^2}{\sec(x) + \tan(x)} + c_1$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = c_1 + 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

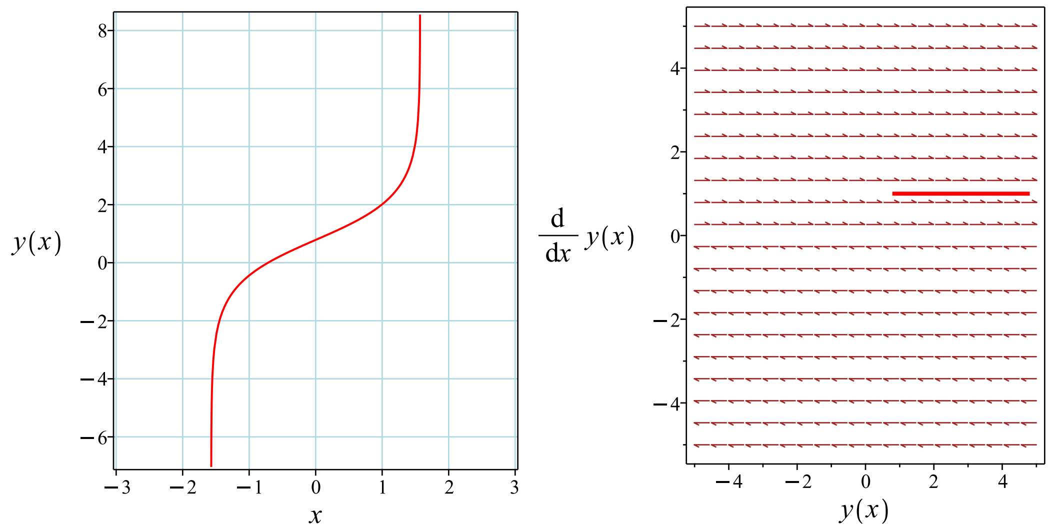
$$c_1 = 0$$
$$c_2 = \frac{\pi}{4}$$

Substituting these values back in above solution results in

$$y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4}$$

Summary
The solution(s) found are the following

$$y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4} \tag{1}$$



(a) Solution plot (b) Slope field plot

<u>Verification of solutions</u>

$$y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4}$$

Verified OK.

18.29.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 0, f(x) = \sec(x)\tan(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(0)^2 - (4)(1)(0)}\\ &= 0\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 0$. Therefore the solution is

$$y = c_1 1 + c_2 x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_2 x + c_1$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}y_1 &= 1\\ y_2 &= x\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & x \\ \frac{d}{dx}(1) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & x \\ 0 & 1 \end{vmatrix}$$

Therefore

$$W = (1)(1) - (x)(0)$$

Which simplifies to

$$W = 1$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x \sec(x) \tan(x)}{1} \, dx$$

Which simplifies to

$$u_1 = -\int x \sec(x) \tan(x) \, dx$$

Hence

$$u_1 = -\frac{x}{\cos(x)} + \ln(\sec(x) + \tan(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sec(x) \tan(x)}{1} \, dx$$

Which simplifies to

$$u_2 = \int \sec(x)\tan(x)\,dx$$

Hence

$$u_2 = \sec(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x}{\cos(x)} + \ln(\sec(x) + \tan(x)) + \sec(x)\,x$$

Which simplifies to

$$y_p(x) = \ln(\sec(x) + \tan(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 x + c_1) + (\ln(\sec(x) + \tan(x))) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_2 x + c_1 + \ln(\sec(x) + \tan(x)) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{\pi}{4}$ and $x = 0$ in the above gives

$$\frac{\pi}{4} = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_2 + \frac{\sec(x)\tan(x) + 1 + \tan(x)^2}{\sec(x) + \tan(x)}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = c_2 + 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

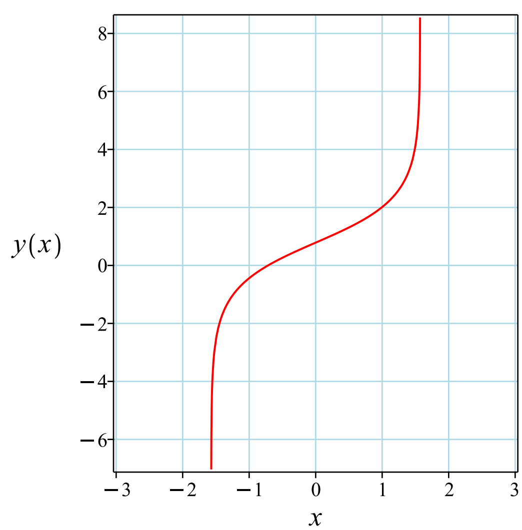
$$
\begin{aligned}
c_1 &= \frac{\pi}{4} \\
c_2 &= 0
\end{aligned}
$$

Substituting these values back in above solution results in

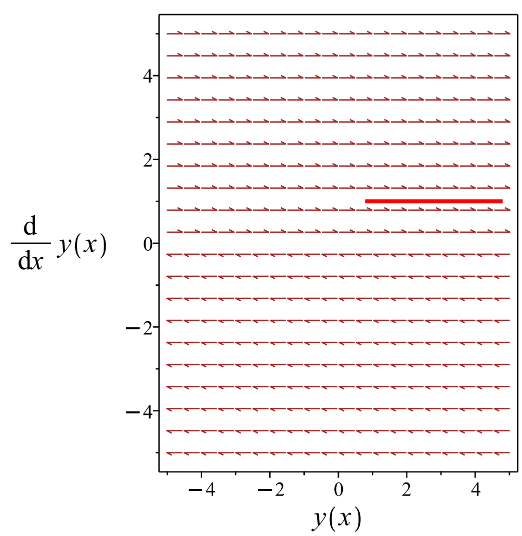
$$
y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4}
$$

Summary
The solution(s) found are the following

$$
y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4} \tag{1}
$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4}
$$

Verified OK.

18.29.3 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$
\begin{aligned}
\int y'' dx &= \int \sec(x) \tan(x)\, dx \\
y' &= \sec(x) + c_1
\end{aligned}
$$

Which is now solved for y. Integrating both sides gives

$$
\begin{aligned}
y &= \int \sec(x) + c_1 \, \mathrm{d}x \\
&= \ln(\sec(x) + \tan(x)) + c_1 x + c_2
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \ln(\sec(x) + \tan(x)) + c_1 x + c_2 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{\pi}{4}$ and $x = 0$ in the above gives

$$
\frac{\pi}{4} = c_2 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = \frac{\sec(x)\tan(x) + 1 + \tan(x)^2}{\sec(x) + \tan(x)} + c_1
$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$
1 = c_1 + 1 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

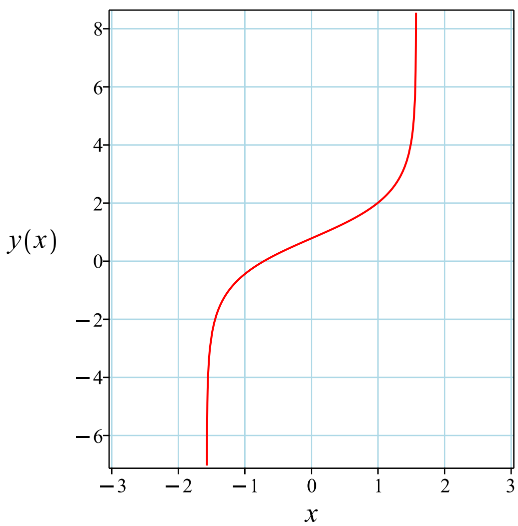
$$
\begin{aligned}
c_1 &= 0 \\
c_2 &= \frac{\pi}{4}
\end{aligned}
$$

Substituting these values back in above solution results in

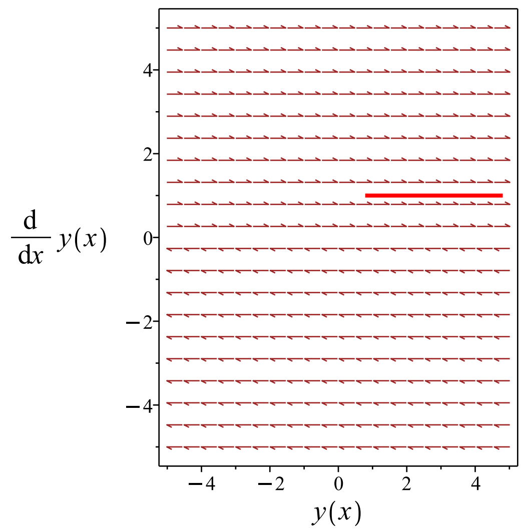
$$
y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4}
$$

Summary
The solution(s) found are the following

$$y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4}$$

Verified OK.

18.29.4 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - \sec(x)\tan(x) = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$
\begin{aligned}
p(x) &= \int \sec(x)\tan(x)\, \mathrm{d}x \\
&= \sec(x) + c_1
\end{aligned}
$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $p = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_1 + 1$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$p(x) = \sec(x)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \sec(x)$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int \sec(x)\, \mathrm{d}x \\
&= \ln(\sec(x) + \tan(x)) + c_2
\end{aligned}
$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $y = \frac{\pi}{4}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{\pi}{4} = c_2$$

$$c_2 = \frac{\pi}{4}$$

Substituting c_2 found above in the general solution gives

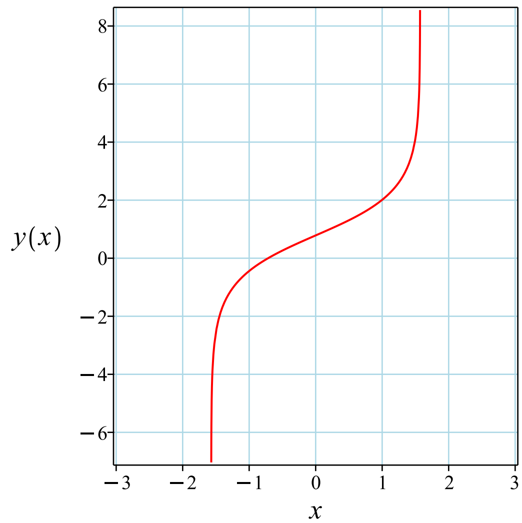
$$y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4}$$

Initial conditions are used to solve for the constants of integration.

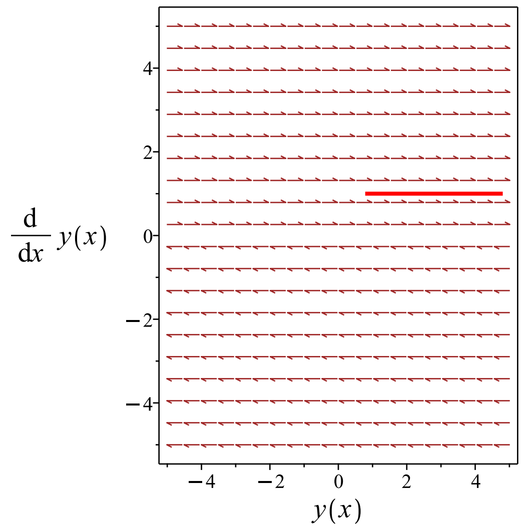
Summary

The solution(s) found are the following

$$y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4}$$

Verified OK.

18.29.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 606: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= 1 \end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= 1 \int \frac{1}{1}\,dx \\ &= 1(x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(1) + c_2(1(x)) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_2 x + c_1$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= 1 \\ y_2 &= x \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & x \\ \frac{d}{dx}(1) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & x \\ 0 & 1 \end{vmatrix}$$

Therefore

$$W = (1)(1) - (x)(0)$$

Which simplifies to

$$W = 1$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x \sec(x) \tan(x)}{1} \, dx$$

Which simplifies to

$$u_1 = -\int x \sec(x) \tan(x) \, dx$$

Hence

$$u_1 = -\frac{x}{\cos(x)} + \ln(\sec(x) + \tan(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sec(x) \tan(x)}{1} \, dx$$

Which simplifies to

$$u_2 = \int \sec(x)\tan(x)\,dx$$

Hence

$$u_2 = \sec(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x}{\cos(x)} + \ln(\sec(x) + \tan(x)) + \sec(x)\,x$$

Which simplifies to

$$y_p(x) = \ln(\sec(x) + \tan(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 x + c_1) + (\ln(\sec(x) + \tan(x))) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_2 x + c_1 + \ln(\sec(x) + \tan(x)) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{\pi}{4}$ and $x = 0$ in the above gives

$$\frac{\pi}{4} = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_2 + \frac{\sec(x)\tan(x) + 1 + \tan(x)^2}{\sec(x) + \tan(x)}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = c_2 + 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

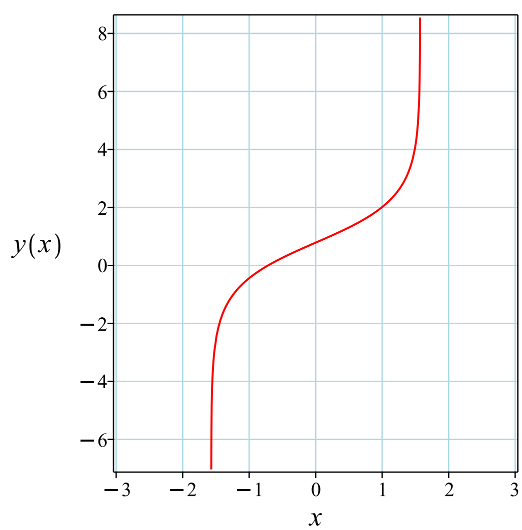
$$c_1 = \frac{\pi}{4}$$
$$c_2 = 0$$

Substituting these values back in above solution results in

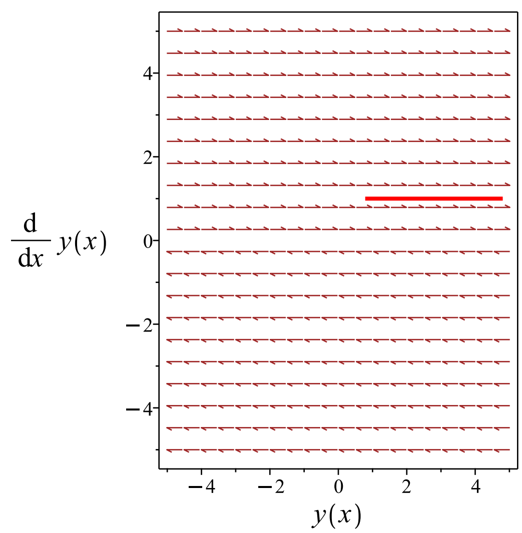
$$y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4}$$

Summary
The solution(s) found are the following

$$y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4}$$

Verified OK.

18.29.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 0 \\ r(x) &= 0 \\ s(x) &= \sec(x)\tan(x) \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\;dx$$

Substituting the above values for p, q, r, s gives

$$y' = \int \sec(x)\tan(x)\;dx$$

We now have a first order ode to solve which is

$$y' = \sec(x) + c_1$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int \sec(x) + c_1 \, dx \\
&= \ln(\sec(x) + \tan(x)) + c_1 x + c_2
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \ln(\sec(x) + \tan(x)) + c_1 x + c_2 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{\pi}{4}$ and $x = 0$ in the above gives

$$
\frac{\pi}{4} = c_2 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = \frac{\sec(x)\tan(x) + 1 + \tan(x)^2}{\sec(x) + \tan(x)} + c_1
$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$
1 = c_1 + 1 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 0 \\
c_2 &= \frac{\pi}{4}
\end{aligned}
$$

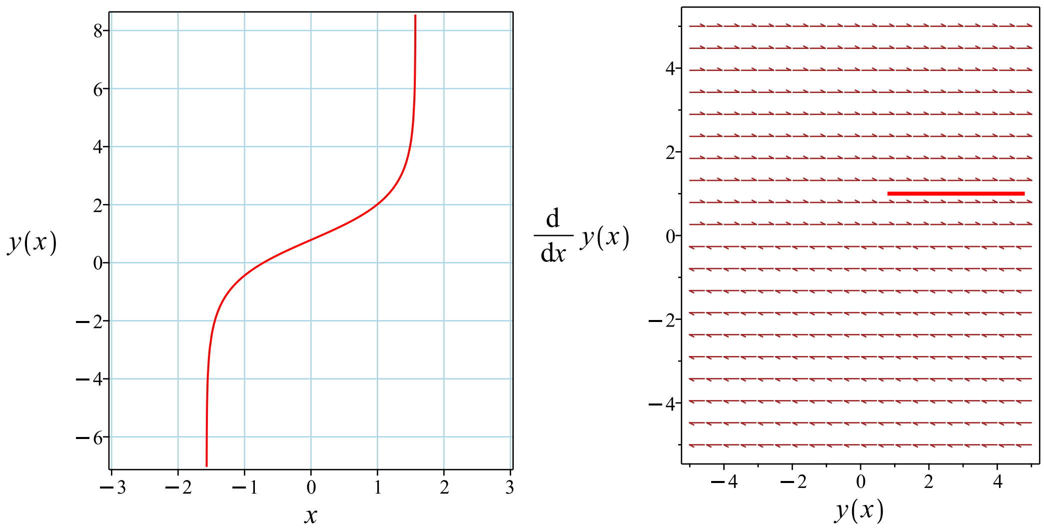
Substituting these values back in above solution results in

$$
y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4}
$$

Summary

The solution(s) found are the following

$$
y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4} \tag{1}
$$



(a) Solution plot

(b) Slope field plot

<u>Verification of solutions</u>

$$y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4}$$

Verified OK.

18.29.7 Maple step by step solution

Let's solve

$$\left[y'' = \sec(x)\tan(x), y(0) = \tfrac{\pi}{4}, y'\Big|_{\{x=0\}} = 1\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{0})}{2}$

- Roots of the characteristic polynomial

  $r = 0$

- 1st solution of the homogeneous ODE

$y_1(x) = 1$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

$y_2(x) = x$

- General solution of the ODE

$y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

$y = c_1 + c_2 x + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

$\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \sec(x)\tan(x)\right]$

  - Wronskian of solutions of the homogeneous equation

$W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & x \\ 0 & 1 \end{bmatrix}$

  - Compute Wronskian

$W(y_1(x), y_2(x)) = 1$

  - Substitute functions into equation for $y_p(x)$

$y_p(x) = -\left(\int x\sec(x)\tan(x)\,dx\right) + x\left(\int \sec(x)\tan(x)\,dx\right)$

  - Compute integrals

$y_p(x) = \ln(\sec(x) + \tan(x))$

- Substitute particular solution into general solution to ODE

$y = c_2 x + c_1 + \ln(\sec(x) + \tan(x))$

□ Check validity of solution $y = c_2 x + c_1 + \ln(\sec(x) + \tan(x))$

  - Use initial condition $y(0) = \frac{\pi}{4}$

$\frac{\pi}{4} = c_1$

  - Compute derivative of the solution

$y' = c_2 + \frac{\sec(x)\tan(x) + 1 + \tan(x)^2}{\sec(x) + \tan(x)}$

  - Use the initial condition $y'\Big|_{\{x=0\}} = 1$

$1 = c_2 + 1$

- Solve for c_1 and c_2

  $\{c_1 = \frac{\pi}{4}, c_2 = 0\}$
- Substitute constant values into general solution and simplify

  $y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4}$

- Solution to the IVP

  $y = \ln(\sec(x) + \tan(x)) + \frac{\pi}{4}$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 30.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

`[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1]]`

$$\boxed{2y'' - \mathrm{e}^{y} = 0}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1]$$

18.30.1 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$2y'y'' - y'\mathrm{e}^{y} = 0$$

Integrating the above w.r.t x gives

$$\int (2y'y'' - y'\mathrm{e}^{y})\, dx = 0$$
$$y'^2 - \mathrm{e}^{y} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{e^y + c_1} \tag{1}$$
$$y' = -\sqrt{e^y + c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{e^y + c_1}} dy = \int dx$$
$$-\frac{2 \operatorname{arctanh}\left(\frac{\sqrt{e^y+c_1}}{\sqrt{c_1}}\right)}{\sqrt{c_1}} = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{e^y + c_1}} dy = \int dx$$
$$\frac{2 \operatorname{arctanh}\left(\frac{\sqrt{e^y+c_1}}{\sqrt{c_1}}\right)}{\sqrt{c_1}} = x + c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$-\frac{2 \operatorname{arctanh}\left(\frac{\sqrt{e^y+c_1}}{\sqrt{c_1}}\right)}{\sqrt{c_1}} = x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$-\frac{2 \operatorname{arctanh}\left(\frac{\sqrt{c_1+1}}{\sqrt{c_1}}\right)}{\sqrt{c_1}} = c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{\tanh\left(\frac{c_2\sqrt{c_1}}{2}+\frac{x\sqrt{c_1}}{2}\right) c_1^{\frac{3}{2}} \left(1-\tanh\left(\frac{c_2\sqrt{c_1}}{2}+\frac{x\sqrt{c_1}}{2}\right)^2\right)}{\tanh\left(\frac{c_2\sqrt{c_1}}{2}+\frac{x\sqrt{c_1}}{2}\right)^2 c_1 - c_1}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = \frac{\left(-\mathrm{e}^{c_2\sqrt{c_1}}+1\right)\sqrt{c_1}}{\mathrm{e}^{c_2\sqrt{c_1}}+1} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Looking at the Second solution

$$\frac{2\,\mathrm{arctanh}\left(\frac{\sqrt{\mathrm{e}^y+c_1}}{\sqrt{c_1}}\right)}{\sqrt{c_1}} = x + c_3 \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$\frac{2\,\mathrm{arctanh}\left(\frac{\sqrt{c_1+1}}{\sqrt{c_1}}\right)}{\sqrt{c_1}} = c_3 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{\tanh\left(\frac{c_3\sqrt{c_1}}{2}+\frac{x\sqrt{c_1}}{2}\right) c_1^{\frac{3}{2}} \left(1-\tanh\left(\frac{c_3\sqrt{c_1}}{2}+\frac{x\sqrt{c_1}}{2}\right)^2\right)}{\tanh\left(\frac{c_3\sqrt{c_1}}{2}+\frac{x\sqrt{c_1}}{2}\right)^2 c_1 - c_1}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = \frac{\left(-\mathrm{e}^{c_3\sqrt{c_1}}+1\right)\sqrt{c_1}}{\mathrm{e}^{c_3\sqrt{c_1}}+1} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

18.30.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$2p(y)\left(\frac{d}{dy}p(y)\right) = e^{y}$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$\begin{aligned} p' &= F(y,p) \\ &= f(y)g(p) \\ &= \frac{e^{y}}{2p} \end{aligned}$$

Where $f(y) = \frac{e^{y}}{2}$ and $g(p) = \frac{1}{p}$. Integrating both sides gives

$$\frac{1}{\frac{1}{p}}\,dp = \frac{e^{y}}{2}\,dy$$

$$\int \frac{1}{\frac{1}{p}}\,dp = \int \frac{e^{y}}{2}\,dy$$

$$\frac{p^{2}}{2} = \frac{e^{y}}{2} + c_{1}$$

The solution is

$$\frac{p(y)^{2}}{2} - \frac{e^{y}}{2} - c_{1} = 0$$

Initial conditions are used to solve for c_1. Substituting $y = 0$ and $p = 1$ in the above solution gives an equation to solve for the constant of integration.

$$-c_1 = 0$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$\frac{p^2}{2} - \frac{e^y}{2} = 0$$

Solving for $p(y)$ from the above gives

$$p(y) = e^{\frac{y}{2}}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = e^{\frac{y}{2}}$$

Integrating both sides gives

$$\int e^{-\frac{y}{2}} dy = x + c_2$$

$$-2\,e^{-\frac{y}{2}} = x + c_2$$

Solving for y gives these solutions

$$y_1 = 2\ln\left(-\frac{2}{x + c_2}\right)$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = 2\ln(2) + 2\ln\left(-\frac{1}{c_2}\right)$$

$$c_2 = -2$$

Substituting c_2 found above in the general solution gives

$$y = 2\ln(2) + 2\ln\left(-\frac{1}{x - 2}\right)$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$y = 2\ln(2) + 2\ln\left(-\frac{1}{x-2}\right) \tag{1}$$

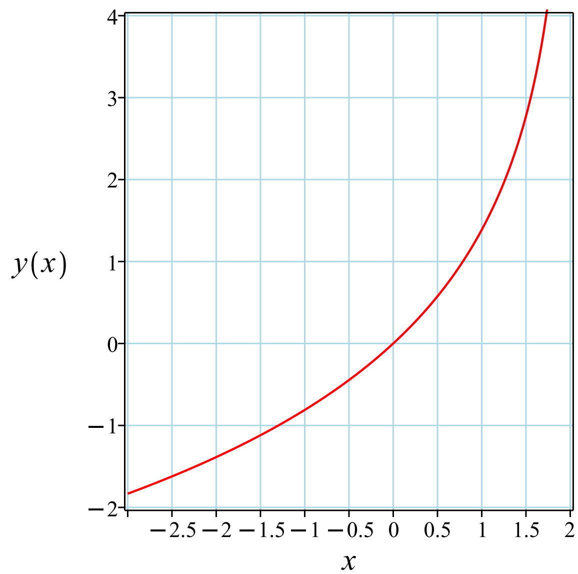

Figure 718: Solution plot

Verification of solutions

$$y = 2\ln(2) + 2\ln\left(-\frac{1}{x-2}\right)$$

Verified OK.

18.30.3 Maple step by step solution

Let's solve

$$\left[2y'' = e^{y}, y(0) = 0, y'\Big|_{\{x=0\}} = 1\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

$u(x) = y'$

- Compute y''

$u'(x) = y''$

- Use chain rule on the lhs

$y'\left(\frac{d}{dy}u(y)\right) = y''$

- Substitute in the definition of u

$u(y)\left(\frac{d}{dy}u(y)\right) = y''$

- Make substitutions $y' = u(y)\,, y'' = u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

$2u(y)\left(\frac{d}{dy}u(y)\right) = \mathrm{e}^{y}$

- Integrate both sides with respect to y

$\int 2u(y)\left(\frac{d}{dy}u(y)\right)dy = \int \mathrm{e}^{y}dy + c_1$

- Evaluate integral

$u(y)^2 = \mathrm{e}^{y} + c_1$

- Solve for $u(y)$

$\left\{u(y) = \sqrt{\mathrm{e}^{y} + c_1}, u(y) = -\sqrt{\mathrm{e}^{y} + c_1}\right\}$

- Solve 1st ODE for $u(y)$

$u(y) = \sqrt{\mathrm{e}^{y} + c_1}$

- Revert to original variables with substitution $u(y) = y', y = y$

$y' = \sqrt{\mathrm{e}^{y} + c_1}$

- Separate variables

$\frac{y'}{\sqrt{\mathrm{e}^{y}+c_1}} = 1$

- Integrate both sides with respect to x

$\int \frac{y'}{\sqrt{\mathrm{e}^{y}+c_1}}dx = \int 1dx + c_2$

- Evaluate integral

$-\frac{2\,\mathrm{arctanh}\left(\frac{\sqrt{\mathrm{e}^{y}+c_1}}{\sqrt{c_1}}\right)}{\sqrt{c_1}} = x + c_2$

- Solve for y

$$y = \ln\left(\tanh\left(\frac{c_2\sqrt{c_1}}{2}+\frac{x\sqrt{c_1}}{2}\right)^2 c_1 - c_1\right)$$

- Solve 2nd ODE for $u(y)$

$$u(y) = -\sqrt{e^y + c_1}$$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = -\sqrt{e^y + c_1}$$

- Separate variables

$$\frac{y'}{\sqrt{e^y + c_1}} = -1$$

- Integrate both sides with respect to x

$$\int \frac{y'}{\sqrt{e^y + c_1}}dx = \int (-1)\, dx + c_2$$

- Evaluate integral

$$-\frac{2\,\mathrm{arctanh}\left(\frac{\sqrt{e^y+c_1}}{\sqrt{c_1}}\right)}{\sqrt{c_1}} = -x + c_2$$

- Solve for y

$$y = \ln\left(\tanh\left(\frac{c_2\sqrt{c_1}}{2}-\frac{x\sqrt{c_1}}{2}\right)^2 c_1 - c_1\right)$$

☐ Check validity of solution $y = \ln\left(\tanh\left(\frac{c_2\sqrt{c_1}}{2}-\frac{x\sqrt{c_1}}{2}\right)^2 c_1 - c_1\right)$

- ○ Use initial condition $y(0) = 0$

$$0 = \ln\left(\tanh\left(\frac{c_2\sqrt{c_1}}{2}\right)^2 c_1 - c_1\right)$$

- ○ Compute derivative of the solution

$$y' = -\frac{\tanh\left(\frac{c_2\sqrt{c_1}}{2}-\frac{x\sqrt{c_1}}{2}\right) c_1^{\frac{3}{2}}\left(1-\tanh\left(\frac{c_2\sqrt{c_1}}{2}-\frac{x\sqrt{c_1}}{2}\right)^2\right)}{\tanh\left(\frac{c_2\sqrt{c_1}}{2}-\frac{x\sqrt{c_1}}{2}\right)^2 c_1 - c_1}$$

- ○ Use the initial condition $y'\Big|_{\{x=0\}} = 1$

$$1 = -\frac{\tanh\left(\frac{c_2\sqrt{c_1}}{2}\right) c_1^{\frac{3}{2}}\left(1-\tanh\left(\frac{c_2\sqrt{c_1}}{2}\right)^2\right)}{\tanh\left(\frac{c_2\sqrt{c_1}}{2}\right)^2 c_1 - c_1}$$

- ○ Solve for c_1 and c_2
- ○ The solution does not satisfy the initial conditions

☐ Check validity of solution $y = \ln\left(\tanh\left(\frac{c_2\sqrt{c_1}}{2}+\frac{x\sqrt{c_1}}{2}\right)^2 c_1 - c_1\right)$

- Use initial condition $y(0) = 0$

$$0 = \ln\left(\tanh\left(\frac{c_2\sqrt{c_1}}{2}\right)^2 c_1 - c_1\right)$$

- Compute derivative of the solution

$$y' = \frac{\tanh\left(\frac{c_2\sqrt{c_1}}{2} + \frac{x\sqrt{c_1}}{2}\right) c_1^{\frac{3}{2}} \left(1 - \tanh\left(\frac{c_2\sqrt{c_1}}{2} + \frac{x\sqrt{c_1}}{2}\right)^2\right)}{\tanh\left(\frac{c_2\sqrt{c_1}}{2} + \frac{x\sqrt{c_1}}{2}\right)^2 c_1 - c_1}$$

- Use the initial condition $y'\big|_{\{x=0\}} = 1$

$$1 = \frac{\tanh\left(\frac{c_2\sqrt{c_1}}{2}\right) c_1^{\frac{3}{2}} \left(1 - \tanh\left(\frac{c_2\sqrt{c_1}}{2}\right)^2\right)}{\tanh\left(\frac{c_2\sqrt{c_1}}{2}\right)^2 c_1 - c_1}$$

- Solve for c_1 and c_2
- The solution does not satisfy the initial conditions

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 31.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1]]
```

$$\boxed{y'' - y^3 = 0}$$

With initial conditions

$$\left[y(0) = -1, y'(0) = \frac{\sqrt{2}}{2}\right]$$

18.31.1 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' - y^3y' = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' - y^3y')\, dx = 0$$

$$\frac{y'^2}{2} - \frac{y^4}{4} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{\sqrt{2y^4 + 8c_1}}{2} \tag{1}$$

$$y' = -\frac{\sqrt{2y^4 + 8c_1}}{2} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{2}{\sqrt{2y^4 + 8c_1}} dy = \int dx$$

$$\frac{\sqrt{2}\,\sqrt{4 - \frac{2iy^2}{\sqrt{c_1}}}\,\sqrt{4 + \frac{2iy^2}{\sqrt{c_1}}}\,\text{EllipticF}\left(\frac{y\sqrt{2}\,\sqrt{\frac{i}{\sqrt{c_1}}}}{2}, i\right)}{2\sqrt{\frac{i}{\sqrt{c_1}}}\,\sqrt{2y^4 + 8c_1}} = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{2}{\sqrt{2y^4 + 8c_1}} dy = \int dx$$

$$-\frac{\sqrt{2}\,\sqrt{4 - \frac{2iy^2}{\sqrt{c_1}}}\,\sqrt{4 + \frac{2iy^2}{\sqrt{c_1}}}\,\text{EllipticF}\left(\frac{y\sqrt{2}\,\sqrt{\frac{i}{\sqrt{c_1}}}}{2}, i\right)}{2\sqrt{\frac{i}{\sqrt{c_1}}}\,\sqrt{2y^4 + 8c_1}} = x + c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$\frac{\sqrt{2}\,\sqrt{4 - \frac{2iy^2}{\sqrt{c_1}}}\,\sqrt{4 + \frac{2iy^2}{\sqrt{c_1}}}\,\text{EllipticF}\left(\frac{y\sqrt{2}\,\sqrt{\frac{i}{\sqrt{c_1}}}}{2}, i\right)}{2\sqrt{\frac{i}{\sqrt{c_1}}}\,\sqrt{2y^4 + 8c_1}} = x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -1$ and $x = 0$ in the above gives

$$\frac{\left(-\frac{1}{2} - \frac{i}{2}\right)\sqrt{\frac{2\sqrt{c_1} - i}{\sqrt{c_1}}}\,\sqrt{\frac{2\sqrt{c_1} + i}{\sqrt{c_1}}}\,\sqrt{2}\,c_1^{\frac{1}{4}}\,\text{EllipticF}\left(\frac{\frac{1}{2} - \frac{i}{2}}{c_1^{\frac{1}{4}}}, i\right)}{\sqrt{4c_1 + 1}} = c_2 \tag{1A}$$

Unable to solve for y to solve for constant of integration

Looking at the Second solution

$$-\frac{\sqrt{2}\,\sqrt{4-\frac{2iy^2}{\sqrt{c_1}}}\,\sqrt{4+\frac{2iy^2}{\sqrt{c_1}}}\,\operatorname{EllipticF}\left(\frac{y\sqrt{2}\,\sqrt{\frac{i}{\sqrt{c_1}}}}{2}, i\right)}{2\sqrt{\frac{i}{\sqrt{c_1}}}\,\sqrt{2y^4+8c_1}} = x + c_3 \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -1$ and $x = 0$ in the above gives

$$\frac{\left(\frac{1}{2}+\frac{i}{2}\right)\sqrt{\frac{2\sqrt{c_1}-i}{\sqrt{c_1}}}\,\sqrt{\frac{2\sqrt{c_1}+i}{\sqrt{c_1}}}\,\sqrt{2}\,c_1^{\frac{1}{4}}\operatorname{EllipticF}\left(\frac{\frac{1}{2}-\frac{i}{2}}{c_1^{\frac{1}{4}}}, i\right)}{\sqrt{4c_1+1}} = c_3 \tag{1A}$$

Unable to solve for y to solve for constant of integration

Verification of solutions N/A

18.31.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right) - y^3 = 0$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$\begin{aligned} p' &= F(y,p) \\ &= f(y)g(p) \\ &= \frac{y^3}{p} \end{aligned}$$

Where $f(y) = y^3$ and $g(p) = \frac{1}{p}$. Integrating both sides gives

$$\frac{1}{\frac{1}{p}}\,dp = y^3\,dy$$

$$\int \frac{1}{\frac{1}{p}}\,dp = \int y^3\,dy$$

$$\frac{p^2}{2} = \frac{y^4}{4} + c_1$$

The solution is

$$\frac{p(y)^2}{2} - \frac{y^4}{4} - c_1 = 0$$

Initial conditions are used to solve for c_1. Substituting $y = -1$ and $p = \frac{\sqrt{2}}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$-c_1 = 0$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$\frac{p^2}{2} - \frac{y^4}{4} = 0$$

Solving for $p(y)$ from the above gives

$$p(y) = \frac{\sqrt{2}\,y^2}{2}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = \frac{\sqrt{2}\,y^2}{2}$$

Integrating both sides gives

$$\int \frac{\sqrt{2}}{y^2} dy = x + c_2$$

$$-\frac{\sqrt{2}}{y} = x + c_2$$

Solving for y gives these solutions

$$y_1 = -\frac{\sqrt{2}}{x + c_2}$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = -\frac{\sqrt{2}}{c_2}$$

$$c_2 = \sqrt{2}$$

Substituting c_2 found above in the general solution gives

$$y = -\frac{\sqrt{2}}{x + \sqrt{2}}$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$y = -\frac{\sqrt{2}}{x + \sqrt{2}} \tag{1}$$

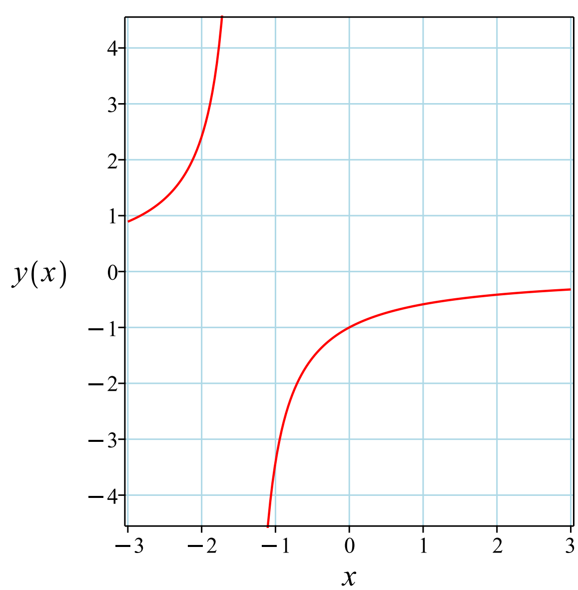

Figure 719: Solution plot

Verification of solutions

$$y = -\frac{\sqrt{2}}{x+\sqrt{2}}$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 32.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y], [_2nd_order, _reducible, _mu_y_y1]]
```

$$\boxed{y'' - {y'}^2 \cos(x) = 0}$$

With initial conditions

$$[y(0) = 2, y'(0) = 1]$$

18.32.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - p(x)^2 \cos(x) = 0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned}
p' &= F(x,p) \\
&= f(x)g(p) \\
&= p^2 \cos(x)
\end{aligned}$$

Where $f(x) = \cos(x)$ and $g(p) = p^2$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{p^2}\,dp &= \cos(x)\,dx \\
\int \frac{1}{p^2}\,dp &= \int \cos(x)\,dx \\
-\frac{1}{p} &= \sin(x) + c_1
\end{aligned}$$

The solution is

$$-\frac{1}{p(x)} - \sin(x) - c_1 = 0$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $p = 1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 - c_1 = 0$$

$$c_1 = -1$$

Substituting c_1 found above in the general solution gives

$$-\frac{\sin(x)\,p + 1 - p}{p} = 0$$

The above simplifies to

$$-\sin(x)\,p + p - 1 = 0$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$-y'\sin(x) + y' - 1 = 0$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int -\frac{1}{\sin (x) - 1}\, \mathrm{d}x \\
&= -\frac{2}{-1 + \tan \left(\frac{x}{2}\right)} + c_2
\end{aligned}
$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$
2 = c_2 + 2
$$

$$
c_2 = 0
$$

Substituting c_2 found above in the general solution gives

$$
y = -\frac{2}{-1 + \tan \left(\frac{x}{2}\right)}
$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$
y = -\frac{2}{-1 + \tan \left(\frac{x}{2}\right)} \tag{1}
$$

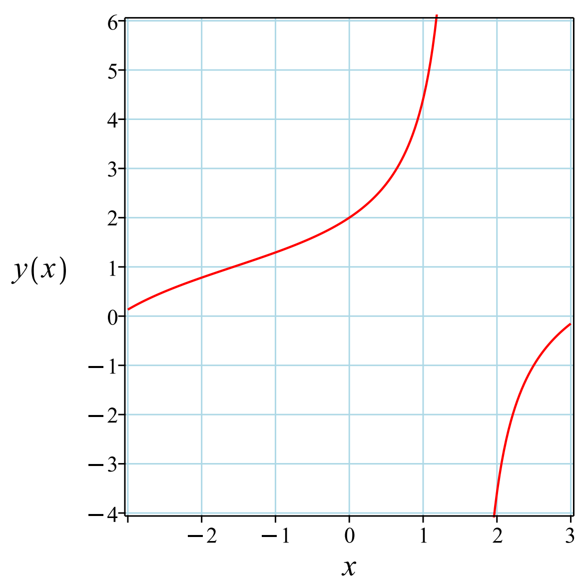

Figure 720: Solution plot

$$y = -\frac{2}{-1 + \tan\left(\frac{x}{2}\right)}$$

Verified OK.

18.32.2 Maple step by step solution

Let's solve

$\left[y'' - y'^2 \cos(x) = 0, y(0) = 2, y'\Big|_{\{x=0\}} = 1\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) - u(x)^2 \cos(x) = 0$

- Separate variables

  $\frac{u'(x)}{u(x)^2} = \cos(x)$

- Integrate both sides with respect to x

  $\int \frac{u'(x)}{u(x)^2} dx = \int \cos(x) dx + c_1$

- Evaluate integral

  $-\frac{1}{u(x)} = \sin(x) + c_1$

- Solve for $u(x)$

  $u(x) = -\frac{1}{\sin(x)+c_1}$

- Solve 1st ODE for $u(x)$

  $u(x) = -\frac{1}{\sin(x)+c_1}$

- Make substitution $u = y'$

  $y' = -\frac{1}{\sin(x)+c_1}$

- Integrate both sides to solve for y

  $\int y' dx = \int -\frac{1}{\sin(x)+c_1} dx + c_2$

- Compute integrals

$$y = -\frac{2\arctan\left(\frac{2\tan\left(\frac{x}{2}\right)c_1+2}{2\sqrt{c_1^2-1}}\right)}{\sqrt{c_1^2-1}} + c_2$$

☐ Check validity of solution $y = -\frac{2\arctan\left(\frac{2\tan\left(\frac{x}{2}\right)c_1+2}{2\sqrt{c_1^2-1}}\right)}{\sqrt{c_1^2-1}} + c_2$

- Use initial condition $y(0) = 2$

$$2 = -\frac{2\arctan\left(\frac{1}{\sqrt{c_1^2-1}}\right)}{\sqrt{c_1^2-1}} + c_2$$

- Compute derivative of the solution

$$y' = -\frac{2\left(\frac{1}{2}+\frac{\tan\left(\frac{x}{2}\right)^2}{2}\right)c_1}{(c_1^2-1)\left(\frac{\left(2\tan\left(\frac{x}{2}\right)c_1+2\right)^2}{4\left(c_1^2-1\right)}+1\right)}$$

- Use the initial condition $y'\Big|_{\{x=0\}} = 1$

$$1 = -\frac{c_1}{(c_1^2-1)\left(\frac{1}{c_1^2-1}+1\right)}$$

- Solve for c_1 and c_2
- The solution does not satisfy the initial conditions

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 33.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order,
   _with_potential_symmetries], [_2nd_order, _reducible, _mu_xy
   ]]
```

$$\boxed{yy'' - y^2y' - y'^2 = 0}$$

With initial conditions

$$[y(0) = 2, y'(0) = 1]$$

18.33.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$yp(y)\left(\frac{d}{dy}p(y)\right)+\left(-y^2-p(y)\right)p(y)=0$$

Which is now solved as first order ode for $p(y)$.

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{1}{y}dy}\\ &= \frac{1}{y}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}y}(\mu p) &= (\mu)(y)\\ \frac{\mathrm{d}}{\mathrm{d}y}\left(\frac{p}{y}\right) &= \left(\frac{1}{y}\right)(y)\\ \mathrm{d}\left(\frac{p}{y}\right) &= \mathrm{d}y\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{p}{y} &= \int \mathrm{d}y\\ \frac{p}{y} &= y+c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu=\frac{1}{y}$ results in

$$p(y)=c_1y+y^2$$

which simplifies to

$$p(y)=y(y+c_1)$$

Initial conditions are used to solve for c_1. Substituting $y=2$ and $p=1$ in the above solution gives an equation to solve for the constant of integration.

$$1=4+2c_1$$

$$c_1=-\frac{3}{2}$$

Substituting c_1 found above in the general solution gives

$$p(y) = \frac{y(2y-3)}{2}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = \frac{y(2y-3)}{2}$$

Integrating both sides gives

$$\int \frac{2}{y(2y-3)} dy = \int dx$$
$$\frac{2\ln(2y-3)}{3} - \frac{2\ln(y)}{3} = x + c_2$$

The above can be written as

$$\left(\frac{2}{3}\right)(\ln(2y-3) - \ln(y)) = x + c_2$$
$$\ln(2y-3) - \ln(y) = \left(\frac{3}{2}\right)(x + c_2)$$
$$= \frac{3x}{2} + \frac{3c_2}{2}$$

Raising both side to exponential gives

$$e^{\ln(2y-3) - \ln(y)} = \frac{3c_2 e^{\frac{3x}{2}}}{2}$$

Which simplifies to

$$\frac{2y-3}{y} = c_3 e^{\frac{3x}{2}}$$

Initial conditions are used to solve for c_3. Substituting $x = 0$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = -\frac{3}{-2 + c_3}$$

$$c_3 = \frac{1}{2}$$

Substituting c_3 found above in the general solution gives

$$y = -\frac{6}{e^{\frac{3x}{2}} - 4}$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$y = -\frac{6}{e^{\frac{3x}{2}} - 4} \tag{1}$$

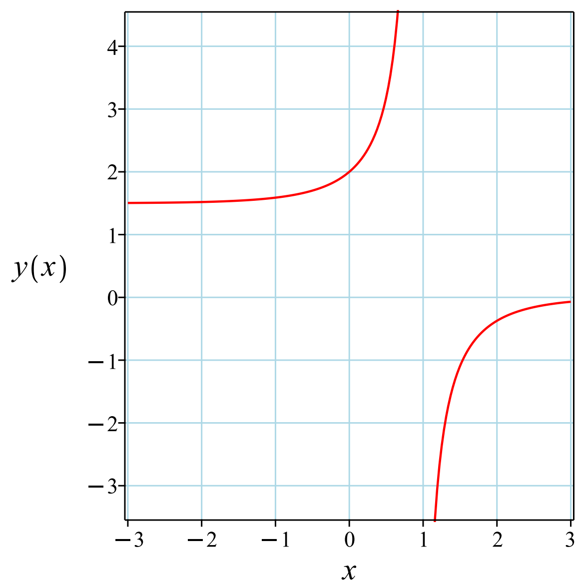

Figure 721: Solution plot

Verification of solutions

$$y = -\frac{6}{e^{\frac{3x}{2}} - 4}$$

Verified OK.

18.33.2 Maple step by step solution

Let's solve

$$\left[y y'' + \left(-y^2 - y'\right) y' = 0, y(0) = 2, y'\Big|_{\{x=0\}} = 1\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

$u(x) = y'$

- Compute y''

$u'(x) = y''$

- Use chain rule on the lhs

$y'\left(\frac{d}{dy}u(y)\right) = y''$

- Substitute in the definition of u

$u(y)\left(\frac{d}{dy}u(y)\right) = y''$

- Make substitutions $y' = u(y)\,, y'' = u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

$yu(y)\left(\frac{d}{dy}u(y)\right) + (-y^2 - u(y))\,u(y) = 0$

- Isolate the derivative

$\frac{d}{dy}u(y) = \frac{u(y)}{y} + y$

- Group terms with $u(y)$ on the lhs of the ODE and the rest on the rhs of the ODE

$\frac{d}{dy}u(y) - \frac{u(y)}{y} = y$

- The ODE is linear; multiply by an integrating factor $\mu(y)$

$\mu(y)\left(\frac{d}{dy}u(y) - \frac{u(y)}{y}\right) = \mu(y)\,y$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dy}(\mu(y)\,u(y))$

$\mu(y)\left(\frac{d}{dy}u(y) - \frac{u(y)}{y}\right) = \left(\frac{d}{dy}\mu(y)\right)u(y) + \mu(y)\left(\frac{d}{dy}u(y)\right)$

- Isolate $\frac{d}{dy}\mu(y)$

$\frac{d}{dy}\mu(y) = -\frac{\mu(y)}{y}$

- Solve to find the integrating factor

$\mu(y) = \frac{1}{y}$

- Integrate both sides with respect to y

$\int \left(\frac{d}{dy}(\mu(y)\,u(y))\right) dy = \int \mu(y)\,y dy + c_1$

- Evaluate the integral on the lhs

$\mu(y)\,u(y) = \int \mu(y)\,y dy + c_1$

- Solve for $u(y)$

$u(y) = \frac{\int \mu(y) y dy + c_1}{\mu(y)}$

- Substitute $\mu(y) = \frac{1}{y}$

  $u(y) = y\left(\int 1 dy + c_1\right)$

- Evaluate the integrals on the rhs

  $u(y) = y(y + c_1)$

- Solve 1st ODE for $u(y)$

  $u(y) = y(y + c_1)$

- Revert to original variables with substitution $u(y) = y', y = y$

  $y' = y(y + c_1)$

- Separate variables

  $\frac{y'}{y(y+c_1)} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'}{y(y+c_1)} dx = \int 1 dx + c_2$

- Evaluate integral

  $-\frac{\ln(y+c_1)}{c_1} + \frac{\ln(y)}{c_1} = x + c_2$

- Solve for y

  $y = -\frac{c_1 \mathrm{e}^{c_1 c_2 + c_1 x}}{-1 + \mathrm{e}^{c_1 c_2 + c_1 x}}$

☐ Check validity of solution $y = -\frac{c_1 \mathrm{e}^{c_1 c_2 + c_1 x}}{-1 + \mathrm{e}^{c_1 c_2 + c_1 x}}$

- ∘ Use initial condition $y(0) = 2$

  $2 = -\frac{c_1 \mathrm{e}^{c_1 c_2}}{-1 + \mathrm{e}^{c_1 c_2}}$

- ∘ Compute derivative of the solution

  $y' = \frac{c_1^2 \left(\mathrm{e}^{c_1 c_2 + c_1 x}\right)^2}{\left(-1 + \mathrm{e}^{c_1 c_2 + c_1 x}\right)^2} - \frac{c_1^2 \mathrm{e}^{c_1 c_2 + c_1 x}}{-1 + \mathrm{e}^{c_1 c_2 + c_1 x}}$

- ∘ Use the initial condition $y'\Big|_{\{x=0\}} = 1$

  $1 = \frac{c_1^2 \left(\mathrm{e}^{c_1 c_2}\right)^2}{\left(-1 + \mathrm{e}^{c_1 c_2}\right)^2} - \frac{c_1^2 \mathrm{e}^{c_1 c_2}}{-1 + \mathrm{e}^{c_1 c_2}}$

- ∘ Solve for c_1 and c_2

  $\left\{c_1 = -\frac{3}{2}, c_2 = -\frac{4 \ln(2)}{3}\right\}$

- ∘ Substitute constant values into general solution and simplify

$$y = \frac{6\,\mathrm{e}^{-\frac{3x}{2}}}{-1+4\,\mathrm{e}^{-\frac{3x}{2}}}$$

- Solution to the IVP

$$y = \frac{6\,\mathrm{e}^{-\frac{3x}{2}}}{-1+4\,\mathrm{e}^{-\frac{3x}{2}}}$$

Section: Exercise 35, page 157
Problem number: 34.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y], [_2nd_order, _reducible, _mu_y_y1]]
```

$$\boxed{(x^2+1)\,y''+y'^2=-1}$$

With initial conditions

$$[y(0)=1, y'(0)=1]$$

18.34.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x)=y'$$

Then

$$p'(x)=y''$$

Hence the ode becomes

$$(x^2+1)\,p'(x)+1+p(x)^2=0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned} p' &= F(x,p) \\ &= f(x)g(p) \\ &= \frac{-p^2-1}{x^2+1} \end{aligned}$$

Where $f(x) = \frac{1}{x^2+1}$ and $g(p) = -p^2-1$. Integrating both sides gives

$$\frac{1}{-p^2-1}\,dp = \frac{1}{x^2+1}\,dx$$

$$\int \frac{1}{-p^2-1}\,dp = \int \frac{1}{x^2+1}\,dx$$

$$-\arctan(p) = \arctan(x) + c_1$$

The solution is

$$-\arctan(p(x)) - \arctan(x) - c_1 = 0$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $p = 1$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{\pi}{4} - c_1 = 0$$

$$c_1 = -\frac{\pi}{4}$$

Substituting c_1 found above in the general solution gives

$$-\arctan(p) - \arctan(x) + \frac{\pi}{4} = 0$$

Solving for $p(x)$ from the above gives

$$p(x) = \cot\left(\arctan(x) + \frac{\pi}{4}\right)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \cot\left(\arctan(x) + \frac{\pi}{4}\right)$$

Integrating both sides gives

$$\begin{aligned} y &= \int \cot\left(\arctan(x) + \frac{\pi}{4}\right) dx \\ &= -x + 2\ln(x+1) + c_2 \end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_2$$

$$c_2 = 1$$

Substituting c_2 found above in the general solution gives

$$y = -x + 2\ln(x+1) + 1$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$y = -x + 2\ln(x+1) + 1 \tag{1}$$

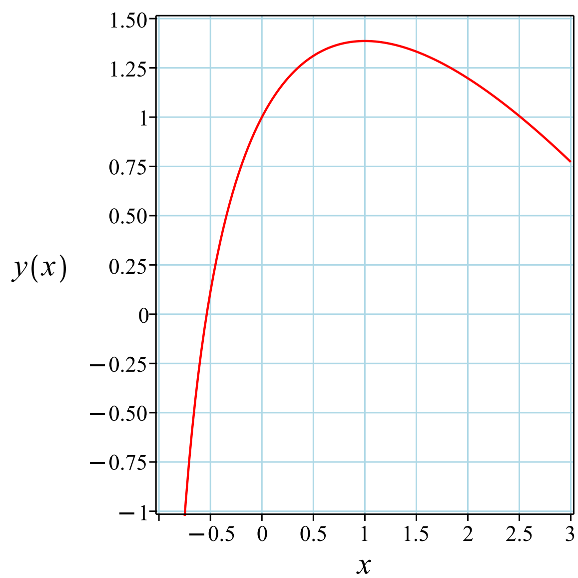

Figure 722: Solution plot

Verification of solutions

$$y = -x + 2\ln(x+1) + 1$$

Verified OK.

18.34.2 Maple step by step solution

Let's solve

$$\left[(x^2+1)\, y''+y'^2=-1, y(0)=1, y'\Big|_{\{x=0\}}=1\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u=y'$ to reduce order of ODE

  $(x^2+1)\, u'(x)+u(x)^2=-1$

- Separate variables

  $\frac{u'(x)}{-u(x)^2-1}=\frac{1}{x^2+1}$

- Integrate both sides with respect to x

  $\int \frac{u'(x)}{-u(x)^2-1}dx=\int \frac{1}{x^2+1}dx+c_1$

- Evaluate integral

  $-\arctan\left(u(x)\right)=\arctan\left(x\right)+c_1$

- Solve for $u(x)$

  $u(x)=-\tan\left(\arctan\left(x\right)+c_1\right)$

- Solve 1st ODE for $u(x)$

  $u(x)=-\tan\left(\arctan\left(x\right)+c_1\right)$

  $y'=-\tan\left(\arctan\left(x\right)+c_1\right)$

- Integrate both sides to solve for y

  $\int y'dx=\int -\tan\left(\arctan\left(x\right)+c_1\right)dx+c_2$

- Compute integrals

  $y=\frac{\mathrm{I}\, \mathrm{e}^{4\, \mathrm{I} c_1} x}{\left(\mathrm{e}^{2\, \mathrm{I} c_1}-1\right)^2}-\frac{4\, \mathrm{e}^{2\, \mathrm{I} c_1} \ln\left(\left(-\mathrm{e}^{2\, \mathrm{I} c_1}+1\right)x+\mathrm{I}\, \mathrm{e}^{2\, \mathrm{I} c_1}+\mathrm{I}\right)}{\left(\mathrm{e}^{2\, \mathrm{I} c_1}-1\right)^2}-\frac{\mathrm{I} x}{\left(\mathrm{e}^{2\, \mathrm{I} c_1}-1\right)^2}+c_2$

□ Check validity of solution $y=\frac{\mathrm{I}\mathrm{e}^{4\, \mathrm{I} c_1} x}{\left(\mathrm{e}^{2\, \mathrm{I} c_1}-1\right)^2}-\frac{4\mathrm{e}^{2\, \mathrm{I} c_1} \ln\left(\left(-\mathrm{e}^{2\, \mathrm{I} c_1}+1\right)x+\mathrm{I}\mathrm{e}^{2\, \mathrm{I} c_1}+\mathrm{I}\right)}{\left(\mathrm{e}^{2\, \mathrm{I} c_1}-1\right)^2}-\frac{\mathrm{I} x}{\left(\mathrm{e}^{2\, \mathrm{I} c_1}-1\right)^2}+c_2$

  - Use initial condition $y(0)=1$

    $1=-\frac{4\, \mathrm{e}^{2\, \mathrm{I} c_1} \ln\left(\mathrm{I}+\mathrm{I}\, \mathrm{e}^{2\, \mathrm{I} c_1}\right)}{\left(\mathrm{e}^{2\, \mathrm{I} c_1}-1\right)^2}+c_2$

  - Compute derivative of the solution

$$y' = \frac{\mathrm{I}\,\mathrm{e}^{4\,\mathrm{I}c_1}}{\left(\mathrm{e}^{2\,\mathrm{I}c_1}-1\right)^2} - \frac{4\,\mathrm{e}^{2\,\mathrm{I}c_1}\left(-\mathrm{e}^{2\,\mathrm{I}c_1}+1\right)}{\left(\mathrm{e}^{2\,\mathrm{I}c_1}-1\right)^2\left(\left(-\mathrm{e}^{2\,\mathrm{I}c_1}+1\right)x+\mathrm{I}\,\mathrm{e}^{2\,\mathrm{I}c_1}+\mathrm{I}\right)} - \frac{\mathrm{I}}{\left(\mathrm{e}^{2\,\mathrm{I}c_1}-1\right)^2}$$

- Use the initial condition $y'\Big|_{\{x=0\}} = 1$

$$1 = \frac{\mathrm{I}\,\mathrm{e}^{4\,\mathrm{I}c_1}}{\left(\mathrm{e}^{2\,\mathrm{I}c_1}-1\right)^2} - \frac{4\,\mathrm{e}^{2\,\mathrm{I}c_1}\left(-\mathrm{e}^{2\,\mathrm{I}c_1}+1\right)}{\left(\mathrm{e}^{2\,\mathrm{I}c_1}-1\right)^2\left(\mathrm{I}+\mathrm{I}\,\mathrm{e}^{2\,\mathrm{I}c_1}\right)} - \frac{\mathrm{I}}{\left(\mathrm{e}^{2\,\mathrm{I}c_1}-1\right)^2}$$

- Solve for c_1 and c_2

$$\left\{c_1 = -\frac{\pi}{4}, c_2 = 1 - 2\ln\left(1+\mathrm{I}\right)\right\}$$

- Substitute constant values into general solution and simplify

$$y = -x + 2\ln\left(\left(1+\mathrm{I}\right)\left(x+1\right)\right) + 1 - \ln\left(2\right) - \frac{\mathrm{I}\pi}{2}$$

- Solution to the IVP

$$y = -x + 2\ln\left(\left(1+\mathrm{I}\right)\left(x+1\right)\right) + 1 - \ln\left(2\right) - \frac{\mathrm{I}\pi}{2}$$

Internal file name [OUTPUT/2307_Tuesday_February_27_2024_08_25_39_AM_11739347/index.tex]

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 35.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{yy'' - y^3 - y'^2 = 0}$$

With initial conditions

$$[y(0) = 1, y'(0) = 2]$$

18.35.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$yp(y) \left(\frac{d}{dy}p(y)\right) - y^3 - p(y)^2 = 0$$

Which is now solved as first order ode for $p(y)$. Using the change of variables $p(y) = u(y)\,y$ on the above ode results in new ode in $u(y)$

$$y^2u(y) \left(\left(\frac{d}{dy}u(y)\right) y + u(y)\right) - u(y)^2\, y^2 = y^3$$

Integrating both sides gives

$$\int u du = y + c_2$$
$$\frac{u^2}{2} = y + c_2$$

Solving for u gives these solutions

$$u_1 = \sqrt{2c_2 + 2y}$$
$$u_2 = -\sqrt{2c_2 + 2y}$$

Therefore the solution $p(y)$ is

$$\begin{aligned} p(y) &= yu \\ &= y\sqrt{2c_2 + 2y} \end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $y = 1$ and $p = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = \sqrt{2c_2 + 2}$$

$$c_2 = 1$$

Substituting c_2 found above in the general solution gives

$$p(y) = \sqrt{2 + 2y}\, y$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = \sqrt{2 + 2y}\, y$$

Integrating both sides gives

$$\int \frac{1}{\sqrt{2+2y}\, y} dy = \int dx$$

$$-\sqrt{2}\, \operatorname{arctanh}\left(\frac{\sqrt{2}\, \sqrt{2+2y}}{2}\right) = x + c_3$$

Initial conditions are used to solve for c_3. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$-\operatorname{arccoth}\left(\sqrt{2}\right) \sqrt{2} + \frac{i\pi\sqrt{2}}{2} = c_3$$

$$c_3 = -\operatorname{arccoth}\left(\sqrt{2}\right) \sqrt{2} + \frac{i\pi\sqrt{2}}{2}$$

Substituting c_3 found above in the general solution gives

$$-\sqrt{2}\, \operatorname{arctanh}\left(\frac{\sqrt{2}\, \sqrt{2+2y}}{2}\right) = x - \operatorname{arccoth}\left(\sqrt{2}\right) \sqrt{2} + \frac{i\pi\sqrt{2}}{2}$$

Initial conditions are used to solve for the constants of integration.

<u>Summary</u>

The solution(s) found are the following

$$y = \tanh\left(\frac{\left(-i\pi\sqrt{2} + 2 \operatorname{arccoth}\left(\sqrt{2}\right) \sqrt{2} - 2x\right) \sqrt{2}}{4}\right)^2 - 1 \tag{1}$$

<u>Verification of solutions</u>

$$y = \tanh\left(\frac{\left(-i\pi\sqrt{2} + 2 \operatorname{arccoth}\left(\sqrt{2}\right) \sqrt{2} - 2x\right) \sqrt{2}}{4}\right)^2 - 1$$

Verified OK.

Problem number: 36.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1]]
```

$$\boxed{\left(1+y'^2\right)^2 - y^2 y'' = 0}$$

With initial conditions

$$\left[y(0) = 3, y'(0) = \sqrt{2}\right]$$

18.36.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$-y^2p(y)\left(\frac{d}{dy}p(y)\right)+\left(p(y)^3+2p(y)\right)p(y)=-1$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$\begin{aligned}p' &= F(y,p)\\ &= f(y)g(p)\\ &= \frac{(p^2+1)^2}{y^2p}\end{aligned}$$

Where $f(y)=\frac{1}{y^2}$ and $g(p)=\frac{(p^2+1)^2}{p}$. Integrating both sides gives

$$\frac{1}{\frac{(p^2+1)^2}{p}}\,dp=\frac{1}{y^2}\,dy$$

$$\int\frac{1}{\frac{(p^2+1)^2}{p}}\,dp=\int\frac{1}{y^2}\,dy$$

$$-\frac{1}{2(p^2+1)}=-\frac{1}{y}+c_1$$

The solution is

$$-\frac{1}{2\left(p(y)^2+1\right)}+\frac{1}{y}-c_1=0$$

Initial conditions are used to solve for c_1. Substituting $y=3$ and $p=\sqrt{2}$ in the above solution gives an equation to solve for the constant of integration.

$$-c_1+\frac{1}{6}=0$$

$$c_1=\frac{1}{6}$$

Substituting c_1 found above in the general solution gives

$$-\frac{p^2y-6p^2+4y-6}{6(p^2+1)y}=0$$

The above simplifies to

$$-p^2y+6p^2-4y+6=0$$

Solving for $p(y)$ from the above gives

$$p(y) = -\frac{\sqrt{2}\,\sqrt{-2y^2+15y-18}}{y-6}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = -\frac{\sqrt{2}\,\sqrt{-2y^2+15y-18}}{y-6}$$

Integrating both sides gives

$$\int -\frac{(y-6)\sqrt{2}}{2\sqrt{-2y^2+15y-18}}dy = \int dx$$

$$-\frac{\sqrt{2}\left(-\frac{\sqrt{-2y^2+15y-18}}{2} - \frac{9\sqrt{2}\arcsin\left(\frac{4y}{9}-\frac{5}{3}\right)}{8}\right)}{2} = x + c_2$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $y = 3$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{9\arcsin\left(\frac{1}{3}\right)}{8} + \frac{3\sqrt{2}}{4} = c_2$$

$$c_2 = -\frac{9\arcsin\left(\frac{1}{3}\right)}{8} + \frac{3\sqrt{2}}{4}$$

Substituting c_2 found above in the general solution gives

$$-\frac{\sqrt{2}\left(-\frac{\sqrt{-2y^2+15y-18}}{2} - \frac{9\sqrt{2}\arcsin\left(\frac{4y}{9}-\frac{5}{3}\right)}{8}\right)}{2} = x - \frac{9\arcsin\left(\frac{1}{3}\right)}{8} + \frac{3\sqrt{2}}{4}$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$\frac{9\arcsin\left(\frac{4y}{9}-\frac{5}{3}\right)}{8} + \frac{\sqrt{2}\,\sqrt{-2y^2+15y-18}}{4} = x - \frac{9\arcsin\left(\frac{1}{3}\right)}{8} + \frac{3\sqrt{2}}{4} \tag{1}$$

Verification of solutions

$$\frac{9\arcsin\left(\frac{4y}{9}-\frac{5}{3}\right)}{8} + \frac{\sqrt{2}\,\sqrt{-2y^2+15y-18}}{4} = x - \frac{9\arcsin\left(\frac{1}{3}\right)}{8} + \frac{3\sqrt{2}}{4}$$

Verified OK.

18.36.2 Maple step by step solution

Let's solve

$$\left[-y^2y''+\left(y'^3+2y'\right)y'=-1, y(0)=3, y'\Big|_{\{x=0\}}=\sqrt{2}\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x)=y'$

- Compute y''

  $u'(x)=y''$

- Use chain rule on the lhs

  $y'\left(\frac{d}{dy}u(y)\right)=y''$

- Substitute in the definition of u

  $u(y)\left(\frac{d}{dy}u(y)\right)=y''$

- Make substitutions $y'=u(y), y''=u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

  $-y^2u(y)\left(\frac{d}{dy}u(y)\right)+\left(u(y)^3+2u(y)\right)u(y)=-1$

- Separate variables

  $\frac{\left(\frac{d}{dy}u(y)\right)u(y)}{-\left(u(y)^3+2u(y)\right)u(y)-1}=-\frac{1}{y^2}$

- Integrate both sides with respect to y

  $\int\frac{\left(\frac{d}{dy}u(y)\right)u(y)}{-\left(u(y)^3+2u(y)\right)u(y)-1}dy=\int-\frac{1}{y^2}dy+c_1$

- Evaluate integral

  $\frac{1}{2\left(u(y)^2+1\right)}=\frac{1}{y}+c_1$

- Solve for $u(y)$

  $\left\{u(y)=-\frac{\sqrt{-2(yc_1+1)(2yc_1-y+2)}}{2(yc_1+1)}, u(y)=\frac{\sqrt{-2(yc_1+1)(2yc_1-y+2)}}{2(yc_1+1)}\right\}$

- Solve 1st ODE for $u(y)$

  $u(y)=-\frac{\sqrt{-2(yc_1+1)(2yc_1-y+2)}}{2(yc_1+1)}$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = -\frac{\sqrt{-2(yc_1+1)(2yc_1-y+2)}}{2(yc_1+1)}$$

- Separate variables

$$\frac{y'(yc_1+1)}{\sqrt{-2(yc_1+1)(2yc_1-y+2)}} = -\frac{1}{2}$$

- Integrate both sides with respect to x

$$\int \frac{y'(yc_1+1)}{\sqrt{-2(yc_1+1)(2yc_1-y+2)}}dx = \int -\frac{1}{2}dx + c_2$$

- Evaluate integral

$$\frac{\sqrt{2}\arctan\left(\frac{\sqrt{2}\sqrt{c_1(-1+2c_1)}\left(y-\frac{-8c_1+2}{4c_1(-1+2c_1)}\right)}{\sqrt{-4-2c_1(-1+2c_1)y^2+(-8c_1+2)y}}\right)}{2\sqrt{c_1(-1+2c_1)}} + c_1\left(-\frac{\sqrt{-4-2c_1(-1+2c_1)y^2+(-8c_1+2)y}}{2c_1(-1+2c_1)} + \frac{(-8c_1+2)\sqrt{2}\arctan\left(\frac{\sqrt{2}\sqrt{c_1}}{\sqrt{-4-}}\right.}{8c_1(-1+2c_1)}\right.$$

- Solve for y

$$\left\{\frac{RootOf\left(\_Z^2+(16c_1-4)\_Z+256c_1^4c_2^2-256c_1^4c_2x+64c_1^4x^2+32\sqrt{2}\sqrt{2c_1^2-c_1}\,c_1c_2RootOf\left((-1+2c_1)c_1\left(-1+48c_1^2c_2^2-4\sqrt{2}\sqrt{2c_1^2-}\right.\right.\right.}{}\right.$$

- Solve 2nd ODE for $u(y)$

$$u(y) = \frac{\sqrt{-2(yc_1+1)(2yc_1-y+2)}}{2(yc_1+1)}$$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = \frac{\sqrt{-2(yc_1+1)(2yc_1-y+2)}}{2(yc_1+1)}$$

- Separate variables

$$\frac{y'(yc_1+1)}{\sqrt{-2(yc_1+1)(2yc_1-y+2)}} = \frac{1}{2}$$

- Integrate both sides with respect to x

$$\int \frac{y'(yc_1+1)}{\sqrt{-2(yc_1+1)(2yc_1-y+2)}}dx = \int \frac{1}{2}dx + c_2$$

- Evaluate integral

$$\frac{\sqrt{2}\arctan\left(\frac{\sqrt{2}\sqrt{c_1(-1+2c_1)}\left(y-\frac{-8c_1+2}{4c_1(-1+2c_1)}\right)}{\sqrt{-4-2c_1(-1+2c_1)y^2+(-8c_1+2)y}}\right)}{2\sqrt{c_1(-1+2c_1)}} + c_1\left(-\frac{\sqrt{-4-2c_1(-1+2c_1)y^2+(-8c_1+2)y}}{2c_1(-1+2c_1)} + \frac{(-8c_1+2)\sqrt{2}\arctan\left(\frac{\sqrt{2}\sqrt{c_1}}{\sqrt{-4-}}\right.}{8c_1(-1+2c_1)}\right.$$

- Solve for y

$$\left\{\frac{RootOf\left(\_Z^2+(16c_1-4)\_Z+256c_1^4c_2^2+256c_1^4c_2x+64c_1^4x^2+32\sqrt{2c_1^2-c_1}\,\sqrt{2}\,c_1c_2\,RootOf\left((-1+2c_1)c_1\left(-1+48c_1^2c_2^2-4\sqrt{2}\,\sqrt{2c_1^2-\right.\right.\right.}{}\right.$$

- Check validity of solution $\frac{RootOf\left(\_Z^2+(16c_1-4)\_Z+256c_1^4c_2^2-256c_1^4c_2x+64c_1^4x^2+32\sqrt{2}\,\sqrt{2c_1^2-c_1}\,c_1c_2\,RootOf\left((-1\right.\right.}{}$
  - Use initial condition $y(0)=3$

    $$\frac{RootOf\left(\_Z^2+(16c_1-4)\_Z+256c_1^4c_2^2+32\sqrt{2}\,\sqrt{2c_1^2-c_1}\,c_1c_2\,RootOf\left((-1+2c_1)c_1\left(-1+48c_1^2c_2^2-4\sqrt{2}\,\sqrt{2c_1^2-c_1}\,c_2\_Z-4\sqrt{2c_1^2-c_1}\right.\right.\right.}{}$$

  - Compute derivative of the solution
  - Use the initial condition $y'\Big|_{\{x=0\}}=\sqrt{2}$
  - Solve for c_1 and c_2

    $$\left\{c_1=c_1, c_2=\frac{2\,RootOf\left(-1+(64c_1^2-32c_1)\_Z^2\right)}{-1+2c_1}\right\}$$

  - Substitute constant values into general solution and simplify

    $$\frac{RootOf\left(\_Z^2+(16c_1-4)\_Z+4\cos\left(RootOf\left(\left(-16c_1^4x^2+4\sqrt{2}\,\sqrt{2c_1^2-c_1}\,c_1x\_Z+64c_1^3\,RootOf\left(-1+(64c_1^2-32c_1)\_Z^2\right)x+24c_1^3x^2\right.\right.\right.\right.}{}$$

- Check validity of solution $\frac{RootOf\left(\_Z^2+(16c_1-4)\_Z+256c_1^4c_2^2+256c_1^4c_2x+64c_1^4x^2+32\sqrt{2c_1^2-c_1}\,\sqrt{2}\,c_1c_2\,RootOf\left((-1\right.\right.}{}$
  - Use initial condition $y(0)=3$

    $$\frac{RootOf\left(\_Z^2+(16c_1-4)\_Z+256c_1^4c_2^2+32\sqrt{2}\,\sqrt{2c_1^2-c_1}\,c_1c_2\,RootOf\left((-1+2c_1)c_1\left(-1+48c_1^2c_2^2-4\sqrt{2}\,\sqrt{2c_1^2-c_1}\,c_2\_Z-4\sqrt{2c_1^2-c_1}\right.\right.\right.}{}$$

  - Compute derivative of the solution
  - Use the initial condition $y'\Big|_{\{x=0\}}=\sqrt{2}$
  - Solve for c_1 and c_2

    $$\left\{c_1=c_1, c_2=\frac{2\,RootOf\left(-1+(64c_1^2-32c_1)\_Z^2\right)}{-1+2c_1}\right\}$$

  - Substitute constant values into general solution and simplify

    $$\frac{RootOf\left(\_Z^2+(16c_1-4)\_Z+4\cos\left(RootOf\left((-1+2c_1)\left(16c_1^4x^2+4\sqrt{2}\,\sqrt{2c_1^2-c_1}\,c_1x\_Z+64c_1^3\,RootOf\left(-1+(64c_1^2-32c_1)\_Z^2\right)x\right.\right.\right.\right.}{}$$

- Solutions to the IVP

$$\begin{cases} \frac{RootOf\left(\_Z^2+(16c_1-4)\_Z+4\cos\left(RootOf\left((-1+2c_1)\left(16c_1^4x^2+4\sqrt{2}\sqrt{2c_1^2-c_1}\,c_1x\_Z+64c_1^3RootOf\left(-1+(64c_1^2-32c_1)\_Z^2\right.\right.\right.\right.\right.}{} \end{cases}$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 37.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y], [_2nd_order, _reducible, _mu_y_y1]]
```

$$\boxed{y'' - {y'}^2 \sin(x) = 0}$$

With initial conditions

$$\left[y(0) = 0, y'(0) = \frac{1}{2}\right]$$

18.37.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - p(x)^2 \sin(x) = 0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned} p' &= F(x,p) \\ &= f(x)g(p) \\ &= p^2 \sin(x) \end{aligned}$$

Where $f(x) = \sin(x)$ and $g(p) = p^2$. Integrating both sides gives

$$\begin{aligned} \frac{1}{p^2}\,dp &= \sin(x)\,dx \\ \int \frac{1}{p^2}\,dp &= \int \sin(x)\,dx \\ -\frac{1}{p} &= -\cos(x) + c_1 \end{aligned}$$

The solution is

$$-\frac{1}{p(x)} + \cos(x) - c_1 = 0$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $p = \frac{1}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$-1 - c_1 = 0$$

$$c_1 = -1$$

Substituting c_1 found above in the general solution gives

$$\frac{\cos(x)\,p - 1 + p}{p} = 0$$

The above simplifies to

$$\cos(x)\,p - 1 + p = 0$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y'\cos(x) - 1 + y' = 0$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int \frac{1}{\cos(x)+1}\, dx \\
&= \tan\left(\frac{x}{2}\right)+c_2
\end{aligned}
$$

Initial conditions are used to solve for c_2. Substituting $x=0$ and $y=0$ in the above solution gives an equation to solve for the constant of integration.

$$
0 = c_2
$$

$$
c_2 = 0
$$

Substituting c_2 found above in the general solution gives

$$
y = \tan\left(\frac{x}{2}\right)
$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$
y = \tan\left(\frac{x}{2}\right) \tag{1}
$$

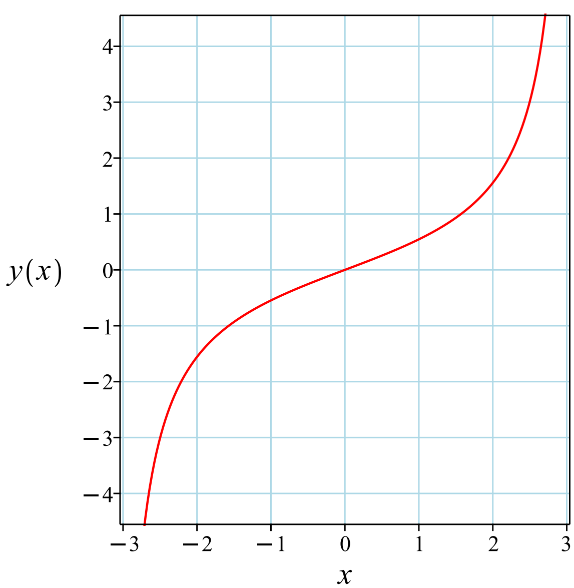

Figure 723: Solution plot

Verification of solutions

$$y = \tan\left(\frac{x}{2}\right)$$

Verified OK.

Problem number: 38.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{2yy'' - y^3 - 2y'^2 = 0}$$

With initial conditions

$$[y(0) = -1, y'(0) = 0]$$

18.38.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$2yp(y)\left(\frac{d}{dy}p(y)\right)-y^3-2p(y)^2=0$$

Which is now solved as first order ode for $p(y)$. Using the change of variables $p(y) = u(y)\,y$ on the above ode results in new ode in $u(y)$

$$2y^2u(y)\left(\left(\frac{d}{dy}u(y)\right)y+u(y)\right)-2u(y)^2\,y^2=y^3$$

Integrating both sides gives

$$\begin{aligned}\int 2udu &= y+c_2\\ u^2 &= y+c_2\end{aligned}$$

Solving for u gives these solutions

$$\begin{aligned}u_1 &= \sqrt{y+c_2}\\ u_2 &= -\sqrt{y+c_2}\end{aligned}$$

Therefore the solution $p(y)$ is

$$\begin{aligned}p(y) &= yu\\ &= y\sqrt{y+c_2}\end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $y=-1$ and $p=0$ in the above solution gives an equation to solve for the constant of integration.

$$0=-\sqrt{c_2-1}$$

$$c_2=1$$

Substituting c_2 found above in the general solution gives

$$p(y)=\sqrt{y+1}\,y$$

For solution (1) found earlier, since $p=y'$ then we now have a new first order ode to solve which is

$$y'=\sqrt{y+1}\,y$$

Integrating both sides gives

$$\int \frac{1}{\sqrt{y+1}\, y} dy = \int dx$$

$$-2 \operatorname{arctanh}\left(\sqrt{y+1}\right) = x + c_3$$

Initial conditions are used to solve for c_3. Substituting $x = 0$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_3$$

$$c_3 = 0$$

Substituting c_3 found above in the general solution gives

$$-2 \operatorname{arctanh}\left(\sqrt{y+1}\right) = x$$

Solving for y from the above gives

$$y = -\operatorname{sech}\left(\frac{x}{2}\right)^2$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$y = -\operatorname{sech}\left(\frac{x}{2}\right)^2 \tag{1}$$

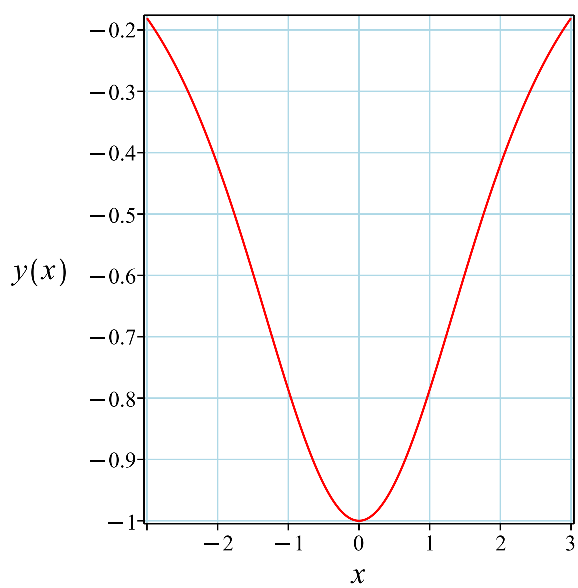

Figure 724: Solution plot

Verification of solutions

$$y = -\operatorname{sech}\left(\frac{x}{2}\right)^2$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 39.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

`[[_2nd_order, _missing_x]]`

$$\boxed{x'' - k^2 x = 0}$$

With initial conditions

$$[x(0) = 0, x'(0) = v_0]$$

18.39.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x'' + p(t)x' + q(t)x = F$$

Where here

$$\begin{aligned} p(t) &= 0 \\ q(t) &= -k^2 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$x'' - k^2 x = 0$$

The domain of $p(t) = 0$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = -k^2$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

18.39.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ax''(t) + Bx'(t) + Cx(t) = 0$$

Where in the above $A = 1, B = 0, C = -k^2$. Let the solution be $x = e^{\lambda t}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda t} - k^2 \mathrm{e}^{\lambda t} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda t}$ gives

$$-k^2 + \lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -k^2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-k^2)} \\ &= \pm\sqrt{k^2}\end{aligned}$$

Hence

$$\lambda_1 = +\sqrt{k^2}$$
$$\lambda_2 = -\sqrt{k^2}$$

Which simplifies to

$$\lambda_1 = \sqrt{k^2}$$
$$\lambda_2 = -\sqrt{k^2}$$

Since roots are real and distinct, then the solution is

$$x = c_1 e^{\lambda_1 t} + c_2 e^{\lambda_2 t}$$
$$x = c_1 e^{\left(\sqrt{k^2}\right)t} + c_2 e^{\left(-\sqrt{k^2}\right)t}$$

Or

$$x = c_1 \mathrm{e}^{\sqrt{k^2}\, t} + c_2 \mathrm{e}^{-\sqrt{k^2}\, t}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$x = c_1 \mathrm{e}^{\sqrt{k^2}\, t} + c_2 \mathrm{e}^{-\sqrt{k^2}\, t} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $x = 0$ and $t = 0$ in the above gives

$$0 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$x' = c_1 \sqrt{k^2}\, \mathrm{e}^{\sqrt{k^2}\, t} - c_2 \sqrt{k^2}\, \mathrm{e}^{-\sqrt{k^2}\, t}$$

substituting $x' = v_0$ and $t = 0$ in the above gives

$$v_0 = \operatorname{csgn}(k)\, k(c_1 - c_2) \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{\operatorname{csgn}(k)\, v_0}{2k}$$
$$c_2 = -\frac{\operatorname{csgn}(k)\, v_0}{2k}$$

Substituting these values back in above solution results in

$$x = \frac{\mathrm{e}^{\sqrt{k^2}\, t} \operatorname{csgn}(k)\, v_0 - \operatorname{csgn}(k)\, v_0 \mathrm{e}^{-\sqrt{k^2}\, t}}{2k}$$

Which simplifies to

$$x = \frac{\operatorname{csgn}(k)\, v_0 \left(e^{\operatorname{csgn}(k) k t} - e^{-\operatorname{csgn}(k) k t}\right)}{2k}$$

Summary

The solution(s) found are the following

$$x = \frac{\operatorname{csgn}(k)\, v_0 \left(e^{\operatorname{csgn}(k) k t} - e^{-\operatorname{csgn}(k) k t}\right)}{2k} \tag{1}$$

Verification of solutions

$$x = \frac{\operatorname{csgn}(k)\, v_0 \left(e^{\operatorname{csgn}(k) k t} - e^{-\operatorname{csgn}(k) k t}\right)}{2k}$$

Verified OK.

18.39.3 Solving as second order ode can be made integrable ode

Multiplying the ode by x' gives

$$x'x'' - k^2 x' x = 0$$

Integrating the above w.r.t t gives

$$\int \left(x'x'' - k^2 x' x\right) dt = 0$$
$$\frac{x'^2}{2} - \frac{k^2 x^2}{2} = c_2$$

Which is now solved for x. Solving the given ode for x' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$x' = \sqrt{k^2 x^2 + 2c_1} \tag{1}$$
$$x' = -\sqrt{k^2 x^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{k^2 x^2 + 2c_1}} dx = \int dt$$
$$\frac{\ln\left(\frac{k^2 x}{\sqrt{k^2}} + \sqrt{k^2 x^2 + 2c_1}\right)}{\sqrt{k^2}} = t + c_2$$

Raising both side to exponential gives

$$e^{\frac{\ln\left(\frac{k^2x}{\sqrt{k^2}}+\sqrt{k^2x^2+2c_1}\right)}{\sqrt{k^2}}} = e^{t+c_2}$$

Which simplifies to

$$\left(kx\ \mathrm{csgn}\left(k\right)+\sqrt{k^2x^2+2c_1}\right)^{\frac{1}{\sqrt{k^2}}} = c_3e^t$$

Simplifying the solution $x = \frac{\mathrm{csgn}(k)\left(\left(c_3e^t\right)^{\mathrm{csgn}(k)k}-2\left(c_3e^t\right)^{-\mathrm{csgn}(k)k}c_1\right)}{2k}$ to $x = \frac{\left(c_3e^t\right)^k-2\left(c_3e^t\right)^{-k}c_1}{2k}$
Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{k^2x^2+2c_1}}dx = \int dt$$

$$-\frac{\ln\left(\frac{k^2x}{\sqrt{k^2}}+\sqrt{k^2x^2+2c_1}\right)}{\sqrt{k^2}} = t+c_4$$

Raising both side to exponential gives

$$e^{-\frac{\ln\left(\frac{k^2x}{\sqrt{k^2}}+\sqrt{k^2x^2+2c_1}\right)}{\sqrt{k^2}}} = e^{t+c_4}$$

Which simplifies to

$$\left(kx\ \mathrm{csgn}\left(k\right)+\sqrt{k^2x^2+2c_1}\right)^{-\frac{\mathrm{csgn}(k)}{k}} = c_5e^t$$

Simplifying the solution $x = -\frac{\mathrm{csgn}(k)\left(2\left(c_5e^t\right)^{\mathrm{csgn}(k)k}c_1-\left(c_5e^t\right)^{-\mathrm{csgn}(k)k}\right)}{2k}$ to $x = -\frac{2\left(c_5e^t\right)^kc_1-\left(c_5e^t\right)^{-k}}{2k}$
Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$x = \frac{\left(c_3e^t\right)^k-2\left(c_3e^t\right)^{-k}c_1}{2k} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $x = 0$ and $t = 0$ in the above gives

$$0 = \frac{c_3^k-2c_3^{-k}c_1}{2k} \tag{1A}$$

Taking derivative of the solution gives

$$x' = \frac{(c_3 e^t)^k k + 2(c_3 e^t)^{-k} k c_1}{2k}$$

substituting $x' = v_0$ and $t = 0$ in the above gives

$$v_0 = \frac{c_3^k}{2} + c_3^{-k} c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. Solving for the constants gives

$$c_1 = \frac{v_0^2}{2}$$
$$c_3 = v_0^{\frac{1}{k}}$$

Substituting these values back in above solution results in

$$x = \frac{\left(v_0^{\frac{1}{k}} e^t\right)^k - \left(v_0^{\frac{1}{k}} e^t\right)^{-k} v_0^2}{2k}$$

Looking at the Second solution

$$x = -\frac{2(c_5 e^t)^k c_1 - (c_5 e^t)^{-k}}{2k} \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $x = 0$ and $t = 0$ in the above gives

$$0 = \frac{-c_5^k c_1 + \frac{c_5^{-k}}{2}}{k} \tag{1A}$$

Taking derivative of the solution gives

$$x' = -\frac{2(c_5 e^t)^k k c_1 + (c_5 e^t)^{-k} k}{2k}$$

substituting $x' = v_0$ and $t = 0$ in the above gives

$$v_0 = -c_5^k c_1 - \frac{c_5^{-k}}{2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_5\}$. Solving for the constants gives

$$c_1 = \frac{v_0^2}{2}$$
$$c_5 = \left(-\frac{1}{v_0}\right)^{\frac{1}{k}}$$

Substituting these values back in above solution results in

$$x = \frac{-\left(\left(-\frac{1}{v_0}\right)^{\frac{1}{k}} \mathrm{e}^t\right)^k v_0^2 + \left(\left(-\frac{1}{v_0}\right)^{\frac{1}{k}} \mathrm{e}^t\right)^{-k}}{2k}$$

Summary

The solution(s) found are the following

$$x = \frac{\left(v_0^{\frac{1}{k}} \mathrm{e}^t\right)^k - \left(v_0^{\frac{1}{k}} \mathrm{e}^t\right)^{-k} v_0^2}{2k} \tag{1}$$

$$x = \frac{-\left(\left(-\frac{1}{v_0}\right)^{\frac{1}{k}} \mathrm{e}^t\right)^k v_0^2 + \left(\left(-\frac{1}{v_0}\right)^{\frac{1}{k}} \mathrm{e}^t\right)^{-k}}{2k} \tag{2}$$

Verification of solutions

$$x = \frac{\left(v_0^{\frac{1}{k}} \mathrm{e}^t\right)^k - \left(v_0^{\frac{1}{k}} \mathrm{e}^t\right)^{-k} v_0^2}{2k}$$

Verified OK.

$$x = \frac{-\left(\left(-\frac{1}{v_0}\right)^{\frac{1}{k}} \mathrm{e}^t\right)^k v_0^2 + \left(\left(-\frac{1}{v_0}\right)^{\frac{1}{k}} \mathrm{e}^t\right)^{-k}}{2k}$$

Verified OK.

18.39.4 Solving using Kovacic algorithm

Writing the ode as

$$x'' - k^2 x = 0 \tag{1}$$

$$Ax'' + Bx' + Cx = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= -k^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = x e^{\int \frac{B}{2A} \, dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{k^2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = k^2$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(t) = \left(k^2\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then x is found using the inverse transformation

$$x = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 613: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = k^2$ is not a function of t, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(t) = e^{\sqrt{k^2}\, t}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in x is found from

$$x_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dt}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}x_1 &= z_1 \\ &= e^{\sqrt{k^2}\, t}\end{aligned}$$

Which simplifies to

$$x_1 = e^{\sqrt{k^2}\, t}$$

The second solution x_2 to the original ode is found using reduction of order

$$x_2 = x_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{x_1^2}\, dt$$

Since $B = 0$ then the above becomes

$$\begin{aligned}x_2 &= x_1 \int \frac{1}{x_1^2}\, dt \\ &= e^{\sqrt{k^2}\, t} \int \frac{1}{e^{2\sqrt{k^2}\, t}}\, dt \\ &= e^{\sqrt{k^2}\, t} \left(-\frac{\operatorname{csgn}(k)\, e^{-2\operatorname{csgn}(k) k t}}{2k} \right)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
x &= c_1 x_1 + c_2 x_2 \\
&= c_1 \left(e^{\sqrt{k^2}\, t}\right) + c_2 \left(e^{\sqrt{k^2}\, t} \left(-\frac{\operatorname{csgn}(k)\, e^{-2 \operatorname{csgn}(k) k t}}{2k}\right)\right)
\end{aligned}
$$

Simplifying the solution $x = c_1 e^{\sqrt{k^2}\, t} - \frac{c_2 \operatorname{csgn}(k) e^{-\operatorname{csgn}(k) k t}}{2k}$ to $x = c_1 e^{\sqrt{k^2}\, t} - \frac{c_2 e^{-kt}}{2k}$ Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
x = c_1 e^{\sqrt{k^2}\, t} - \frac{c_2 e^{-kt}}{2k} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $x = 0$ and $t = 0$ in the above gives

$$
0 = \frac{2c_1 k - c_2}{2k} \tag{1A}
$$

Taking derivative of the solution gives

$$
x' = c_1 \sqrt{k^2}\, e^{\sqrt{k^2}\, t} + \frac{c_2 e^{-kt}}{2}
$$

substituting $x' = v_0$ and $t = 0$ in the above gives

$$
v_0 = \operatorname{csgn}(k)\, k c_1 + \frac{c_2}{2} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= \frac{v_0}{k\left(\operatorname{csgn}(k) + 1\right)} \\
c_2 &= \frac{2v_0}{\operatorname{csgn}(k) + 1}
\end{aligned}
$$

Substituting these values back in above solution results in

$$
x = \frac{e^{\sqrt{k^2}\, t} v_0 - e^{-kt} v_0}{\operatorname{csgn}(k)\, k + k}
$$

Which simplifies to

$$
x = -\frac{v_0 \left(e^{-kt} - e^{\operatorname{csgn}(k) k t}\right)}{k\left(\operatorname{csgn}(k) + 1\right)}
$$

Summary

The solution(s) found are the following

$$x = -\frac{v_0 \left(\mathrm{e}^{-kt} - \mathrm{e}^{\mathrm{csgn}(k) k t}\right)}{k \left(\mathrm{csgn}\left(k\right)+1\right)} \tag{1}$$

Verification of solutions

$$x = -\frac{v_0 \left(\mathrm{e}^{-kt} - \mathrm{e}^{\mathrm{csgn}(k) k t}\right)}{k \left(\mathrm{csgn}\left(k\right)+1\right)}$$

Verified OK.

18.39.5 Maple step by step solution

Let's solve

$\left[x'' - k^2 x = 0, x(0) = 0, x'\Big|_{\{t=0\}} = v_0\right]$

- Highest derivative means the order of the ODE is 2

  x''

- Characteristic polynomial of ODE

  $-k^2 + r^2 = 0$

- Factor the characteristic polynomial

  $-(k-r)(k+r) = 0$

- Roots of the characteristic polynomial

  $r = (k, -k)$

- 1st solution of the ODE

  $x_1(t) = \mathrm{e}^{kt}$

- 2nd solution of the ODE

  $x_2(t) = \mathrm{e}^{-kt}$

- General solution of the ODE

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 40.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_xy]]
```

$$\boxed{yy'' - 2y'^2 - y^2 = 0}$$

With initial conditions

$$\left[y(0) = 1, y'(0) = \sqrt{3}\right]$$

18.40.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$yp(y)\left(\frac{d}{dy}p(y)\right)-2p(y)^2-y^2=0$$

Which is now solved as first order ode for $p(y)$. Using the change of variables $p(y) = u(y)\, y$ on the above ode results in new ode in $u(y)$

$$y^2u(y)\left(\left(\frac{d}{dy}u(y)\right)y+u(y)\right)-2u(y)^2\,y^2=y^2$$

In canonical form the ODE is

$$\begin{aligned}
u' &= F(y,u)\\
&= f(y)g(u)\\
&= \frac{u^2+1}{uy}
\end{aligned}$$

Where $f(y)=\frac{1}{y}$ and $g(u)=\frac{u^2+1}{u}$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{\frac{u^2+1}{u}}\,du &= \frac{1}{y}\,dy\\
\int\frac{1}{\frac{u^2+1}{u}}\,du &= \int\frac{1}{y}\,dy\\
\frac{\ln\left(u^2+1\right)}{2} &= \ln\left(y\right)+c_2
\end{aligned}$$

Raising both side to exponential gives

$$\sqrt{u^2+1}=\mathrm{e}^{\ln(y)+c_2}$$

Which simplifies to

$$\sqrt{u^2+1}=c_3y$$

Which simplifies to

$$\sqrt{u\left(y\right)^2+1}=c_3\mathrm{e}^{c_2}y$$

The solution is

$$\sqrt{u\left(y\right)^2+1}=c_3\mathrm{e}^{c_2}y$$

Replacing $u(y)$ in the above solution by $\frac{p(y)}{y}$ results in the solution for $p(y)$ in implicit form

$$\sqrt{\frac{p(y)^2}{y^2}+1} = c_3 e^{c_2} y$$
$$\sqrt{\frac{p(y)^2+y^2}{y^2}} = c_3 e^{c_2} y$$

Substituting initial conditions and solving for c_2 gives $c_2 = \frac{\ln\left(\frac{4}{c_3^2}\right)}{2}$. Hence the solution becomes Initial conditions are used to solve for c_3. Substituting $y = 1$ and $p = \sqrt{3}$ in the above solution gives an equation to solve for the constant of integration.

$$2 = 2c_3\sqrt{\frac{1}{c_3^2}}$$

This solution is valid for any c_3. Hence there are infinite number of solutions.

Solving for $p(y)$ from the above gives

$$p(y) = \sqrt{4y^2-1}\,y$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = \sqrt{4y^2-1}\,y$$

Integrating both sides gives

$$\int \frac{1}{\sqrt{4y^2-1}\,y} dy = \int dx$$
$$-\arctan\left(\frac{1}{\sqrt{4y^2-1}}\right) = x + c_4$$

Initial conditions are used to solve for c_4. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{\pi}{6} = c_4$$

$$c_4 = -\frac{\pi}{6}$$

Substituting c_4 found above in the general solution gives

$$-\arctan\left(\frac{1}{\sqrt{4y^2-1}}\right) = x - \frac{\pi}{6}$$

Solving for y from the above gives

$$y = \frac{\sqrt{\cot\left(x+\frac{\pi}{3}\right)^2+1}}{2\cot\left(x+\frac{\pi}{3}\right)}$$

Simplifying the solution $y = \frac{\sec\left(x+\frac{\pi}{3}\right)\operatorname{csgn}\left(\csc\left(x+\frac{\pi}{3}\right)\right)}{2}$ to $y = \frac{\sec\left(x+\frac{\pi}{3}\right)}{2}$ Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$y = \frac{\sec\left(x+\frac{\pi}{3}\right)}{2} \tag{1}$$

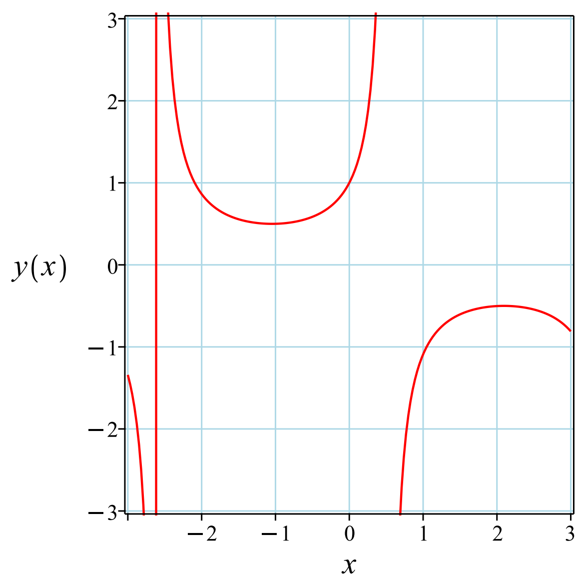

Figure 725: Solution plot

Verification of solutions

$$y = \frac{\sec\left(x+\frac{\pi}{3}\right)}{2}$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 35, page 157
Problem number: 41.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{(1-\mathrm{e}^{x})\, y''-\mathrm{e}^{x} y'=0}$$

With initial conditions

$$[y(1)=0, y'(1)=1]$$

18.41.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -\frac{e^x}{1 - e^x} \\ q(x) &= 0 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - \frac{e^x y'}{1 - e^x} = 0$$

The domain of $p(x) = -\frac{e^x}{1-e^x}$ is

$$\{2i\pi\_Z82 < x\}$$

But the point $x_0 = 1$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

18.41.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\begin{aligned} \int ((1 - e^x) y'' - e^x y') \, dx &= 0 \\ -(-1 + e^x) y' &= c_1 \end{aligned}$$

Which is now solved for y. Integrating both sides gives

$$\begin{aligned} y &= \int -\frac{c_1}{-1 + e^x} \, dx \\ &= -c_1(\ln(-1 + e^x) - \ln(e^x)) + c_2 \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -c_1(\ln(-1 + e^x) - \ln(e^x)) + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 1$ in the above gives

$$0 = -c_1 \ln (-1 + \mathrm{e}) + c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 \left(\frac{\mathrm{e}^x}{-1 + \mathrm{e}^x} - 1 \right)$$

substituting $y' = 1$ and $x = 1$ in the above gives

$$1 = -\frac{c_1}{-1 + \mathrm{e}} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 1 - \mathrm{e} \\ c_2 &= -(-1 + \mathrm{e}) (\ln (-1 + \mathrm{e}) - 1) \end{aligned}$$

Substituting these values back in above solution results in

$$y = -\ln (-1 + \mathrm{e}) \mathrm{e} + \mathrm{e} \ln (-1 + \mathrm{e}^x) - \mathrm{e} \ln (\mathrm{e}^x) + \ln (-1 + \mathrm{e}) + \mathrm{e} - \ln (-1 + \mathrm{e}^x) + \ln (\mathrm{e}^x) - 1$$

Which simplifies to

$$y = -(\ln (\mathrm{e}^x) + \ln (-1 + \mathrm{e}) - \ln (-1 + \mathrm{e}^x) - 1) (-1 + \mathrm{e})$$

Summary

The solution(s) found are the following

$$y = -(\ln (\mathrm{e}^x) + \ln (-1 + \mathrm{e}) - \ln (-1 + \mathrm{e}^x) - 1) (-1 + \mathrm{e}) \tag{1}$$

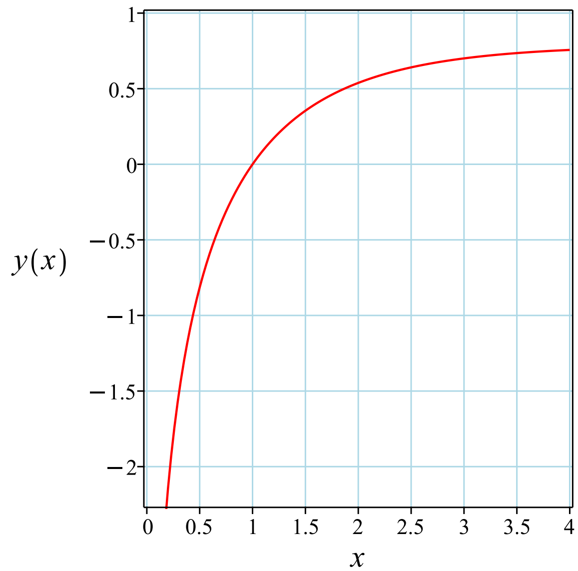

Figure 726: Solution plot

Verification of solutions

$$y = -(\ln(\mathrm{e}^{x}) + \ln(-1+\mathrm{e}) - \ln(-1+\mathrm{e}^{x}) - 1)(-1+\mathrm{e})$$

Verified OK.

18.41.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$(1-\mathrm{e}^{x})\, p'(x) - \mathrm{e}^{x} p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned} p' &= F(x,p) \\ &= f(x)g(p) \\ &= -\frac{\mathrm{e}^{x} p}{-1+\mathrm{e}^{x}} \end{aligned}$$

Where $f(x) = -\frac{e^x}{-1+e^x}$ and $g(p) = p$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{p}\, dp &= -\frac{e^x}{-1+e^x}\, dx \\
\int \frac{1}{p}\, dp &= \int -\frac{e^x}{-1+e^x}\, dx \\
\ln(p) &= -\ln(-1+e^x) + c_1 \\
p &= e^{-\ln(-1+e^x)+c_1} \\
&= \frac{c_1}{-1+e^x}
\end{aligned}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $p = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{c_1}{-1+e}$$

$$c_1 = -1 + e$$

Substituting c_1 found above in the general solution gives

$$p(x) = \frac{-1+e}{-1+e^x}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{-1+e}{-1+e^x}$$

Integrating both sides gives

$$\begin{aligned}
y &= \int \frac{-1+e}{-1+e^x}\, \mathrm{d}x \\
&= (-1+e)\left(\ln(-1+e^x) - \ln(e^x)\right) + c_2
\end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \ln(-1+e)\, e - \ln(-1+e) - e + 1 + c_2$$

$$c_2 = -\ln(-1+e)\, e + \ln(-1+e) + e - 1$$

Substituting c_2 found above in the general solution gives

$$y = -\ln(-1+e)\, e + e\ln(-1+e^x) - e\ln(e^x) + \ln(-1+e) + e - \ln(-1+e^x) + \ln(e^x) - 1$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = &-\ln(-1+\mathrm{e})\,\mathrm{e}+\mathrm{e}\ln(-1+\mathrm{e}^{x})-\mathrm{e}\ln(\mathrm{e}^{x}) \\
&+\ln(-1+\mathrm{e})+\mathrm{e}-\ln(-1+\mathrm{e}^{x})+\ln(\mathrm{e}^{x})-1
\end{aligned} \tag{1}
$$

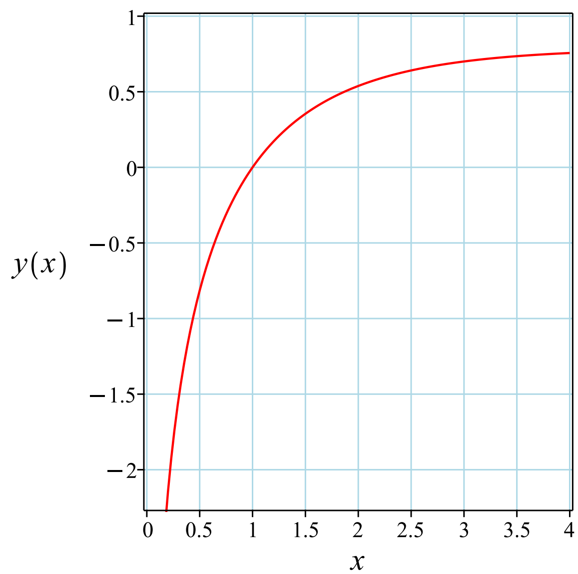

Figure 727: Solution plot

Verification of solutions

$$
y=-\ln(-1+\mathrm{e})\,\mathrm{e}+\mathrm{e}\ln(-1+\mathrm{e}^{x})-\mathrm{e}\ln(\mathrm{e}^{x})+\ln(-1+\mathrm{e})+\mathrm{e}-\ln(-1+\mathrm{e}^{x})+\ln(\mathrm{e}^{x})-1
$$

Verified OK.

18.41.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$
(1-\mathrm{e}^{x})\,y''-\mathrm{e}^{x}y'=0
$$

Integrating both sides of the ODE w.r.t x gives

$$
\int \left((1-\mathrm{e}^{x})\,y''-\mathrm{e}^{x}y'\right)dx = 0
$$

$$
-(-1+\mathrm{e}^{x})\,y' = c_1
$$

Which is now solved for y. Integrating both sides gives

$$
\begin{aligned}
y &= \int -\frac{c_1}{-1+\mathrm{e}^x}\,\mathrm{d}x \\
&= -c_1(\ln(-1+\mathrm{e}^x) - \ln(\mathrm{e}^x)) + c_2
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = -c_1(\ln(-1+\mathrm{e}^x) - \ln(\mathrm{e}^x)) + c_2 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 1$ in the above gives

$$
0 = -c_1 \ln(-1+\mathrm{e}) + c_1 + c_2 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -c_1\left(\frac{\mathrm{e}^x}{-1+\mathrm{e}^x} - 1\right)
$$

substituting $y' = 1$ and $x = 1$ in the above gives

$$
1 = -\frac{c_1}{-1+\mathrm{e}} \tag{2A}
$$

Equations $\{1A,2A\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 1-\mathrm{e} \\
c_2 &= -(-1+\mathrm{e})(\ln(-1+\mathrm{e}) - 1)
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = -\ln(-1+\mathrm{e})\,\mathrm{e} + \mathrm{e}\ln(-1+\mathrm{e}^x) - \mathrm{e}\ln(\mathrm{e}^x) + \ln(-1+\mathrm{e}) + \mathrm{e} - \ln(-1+\mathrm{e}^x) + \ln(\mathrm{e}^x) - 1
$$

Which simplifies to

$$
y = -(\ln(\mathrm{e}^x) + \ln(-1+\mathrm{e}) - \ln(-1+\mathrm{e}^x) - 1)(-1+\mathrm{e})
$$

<u>Summary</u>
The solution(s) found are the following

$$
y = -(\ln(\mathrm{e}^x) + \ln(-1+\mathrm{e}) - \ln(-1+\mathrm{e}^x) - 1)(-1+\mathrm{e}) \tag{1}
$$

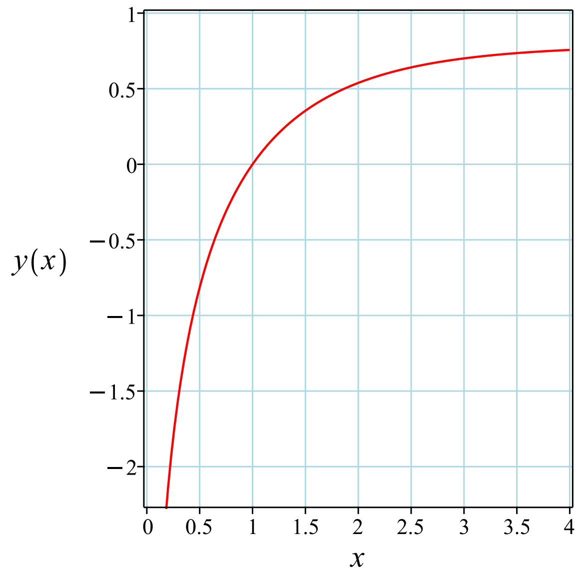

Figure 728: Solution plot

Verification of solutions

$$y = -(\ln(e^x) + \ln(-1+e) - \ln(-1+e^x) - 1)(-1+e)$$

Verified OK.

18.41.5 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 - e^x \\ q(x) &= -e^x \\ r(x) &= 0 \\ s(x) &= 0 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= -e^x \\ q'(x) &= -e^x \end{aligned}$$

Therefore (1) becomes

$$-e^x - (-e^x) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$(1 - e^x)\, y' = c_1$$

We now have a first order ode to solve which is

$$(1 - e^x)\, y' = c_1$$

Integrating both sides gives

$$\begin{aligned} y &= \int -\frac{c_1}{-1 + e^x}\, \mathrm{d}x \\ &= -c_1(\ln(-1 + e^x) - \ln(e^x)) + c_2 \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -c_1(\ln(-1 + e^x) - \ln(e^x)) + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 1$ in the above gives

$$0 = -c_1 \ln(-1 + e) + c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1\left(\frac{e^x}{-1 + e^x} - 1\right)$$

substituting $y' = 1$ and $x = 1$ in the above gives

$$1 = -\frac{c_1}{-1 + e} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1 - \mathrm{e}$$
$$c_2 = -(-1 + \mathrm{e})(\ln(-1 + \mathrm{e}) - 1)$$

Substituting these values back in above solution results in

$$y = -\ln(-1 + \mathrm{e})\,\mathrm{e} + \mathrm{e}\ln(-1 + \mathrm{e}^x) - \mathrm{e}\ln(\mathrm{e}^x) + \ln(-1 + \mathrm{e}) + \mathrm{e} - \ln(-1 + \mathrm{e}^x) + \ln(\mathrm{e}^x) - 1$$

Which simplifies to

$$y = -(\ln(\mathrm{e}^x) + \ln(-1 + \mathrm{e}) - \ln(-1 + \mathrm{e}^x) - 1)(-1 + \mathrm{e})$$

Summary

The solution(s) found are the following

$$y = -(\ln(\mathrm{e}^x) + \ln(-1 + \mathrm{e}) - \ln(-1 + \mathrm{e}^x) - 1)(-1 + \mathrm{e}) \tag{1}$$

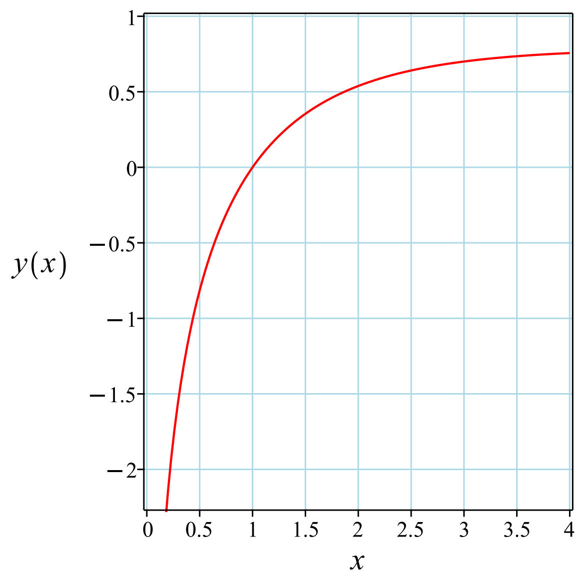

Figure 729: Solution plot

Verification of solutions

$$y = -(\ln(\mathrm{e}^x) + \ln(-1 + \mathrm{e}) - \ln(-1 + \mathrm{e}^x) - 1)(-1 + \mathrm{e})$$

Verified OK.

18.41.6 Maple step by step solution

Let's solve

$$\left[(1-e^x)\,y''-e^x y'=0, y(1)=0, y'\Big|_{\{x=1\}}=1\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u=y'$ to reduce order of ODE

  $(1-e^x)\,u'(x)-e^x u(x)=0$

- Integrate both sides with respect to x

  $\int ((1-e^x)\,u'(x)-e^x u(x))\,dx=\int 0dx+c_1$

- Evaluate integral

  $-(-1+e^x)\,u(x)=c_1$

- Solve for $u(x)$

  $u(x)=-\frac{c_1}{-1+e^x}$

- Solve 1st ODE for $u(x)$

  $u(x)=-\frac{c_1}{-1+e^x}$

- Make substitution $u=y'$

  $y'=-\frac{c_1}{-1+e^x}$

- Integrate both sides to solve for y

  $\int y'dx=\int -\frac{c_1}{-1+e^x}dx+c_2$

- Compute integrals

  $y=-c_1(\ln(-1+e^x)-\ln(e^x))+c_2$

□ Check validity of solution $y=-c_1(\ln(-1+e^x)-\ln(e^x))+c_2$

- ○ Use initial condition $y(1)=0$

  $0=-(\ln(-1+e)-1)\,c_1+c_2$

- ○ Compute derivative of the solution

  $y'=-c_1\left(\frac{e^x}{-1+e^x}-1\right)$

- ○ Use the initial condition $y'\Big|_{\{x=1\}}=1$

$$1=-c_1\left(\frac{\mathrm{e}}{-1+\mathrm{e}}-1\right)$$

- Solve for c_1 and c_2

$$\{c_1=1-\mathrm{e}, c_2=-\ln(-1+\mathrm{e})\,\mathrm{e}+\ln(-1+\mathrm{e})+\mathrm{e}-1\}$$

- Substitute constant values into general solution and simplify

$$y=-(\ln(\mathrm{e}^x)+\ln(-1+\mathrm{e})-\ln(-1+\mathrm{e}^x)-1)(-1+\mathrm{e})$$

- Solution to the IVP

$$y=-(\ln(\mathrm{e}^x)+\ln(-1+\mathrm{e})-\ln(-1+\mathrm{e}^x)-1)(-1+\mathrm{e})$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 37, page 171
Problem number: 1.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"first_order_nonlinear_p_but_separable"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{4y^2 - y'^2 x^2 = 0}$$

19.1.1 Solving as first order nonlinear p but separable ode

The ode has the form

$$(y')^{\frac{n}{m}} = f(x)g(y) \tag{1}$$

Where $n = 2, m = 1, f = \frac{4}{x^2}, g = y^2$. Hence the ode is

$$(y')^2 = \frac{4y^2}{x^2}$$

Solving for y' from (1) gives

$$y' = \sqrt{fg}$$
$$y' = -\sqrt{fg}$$

To be able to solve as separable ode, we have to now assume that $f > 0, g > 0$.

$$\frac{4}{x^2} > 0$$
$$y^2 > 0$$

Under the above assumption the differential equations become separable and can be written as

$$
\begin{aligned}
y' &= \sqrt{f}\, \sqrt{g} \\
y' &= -\sqrt{f}\, \sqrt{g}
\end{aligned}
$$

Therefore

$$
\begin{aligned}
\frac{1}{\sqrt{g}}\, dy &= \left(\sqrt{f}\right)\, dx \\
-\frac{1}{\sqrt{g}}\, dy &= \left(\sqrt{f}\right)\, dx
\end{aligned}
$$

Replacing $f(x), g(y)$ by their values gives

$$
\begin{aligned}
\frac{1}{\sqrt{y^2}}\, dy &= \left(\sqrt{4}\, \sqrt{\frac{1}{x^2}}\right)\, dx \\
-\frac{1}{\sqrt{y^2}}\, dy &= \left(\sqrt{4}\, \sqrt{\frac{1}{x^2}}\right)\, dx
\end{aligned}
$$

Integrating now gives the solutions.

$$
\begin{aligned}
\int \frac{1}{\sqrt{y^2}} dy &= \int \sqrt{4}\, \sqrt{\frac{1}{x^2}} dx + c_1 \\
\int -\frac{1}{\sqrt{y^2}} dy &= \int \sqrt{4}\, \sqrt{\frac{1}{x^2}} dx + c_1
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\frac{y \ln (y)}{\sqrt{y^2}} &= \sqrt{4}\, \sqrt{\frac{1}{x^2}}\, x \ln (x) + c_1 \\
-\frac{y \ln (y)}{\sqrt{y^2}} &= \sqrt{4}\, \sqrt{\frac{1}{x^2}}\, x \ln (x) + c_1
\end{aligned}
$$

Therefore

$$
\frac{y \ln (y)}{\sqrt{y^2}} = \sqrt{4}\, \sqrt{\frac{1}{x^2}}\, x \ln (x) + c_1
$$

$$
-\frac{y \ln (y)}{\sqrt{y^2}} = \sqrt{4}\, \sqrt{\frac{1}{x^2}}\, x \ln (x) + c_1
$$

Summary
The solution(s) found are the following

$$\frac{y \ln(y)}{\sqrt{y^2}} = \sqrt{4}\,\sqrt{\frac{1}{x^2}}\, x \ln(x) + c_1 \tag{1}$$

$$-\frac{y \ln(y)}{\sqrt{y^2}} = \sqrt{4}\,\sqrt{\frac{1}{x^2}}\, x \ln(x) + c_1 \tag{2}$$

Verification of solutions

$$\frac{y \ln(y)}{\sqrt{y^2}} = \sqrt{4}\,\sqrt{\frac{1}{x^2}}\, x \ln(x) + c_1$$

Verified OK. `{0 < y^2, 0 < 4/x^2}`

$$-\frac{y \ln(y)}{\sqrt{y^2}} = \sqrt{4}\,\sqrt{\frac{1}{x^2}}\, x \ln(x) + c_1$$

Verified OK. `{0 < y^2, 0 < 4/x^2}`

19.1.2 Maple step by step solution

Let's solve

$4y^2 - y'^2x^2 = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = \frac{2}{x}$

- Integrate both sides with respect to x

  $\int \frac{y'}{y}dx = \int \frac{2}{x}dx + c_1$

- Evaluate integral

  $\ln(y) = 2\ln(x) + c_1$

- Solve for y

  $y = e^{c_1}x^2$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 37, page 171
Problem number: 2.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

```
[_quadrature]
```

$$\boxed{xyy'^2 + (y + x)\, y' = -1}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = -\frac{1}{y} \tag{1}$$

$$y' = -\frac{1}{x} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int -y dy = x + c_1$$
$$-\frac{y^2}{2} = x + c_1$$

Solving for y gives these solutions

$$y_1 = \sqrt{-2x - 2c_1}$$
$$y_2 = -\sqrt{-2x - 2c_1}$$

Summary
The solution(s) found are the following

$$y = \sqrt{-2x - 2c_1} \tag{1}$$
$$y = -\sqrt{-2x - 2c_1} \tag{2}$$

Verification of solutions

$$y = \sqrt{-2x - 2c_1}$$

Verified OK.

$$y = -\sqrt{-2x - 2c_1}$$

Verified OK.

Solving equation (2)

Integrating both sides gives

$$\begin{aligned} y &= \int -\frac{1}{x}\, \mathrm{d}x \\ &= -\ln(x) + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = -\ln(x) + c_2 \tag{1}$$

Verification of solutions

$$y = -\ln(x) + c_2$$

Verified OK.

Internal problem ID [2317]
Internal file name [`OUTPUT/2317_Tuesday_February_27_2024_08_25_59_AM_8183189/index.tex`]

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 37, page 171
Problem number: 4.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _dAlembert]
```

$$\boxed{x\left(-1+y'^2\right)-2yy'=0}$$

19.4.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$x(p^2-1)-2yp=0$$

Solving for y from the above results in

$$y=\frac{x(p^2-1)}{2p} \tag{1A}$$

This has the form

$$y = xf(p)+g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f+(xf'+g')\frac{dp}{dx}$$
$$p-f = (xf'+g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= \frac{p^2 - 1}{2p} \\
g &= 0
\end{aligned}
$$

Hence (2) becomes

$$
p - \frac{p^2 - 1}{2p} = x\left(1 - \frac{p^2 - 1}{2p^2}\right) p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
p - \frac{p^2 - 1}{2p} = 0
$$

Solving for p from the above gives

$$
\begin{aligned}
p &= i \\
p &= -i
\end{aligned}
$$

Substituting these in (1A) gives

$$
\begin{aligned}
y &= -ix \\
y &= ix
\end{aligned}
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{p(x) - \frac{p(x)^2 - 1}{2p(x)}}{x\left(1 - \frac{p(x)^2 - 1}{2p(x)^2}\right)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
p'(x) + p(x)p(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= 0
\end{aligned}
$$

Hence the ode is

$$p'(x) - \frac{p(x)}{x} = 0$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{x}dx}$$
$$= \frac{1}{x}$$

The ode becomes

$$\frac{d}{dx}\mu p = 0$$
$$\frac{d}{dx}\left(\frac{p}{x}\right) = 0$$

Integrating gives

$$\frac{p}{x} = c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$p(x) = c_1 x$$

Substituing the above solution for p in (2A) gives

$$y = \frac{c_1^2 x^2 - 1}{2c_1}$$

Summary

The solution(s) found are the following

$$y = -ix \tag{1}$$
$$y = ix \tag{2}$$
$$y = \frac{c_1^2 x^2 - 1}{2c_1} \tag{3}$$

Verification of solutions

$$y = -ix$$

Verified OK.

$$y = ix$$

Verified OK.

$$y = \frac{c_1^2 x^2 - 1}{2c_1}$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 37, page 171
Problem number: 7.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"exact", "separable", "differentialType", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y^2 {y'}^2 + xyy' = 2x^2}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{x}{y} \tag{1}$$

$$y' = -\frac{2x}{y} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{x}{y} \end{aligned}$$

Where $f(x) = x$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y}}\,dy = x\,dx$$

$$\int \frac{1}{\frac{1}{y}}\,dy = \int x\,dx$$

$$\frac{y^2}{2} = \frac{x^2}{2} + c_1$$

Which results in

$$y = \sqrt{x^2 + 2c_1}$$

$$y = -\sqrt{x^2 + 2c_1}$$

Summary

The solution(s) found are the following

$$y = \sqrt{x^2 + 2c_1} \tag{1}$$

$$y = -\sqrt{x^2 + 2c_1} \tag{2}$$

Verification of solutions

$$y = \sqrt{x^2 + 2c_1}$$

Verified OK.

$$y = -\sqrt{x^2 + 2c_1}$$

Verified OK.

Solving equation (2)

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= f(x)g(y) \\ &= -\frac{2x}{y} \end{aligned}$$

Where $f(x) = -2x$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y}}\,dy = -2x\,dx$$
$$\int \frac{1}{\frac{1}{y}}\,dy = \int -2x\,dx$$
$$\frac{y^2}{2} = -x^2 + c_2$$

Which results in

$$y = \sqrt{-2x^2 + 2c_2}$$
$$y = -\sqrt{-2x^2 + 2c_2}$$

Summary

The solution(s) found are the following

$$y = \sqrt{-2x^2 + 2c_2} \tag{1}$$
$$y = -\sqrt{-2x^2 + 2c_2} \tag{2}$$

Verification of solutions

$$y = \sqrt{-2x^2 + 2c_2}$$

Verified OK.

$$y = -\sqrt{-2x^2 + 2c_2}$$

Verified OK.

19.7.1 Maple step by step solution

Let's solve

$y^2 y'^2 + xyy' = 2x^2$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $yy' = x$

- Integrate both sides with respect to x

$$\int yy'dx = \int xdx + c_1$$

- Evaluate integral

$$\frac{y^2}{2} = \frac{x^2}{2} + c_1$$

- Solve for y

$$\left\{y = \sqrt{x^2 + 2c_1}, y = -\sqrt{x^2 + 2c_1}\right\}$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 37, page 171
Problem number: 8.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[[_homogeneous, `class A`], _rational, _dAlembert]`

$$\boxed{y^2y'^2 - 2xyy' + 2y^2 = x^2}$$

19.8.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$y^2p^2 - 2xyp + 2y^2 = x^2$$

Solving for y from the above results in

$$y = \frac{\left(p + \sqrt{2p^2 + 2}\right)x}{p^2 + 2} \tag{1A}$$

$$y = -\frac{\left(-p + \sqrt{2p^2 + 2}\right)x}{p^2 + 2} \tag{2A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. Each of the above ode's is dAlembert ode which is now solved. Solving ode 1A Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$

$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= \frac{p + \sqrt{2p^2 + 2}}{p^2 + 2} \\
g &= 0
\end{aligned}
$$

Hence (2) becomes

$$
p - \frac{p + \sqrt{2p^2 + 2}}{p^2 + 2} = x \left(\frac{1 + \frac{2p}{\sqrt{2p^2+2}}}{p^2 + 2} - \frac{2\left(p + \sqrt{2p^2 + 2}\right) p}{\left(p^2 + 2\right)^2} \right) p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
p - \frac{p + \sqrt{2p^2 + 2}}{p^2 + 2} = 0
$$

Solving for p from the above gives

$$
\begin{aligned}
p &= 1 \\
p &= i \\
p &= -i
\end{aligned}
$$

Substituting these in (1A) gives

$$
\begin{aligned}
y &= x \\
y &= -ix \\
y &= ix
\end{aligned}
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{p(x) - \frac{p(x)+\sqrt{2p(x)^2+2}}{p(x)^2+2}}{x \left(\frac{1+\frac{2p(x)}{\sqrt{2p(x)^2+2}}}{p(x)^2+2} - \frac{2\left(p(x)+\sqrt{2p(x)^2+2}\right)p(x)}{\left(p(x)^2+2\right)^2} \right)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$
\frac{d}{dp}x(p) = \frac{x(p) \left(\frac{1+\frac{2p}{\sqrt{2p^2+2}}}{p^2+2} - \frac{2\left(p+\sqrt{2p^2+2}\right)p}{\left(p^2+2\right)^2} \right)}{p - \frac{p+\sqrt{2p^2+2}}{p^2+2}} \tag{4}
$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = \frac{p^2\sqrt{2p^2+2} + 2p^3 - 2\sqrt{2p^2+2}}{\left(p^3 - \sqrt{2p^2+2} + p\right)\sqrt{2p^2+2}\,(p^2+2)}$$
$$q(p) = 0$$

Hence the ode is

$$\frac{d}{dp}x(p) + \frac{2\left(p^3 + \frac{p^2\sqrt{2p^2+2}}{2} - \sqrt{2p^2+2}\right)x(p)}{\sqrt{2p^2+2}\,\left(p^3 - \sqrt{2p^2+2} + p\right)(p^2+2)} = 0$$

The integrating factor μ is

$$\mu = e^{\int \frac{p^2\sqrt{2p^2+2}+2p^3-2\sqrt{2p^2+2}}{\left(p^3-\sqrt{2p^2+2}+p\right)\sqrt{2p^2+2}\,(p^2+2)}dp}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}p}\mu x = 0$$

$$\frac{\mathrm{d}}{\mathrm{d}p}\left(e^{\int \frac{p^2\sqrt{2p^2+2}+2p^3-2\sqrt{2p^2+2}}{\left(p^3-\sqrt{2p^2+2}+p\right)\sqrt{2p^2+2}\,(p^2+2)}dp}x\right) = 0$$

Integrating gives

$$e^{\int \frac{p^2\sqrt{2p^2+2}+2p^3-2\sqrt{2p^2+2}}{\left(p^3-\sqrt{2p^2+2}+p\right)\sqrt{2p^2+2}\,(p^2+2)}dp}x = c_2$$

Dividing both sides by the integrating factor $\mu = e^{\int \frac{p^2\sqrt{2p^2+2}+2p^3-2\sqrt{2p^2+2}}{\left(p^3-\sqrt{2p^2+2}+p\right)\sqrt{2p^2+2}\,(p^2+2)}dp}$ results in

$$x(p) = c_2 e^{\int -\frac{2\left(p^3+\frac{p^2\sqrt{2p^2+2}}{2}-\sqrt{2p^2+2}\right)}{\sqrt{2p^2+2}\,\left(p^3-\sqrt{2p^2+2}+p\right)(p^2+2)}dp}$$

Since the solution $x(p)$ has unresolved integral, unable to continue.

Solving ode 2A Taking derivative of (*) w.r.t. x gives

$$
\begin{aligned}
p &= f + (xf' + g')\frac{dp}{dx} \\
p - f &= (xf' + g')\frac{dp}{dx}
\end{aligned}
\tag{2}
$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= \frac{p - \sqrt{2p^2 + 2}}{p^2 + 2} \\
g &= 0
\end{aligned}
$$

Hence (2) becomes

$$
p - \frac{p - \sqrt{2p^2 + 2}}{p^2 + 2} = x\left(\frac{1 - \frac{2p}{\sqrt{2p^2+2}}}{p^2 + 2} - \frac{2\left(p - \sqrt{2p^2 + 2}\right)p}{\left(p^2 + 2\right)^2}\right)p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
p - \frac{p - \sqrt{2p^2 + 2}}{p^2 + 2} = 0
$$

Solving for p from the above gives

$$
\begin{aligned}
p &= -1 \\
p &= i \\
p &= -i
\end{aligned}
$$

Substituting these in (1A) gives

$$
\begin{aligned}
y &= -x \\
y &= -ix \\
y &= ix
\end{aligned}
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{p(x) - \frac{p(x) - \sqrt{2p(x)^2+2}}{p(x)^2+2}}{x\left(\frac{1 - \frac{2p(x)}{\sqrt{2p(x)^2+2}}}{p(x)^2+2} - \frac{2\left(p(x) - \sqrt{2p(x)^2+2}\right)p(x)}{\left(p(x)^2+2\right)^2}\right)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = \frac{x(p)\left(\frac{1-\frac{2p}{\sqrt{2p^2+2}}}{p^2+2} - \frac{2\left(p-\sqrt{2p^2+2}\right)p}{\left(p^2+2\right)^2}\right)}{p - \frac{p-\sqrt{2p^2+2}}{p^2+2}} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = -\frac{-p^2\sqrt{2p^2+2} + 2p^3 + 2\sqrt{2p^2+2}}{\left(p^3+\sqrt{2p^2+2}+p\right)\sqrt{2p^2+2}\,\left(p^2+2\right)}$$
$$q(p) = 0$$

Hence the ode is

$$\frac{d}{dp}x(p) - \frac{\left(-p^2\sqrt{2p^2+2} + 2p^3 + 2\sqrt{2p^2+2}\right)x(p)}{\left(p^3+\sqrt{2p^2+2}+p\right)\sqrt{2p^2+2}\,\left(p^2+2\right)} = 0$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int -\frac{-p^2\sqrt{2p^2+2}+2p^3+2\sqrt{2p^2+2}}{\left(p^3+\sqrt{2p^2+2}+p\right)\sqrt{2p^2+2}\,\left(p^2+2\right)}dp}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}p}\mu x = 0$$
$$\frac{\mathrm{d}}{\mathrm{d}p}\left(\mathrm{e}^{\int -\frac{-p^2\sqrt{2p^2+2}+2p^3+2\sqrt{2p^2+2}}{\left(p^3+\sqrt{2p^2+2}+p\right)\sqrt{2p^2+2}\,\left(p^2+2\right)}dp}x\right) = 0$$

Integrating gives

$$\mathrm{e}^{\int -\frac{-p^2\sqrt{2p^2+2}+2p^3+2\sqrt{2p^2+2}}{\left(p^3+\sqrt{2p^2+2}+p\right)\sqrt{2p^2+2}\,\left(p^2+2\right)}dp}x = c_4$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\int -\frac{-p^2\sqrt{2p^2+2}+2p^3+2\sqrt{2p^2+2}}{\left(p^3+\sqrt{2p^2+2}+p\right)\sqrt{2p^2+2}\,(p^2+2)}dp}$ results in

$$x(p) = c_4 \mathrm{e}^{-\left(\int -\frac{2\left(p^3-\frac{p^2\sqrt{2p^2+2}}{2}+\sqrt{2p^2+2}\right)}{\sqrt{2p^2+2}\left(p^3+\sqrt{2p^2+2}+p\right)(p^2+2)}dp\right)}$$

Since the solution $x(p)$ has unresolved integral, unable to continue.

Summary

The solution(s) found are the following

$$y = x \tag{1}$$
$$y = -ix \tag{2}$$
$$y = ix \tag{3}$$
$$y = -x \tag{4}$$
$$y = -ix \tag{5}$$
$$y = ix \tag{6}$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 37, page 171
Problem number: 9.
ODE order: 1.
ODE degree: 3.

The type(s) of ODE detected by this program : **"exact", "linear", "quadrature", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y'^3 + (x + y - 2yx)\, y'^2 - 2y'xy(y + x) = 0}$$

Solving the given ode for y' results in 3 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = 0 \tag{1}$$
$$y' = 2yx \tag{2}$$
$$y' = -y - x \tag{3}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\begin{aligned} y &= \int 0 \,\mathrm{d}x \\ &= c_1 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \tag{1}$$

Verification of solutions

$$y = c_1$$

Verified OK.

Solving equation (2)

In canonical form the ODE is

$$\begin{aligned}
y' &= F(x, y) \\
&= f(x)g(y) \\
&= 2xy
\end{aligned}$$

Where $f(x) = 2x$ and $g(y) = y$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{y}\,dy &= 2x\,dx \\
\int \frac{1}{y}\,dy &= \int 2x\,dx \\
\ln(y) &= x^2 + c_2 \\
y &= e^{x^2+c_2} \\
&= c_2 e^{x^2}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_2 e^{x^2} \tag{1}$$

Verification of solutions

$$y = c_2 e^{x^2}$$

Verified OK.

Solving equation (3)

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}
p(x) &= 1 \\
q(x) &= -x
\end{aligned}$$

Hence the ode is

$$y' + y = -x$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int 1dx} \\ &= e^{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)(-x) \\ \frac{d}{dx}(e^{x} y) &= (e^{x})(-x) \\ d(e^{x} y) &= (-x\, e^{x})\, dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{x} y &= \int -x\, e^{x}\, dx \\ e^{x} y &= -(x-1)\, e^{x} + c_3\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{x}$ results in

$$y = -e^{-x}(x-1)\, e^{x} + c_3 e^{-x}$$

which simplifies to

$$y = 1 - x + c_3 e^{-x}$$

Summary
The solution(s) found are the following

$$y = 1 - x + c_3 e^{-x} \tag{1}$$

Verification of solutions

$$y = 1 - x + c_3 e^{-x}$$

Verified OK.

19.9.1 Maple step by step solution

19.10 problem 10

Internal problem ID [2323]
Internal file name [OUTPUT/2323_Tuesday_February_27_2024_08_26_06_AM_46129370/index.tex]

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 37, page 171
Problem number: 10.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"exact", "bernoulli", "quadrature", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_quadrature]
```

$$\boxed{y{y'}^{2}+\left(y^{2}-x^{3}-y^{2}x\right)y'-xy\left(y^{2}+x^{2}\right)=0}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = -y \tag{1}$$

$$y' = \frac{x(y^2+x^2)}{y} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int -\frac{1}{y}dy = \int dx$$

$$-\ln\left(y\right) = x + c_1$$

Raising both side to exponential gives

$$\frac{1}{y} = \mathrm{e}^{x+c_1}$$

Which simplifies to

$$\frac{1}{y} = c_2 e^{x}$$

Summary
The solution(s) found are the following

$$y = \frac{e^{-x}}{c_2} \tag{1}$$

Verification of solutions

$$y = \frac{e^{-x}}{c_2}$$

Verified OK.

Solving equation (2)

Writing the ode as

$$\begin{aligned} y' &= \frac{x(x^2+y^2)}{y} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 621: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$

homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \frac{e^{x^2}}{y}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{e^{x^2}}{y}} dy \end{aligned}$$

Which results in

$$S = \frac{y^2 e^{-x^2}}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{x(x^2 + y^2)}{y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -y^2 x\, e^{-x^2} \\ S_y &= y\, e^{-x^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = e^{-x^2} x^3 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = e^{-R^2} R^3$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{(R^2+1)\,\mathrm{e}^{-R^2}}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y^2\mathrm{e}^{-x^2}}{2} = -\frac{(x^2+1)\,\mathrm{e}^{-x^2}}{2} + c_1$$

Which simplifies to

$$\frac{(x^2+y^2+1)\,\mathrm{e}^{-x^2}}{2} - c_1 = 0$$

Summary

The solution(s) found are the following

$$\frac{(x^2+y^2+1)\,\mathrm{e}^{-x^2}}{2} - c_1 = 0 \tag{1}$$

Verification of solutions

$$\frac{(x^2+y^2+1)\,\mathrm{e}^{-x^2}}{2} - c_1 = 0$$

Verified OK.

19.10.1 Maple step by step solution

Let's solve

$yy'^2 + (y^2 - x^3 - y^2x)\,y' - xy(y^2+x^2) = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = -1$

- Integrate both sides with respect to x

  $\int \frac{y'}{y}dx = \int (-1)\,dx + c_1$

- Evaluate integral

  $\ln(y) = -x + c_1$
- Solve for y

  $y = e^{-x+c_1}$

ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _dAlembert]
```

$$\boxed{y - y'x(y'+1) = 0}$$

19.11.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$y - px(p+1) = 0$$

Solving for y from the above results in

$$y = px(p+1) \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$\begin{aligned} p &= f + (xf' + g')\frac{dp}{dx} \\ p - f &= (xf' + g')\frac{dp}{dx} \end{aligned} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= p(p+1) \\
g &= 0
\end{aligned}
$$

Hence (2) becomes

$$
p - p(p+1) = x(2p+1)\,p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
p - p(p+1) = 0
$$

Solving for p from the above gives

$$
\begin{aligned}
p &= 0 \\
p &= 0
\end{aligned}
$$

Removing solutions for p which leads to undefined results and substituting these in (1A) gives

$$
y = 0
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{p(x) - p(x)\,(p(x)+1)}{x\,(2p\,(x)+1)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$
\frac{d}{dp}x(p) = \frac{x(p)\,(2p+1)}{p - p\,(p+1)} \tag{4}
$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
\frac{d}{dp}x(p) + p(p)x(p) = q(p)
$$

Where here

$$
\begin{aligned}
p(p) &= -\frac{-2p-1}{p^2} \\
q(p) &= 0
\end{aligned}
$$

Hence the ode is

$$\frac{d}{dp}x(p) - \frac{(-2p-1)\,x(p)}{p^2} = 0$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{-2p-1}{p^2}dp} \\ &= e^{-\frac{1}{p}+2\ln(p)}\end{aligned}$$

Which simplifies to

$$\mu = p^2 e^{-\frac{1}{p}}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}p}\mu x &= 0 \\ \frac{\mathrm{d}}{\mathrm{d}p}\left(p^2 e^{-\frac{1}{p}} x\right) &= 0\end{aligned}$$

Integrating gives

$$p^2 e^{-\frac{1}{p}} x = c_2$$

Dividing both sides by the integrating factor $\mu = p^2 e^{-\frac{1}{p}}$ results in

$$x(p) = \frac{c_2 e^{\frac{1}{p}}}{p^2}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$\begin{aligned}p &= \frac{-x+\sqrt{x^2+4yx}}{2x} \\ p &= -\frac{x+\sqrt{x^2+4yx}}{2x}\end{aligned}$$

Substituting the above in the solution for x found above gives

$$x = \frac{4c_2 x^2 e^{\frac{2x}{-x+\sqrt{x(4y+x)}}}}{\left(-x+\sqrt{x\,(4y+x)}\right)^2}$$

$$x = \frac{4c_2 x^2 e^{-\frac{2x}{x+\sqrt{x(4y+x)}}}}{\left(x+\sqrt{x\,(4y+x)}\right)^2}$$

Summary

The solution(s) found are the following

$$y = 0 \tag{1}$$

$$x = \frac{4c_2 x^2 \mathrm{e}^{\frac{2x}{-x+\sqrt{x(4y+x)}}}}{\left(-x+\sqrt{x\left(4y+x\right)}\right)^2} \tag{2}$$

$$x = \frac{4c_2 x^2 \mathrm{e}^{-\frac{2x}{x+\sqrt{x(4y+x)}}}}{\left(x+\sqrt{x\left(4y+x\right)}\right)^2} \tag{3}$$

Verification of solutions

$$y = 0$$

Verified OK.

$$x = \frac{4c_2 x^2 \mathrm{e}^{\frac{2x}{-x+\sqrt{x(4y+x)}}}}{\left(-x+\sqrt{x\left(4y+x\right)}\right)^2}$$

Section: Exercise 37, page 171
Problem number: 12.
ODE order: 1.
ODE degree: 0.

The type(s) of ODE detected by this program : **"dAlembert", "separable"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y - 3\ln(y') = x}$$

19.12.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= e^{\frac{y}{3}} e^{-\frac{x}{3}} \end{aligned}$$

Where $f(x) = e^{-\frac{x}{3}}$ and $g(y) = e^{\frac{y}{3}}$. Integrating both sides gives

$$\begin{aligned} \frac{1}{e^{\frac{y}{3}}}\, dy &= e^{-\frac{x}{3}}\, dx \\ \int \frac{1}{e^{\frac{y}{3}}}\, dy &= \int e^{-\frac{x}{3}}\, dx \\ -3\, e^{-\frac{y}{3}} &= -3\, e^{-\frac{x}{3}} + c_1 \end{aligned}$$

Which results in

$$y = 3\ln\left(\frac{3}{3\,e^{-\frac{x}{3}} - c_1}\right)$$

Summary

The solution(s) found are the following

$$y = 3\ln\left(\frac{3}{3\,e^{-\frac{x}{3}} - c_1}\right) \tag{1}$$

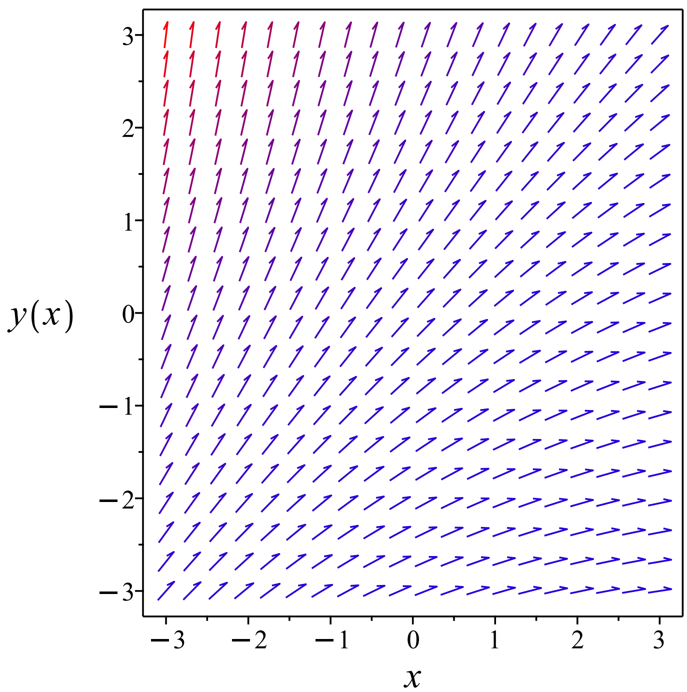

Figure 730: Slope field plot

Verification of solutions

$$y = 3\ln\left(\frac{3}{3\,e^{-\frac{x}{3}} - c_1}\right)$$

Verified OK.

19.12.2 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$y - 3\ln(p) = x$$

Solving for y from the above results in

$$y = x + 3\ln(p) \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = 1$$
$$g = 3\ln(p)$$

Hence (2) becomes

$$p - 1 = \frac{3p'(x)}{p} \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$p - 1 = 0$$

Solving for p from the above gives

$$p = 1$$

Substituting these in (1A) gives

$$y = x$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$p'(x) = \frac{(p(x) - 1)\,p(x)}{3} \tag{3}$$

This ODE is now solved for $p(x)$. Integrating both sides gives

$$
\begin{aligned}
\int \frac{3}{(p-1)\,p} dp &= \int dx \\
3\ln(p-1) - 3\ln(p) &= x + c_1
\end{aligned}
$$

The above can be written as

$$
\begin{aligned}
(3)\left(\ln(p-1) - \ln(p)\right) &= x + c_1 \\
\ln(p-1) - \ln(p) &= \left(\frac{1}{3}\right)(x + c_1) \\
&= \frac{x}{3} + \frac{c_1}{3}
\end{aligned}
$$

Raising both side to exponential gives

$$
\mathrm{e}^{\ln(p-1) - \ln(p)} = \frac{c_1 \mathrm{e}^{\frac{x}{3}}}{3}
$$

Which simplifies to

$$
\frac{p-1}{p} = c_2 \mathrm{e}^{\frac{x}{3}}
$$

Substituing the above solution for p in (2A) gives

$$
y = x + 3\ln\left(-\frac{1}{-1 + c_2 \mathrm{e}^{\frac{x}{3}}}\right)
$$

Summary

The solution(s) found are the following

$$
y = x \tag{1}
$$

$$
y = x + 3\ln\left(-\frac{1}{-1 + c_2 \mathrm{e}^{\frac{x}{3}}}\right) \tag{2}
$$

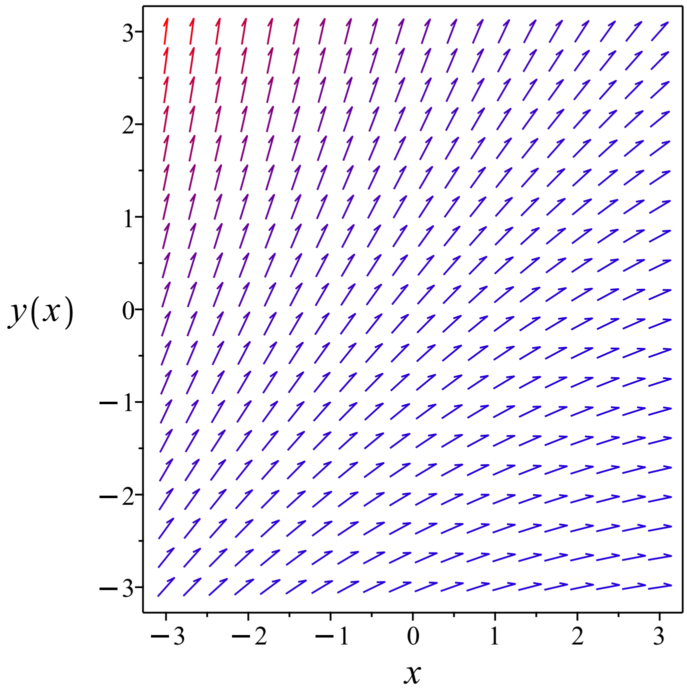

Figure 731: Slope field plot

Verification of solutions

$$y = x$$

Verified OK.

$$y = x + 3\ln\left(-\frac{1}{-1 + c_2 \mathrm{e}^{\frac{x}{3}}}\right)$$

Verified OK.

ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _dAlembert]
```

$$\boxed{yy'^2 - 2xy' + y = 0}$$

19.14.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$y\,p^2 - 2xp + y = 0$$

Solving for y from the above results in

$$y = \frac{2xp}{p^2 + 1} \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = \frac{2p}{p^2+1}$$
$$g = 0$$

Hence (2) becomes

$$p - \frac{2p}{p^2+1} = x\left(\frac{2}{p^2+1} - \frac{4p^2}{\left(p^2+1\right)^2}\right)p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$p - \frac{2p}{p^2+1} = 0$$

Solving for p from the above gives

$$p = 0$$
$$p = 1$$
$$p = -1$$

Substituting these in (1A) gives

$$y = -x$$
$$y = 0$$
$$y = x$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$p'(x) = \frac{p(x) - \frac{2p(x)}{p(x)^2+1}}{x\left(\frac{2}{p(x)^2+1} - \frac{4p(x)^2}{\left(p(x)^2+1\right)^2}\right)} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = \frac{x(p)\left(\frac{2}{p^2+1} - \frac{4p^2}{\left(p^2+1\right)^2}\right)}{p - \frac{2p}{p^2+1}} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = \frac{2}{p(p^2+1)}$$
$$q(p) = 0$$

Hence the ode is

$$\frac{d}{dp}x(p) + \frac{2x(p)}{p(p^2+1)} = 0$$

The integrating factor μ is

$$\mu = e^{\int \frac{2}{p(p^2+1)}dp}$$
$$= e^{-\ln(p^2+1)+2\ln(p)}$$

Which simplifies to

$$\mu = \frac{p^2}{p^2+1}$$

The ode becomes

$$\frac{d}{dp}\mu x = 0$$
$$\frac{d}{dp}\left(\frac{p^2 x}{p^2+1}\right) = 0$$

Integrating gives

$$\frac{p^2 x}{p^2+1} = c_3$$

Dividing both sides by the integrating factor $\mu = \frac{p^2}{p^2+1}$ results in

$$x(p) = \frac{c_3(p^2+1)}{p^2}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p = \frac{x+\sqrt{x^2-y^2}}{y}$$
$$p = -\frac{-x+\sqrt{x^2-y^2}}{y}$$

Substituting the above in the solution for x found above gives

$$x = \frac{2c_3 x}{x + \sqrt{x^2 - y^2}}$$
$$x = -\frac{2c_3 x}{-x + \sqrt{x^2 - y^2}}$$

Summary

The solution(s) found are the following

$$y = -x \tag{1}$$
$$y = 0 \tag{2}$$
$$y = x \tag{3}$$
$$x = \frac{2c_3 x}{x + \sqrt{x^2 - y^2}} \tag{4}$$
$$x = -\frac{2c_3 x}{-x + \sqrt{x^2 - y^2}} \tag{5}$$

Verification of solutions

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y'^2 + y^2 = 1}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{1 - y^2} \tag{1}$$
$$y' = -\sqrt{1 - y^2} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-y^2 + 1}} dy = x + c_1$$
$$\arcsin(y) = x + c_1$$

Solving for y gives these solutions

$$y_1 = \sin(x + c_1)$$

Summary
The solution(s) found are the following

$$y = \sin(x + c_1) \tag{1}$$

Verification of solutions

$$y = \sin(x + c_1)$$

Verified OK.
Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-y^2+1}} dy = x + c_2$$
$$-\arcsin(y) = x + c_2$$

Solving for y gives these solutions

$$y_1 = -\sin(x + c_2)$$

Summary
The solution(s) found are the following

$$y = -\sin(x + c_2) \tag{1}$$

Verification of solutions

$$y = -\sin(x + c_2)$$

Verified OK.

19.15.1 Maple step by step solution

Let's solve

$y'^2 + y^2 = 1$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{\sqrt{1-y^2}} = 1$

- Integrate both sides with respect to x

$$\int \frac{y'}{\sqrt{1-y^2}}dx = \int 1dx + c_1$$

- Evaluate integral

$$\arcsin(y) = x + c_1$$

- Solve for y

$$y = \sin(x + c_1)$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 37, page 171
Problem number: 16.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _dAlembert]
```

$$\boxed{x\left(-1+y'^2\right)-2yy'=0}$$

19.16.1 Solving as dAlembert ode

Let $p=y'$ the ode becomes

$$x(p^2-1)-2yp=0$$

Solving for y from the above results in

$$y=\frac{x(p^2-1)}{2p} \tag{1A}$$

This has the form

$$y=xf(p)+g(p) \tag{*}$$

Where f,g are functions of $p=y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p=f+(xf'+g')\frac{dp}{dx}$$
$$p-f=(xf'+g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= \frac{p^2 - 1}{2p} \\
g &= 0
\end{aligned}
$$

Hence (2) becomes

$$
p - \frac{p^2 - 1}{2p} = x\left(1 - \frac{p^2 - 1}{2p^2}\right) p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
p - \frac{p^2 - 1}{2p} = 0
$$

Solving for p from the above gives

$$
\begin{aligned}
p &= i \\
p &= -i
\end{aligned}
$$

Substituting these in (1A) gives

$$
\begin{aligned}
y &= -ix \\
y &= ix
\end{aligned}
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{p(x) - \frac{p(x)^2 - 1}{2p(x)}}{x\left(1 - \frac{p(x)^2 - 1}{2p(x)^2}\right)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
p'(x) + p(x)p(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= 0
\end{aligned}
$$

Hence the ode is

$$p'(x) - \frac{p(x)}{x} = 0$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{x}dx}$$
$$= \frac{1}{x}$$

The ode becomes

$$\frac{d}{dx}\mu p = 0$$
$$\frac{d}{dx}\left(\frac{p}{x}\right) = 0$$

Integrating gives

$$\frac{p}{x} = c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$p(x) = c_1 x$$

Substituing the above solution for p in (2A) gives

$$y = \frac{c_1^2 x^2 - 1}{2c_1}$$

Summary
The solution(s) found are the following

$$y = -ix \tag{1}$$
$$y = ix \tag{2}$$
$$y = \frac{c_1^2 x^2 - 1}{2c_1} \tag{3}$$

Verification of solutions

$$y = -ix$$

Verified OK.

$$y = ix$$

Verified OK.

$$y = \frac{c_1^2 x^2 - 1}{2c_1}$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 37, page 171
Problem number: 17.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _dAlembert]
```

$$\boxed{-2yy' + {y'}^2 x = -4x}$$

19.17.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$p^2 x - 2yp = -4x$$

Solving for y from the above results in

$$y = \frac{x(p^2 + 4)}{2p} \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= \frac{p^2 + 4}{2p} \\
g &= 0
\end{aligned}
$$

Hence (2) becomes

$$
p - \frac{p^2 + 4}{2p} = x\left(1 - \frac{p^2 + 4}{2p^2}\right) p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
p - \frac{p^2 + 4}{2p} = 0
$$

Solving for p from the above gives

$$
\begin{aligned}
p &= 2 \\
p &= -2
\end{aligned}
$$

Substituting these in (1A) gives

$$
\begin{aligned}
y &= -2x \\
y &= 2x
\end{aligned}
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{p(x) - \frac{p(x)^2+4}{2p(x)}}{x\left(1 - \frac{p(x)^2+4}{2p(x)^2}\right)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
p'(x) + p(x)p(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= 0
\end{aligned}
$$

Hence the ode is

$$p'(x) - \frac{p(x)}{x} = 0$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{x}dx}$$
$$= \frac{1}{x}$$

The ode becomes

$$\frac{d}{dx}\mu p = 0$$
$$\frac{d}{dx}\left(\frac{p}{x}\right) = 0$$

Integrating gives

$$\frac{p}{x} = c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$p(x) = c_1 x$$

Substituing the above solution for p in (2A) gives

$$y = \frac{c_1^2 x^2 + 4}{2c_1}$$

Summary
The solution(s) found are the following

$$y = -2x \tag{1}$$
$$y = 2x \tag{2}$$
$$y = \frac{c_1^2 x^2 + 4}{2c_1} \tag{3}$$

Verification of solutions

$$y = -2x$$

Verified OK.

$$y = 2x$$

Verified OK.

$$y = \frac{c_1^2 x^2 + 4}{2c_1}$$

Verified OK.

Internal problem ID [2331]
Internal file name [`OUTPUT/2331_Tuesday_February_27_2024_08_26_08_AM_65434278/index.tex`]

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 37, page 171
Problem number: 18.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_1st_order, _with_linear_symmetries]]
```

$$\boxed{2x^2y + y'^2 - y'x^3 = 0}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \left(\frac{x^2}{2} + \frac{\sqrt{x^4 - 8y}}{2}\right) x \tag{1}$$

$$y' = \left(\frac{x^2}{2} - \frac{\sqrt{x^4 - 8y}}{2}\right) x \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Writing the ode as

$$y' = \frac{\left(x^2 + \sqrt{x^4 - 8y}\right) x}{2}$$

$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \frac{\left(x^2 + \sqrt{x^4 - 8y}\right) x(b_3 - a_2)}{2} - \frac{\left(x^2 + \sqrt{x^4 - 8y}\right)^2 x^2 a_3}{4} - \left(\frac{\left(2x + \frac{2x^3}{\sqrt{x^4 - 8y}}\right) x}{2} + \frac{x^2}{2} + \frac{\sqrt{x^4 - 8y}}{2}\right)(xa_2 + ya_3 + a_1) + \frac{2x(xb_2 + yb_3 + b_1)}{\sqrt{x^4 - 8y}} = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{2x^8a_3 + \sqrt{x^4 - 8y}\, x^6 a_3 + (x^4 - 8y)^{\frac{3}{2}} x^2 a_3 + 8x^5 a_2 - 2x^5 b_3 - 10x^4 y a_3 + 8\sqrt{x^4 - 8y}\, x^3 a_2 - 2\sqrt{x^4 - 8y}\, x}{} = 0$$

Setting the numerator to zero gives

$$\begin{aligned} &-2x^8a_3 - \sqrt{x^4 - 8y}\, x^6 a_3 - \left(x^4 - 8y\right)^{\frac{3}{2}} x^2 a_3 - 8x^5 a_2 \\ &+ 2x^5 b_3 + 10x^4 y a_3 - 8\sqrt{x^4 - 8y}\, x^3 a_2 + 2\sqrt{x^4 - 8y}\, x^3 b_3 \\ &- 6\sqrt{x^4 - 8y}\, x^2 y a_3 - 6x^4 a_1 - 6\sqrt{x^4 - 8y}\, x^2 a_1 + 8x^2 b_2 \\ &+ 32xya_2 - 8xyb_3 + 16y^2 a_3 + 4b_2\sqrt{x^4 - 8y} + 8xb_1 + 16ya_1 = 0 \end{aligned} \tag{6E}$$

Simplifying the above gives

$$\begin{aligned} &-\sqrt{x^4 - 8y}\, x^6 a_3 - 2\left(x^4 - 8y\right) x^4 a_3 - \left(x^4 - 8y\right)^{\frac{3}{2}} x^2 a_3 - 4x^5 a_2 - 4x^4 y a_3 \\ &- 8\sqrt{x^4 - 8y}\, x^3 a_2 + 2\sqrt{x^4 - 8y}\, x^3 b_3 - 6\sqrt{x^4 - 8y}\, x^2 y a_3 - 4x^4 a_1 \\ &- 4\left(x^4 - 8y\right) x a_2 + 2\left(x^4 - 8y\right) x b_3 - 2\left(x^4 - 8y\right) y a_3 - 6\sqrt{x^4 - 8y}\, x^2 a_1 \\ &- 2\left(x^4 - 8y\right) a_1 + 8x^2 b_2 + 8xyb_3 + 4b_2\sqrt{x^4 - 8y} + 8xb_1 = 0 \end{aligned} \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$\begin{aligned}
&-2x^8a_3 - 2\sqrt{x^4-8y}\,x^6a_3 - 8x^5a_2 + 2x^5b_3 + 10x^4ya_3 - 6x^4a_1 \\
&- 8\sqrt{x^4-8y}\,x^3a_2 + 2\sqrt{x^4-8y}\,x^3b_3 + 2\sqrt{x^4-8y}\,x^2ya_3 - 6\sqrt{x^4-8y}\,x^2a_1 \\
&+ 8x^2b_2 + 32xya_2 - 8xyb_3 + 16y^2a_3 + 8xb_1 + 4b_2\sqrt{x^4-8y} + 16ya_1 = 0
\end{aligned}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, \sqrt{x^4-8y}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, \sqrt{x^4-8y} = v_3\right\}$$

The above PDE (6E) now becomes

$$\begin{aligned}
&-2v_1^8a_3 - 2v_3v_1^6a_3 - 8v_1^5a_2 + 10v_1^4v_2a_3 + 2v_1^5b_3 - 6v_1^4a_1 \\
&- 8v_3v_1^3a_2 + 2v_3v_1^2v_2a_3 + 2v_3v_1^3b_3 - 6v_3v_1^2a_1 + 32v_1v_2a_2 \\
&+ 16v_2^2a_3 + 8v_1^2b_2 - 8v_1v_2b_3 + 16v_2a_1 + 8v_1b_1 + 4b_2v_3 = 0
\end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3\}$$

Equation (7E) now becomes

$$\begin{aligned}
&-2v_1^8a_3 - 2v_3v_1^6a_3 + (-8a_2 + 2b_3)\,v_1^5 + 10v_1^4v_2a_3 - 6v_1^4a_1 \\
&+ (-8a_2 + 2b_3)\,v_1^3v_3 + 2v_3v_1^2v_2a_3 - 6v_3v_1^2a_1 + 8v_1^2b_2 \\
&+ (32a_2 - 8b_3)\,v_1v_2 + 8v_1b_1 + 16v_2^2a_3 + 16v_2a_1 + 4b_2v_3 = 0
\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-6a_1 &= 0 \\
16a_1 &= 0 \\
-2a_3 &= 0 \\
2a_3 &= 0 \\
10a_3 &= 0 \\
16a_3 &= 0 \\
8b_1 &= 0 \\
4b_2 &= 0 \\
8b_2 &= 0 \\
-8a_2 + 2b_3 &= 0 \\
32a_2 - 8b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= a_2 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= 4a_2
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= 4y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= 4y - \left(\frac{\left(x^2 + \sqrt{x^4 - 8y}\right) x}{2}\right)(x) \\
&= -\frac{x^4}{2} - \frac{\sqrt{x^4 - 8y}\, x^2}{2} + 4y \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{-\frac{x^4}{2} - \frac{\sqrt{x^4-8y}\, x^2}{2} + 4y} dy \end{aligned}$$

Which results in

$$S = \frac{\ln(y)}{4} + \frac{\ln\left(x^2 + \sqrt{x^4 - 8y}\right)}{4} - \frac{\ln\left(-x^2 + \sqrt{x^4 - 8y}\right)}{4}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{\left(x^2 + \sqrt{x^4 - 8y}\right) x}{2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{x}{\sqrt{x^4 - 8y}} \\ S_y &= -\frac{2}{\left(x^2 + \sqrt{x^4 - 8y}\right) \sqrt{x^4 - 8y}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(y)}{4} + \frac{\ln\left(x^2 + \sqrt{x^4 - 8y}\right)}{4} - \frac{\ln\left(-x^2 + \sqrt{x^4 - 8y}\right)}{4} = c_1$$

Which simplifies to

$$\frac{\ln(y)}{4} + \frac{\ln\left(x^2 + \sqrt{x^4 - 8y}\right)}{4} - \frac{\ln\left(-x^2 + \sqrt{x^4 - 8y}\right)}{4} = c_1$$

Summary

The solution(s) found are the following

$$\frac{\ln(y)}{4} + \frac{\ln\left(x^2 + \sqrt{x^4 - 8y}\right)}{4} - \frac{\ln\left(-x^2 + \sqrt{x^4 - 8y}\right)}{4} = c_1 \tag{1}$$

Verification of solutions

$$\frac{\ln(y)}{4} + \frac{\ln\left(x^2 + \sqrt{x^4 - 8y}\right)}{4} - \frac{\ln\left(-x^2 + \sqrt{x^4 - 8y}\right)}{4} = c_1$$

Verified OK.

Solving equation (2)

Writing the ode as

$$y' = -\frac{\left(-x^2 + \sqrt{x^4 - 8y}\right)x}{2}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} b_2 &- \frac{\left(-x^2+\sqrt{x^4-8y}\right)x(b_3-a_2)}{2} - \frac{\left(-x^2+\sqrt{x^4-8y}\right)^2 x^2 a_3}{4} \\ &- \left(-\frac{\left(-2x+\frac{2x^3}{\sqrt{x^4-8y}}\right)x}{2} + \frac{x^2}{2} - \frac{\sqrt{x^4-8y}}{2}\right)(xa_2+ya_3+a_1) \\ &- \frac{2x(xb_2+yb_3+b_1)}{\sqrt{x^4-8y}} = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{-2x^8a_3 + \sqrt{x^4-8y}\,x^6a_3 + (x^4-8y)^{\frac{3}{2}}x^2a_3 - 8x^5a_2 + 2x^5b_3 + 10x^4ya_3 + 8\sqrt{x^4-8y}\,x^3a_2 - 2\sqrt{x^4-8y}}{}$$

$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} 2x^8a_3 &- \sqrt{x^4-8y}\,x^6a_3 - \left(x^4-8y\right)^{\frac{3}{2}}x^2a_3 + 8x^5a_2 - 2x^5b_3 \\ &- 10x^4ya_3 - 8\sqrt{x^4-8y}\,x^3a_2 + 2\sqrt{x^4-8y}\,x^3b_3 \\ &- 6\sqrt{x^4-8y}\,x^2ya_3 + 6x^4a_1 - 6\sqrt{x^4-8y}\,x^2a_1 - 8x^2b_2 \\ &- 32xa_2y + 8xyb_3 - 16y^2a_3 + 4b_2\sqrt{x^4-8y} - 8xb_1 - 16a_1y = 0 \end{aligned} \tag{6E}$$

Simplifying the above gives

$$
\begin{aligned}
&-\sqrt{x^4-8y}\,x^6a_3+2\left(x^4-8y\right)x^4a_3-\left(x^4-8y\right)^{\frac{3}{2}}x^2a_3+4x^5a_2+4x^4ya_3\\
&-8\sqrt{x^4-8y}\,x^3a_2+2\sqrt{x^4-8y}\,x^3b_3-6\sqrt{x^4-8y}\,x^2ya_3+4x^4a_1\\
&+4\left(x^4-8y\right)xa_2-2\left(x^4-8y\right)xb_3+2\left(x^4-8y\right)ya_3-6\sqrt{x^4-8y}\,x^2a_1\\
&+2\left(x^4-8y\right)a_1-8x^2b_2-8xyb_3+4b_2\sqrt{x^4-8y}-8xb_1=0
\end{aligned} \tag{6E}
$$

Since the PDE has radicals, simplifying gives

$$
\begin{aligned}
&2x^8a_3-2\sqrt{x^4-8y}\,x^6a_3+8x^5a_2-2x^5b_3-10x^4ya_3+6x^4a_1-8\sqrt{x^4-8y}\,x^3a_2\\
&+2\sqrt{x^4-8y}\,x^3b_3+2\sqrt{x^4-8y}\,x^2ya_3-6\sqrt{x^4-8y}\,x^2a_1-8x^2b_2\\
&-32xa_2y+8xyb_3-16y^2a_3-8xb_1+4b_2\sqrt{x^4-8y}-16a_1y=0
\end{aligned}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$
\left\{x, y, \sqrt{x^4-8y}\right\}
$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$
\left\{x=v_1, y=v_2, \sqrt{x^4-8y}=v_3\right\}
$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&2v_1^8a_3-2v_3v_1^6a_3+8v_1^5a_2-10v_1^4v_2a_3-2v_1^5b_3+6v_1^4a_1\\
&-8v_3v_1^3a_2+2v_3v_1^2v_2a_3+2v_3v_1^3b_3-6v_3v_1^2a_1-32v_1a_2v_2\\
&-16v_2^2a_3-8v_1^2b_2+8v_1v_2b_3-16a_1v_2-8v_1b_1+4b_2v_3=0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$
\{v_1, v_2, v_3\}
$$

Equation (7E) now becomes

$$
\begin{aligned}
&2v_1^8a_3-2v_3v_1^6a_3+(8a_2-2b_3)\,v_1^5-10v_1^4v_2a_3+6v_1^4a_1\\
&+(-8a_2+2b_3)\,v_1^3v_3+2v_3v_1^2v_2a_3-6v_3v_1^2a_1-8v_1^2b_2\\
&+(-32a_2+8b_3)\,v_1v_2-8v_1b_1-16v_2^2a_3-16a_1v_2+4b_2v_3=0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
-16a_1 &= 0 \\
-6a_1 &= 0 \\
6a_1 &= 0 \\
-16a_3 &= 0 \\
-10a_3 &= 0 \\
-2a_3 &= 0 \\
2a_3 &= 0 \\
-8b_1 &= 0 \\
-8b_2 &= 0 \\
4b_2 &= 0 \\
-32a_2 + 8b_3 &= 0 \\
-8a_2 + 2b_3 &= 0 \\
8a_2 - 2b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= 0 \\
a_2 &= a_2 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= 4a_2
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi &= x \\
\eta &= 4y
\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= 4y - \left(-\frac{\left(-x^2 + \sqrt{x^4 - 8y}\right)x}{2}\right)(x) \\
&= -\frac{x^4}{2} + \frac{\sqrt{x^4 - 8y}\,x^2}{2} + 4y \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{-\frac{x^4}{2} + \frac{\sqrt{x^4 - 8y}\, x^2}{2} + 4y} dy \end{aligned}$$

Which results in

$$S = \frac{\ln(y)}{4} - \frac{\ln\left(x^2 + \sqrt{x^4 - 8y}\right)}{4} + \frac{\ln\left(-x^2 + \sqrt{x^4 - 8y}\right)}{4}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{\left(-x^2 + \sqrt{x^4 - 8y}\right) x}{2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{x}{\sqrt{x^4 - 8y}} \\ S_y &= -\frac{2}{\sqrt{x^4 - 8y}\, \left(-x^2 + \sqrt{x^4 - 8y}\right)} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(y)}{4} - \frac{\ln\left(x^2+\sqrt{x^4-8y}\right)}{4} + \frac{\ln\left(-x^2+\sqrt{x^4-8y}\right)}{4} = c_1$$

Which simplifies to

$$\frac{\ln(y)}{4} - \frac{\ln\left(x^2+\sqrt{x^4-8y}\right)}{4} + \frac{\ln\left(-x^2+\sqrt{x^4-8y}\right)}{4} = c_1$$

Summary

The solution(s) found are the following

$$\frac{\ln(y)}{4} - \frac{\ln\left(x^2+\sqrt{x^4-8y}\right)}{4} + \frac{\ln\left(-x^2+\sqrt{x^4-8y}\right)}{4} = c_1 \tag{1}$$

Verification of solutions

$$\frac{\ln(y)}{4} - \frac{\ln\left(x^2+\sqrt{x^4-8y}\right)}{4} + \frac{\ln\left(-x^2+\sqrt{x^4-8y}\right)}{4} = c_1$$

Verified OK.

Section: Exercise 37, page 171
Problem number: 19.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[[_homogeneous, `class A`], _rational, _dAlembert]`

$$\boxed{yy'^2 - 3xy' - y = 0}$$

19.19.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$y\,p^2 - 3xp - y = 0$$

Solving for y from the above results in

$$y = \frac{3xp}{p^2 - 1} \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= \frac{3p}{p^2 - 1} \\
g &= 0
\end{aligned}
$$

Hence (2) becomes

$$
p - \frac{3p}{p^2 - 1} = x\left(\frac{3}{p^2 - 1} - \frac{6p^2}{(p^2 - 1)^2}\right) p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
p - \frac{3p}{p^2 - 1} = 0
$$

Solving for p from the above gives

$$
\begin{aligned}
p &= 0 \\
p &= 2 \\
p &= -2
\end{aligned}
$$

Substituting these in (1A) gives

$$
\begin{aligned}
y &= -2x \\
y &= 0 \\
y &= 2x
\end{aligned}
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{p(x) - \frac{3p(x)}{p(x)^2 - 1}}{x\left(\frac{3}{p(x)^2 - 1} - \frac{6p(x)^2}{\left(p(x)^2 - 1\right)^2}\right)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$
\frac{d}{dp}x(p) = \frac{x(p)\left(\frac{3}{p^2 - 1} - \frac{6p^2}{(p^2 - 1)^2}\right)}{p - \frac{3p}{p^2 - 1}} \tag{4}
$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = -\frac{-3p^2 - 3}{p^5 - 5p^3 + 4p}$$
$$q(p) = 0$$

Hence the ode is

$$\frac{d}{dp}x(p) - \frac{(-3p^2 - 3)\, x(p)}{p^5 - 5p^3 + 4p} = 0$$

The integrating factor μ is

$$\mu = e^{\int -\frac{-3p^2-3}{p^5-5p^3+4p}dp}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}p}\mu x = 0$$
$$\frac{\mathrm{d}}{\mathrm{d}p}\left(e^{\int -\frac{-3p^2-3}{p^5-5p^3+4p}dp} x\right) = 0$$

Integrating gives

$$e^{\int -\frac{-3p^2-3}{p^5-5p^3+4p}dp} x = c_3$$

Dividing both sides by the integrating factor $\mu = e^{\int -\frac{-3p^2-3}{p^5-5p^3+4p}dp}$ results in

$$x(p) = c_3 e^{-3\left(\int \frac{p^2+1}{p^5-5p^3+4p}dp\right)}$$

Since the solution $x(p)$ has unresolved integral, unable to continue.

Summary

The solution(s) found are the following

$$y = -2x \tag{1}$$
$$y = 0 \tag{2}$$
$$y = 2x \tag{3}$$

Verification of solutions

$$y = -2x$$

Verified OK.

$$y = 0$$

Verified OK.

$$y = 2x$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 37, page 171
Problem number: 20.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _rational, _dAlembert]
```

$$\boxed{-y{y'}^{2} = -8x - 1}$$

19.20.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$-y\,p^{2} = -8x - 1$$

Solving for y from the above results in

$$y = \frac{8x}{p^{2}} + \frac{1}{p^{2}} \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = \frac{8}{p^2}$$
$$g = \frac{1}{p^2}$$

Hence (2) becomes

$$p - \frac{8}{p^2} = \left(-\frac{16x}{p^3} - \frac{2}{p^3}\right) p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$p - \frac{8}{p^2} = 0$$

Solving for p from the above gives

$$p = 2$$
$$p = -1 - i\sqrt{3}$$
$$p = -1 + i\sqrt{3}$$

Substituting these in (1A) gives

$$y = 2x + \frac{1}{4}$$
$$y = \frac{8x + 1}{-2 + 2i\sqrt{3}}$$
$$y = \frac{8x + 1}{-2 - 2i\sqrt{3}}$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$p'(x) = \frac{p(x) - \frac{8}{p(x)^2}}{-\frac{16x}{p(x)^3} - \frac{2}{p(x)^3}} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = \frac{-\frac{16x(p)}{p^3} - \frac{2}{p^3}}{p - \frac{8}{p^2}} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = \frac{16}{p^4 - 8p}$$
$$q(p) = -\frac{2}{p^4 - 8p}$$

Hence the ode is

$$\frac{d}{dp}x(p) + \frac{16x(p)}{p^4 - 8p} = -\frac{2}{p^4 - 8p}$$

The integrating factor μ is

$$\mu = e^{\int \frac{16}{p^4 - 8p}dp}$$
$$= e^{\frac{2\ln\left(p^2+2p+4\right)}{3} + \frac{2\ln(p-2)}{3} - 2\ln(p)}$$

Which simplifies to

$$\mu = \frac{\left(p^2 + 2p + 4\right)^{\frac{2}{3}} (p-2)^{\frac{2}{3}}}{p^2}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}p}(\mu x) = (\mu)\left(-\frac{2}{p^4 - 8p}\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}p}\left(\frac{\left(p^2 + 2p + 4\right)^{\frac{2}{3}} (p-2)^{\frac{2}{3}} x}{p^2}\right) = \left(\frac{\left(p^2 + 2p + 4\right)^{\frac{2}{3}} (p-2)^{\frac{2}{3}}}{p^2}\right)\left(-\frac{2}{p^4 - 8p}\right)$$
$$\mathrm{d}\left(\frac{\left(p^2 + 2p + 4\right)^{\frac{2}{3}} (p-2)^{\frac{2}{3}} x}{p^2}\right) = \left(-\frac{2\left(p^2 + 2p + 4\right)^{\frac{2}{3}} (p-2)^{\frac{2}{3}}}{p^3 \left(p^3 - 8\right)}\right) \mathrm{d}p$$

Integrating gives

$$\frac{\left(p^2 + 2p + 4\right)^{\frac{2}{3}} (p-2)^{\frac{2}{3}} x}{p^2} = \int -\frac{2\left(p^2 + 2p + 4\right)^{\frac{2}{3}} (p-2)^{\frac{2}{3}}}{p^3 \left(p^3 - 8\right)} \mathrm{d}p$$
$$\frac{\left(p^2 + 2p + 4\right)^{\frac{2}{3}} (p-2)^{\frac{2}{3}} x}{p^2} = -\frac{(p-2)^{\frac{5}{3}} \left(p^2 + 2p + 4\right)^{\frac{5}{3}}}{8p^2 \left(p^3 - 8\right)} + c_3$$

Dividing both sides by the integrating factor $\mu = \frac{(p^2+2p+4)^{\frac{2}{3}}(p-2)^{\frac{2}{3}}}{p^2}$ results in

$$x(p) = -\frac{(p^2+2p+4)(p-2)}{8(p^3-8)} + \frac{c_3 p^2}{(p^2+2p+4)^{\frac{2}{3}}(p-2)^{\frac{2}{3}}}$$

which simplifies to

$$x(p) = -\frac{1}{8} + \frac{c_3 p^2}{(p^2+2p+4)^{\frac{2}{3}}(p-2)^{\frac{2}{3}}}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p = \frac{\sqrt{y(8x+1)}}{y}$$
$$p = -\frac{\sqrt{y(8x+1)}}{y}$$

Substituting the above in the solution for x found above gives

$$x = -\frac{1}{8} + \frac{c_3(8x+1)}{\left(\frac{8x+1+2\sqrt{y(8x+1)}+4y}{y}\right)^{\frac{2}{3}}\left(\frac{\sqrt{y(8x+1)}-2y}{y}\right)^{\frac{2}{3}} y}$$
$$x = -\frac{1}{8} + \frac{c_3(8x+1)}{\left(\frac{8x+1-2\sqrt{y(8x+1)}+4y}{y}\right)^{\frac{2}{3}}\left(\frac{-\sqrt{y(8x+1)}-2y}{y}\right)^{\frac{2}{3}} y}$$

Summary

The solution(s) found are the following

$$y = 2x + \frac{1}{4} \tag{1}$$
$$y = \frac{8x+1}{-2+2i\sqrt{3}} \tag{2}$$
$$y = \frac{8x+1}{-2-2i\sqrt{3}} \tag{3}$$
$$x = -\frac{1}{8} + \frac{c_3(8x+1)}{\left(\frac{8x+1+2\sqrt{y(8x+1)}+4y}{y}\right)^{\frac{2}{3}}\left(\frac{\sqrt{y(8x+1)}-2y}{y}\right)^{\frac{2}{3}} y} \tag{4}$$
$$x = -\frac{1}{8} + \frac{c_3(8x+1)}{\left(\frac{8x+1-2\sqrt{y(8x+1)}+4y}{y}\right)^{\frac{2}{3}}\left(\frac{-\sqrt{y(8x+1)}-2y}{y}\right)^{\frac{2}{3}} y} \tag{5}$$

Verification of solutions

$$y = 2x + \frac{1}{4}$$

Verified OK.

$$y = \frac{8x + 1}{-2 + 2i\sqrt{3}}$$

Verified OK.

$$y = \frac{8x + 1}{-2 - 2i\sqrt{3}}$$

Verified OK.

$$x = -\frac{1}{8} + \frac{c_3(8x + 1)}{\left(\frac{8x+1+2\sqrt{y(8x+1)}+4y}{y}\right)^{\frac{2}{3}} \left(\frac{\sqrt{y(8x+1)}-2y}{y}\right)^{\frac{2}{3}} y}$$

Verified OK.

$$x = -\frac{1}{8} + \frac{c_3(8x + 1)}{\left(\frac{8x+1-2\sqrt{y(8x+1)}+4y}{y}\right)^{\frac{2}{3}} \left(\frac{-\sqrt{y(8x+1)}-2y}{y}\right)^{\frac{2}{3}} y}$$

Verified OK.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{yy'^2 + 2y' = -1}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{-1 + \sqrt{1-y}}{y} \tag{1}$$

$$y' = -\frac{1 + \sqrt{1-y}}{y} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{y}{-1 + \sqrt{1-y}} dy = \int dx$$

$$\frac{2(1-y)^{\frac{3}{2}}}{3} + 1 - y = x + c_1$$

Summary
The solution(s) found are the following

$$\frac{2(1-y)^{\frac{3}{2}}}{3}+1-y=x+c_1 \tag{1}$$

Verification of solutions

$$\frac{2(1-y)^{\frac{3}{2}}}{3}+1-y=x+c_1$$

Verified OK.

Solving equation (2)

Integrating both sides gives

$$\int -\frac{y}{1+\sqrt{1-y}}dy=\int dx$$

$$-\frac{2(1-y)^{\frac{3}{2}}}{3}+1-y=x+c_2$$

Summary
The solution(s) found are the following

$$-\frac{2(1-y)^{\frac{3}{2}}}{3}+1-y=x+c_2 \tag{1}$$

Verification of solutions

$$-\frac{2(1-y)^{\frac{3}{2}}}{3}+1-y=x+c_2$$

Verified OK.

19.21.1 Maple step by step solution

Let's solve

$yy'^2+2y'=-1$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'y}{-1+\sqrt{1-y}}=1$

- Integrate both sides with respect to x

  $\int \frac{y' y}{-1+\sqrt{1-y}} dx = \int 1 dx + c_1$

- Evaluate integral

  $\frac{2(1-y)^{\frac{3}{2}}}{3} + 1 - y = x + c_1$

- Solve for y

  $y = -\left(\frac{\left(-1+6c_1+6x+2\sqrt{9c_1^2+18c_1x+9x^2-3c_1-3x}\right)^{\frac{1}{3}}}{2} + \frac{1}{2\left(-1+6c_1+6x+2\sqrt{9c_1^2+18c_1x+9x^2-3c_1-3x}\right)^{\frac{1}{3}}} - \frac{1}{2}\right)^2 + 1$

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _dAlembert]
```

$$\boxed{\left(1+y'^2\right) x-(y+x)\, y'=0}$$

19.22.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$\left(p^2+1\right) x-(y+x)\, p=0$$

Solving for y from the above results in

$$y = \frac{x(p^2-p+1)}{p} \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$

$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= \frac{p^2 - p + 1}{p} \\
g &= 0
\end{aligned}
$$

Hence (2) becomes

$$
p - \frac{p^2 - p + 1}{p} = x\left(\frac{2p - 1}{p} - \frac{p^2 - p + 1}{p^2}\right) p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
p - \frac{p^2 - p + 1}{p} = 0
$$

Solving for p from the above gives

$$
p = 1
$$

Substituting these in (1A) gives

$$
y = x
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{p(x) - \frac{p(x)^2 - p(x) + 1}{p(x)}}{x\left(\frac{2p(x) - 1}{p(x)} - \frac{p(x)^2 - p(x) + 1}{p(x)^2}\right)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$
\frac{d}{dp}x(p) = \frac{x(p)\left(\frac{2p-1}{p} - \frac{p^2 - p + 1}{p^2}\right)}{p - \frac{p^2 - p + 1}{p}} \tag{4}
$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
\frac{d}{dp}x(p) + p(p)x(p) = q(p)
$$

Where here

$$p(p) = -\frac{p+1}{p}$$
$$q(p) = 0$$

Hence the ode is

$$\frac{d}{dp}x(p) - \frac{(p+1)\,x(p)}{p} = 0$$

The integrating factor μ is

$$\mu = e^{\int -\frac{p+1}{p}dp}$$
$$= e^{-p-\ln(p)}$$

Which simplifies to

$$\mu = \frac{e^{-p}}{p}$$

The ode becomes

$$\frac{d}{dp}\mu x = 0$$
$$\frac{d}{dp}\left(\frac{e^{-p}x}{p}\right) = 0$$

Integrating gives

$$\frac{e^{-p}x}{p} = c_2$$

Dividing both sides by the integrating factor $\mu = \frac{e^{-p}}{p}$ results in

$$x(p) = c_2 p\, e^{p}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p = \frac{y + x + \sqrt{y^2 + 2yx - 3x^2}}{2x}$$
$$p = -\frac{-y - x + \sqrt{y^2 + 2yx - 3x^2}}{2x}$$

Substituting the above in the solution for x found above gives

$$x = \frac{c_2\left(y + x + \sqrt{y^2 + 2yx - 3x^2}\right) e^{\frac{y+x+\sqrt{y^2+2yx-3x^2}}{2x}}}{2x}$$

$$x = \frac{c_2\left(y + x - \sqrt{y^2 + 2yx - 3x^2}\right) e^{\frac{y+x-\sqrt{y^2+2yx-3x^2}}{2x}}}{2x}$$

Summary

The solution(s) found are the following

$$y = x \tag{1}$$

$$x = \frac{c_2\left(y + x + \sqrt{y^2 + 2yx - 3x^2}\right) e^{\frac{y+x+\sqrt{y^2+2yx-3x^2}}{2x}}}{2x} \tag{2}$$

$$x = \frac{c_2\left(y + x - \sqrt{y^2 + 2yx - 3x^2}\right) e^{\frac{y+x-\sqrt{y^2+2yx-3x^2}}{2x}}}{2x} \tag{3}$$

Verification of solutions

$$y = x$$

Verified OK.

$$x = \frac{c_2\left(y + x + \sqrt{y^2 + 2yx - 3x^2}\right) e^{\frac{y+x+\sqrt{y^2+2yx-3x^2}}{2x}}}{2x}$$

Verified OK.

$$x = \frac{c_2\left(y + x - \sqrt{y^2 + 2yx - 3x^2}\right) e^{\frac{y+x-\sqrt{y^2+2yx-3x^2}}{2x}}}{2x}$$

Verified OK.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational]
```

$$\boxed{-3yy' + y'^2x = -x^2}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{3y + \sqrt{9y^2 - 4x^3}}{2x} \tag{1}$$
$$y' = \frac{3y - \sqrt{9y^2 - 4x^3}}{2x} \tag{2}$$

Now each one of the above ODE is solved.

<u>Solving equation (1)</u>

Writing the ode as

$$y' = \frac{3y + \sqrt{-4x^3 + 9y^2}}{2x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} &b_2 + \frac{\left(3y + \sqrt{-4x^3 + 9y^2}\right)(b_3 - a_2)}{2x} - \frac{\left(3y + \sqrt{-4x^3 + 9y^2}\right)^2 a_3}{4x^2} \\ &- \left(-\frac{3y + \sqrt{-4x^3 + 9y^2}}{2x^2} - \frac{3x}{\sqrt{-4x^3 + 9y^2}}\right)(xa_2 + ya_3 + a_1) \\ &- \frac{\left(3 + \frac{9y}{\sqrt{-4x^3+9y^2}}\right)(xb_2 + yb_3 + b_1)}{2x} = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{-12x^4a_2 + 8x^4b_3 - 28x^3ya_3 + (-4x^3 + 9y^2)^{\frac{3}{2}} a_3 + 2b_2x^2\sqrt{-4x^3 + 9y^2} + 3\sqrt{-4x^3 + 9y^2}\, y^2a_3 - 4x^3a_1 +}{4x^2\sqrt{-4x^3 + 9y^2}}$$
$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} &12x^4a_2 - 8x^4b_3 + 28x^3ya_3 - \left(-4x^3 + 9y^2\right)^{\frac{3}{2}} a_3 - 2b_2x^2\sqrt{-4x^3 + 9y^2} \\ &- 3\sqrt{-4x^3 + 9y^2}\, y^2a_3 + 4x^3a_1 - 18x^2yb_2 - 36y^3a_3 \\ &- 6\sqrt{-4x^3 + 9y^2}\, xb_1 + 6\sqrt{-4x^3 + 9y^2}\, ya_1 - 18xyb_1 + 18y^2a_1 = 0 \end{aligned} \tag{6E}$$

Simplifying the above gives

$$\begin{aligned} &12x^4a_2 + 12x^3ya_3 - \left(-4x^3 + 9y^2\right)^{\frac{3}{2}} a_3 + 2\left(-4x^3 + 9y^2\right)xb_3 - 4\left(-4x^3\right. \\ &\left.+ 9y^2\right)ya_3 - 2b_2x^2\sqrt{-4x^3 + 9y^2} - 3\sqrt{-4x^3 + 9y^2}\, y^2a_3 + 12x^3a_1 - 18x^2yb_2 \\ &- 18x\,y^2b_3 + 2\left(-4x^3 + 9y^2\right)a_1 - 6\sqrt{-4x^3 + 9y^2}\, xb_1 + 6\sqrt{-4x^3 + 9y^2}\, ya_1 \\ &- 18xyb_1 = 0 \end{aligned} \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$
\begin{aligned}
&12x^4a_2 - 8x^4b_3 + 4x^3\sqrt{-4x^3+9y^2}\,a_3 + 28x^3ya_3 + 4x^3a_1 \\
&- 2b_2x^2\sqrt{-4x^3+9y^2} - 18x^2yb_2 - 12\sqrt{-4x^3+9y^2}\,y^2a_3 - 36y^3a_3 \\
&- 6\sqrt{-4x^3+9y^2}\,xb_1 - 18xyb_1 + 6\sqrt{-4x^3+9y^2}\,ya_1 + 18y^2a_1 = 0
\end{aligned}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$
\left\{x, y, \sqrt{-4x^3+9y^2}\right\}
$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$
\left\{x = v_1, y = v_2, \sqrt{-4x^3+9y^2} = v_3\right\}
$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&12v_1^4a_2 + 28v_1^3v_2a_3 + 4v_1^3v_3a_3 - 8v_1^4b_3 + 4v_1^3a_1 - 36v_2^3a_3 - 12v_3v_2^2a_3 \\
&- 18v_1^2v_2b_2 - 2b_2v_1^2v_3 + 18v_2^2a_1 + 6v_3v_2a_1 - 18v_1v_2b_1 - 6v_3v_1b_1 = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$
\{v_1, v_2, v_3\}
$$

Equation (7E) now becomes

$$
\begin{aligned}
&(12a_2 - 8b_3)\,v_1^4 + 28v_1^3v_2a_3 + 4v_1^3v_3a_3 + 4v_1^3a_1 - 18v_1^2v_2b_2 - 2b_2v_1^2v_3 \\
&- 18v_1v_2b_1 - 6v_3v_1b_1 - 36v_2^3a_3 - 12v_3v_2^2a_3 + 18v_2^2a_1 + 6v_3v_2a_1 = 0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
4a_1 &= 0 \\
6a_1 &= 0 \\
18a_1 &= 0 \\
-36a_3 &= 0 \\
-12a_3 &= 0 \\
4a_3 &= 0 \\
28a_3 &= 0 \\
-18b_1 &= 0 \\
-6b_1 &= 0 \\
-18b_2 &= 0 \\
-2b_2 &= 0 \\
12a_2 - 8b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= a_2 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= \frac{3a_2}{2}
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= \frac{3y}{2}
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= \frac{3y}{2} - \left(\frac{3y + \sqrt{-4x^3 + 9y^2}}{2x}\right)(x) \\
&= -\frac{\sqrt{-4x^3 + 9y^2}}{2} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{-\frac{\sqrt{-4x^3+9y^2}}{2}} dy \end{aligned}$$

Which results in

$$S = -\frac{2 \ln\left(y\sqrt{9} + \sqrt{-4x^3 + 9y^2}\right) \sqrt{9}}{9}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{3y + \sqrt{-4x^3 + 9y^2}}{2x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{4x^2}{\sqrt{-4x^3 + 9y^2}\,\left(3y + \sqrt{-4x^3 + 9y^2}\right)} \\ S_y &= -\frac{2}{\sqrt{-4x^3 + 9y^2}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{8x^3 - 18y^2 - 6\sqrt{-4x^3 + 9y^2}\, y}{x\sqrt{-4x^3 + 9y^2}\, \left(3y + \sqrt{-4x^3 + 9y^2}\right)} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{2}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -2\ln(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{2\ln\left(3y + \sqrt{9y^2 - 4x^3}\right)}{3} = -2\ln(x) + c_1$$

Which simplifies to

$$-\frac{2\ln\left(3y + \sqrt{9y^2 - 4x^3}\right)}{3} = -2\ln(x) + c_1$$

Which gives

$$y = \frac{\left(4\,\mathrm{e}^{3c_1} + x^3\right)\mathrm{e}^{-\frac{3c_1}{2}}}{6}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(4\,\mathrm{e}^{3c_1} + x^3\right)\mathrm{e}^{-\frac{3c_1}{2}}}{6} \tag{1}$$

Verification of solutions

$$y = \frac{\left(4\,\mathrm{e}^{3c_1} + x^3\right)\mathrm{e}^{-\frac{3c_1}{2}}}{6}$$

Verified OK.

Solving equation (2)

Writing the ode as

$$y' = -\frac{\sqrt{-4x^3+9y^2}-3y}{2x}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 - \frac{\left(\sqrt{-4x^3+9y^2}-3y\right)(b_3-a_2)}{2x} - \frac{\left(\sqrt{-4x^3+9y^2}-3y\right)^2 a_3}{4x^2} - \left(\frac{3x}{\sqrt{-4x^3+9y^2}} + \frac{\sqrt{-4x^3+9y^2}-3y}{2x^2}\right)(xa_2+ya_3+a_1) + \frac{\left(\frac{9y}{\sqrt{-4x^3+9y^2}}-3\right)(xb_2+yb_3+b_1)}{2x} = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{12x^4a_2 - 8x^4b_3 + 28x^3ya_3 + (-4x^3+9y^2)^{\frac{3}{2}}a_3 + 2b_2\sqrt{-4x^3+9y^2}\,x^2 + 3\sqrt{-4x^3+9y^2}\,y^2a_3 + 4x^3a_1 - 1}{4\sqrt{-4x^3+9y^2}\,x^2} = 0$$

Setting the numerator to zero gives

$$-12x^4a_2 + 8x^4b_3 - 28x^3ya_3 - \left(-4x^3+9y^2\right)^{\frac{3}{2}}a_3 - 2b_2\sqrt{-4x^3+9y^2}\,x^2 - 3\sqrt{-4x^3+9y^2}\,y^2a_3 - 4x^3a_1 + 18x^2yb_2 + 36y^3a_3 - 6\sqrt{-4x^3+9y^2}\,xb_1 + 6\sqrt{-4x^3+9y^2}\,ya_1 + 18xyb_1 - 18y^2a_1 = 0 \tag{6E}$$

Simplifying the above gives

$$
\begin{aligned}
&-12x^4a_2 - 12x^3ya_3 - \left(-4x^3+9y^2\right)^{\frac{3}{2}} a_3 - 2\left(-4x^3+9y^2\right) xb_3 \\
&+ 4\left(-4x^3+9y^2\right) ya_3 - 2b_2\sqrt{-4x^3+9y^2}\, x^2 - 3\sqrt{-4x^3+9y^2}\, y^2a_3 \\
&- 12x^3a_1 + 18x^2yb_2 + 18x\,y^2b_3 - 2\left(-4x^3+9y^2\right) a_1 \\
&- 6\sqrt{-4x^3+9y^2}\, xb_1 + 6\sqrt{-4x^3+9y^2}\, ya_1 + 18xyb_1 = 0
\end{aligned} \tag{6E}
$$

Since the PDE has radicals, simplifying gives

$$
\begin{aligned}
&-12x^4a_2 + 8x^4b_3 + 4x^3\sqrt{-4x^3+9y^2}\, a_3 - 28x^3ya_3 - 4x^3a_1 \\
&- 2b_2\sqrt{-4x^3+9y^2}\, x^2 + 18x^2yb_2 - 12\sqrt{-4x^3+9y^2}\, y^2a_3 + 36y^3a_3 \\
&- 6\sqrt{-4x^3+9y^2}\, xb_1 + 18xyb_1 + 6\sqrt{-4x^3+9y^2}\, ya_1 - 18y^2a_1 = 0
\end{aligned}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$
\left\{x, y, \sqrt{-4x^3+9y^2}\right\}
$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$
\left\{x = v_1, y = v_2, \sqrt{-4x^3+9y^2} = v_3\right\}
$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&-12v_1^4a_2 - 28v_1^3v_2a_3 + 4v_1^3v_3a_3 + 8v_1^4b_3 - 4v_1^3a_1 + 36v_2^3a_3 - 12v_3v_2^2a_3 \\
&+ 18v_1^2v_2b_2 - 2b_2v_3v_1^2 - 18v_2^2a_1 + 6v_3v_2a_1 + 18v_1v_2b_1 - 6v_3v_1b_1 = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$
\{v_1, v_2, v_3\}
$$

Equation (7E) now becomes

$$
\begin{aligned}
&(-12a_2 + 8b_3)\, v_1^4 - 28v_1^3v_2a_3 + 4v_1^3v_3a_3 - 4v_1^3a_1 + 18v_1^2v_2b_2 - 2b_2v_3v_1^2 \\
&+ 18v_1v_2b_1 - 6v_3v_1b_1 + 36v_2^3a_3 - 12v_3v_2^2a_3 - 18v_2^2a_1 + 6v_3v_2a_1 = 0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-18a_1 &= 0 \\
-4a_1 &= 0 \\
6a_1 &= 0 \\
-28a_3 &= 0 \\
-12a_3 &= 0 \\
4a_3 &= 0 \\
36a_3 &= 0 \\
-6b_1 &= 0 \\
18b_1 &= 0 \\
-2b_2 &= 0 \\
18b_2 &= 0 \\
-12a_2 + 8b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= a_2 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= \frac{3a_2}{2}
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= \frac{3y}{2}
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= \frac{3y}{2} - \left(-\frac{\sqrt{-4x^3 + 9y^2} - 3y}{2x}\right)(x) \\
&= \frac{\sqrt{-4x^3 + 9y^2}}{2} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{\sqrt{-4x^3+9y^2}}{2}} dy \end{aligned}$$

Which results in

$$S = \frac{2 \ln \left(y\sqrt{9} + \sqrt{-4x^3 + 9y^2}\right) \sqrt{9}}{9}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{\sqrt{-4x^3 + 9y^2} - 3y}{2x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{4x^2}{\sqrt{-4x^3 + 9y^2}\,\left(3y + \sqrt{-4x^3 + 9y^2}\right)} \\ S_y &= \frac{2}{\sqrt{-4x^3 + 9y^2}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{2\ln\left(3y + \sqrt{9y^2 - 4x^3}\right)}{3} = c_1$$

Which simplifies to

$$\frac{2\ln\left(3y + \sqrt{9y^2 - 4x^3}\right)}{3} = c_1$$

Which gives

$$y = \frac{(4x^3 + e^{3c_1})\, e^{-\frac{3c_1}{2}}}{6}$$

Summary

The solution(s) found are the following

$$y = \frac{(4x^3 + e^{3c_1})\, e^{-\frac{3c_1}{2}}}{6} \tag{1}$$

Verification of solutions

$$y = \frac{(4x^3 + e^{3c_1})\, e^{-\frac{3c_1}{2}}}{6}$$

Verified OK.

Section: Exercise 37, page 171
Problem number: 24.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _dAlembert]
```

$$\boxed{y + 2xy' - y'^2x = 0}$$

19.24.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$-p^2x + 2xp + y = 0$$

Solving for y from the above results in

$$y = (p^2 - 2p)\,x \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = p^2 - 2p$$
$$g = 0$$

Hence (2) becomes

$$-p^2 + 3p = x(2p - 2)\,p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$-p^2 + 3p = 0$$

Solving for p from the above gives

$$p = 0$$
$$p = 3$$

Substituting these in (1A) gives

$$y = 0$$
$$y = 3x$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$p'(x) = \frac{-p(x)^2 + 3p(x)}{x\,(2p\,(x) - 2)} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = \frac{x(p)\,(2p - 2)}{-p^2 + 3p} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = -\frac{-2p + 2}{p\,(p - 3)}$$
$$q(p) = 0$$

Hence the ode is

$$\frac{d}{dp}x(p) - \frac{(-2p+2)\,x(p)}{p\,(p-3)} = 0$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{-2p+2}{p(p-3)}dp} \\ &= \mathrm{e}^{\frac{4\ln(p-3)}{3}+\frac{2\ln(p)}{3}}\end{aligned}$$

Which simplifies to

$$\mu = (p-3)^{\frac{4}{3}}\,p^{\frac{2}{3}}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}p}\mu x &= 0 \\ \frac{\mathrm{d}}{\mathrm{d}p}\left((p-3)^{\frac{4}{3}}\,p^{\frac{2}{3}}x\right) &= 0\end{aligned}$$

Integrating gives

$$(p-3)^{\frac{4}{3}}\,p^{\frac{2}{3}}x = c_3$$

Dividing both sides by the integrating factor $\mu = (p-3)^{\frac{4}{3}}\,p^{\frac{2}{3}}$ results in

$$x(p) = \frac{c_3}{(p-3)^{\frac{4}{3}}\,p^{\frac{2}{3}}}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$\begin{aligned}p &= \frac{x+\sqrt{x^2+yx}}{x} \\ p &= -\frac{-x+\sqrt{x^2+yx}}{x}\end{aligned}$$

Substituting the above in the solution for x found above gives

$$x = \frac{c_3 x}{\left(-2x+\sqrt{x\,(y+x)}\right)\left(\frac{-2x+\sqrt{x(y+x)}}{x}\right)^{\frac{1}{3}}\left(\frac{x+\sqrt{x(y+x)}}{x}\right)^{\frac{2}{3}}}$$

$$x = -\frac{c_3 x}{\left(2x+\sqrt{x\,(y+x)}\right)\left(\frac{-2x-\sqrt{x(y+x)}}{x}\right)^{\frac{1}{3}}\left(\frac{x-\sqrt{x(y+x)}}{x}\right)^{\frac{2}{3}}}$$

Summary

The solution(s) found are the following

$$y = 0 \tag{1}$$
$$y = 3x \tag{2}$$
$$x = \frac{c_3 x}{\left(-2x + \sqrt{x(y+x)}\right)\left(\frac{-2x+\sqrt{x(y+x)}}{x}\right)^{\frac{1}{3}}\left(\frac{x+\sqrt{x(y+x)}}{x}\right)^{\frac{2}{3}}} \tag{3}$$
$$x = -\frac{c_3 x}{\left(2x + \sqrt{x(y+x)}\right)\left(\frac{-2x-\sqrt{x(y+x)}}{x}\right)^{\frac{1}{3}}\left(\frac{x-\sqrt{x(y+x)}}{x}\right)^{\frac{2}{3}}} \tag{4}$$

Verification of solutions

$$y = 0$$

Verified OK.

$$y = 3x$$

Verified OK.

$$x = \frac{c_3 x}{\left(-2x + \sqrt{x(y+x)}\right)\left(\frac{-2x+\sqrt{x(y+x)}}{x}\right)^{\frac{1}{3}}\left(\frac{x+\sqrt{x(y+x)}}{x}\right)^{\frac{2}{3}}}$$

Verified OK.

$$x = -\frac{c_3 x}{\left(2x + \sqrt{x(y+x)}\right)\left(\frac{-2x-\sqrt{x(y+x)}}{x}\right)^{\frac{1}{3}}\left(\frac{x-\sqrt{x(y+x)}}{x}\right)^{\frac{2}{3}}}$$

Verified OK.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{-{y'}^{2}-y' = -x}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = -\frac{1}{2}+\frac{\sqrt{1+4x}}{2} \tag{1}$$

$$y' = -\frac{1}{2}-\frac{\sqrt{1+4x}}{2} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\begin{aligned} y &= \int -\frac{1}{2}+\frac{\sqrt{1+4x}}{2}\,\mathrm{d}x \\ &= -\frac{x}{2}+\frac{(1+4x)^{\frac{3}{2}}}{12}+c_1 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = -\frac{x}{2}+\frac{(1+4x)^{\frac{3}{2}}}{12}+c_1 \tag{1}$$

Verification of solutions

$$y = -\frac{x}{2} + \frac{(1+4x)^{\frac{3}{2}}}{12} + c_1$$

Verified OK.

Solving equation (2)

Integrating both sides gives

$$\begin{aligned} y &= \int -\frac{1}{2} - \frac{\sqrt{1+4x}}{2}\,\mathrm{d}x \\ &= -\frac{x}{2} - \frac{(1+4x)^{\frac{3}{2}}}{12} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{x}{2} - \frac{(1+4x)^{\frac{3}{2}}}{12} + c_2 \tag{1}$$

Verification of solutions

$$y = -\frac{x}{2} - \frac{(1+4x)^{\frac{3}{2}}}{12} + c_2$$

Verified OK.

20.1.1 Maple step by step solution

Let's solve

$-y'^2 - y' = -x$

- Highest derivative means the order of the ODE is 1

  y'

- Integrate both sides with respect to x

  $\int \left(-y'^2 - y'\right) dx = \int -x dx + c_1$

- Cannot compute integral

  $\int \left(-y'^2 - y'\right) dx = -\frac{x^2}{2} + c_1$

Problem number: 2.
ODE order: 1.
ODE degree: 3.

The type(s) of ODE detected by this program : **"dAlembert", "first_order_nonlinear_p_but_linear_in_x_y"**

Maple gives the following as the ode type

`[[_homogeneous, `class C`], _dAlembert]`

$$\boxed{-y + y'^3 = -x}$$

20.2.1 Solving as first order nonlinear p but linear in x y ode

The ode has the form

$$(y')^{\frac{n}{m}} = ax + by + c \tag{1}$$

Where $n = 3, m = 1, a = -1, b = 1, c = 0$. Hence the ode is

$$(y')^3 = y - x$$

Let

$$u = ax + by + c$$

Hence

$$u' = a + by'$$
$$y' = \frac{u' - a}{b}$$

Substituting the above in (1) gives

$$\left(\frac{u' - a}{b}\right)^{\frac{n}{m}} = u$$
$$\left(\frac{u' - a}{b}\right)^{n} = u^{m}$$

Plugging in the above the values for n, m, a, b, c gives

$$(u'(x) + 1)^3 = u$$

Therefore the solutions are

$$u'(x) + 1 = u^{\frac{1}{3}}$$
$$u'(x) + 1 = -\frac{u^{\frac{1}{3}}}{2} + \frac{i\sqrt{3}\, u^{\frac{1}{3}}}{2}$$
$$u'(x) + 1 = -\frac{u^{\frac{1}{3}}}{2} - \frac{i\sqrt{3}\, u^{\frac{1}{3}}}{2}$$

Rewriting the above gives

$$u'(x) = u^{\frac{1}{3}} - 1$$
$$u'(x) = -\frac{u^{\frac{1}{3}}}{2} + \frac{i\sqrt{3}\, u^{\frac{1}{3}}}{2} - 1$$
$$u'(x) = -\frac{u^{\frac{1}{3}}}{2} - \frac{i\sqrt{3}\, u^{\frac{1}{3}}}{2} - 1$$

Each of the above is a separable ODE in $u(x)$. This results in

$$\frac{du}{u^{\frac{1}{3}} - 1} = dx$$
$$\frac{du}{-\frac{u^{\frac{1}{3}}}{2} + \frac{i\sqrt{3}\, u^{\frac{1}{3}}}{2} - 1} = dx$$
$$\frac{du}{-\frac{u^{\frac{1}{3}}}{2} - \frac{i\sqrt{3}\, u^{\frac{1}{3}}}{2} - 1} = dx$$

Integrating each of the above solutions gives

$$\int \frac{du}{u^{\frac{1}{3}} - 1} = x + c_1$$
$$\int \frac{du}{-\frac{u^{\frac{1}{3}}}{2} + \frac{i\sqrt{3}\, u^{\frac{1}{3}}}{2} - 1} = x + c_1$$
$$\int \frac{du}{-\frac{u^{\frac{1}{3}}}{2} - \frac{i\sqrt{3}\, u^{\frac{1}{3}}}{2} - 1} = x + c_1$$

But since

$$
\begin{aligned}
u &= ax + by + c \\
&= y - x
\end{aligned}
$$

Then the solutions can be written as

$$
\begin{aligned}
\int^{y-x} \frac{1}{\tau^{\frac{1}{3}} - 1} d\tau &= x + c_1 \\
\int^{y-x} \frac{1}{-\frac{\tau^{\frac{1}{3}}}{2} + \frac{i\sqrt{3}\,\tau^{\frac{1}{3}}}{2} - 1} d\tau &= x + c_1 \\
\int^{y-x} \frac{1}{-\frac{\tau^{\frac{1}{3}}}{2} - \frac{i\sqrt{3}\,\tau^{\frac{1}{3}}}{2} - 1} d\tau &= x + c_1
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
\int^{y-x} \frac{1}{\tau^{\frac{1}{3}} - 1} d\tau = x + c_1 \tag{1}
$$

$$
\int^{y-x} \frac{1}{-\frac{\tau^{\frac{1}{3}}}{2} + \frac{i\sqrt{3}\,\tau^{\frac{1}{3}}}{2} - 1} d\tau = x + c_1 \tag{2}
$$

$$
\int^{y-x} \frac{1}{-\frac{\tau^{\frac{1}{3}}}{2} - \frac{i\sqrt{3}\,\tau^{\frac{1}{3}}}{2} - 1} d\tau = x + c_1 \tag{3}
$$

Verification of solutions

$$
\int^{y-x} \frac{1}{\tau^{\frac{1}{3}} - 1} d\tau = x + c_1
$$

Verified OK.

$$
\int^{y-x} \frac{1}{-\frac{\tau^{\frac{1}{3}}}{2} + \frac{i\sqrt{3}\,\tau^{\frac{1}{3}}}{2} - 1} d\tau = x + c_1
$$

Verified OK.

$$
\int^{y-x} \frac{1}{-\frac{\tau^{\frac{1}{3}}}{2} - \frac{i\sqrt{3}\,\tau^{\frac{1}{3}}}{2} - 1} d\tau = x + c_1
$$

Verified OK.

20.2.2 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$p^3 - y = -x$$

Solving for y from the above results in

$$y = p^3 + x \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$\begin{aligned} p &= f + (xf' + g')\frac{dp}{dx} \\ p - f &= (xf' + g')\frac{dp}{dx} \end{aligned} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$\begin{aligned} f &= 1 \\ g &= p^3 \end{aligned}$$

Hence (2) becomes

$$p - 1 = 3p^2p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$p - 1 = 0$$

Solving for p from the above gives

$$p = 1$$

Substituting these in (1A) gives

$$y = x + 1$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$p'(x) = \frac{p(x) - 1}{3p(x)^2} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = \frac{3p^2}{p-1} \tag{4}$$

This ODE is now solved for $x(p)$. Integrating both sides gives

$$\begin{aligned} x(p) &= \int \frac{3p^2}{p-1}\, \mathrm{d}p \\ &= \frac{3p^2}{2} + 3p + 3\ln(p-1) + c_2 \end{aligned}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$\begin{aligned} p &= (y-x)^{\frac{1}{3}} \\ p &= -\frac{(y-x)^{\frac{1}{3}}}{2} - \frac{i\sqrt{3}\,(y-x)^{\frac{1}{3}}}{2} \\ p &= -\frac{(y-x)^{\frac{1}{3}}}{2} + \frac{i\sqrt{3}\,(y-x)^{\frac{1}{3}}}{2} \end{aligned}$$

Substituting the above in the solution for x found above gives

$$\begin{aligned} x &= \frac{3(y-x)^{\frac{2}{3}}}{2} + 3(y-x)^{\frac{1}{3}} + 3\ln\left((y-x)^{\frac{1}{3}} - 1\right) + c_2 \\ x &= -\frac{3(y-x)^{\frac{2}{3}}}{4} + \frac{3i\sqrt{3}\,(y-x)^{\frac{2}{3}}}{4} - \frac{3(y-x)^{\frac{1}{3}}}{2} - \frac{3i\sqrt{3}\,(y-x)^{\frac{1}{3}}}{2} \\ &\quad - 3\ln(2) + 3\ln\left(-(y-x)^{\frac{1}{3}} - i\sqrt{3}\,(y-x)^{\frac{1}{3}} - 2\right) + c_2 \\ x &= -\frac{3(y-x)^{\frac{2}{3}}}{4} - \frac{3i\sqrt{3}\,(y-x)^{\frac{2}{3}}}{4} - \frac{3(y-x)^{\frac{1}{3}}}{2} + \frac{3i\sqrt{3}\,(y-x)^{\frac{1}{3}}}{2} \\ &\quad - 3\ln(2) + 3\ln\left(i\sqrt{3}\,(y-x)^{\frac{1}{3}} - (y-x)^{\frac{1}{3}} - 2\right) + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = x + 1 \tag{1}$$

$$x = \frac{3(y-x)^{\frac{2}{3}}}{2} + 3(y-x)^{\frac{1}{3}} + 3\ln\left((y-x)^{\frac{1}{3}} - 1\right) + c_2 \tag{2}$$

$$\begin{aligned} x = &-\frac{3(y-x)^{\frac{2}{3}}}{4} + \frac{3i\sqrt{3}\,(y-x)^{\frac{2}{3}}}{4} - \frac{3(y-x)^{\frac{1}{3}}}{2} - \frac{3i\sqrt{3}\,(y-x)^{\frac{1}{3}}}{2} \\ &- 3\ln(2) + 3\ln\left(-(y-x)^{\frac{1}{3}} - i\sqrt{3}\,(y-x)^{\frac{1}{3}} - 2\right) + c_2 \end{aligned} \tag{3}$$

$$\begin{aligned} x = &-\frac{3(y-x)^{\frac{2}{3}}}{4} - \frac{3i\sqrt{3}\,(y-x)^{\frac{2}{3}}}{4} - \frac{3(y-x)^{\frac{1}{3}}}{2} + \frac{3i\sqrt{3}\,(y-x)^{\frac{1}{3}}}{2} \\ &- 3\ln(2) + 3\ln\left(i\sqrt{3}\,(y-x)^{\frac{1}{3}} - (y-x)^{\frac{1}{3}} - 2\right) + c_2 \end{aligned} \tag{4}$$

Verification of solutions

$$y = x + 1$$

Verified OK.

$$x = \frac{3(y-x)^{\frac{2}{3}}}{2} + 3(y-x)^{\frac{1}{3}} + 3\ln\left((y-x)^{\frac{1}{3}} - 1\right) + c_2$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 38, page 173
Problem number: 3.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _dAlembert]
```

$$\boxed{2yy' - {y'}^2 x = -x}$$

20.3.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$-p^2 x + 2yp = -x$$

Solving for y from the above results in

$$y = \frac{x(p^2 - 1)}{2p} \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= \frac{p^2 - 1}{2p} \\
g &= 0
\end{aligned}
$$

Hence (2) becomes

$$
p - \frac{p^2 - 1}{2p} = x\left(1 - \frac{p^2 - 1}{2p^2}\right) p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
p - \frac{p^2 - 1}{2p} = 0
$$

Solving for p from the above gives

$$
\begin{aligned}
p &= i \\
p &= -i
\end{aligned}
$$

Substituting these in (1A) gives

$$
\begin{aligned}
y &= -ix \\
y &= ix
\end{aligned}
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{p(x) - \frac{p(x)^2 - 1}{2p(x)}}{x\left(1 - \frac{p(x)^2 - 1}{2p(x)^2}\right)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
p'(x) + p(x)p(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= 0
\end{aligned}
$$

Hence the ode is

$$p'(x) - \frac{p(x)}{x} = 0$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{1}{x}dx} \\ &= \frac{1}{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}\mu p &= 0 \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{p}{x}\right) &= 0\end{aligned}$$

Integrating gives

$$\frac{p}{x} = c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$p(x) = c_1 x$$

Substituing the above solution for p in (2A) gives

$$y = \frac{c_1^2 x^2 - 1}{2c_1}$$

Summary

The solution(s) found are the following

$$y = -ix \tag{1}$$

$$y = ix \tag{2}$$

$$y = \frac{c_1^2 x^2 - 1}{2c_1} \tag{3}$$

Verification of solutions

$$y = -ix$$

Verified OK.

$$y = ix$$

Verified OK.

$$y = \frac{c_1^2 x^2 - 1}{2c_1}$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 38, page 173
Problem number: 4.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[[_homogeneous, `class A`], _rational, _dAlembert]`

$$\boxed{-2yy' + {y'}^2 x = -4x}$$

20.4.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$p^2 x - 2yp = -4x$$

Solving for y from the above results in

$$y = \frac{x(p^2 + 4)}{2p} \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= \frac{p^2+4}{2p} \\
g &= 0
\end{aligned}
$$

Hence (2) becomes

$$
p - \frac{p^2+4}{2p} = x\left(1 - \frac{p^2+4}{2p^2}\right) p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
p - \frac{p^2+4}{2p} = 0
$$

Solving for p from the above gives

$$
\begin{aligned}
p &= 2 \\
p &= -2
\end{aligned}
$$

Substituting these in (1A) gives

$$
\begin{aligned}
y &= -2x \\
y &= 2x
\end{aligned}
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{p(x) - \frac{p(x)^2+4}{2p(x)}}{x\left(1 - \frac{p(x)^2+4}{2p(x)^2}\right)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
p'(x) + p(x)p(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= 0
\end{aligned}
$$

Hence the ode is

$$p'(x) - \frac{p(x)}{x} = 0$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{1}{x}dx} \\ &= \frac{1}{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}\mu p &= 0 \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{p}{x}\right) &= 0\end{aligned}$$

Integrating gives

$$\frac{p}{x} = c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$p(x) = c_1 x$$

Substituing the above solution for p in (2A) gives

$$y = \frac{c_1^2 x^2 + 4}{2c_1}$$

Summary

The solution(s) found are the following

$$y = -2x \tag{1}$$

$$y = 2x \tag{2}$$

$$y = \frac{c_1^2 x^2 + 4}{2c_1} \tag{3}$$

Verification of solutions

$$y = -2x$$

Verified OK.

$$y = 2x$$

Verified OK.

$$y = \frac{c_1^2 x^2 + 4}{2c_1}$$

Verified OK.

20.5 problem 5

Internal problem ID [2342]
Internal file name [OUTPUT/2342_Tuesday_February_27_2024_08_27_23_AM_77458122/index.tex]

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 38, page 173
Problem number: 5.
ODE order: 1.
ODE degree: 3.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[_dAlembert]`

$$\boxed{xy'^3 - yy' = 1}$$

20.5.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$x\,p^3 - yp = 1$$

Solving for y from the above results in

$$y = p^2 x - \frac{1}{p} \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$\begin{aligned} p &= f + (xf' + g')\frac{dp}{dx} \\ p - f &= (xf' + g')\frac{dp}{dx} \end{aligned} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = p^2$$
$$g = -\frac{1}{p}$$

Hence (2) becomes

$$-p^2 + p = \left(2xp + \frac{1}{p^2}\right) p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$-p^2 + p = 0$$

Solving for p from the above gives

$$p = 0$$
$$p = 1$$

Removing solutions for p which leads to undefined results and substituting these in (1A) gives

$$y = x - 1$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$p'(x) = \frac{-p(x)^2 + p(x)}{2p(x)\,x + \frac{1}{p(x)^2}} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = \frac{2x(p)\,p + \frac{1}{p^2}}{-p^2 + p} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$
\begin{aligned}
p(p) &= \frac{2}{p-1} \\
q(p) &= -\frac{1}{p^3 (p-1)}
\end{aligned}
$$

Hence the ode is

$$
\frac{d}{dp}x(p) + \frac{2x(p)}{p-1} = -\frac{1}{p^3 (p-1)}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int \frac{2}{p-1}dp} \\
&= (p-1)^2
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}p}(\mu x) &= (\mu)\left(-\frac{1}{p^3 (p-1)}\right) \\
\frac{\mathrm{d}}{\mathrm{d}p}\left((p-1)^2 x\right) &= \left((p-1)^2\right)\left(-\frac{1}{p^3 (p-1)}\right) \\
\mathrm{d}\left((p-1)^2 x\right) &= \left(\frac{-p+1}{p^3}\right) \mathrm{d}p
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
(p-1)^2 x &= \int \frac{-p+1}{p^3} \,\mathrm{d}p \\
(p-1)^2 x &= \frac{1}{p} - \frac{1}{2p^2} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = (p-1)^2$ results in

$$
x(p) = \frac{\frac{1}{p} - \frac{1}{2p^2}}{(p-1)^2} + \frac{c_1}{(p-1)^2}
$$

which simplifies to

$$
x(p) = \frac{2c_1 p^2 + 2p - 1}{2 (p-1)^2 p^2}
$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p = \frac{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{1}{3}}}{6x} + \frac{2y}{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{1}{3}}}$$

$$p = -\frac{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{1}{3}}}{12x} - \frac{y}{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(\frac{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+\cdots}{x}}\cdots\right.\right.}{6x}\cdots\right.}{\cdots}$$

$$p = -\frac{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{1}{3}}}{12x} - \frac{y}{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(\frac{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+\cdots}{x}}\cdots\right.\right.}{6x}\cdots\right.}{\cdots}$$

Substituting the above in the solution for x found above gives

$$x = -\frac{54\left(\left(\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}+9\right)x^2\right)^{\frac{2}{3}} 3^{\frac{1}{3}}\left(-\frac{2^{\frac{1}{3}}\left(\sqrt{\frac{-4y^3+27x}{x}}\,c_1 3^{\frac{1}{6}}+2\left(y+\frac{3c_1}{2}\right)3^{\frac{2}{3}}\right)x\left(\left(\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}+9\right)x^2\right)^{\frac{1}{3}}}{3} - \frac{2^{\frac{2}{3}}3^{\frac{5}{6}}x^2\cdots}{\cdots}\cdots\right.}{\left(2^{\frac{2}{3}}3^{\frac{1}{3}}xy+\left(\left(\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}+9\right)x^2\right)^{\frac{2}{3}}\right)^2\left(2\,2^{\frac{1}{3}}3^{\frac{2}{3}}xy+2^{\frac{2}{3}}3^{\frac{1}{3}}\left(\left(\sqrt{3}\,\sqrt{\cdots}\cdots\right.\right.\right.}$$

$$x = -\frac{36\left(\left(\frac{8yc_1}{9}-\frac{2x}{3}\right)\left(\left(\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}+9\right)x^2\right)^{\frac{2}{3}}+\left(-\frac{\left(c_1\left(i3^{\frac{2}{3}}+3^{\frac{1}{6}}\right)\sqrt{\frac{-4y^3+27x}{x}}+6\left(i3^{\frac{1}{6}}+\frac{3^{\frac{2}{3}}}{3}\right)\left(y+\frac{3c_1}{2}\right)\right)2^{\frac{1}{3}}\left(\left(\sqrt{3}\,\cdots\right.\right.}{9}\cdots\right.\right.}{\left(-\frac{\left(i3^{\frac{5}{6}}-3^{\frac{1}{3}}\right)2^{\frac{2}{3}}\left(\left(\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}+9\right)x^2\right)^{\frac{2}{3}}}{6}+\left(2\left(\left(\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}+9\right)x^2\right)^{\frac{1}{3}}\cdots\right.\right.}$$

$$x = \frac{36\, 3^{\frac{1}{3}} \left(\left(\sqrt{3}\, \sqrt{\frac{-4y^3+27x}{x}} + 9\right) x^2\right)^{\frac{2}{3}} 2^{\frac{2}{3}} \Bigg(\left(-\frac{8yc_1}{9} + \frac{2x}{3}\right) \left(\left(\sqrt{3}\, \sqrt{\frac{-4y^3+27x}{x}} + 9\right) x^2\right)^{\frac{2}{3}} + x \Bigg(-\frac{\left(\left(i 3^{\frac{2}{3}} - 3^{\frac{1}{6}}\right) c_1 \sqrt{\cdots}\right.}{\cdots}}{\left(\left(i - \sqrt{3}\right) \left(\left(\sqrt{3}\, \sqrt{\frac{-4y^3+27x}{x}} + 9\right) x^2\right)^{\frac{2}{3}} + \left(3^{\frac{5}{6}} + i 3^{\frac{1}{3}}\right) y 2^{\frac{2}{3}} x\right)^2 \Bigg(-\frac{\left(3^{\frac{1}{3}} + i 3^{\frac{5}{6}}\right) \cdots}{\cdots}}$$

Summary

The solution(s) found are the following

$$y = x - 1 \tag{1}$$

$$x = -\frac{54 \left(\left(\sqrt{3}\, \sqrt{\frac{-4y^3+27x}{x}} + 9\right) x^2\right)^{\frac{2}{3}} 3^{\frac{1}{3}} \Bigg(-\frac{2^{\frac{1}{3}} \left(\sqrt{\frac{-4y^3+27x}{x}}\, c_1 3^{\frac{1}{6}} + 2\left(y + \frac{3c_1}{2}\right) 3^{\frac{2}{3}}\right) x \left(\left(\sqrt{3}\, \sqrt{\frac{-4y^3+27x}{x}} + 9\right) x^2\right)^{\frac{1}{3}}}{3} - \frac{2^{\frac{2}{3}} 3^{\frac{5}{6}} x^2 \cdots}{\cdots}}{\left(2^{\frac{2}{3}} 3^{\frac{1}{3}} xy + \left(\left(\sqrt{3}\, \sqrt{\frac{-4y^3+27x}{x}} + 9\right) x^2\right)^{\frac{2}{3}}\right)^2 \Bigg(2\, 2^{\frac{1}{3}} 3^{\frac{2}{3}} xy + 2^{\frac{2}{3}} 3^{\frac{1}{3}} \Bigg(\Bigg(\sqrt{3}\, \sqrt{\cdots}} \tag{2}$$

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[[_homogeneous, `class A`], _rational, _dAlembert]`

$$\boxed{y\left(1+y'^2\right)-2xy'=0}$$

20.6.1 Solving as dAlembert ode

Let $p=y'$ the ode becomes

$$y(p^2+1)-2xp=0$$

Solving for y from the above results in

$$y=\frac{2xp}{p^2+1} \tag{1A}$$

This has the form

$$y=xf(p)+g(p) \tag{*}$$

Where f,g are functions of $p=y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p=f+(xf'+g')\frac{dp}{dx}$$
$$p-f=(xf'+g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= \frac{2p}{p^2+1} \\
g &= 0
\end{aligned}
$$

Hence (2) becomes

$$
p - \frac{2p}{p^2+1} = x\left(\frac{2}{p^2+1} - \frac{4p^2}{\left(p^2+1\right)^2}\right) p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
p - \frac{2p}{p^2+1} = 0
$$

Solving for p from the above gives

$$
\begin{aligned}
p &= 0 \\
p &= 1 \\
p &= -1
\end{aligned}
$$

Substituting these in (1A) gives

$$
\begin{aligned}
y &= -x \\
y &= 0 \\
y &= x
\end{aligned}
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{p(x) - \frac{2p(x)}{p(x)^2+1}}{x\left(\frac{2}{p(x)^2+1} - \frac{4p(x)^2}{\left(p(x)^2+1\right)^2}\right)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$
\frac{d}{dp}x(p) = \frac{x(p)\left(\frac{2}{p^2+1} - \frac{4p^2}{\left(p^2+1\right)^2}\right)}{p - \frac{2p}{p^2+1}} \tag{4}
$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = \frac{2}{p(p^2+1)}$$
$$q(p) = 0$$

Hence the ode is

$$\frac{d}{dp}x(p) + \frac{2x(p)}{p(p^2+1)} = 0$$

The integrating factor μ is

$$\mu = e^{\int \frac{2}{p(p^2+1)}dp}$$
$$= e^{-\ln(p^2+1)+2\ln(p)}$$

Which simplifies to

$$\mu = \frac{p^2}{p^2+1}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}p}\mu x = 0$$
$$\frac{\mathrm{d}}{\mathrm{d}p}\left(\frac{p^2 x}{p^2+1}\right) = 0$$

Integrating gives

$$\frac{p^2 x}{p^2+1} = c_3$$

Dividing both sides by the integrating factor $\mu = \frac{p^2}{p^2+1}$ results in

$$x(p) = \frac{c_3(p^2+1)}{p^2}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p = \frac{x+\sqrt{x^2-y^2}}{y}$$
$$p = -\frac{-x+\sqrt{x^2-y^2}}{y}$$

Substituting the above in the solution for x found above gives

$$
\begin{aligned}
x &= \frac{2c_3 x}{x + \sqrt{x^2 - y^2}} \\
x &= -\frac{2c_3 x}{-x + \sqrt{x^2 - y^2}}
\end{aligned}
$$

<u>Summary</u>
The solution(s) found are the following

$$y = -x \tag{1}$$
$$y = 0 \tag{2}$$
$$y = x \tag{3}$$
$$x = \frac{2c_3 x}{x + \sqrt{x^2 - y^2}} \tag{4}$$
$$x = -\frac{2c_3 x}{-x + \sqrt{x^2 - y^2}} \tag{5}$$

<u>Verification of solutions</u>

$$y = -x$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 38, page 173
Problem number: 7.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _dAlembert]
```

$$\boxed{-2yy' + {y'}^2 x = -2x}$$

20.7.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$p^2 x - 2yp = -2x$$

Solving for y from the above results in

$$y = \frac{x(p^2 + 2)}{2p} \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$\begin{aligned} p &= f + (xf' + g')\frac{dp}{dx} \\ p - f &= (xf' + g')\frac{dp}{dx} \end{aligned} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$\begin{aligned} f &= \frac{p^2+2}{2p} \\ g &= 0 \end{aligned}$$

Hence (2) becomes

$$p - \frac{p^2+2}{2p} = x\left(1 - \frac{p^2+2}{2p^2}\right) p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$p - \frac{p^2+2}{2p} = 0$$

Solving for p from the above gives

$$\begin{aligned} p &= \sqrt{2} \\ p &= -\sqrt{2} \end{aligned}$$

Substituting these in (1A) gives

$$\begin{aligned} y &= \sqrt{2}\, x \\ y &= -\sqrt{2}\, x \end{aligned}$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$p'(x) = \frac{p(x) - \frac{p(x)^2+2}{2p(x)}}{x\left(1 - \frac{p(x)^2+2}{2p(x)^2}\right)} \tag{3}$$

This ODE is now solved for $p(x)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= 0 \end{aligned}$$

Hence the ode is

$$p'(x) - \frac{p(x)}{x} = 0$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{x}dx}$$
$$= \frac{1}{x}$$

The ode becomes

$$\frac{d}{dx}\mu p = 0$$
$$\frac{d}{dx}\left(\frac{p}{x}\right) = 0$$

Integrating gives

$$\frac{p}{x} = c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$p(x) = c_1 x$$

Substituing the above solution for p in (2A) gives

$$y = \frac{c_1^2x^2 + 2}{2c_1}$$

Summary
The solution(s) found are the following

$$y = \sqrt{2}\, x \tag{1}$$
$$y = -\sqrt{2}\, x \tag{2}$$
$$y = \frac{c_1^2x^2 + 2}{2c_1} \tag{3}$$

Verification of solutions

$$y = \sqrt{2}\, x$$

Verified OK.

$$y = -\sqrt{2}\, x$$

Verified OK.

$$y = \frac{c_1^2 x^2 + 2}{2c_1}$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 38, page 173
Problem number: 8.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[_dAlembert]`

$$\boxed{-yy' - y'^2 = -x}$$

20.8.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$-p^2 - yp = -x$$

Solving for y from the above results in

$$y = \frac{x}{p} - p \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= \frac{1}{p} \\
g &= -p
\end{aligned}
$$

Hence (2) becomes

$$
p - \frac{1}{p} = \left(-\frac{x}{p^2} - 1\right) p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
p - \frac{1}{p} = 0
$$

Solving for p from the above gives

$$
\begin{aligned}
p &= 1 \\
p &= -1
\end{aligned}
$$

Substituting these in (1A) gives

$$
\begin{aligned}
y &= 1 - x \\
y &= x - 1
\end{aligned}
$$

The general solution is found when $\frac{dp}{dx} \neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{p(x) - \frac{1}{p(x)}}{-\frac{x}{p(x)^2} - 1} \tag{3}
$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$
\frac{d}{dp}x(p) = \frac{-\frac{x(p)}{p^2} - 1}{p - \frac{1}{p}} \tag{4}
$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
\frac{d}{dp}x(p) + p(p)x(p) = q(p)
$$

Where here

$$
\begin{aligned}
p(p) &= \frac{1}{p^3 - p} \\
q(p) &= -\frac{p}{p^2 - 1}
\end{aligned}
$$

Hence the ode is

$$
\frac{d}{dp}x(p) + \frac{x(p)}{p^3 - p} = -\frac{p}{p^2 - 1}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int \frac{1}{p^3 - p}dp} \\
&= \mathrm{e}^{\frac{\ln(p+1)}{2} + \frac{\ln(p-1)}{2} - \ln(p)}
\end{aligned}
$$

Which simplifies to

$$
\mu = \frac{\sqrt{p+1}\,\sqrt{p-1}}{p}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}p}(\mu x) &= (\mu)\left(-\frac{p}{p^2 - 1}\right) \\
\frac{\mathrm{d}}{\mathrm{d}p}\left(\frac{\sqrt{p+1}\,\sqrt{p-1}\,x}{p}\right) &= \left(\frac{\sqrt{p+1}\,\sqrt{p-1}}{p}\right)\left(-\frac{p}{p^2 - 1}\right) \\
\mathrm{d}\left(\frac{\sqrt{p+1}\,\sqrt{p-1}\,x}{p}\right) &= \left(-\frac{\sqrt{p+1}\,\sqrt{p-1}}{p^2 - 1}\right)\mathrm{d}p
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\frac{\sqrt{p+1}\,\sqrt{p-1}\,x}{p} &= \int -\frac{\sqrt{p+1}\,\sqrt{p-1}}{p^2 - 1}\,\mathrm{d}p \\
\frac{\sqrt{p+1}\,\sqrt{p-1}\,x}{p} &= -\frac{\sqrt{p-1}\,\sqrt{p+1}\,\ln\left(p + \sqrt{p^2 - 1}\right)}{\sqrt{p^2 - 1}} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{\sqrt{p+1}\,\sqrt{p-1}}{p}$ results in

$$
x(p) = -\frac{p\ln\left(p + \sqrt{p^2 - 1}\right)}{\sqrt{p^2 - 1}} + \frac{c_1 p}{\sqrt{p+1}\,\sqrt{p-1}}
$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$
\begin{aligned}
p &= -\frac{y}{2}+\frac{\sqrt{y^{2}+4x}}{2} \\
p &= -\frac{y}{2}-\frac{\sqrt{y^{2}+4x}}{2}
\end{aligned}
$$

Substituting the above in the solution for x found above gives

$$
x = \left(-y + \sqrt{y^{2}+4x}\right)\left(-\frac{-\ln\left(2\right)+\ln\left(-y+\sqrt{y^{2}+4x}+\sqrt{2y^{2}+4x-2y\sqrt{y^{2}+4x}-4}\right)}{\sqrt{2y^{2}+4x-2y\sqrt{y^{2}+4x}-4}} + \frac{2c_{1}}{\sqrt{-2y+2\sqrt{y^{2}+4x}+4}\,\sqrt{-2y+2\sqrt{y^{2}+4x}-4}}\right)
$$

$$
x = \left(y+\sqrt{y^{2}+4x}\right)\left(\frac{-\ln\left(2\right)+\ln\left(-y-\sqrt{y^{2}+4x}+\sqrt{2y^{2}+4x+2y\sqrt{y^{2}+4x}-4}\right)}{\sqrt{2y^{2}+4x+2y\sqrt{y^{2}+4x}-4}} - \frac{2c_{1}}{\sqrt{-2y-2\sqrt{y^{2}+4x}+4}\,\sqrt{-2y-2\sqrt{y^{2}+4x}-4}}\right)
$$

Summary
The solution(s) found are the following

$$y = 1 - x \tag{1}$$

$$y = x - 1 \tag{2}$$

$$x = \left(-y + \sqrt{y^2 + 4x}\right)\left(-\frac{-\ln(2) + \ln\left(-y + \sqrt{y^2 + 4x} + \sqrt{2y^2 + 4x - 2y\sqrt{y^2 + 4x} - 4}\right)}{\sqrt{2y^2 + 4x - 2y\sqrt{y^2 + 4x} - 4}} + \frac{2c_1}{\sqrt{-2y + 2\sqrt{y^2 + 4x} + 4}\,\sqrt{-2y + 2\sqrt{y^2 + 4x} - 4}}\right) \tag{3}$$

$$x = \left(y + \sqrt{y^2 + 4x}\right)\left(\frac{-\ln(2) + \ln\left(-y - \sqrt{y^2 + 4x} + \sqrt{2y^2 + 4x + 2y\sqrt{y^2 + 4x} - 4}\right)}{\sqrt{2y^2 + 4x + 2y\sqrt{y^2 + 4x} - 4}} - \frac{2c_1}{\sqrt{-2y - 2\sqrt{y^2 + 4x} + 4}\,\sqrt{-2y - 2\sqrt{y^2 + 4x} - 4}}\right) \tag{4}$$

Verification of solutions

$$y = 1 - x$$

Verified OK.

$$y = x - 1$$

Verified OK.

$$x = \left(-y + \sqrt{y^2 + 4x}\right)\left(-\frac{-\ln(2) + \ln\left(-y + \sqrt{y^2 + 4x} + \sqrt{2y^2 + 4x - 2y\sqrt{y^2 + 4x} - 4}\right)}{\sqrt{2y^2 + 4x - 2y\sqrt{y^2 + 4x} - 4}} + \frac{2c_1}{\sqrt{-2y + 2\sqrt{y^2 + 4x} + 4}\,\sqrt{-2y + 2\sqrt{y^2 + 4x} - 4}}\right)$$

Verified OK.

$$x = \left(y + \sqrt{y^2 + 4x}\right)\left(\frac{-\ln(2) + \ln\left(-y - \sqrt{y^2 + 4x} + \sqrt{2y^2 + 4x + 2y\sqrt{y^2 + 4x} - 4}\right)}{\sqrt{2y^2 + 4x + 2y\sqrt{y^2 + 4x} - 4}} - \frac{2c_1}{\sqrt{-2y - 2\sqrt{y^2 + 4x} + 4}\,\sqrt{-2y - 2\sqrt{y^2 + 4x} - 4}}\right)$$

Verified OK.

Section: Exercise 38, page 173
Problem number: 9.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _dAlembert]
```

$$\boxed{4{y'}^2x+2xy'-y=0}$$

20.9.1 Solving as dAlembert ode

Let $p=y'$ the ode becomes

$$4p^2x+2xp-y=0$$

Solving for y from the above results in

$$y=\left(4p^2+2p\right)x \tag{1A}$$

This has the form

$$y=xf(p)+g(p) \tag{*}$$

Where f,g are functions of $p=y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p=f+(xf'+g')\frac{dp}{dx}$$
$$p-f=(xf'+g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= 4p^2 + 2p \\
g &= 0
\end{aligned}
$$

Hence (2) becomes

$$
-4p^2 - p = x(8p + 2)\, p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
-4p^2 - p = 0
$$

Solving for p from the above gives

$$
\begin{aligned}
p &= 0 \\
p &= -\frac{1}{4}
\end{aligned}
$$

Substituting these in (1A) gives

$$
\begin{aligned}
y &= 0 \\
y &= -\frac{x}{4}
\end{aligned}
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{-4p(x)^2 - p(x)}{x\,(8p\,(x) + 2)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
p'(x) + p(x)p(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= \frac{1}{2x} \\
q(x) &= 0
\end{aligned}
$$

Hence the ode is

$$
p'(x) + \frac{p(x)}{2x} = 0
$$

The integrating factor μ is

$$\mu = e^{\int \frac{1}{2x} dx}$$
$$= \sqrt{x}$$

The ode becomes

$$\frac{d}{dx}\mu p = 0$$
$$\frac{d}{dx}\left(\sqrt{x}\, p\right) = 0$$

Integrating gives

$$\sqrt{x}\, p = c_1$$

Dividing both sides by the integrating factor $\mu = \sqrt{x}$ results in

$$p(x) = \frac{c_1}{\sqrt{x}}$$

Substituing the above solution for p in (2A) gives

$$y = \left(\frac{4c_1^2}{x} + \frac{2c_1}{\sqrt{x}}\right) x$$

Summary

The solution(s) found are the following

$$y = 0 \tag{1}$$
$$y = -\frac{x}{4} \tag{2}$$
$$y = \left(\frac{4c_1^2}{x} + \frac{2c_1}{\sqrt{x}}\right) x \tag{3}$$

Verification of solutions

$$y = 0$$

Verified OK.

$$y = -\frac{x}{4}$$

Verified OK.

$$y = \left(\frac{4c_1^2}{x} + \frac{2c_1}{\sqrt{x}}\right) x$$

Verified OK.

20.10 problem 10

Internal problem ID [2347]
Internal file name [`OUTPUT/2347_Tuesday_February_27_2024_08_30_26_AM_72406962/index.tex`]

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 38, page 173
Problem number: 10.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _dAlembert]
```

$$\boxed{y - y'x(y'+1) = 0}$$

20.10.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$y - px(p+1) = 0$$

Solving for y from the above results in

$$y = px(p+1) \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$\begin{aligned} p &= f + (xf' + g')\frac{dp}{dx} \\ p - f &= (xf' + g')\frac{dp}{dx} \end{aligned} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = p(p+1)$$
$$g = 0$$

Hence (2) becomes

$$p - p(p+1) = x(2p+1)\,p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$p - p(p+1) = 0$$

Solving for p from the above gives

$$p = 0$$
$$p = 0$$

Removing solutions for p which leads to undefined results and substituting these in (1A) gives

$$y = 0$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$p'(x) = \frac{p(x) - p(x)\,(p(x)+1)}{x\,(2p\,(x)+1)} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = \frac{x(p)\,(2p+1)}{p - p\,(p+1)} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = -\frac{-2p-1}{p^2}$$
$$q(p) = 0$$

Hence the ode is

$$\frac{d}{dp}x(p) - \frac{(-2p-1)\,x(p)}{p^2} = 0$$

The integrating factor μ is

$$\mu = e^{\int -\frac{-2p-1}{p^2}dp}$$
$$= e^{-\frac{1}{p}+2\ln(p)}$$

Which simplifies to

$$\mu = p^2 e^{-\frac{1}{p}}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}p}\mu x = 0$$
$$\frac{\mathrm{d}}{\mathrm{d}p}\left(p^2 e^{-\frac{1}{p}} x\right) = 0$$

Integrating gives

$$p^2 e^{-\frac{1}{p}} x = c_2$$

Dividing both sides by the integrating factor $\mu = p^2 e^{-\frac{1}{p}}$ results in

$$x(p) = \frac{c_2 e^{\frac{1}{p}}}{p^2}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p = \frac{-x + \sqrt{x^2 + 4yx}}{2x}$$
$$p = -\frac{x + \sqrt{x^2 + 4yx}}{2x}$$

Substituting the above in the solution for x found above gives

$$x = \frac{4c_2 x^2 e^{\frac{2x}{-x+\sqrt{x(4y+x)}}}}{\left(-x + \sqrt{x\,(4y+x)}\right)^2}$$

$$x = \frac{4c_2 x^2 e^{-\frac{2x}{x+\sqrt{x(4y+x)}}}}{\left(x + \sqrt{x\,(4y+x)}\right)^2}$$

Summary

The solution(s) found are the following

$$y = 0 \tag{1}$$

$$x = \frac{4c_2 x^2 e^{\frac{2x}{-x+\sqrt{x(4y+x)}}}}{\left(-x+\sqrt{x\,(4y+x)}\right)^2} \tag{2}$$

$$x = \frac{4c_2 x^2 e^{-\frac{2x}{x+\sqrt{x(4y+x)}}}}{\left(x+\sqrt{x\,(4y+x)}\right)^2} \tag{3}$$

Verification of solutions

$$y = 0$$

Verified OK.

$$x = \frac{4c_2 x^2 e^{\frac{2x}{-x+\sqrt{x(4y+x)}}}}{\left(-x+\sqrt{x\,(4y+x)}\right)^2}$$

Verified OK.

$$x = \frac{4c_2 x^2 e^{-\frac{2x}{x+\sqrt{x(4y+x)}}}}{\left(x+\sqrt{x\,(4y+x)}\right)^2}$$

Verified OK.

20.11 problem 11

Internal problem ID [2348]
Internal file name [`OUTPUT/2348_Tuesday_February_27_2024_08_30_26_AM_23240955/index.tex`]

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 38, page 173
Problem number: 11.
ODE order: 1.
ODE degree: 3.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

```
[[_1st_order, _with_linear_symmetries], _dAlembert]
```

$$\boxed{2xy'^3 - yy'^2 = -1}$$

20.11.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$2x\,p^3 - y\,p^2 = -1$$

Solving for y from the above results in

$$y = 2px + \frac{1}{p^2} \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$\begin{aligned} p &= f + (xf' + g')\frac{dp}{dx} \\ p - f &= (xf' + g')\frac{dp}{dx} \end{aligned} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = 2p$$
$$g = \frac{1}{p^2}$$

Hence (2) becomes

$$-p = \left(2x - \frac{2}{p^3}\right) p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$-p = 0$$

Solving for p from the above gives

$$p = 0$$

Substituting these in (1A) gives

$$y = \infty$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$p'(x) = -\frac{p(x)}{2x - \frac{2}{p(x)^3}} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = -\frac{2x(p) - \frac{2}{p^3}}{p} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = \frac{2}{p}$$
$$q(p) = \frac{2}{p^4}$$

Hence the ode is

$$\frac{d}{dp}x(p) + \frac{2x(p)}{p} = \frac{2}{p^4}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{2}{p}dp} \\ &= p^2\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}p}(\mu x) &= (\mu)\left(\frac{2}{p^4}\right) \\ \frac{\mathrm{d}}{\mathrm{d}p}(p^2 x) &= (p^2)\left(\frac{2}{p^4}\right) \\ \mathrm{d}(p^2 x) &= \left(\frac{2}{p^2}\right)\mathrm{d}p\end{aligned}$$

Integrating gives

$$\begin{aligned}p^2 x &= \int \frac{2}{p^2}\,\mathrm{d}p \\ p^2 x &= -\frac{2}{p} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = p^2$ results in

$$x(p) = -\frac{2}{p^3} + \frac{c_1}{p^2}$$

which simplifies to

$$x(p) = \frac{c_1 p - 2}{p^3}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p = \frac{\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{1}{3}}}{6x} + \frac{y^2}{6x\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{1}{3}}} + \frac{y}{6x}$$

$$p = -\frac{\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{1}{3}}}{12x} - \frac{y^2}{12x\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{1}{3}}} + \frac{y}{6x} + \frac{i\sqrt{3}\left(\frac{(6\sqrt{}}{}\right.}{}$$

$$p = -\frac{\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{1}{3}}}{12x} - \frac{y^2}{12x\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{1}{3}}} + \frac{y}{6x} - \frac{i\sqrt{3}\left(\frac{(6\sqrt{}}{}\right.}{}$$

Substituting the above in the solution for x found above gives

$$x = \frac{36\left(\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}} c_1+\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{1}{3}} c_1 y+c_1 y^2-12x\left(6\sqrt{\cdots}\right.\right.}{\left(\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}+y\left(6\sqrt{3}\,\sqrt{-y^3+2\cdots}\right.\right.}$$

$$x = \frac{144\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}\left(\left(-i\sqrt{3}\,c_1+c_1\right)\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}+\left(-2yc_1\cdots\right.\right.}{\left(-i\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}\sqrt{3}+i\sqrt{3}\,y^2+\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x\cdots\right.\right.}$$

$$x = \frac{144\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}} x^2\left(c_1\left(-1-i\sqrt{3}\right)\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}+2(yc_1\cdots\right.}{\left(-i\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}\sqrt{3}+i\sqrt{3}\,y^2-\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\cdots\right.\right.}$$

Summary

The solution(s) found are the following

$$y = \infty \tag{1}$$

$$x = \frac{36\left(\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}} c_1+\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{1}{3}} c_1 y+c_1 y^2-12x\left(6\sqrt{\cdots}\right.\right.}{\left(\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}+y\left(6\sqrt{3}\,\sqrt{-y^3+2\cdots}\right.\right.} \tag{2}$$

$$x = \frac{144\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}\left(\left(-i\sqrt{3}\,c_1+c_1\right)\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}+\left(-2yc_1\cdots\right.\right.}{\left(-i\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}\sqrt{3}+i\sqrt{3}\,y^2+\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x\cdots\right.\right.} \tag{3}$$

$$x = \frac{144\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}} x^2\left(c_1\left(-1-i\sqrt{3}\right)\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}+2(yc_1\cdots\right.}{\left(-i\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}\sqrt{3}+i\sqrt{3}\,y^2-\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\cdots\right.\right.} \tag{4}$$

Verification of solutions

$$y = \infty$$

Verified OK.

$$x = \frac{36\Big(\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}c_1+\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{1}{3}}c_1y+c_1y^2-12x\big(6\sqrt{}}{\Big(\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}+y\left(6\sqrt{3}\,\sqrt{-y^3+2}\right.}$$

Verified OK.

$$x = \frac{144\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}\Big(\left(-i\sqrt{3}\,c_1+c_1\right)\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}+(-2yc_1}{\Big(-i\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}\sqrt{3}+i\sqrt{3}\,y^2+\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x\right.}$$

Warning, solution could not be verified

$$x = \frac{144\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}x^2\Big(c_1\left(-1-i\sqrt{3}\right)\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}+2(yc_1}{\Big(-i\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right)^{\frac{2}{3}}\sqrt{3}+i\sqrt{3}\,y^2-\left(6\sqrt{3}\,\sqrt{-y^3+27x^2}\,x+y^3-54x^2\right.}$$

Problem number: 12.
ODE order: 1.
ODE degree: 3.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

`[[_1st_order, _with_linear_symmetries]]`

$$\boxed{{y'}^3 + xyy' - 2y^2 = 0}$$

Solving the given ode for y' results in 3 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{\left(27y^2 + 3\sqrt{3y^3x^3 + 81y^4}\right)^{\frac{1}{3}}}{3} - \frac{yx}{\left(27y^2 + 3\sqrt{3y^3x^3 + 81y^4}\right)^{\frac{1}{3}}} \tag{1}$$

$$y' = -\frac{\left(27y^2 + 3\sqrt{3y^3x^3 + 81y^4}\right)^{\frac{1}{3}}}{6} + \frac{yx}{2\left(27y^2 + 3\sqrt{3y^3x^3 + 81y^4}\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(\frac{\left(27y^2+3\sqrt{3y^3x^3+81y^4}\right)^{\frac{1}{3}}}{3} + \frac{\cdots}{\left(27y^2+3\cdots\right.}\right.}{2} \tag{2}$$

$$y' = -\frac{\left(27y^2 + 3\sqrt{3y^3x^3 + 81y^4}\right)^{\frac{1}{3}}}{6} + \frac{yx}{2\left(27y^2 + 3\sqrt{3y^3x^3 + 81y^4}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(\frac{\left(27y^2+3\sqrt{3y^3x^3+81y^4}\right)^{\frac{1}{3}}}{3} + \frac{\cdots}{\left(27y^2+3\cdots\right.}\right.}{2} \tag{3}$$

Now each one of the above ODE is solved.

Solving equation (1)

Writing the ode as

$$
\begin{aligned}
y' &= \frac{\left(27y^2 + 3\sqrt{3x^3y^3 + 81y^4}\right)^{\frac{2}{3}} - 3xy}{3\left(27y^2 + 3\sqrt{3x^3y^3 + 81y^4}\right)^{\frac{1}{3}}} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}
$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$
\xi = xa_2 + ya_3 + a_1 \tag{1E}
$$

$$
\eta = xb_2 + yb_3 + b_1 \tag{2E}
$$

Where the unknown coefficients are

$$
\{a_1, a_2, a_3, b_1, b_2, b_3\}
$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2+\frac{\left(\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}-3xy\right)(b_3-a_2)}{3\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}}-\frac{\left(\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}-3xy\right)^2 a_3}{9\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}}-\left(\frac{\frac{9y^3x^2}{\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}\sqrt{3x^3y^3+81y^4}}-3y}{3\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}}-\frac{3\left(\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}-3xy\right)y^3x^2}{2\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{4}{3}}\sqrt{3x^3y^3+81y^4}}\right)(xa_2+ya_3+a_1)-\left(\frac{\frac{36y+\frac{2\left(\frac{27}{2}x^3y^2+486y^3\right)}{3\sqrt{3x^3y^3+81y^4}}}{\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}}-3x}{3\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}}-\frac{\left(\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}-3xy\right)\left(54y+\frac{\frac{27}{2}x^3y^2+486y^3}{\sqrt{3x^3y^3+81y^4}}\right)}{9\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{4}{3}}}\right)(xb_2+yb_3+b_1)=0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{9\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}x^4y^2b_2+9\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}x^3y^3a_2+9\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)}{}$$

$$=0$$

Setting the numerator to zero gives

$$
\begin{aligned}
&-9\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}} x^4y^2b_2 \\
&-9\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}} x^3y^3a_2 \\

&+27x^3y^4a_1+27x^5y^3b_2-27x^4y^4b_3+27x^4y^3b_1 \\
&+486x^2y^4b_2-972x\,y^5b_3+486x\,y^4b_1 \\
&-2\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{5}{3}} \sqrt{3x^3y^3+81y^4}\,a_2 \\
&+2\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{5}{3}} \sqrt{3x^3y^3+81y^4}\,b_3 \\
&-324\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}} y^4b_3 \\
&+6b_2\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{4}{3}} \sqrt{3x^3y^3+81y^4} \\
&-324\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}} y^3b_1 \\
&-6\left(3x^3y^3+81y^4\right)^{\frac{3}{2}} a_3-7290y^6a_3+1458y^5a_1=0
\end{aligned} \tag{6E}
$$

Simplifying the above gives

$$\text{Expression too large to display} \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$\text{Expression too large to display}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, \sqrt{y^3\left(x^3+27y\right)}, \left(27y^2+3\sqrt{3}\,\sqrt{y^3\left(x^3+27y\right)}\right)^{\frac{1}{3}}, \left(27y^2+3\sqrt{3}\,\sqrt{y^3\left(x^3+27y\right)}\right)^{\frac{2}{3}}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, \sqrt{y^3\left(x^3+27y\right)} = v_3, \left(27y^2 + 3\sqrt{3}\,\sqrt{y^3\left(x^3+27y\right)}\right)^{\frac{1}{3}} = v_4, \left(27y^2+3\sqrt{3}\,\sqrt{y^3\left(x^3+27y\right)}\right)^{\frac{2}{3}} = v_5\right\}$$

The above PDE (6E) now becomes

$$\begin{aligned}
-9v_2\Big(&6\sqrt{3}\,v_3v_1^3v_2^2a_3 + 12\sqrt{3}\,v_5v_3v_1b_2 + 18\sqrt{3}\,v_5v_3v_2a_2 \\
&- 6\sqrt{3}\,v_5v_3v_2b_3 - 18\sqrt{3}\,v_3v_1^2v_2b_2 - 108\sqrt{3}\,v_3v_1v_2^2a_2 + 36\sqrt{3}\,v_3v_1v_2^2b_3 \\
&- 54\sqrt{3}\,v_4v_3v_2b_2 - 18\sqrt{3}\,v_3v_1v_2b_1 + 3v_5v_1^2v_2^2a_1 - 18v_4v_1^3v_2^2b_2 \\
&- 324v_4v_1v_2^4a_3 + 270\sqrt{3}\,v_3v_2^3a_3 + 108v_5v_1v_2^2b_2 + 12\sqrt{3}\,v_5v_3b_1 \\
&- 54\sqrt{3}\,v_3v_2^2a_1 - 12v_4v_1^4v_2^3a_3 + 3v_5v_1^4v_2b_2 + 9v_5v_1^3v_2^2a_2 - 3v_5v_1^3v_2^2b_3 \\
&+ 3v_5v_1^2v_2^3a_3 + 2\sqrt{3}\,v_5v_3v_1^2v_2a_3 - 36\sqrt{3}\,v_4v_3v_1v_2^2a_3 + 2430v_2^5a_3 \\
&- 486v_2^4a_1 + 3v_5v_1^3v_2b_1 - 9v_1^5v_2^2b_2 - 27v_1^4v_2^3a_2 + 9v_1^4v_2^3b_3 + 99v_1^3v_2^4a_3 \\
&- 9v_1^4v_2^2b_1 - 9v_1^3v_2^3a_1 + 324v_1v_2^4b_3 + 162v_5v_2^3a_2 - 54v_5v_2^3b_3 \\
&+ 108v_5v_2^2b_1 - 486v_4v_2^3b_2 - 162v_2^3v_1^2b_2 - 972v_2^4v_1a_2 - 162v_2^3v_1b_1\Big) = 0
\end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3, v_4, v_5\}$$

Equation (7E) now becomes

$$
\begin{aligned}
&1458 b_1 v_1 v_2^4 + 4374 b_2 v_4 v_2^4 + (-1458 a_2 + 486 b_3)\, v_5 v_2^4 - 972 b_1 v_5 v_2^3 \\
&- 54\sqrt{3}\, a_3 v_3 v_1^3 v_2^3 + 162\sqrt{3}\, b_2 v_3 v_1^2 v_2^2 + 162\sqrt{3}\, b_1 v_3 v_1 v_2^2 \\
&- 21870 a_3 v_2^6 + 4374 a_1 v_2^5 - 18\sqrt{3}\, a_3 v_3 v_5 v_1^2 v_2^2 + 324\sqrt{3}\, a_3 v_3 v_4 v_1 v_2^3 \\
&- 108\sqrt{3}\, b_2 v_3 v_5 v_1 v_2 + 2916 a_3 v_4 v_1 v_2^5 + (8748 a_2 - 2916 b_3)\, v_1 v_2^5 \\
&+ \left(972\sqrt{3}\, a_2 - 324\sqrt{3}\, b_3\right) v_3 v_1 v_2^3 - 972 b_2 v_5 v_1 v_2^3 - 2430\sqrt{3}\, a_3 v_3 v_2^4 \\
&+ 486\sqrt{3}\, a_1 v_3 v_2^3 + \left(-162\sqrt{3}\, a_2 + 54\sqrt{3}\, b_3\right) v_3 v_5 v_2^2 \\
&+ 108 a_3 v_4 v_1^4 v_2^4 + (243 a_2 - 81 b_3)\, v_1^4 v_2^4 - 27 b_2 v_5 v_1^4 v_2^2 + 162 b_2 v_4 v_1^3 v_2^3 \\
&+ (-81 a_2 + 27 b_3)\, v_5 v_1^3 v_2^3 - 27 b_1 v_5 v_1^3 v_2^2 - 27 a_3 v_5 v_1^2 v_2^4 \\
&- 27 a_1 v_5 v_1^2 v_2^3 + 486\sqrt{3}\, b_2 v_3 v_4 v_2^2 - 108\sqrt{3}\, v_5 v_3 b_1 v_2 + 81 v_2^3 b_2 v_1^5 \\
&+ 81 b_1 v_1^4 v_2^3 - 891 a_3 v_1^3 v_2^5 + 81 a_1 v_1^3 v_2^4 + 1458 b_2 v_1^2 v_2^4 = 0
\end{aligned}
\tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-27a_1 &= 0\\
81a_1 &= 0\\
4374a_1 &= 0\\
-21870a_3 &= 0\\
-891a_3 &= 0\\
-27a_3 &= 0\\
108a_3 &= 0\\
2916a_3 &= 0\\
-972b_1 &= 0\\
-27b_1 &= 0\\
81b_1 &= 0\\
1458b_1 &= 0\\
-972b_2 &= 0\\
-27b_2 &= 0\\
81b_2 &= 0\\
162b_2 &= 0\\
1458b_2 &= 0\\
4374b_2 &= 0\\
486\sqrt{3}\, a_1 &= 0\\
-2430\sqrt{3}\, a_3 &= 0\\
-54\sqrt{3}\, a_3 &= 0\\
-18\sqrt{3}\, a_3 &= 0\\
324\sqrt{3}\, a_3 &= 0\\
-108\sqrt{3}\, b_1 &= 0\\
162\sqrt{3}\, b_1 &= 0\\
-108\sqrt{3}\, b_2 &= 0\\
162\sqrt{3}\, b_2 &= 0\\
486\sqrt{3}\, b_2 &= 0\\
-1458a_2 + 486b_3 &= 0\\
-81a_2 + 27b_3 &= 0\\
243a_2 - 81b_3 &= 0\\
8748a_2 - 2916b_3 &= 0\\
-162\sqrt{3}\, a_2 + 54\sqrt{3}\, b_3 &= 0\\
972\sqrt{3}\, a_2 - 324\sqrt{3}\, b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= \frac{b_3}{3} \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= \frac{x}{3} \\
\eta &= y
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Therefore

$$
\begin{aligned}
\frac{dy}{dx} &= \frac{\eta}{\xi} \\
&= \frac{y}{\frac{x}{3}} \\
&= \frac{3y}{x}
\end{aligned}
$$

This is easily solved to give

$$
y = c_1 x^3
$$

Where now the coordinate R is taken as the constant of integration. Hence

$$
R = \frac{y}{x^3}
$$

And S is found from

$$\begin{aligned} dS &= \frac{dx}{\xi} \\ &= \frac{dx}{\frac{x}{3}} \end{aligned}$$

Integrating gives

$$\begin{aligned} S &= \int \frac{dx}{T} \\ &= 3\ln(x) \end{aligned}$$

Where the constant of integration is set to zero as we just need one solution. Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{\left(27y^2 + 3\sqrt{3x^3y^3 + 81y^4}\right)^{\frac{2}{3}} - 3xy}{3\left(27y^2 + 3\sqrt{3x^3y^3 + 81y^4}\right)^{\frac{1}{3}}}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= -\frac{3y}{x^4} \\ R_y &= \frac{1}{x^3} \\ S_x &= \frac{3}{x} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{9x^3\left(27y^2 + 3\sqrt{3}\,\sqrt{y^3(x^3+27y)}\right)^{\frac{1}{3}}}{-\left(27y^2 + 3\sqrt{3}\,\sqrt{y^3(x^3+27y)}\right)^{\frac{2}{3}} x + 3y\left(x^2 + 3\left(27y^2 + 3\sqrt{3}\,\sqrt{y^3(x^3+27y)}\right)^{\frac{1}{3}}\right)} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{9\,3^{\frac{1}{3}} \left(\sqrt{3}\,\sqrt{27R+1}+9\sqrt{R}\right)^{\frac{1}{3}}}{\sqrt{R}\,\left(3^{\frac{2}{3}} \left(\sqrt{3}\,\sqrt{27R+1}+9\sqrt{R}\right)^{\frac{2}{3}} - 9\,3^{\frac{1}{3}}\sqrt{R}\,\left(\sqrt{3}\,\sqrt{27R+1}+9\sqrt{R}\right)^{\frac{1}{3}} - 3\right)}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \int \frac{9\left(3\sqrt{81R+3}+27\sqrt{R}\right)^{\frac{1}{3}}}{\left(9^{\frac{1}{3}}\left(\left(\sqrt{81R+3}+9\sqrt{R}\right)^{2}\right)^{\frac{1}{3}} - 9\sqrt{R}\,\left(3\sqrt{81R+3}+27\sqrt{R}\right)^{\frac{1}{3}} - 3\right)\sqrt{R}} dR + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$3\ln(x) = \int^{\frac{y}{x^3}} \frac{9(3\sqrt{81\_a+3}+27\sqrt{\_a})^{\frac{1}{3}}}{\left(9^{\frac{1}{3}}\left((\sqrt{81\_a+3}+9\sqrt{\_a})^{2}\right)^{\frac{1}{3}} - 9\sqrt{\_a}\,(3\sqrt{81\_a+3}+27\sqrt{\_a})^{\frac{1}{3}} - 3\right)\sqrt{\_a}} d\_a + c_1$$

Which simplifies to

$$3\ln(x) = \int^{\frac{y}{x^3}} \frac{9(3\sqrt{81\_a+3}+27\sqrt{\_a})^{\frac{1}{3}}}{\left(9^{\frac{1}{3}}\left((\sqrt{81\_a+3}+9\sqrt{\_a})^{2}\right)^{\frac{1}{3}} - 9\sqrt{\_a}\,(3\sqrt{81\_a+3}+27\sqrt{\_a})^{\frac{1}{3}} - 3\right)\sqrt{\_a}} d\_a + c_1$$

Summary

The solution(s) found are the following

$$3\ln(x) = \int^{\frac{y}{x^3}} \frac{9(3\sqrt{81\_a+3}+27\sqrt{\_a})^{\frac{1}{3}}}{\left(9^{\frac{1}{3}}\left((\sqrt{81\_a+3}+9\sqrt{\_a})^{2}\right)^{\frac{1}{3}} - 9\sqrt{\_a}\,(3\sqrt{81\_a+3}+27\sqrt{\_a})^{\frac{1}{3}} - 3\right)\sqrt{\_a}} d\_a + c_1 \tag{1}$$

Verification of solutions

$$3 \ln(x) = \int^{\frac{y}{x^3}} \frac{9\left(3\sqrt{81\_a+3}+27\sqrt{\_a}\right)^{\frac{1}{3}}}{\left(9^{\frac{1}{3}}\left(\left(\sqrt{81\_a+3}+9\sqrt{\_a}\right)^2\right)^{\frac{1}{3}}-9\sqrt{\_a}\left(3\sqrt{81\_a+3}+27\sqrt{\_a}\right)^{\frac{1}{3}}-3\right)\sqrt{\_a}}d\_a + c_1$$

Verified OK.

Solving equation (2)

Writing the ode as

$$y' = \frac{i\sqrt{3}\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}+3i\sqrt{3}\,yx-\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}+3xy}{6\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
& b_2 \\
& + \frac{\left(i\sqrt{3}\,\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}+3i\sqrt{3}\,yx-\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}+3xy\right)(b_3-a_2)}{6\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}} \\
& - \frac{\left(i\sqrt{3}\,\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}+3i\sqrt{3}\,yx-\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}+3xy\right)^2 a_3}{36\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}} \\
& - \left(\frac{\frac{9i\sqrt{3}\,y^3x^2}{\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}\sqrt{3x^3y^3+81y^4}}+3i\sqrt{3}\,y-\frac{9y^3x^2}{\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}\sqrt{3x^3y^3+81y^4}}+3y}{6\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}}\right. \\
& \left. - \frac{3\left(i\sqrt{3}\,\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}+3i\sqrt{3}\,yx-\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}+3xy\right)y^3x^2}{4\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{4}{3}}\sqrt{3x^3y^3+81y^4}}\right)(xa_2 \\
& + ya_3+a_1) - \left(\frac{\frac{2i\sqrt{3}\,\left(54y+\frac{\frac{27}{2}x^3y^2+486y^3}{\sqrt{3x^3y^3+81y^4}}\right)}{3\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}}+3i\sqrt{3}\,x-\frac{2\left(54y+\frac{\frac{27}{2}x^3y^2+486y^3}{\sqrt{3x^3y^3+81y^4}}\right)}{3\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}}+3x}{6\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}}\right. \\
& - \frac{\left(i\sqrt{3}\,\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}+3i\sqrt{3}\,yx-\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}+3xy\right)\left(54y+\frac{\frac{27}{2}x^3y^2+486y^3}{\sqrt{3x^3y^3+81y^4}}\right)}{18\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{4}{3}}} \\
& + yb_3+b_1) = 0
\end{aligned}
\tag{5E}
$$

Putting the above in normal form gives

Expression too large to display

Setting the numerator to zero gives

Expression too large to display (6E)

Simplifying the above gives

Expression too large to display (6E)

Since the PDE has radicals, simplifying gives

Expression too large to display

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, \sqrt{y^3\left(x^3+27y\right)}, \left(27y^2+3\sqrt{3}\,\sqrt{y^3\left(x^3+27y\right)}\right)^{\frac{1}{3}}, \left(27y^2+3\sqrt{3}\,\sqrt{y^3\left(x^3+27y\right)}\right)^{\frac{2}{3}}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, \sqrt{y^3\left(x^3+27y\right)} = v_3, \left(27y^2 + 3\sqrt{3}\,\sqrt{y^3\left(x^3+27y\right)}\right)^{\frac{1}{3}} = v_4, \left(27y^2+3\sqrt{3}\,\sqrt{y^3\left(x^3+27y\right)}\right)^{\frac{2}{3}} = v_5\right\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
-9v_2\Big(&-2\sqrt{3}\,v_5v_3v_1^2v_2a_3 - 72\sqrt{3}\,v_4v_3v_1v_2^2a_3 + 162v_2^3v_1^2b_2\\
&+ 972v_2^4v_1a_2 + 162v_2^3v_1b_1 + 9v_1^5v_2^2b_2 + 27v_1^4v_2^3a_2 - 9v_1^4v_2^3b_3\\
&- 99v_1^3v_2^4a_3 + 9v_1^4v_2^2b_1 + 9v_1^3v_2^3a_1 - 324v_1v_2^4b_3 - 162v_5v_2^3a_2\\
&+ 54v_5v_2^3b_3 - 108v_5v_2^2b_1 - 972v_4v_2^3b_2 + 972i\sqrt{3}\,v_2^4v_1a_2\\
&- 324i\sqrt{3}\,v_1v_2^4b_3 - 18iv_3v_1^3v_2^2a_3 + 108i\sqrt{3}\,v_5v_2^2b_1\\
&+ 162i\sqrt{3}\,v_2^3v_1b_1 + 36iv_5v_3v_1b_2 + 54iv_5v_3v_2a_2 - 18iv_5v_3v_2b_3\\
&+ 54iv_3v_1^2v_2b_2 + 324iv_3v_1v_2^2a_2 - 108iv_3v_1v_2^2b_3 + 54iv_3v_1v_2b_1\\
&- 24v_4v_1^4v_2^3a_3 - 3v_5v_1^4v_2b_2 - 9v_5v_1^3v_2^2a_2 + 3v_5v_1^3v_2^2b_3\\
&- 3v_5v_1^2v_2^3a_3 - 3v_5v_1^3v_2b_1 - 3v_5v_1^2v_2^2a_1 - 36v_4v_1^3v_2^2b_2\\
&- 648v_4v_1v_2^4a_3 - 270\sqrt{3}\,v_3v_2^3a_3 - 108v_5v_1v_2^2b_2\\
&- 12\sqrt{3}\,v_5v_3b_1 + 54\sqrt{3}\,v_3v_2^2a_1 - 2430i\sqrt{3}\,v_2^5a_3\\
&+ 486i\sqrt{3}\,v_2^4a_1 + 3i\sqrt{3}\,v_5v_1^4v_2b_2 + 9i\sqrt{3}\,v_5v_1^3v_2^2a_2\\
&- 3i\sqrt{3}\,v_5v_1^3v_2^2b_3 + 3i\sqrt{3}\,v_5v_1^2v_2^3a_3 + 3i\sqrt{3}\,v_5v_1^3v_2b_1\\
&+ 3i\sqrt{3}\,v_5v_1^2v_2^2a_1 + 108i\sqrt{3}\,v_5v_1v_2^2b_2 + 6iv_5v_3v_1^2v_2a_3\\
&+ 9i\sqrt{3}\,v_1^5v_2^2b_2 + 27i\sqrt{3}\,v_1^4v_2^3a_2 - 9i\sqrt{3}\,v_1^4v_2^3b_3\\
&- 99i\sqrt{3}\,v_1^3v_2^4a_3 + 9i\sqrt{3}\,v_1^4v_2^2b_1 + 9i\sqrt{3}\,v_1^3v_2^3a_1\\
&+ 162i\sqrt{3}\,v_5v_2^3a_2 - 54i\sqrt{3}\,v_5v_2^3b_3 + 162i\sqrt{3}\,v_2^3v_1^2b_2\\
&- 810iv_3v_2^3a_3 + 36iv_5v_3b_1 + 162iv_3v_2^2a_1 - 2430v_2^5a_3\\
&+ 486v_2^4a_1 - 6\sqrt{3}\,v_3v_1^3v_2^2a_3 - 12\sqrt{3}\,v_5v_3v_1b_2 - 18\sqrt{3}\,v_5v_3v_2a_2\\
&+ 6\sqrt{3}\,v_5v_3v_2b_3 + 18\sqrt{3}\,v_3v_1^2v_2b_2 + 108\sqrt{3}\,v_3v_1v_2^2a_2\\
&- 36\sqrt{3}\,v_3v_1v_2^2b_3 - 108\sqrt{3}\,v_4v_3v_2b_2 + 18\sqrt{3}\,v_3v_1v_2b_1\Big) = 0
\end{aligned}
\tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$
\{v_1, v_2, v_3, v_4, v_5\}
$$

Equation (7E) now becomes

$$
\begin{aligned}
&5832a_3v_4v_1v_2^5 + \left(-54ia_3 + 18\sqrt{3}\,a_3\right) v_3v_5v_1^2v_2^2\\
&+ \left(-324ib_2 + 108\sqrt{3}\,b_2\right) v_3v_5v_1v_2\\
&+ 8748b_2v_4v_2^4 + 648\sqrt{3}\,a_3v_3v_4v_1v_2^3\\
&+ \left(-8748i\sqrt{3}\,a_2 + 2916i\sqrt{3}\,b_3 - 8748a_2 + 2916b_3\right) v_1v_2^5\\
&+ \left(-1458i\sqrt{3}\,b_1 - 1458b_1\right) v_1v_2^4\\
&+ \left(7290ia_3 + 2430\sqrt{3}\,a_3\right) v_3v_2^4\\

&+ \left(-81i\sqrt{3}\,a_2 + 27i\sqrt{3}\,b_3 + 81a_2 - 27b_3\right) v_5v_1^3v_2^3\\
&+ \left(-27i\sqrt{3}\,b_1 + 27b_1\right) v_5v_1^3v_2^2 + \left(-27i\sqrt{3}\,b_2 + 27b_2\right) v_5v_1^4v_2^2\\
&+ \left(-486ia_2 + 162ib_3 + 162\sqrt{3}\,a_2 - 54\sqrt{3}\,b_3\right) v_3v_5v_2^2\\
&+ \left(-324ib_1 + 108\sqrt{3}\,b_1\right) v_3v_5v_2 = 0
\end{aligned}
\tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
216a_3 &= 0\\
5832a_3 &= 0\\
324b_2 &= 0\\
8748b_2 &= 0\\
648\sqrt{3}\,a_3 &= 0\\
972\sqrt{3}\,b_2 &= 0\\
-1458ia_1 - 486\sqrt{3}\,a_1 &= 0\\
-486ib_1 - 162\sqrt{3}\,b_1 &= 0\\
-486ib_2 - 162\sqrt{3}\,b_2 &= 0\\
-324ib_1 + 108\sqrt{3}\,b_1 &= 0\\
-324ib_2 + 108\sqrt{3}\,b_2 &= 0\\
-54ia_3 + 18\sqrt{3}\,a_3 &= 0\\
162ia_3 + 54\sqrt{3}\,a_3 &= 0\\
7290ia_3 + 2430\sqrt{3}\,a_3 &= 0\\
-4374i\sqrt{3}\,a_1 - 4374a_1 &= 0\\
-1458i\sqrt{3}\,b_1 - 1458b_1 &= 0\\
-1458i\sqrt{3}\,b_2 - 1458b_2 &= 0\\
-972i\sqrt{3}\,b_1 + 972b_1 &= 0\\
-972i\sqrt{3}\,b_2 + 972b_2 &= 0\\
-81i\sqrt{3}\,a_1 - 81a_1 &= 0\\
-81i\sqrt{3}\,b_1 - 81b_1 &= 0\\
-81i\sqrt{3}\,b_2 - 81b_2 &= 0\\
-27i\sqrt{3}\,a_1 + 27a_1 &= 0\\
-27i\sqrt{3}\,a_3 + 27a_3 &= 0\\
-27i\sqrt{3}\,b_1 + 27b_1 &= 0\\
-27i\sqrt{3}\,b_2 + 27b_2 &= 0\\
891i\sqrt{3}\,a_3 + 891a_3 &= 0\\
21870i\sqrt{3}\,a_3 + 21870a_3 &= 0\\
-2916ia_2 + 972ib_3 - 972\sqrt{3}\,a_2 + 324\sqrt{3}\,b_3 &= 0\\
-486ia_2 + 162ib_3 + 162\sqrt{3}\,a_2 - 54\sqrt{3}\,b_3 &= 0\\
-8748i\sqrt{3}\,a_2 + 2916i\sqrt{3}\,b_3 - 8748a_2 + 2916b_3 &= 0\\
-1458i\sqrt{3}\,a_2 + 486i\sqrt{3}\,b_3 + 1458a_2 - 486b_3 &= 0\\
-243i\sqrt{3}\,a_2 + 81i\sqrt{3}\,b_3 - 243a_2 + 81b_3 &= 0\\
-81i\sqrt{3}\,a_2 + 27i\sqrt{3}\,b_3 + 81a_2 - 27b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= \frac{b_3}{3} \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= \frac{x}{3} \\
\eta &= y
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Unable to determine R. Terminating

Unable to determine ODE type.

Solving equation (3)

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{i\sqrt{3}\left(27y^2 + 3\sqrt{3x^3y^3 + 81y^4}\right)^{\frac{2}{3}} + 3i\sqrt{3}\,yx + \left(27y^2 + 3\sqrt{3x^3y^3 + 81y^4}\right)^{\frac{2}{3}} - 3xy}{6\left(27y^2 + 3\sqrt{3x^3y^3 + 81y^4}\right)^{\frac{1}{3}}} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 - \frac{\left(i\sqrt{3}\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}} + 3i\sqrt{3}\,yx + \left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}} - 3xy\right)(b_3-a_2)}{6\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}} - \frac{\left(i\sqrt{3}\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}} + 3i\sqrt{3}\,yx + \left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}} - 3xy\right)^2 a_3}{36\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}}} - \left(-\frac{\frac{9i\sqrt{3}\,y^3x^2}{\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}\sqrt{3x^3y^3+81y^4}} + 3i\sqrt{3}\,y + \frac{9y^3x^2}{\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}\sqrt{3x^3y^3+81y^4}} - 3y}{6\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}} + \frac{3\left(i\sqrt{3}\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}} + 3i\sqrt{3}\,yx + \left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}} - 3xy\right)y^3x^2}{4\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{4}{3}}\sqrt{3x^3y^3+81y^4}}\right)(xa_2 + ya_3 + a_1) - \left(-\frac{\frac{2i\sqrt{3}\left(54y+\frac{\frac{27}{2}x^3y^2+486y^3}{\sqrt{3x^3y^3+81y^4}}\right)}{3\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}} + 3i\sqrt{3}\,x + \frac{36y+\frac{2\left(\frac{27}{2}x^3y^2+486y^3\right)}{3\sqrt{3x^3y^3+81y^4}}}{\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}} - 3x}{6\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{1}{3}}} + \frac{\left(i\sqrt{3}\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}} + 3i\sqrt{3}\,yx + \left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{2}{3}} - 3xy\right)\left(54y+\frac{\frac{27}{2}x^3y^2+486y^3}{\sqrt{3x^3y^3+81y^4}}\right)}{18\left(27y^2+3\sqrt{3x^3y^3+81y^4}\right)^{\frac{4}{3}}}\right)(xb_2 + yb_3 + b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

Expression too large to display

Setting the numerator to zero gives

Expression too large to display (6E)

Simplifying the above gives

Expression too large to display (6E)

Since the PDE has radicals, simplifying gives

Expression too large to display

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, \sqrt{y^3 (x^3 + 27y)}, \left(27y^2+3\sqrt{3}\,\sqrt{y^3 (x^3 + 27y)}\right)^{\frac{1}{3}}, \left(27y^2+3\sqrt{3}\,\sqrt{y^3 (x^3 + 27y)}\right)^{\frac{2}{3}}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, \sqrt{y^3 (x^3 + 27y)} = v_3, \left(27y^2 + 3\sqrt{3}\,\sqrt{y^3 (x^3 + 27y)}\right)^{\frac{1}{3}} = v_4, \left(27y^2 + 3\sqrt{3}\,\sqrt{y^3 (x^3 + 27y)}\right)^{\frac{2}{3}} = v_5\right\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&9v_2\Big(6v_3\sqrt{3}\,v_1^3v_2^2a_3+12v_3\sqrt{3}\,v_5v_1b_2+18v_3\sqrt{3}\,v_5v_2a_2\\
&-6v_3\sqrt{3}\,v_5v_2b_3-18v_3\sqrt{3}\,v_1^2v_2b_2-108v_3\sqrt{3}\,v_1v_2^2a_2\\
&+36v_3\sqrt{3}\,v_1v_2^2b_3+108v_3\sqrt{3}\,v_4v_2b_2-18v_3\sqrt{3}\,v_1v_2b_1\\
&+54iv_3v_5v_2a_2-18iv_3v_5v_2b_3+54iv_3v_1^2v_2b_2+324iv_3v_1v_2^2a_2\\
&-108iv_3v_1v_2^2b_3+54iv_3v_1v_2b_1+9i\sqrt{3}\,v_1^5v_2^2b_2+24v_4v_1^4v_2^3a_3\\
&+27i\sqrt{3}\,v_1^4v_2^3a_2-9i\sqrt{3}\,v_1^4v_2^3b_3-99i\sqrt{3}\,v_1^3v_2^4a_3\\

&+162i\sqrt{3}\,v_5v_2^3a_2-54i\sqrt{3}\,v_5v_2^3b_3+162iv_2^3\sqrt{3}\,v_1^2b_2\\
&+972iv_2^4\sqrt{3}\,v_1a_2-324i\sqrt{3}\,v_1v_2^4b_3+108i\sqrt{3}\,v_5v_2^2b_1\\
&+162iv_2^3\sqrt{3}\,v_1b_1+36iv_3v_5v_1b_2+3i\sqrt{3}\,v_5v_1^3v_2b_1\\
&+3i\sqrt{3}\,v_5v_1^2v_2^2a_1+6iv_3v_5v_1^2v_2a_3+108i\sqrt{3}\,v_5v_1v_2^2b_2\\
&-2430iv_2^5\sqrt{3}\,a_3+486iv_2^4\sqrt{3}\,a_1-810iv_3v_2^3a_3+36iv_3v_5b_1\\
&+162iv_3v_2^2a_1+3v_5v_1^4v_2b_2+9v_5v_1^3v_2^2a_2-3v_5v_1^3v_2^2b_3\\
&+3v_5v_1^2v_2^3a_3+3v_5v_1^3v_2b_1+3v_5v_1^2v_2^2a_1+36v_4v_1^3v_2^2b_2\\
&+648v_4v_1v_2^4a_3+270v_3\sqrt{3}\,v_2^3a_3+108v_5v_1v_2^2b_2\\
&+12v_3\sqrt{3}\,v_5b_1-54v_3\sqrt{3}\,v_2^2a_1+2v_3\sqrt{3}\,v_5v_1^2v_2a_3\\
&+72v_3\sqrt{3}\,v_4v_1v_2^2a_3+3i\sqrt{3}\,v_5v_1^4v_2b_2+9i\sqrt{3}\,v_5v_1^3v_2^2a_2\\
&-3i\sqrt{3}\,v_5v_1^3v_2^2b_3+3i\sqrt{3}\,v_5v_1^2v_2^3a_3-54v_5v_2^3b_3+108v_5v_2^2b_1\\
&+972v_4v_2^3b_2+324v_1v_2^4b_3-27v_1^4v_2^3a_2+9v_1^4v_2^3b_3+99v_1^3v_2^4a_3\\
&-9v_1^4v_2^2b_1-9v_1^3v_2^3a_1+162v_5v_2^3a_2-162v_2^3v_1^2b_2-972v_2^4v_1a_2\\
&-162v_2^3v_1b_1-9v_1^5v_2^2b_2+2430v_2^5a_3-486v_2^4a_1\Big)=0
\end{aligned}
\tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1,v_2,v_3,v_4,v_5\}$$

Equation (7E) now becomes

$$
\begin{aligned}
&216a_3v_4v_1^4v_2^4+324b_2v_4v_1^3v_2^3+5832a_3v_4v_1v_2^5+972\sqrt{3}\,b_2v_3v_4v_2^2\\
&+\left(27i\sqrt{3}\,b_2+27b_2\right)v_5v_1^4v_2^2+\left(-162ia_3+54\sqrt{3}\,a_3\right)v_3v_1^3v_2^3\\

&+8748b_2v_4v_2^4+\left(4374i\sqrt{3}\,a_1-4374a_1\right)v_2^5\\
&+\left(-21870i\sqrt{3}\,a_3+21870a_3\right)v_2^6=0
\end{aligned}
\tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$216a_3 = 0$$
$$5832a_3 = 0$$
$$324b_2 = 0$$
$$8748b_2 = 0$$
$$648\sqrt{3}\, a_3 = 0$$
$$972\sqrt{3}\, b_2 = 0$$
$$-7290ia_3 + 2430\sqrt{3}\, a_3 = 0$$
$$-162ia_3 + 54\sqrt{3}\, a_3 = 0$$
$$54ia_3 + 18\sqrt{3}\, a_3 = 0$$
$$324ib_1 + 108\sqrt{3}\, b_1 = 0$$
$$324ib_2 + 108\sqrt{3}\, b_2 = 0$$
$$486ib_1 - 162\sqrt{3}\, b_1 = 0$$
$$486ib_2 - 162\sqrt{3}\, b_2 = 0$$
$$1458ia_1 - 486\sqrt{3}\, a_1 = 0$$
$$-21870i\sqrt{3}\, a_3 + 21870a_3 = 0$$
$$-891i\sqrt{3}\, a_3 + 891a_3 = 0$$
$$27i\sqrt{3}\, a_1 + 27a_1 = 0$$
$$27i\sqrt{3}\, a_3 + 27a_3 = 0$$
$$27i\sqrt{3}\, b_1 + 27b_1 = 0$$
$$27i\sqrt{3}\, b_2 + 27b_2 = 0$$
$$81i\sqrt{3}\, a_1 - 81a_1 = 0$$
$$81i\sqrt{3}\, b_1 - 81b_1 = 0$$
$$81i\sqrt{3}\, b_2 - 81b_2 = 0$$
$$972i\sqrt{3}\, b_1 + 972b_1 = 0$$
$$972i\sqrt{3}\, b_2 + 972b_2 = 0$$
$$1458i\sqrt{3}\, b_1 - 1458b_1 = 0$$
$$1458i\sqrt{3}\, b_2 - 1458b_2 = 0$$
$$4374i\sqrt{3}\, a_1 - 4374a_1 = 0$$
$$486ia_2 - 162ib_3 + 162\sqrt{3}\, a_2 - 54\sqrt{3}\, b_3 = 0$$
$$2916ia_2 - 972ib_3 - 972\sqrt{3}\, a_2 + 324\sqrt{3}\, b_3 = 0$$
$$81i\sqrt{3}\, a_2 - 27i\sqrt{3}\, b_3 + 81a_2 - 27b_3 = 0$$
$$243i\sqrt{3}\, a_2 - 81i\sqrt{3}\, b_3 - 243a_2 + 81b_3 = 0$$
$$1458i\sqrt{3}\, a_2 - 486i\sqrt{3}\, b_3 + 1458a_2 - 486b_3 = 0$$
$$8748i\sqrt{3}\, a_2 - 2916i\sqrt{3}\, b_3 - 8748a_2 + 2916b_3 = 0$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= \frac{b_3}{3} \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= \frac{x}{3} \\
\eta &= y
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Unable to determine R. Terminating

Unable to determine ODE type.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 38, page 173
Problem number: 13.
ODE order: 1.
ODE degree: 4.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[[_1st_order, _with_linear_symmetries], _dAlembert]`

$$\boxed{3y'^4x - y'^3y = 1}$$

20.13.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$3p^4x - p^3y = 1$$

Solving for y from the above results in

$$y = 3px - \frac{1}{p^3} \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = 3p$$
$$g = -\frac{1}{p^3}$$

Hence (2) becomes

$$-2p = \left(3x + \frac{3}{p^4}\right) p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$-2p = 0$$

Solving for p from the above gives

$$p = 0$$

None of these values lead to defined solutions. Hence no singular solutions exist

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$p'(x) = -\frac{2p(x)}{3x + \frac{3}{p(x)^4}} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = -\frac{3x(p) + \frac{3}{p^4}}{2p} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = \frac{3}{2p}$$
$$q(p) = -\frac{3}{2p^5}$$

Hence the ode is

$$\frac{d}{dp}x(p) + \frac{3x(p)}{2p} = -\frac{3}{2p^5}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{3}{2p}dp} \\ &= p^{\frac{3}{2}}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}p}(\mu x) &= (\mu)\left(-\frac{3}{2p^5}\right) \\ \frac{\mathrm{d}}{\mathrm{d}p}\left(p^{\frac{3}{2}}x\right) &= \left(p^{\frac{3}{2}}\right)\left(-\frac{3}{2p^5}\right) \\ \mathrm{d}\left(p^{\frac{3}{2}}x\right) &= \left(-\frac{3}{2p^{\frac{7}{2}}}\right)\mathrm{d}p\end{aligned}$$

Integrating gives

$$\begin{aligned}p^{\frac{3}{2}}x &= \int -\frac{3}{2p^{\frac{7}{2}}}\,\mathrm{d}p \\ p^{\frac{3}{2}}x &= \frac{3}{5p^{\frac{5}{2}}} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = p^{\frac{3}{2}}$ results in

$$x(p) = \frac{3}{5p^4} + \frac{c_1}{p^{\frac{3}{2}}}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p = \mathrm{RootOf}\left(3x\_Z^4 - y\_Z^3 - 1\right)$$

Substituting the above in the solution for x found above gives

$$x = \frac{5\,\mathrm{RootOf}\left(3x\_Z^4 - y\_Z^3 - 1\right)^3 c_1 y + 9\,\mathrm{RootOf}\left(3x\_Z^4 - y\_Z^3 - 1\right)^{\frac{3}{2}} x + 5c_1}{15x\,\mathrm{RootOf}\left(3x\_Z^4 - y\_Z^3 - 1\right)^{\frac{11}{2}}}$$

Summary

The solution(s) found are the following

$$x = \frac{5\,\mathrm{RootOf}\left(3x\_Z^4 - y\_Z^3 - 1\right)^3 c_1 y + 9\,\mathrm{RootOf}\left(3x\_Z^4 - y\_Z^3 - 1\right)^{\frac{3}{2}} x + 5c_1}{15x\,\mathrm{RootOf}\left(3x\_Z^4 - y\_Z^3 - 1\right)^{\frac{11}{2}}} \tag{1}$$

Verification of solutions

$$x = \frac{5 \operatorname{RootOf}\left(3x\_Z^4 - y\_Z^3 - 1\right)^3 c_1 y + 9 \operatorname{RootOf}\left(3x\_Z^4 - y\_Z^3 - 1\right)^{\frac{3}{2}} x + 5c_1}{15x \operatorname{RootOf}\left(3x\_Z^4 - y\_Z^3 - 1\right)^{\frac{11}{2}}}$$

Verified OK.

Problem number: 14.
ODE order: 1.
ODE degree: 5.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[_dAlembert]`

$$\boxed{2y'^5 + 2xy' - y = 0}$$

20.14.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$2p^5 + 2xp - y = 0$$

Solving for y from the above results in

$$y = 2p^5 + 2xp \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= 2p \\
g &= 2p^5
\end{aligned}
$$

Hence (2) becomes

$$
-p = \left(10p^4 + 2x\right) p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
-p = 0
$$

Solving for p from the above gives

$$
p = 0
$$

Substituting these in (1A) gives

$$
y = 0
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = -\frac{p(x)}{10p\left(x\right)^4 + 2x} \tag{3}
$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$
\frac{d}{dp}x(p) = -\frac{10p^4 + 2x(p)}{p} \tag{4}
$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
\frac{d}{dp}x(p) + p(p)x(p) = q(p)
$$

Where here

$$
\begin{aligned}
p(p) &= \frac{2}{p} \\
q(p) &= -10p^3
\end{aligned}
$$

Hence the ode is

$$\frac{d}{dp}x(p)+\frac{2x(p)}{p}=-10p^3$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{2}{p}dp}\\ &= p^2\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}p}(\mu x) &= (\mu)\left(-10p^3\right)\\ \frac{\mathrm{d}}{\mathrm{d}p}\left(p^2x\right) &= \left(p^2\right)\left(-10p^3\right)\\ \mathrm{d}\left(p^2x\right) &= \left(-10p^5\right)\,\mathrm{d}p\end{aligned}$$

Integrating gives

$$\begin{aligned}p^2x &= \int -10p^5\,\mathrm{d}p\\ p^2x &= -\frac{5p^6}{3}+c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu=p^2$ results in

$$x(p)=-\frac{5p^4}{3}+\frac{c_1}{p^2}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p=\mathrm{RootOf}\left(2\_Z^5+2\_Zx-y\right)$$

Substituting the above in the solution for x found above gives

$$x=\frac{10x\,\mathrm{RootOf}\left(2\_Z^5+2\_Zx-y\right)^2-5y\,\mathrm{RootOf}\left(2\_Z^5+2\_Zx-y\right)+6c_1}{6\,\mathrm{RootOf}\left(2\_Z^5+2\_Zx-y\right)^2}$$

Summary

The solution(s) found are the following

$$y=0 \tag{1}$$

$$x=\frac{10x\,\mathrm{RootOf}\left(2\_Z^5+2\_Zx-y\right)^2-5y\,\mathrm{RootOf}\left(2\_Z^5+2\_Zx-y\right)+6c_1}{6\,\mathrm{RootOf}\left(2\_Z^5+2\_Zx-y\right)^2} \tag{2}$$

Verification of solutions

$$y = 0$$

Verified OK.

$$x = \frac{10x \operatorname{RootOf}\left(2\_Z^5 + 2\_Zx - y\right)^2 - 5y \operatorname{RootOf}\left(2\_Z^5 + 2\_Zx - y\right) + 6c_1}{6 \operatorname{RootOf}\left(2\_Z^5 + 2\_Zx - y\right)^2}$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 38, page 173
Problem number: 15.
ODE order: 1.
ODE degree: 3.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[[_1st_order, _with_linear_symmetries], _dAlembert]`

$$\boxed{\frac{1}{y'^2} + xy' - 2y = 0}$$

20.15.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$\frac{1}{p^2} + xp - 2y = 0$$

Solving for y from the above results in

$$y = \frac{xp}{2} + \frac{1}{2p^2} \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = \frac{p}{2}$$
$$g = \frac{1}{2p^2}$$

Hence (2) becomes

$$\frac{p}{2} = \left(\frac{x}{2} - \frac{1}{p^3}\right) p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$\frac{p}{2} = 0$$

Solving for p from the above gives

$$p = 0$$

Substituting these in (1A) gives

$$y = \infty$$

The general solution is found when $\frac{dp}{dx} \neq 0$. From eq. (2A). This results in

$$p'(x) = \frac{p(x)}{x - \frac{2}{p(x)^3}} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = \frac{x(p) - \frac{2}{p^3}}{p} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = -\frac{1}{p}$$
$$q(p) = -\frac{2}{p^4}$$

Hence the ode is

$$\frac{d}{dp}x(p) - \frac{x(p)}{p} = -\frac{2}{p^4}$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{1}{p}dp} \\ &= \frac{1}{p}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}p}(\mu x) &= (\mu)\left(-\frac{2}{p^4}\right) \\ \frac{\mathrm{d}}{\mathrm{d}p}\left(\frac{x}{p}\right) &= \left(\frac{1}{p}\right)\left(-\frac{2}{p^4}\right) \\ \mathrm{d}\left(\frac{x}{p}\right) &= \left(-\frac{2}{p^5}\right)\mathrm{d}p\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{x}{p} &= \int -\frac{2}{p^5}\,\mathrm{d}p \\ \frac{x}{p} &= \frac{1}{2p^4} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{p}$ results in

$$x(p) = \frac{1}{2p^3} + c_1 p$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p = \frac{\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}}{6x} + \frac{8y^2}{3x\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}} + \frac{2y}{3x}$$

$$p = -\frac{\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}}{12x} - \frac{4y^2}{3x\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}} + \frac{2y}{3x}$$

$$p = -\frac{\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}}{12x} - \frac{4y^2}{3x\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}} + \frac{2y}{3x}$$

Substituting the above in the solution for x found above gives

$$x = \frac{108x^3}{\left(\frac{16y^2}{\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}} + 4y + \left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}\right)^3} + \frac{c_1\left(\frac{16y^2}{\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}} + 4y + \left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}\right)}{6x}$$

$$x = \frac{-10368x^4\sqrt{3}\,\sqrt{-32y^3+27x^2} - 55296y^3x^3 + \cdots}{\left(-i\sqrt{3}\,\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{2}{3}} + 16i\sqrt{3}\,y^2 + \left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-10\cdots\right.} + \frac{\left(\left(-1+i\sqrt{3}\right)\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{2}{3}} + 8y\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108\cdots\right.\right.}{12\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}x}$$

$$x = \frac{3456\left(-3\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x - 16y^3 + 27x\cdots\right.}{\left(i\sqrt{3}\,\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{2}{3}} - 16i\sqrt{3}\,y^2 + \left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108\cdots\right.} - \frac{\left(\left(1+i\sqrt{3}\right)\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{2}{3}} - 8y\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x\cdots\right.\right.}{12\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}x}$$

Summary

The solution(s) found are the following

$$y = \infty \tag{1}$$

$$x = \frac{108x^3}{\left(\frac{16y^2}{\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}} + 4y + \left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}\right)^3} + \frac{c_1\left(\frac{16y^2}{\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}} + 4y + \left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}\right)}{6x} \tag{2}$$

$$x = \frac{-10368x^4\sqrt{3}\,\sqrt{-32y^3+27x^2} - 55296y^3x^3 + \cdots}{\left(-i\sqrt{3}\,\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{2}{3}} + 16i\sqrt{3}\,y^2 + \left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-10\cdots\right.\right.} + \frac{\left(\left(-1+i\sqrt{3}\right)\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{2}{3}} + 8y\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108\cdots\right.\right.}{12\left(12\sqrt{3}\,\sqrt{-32y^3+27x^2}\,x+64y^3-108x^2\right)^{\frac{1}{3}}x} \tag{3}$$

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[[_1st_order, _with_linear_symmetries], _dAlembert]`

$$\boxed{2y - 3xy' - 2\ln(y') = 4}$$

20.16.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$2y - 3xp - 2\ln(p) = 4$$

Solving for y from the above results in

$$y = \frac{3xp}{2} + \ln(p) + 2 \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= \frac{3p}{2} \\
g &= \ln(p) + 2
\end{aligned}
$$

Hence (2) becomes

$$
-\frac{p}{2} = \left(\frac{3x}{2} + \frac{1}{p}\right) p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
-\frac{p}{2} = 0
$$

Solving for p from the above gives

$$
p = 0
$$

Substituting these in (1A) gives

$$
y = -\infty
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = -\frac{p(x)}{2\left(\frac{3x}{2} + \frac{1}{p(x)}\right)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$
\frac{d}{dp}x(p) = -\frac{2\left(\frac{3x(p)}{2} + \frac{1}{p}\right)}{p} \tag{4}
$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
\frac{d}{dp}x(p) + p(p)x(p) = q(p)
$$

Where here

$$
\begin{aligned}
p(p) &= \frac{3}{p} \\
q(p) &= -\frac{2}{p^2}
\end{aligned}
$$

Hence the ode is

$$\frac{d}{dp}x(p) + \frac{3x(p)}{p} = -\frac{2}{p^2}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{3}{p}dp} \\ &= p^3\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dp}(\mu x) &= (\mu)\left(-\frac{2}{p^2}\right) \\ \frac{d}{dp}(p^3 x) &= (p^3)\left(-\frac{2}{p^2}\right) \\ d(p^3 x) &= (-2p)\, dp\end{aligned}$$

Integrating gives

$$\begin{aligned}p^3 x &= \int -2p\, dp \\ p^3 x &= -p^2 + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = p^3$ results in

$$x(p) = -\frac{1}{p} + \frac{c_1}{p^3}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p = e^{-\operatorname{LambertW}\left(\frac{3x\,e^{y-2}}{2}\right)+y-2}$$

Substituting the above in the solution for x found above gives

$$x = -\frac{3x\left(-9c_1x^2 + 4\operatorname{LambertW}\left(\frac{3x\,e^{y-2}}{2}\right)^2\right)}{8\operatorname{LambertW}\left(\frac{3x\,e^{y-2}}{2}\right)^3}$$

<u>Summary</u>

The solution(s) found are the following

$$y = -\infty \tag{1}$$

$$x = -\frac{3x\left(-9c_1x^2 + 4\operatorname{LambertW}\left(\frac{3x\,e^{y-2}}{2}\right)^2\right)}{8\operatorname{LambertW}\left(\frac{3x\,e^{y-2}}{2}\right)^3} \tag{2}$$

Verification of solutions

$$y = -\infty$$

Warning, solution could not be verified

$$x = -\frac{3x\left(-9c_1x^2 + 4\,\mathrm{LambertW}\left(\frac{3x\,\mathrm{e}^{y-2}}{2}\right)^2\right)}{8\,\mathrm{LambertW}\left(\frac{3x\,\mathrm{e}^{y-2}}{2}\right)^3}$$

Verified OK.

The type(s) of ODE detected by this program : **"clairaut"**

Maple gives the following as the ode type

```
[[_1st_order, _with_linear_symmetries], _Clairaut]
```

$$\boxed{y - xy' - {y'}^2 = 0}$$

21.1.1 Solving as clairaut ode

This is Clairaut ODE. It has the form

$$y = xy' + g(y')$$

Where g is function of $y'(x)$. Let $p = y'$ the ode becomes

$$-p^2 - xp + y = 0$$

Solving for y from the above results in

$$y = p^2 + xp \tag{1A}$$

The above ode is a Clairaut ode which is now solved. We start by replacing y' by p which gives

$$\begin{aligned} y &= p^2 + xp \\ &= p^2 + xp \end{aligned}$$

Writing the ode as

$$y = xp + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = xp + g \tag{1}$$

Then we see that

$$g = p^2$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned} p &= \frac{d}{dx}(xp + g) \\ p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\ p &= p + (x + g')\frac{dp}{dx} \\ 0 &= (x + g')\frac{dp}{dx} \end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned} \frac{dp}{dx} &= 0 \\ p &= c_1 \end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_1^2 + c_1 x$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = p^2$, then the above equation becomes

$$\begin{aligned} x + g'(p) &= x + 2p \\ &= 0 \end{aligned}$$

Solving the above for p results in

$$p_1 = -\frac{x}{2}$$

Substituting the above back in (1) results in

$$y_1 = -\frac{x^2}{4}$$

Summary

The solution(s) found are the following

$$y = c_1^2 + c_1 x \tag{1}$$

$$y = -\frac{x^2}{4} \tag{2}$$

Verification of solutions

$$y = c_1^2 + c_1 x$$

Verified OK.

$$y = -\frac{x^2}{4}$$

Verified OK.

Internal problem ID [2355]
Internal file name [`OUTPUT/2355_Tuesday_February_27_2024_08_36_04_AM_11769021/index.tex`]

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 39, page 179
Problem number: 24.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"clairaut"**

Maple gives the following as the ode type

`[[_homogeneous, `class G`], _rational, _Clairaut]`

$$\boxed{y - xy' - \frac{1}{y'} = 0}$$

21.2.1 Solving as clairaut ode

This is Clairaut ODE. It has the form

$$y = xy' + g(y')$$

Where g is function of $y'(x)$. Let $p = y'$ the ode becomes

$$y - xp - \frac{1}{p} = 0$$

Solving for y from the above results in

$$y = \frac{x\,p^2 + 1}{p} \tag{1A}$$

The above ode is a Clairaut ode which is now solved. We start by replacing y' by p which gives

$$\begin{aligned} y &= xp + \frac{1}{p} \\ &= xp + \frac{1}{p} \end{aligned}$$

Writing the ode as

$$y = xp + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = xp + g \tag{1}$$

Then we see that

$$g = \frac{1}{p}$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned}
p &= \frac{d}{dx}(xp + g) \\
p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\
p &= p + (x + g')\frac{dp}{dx} \\
0 &= (x + g')\frac{dp}{dx}
\end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned}
\frac{dp}{dx} &= 0 \\
p &= c_1
\end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_1 x + \frac{1}{c_1}$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = \frac{1}{p}$, then the above equation becomes

$$\begin{aligned}
x + g'(p) &= x - \frac{1}{p^2} \\
&= 0
\end{aligned}$$

Solving the above for p results in

$$p_1 = \frac{1}{\sqrt{x}}$$
$$p_2 = -\frac{1}{\sqrt{x}}$$

Substituting the above back in (1) results in

$$y_1 = 2\sqrt{x}$$
$$y_2 = -2\sqrt{x}$$

Summary
The solution(s) found are the following

$$y = c_1 x + \frac{1}{c_1} \tag{1}$$
$$y = 2\sqrt{x} \tag{2}$$
$$y = -2\sqrt{x} \tag{3}$$

Verification of solutions

$$y = c_1 x + \frac{1}{c_1}$$

Verified OK.

$$y = 2\sqrt{x}$$

Verified OK.

$$y = -2\sqrt{x}$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 39, page 179
Problem number: 25.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"clairaut"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _Clairaut]
```

$$\boxed{y - xy' + \sqrt{y'} = 0}$$

21.3.1 Solving as clairaut ode

This is Clairaut ODE. It has the form

$$y = xy' + g(y')$$

Where g is function of $y'(x)$. Let $p = y'$ the ode becomes

$$y - xp + \sqrt{p} = 0$$

Solving for y from the above results in

$$y = xp - \sqrt{p} \tag{1A}$$

The above ode is a Clairaut ode which is now solved. We start by replacing y' by p which gives

$$\begin{aligned} y &= xp - \sqrt{p} \\ &= xp - \sqrt{p} \end{aligned}$$

Writing the ode as

$$y = xp + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = xp + g \tag{1}$$

Then we see that

$$g = -\sqrt{p}$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned}
p &= \frac{d}{dx}(xp + g) \\
p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\
p &= p + (x + g')\frac{dp}{dx} \\
0 &= (x + g')\frac{dp}{dx}
\end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned}
\frac{dp}{dx} &= 0 \\
p &= c_1
\end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_1 x - \sqrt{c_1}$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = -\sqrt{p}$, then the above equation becomes

$$\begin{aligned}
x + g'(p) &= x - \frac{1}{2\sqrt{p}} \\
&= 0
\end{aligned}$$

Solving the above for p results in

$$p_1 = \frac{1}{4x^2}$$

Substituting the above back in (1) results in

$$y_1 = \frac{\left(\operatorname{csgn}\left(\frac{1}{x}\right) - 2\right)\sqrt{\frac{1}{x^2}}}{4}$$

Simplifying the solution $y = \frac{\left(\operatorname{csgn}\left(\frac{1}{x}\right)-2\right)\sqrt{\frac{1}{x^2}}}{4}$ to $y = -\frac{\sqrt{\frac{1}{x^2}}}{4}$

Summary

The solution(s) found are the following

$$y = c_1 x - \sqrt{c_1}$$

$$y = -\frac{\sqrt{\frac{1}{x^2}}}{4}$$

Verification of solutions

$$y = c_1 x - \sqrt{c_1}$$

Verified OK.

$$y = -\frac{\sqrt{\frac{1}{x^2}}}{4}$$

Verified OK.

ODE degree: 0.

The type(s) of ODE detected by this program : **"clairaut"**

Maple gives the following as the ode type

`[[_1st_order, _with_linear_symmetries], _Clairaut]`

$$\boxed{y - xy' - \ln(y') = 0}$$

21.4.1 Solving as clairaut ode

This is Clairaut ODE. It has the form

$$y = xy' + g(y')$$

Where g is function of $y'(x)$. Let $p = y'$ the ode becomes

$$y - xp - \ln(p) = 0$$

Solving for y from the above results in

$$y = xp + \ln(p) \tag{1A}$$

The above ode is a Clairaut ode which is now solved. We start by replacing y' by p which gives

$$\begin{aligned} y &= xp + \ln(p) \\ &= xp + \ln(p) \end{aligned}$$

Writing the ode as

$$y = xp + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = xp + g \tag{1}$$

Then we see that

$$g = \ln(p)$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned}
p &= \frac{d}{dx}(xp + g) \\
p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\
p &= p + (x + g')\frac{dp}{dx} \\
0 &= (x + g')\frac{dp}{dx}
\end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned}
\frac{dp}{dx} &= 0 \\
p &= c_1
\end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_1 x + \ln(c_1)$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = \ln(p)$, then the above equation becomes

$$\begin{aligned}
x + g'(p) &= x + \frac{1}{p} \\
&= 0
\end{aligned}$$

Solving the above for p results in

$$p_1 = -\frac{1}{x}$$

Substituting the above back in (1) results in

$$y_1 = \ln\left(-\frac{1}{x}\right) - 1$$

Summary

The solution(s) found are the following

$$y = c_1 x + \ln(c_1) \tag{1}$$

$$y = \ln\left(-\frac{1}{x}\right) - 1 \tag{2}$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 39, page 179
Problem number: 27.
ODE order: 1.
ODE degree: 3.

The type(s) of ODE detected by this program : **"clairaut"**

Maple gives the following as the ode type

`[[_1st_order, _with_linear_symmetries], _Clairaut]`

$$\boxed{y - xy' - \frac{3}{y'^2} = 0}$$

21.5.1 Solving as clairaut ode

This is Clairaut ODE. It has the form

$$y = xy' + g(y')$$

Where g is function of $y'(x)$. Let $p = y'$ the ode becomes

$$y - xp - \frac{3}{p^2} = 0$$

Solving for y from the above results in

$$y = \frac{x\,p^3 + 3}{p^2} \tag{1A}$$

The above ode is a Clairaut ode which is now solved. We start by replacing y' by p which gives

$$\begin{aligned} y &= xp + \frac{3}{p^2} \\ &= xp + \frac{3}{p^2} \end{aligned}$$

Writing the ode as

$$y = xp + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = xp + g \tag{1}$$

Then we see that

$$g = \frac{3}{p^2}$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned}
p &= \frac{d}{dx}(xp + g) \\
p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\
p &= p + (x + g')\frac{dp}{dx} \\
0 &= (x + g')\frac{dp}{dx}
\end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned}
\frac{dp}{dx} &= 0 \\
p &= c_1
\end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_1 x + \frac{3}{c_1^2}$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = \frac{3}{p^2}$, then the above equation becomes

$$\begin{aligned}
x + g'(p) &= x - \frac{6}{p^3} \\
&= 0
\end{aligned}$$

Solving the above for p results in

$$p_1 = \frac{6^{\frac{1}{3}} \left(x^2\right)^{\frac{1}{3}}}{x}$$
$$p_2 = -\frac{6^{\frac{1}{3}} \left(x^2\right)^{\frac{1}{3}}}{2x} + \frac{i\sqrt{3}\, 6^{\frac{1}{3}} \left(x^2\right)^{\frac{1}{3}}}{2x}$$
$$p_3 = -\frac{6^{\frac{1}{3}} \left(x^2\right)^{\frac{1}{3}}}{2x} - \frac{i\sqrt{3}\, 6^{\frac{1}{3}} \left(x^2\right)^{\frac{1}{3}}}{2x}$$

Substituting the above back in (1) results in

$$y_1 = \frac{3x^2 6^{\frac{1}{3}}}{2 \left(x^2\right)^{\frac{2}{3}}}$$
$$y_2 = -\frac{9x^2 2^{\frac{1}{3}}}{\left(x^2\right)^{\frac{2}{3}} \left(3i3^{\frac{1}{6}} + 3^{\frac{2}{3}}\right)}$$
$$y_3 = \frac{9x^2 2^{\frac{1}{3}}}{\left(x^2\right)^{\frac{2}{3}} \left(3i3^{\frac{1}{6}} - 3^{\frac{2}{3}}\right)}$$

Summary

The solution(s) found are the following

$$y = c_1 x + \frac{3}{c_1^2} \tag{1}$$
$$y = \frac{3x^2 6^{\frac{1}{3}}}{2 \left(x^2\right)^{\frac{2}{3}}} \tag{2}$$
$$y = -\frac{9x^2 2^{\frac{1}{3}}}{\left(x^2\right)^{\frac{2}{3}} \left(3i3^{\frac{1}{6}} + 3^{\frac{2}{3}}\right)} \tag{3}$$
$$y = \frac{9x^2 2^{\frac{1}{3}}}{\left(x^2\right)^{\frac{2}{3}} \left(3i3^{\frac{1}{6}} - 3^{\frac{2}{3}}\right)} \tag{4}$$

Section: Exercise 39, page 179
Problem number: 28.
ODE order: 1.
ODE degree: 3.

The type(s) of ODE detected by this program : **"clairaut"**

Maple gives the following as the ode type

```
[[_1st_order, _with_linear_symmetries], _Clairaut]
```

$$\boxed{y - xy' + y'^{\frac{2}{3}} = 0}$$

21.6.1 Solving as clairaut ode

This is Clairaut ODE. It has the form

$$y = xy' + g(y')$$

Where g is function of $y'(x)$. Let $p = y'$ the ode becomes

$$y - xp + p^{\frac{2}{3}} = 0$$

Solving for y from the above results in

$$y = -p^{\frac{2}{3}} + xp \tag{1A}$$

The above ode is a Clairaut ode which is now solved. We start by replacing y' by p which gives

$$\begin{aligned} y &= -p^{\frac{2}{3}} + xp \\ &= -p^{\frac{2}{3}} + xp \end{aligned}$$

Writing the ode as

$$y = xp + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = xp + g \tag{1}$$

Then we see that

$$g = -p^{\frac{2}{3}}$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned}
p &= \frac{d}{dx}(xp + g) \\
p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\
p &= p + (x + g')\frac{dp}{dx} \\
0 &= (x + g')\frac{dp}{dx}
\end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned}
\frac{dp}{dx} &= 0 \\
p &= c_1
\end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_1 x - c_1^{\frac{2}{3}}$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = -p^{\frac{2}{3}}$, then the above equation becomes

$$\begin{aligned}
x + g'(p) &= x - \frac{2}{3p^{\frac{1}{3}}} \\
&= 0
\end{aligned}$$

Solving the above for p results in

$$p_1 = \frac{8}{27x^3}$$

Substituting the above back in (1) results in

$$y_1 = \frac{-\frac{4\left(\frac{1}{x^3}\right)^{\frac{2}{3}} x^2}{9} + \frac{8}{27}}{x^2}$$

Summary

The solution(s) found are the following

$$y = c_1 x - c_1^{\frac{2}{3}} \tag{1}$$

$$y = \frac{-\frac{4\left(\frac{1}{x^3}\right)^{\frac{2}{3}} x^2}{9} + \frac{8}{27}}{x^2} \tag{2}$$

Verification of solutions

$$y = c_1 x - c_1^{\frac{2}{3}}$$

Verified OK.

$$y = \frac{-\frac{4\left(\frac{1}{x^3}\right)^{\frac{2}{3}} x^2}{9} + \frac{8}{27}}{x^2}$$

Verified OK.

The type(s) of ODE detected by this program : **"clairaut"**

Maple gives the following as the ode type

```
[[_1st_order, _with_linear_symmetries], _Clairaut]
```

$$\boxed{y - xy' - e^{y'} = 0}$$

21.7.1 Solving as clairaut ode

This is Clairaut ODE. It has the form

$$y = xy' + g(y')$$

Where g is function of $y'(x)$. Let $p = y'$ the ode becomes

$$y - xp - e^{p} = 0$$

Solving for y from the above results in

$$y = xp + e^{p} \tag{1A}$$

The above ode is a Clairaut ode which is now solved. We start by replacing y' by p which gives

$$\begin{aligned} y &= xp + e^{p} \\ &= xp + e^{p} \end{aligned}$$

Writing the ode as

$$y = xp + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = xp + g \tag{1}$$

Then we see that

$$g = e^p$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned}
p &= \frac{d}{dx}(xp + g) \\
p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\
p &= p + (x + g')\frac{dp}{dx} \\
0 &= (x + g')\frac{dp}{dx}
\end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned}
\frac{dp}{dx} &= 0 \\
p &= c_1
\end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_1 x + e^{c_1}$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = e^p$, then the above equation becomes

$$\begin{aligned}
x + g'(p) &= x + e^p \\
&= 0
\end{aligned}$$

Solving the above for p results in

$$p_1 = \ln(-x)$$

Substituting the above back in (1) results in

$$y_1 = x(\ln(-x) - 1)$$

Summary

The solution(s) found are the following

$$y = c_1 x + e^{c_1} \tag{1}$$

$$y = x(\ln(-x) - 1) \tag{2}$$

The type(s) of ODE detected by this program : **"clairaut"**

Maple gives the following as the ode type

`[[_1st_order, _with_linear_symmetries], _rational, _Clairaut]`

$$\boxed{(y - xy')^2 - y'^2 = 1}$$

21.8.1 Solving as clairaut ode

This is Clairaut ODE. It has the form

$$y = xy' + g(y')$$

Where g is function of $y'(x)$. Let $p = y'$ the ode becomes

$$(-xp + y)^2 - p^2 = 1$$

Solving for y from the above results in

$$y = xp + \sqrt{p^2 + 1} \tag{1A}$$

$$y = xp - \sqrt{p^2 + 1} \tag{2A}$$

Each of the above ode's is a Clairaut ode which is now solved. Solving ode 1A We start by replacing y' by p which gives

$$\begin{aligned} y &= xp + \sqrt{p^2 + 1} \\ &= xp + \sqrt{p^2 + 1} \end{aligned}$$

Writing the ode as

$$y = xp + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = xp + g \tag{1}$$

Then we see that

$$g = \sqrt{p^2 + 1}$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned}
p &= \frac{d}{dx}(xp + g) \\
p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\
p &= p + (x + g')\frac{dp}{dx} \\
0 &= (x + g')\frac{dp}{dx}
\end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned}
\frac{dp}{dx} &= 0 \\
p &= c_1
\end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_1 x + \sqrt{c_1^2 + 1}$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = \sqrt{p^2 + 1}$, then the above equation becomes

$$\begin{aligned}
x + g'(p) &= x + \frac{p}{\sqrt{p^2 + 1}} \\
&= 0
\end{aligned}$$

Solving the above for p results in

$$p_1 = -x\sqrt{-\frac{1}{x^2-1}}$$

Substituting the above back in (1) results in

$$y_1 = \left(-x^2+1\right)\sqrt{-\frac{1}{x^2-1}}$$

Solving ode 2A We start by replacing y' by p which gives

$$\begin{aligned} y &= xp - \sqrt{p^2+1} \\ &= xp - \sqrt{p^2+1} \end{aligned}$$

Writing the ode as

$$y = xp + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = xp + g \tag{1}$$

Then we see that

$$g = -\sqrt{p^2+1}$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned} p &= \frac{d}{dx}(xp+g) \\ p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\ p &= p + (x+g')\frac{dp}{dx} \\ 0 &= (x+g')\frac{dp}{dx} \end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned} \frac{dp}{dx} &= 0 \\ p &= c_1 \end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_2 x - \sqrt{c_2^2 + 1}$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = -\sqrt{p^2 + 1}$, then the above equation becomes

$$\begin{aligned} x + g'(p) &= x - \frac{p}{\sqrt{p^2 + 1}} \\ &= 0 \end{aligned}$$

Solving the above for p results in

$$p_1 = x\sqrt{-\frac{1}{x^2 - 1}}$$

Substituting the above back in (1) results in

$$y_1 = \sqrt{-\frac{1}{x^2 - 1}}\,(x^2 - 1)$$

Summary
The solution(s) found are the following

$$y = c_1 x + \sqrt{c_1^2 + 1} \tag{1}$$

$$y = (-x^2 + 1)\sqrt{-\frac{1}{x^2 - 1}} \tag{2}$$

$$y = c_2 x - \sqrt{c_2^2 + 1} \tag{3}$$

$$y = \sqrt{-\frac{1}{x^2 - 1}}\,(x^2 - 1) \tag{4}$$

Verification of solutions

$$y = c_1x + \sqrt{c_1^2 + 1}$$

Verified OK.

$$y = (-x^2 + 1)\sqrt{-\frac{1}{x^2 - 1}}$$

Verified OK.

$$y = c_2x - \sqrt{c_2^2 + 1}$$

Verified OK.

$$y = \sqrt{-\frac{1}{x^2 - 1}}\,(x^2 - 1)$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 39, page 179
Problem number: 31.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"clairaut"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational, _Clairaut]
```

$$\boxed{{y'}^2 x - y y' = 2}$$

21.9.1 Solving as clairaut ode

This is Clairaut ODE. It has the form

$$y = x y' + g(y')$$

Where g is function of $y'(x)$. Let $p = y'$ the ode becomes

$$p^2 x - y p = 2$$

Solving for y from the above results in

$$y = \frac{p^2 x - 2}{p} \tag{1A}$$

The above ode is a Clairaut ode which is now solved. We start by replacing y' by p which gives

$$\begin{aligned} y &= p x - \frac{2}{p} \\ &= p x - \frac{2}{p} \end{aligned}$$

Writing the ode as

$$y = px + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = px + g \tag{1}$$

Then we see that

$$g = -\frac{2}{p}$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned}
p &= \frac{d}{dx}(xp + g) \\
p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\
p &= p + (x + g')\frac{dp}{dx} \\
0 &= (x + g')\frac{dp}{dx}
\end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned}
\frac{dp}{dx} &= 0 \\
p &= c_1
\end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_1 x - \frac{2}{c_1}$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = -\frac{2}{p}$, then the above equation becomes

$$\begin{aligned}
x + g'(p) &= x + \frac{2}{p^2} \\
&= 0
\end{aligned}$$

Solving the above for p results in

$$p_1 = -\frac{2}{\sqrt{-2x}}$$
$$p_2 = \frac{2}{\sqrt{-2x}}$$

Substituting the above back in (1) results in

$$y_1 = 2\sqrt{2}\,\sqrt{-x}$$
$$y_2 = -2\sqrt{2}\,\sqrt{-x}$$

Summary
The solution(s) found are the following

$$y = c_1 x - \frac{2}{c_1} \tag{1}$$
$$y = 2\sqrt{2}\,\sqrt{-x} \tag{2}$$
$$y = -2\sqrt{2}\,\sqrt{-x} \tag{3}$$

Verification of solutions

$$y = c_1 x - \frac{2}{c_1}$$

Verified OK.

$$y = 2\sqrt{2}\,\sqrt{-x}$$

Verified OK.

$$y = -2\sqrt{2}\,\sqrt{-x}$$

Verified OK.

ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "homogeneousTypeMapleC", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{y^2 - 2xyy' + y'^2(x^2 - 1) = 0}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{y}{x+1} \tag{1}$$

$$y' = \frac{y}{x-1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{y}{x+1} \end{aligned}$$

Where $f(x) = \frac{1}{x+1}$ and $g(y) = y$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{y}\,dy &= \frac{1}{x+1}\,dx \\
\int \frac{1}{y}\,dy &= \int \frac{1}{x+1}\,dx \\
\ln(y) &= \ln(x+1) + c_1 \\
y &= \mathrm{e}^{\ln(x+1)+c_1} \\
&= c_1(x+1)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1(x+1) \tag{1}$$

Verification of solutions

$$y = c_1(x+1)$$

Verified OK.

Solving equation (2)

In canonical form the ODE is

$$\begin{aligned}
y' &= F(x,y) \\
&= f(x)g(y) \\
&= \frac{y}{x-1}
\end{aligned}$$

Where $f(x) = \frac{1}{x-1}$ and $g(y) = y$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{y}\,dy &= \frac{1}{x-1}\,dx \\
\int \frac{1}{y}\,dy &= \int \frac{1}{x-1}\,dx \\
\ln(y) &= \ln(x-1) + c_2 \\
y &= \mathrm{e}^{\ln(x-1)+c_2} \\
&= c_2(x-1)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_2(x-1) \tag{1}$$

Verification of solutions

$$y = c_2(x-1)$$

Verified OK.

21.10.1 Maple step by step solution

Let's solve

$y^2 - 2xyy' + y'^2(x^2-1) = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = \frac{1}{x+1}$

- Integrate both sides with respect to x

  $\int \frac{y'}{y} dx = \int \frac{1}{x+1} dx + c_1$

- Evaluate integral

  $\ln(y) = \ln(x+1) + c_1$

- Solve for y

  $y = e^{c_1}(x+1)$

22 Exercise 40, page 186

22.1 problem 1

Internal problem ID [2364]
Internal file name [`OUTPUT/2364_Tuesday_February_27_2024_08_36_09_AM_55827639/index.tex`]

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 40, page 186
Problem number: 1.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"quadrature", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y' - \sqrt{1-y} = 0}$$

With initial conditions

$$[y(0) = 0]$$

With the expansion point for the power series method at $x = 0$.

22.1.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= \sqrt{1-y} \end{aligned}$$

The y domain of $f(x,y)$ when $x = 0$ is

$$\{y \leq 1\}$$

And the point $y_0 = 0$ is inside this domain. Now we will look at the continuity of

$$
\begin{aligned}
\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(\sqrt{1-y}\right) \\
&= -\frac{1}{2\sqrt{1-y}}
\end{aligned}
$$

The y domain of $\frac{\partial f}{\partial y}$ when $x = 0$ is

$$
\{y < 1\}
$$

And the point $y_0 = 0$ is inside this domain. Therefore solution exists and is unique.

22.1.2 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$
y' = f(x, y)
$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor series

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f && (1) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y)$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y) \qquad (4)\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)F_0 \qquad (5)
\end{aligned}
$$

For example, for $n=1$ we see that

$$
\begin{aligned}
F_1 &= \frac{d}{dx}(F_0)\\
&= \frac{\partial}{\partial x}F_0 + \left(\frac{\partial F_0}{\partial y}\right)F_0\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f
\end{aligned}
$$

Which is (1). And when $n=2$

$$
\begin{aligned}
F_2 &= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)F_0\\
&= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right)f\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)f
\end{aligned}
$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$
y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} F_n\big|_{x_0,y_0} \qquad (6)
$$

Hence

$$
\begin{aligned}
F_0 &= \sqrt{1-y} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} F_0 \\
&= -\frac{1}{2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} F_1 \\
&= 0 \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} F_2 \\
&= 0
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = 0$ gives

$$
\begin{aligned}
F_0 &= 1 \\
F_1 &= -\frac{1}{2} \\
F_2 &= 0 \\
F_3 &= 0
\end{aligned}
$$

Substituting all the above in (6) and simplifying gives the solution as

$$
y = x - \frac{x^2}{4} + O(x^5)
$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$
y(0) = y(0)
$$

Therefore the solution becomes

$$
y = x - \frac{1}{4}x^2
$$

Hence the solution can be written as

$$y = x - \frac{x^2}{4} + O(x^5)$$

which simplifies to

$$y = x - \frac{x^2}{4} + O(x^5)$$

Unable to also solve using normal power series since not linear ode. Not currently supported.

Summary

The solution(s) found are the following

$$y = x - \frac{x^2}{4} + O(x^5) \tag{1}$$

Verification of solutions

$$y = x - \frac{x^2}{4} + O(x^5)$$

Verified OK.

22.1.3 Maple step by step solution

Let's solve

$\left[y' = \sqrt{1-y}, y(0) = 0\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{\sqrt{1-y}} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'}{\sqrt{1-y}} dx = \int 1 dx + c_1$

- Evaluate integral

  $-2\sqrt{1-y} = x + c_1$

- Solve for y

  $y = -\frac{1}{4}c_1^2 - \frac{1}{2}c_1 x - \frac{1}{4}x^2 + 1$

- Use initial condition $y(0) = 0$

  $0 = -\frac{c_1^2}{4} + 1$

- Solve for c_1

  $c_1 = (2, -2)$
- Substitute $c_1 = (2, -2)$ into general solution and simplify

  $y = -\frac{(2+x)(x-2)}{4}$
- Solution to the IVP

  $y = -\frac{(2+x)(x-2)}{4}$

Internal file name [OUTPUT/2365_Tuesday_February_27_2024_08_36_10_AM_12373942/index.tex]

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 40, page 186
Problem number: 2.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup", "first order ode series method. Ordinary point", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y' - yx = -x^2}$$

With initial conditions

$$[y(0) = 2]$$

With the expansion point for the power series method at $x = 0$.

22.2.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -x$$
$$q(x) = -x^2$$

Hence the ode is

$$y' - yx = -x^2$$

The domain of $p(x) = -x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -x^2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

22.2.2 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor series

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0, y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0, y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f && (1) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y)$ then the above can be written as

$$\begin{align*} F_0 &= f(x,y) \tag{4}\\ F_n &= \frac{d}{dx}(F_{n-1}) \\ &= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \tag{5} \end{align*}$$

For example, for $n=1$ we see that

$$\begin{align*} F_1 &= \frac{d}{dx}(F_0) \\ &= \frac{\partial}{\partial x}F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\ &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \end{align*}$$

Which is (1). And when $n=2$

$$\begin{align*} F_2 &= \frac{d}{dx}(F_1) \\ &= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right) F_0 \\ &= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) f \\ &= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \end{align*}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} F_n|_{x_0,y_0} \tag{6}$$

Hence

$$
\begin{aligned}
F_0 &= yx - x^2 \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} F_0 \\
&= x^2 y - x^3 + y - 2x \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} F_1 \\
&= \left(x^3 + 3x\right) y - x^4 - 4x^2 - 2 \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} F_2 \\
&= \left(x^4 + 6x^2 + 3\right) y - x^5 - 7x^3 - 8x
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = 2$ gives

$$
\begin{aligned}
F_0 &= 0 \\
F_1 &= 2 \\
F_2 &= -2 \\
F_3 &= 6
\end{aligned}
$$

Substituting all the above in (6) and simplifying gives the solution as

$$
y = x^2 + 2 - \frac{x^3}{3} + \frac{x^4}{4} + O\left(x^5\right)
$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$
y(0) = y(0)
$$

Therefore the solution becomes

$$
y = x^2 + 2 - \frac{1}{3}x^3 + \frac{1}{4}x^4
$$

Hence the solution can be written as

$$y = x^2 + 2 - \frac{x^3}{3} + \frac{x^4}{4} + O(x^5)$$

which simplifies to

$$y = x^2 + 2 - \frac{x^3}{3} + \frac{x^4}{4} + O(x^5)$$

Since $x = 0$ is also an ordinary point, then standard power series can also be used. Writing the ODE as

$$\begin{aligned} y' + q(x)y &= p(x) \\ y' - yx &= -x^2 \end{aligned}$$

Where

$$\begin{aligned} q(x) &= -x \\ p(x) &= -x^2 \end{aligned}$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not. Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^n\right) x = -x^2 \tag{1}$$

Expanding $-x^2$ as Taylor series around $x = 0$ and keeping only the first 5 terms gives

$$\begin{aligned}-x^2 &= -x^2 + \dots \\ &= -x^2\end{aligned}$$

Hence the ODE in Eq (1) becomes

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^n\right) x = -x^2 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \sum_{n=0}^{\infty} \left(-x^{1+n} a_n\right) = -x^2 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\begin{aligned}\sum_{n=1}^{\infty} n a_n x^{n-1} &= \sum_{n=0}^{\infty} (1+n) a_{1+n} x^n \\ \sum_{n=0}^{\infty} \left(-x^{1+n} a_n\right) &= \sum_{n=1}^{\infty} \left(-a_{n-1} x^n\right)\end{aligned}$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (1+n) a_{1+n} x^n\right) + \sum_{n=1}^{\infty} \left(-a_{n-1} x^n\right) = -x^2 \tag{3}$$

For $1 \leq n$, the recurrence equation is

$$\left((1+n) a_{1+n} - a_{n-1}\right) x^n = -x^2 \tag{4}$$

For $n = 1$ the recurrence equation gives

$$\begin{aligned}(2a_2 - a_0) x &= 0 \\ 2a_2 - a_0 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_2 = \frac{a_0}{2}$$

For $n = 2$ the recurrence equation gives

$$\begin{aligned}(3a_3 - a_1) x^2 &= -x^2 \\ 3a_3 - a_1 &= -1\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{1}{3}$$

For $n = 3$ the recurrence equation gives

$$\begin{aligned}(4a_4 - a_2) x^3 &= 0 \\ 4a_4 - a_2 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{8}$$

For $n = 4$ the recurrence equation gives

$$\begin{aligned}(5a_5 - a_3) x^4 &= 0 \\ 5a_5 - a_3 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{1}{15}$$

And so on. Therefore the solution is

$$\begin{aligned}y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots\end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + \frac{1}{2}a_0x^2 - \frac{1}{3}x^3 + \frac{1}{8}a_0x^4 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + \frac{1}{2}x^2 + \frac{1}{8}x^4\right)a_0 - \frac{x^3}{3} + O(x^5) \tag{3}$$

At $x = 0$ the solution above becomes

$$y(0) = a_0$$

Therefore the solution in Eq(3) now can be written as

$$y = \left(1 + \frac{1}{2}x^2 + \frac{1}{8}x^4\right)y(0) - \frac{x^3}{3} + O(x^5)$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = 2$$

Therefore the solution becomes

$$y = x^2 + 2 - \frac{1}{3}x^3 + \frac{1}{4}x^4$$

Hence the solution can be written as

$$y = x^2 + 2 - \frac{x^3}{3} + \frac{x^4}{4} + O(x^5)$$

which simplifies to

$$y = x^2 + 2 - \frac{x^3}{3} + \frac{x^4}{4} + O(x^5)$$

Summary

The solution(s) found are the following

$$y = x^2 + 2 - \frac{x^3}{3} + \frac{x^4}{4} + O(x^5) \tag{1}$$

$$y = x^2 + 2 - \frac{x^3}{3} + \frac{x^4}{4} + O(x^5) \tag{2}$$

Verification of solutions

$$y = x^2 + 2 - \frac{x^3}{3} + \frac{x^4}{4} + O(x^5)$$

Verified OK.

$$y = x^2 + 2 - \frac{x^3}{3} + \frac{x^4}{4} + O(x^5)$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 40, page 186
Problem number: 3.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Taylor series method"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - y^2x^2 = 0}$$

With initial conditions

$$[y(1) = 0]$$

With the expansion point for the power series method at $x = 1$.

22.3.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= y^2x^2 \end{aligned}$$

The x domain of $f(x, y)$ when $y = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 1$ is inside this domain. The y domain of $f(x, y)$ when $x = 1$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 0$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned} \frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}(y^2 x^2) \\ &= 2x^2 y \end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 1$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 1$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 0$ is inside this domain. Therefore solution exists and is unique.

22.3.2 Solving as series ode

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - 1$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\frac{d}{dt}y(t) - y(t)^2 (t + 1)^2 = 0$$

With its expansion point and initial conditions now at $t = 0$. With initial conditions now becoming

$$y(0) = 0$$

The transformed ODE is now solved.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x,y)$$

Where $f(x,y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor series

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \qquad (1) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \qquad (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) f \qquad (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y)$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y) \qquad (4) \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \qquad (5)
\end{aligned}$$

For example, for $n=1$ we see that

$$\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x}F_0 + \left(\frac{\partial F_0}{\partial y}\right)F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f
\end{aligned}$$

Which is (1). And when $n=2$

$$\begin{aligned}
F_2 &= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)F_0 \\
&= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right)f \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)f
\end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} F_n|_{x_0,y_0} \tag{6}$$

Hence

$$\begin{aligned}
F_0 &= y(t)^2 (t+1)^2 \\
F_1 &= \frac{dF_0}{dt} \\
&= \frac{\partial F_0}{\partial t} + \frac{\partial F_0}{\partial y}F_0 \\
&= 2\left(1 + (t+1)^3 y(t)\right) y(t)^2 (t+1) \\
F_2 &= \frac{dF_1}{dt} \\
&= \frac{\partial F_1}{\partial t} + \frac{\partial F_1}{\partial y}F_1 \\
&= 6\left(\frac{1}{3} + (t+1)^6 y(t)^2 + 2(t+1)^3 y(t)\right) y(t)^2 \\
F_3 &= \frac{dF_2}{dt} \\
&= \frac{\partial F_2}{\partial t} + \frac{\partial F_2}{\partial y}F_2 \\
&= 24y(t)^3 (t+1)^2 \left(\frac{5}{3} + (t+1)^6 y(t)^2 + 3(t+1)^3 y(t)\right)
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $t(0) = 0$ and $y(0) = 0$ gives

$$F_0 = 0$$
$$F_1 = 0$$
$$F_2 = 0$$
$$F_3 = 0$$

Substituting all the above in (6) and simplifying gives the solution as

$$y(t) = O(t^5)$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = y(0)$$

Therefore the solution becomes

$$y(t) = 0$$

Hence the solution can be written as

$$y(t) = O(t^5)$$

which simplifies to

$$y(t) = O(t^5)$$

Unable to also solve using normal power series since not linear ode. Not currently supported. Replacing t in the above with the original independent variable xs using $t = x - 1$ results in

$$y = O((x-1)^5)$$

Summary

The solution(s) found are the following

$$y = O((x-1)^5) \tag{1}$$

Verification of solutions

$$y = O((x-1)^5)$$

Verified OK.

22.3.3 Maple step by step solution

Let's solve

$[y' - y^2x^2 = 0, y(1) = 0]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y^2} = x^2$

- Integrate both sides with respect to x

  $\int \frac{y'}{y^2}dx = \int x^2dx + c_1$

- Evaluate integral

  $-\frac{1}{y} = \frac{x^3}{3} + c_1$

- Solve for y

  $y = -\frac{3}{x^3+3c_1}$

- Use initial condition $y(1) = 0$

  $0 = -\frac{3}{3c_1+1}$

- Solution does not satisfy initial condition

22.4 problem 4

Internal problem ID [2367]
Internal file name [`OUTPUT/2367_Tuesday_February_27_2024_08_36_12_AM_97136872/index.tex`]

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 40, page 186
Problem number: 4.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Ordinary point", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y' - \frac{y}{x} = 3x}$$

With initial conditions

$$[y(1) = 3]$$

With the expansion point for the power series method at $x = 1$.

22.4.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{1}{x}$$
$$q(x) = 3x$$

Hence the ode is

$$y' - \frac{y}{x} = 3x$$

The domain of $p(x) = -\frac{1}{x}$ is

$$\{x < 0 \vee 0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $q(x) = 3x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

22.4.2 Solving as series ode

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - 1$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\frac{d}{dt}y(t) - \frac{y(t)}{t+1} = 3t + 3$$

With its expansion point and initial conditions now at $t = 0$. With initial conditions now becoming

$$y(0) = 3$$

The transformed ODE is now solved.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x,y)$ is analytic at expansion point x_0. We can always shift to $x_0=0$ if x_0 is not zero. So from now we assume $x_0=0$. Assume also that $y(x_0)=y_0$. Using Taylor series

$$\begin{aligned}
y(x) &= y(x_0) + (x-x_0)\,y'(x_0) + \frac{(x-x_0)^2}{2}y''(x_0) + \frac{(x-x_0)^3}{3!}y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2}\frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!}\frac{d^2f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty}\frac{x^{n+1}}{(n+1)\,!}\frac{d^nf}{dx^n}\bigg|_{x_0,y_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f &(1)\\
\frac{d^2f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)f &(2)\\
\frac{d^3f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2f}{dx^2}\right)f &(3)\\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0=f(x,y)$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y) &(4)\\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)F_0 &(5)
\end{aligned}$$

For example, for $n=1$ we see that

$$\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x}F_0 + \left(\frac{\partial F_0}{\partial y}\right)F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f
\end{aligned}$$

Which is (1). And when $n=2$

$$\begin{aligned}
F_2 &= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)F_0\\
&= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x}+\frac{\partial f}{\partial y}f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x}+\frac{\partial f}{\partial y}f\right)f\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)f
\end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} F_n|_{x_0,y_0} \tag{6}$$

Hence

$$\begin{aligned}
F_0 &= \frac{3t^2+6t+y(t)+3}{t+1}\\
F_1 &= \frac{dF_0}{dt}\\
&= \frac{\partial F_0}{\partial t} + \frac{\partial F_0}{\partial y}F_0\\
&= 6\\
F_2 &= \frac{dF_1}{dt}\\
&= \frac{\partial F_1}{\partial t} + \frac{\partial F_1}{\partial y}F_1\\
&= 0\\
F_3 &= \frac{dF_2}{dt}\\
&= \frac{\partial F_2}{\partial t} + \frac{\partial F_2}{\partial y}F_2\\
&= 0
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $t(0)=0$ and $y(0)=3$ gives

$$\begin{aligned}
F_0 &= 6\\
F_1 &= 6\\
F_2 &= 0\\
F_3 &= 0
\end{aligned}$$

Substituting all the above in (6) and simplifying gives the solution as

$$y(t) = 3t^2 + 6t + 3 + O(t^5)$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = y(0)$$

Therefore the solution becomes

$$y(t) = 3t^2 + 6t + 3$$

Hence the solution can be written as

$$y(t) = 3t^2 + 6t + 3 + O(t^5)$$

which simplifies to

$$y(t) = 3t^2 + 6t + 3 + O(t^5)$$

Since $t = 0$ is also an ordinary point, then standard power series can also be used. Writing the ODE as

$$\frac{d}{dt}y(t) + q(t)y(t) = p(t)$$
$$\frac{d}{dt}y(t) - \frac{y(t)}{t+1} = 3t + 3$$

Where

$$q(t) = -\frac{1}{t+1}$$
$$p(t) = 3t + 3$$

Next, the type of the expansion point $t = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $t = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $t = 0$ is called an ordinary point $q(t)$ has a Taylor series expansion around the point $t = 0$. $t = 0$ is called a regular singular point if $q(t)$ is not not analytic at $t = 0$ but $tq(t)$ has Taylor series expansion. And finally, $t = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This is the most complicated case. Now the expansion point $t = 0$ is checked to see if it is an ordinary point or not. Now the ode is normalized by writing it as

$$(t+1)\left(\frac{d}{dt}y(t)\right) - y(t) = 3(t+1)^2$$

Let the solution be represented as power series of the form

$$y(t) = \sum_{n=0}^{\infty} a_n t^n$$

Then

$$\frac{d}{dt}y(t) = \sum_{n=1}^{\infty} n a_n t^{n-1}$$

Substituting the above back into the ode gives

$$(t+1)\left(\sum_{n=1}^{\infty} n a_n t^{n-1}\right) - \left(\sum_{n=0}^{\infty} a_n t^n\right) = 3(t+1)^2 \tag{1}$$

Expanding $3(t+1)^2$ as Taylor series around $t = 0$ and keeping only the first 5 terms gives

$$\begin{aligned} 3(t+1)^2 &= 3t^2 + 6t + 3 + \dots \\ &= 3t^2 + 6t + 3 \end{aligned}$$

Hence the ODE in Eq (1) becomes

$$(t+1)\left(\sum_{n=1}^{\infty} n a_n t^{n-1}\right) - \left(\sum_{n=0}^{\infty} a_n t^n\right) = 3t^2 + 6t + 3 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=1}^{\infty} n a_n t^n\right) + \left(\sum_{n=1}^{\infty} n a_n t^{n-1}\right) + \sum_{n=0}^{\infty} (-a_n t^n) = 3t^2 + 6t + 3 \tag{2}$$

The next step is to make all powers of t be n in each summation term. Going over each summation term above with power of t in it which is not already t^n and adjusting the power and the corresponding index gives

$$\sum_{n=1}^{\infty} n a_n t^{n-1} = \sum_{n=0}^{\infty} (n+1) a_{n+1} t^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of t are the same and equal to n.

$$\left(\sum_{n=1}^{\infty} n a_n t^n\right)+\left(\sum_{n=0}^{\infty}(n+1) a_{n+1} t^n\right)+\sum_{n=0}^{\infty}\left(-a_n t^n\right)=3t^2+6t+3 \tag{3}$$

$n=0$ gives

$$\begin{aligned}(a_1-a_0)\, t^0 &= 3\\ a_1-a_0 &= 3\\ a_1 &= a_0+3\end{aligned}$$

For $1 \leq n$, the recurrence equation is

$$\left(n a_n+(n+1) a_{n+1}-a_n\right) t^n=3t^2+6t+3 \tag{4}$$

For $n=1$ the recurrence equation gives

$$\begin{aligned}(2a_2)\, t &= 6t\\ 2a_2 &= 6\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_2=3$$

For $n=2$ the recurrence equation gives

$$\begin{aligned}(a_2+3a_3)\, t^2 &= 3t^2\\ a_2+3a_3 &= 3\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_3=0$$

For $n=3$ the recurrence equation gives

$$\begin{aligned}(2a_3+4a_4)\, t^3 &= 0\\ 2a_3+4a_4 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_4 = 0$$

For $n = 4$ the recurrence equation gives

$$\begin{aligned}(3a_4 + 5a_5)\, t^4 &= 0 \\ 3a_4 + 5a_5 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_5 = 0$$

And so on. Therefore the solution is

$$\begin{aligned}y(t) &= \sum_{n=0}^{\infty} a_n t^n \\ &= a_3 t^3 + a_2 t^2 + a_1 t + a_0 + \dots\end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y(t) = a_0 + (a_0 + 3)\, t + 3t^2 + \dots$$

Collecting terms, the solution becomes

$$y(t) = (t + 1)\, a_0 + 3t^2 + O(t^5) + 3t \tag{3}$$

At $t = 0$ the solution above becomes

$$y(0) = a_0$$

Therefore the solution in Eq(3) now can be written as

$$y(t) = (t + 1)\, y(0) + 3t^2 + O(t^5) + 3t$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = 3$$

Therefore the solution becomes

$$y(t) = 3t^2 + 6t + 3$$

Hence the solution can be written as

$$y(t) = 3t^2 + 6t + 3 + O(t^5)$$

which simplifies to

$$y(t) = 3t^2 + 6t + 3 + O(t^5)$$

Replacing t in the above with the original independent variable xs using $t = x - 1$ results in

$$y = 3(x-1)^2 + 6x - 3 + O\left((x-1)^5\right)$$

Summary

The solution(s) found are the following

$$y = 3(x-1)^2 + 6x - 3 + O\left((x-1)^5\right) \tag{1}$$

Verification of solutions

$$y = 3(x-1)^2 + 6x - 3 + O\left((x-1)^5\right)$$

Verified OK.

22.4.3 Maple step by step solution

Let's solve

$\left[y' - \frac{y}{x} = 3x, y(1) = 3\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = 3x + \frac{y}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - \frac{y}{x} = 3x$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' - \frac{y}{x}\right) = 3\mu(x)\, x$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y'-\frac{y}{x}\right)=\mu'(x)\,y+\mu(x)\,y'$
- Isolate $\mu'(x)$

  $\mu'(x)=-\frac{\mu(x)}{x}$
- Solve to find the integrating factor

  $\mu(x)=\frac{1}{x}$
- Integrate both sides with respect to x

  $\int\left(\frac{d}{dx}(\mu(x)\,y)\right)dx=\int 3\mu(x)\,x dx+c_1$
- Evaluate the integral on the lhs

  $\mu(x)\,y=\int 3\mu(x)\,x dx+c_1$
- Solve for y

  $y=\frac{\int 3\mu(x)x dx+c_1}{\mu(x)}$
- Substitute $\mu(x)=\frac{1}{x}$

  $y=x\left(\int 3dx+c_1\right)$
- Evaluate the integrals on the rhs

  $y=x(3x+c_1)$
- Use initial condition $y(1)=3$

  $3=3+c_1$
- Solve for c_1

  $c_1=0$
- Substitute $c_1=0$ into general solution and simplify

  $y=3x^2$
- Solution to the IVP

  $y=3x^2$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Taylor series method"**

Maple gives the following as the ode type

```
[`y=_G(x,y')`]
```

$$\boxed{y' - \ln(yx) = 0}$$

With initial conditions

$$[y(1) = 1]$$

With the expansion point for the power series method at $x = 1$.

22.5.1 Solving as series ode

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - 1$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\frac{d}{dt}y(t) - \ln(y(t)(t+1)) = 0$$

With its expansion point and initial conditions now at $t = 0$. With initial conditions now becoming

$$y(0) = 1$$

The transformed ODE is now solved.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor series

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \tag{1}$$

$$\begin{aligned}
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f
\end{aligned} \tag{2}$$

$$\begin{aligned}
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) f
\end{aligned} \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x, y)$ then the above can be written as

$$F_0 = f(x, y) \tag{4}$$

$$\begin{aligned}
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0
\end{aligned} \tag{5}$$

For example, for $n=1$ we see that

$$\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x}F_0 + \left(\frac{\partial F_0}{\partial y}\right)F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f
\end{aligned}$$

Which is (1). And when $n=2$

$$\begin{aligned}
F_2 &= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)F_0 \\
&= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right)f \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)f
\end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} F_n\big|_{x_0,y_0} \tag{6}$$

Hence

$$
\begin{aligned}
F_0 &= \ln\left(y(t)\,(t+1)\right)\\
F_1 &= \frac{dF_0}{dt}\\
&= \frac{\partial F_0}{\partial t} + \frac{\partial F_0}{\partial y} F_0\\
&= \frac{(t+1)\ln\left(y(t)\,(t+1)\right) + y(t)}{y\left(t\right)(t+1)}\\
F_2 &= \frac{dF_1}{dt}\\
&= \frac{\partial F_1}{\partial t} + \frac{\partial F_1}{\partial y} F_1\\
&= \frac{-\ln\left(y(t)\,(t+1)\right)^2 (t+1)^2 + \ln\left(y(t)\,(t+1)\right)(t+1)^2 + y(t)\,(t-y(t)+1)}{y\left(t\right)^2 (t+1)^2}\\
F_3 &= \frac{dF_2}{dt}\\
&= \frac{\partial F_2}{\partial t} + \frac{\partial F_2}{\partial y} F_2\\
&= \frac{2\ln\left(y(t)\,(t+1)\right)^3 (t+1)^3 - 4(t+1)^3 \ln\left(y(t)\,(t+1)\right)^2 + (t+1)^2 (t-3y(t)+1)\ln\left(y(t)\,(t+1)\right) + (}{y\left(t\right)^3 (t+1)^3}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $t(0)=0$ and $y(0)=1$ gives

$$
\begin{aligned}
F_0 &= 0\\
F_1 &= 1\\
F_2 &= 0\\
F_3 &= 2
\end{aligned}
$$

Substituting all the above in (6) and simplifying gives the solution as

$$
y(t) = 1 + \frac{t^2}{2} + \frac{t^4}{12} + O\left(t^5\right)
$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$
y(0) = y(0)
$$

Therefore the solution becomes

$$
y(t) = 1 + \frac{1}{2}t^2 + \frac{1}{12}t^4
$$

Hence the solution can be written as

$$y(t) = 1 + \frac{t^2}{2} + \frac{t^4}{12} + O(t^5)$$

which simplifies to

$$y(t) = 1 + \frac{t^2}{2} + \frac{t^4}{12} + O(t^5)$$

Unable to also solve using normal power series since not linear ode. Not currently supported. Replacing t in the above with the original independent variable xs using $t = x - 1$ results in

$$y = 1 + \frac{(x-1)^2}{2} + \frac{(x-1)^4}{12} + O\left((x-1)^5\right)$$

Summary

The solution(s) found are the following

$$y = 1 + \frac{(x-1)^2}{2} + \frac{(x-1)^4}{12} + O\left((x-1)^5\right) \tag{1}$$

Verification of solutions

$$y = 1 + \frac{(x-1)^2}{2} + \frac{(x-1)^4}{12} + O\left((x-1)^5\right)$$

Verified OK.

Problem number: 6.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Taylor series method"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y' - y^2 = 1}$$

With initial conditions

$$[y(1) = -1]$$

With the expansion point for the power series method at $x = 1$.

22.6.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= y^2 + 1 \end{aligned}$$

The y domain of $f(x, y)$ when $x = 1$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = -1$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}(y^2+1) \\ &= 2y\end{aligned}$$

The y domain of $\frac{\partial f}{\partial y}$ when $x = 1$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = -1$ is inside this domain. Therefore solution exists and is unique.

22.6.2 Solving as series ode

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - 1$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\frac{d}{dt}y(t) - y(t)^2 = 1$$

With its expansion point and initial conditions now at $t = 0$. With initial conditions now becoming

$$y(0) = -1$$

The transformed ODE is now solved.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor series

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \qquad (1) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \qquad (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2}\right) f \qquad (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x, y)$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y) \qquad (4) \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \qquad (5)
\end{aligned}
$$

For example, for $n = 1$ we see that

$$
\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f
\end{aligned}
$$

Which is (1). And when $n=2$

$$\begin{aligned}
F_2 &= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)F_0\\
&= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x}+\frac{\partial f}{\partial y}f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x}+\frac{\partial f}{\partial y}f\right)f\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)f
\end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty}\frac{x^{n+1}}{(n+1)\,!}F_n|_{x_0,y_0} \tag{6}$$

Hence

$$\begin{aligned}
F_0 &= y(t)^2+1\\
F_1 &= \frac{dF_0}{dt}\\
&= \frac{\partial F_0}{\partial t}+\frac{\partial F_0}{\partial y}F_0\\
&= 2y(t)\left(y(t)^2+1\right)\\
F_2 &= \frac{dF_1}{dt}\\
&= \frac{\partial F_1}{\partial t}+\frac{\partial F_1}{\partial y}F_1\\
&= 6\left(y(t)^2+\frac{1}{3}\right)\left(y(t)^2+1\right)\\
F_3 &= \frac{dF_2}{dt}\\
&= \frac{\partial F_2}{\partial t}+\frac{\partial F_2}{\partial y}F_2\\
&= 24y(t)^5+40y(t)^3+16y(t)
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $t(0)=0$ and $y(0)=-1$ gives

$$\begin{aligned}
F_0 &= 2\\
F_1 &= -4\\
F_2 &= 16\\
F_3 &= -80
\end{aligned}$$

Substituting all the above in (6) and simplifying gives the solution as

$$y(t) = -2t^2 + 2t - 1 + \frac{8t^3}{3} - \frac{10t^4}{3} + O(t^5)$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = y(0)$$

Therefore the solution becomes

$$y(t) = -2t^2 + 2t - 1 + \frac{8}{3}t^3 - \frac{10}{3}t^4$$

Hence the solution can be written as

$$y(t) = -2t^2 + 2t - 1 + \frac{8t^3}{3} - \frac{10t^4}{3} + O(t^5)$$

which simplifies to

$$y(t) = -2t^2 + 2t - 1 + \frac{8t^3}{3} - \frac{10t^4}{3} + O(t^5)$$

Unable to also solve using normal power series since not linear ode. Not currently supported. Replacing t in the above with the original independent variable xs using $t = x - 1$ results in

$$y = -2(x-1)^2 + 2x - 3 + \frac{8(x-1)^3}{3} - \frac{10(x-1)^4}{3} + O\left((x-1)^5\right)$$

Summary

The solution(s) found are the following

$$y = -2(x-1)^2 + 2x - 3 + \frac{8(x-1)^3}{3} - \frac{10(x-1)^4}{3} + O\left((x-1)^5\right) \tag{1}$$

Verification of solutions

$$y = -2(x-1)^2 + 2x - 3 + \frac{8(x-1)^3}{3} - \frac{10(x-1)^4}{3} + O\left((x-1)^5\right)$$

Verified OK.

22.6.3 Maple step by step solution

Let's solve

$[y' - y^2 = 1, y(1) = -1]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{1+y^2} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'}{1+y^2} dx = \int 1 dx + c_1$

- Evaluate integral

  $\arctan(y) = x + c_1$

- Solve for y

  $y = \tan(x + c_1)$

- Use initial condition $y(1) = -1$

  $-1 = \tan(c_1 + 1)$

- Solve for c_1

  $c_1 = -1 - \frac{\pi}{4}$

- Substitute $c_1 = -1 - \frac{\pi}{4}$ into general solution and simplify

  $y = -\cot\left(x - 1 + \frac{\pi}{4}\right)$

- Solution to the IVP

  $y = -\cot\left(x - 1 + \frac{\pi}{4}\right)$

22.7 problem 7

Internal problem ID [2370]
Internal file name [OUTPUT/2370_Tuesday_February_27_2024_08_36_16_AM_89319918/index.tex]

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 40, page 186
Problem number: 7.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_Riccati, _special]]
```

$$\boxed{y' - y^2 = x^2}$$

With initial conditions

$$[y(2) = 0]$$

With the expansion point for the power series method at $x = 2$.

22.7.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= x^2 + y^2 \end{aligned}$$

The x domain of $f(x, y)$ when $y = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 2$ is inside this domain. The y domain of $f(x, y)$ when $x = 2$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 0$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}(x^2 + y^2) \\ &= 2y\end{aligned}$$

The y domain of $\frac{\partial f}{\partial y}$ when $x = 2$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 0$ is inside this domain. Therefore solution exists and is unique.

22.7.2 Solving as series ode

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - 2$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\frac{d}{dt}y(t) - y(t)^2 = (t + 2)^2$$

With its expansion point and initial conditions now at $t = 0$. With initial conditions now becoming

$$y(0) = 0$$

The transformed ODE is now solved.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x,y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor series

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \qquad (1) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \qquad (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2}\right) f \qquad (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y)$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y) \qquad (4) \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \qquad (5)
\end{aligned}$$

For example, for $n = 1$ we see that

$$\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f
\end{aligned}$$

Which is (1). And when $n = 2$

$$\begin{aligned}
F_2 &= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) F_0 \\
&= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) f \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f
\end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} F_n|_{x_0,y_0} \tag{6}$$

Hence

$$\begin{aligned}
F_0 &= t^2 + y(t)^2 + 4t + 4 \\
F_1 &= \frac{dF_0}{dt} \\
&= \frac{\partial F_0}{\partial t} + \frac{\partial F_0}{\partial y} F_0 \\
&= 2y(t)^3 + 2(t+2)^2\, y(t) + 2t + 4 \\
F_2 &= \frac{dF_1}{dt} \\
&= \frac{\partial F_1}{\partial t} + \frac{\partial F_1}{\partial y} F_1 \\
&= 6y(t)^4 + 8(t+2)^2\, y(t)^2 + (4t+8)\, y(t) + 2t^4 + 16t^3 + 48t^2 + 64t + 34 \\
F_3 &= \frac{dF_2}{dt} \\
&= \frac{\partial F_2}{\partial t} + \frac{\partial F_2}{\partial y} F_2 \\
&= 24y(t)^5 + 40(t+2)^2\, y(t)^3 + 20(t+2)\, y(t)^2 + 4\left(4t^4 + 32t^3 + 96t^2 + 128t + 65\right) y(t) + 12(t+2)^3 \\
F_4 &= \frac{dF_3}{dt} \\
&= \frac{\partial F_3}{\partial t} + \frac{\partial F_3}{\partial y} F_3 \\
&= 120y(t)^6 + 240(t+2)^2\, y(t)^4 + 120(t+2)\, y(t)^3 + 8\left(17t^4 + 136t^3 + 408t^2 + 544t + 275\right) y(t)^2 + 104(t
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $t(0) = 0$ and $y(0) = 0$ gives

$$
\begin{aligned}
F_0 &= 4 \\
F_1 &= 4 \\
F_2 &= 34 \\
F_3 &= 96 \\
F_4 &= 1184
\end{aligned}
$$

Substituting all the above in (6) and simplifying gives the solution as

$$
y(t) = 2t^2 + 4t + \frac{17t^3}{3} + 4t^4 + \frac{148t^5}{15} + O(t^6)
$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$
y(0) = y(0)
$$

Therefore the solution becomes

$$
y(t) = 2t^2 + 4t + \frac{17}{3}t^3 + 4t^4 + \frac{148}{15}t^5
$$

Hence the solution can be written as

$$
y(t) = 2t^2 + 4t + \frac{17t^3}{3} + 4t^4 + \frac{148t^5}{15} + O(t^6)
$$

which simplifies to

$$
y(t) = 2t^2 + 4t + \frac{17t^3}{3} + 4t^4 + \frac{148t^5}{15} + O(t^6)
$$

Unable to also solve using normal power series since not linear ode. Not currently supported. Replacing t in the above with the original independent variable xs using $t = x - 2$ results in

$$
y = 2(x-2)^2 + 4x - 8 + \frac{17(x-2)^3}{3} + 4(x-2)^4 + \frac{148(x-2)^5}{15} + O\left((x-2)^6\right)
$$

Summary
The solution(s) found are the following

$$
y = 2(x-2)^2 + 4x - 8 + \frac{17(x-2)^3}{3} + 4(x-2)^4 + \frac{148(x-2)^5}{15} + O\left((x-2)^6\right) \quad (1)
$$

Verification of solutions

$$y = 2(x-2)^2 + 4x - 8 + \frac{17(x-2)^3}{3} + 4(x-2)^4 + \frac{148(x-2)^5}{15} + O\left((x-2)^6\right)$$

Verified OK.

The type(s) of ODE detected by this program : **"first order ode series method. Taylor series method"**

Maple gives the following as the ode type

```
[`y=_G(x,y')`]
```

$$\boxed{y' - \sqrt{1 + yx} = 0}$$

With initial conditions

$$[y(0) = 1]$$

With the expansion point for the power series method at $x = 0$.

22.8.1 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor series

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + x f + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0, y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0, y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \qquad (1) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \qquad (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2}\right) f \qquad (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x, y)$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y) \qquad (4) \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \qquad (5)
\end{aligned}
$$

For example, for $n = 1$ we see that

$$
\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f
\end{aligned}
$$

Which is (1). And when $n = 2$

$$\begin{aligned}
F_2 &= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) F_0 \\
&= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) f \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f
\end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} F_n|_{x_0,y_0} \tag{6}$$

Hence

$$\begin{aligned}
F_0 &= \sqrt{1 + yx} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} F_0 \\
&= \frac{x\sqrt{1 + yx} + y}{2\sqrt{1 + yx}} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} F_1 \\
&= \frac{3yx\sqrt{1 + yx} - y^2 + 4\sqrt{1 + yx}}{4(1 + yx)^{\frac{3}{2}}}
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = 1$ gives

$$\begin{aligned}
F_0 &= 1 \\
F_1 &= \frac{1}{2} \\
F_2 &= \frac{3}{4}
\end{aligned}$$

Substituting all the above in (6) and simplifying gives the solution as

$$y = x + 1 + \frac{x^2}{4} + \frac{x^3}{8} + O(x^4)$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = y(0)$$

Therefore the solution becomes

$$y = x + 1 + \frac{1}{4}x^2 + \frac{1}{8}x^3$$

Hence the solution can be written as

$$y = x + 1 + \frac{x^2}{4} + \frac{x^3}{8} + O(x^4)$$

which simplifies to

$$y = x + 1 + \frac{x^2}{4} + \frac{x^3}{8} + O(x^4)$$

Unable to also solve using normal power series since not linear ode. Not currently supported.

Summary

The solution(s) found are the following

$$y = x + 1 + \frac{x^2}{4} + \frac{x^3}{8} + O(x^4) \quad (1)$$

Verification of solutions

$$y = x + 1 + \frac{x^2}{4} + \frac{x^3}{8} + O(x^4)$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 40, page 186
Problem number: 9.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Taylor series method"**

Maple gives the following as the ode type

```
[`y=_G(x,y')`]
```

$$\boxed{y' - \sin(y) = \cos(x)}$$

With initial conditions

$$\left[y\left(\frac{\pi}{2}\right) = \frac{\pi}{2}\right]$$

With the expansion point for the power series method at $x = \frac{\pi}{2}$.

22.9.1 Solving as series ode

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - \frac{\pi}{2}$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\frac{d}{dt}y(t) - \sin(y(t)) = -\sin(t)$$

With its expansion point and initial conditions now at $t = 0$. With initial conditions now becoming

$$y(0) = \frac{\pi}{2}$$

The transformed ODE is now solved.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor series

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f &(1)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f &(2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2}\right) f &(3)\\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x, y)$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x, y) &(4)\\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 &(5)
\end{aligned}$$

For example, for $n=1$ we see that

$$\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x}F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f
\end{aligned}$$

Which is (1). And when $n=2$

$$\begin{aligned}
F_2 &= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right) F_0 \\
&= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) f \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f
\end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} F_n|_{x_0,y_0} \tag{6}$$

Hence

$$\begin{aligned}
F_0 &= \sin(y(t)) - \sin(t) \\
F_1 &= \frac{dF_0}{dt} \\
&= \frac{\partial F_0}{\partial t} + \frac{\partial F_0}{\partial y} F_0 \\
&= (\sin(y(t)) - \sin(t)) \cos(y(t)) - \cos(t) \\
F_2 &= \frac{dF_1}{dt} \\
&= \frac{\partial F_1}{\partial t} + \frac{\partial F_1}{\partial y} F_1 \\
&= \cos(t)^2 \sin(y(t)) + 3\sin(y(t))^2 \sin(t) - 2\sin(y(t))^3 - \cos(y(t)) \cos(t)
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $t(0)=0$ and $y(0)=\frac{\pi}{2}$ gives

$$\begin{aligned}
F_0 &= 1 \\
F_1 &= -1 \\
F_2 &= -1
\end{aligned}$$

Substituting all the above in (6) and simplifying gives the solution as

$$y(t) = t + \frac{\pi}{2} - \frac{t^2}{2} - \frac{t^3}{6} + O(t^4)$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = y(0)$$

Therefore the solution becomes

$$y(t) = t + \frac{1}{2}\pi - \frac{1}{2}t^2 - \frac{1}{6}t^3$$

Hence the solution can be written as

$$y(t) = t + \frac{\pi}{2} - \frac{t^2}{2} - \frac{t^3}{6} + O(t^4)$$

which simplifies to

$$y(t) = t + \frac{\pi}{2} - \frac{t^2}{2} - \frac{t^3}{6} + O(t^4)$$

Unable to also solve using normal power series since not linear ode. Not currently supported. Replacing t in the above with the original independent variable xs using $t = x - \frac{\pi}{2}$ results in

$$y = x - \frac{\left(x - \frac{\pi}{2}\right)^2}{2} - \frac{\left(x - \frac{\pi}{2}\right)^3}{6} + O\left(\left(x - \frac{\pi}{2}\right)^4\right)$$

Summary

The solution(s) found are the following

$$y = x - \frac{\left(x - \frac{\pi}{2}\right)^2}{2} - \frac{\left(x - \frac{\pi}{2}\right)^3}{6} + O\left(\left(x - \frac{\pi}{2}\right)^4\right) \tag{1}$$

Verification of solutions

$$y = x - \frac{\left(x - \frac{\pi}{2}\right)^2}{2} - \frac{\left(x - \frac{\pi}{2}\right)^3}{6} + O\left(\left(x - \frac{\pi}{2}\right)^4\right)$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_linear_constant_coeff", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - y = \sin(x)}$$

With initial conditions

$$[y(0) = 1, y'(0) = 2]$$

With the expansion point for the power series method at $x = 0$.

22.10.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= -1 \\ F &= \sin(x) \end{aligned}$$

Hence the ode is

$$y'' - y = \sin(x)$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = \sin(x)$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (1084)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (1085)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3)\\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') && (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 && (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y'_0} \tag{7}
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= y+\sin(x) \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x}+\frac{\partial F_0}{\partial y}y'+\frac{\partial F_0}{\partial y'}F_0 \\
&= y'+\cos(x) \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x}+\frac{\partial F_1}{\partial y}y'+\frac{\partial F_1}{\partial y'}F_1 \\
&= y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x}+\frac{\partial F_2}{\partial y}y'+\frac{\partial F_2}{\partial y'}F_2 \\
&= y' \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x}+\frac{\partial F_3}{\partial y}y'+\frac{\partial F_3}{\partial y'}F_3 \\
&= y+\sin(x) \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x}+\frac{\partial F_4}{\partial y}y'+\frac{\partial F_4}{\partial y'}F_4 \\
&= y'+\cos(x)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=1$ and $y'(0)=2$ gives

$$
\begin{aligned}
F_0 &= 1 \\
F_1 &= 3 \\
F_2 &= 1 \\
F_3 &= 2 \\
F_4 &= 1 \\
F_5 &= 3
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = 1 + 2x + \frac{x^2}{2} + \frac{x^3}{2} + \frac{x^4}{24} + \frac{x^5}{60} + \frac{x^6}{720} + \frac{x^7}{1680} + O(x^7)$$

$$y = 1 + 2x + \frac{x^2}{2} + \frac{x^3}{2} + \frac{x^4}{24} + \frac{x^5}{60} + \frac{x^6}{720} + \frac{x^7}{1680} + O(x^7)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$\begin{aligned} y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\ y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} \end{aligned}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \left(\sum_{n=0}^{\infty} a_n x^n\right) + \sin(x) \tag{1}$$

Expanding $\sin(x)$ as Taylor series around $x = 0$ and keeping only the first 7 terms gives

$$\begin{aligned} \sin(x) &= x - \frac{1}{6}x^3 + \frac{1}{120}x^5 + \dots \\ &= x - \frac{1}{6}x^3 + \frac{1}{120}x^5 \end{aligned}$$

Hence the ODE in Eq (1) becomes

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) - \left(\sum_{n=0}^{\infty} a_n x^n\right) = x - \frac{1}{6}x^3 + \frac{1}{120}x^5$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \sum_{n=0}^{\infty} (-a_n x^n) = x - \frac{1}{6}x^3 + \frac{1}{120}x^5 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \sum_{n=0}^{\infty} (-a_n x^n) = x - \frac{1}{6}x^3 + \frac{1}{120}x^5 \tag{3}$$

For $0 \leq n$, the recurrence equation is

$$((n+2)\, a_{n+2}(n+1) - a_n)\, x^n = x - \frac{1}{6}x^3 + \frac{1}{120}x^5 \tag{4}$$

For $n = 0$ the recurrence equation gives

$$(2a_2 - a_0)\, 1 = 0$$
$$2a_2 - a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_2 = \frac{a_0}{2}$$

For $n = 1$ the recurrence equation gives

$$(6a_3 - a_1)\, x = x$$
$$6a_3 - a_1 = 1$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{1}{6} + \frac{a_1}{6}$$

For $n = 2$ the recurrence equation gives

$$(12a_4 - a_2) x^2 = 0$$
$$12a_4 - a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{24}$$

For $n = 3$ the recurrence equation gives

$$(20a_5 - a_3) x^3 = -\frac{x^3}{6}$$
$$20a_5 - a_3 = -\frac{1}{6}$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_1}{120}$$

For $n = 4$ the recurrence equation gives

$$(30a_6 - a_4) x^4 = 0$$
$$30a_6 - a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_0}{720}$$

For $n = 5$ the recurrence equation gives

$$(42a_7 - a_5) x^5 = \frac{x^5}{120}$$
$$42a_7 - a_5 = \frac{1}{120}$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{1}{5040} + \frac{a_1}{5040}$$

For $n = 6$ the recurrence equation gives

$$\begin{aligned}(56a_8 - a_6)\, x^6 &= 0\\ 56a_8 - a_6 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{a_0}{40320}$$

And so on. Therefore the solution is

$$\begin{aligned}y &= \sum_{n=0}^{\infty} a_n x^n\\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots\end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + \frac{a_0 x^2}{2} + \left(\frac{1}{6} + \frac{a_1}{6}\right) x^3 + \frac{a_0 x^4}{24} + \frac{a_1 x^5}{120} + \frac{a_0 x^6}{720} + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + \frac{1}{2}x^2 + \frac{1}{24}x^4 + \frac{1}{720}x^6\right) a_0 + \left(x + \frac{1}{6}x^3 + \frac{1}{120}x^5\right) a_1 + \frac{x^3}{6} + O(x^7) \quad (3)$$

At $x = 0$ the solution above becomes

$$y = \left(1 + \frac{1}{2}x^2 + \frac{1}{24}x^4 + \frac{1}{720}x^6\right) c_1 + \left(x + \frac{1}{6}x^3 + \frac{1}{120}x^5\right) c_2 + \frac{x^3}{6} + O(x^7)$$

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{24} + \frac{x^6}{720} + 2x + \frac{x^3}{2} + \frac{x^5}{60} + O(x^7)$$

Summary
The solution(s) found are the following

$$y = 1 + 2x + \frac{x^2}{2} + \frac{x^3}{2} + \frac{x^4}{24} + \frac{x^5}{60} + \frac{x^6}{720} + \frac{x^7}{1680} + O(x^7) \tag{1}$$

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{24} + \frac{x^6}{720} + 2x + \frac{x^3}{2} + \frac{x^5}{60} + O(x^7) \tag{2}$$

Verification of solutions

$$y = 1 + 2x + \frac{x^2}{2} + \frac{x^3}{2} + \frac{x^4}{24} + \frac{x^5}{60} + \frac{x^6}{720} + \frac{x^7}{1680} + O(x^7)$$

Verified OK.

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{24} + \frac{x^6}{720} + 2x + \frac{x^3}{2} + \frac{x^5}{60} + O(x^7)$$

Verified OK.

22.10.2 Maple step by step solution

Let's solve

$\left[y'' = y + \sin(x), y(0) = 1, y'\Big|_{\{x=0\}} = 2\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - y = \sin(x)$

- Characteristic polynomial of homogeneous ODE

  $r^2 - 1 = 0$

- Factor the characteristic polynomial

  $(r-1)(r+1) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} + y_p(x)$
- ☐ Find a particular solution $y_p(x)$ of the ODE
  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \sin(x)\right]$
  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-x} & \mathrm{e}^{x} \\ -\mathrm{e}^{-x} & \mathrm{e}^{x} \end{bmatrix}$
  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2$
  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\frac{\mathrm{e}^{-x}\left(\int \mathrm{e}^{x} \sin(x) dx\right)}{2} + \frac{\mathrm{e}^{x}\left(\int \mathrm{e}^{-x} \sin(x) dx\right)}{2}$
  - Compute integrals

    $y_p(x) = -\frac{\sin(x)}{2}$
- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} - \frac{\sin(x)}{2}$
- ☐ Check validity of solution $y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} - \frac{\sin(x)}{2}$
  - Use initial condition $y(0) = 1$

    $1 = c_1 + c_2$
  - Compute derivative of the solution

    $y' = -c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} - \frac{\cos(x)}{2}$
  - Use the initial condition $y'\Big|_{\{x=0\}} = 2$

    $2 = -c_1 + c_2 - \frac{1}{2}$
  - Solve for c_1 and c_2

    $\left\{c_1 = -\frac{3}{4}, c_2 = \frac{7}{4}\right\}$
  - Substitute constant values into general solution and simplify

$$y = -\frac{3\,e^{-x}}{4} + \frac{7\,e^{x}}{4} - \frac{\sin(x)}{2}$$

- Solution to the IVP

$$y = -\frac{3\,e^{-x}}{4} + \frac{7\,e^{x}}{4} - \frac{\sin(x)}{2}$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 40, page 186
Problem number: 11.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second__order__linear__constant__coeff", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 2y = e^{2x}}$$

With initial conditions

$$[y(0) = 0, y'(0) = 0]$$

With the expansion point for the power series method at $x = 0$.

22.11.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= -2 \\ F &= e^{2x} \end{aligned}$$

Hence the ode is

$$y'' - 2y = e^{2x}$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = e^{2x}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned} y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\ &= y_0 + xy'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\ &= y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0} \end{aligned}$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (1087) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (1088) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x=0$. Hence

$$\begin{aligned}
F_0 &= 2y + \mathrm{e}^{2x} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= 2y' + 2\,\mathrm{e}^{2x} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= 4y + 6\,\mathrm{e}^{2x} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= 4y' + 12\,\mathrm{e}^{2x} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= 8y + 28\,\mathrm{e}^{2x} \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= 8y' + 56\,\mathrm{e}^{2x}
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=0$ and $y'(0)=0$ gives

$$\begin{aligned}
F_0 &= 1 \\
F_1 &= 2 \\
F_2 &= 6 \\
F_3 &= 12 \\
F_4 &= 28 \\
F_5 &= 56
\end{aligned}$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \frac{x^5}{10} + \frac{7x^6}{180} + \frac{x^7}{90} + O(x^7)$$

$$y = \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \frac{x^5}{10} + \frac{7x^6}{180} + \frac{x^7}{90} + O(x^7)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = 2\left(\sum_{n=0}^{\infty} a_n x^n\right) + e^{2x} \tag{1}$$

Expanding e^{2x} as Taylor series around $x = 0$ and keeping only the first 7 terms gives

$$\begin{aligned} e^{2x} &= 1 + 2x + 2x^2 + \frac{4}{3}x^3 + \frac{2}{3}x^4 + \frac{4}{15}x^5 + \frac{4}{45}x^6 + \dots \\ &= 1 + 2x + 2x^2 + \frac{4}{3}x^3 + \frac{2}{3}x^4 + \frac{4}{15}x^5 + \frac{4}{45}x^6 \end{aligned}$$

Hence the ODE in Eq (1) becomes

$$\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) - 2\left(\sum_{n=0}^{\infty} a_n x^n\right) = 1 + 2x + 2x^2 + \frac{4}{3}x^3 + \frac{2}{3}x^4 + \frac{4}{15}x^5 + \frac{4}{45}x^6$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + \sum_{n=0}^{\infty} (-2a_n x^n) = 1 + 2x + 2x^2 + \frac{4}{3}x^3 + \frac{2}{3}x^4 + \frac{4}{15}x^5 + \frac{4}{45}x^6 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \sum_{n=0}^{\infty} (-2a_n x^n) = 1 + 2x + 2x^2 + \frac{4}{3}x^3 + \frac{2}{3}x^4 + \frac{4}{15}x^5 + \frac{4}{45}x^6 \tag{3}$$

For $0 \le n$, the recurrence equation is

$$((n+2)\, a_{n+2}(n+1) - 2a_n)\, x^n = 1 + 2x + 2x^2 + \frac{4}{3}x^3 + \frac{2}{3}x^4 + \frac{4}{15}x^5 + \frac{4}{45}x^6 \tag{4}$$

For $n = 0$ the recurrence equation gives

$$(2a_2 - 2a_0)\, 1 = 1$$
$$2a_2 - 2a_0 = 1$$

Which after substituting the earlier terms found becomes

$$a_2 = \frac{1}{2} + a_0$$

For $n = 1$ the recurrence equation gives

$$(6a_3 - 2a_1)\, x = 2x$$
$$6a_3 - 2a_1 = 2$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{1}{3} + \frac{a_1}{3}$$

For $n = 2$ the recurrence equation gives

$$(12a_4 - 2a_2)\, x^2 = 2x^2$$
$$12a_4 - 2a_2 = 2$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{1}{4} + \frac{a_0}{6}$$

For $n = 3$ the recurrence equation gives

$$(20a_5 - 2a_3)\, x^3 = \frac{4x^3}{3}$$
$$20a_5 - 2a_3 = \frac{4}{3}$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{1}{10} + \frac{a_1}{30}$$

For $n = 4$ the recurrence equation gives

$$(30a_6 - 2a_4)\, x^4 = \frac{2x^4}{3}$$
$$30a_6 - 2a_4 = \frac{2}{3}$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{7}{180} + \frac{a_0}{90}$$

For $n = 5$ the recurrence equation gives

$$(42a_7 - 2a_5)\, x^5 = \frac{4x^5}{15}$$
$$42a_7 - 2a_5 = \frac{4}{15}$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{1}{90} + \frac{a_1}{630}$$

For $n = 6$ the recurrence equation gives

$$\left(56a_8 - 2a_6\right) x^6 = \frac{4x^6}{45}$$
$$56a_8 - 2a_6 = \frac{4}{45}$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{1}{336} + \frac{a_0}{2520}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + \left(\frac{1}{2} + a_0\right) x^2 + \left(\frac{1}{3} + \frac{a_1}{3}\right) x^3 + \left(\frac{1}{4} + \frac{a_0}{6}\right) x^4 + \left(\frac{1}{10} + \frac{a_1}{30}\right) x^5 + \left(\frac{7}{180} + \frac{a_0}{90}\right) x^6 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + x^2 + \frac{1}{6}x^4 + \frac{1}{90}x^6\right) a_0 + \left(x + \frac{1}{3}x^3 + \frac{1}{30}x^5\right) a_1 + \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \frac{x^5}{10} + \frac{7x^6}{180} + O\left(x^7\right) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1+x^2+\frac{1}{6}x^4+\frac{1}{90}x^6\right) c_1 + \left(x+\frac{1}{3}x^3+\frac{1}{30}x^5\right) c_2 + \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \frac{x^5}{10} + \frac{7x^6}{180} + O\left(x^7\right)$$

$$y=\frac{x^{2}}{2}+\frac{x^{3}}{3}+\frac{x^{4}}{4}+\frac{x^{5}}{10}+\frac{7x^{6}}{180}+O(x^{7})$$

Summary
The solution(s) found are the following

$$y=\frac{x^{2}}{2}+\frac{x^{3}}{3}+\frac{x^{4}}{4}+\frac{x^{5}}{10}+\frac{7x^{6}}{180}+\frac{x^{7}}{90}+O(x^{7}) \tag{1}$$
$$y=\frac{x^{2}}{2}+\frac{x^{3}}{3}+\frac{x^{4}}{4}+\frac{x^{5}}{10}+\frac{7x^{6}}{180}+O(x^{7}) \tag{2}$$

Verification of solutions

$$y=\frac{x^{2}}{2}+\frac{x^{3}}{3}+\frac{x^{4}}{4}+\frac{x^{5}}{10}+\frac{7x^{6}}{180}+\frac{x^{7}}{90}+O(x^{7})$$

Verified OK.

$$y=\frac{x^{2}}{2}+\frac{x^{3}}{3}+\frac{x^{4}}{4}+\frac{x^{5}}{10}+\frac{7x^{6}}{180}+O(x^{7})$$

Verified OK.

22.11.2 Maple step by step solution

Let's solve

$\left[y''=2y+e^{2x}, y(0)=0, y'\Big|_{\{x=0\}}=0\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-2y=e^{2x}$

- Characteristic polynomial of homogeneous ODE

  $r^{2}-2=0$

- Use quadratic formula to solve for r

  $r=\frac{0\pm(\sqrt{8})}{2}$

- Roots of the characteristic polynomial

  $r=(\sqrt{2}, -\sqrt{2})$

- 1st solution of the homogeneous ODE

$y_1(x) = e^{\sqrt{2}\,x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-\sqrt{2}\,x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{\sqrt{2}\,x} + c_2 e^{-\sqrt{2}\,x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = e^{2x}\right]$

- Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{\sqrt{2}\,x} & e^{-\sqrt{2}\,x} \\ \sqrt{2}\,e^{\sqrt{2}\,x} & -\sqrt{2}\,e^{-\sqrt{2}\,x} \end{bmatrix}$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = -2\sqrt{2}$

- Substitute functions into equation for $y_p(x)$

  $y_p(x) = \frac{\sqrt{2}\left(e^{\sqrt{2}\,x}\left(\int e^{-x(\sqrt{2}-2)}dx\right) - e^{-\sqrt{2}\,x}\left(\int e^{x(2+\sqrt{2})}dx\right)\right)}{4}$

- Compute integrals

  $y_p(x) = \frac{e^{2x}}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{\sqrt{2}\,x} + c_2 e^{-\sqrt{2}\,x} + \frac{e^{2x}}{2}$

☐ Check validity of solution $y = c_1 e^{\sqrt{2}\,x} + c_2 e^{-\sqrt{2}\,x} + \frac{e^{2x}}{2}$

- Use initial condition $y(0) = 0$

  $0 = c_1 + c_2 + \frac{1}{2}$

- Compute derivative of the solution

  $y' = c_1\sqrt{2}\,e^{\sqrt{2}\,x} - c_2\sqrt{2}\,e^{-\sqrt{2}\,x} + e^{2x}$

- Use the initial condition $y'\Big|_{\{x=0\}} = 0$

  $0 = c_1\sqrt{2} - c_2\sqrt{2} + 1$

- Solve for c_1 and c_2

  $$\left\{c_1 = -\frac{1}{4} - \frac{\sqrt{2}}{4}, c_2 = -\frac{1}{4} + \frac{\sqrt{2}}{4}\right\}$$

- Substitute constant values into general solution and simplify

  $$y = \frac{\left(\sqrt{2}-1\right)e^{-\sqrt{2}\,x}}{4} + \frac{\left(-1-\sqrt{2}\right)e^{\sqrt{2}\,x}}{4} + \frac{e^{2x}}{2}$$

- Solution to the IVP

  $$y = \frac{\left(\sqrt{2}-1\right)e^{-\sqrt{2}\,x}}{4} + \frac{\left(-1-\sqrt{2}\right)e^{\sqrt{2}\,x}}{4} + \frac{e^{2x}}{2}$$

Section: Exercise 40, page 186
Problem number: 12.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_integrable_as_is", "second_order_ode_missing_x", "exact nonlinear second order ode", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _exact, _nonlinear],
   _Lagerstrom, [_2nd_order, _reducible, _mu_x_y1], [_2nd_order,
    _reducible, _mu_xy]]
```

$$\boxed{y'' + 2yy' = 0}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1]$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using

Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0, y_0, y_0'} + \frac{x^3}{3!} f'|_{x_0, y_0, y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y_0'}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (1090) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (1091) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}F_n|_{x_0,y_0,y_0'} \qquad (7)$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -2yy' \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0 \\
&= 4y^2y' - 2y'^2 \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y}y' + \frac{\partial F_1}{\partial y'}F_1 \\
&= -8yy'\left(y^2 - 2y'\right) \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y}y' + \frac{\partial F_2}{\partial y'}F_2 \\
&= 16\left(y^4 - \frac{11y^2y'}{2} + y'^2\right)y' \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y}y' + \frac{\partial F_3}{\partial y'}F_3 \\
&= -32y'y\left(y^4 - 13y^2y' + \frac{17y'^2}{2}\right) \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y}y' + \frac{\partial F_4}{\partial y'}F_4 \\
&= 64\left(y^6 - \frac{57y^4y'}{2} + 45y^2y'^2 - \frac{17y'^3}{4}\right)y'
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=0$ and

$y'(0) = 1$ gives

$$
\begin{aligned}
F_0 &= 0 \\
F_1 &= -2 \\
F_2 &= 0 \\
F_3 &= 16 \\
F_4 &= 0 \\
F_5 &= -272
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = x - \frac{x^3}{3} + \frac{2x^5}{15} - \frac{17x^7}{315} + O(x^7)$$

$$y = x - \frac{x^3}{3} + \frac{2x^5}{15} - \frac{17x^7}{315} + O(x^7)$$

Unable to also solve using normal power series since not linear ode. Not currently supported.

Summary

The solution(s) found are the following

$$y = x - \frac{x^3}{3} + \frac{2x^5}{15} - \frac{17x^7}{315} + O(x^7) \tag{1}$$

Verification of solutions

$$y = x - \frac{x^3}{3} + \frac{2x^5}{15} - \frac{17x^7}{315} + O(x^7)$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 40, page 186
Problem number: 13.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_can_be_made_integrable", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1]]
```

$$\boxed{y'' - \sin(y) = 0}$$

With initial conditions

$$\left[y(0) = \frac{\pi}{4}, y'(0) = 0\right]$$

With the expansion point for the power series method at $x = \frac{\pi}{4}$.

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - \frac{\pi}{4}$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\frac{d^2}{dt^2}y(t) = \sin(y(t))$$

With its expansion point and initial conditions now at $t = 0$. With initial conditions now becoming

$$
\begin{aligned}
y(0) &= \frac{\pi}{4} \\
y'(0) &= 0
\end{aligned}
$$

The transformed ODE is now solved. Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$
y'' = f(x, y, y')
$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (1093) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (1094) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') && (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 && (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \tag{7}
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= \sin(y(t)) \\
F_1 &= \frac{dF_0}{dt} \\
&= \frac{\partial F_0}{\partial t} + \frac{\partial F_0}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_0}{\partial \frac{d}{dt}y(t)}F_0 \\
&= \left(\frac{d}{dt}y(t)\right)\cos(y(t)) \\
F_2 &= \frac{dF_1}{dt} \\
&= \frac{\partial F_1}{\partial t} + \frac{\partial F_1}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_1}{\partial \frac{d}{dt}y(t)}F_1 \\
&= \sin(y(t))\left(\cos(y(t)) - \left(\frac{d}{dt}y(t)\right)^2\right) \\
F_3 &= \frac{dF_2}{dt} \\
&= \frac{\partial F_2}{\partial t} + \frac{\partial F_2}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_2}{\partial \frac{d}{dt}y(t)}F_2 \\
&= \left(4\cos(y(t))^2 - 3 - \left(\frac{d}{dt}y(t)\right)^2\cos(y(t))\right)\left(\frac{d}{dt}y(t)\right) \\
F_4 &= \frac{dF_3}{dt} \\
&= \frac{\partial F_3}{\partial t} + \frac{\partial F_3}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_3}{\partial \frac{d}{dt}y(t)}F_3 \\
&= \sin(y(t))\left(\left(\frac{d}{dt}y(t)\right)^4 - 11\left(\frac{d}{dt}y(t)\right)^2\cos(y(t)) + 4\cos(y(t))^2 - 3\right) \\
F_5 &= \frac{dF_4}{dt} \\
&= \frac{\partial F_4}{\partial t} + \frac{\partial F_4}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_4}{\partial \frac{d}{dt}y(t)}F_4 \\
&= \left(\frac{d}{dt}y(t)\right)^5\cos(y(t)) + \left(-26\cos(y(t))^2 + 15\right)\left(\frac{d}{dt}y(t)\right)^3 + \left(34\cos(y(t))^3 - 33\cos(y(t))\right)\left(\frac{d}{dt}y(t)\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $t = 0$ and $y(0) = \frac{\pi}{4}$ and

$y'(0) = 0$ gives

$$
\begin{aligned}
F_0 &= \frac{\sqrt{2}}{2} \\
F_1 &= 0 \\
F_2 &= \frac{1}{2} \\
F_3 &= 0 \\
F_4 &= -\frac{\sqrt{2}}{2} \\
F_5 &= 0
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y(t) = \frac{\pi}{4} + \frac{\sqrt{2}\, t^2}{4} + \frac{t^4}{48} - \frac{\sqrt{2}\, t^6}{1440} + O(t^7)
$$

$$
y(t) = \frac{\pi}{4} + \frac{\sqrt{2}\, t^2}{4} + \frac{t^4}{48} - \frac{\sqrt{2}\, t^6}{1440} + O(t^7)
$$

Unable to also solve using normal power series since not linear ode. Not currently supported. Replacing t in the above with the original independent variable $x$using $t = x - \frac{\pi}{4}$ results in

$$
y = \frac{\pi}{4} + \frac{\sqrt{2}\left(x - \frac{\pi}{4}\right)^2}{4} + \frac{\left(x - \frac{\pi}{4}\right)^4}{48} - \frac{\sqrt{2}\left(x - \frac{\pi}{4}\right)^6}{1440} + O\left(\left(x - \frac{\pi}{4}\right)^7\right)
$$

Summary

The solution(s) found are the following

$$
y = \frac{\pi}{4} + \frac{\sqrt{2}\left(x - \frac{\pi}{4}\right)^2}{4} + \frac{\left(x - \frac{\pi}{4}\right)^4}{48} - \frac{\sqrt{2}\left(x - \frac{\pi}{4}\right)^6}{1440} + O\left(\left(x - \frac{\pi}{4}\right)^7\right) \tag{1}
$$

Verification of solutions

$$
y = \frac{\pi}{4} + \frac{\sqrt{2}\left(x - \frac{\pi}{4}\right)^2}{4} + \frac{\left(x - \frac{\pi}{4}\right)^4}{48} - \frac{\sqrt{2}\left(x - \frac{\pi}{4}\right)^6}{1440} + O\left(\left(x - \frac{\pi}{4}\right)^7\right)
$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 40, page 186
Problem number: 14.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + \frac{y'^2}{2} - y = 0}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1]$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using

Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0, y_0, y_0'} + \frac{x^3}{3!} f'|_{x_0, y_0, y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left.\frac{d^n f}{dx^n}\right|_{x_0, y_0, y_0'}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (1096) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (1097) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \qquad (7)$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{y'^2}{2}+y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x}+\frac{\partial F_0}{\partial y}y'+\frac{\partial F_0}{\partial y'}F_0 \\
&= \frac{y'^3}{2}+(1-y)\,y' \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x}+\frac{\partial F_1}{\partial y}y'+\frac{\partial F_1}{\partial y'}F_1 \\
&= -\frac{\left(-y'^2+2y-2\right)\left(-3y'^2+2y\right)}{4} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x}+\frac{\partial F_2}{\partial y}y'+\frac{\partial F_2}{\partial y'}F_2 \\
&= \frac{\left(-3y'^2+4y-1\right)y'\left(-y'^2+2y-2\right)}{2} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x}+\frac{\partial F_3}{\partial y}y'+\frac{\partial F_3}{\partial y'}F_3 \\
&= 4\left(\frac{15y'^4}{8}+\left(-\frac{15y}{4}+\frac{11}{8}\right)y'^2+y^2-\frac{y}{4}\right)\left(-\frac{y'^2}{2}+y-1\right) \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x}+\frac{\partial F_4}{\partial y}y'+\frac{\partial F_4}{\partial y'}F_4 \\
&= -34y'\left(\frac{1}{34}+\frac{45y'^4}{68}+\frac{(13-30y)\,y'^2}{17}+y^2-\frac{10y}{17}\right)\left(-\frac{y'^2}{2}+y-1\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=0$ and

$y'(0) = 1$ gives

$$
\begin{aligned}
F_0 &= -\frac{1}{2} \\
F_1 &= \frac{3}{2} \\
F_2 &= -\frac{9}{4} \\
F_3 &= 6 \\
F_4 &= -\frac{39}{2} \\
F_5 &= \frac{297}{4}
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = x - \frac{x^2}{4} + \frac{x^3}{4} - \frac{3x^4}{32} + \frac{x^5}{20} - \frac{13x^6}{480} + \frac{33x^7}{2240} + O(x^7)
$$

$$
y = x - \frac{x^2}{4} + \frac{x^3}{4} - \frac{3x^4}{32} + \frac{x^5}{20} - \frac{13x^6}{480} + \frac{33x^7}{2240} + O(x^7)
$$

Unable to also solve using normal power series since not linear ode. Not currently supported.

Summary

The solution(s) found are the following

$$
y = x - \frac{x^2}{4} + \frac{x^3}{4} - \frac{3x^4}{32} + \frac{x^5}{20} - \frac{13x^6}{480} + \frac{33x^7}{2240} + O(x^7) \tag{1}
$$

Verification of solutions

$$
y = x - \frac{x^2}{4} + \frac{x^3}{4} - \frac{3x^4}{32} + \frac{x^5}{20} - \frac{13x^6}{480} + \frac{33x^7}{2240} + O(x^7)
$$

Verified OK.

The type(s) of ODE detected by this program : **"second order series method. Taylor series method"**

Maple gives the following as the ode type

`[NONE]`

$$\boxed{y'' - \sin(yx) = 0}$$

With initial conditions

$$\left[y\left(\frac{\pi}{2}\right) = 1, y'\left(\frac{\pi}{2}\right) = 1\right]$$

With the expansion point for the power series method at $x = \frac{\pi}{2}$.

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - \frac{\pi}{2}$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\frac{d^2}{dt^2}y(t) = \sin\left(y(t)\left(t + \frac{\pi}{2}\right)\right)$$

With its expansion point and initial conditions now at $t = 0$. With initial conditions now becoming

$$\begin{aligned}
y(0) &= 1 \\
y'(0) &= 1
\end{aligned}$$

The transformed ODE is now solved. Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (1099) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (1100) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') && (4) \\
F_1 &= \frac{df}{dx} \\
&= \frac{dF_0}{dx} \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (5) \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right) \\
&= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y'' \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0 \\
&\vdots \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y'' \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 && (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \tag{7}
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$F_0 = \sin\left(y(t)\left(t+\frac{\pi}{2}\right)\right)$$

$$\begin{aligned}
F_1 &= \frac{dF_0}{dt} \\
&= \frac{\partial F_0}{\partial t} + \frac{\partial F_0}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_0}{\partial \frac{d}{dt}y(t)}F_0 \\
&= \left(\left(\frac{d}{dt}y(t)\right)\left(t+\frac{\pi}{2}\right) + y(t)\right)\cos\left(y(t)\left(t+\frac{\pi}{2}\right)\right) \\
F_2 &= \frac{dF_1}{dt} \\
&= \frac{\partial F_1}{\partial t} + \frac{\partial F_1}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_1}{\partial \frac{d}{dt}y(t)}F_1 \\
&= \frac{\left((4t+2\pi)\cos\left(y(t)\left(t+\frac{\pi}{2}\right)\right) - 4\left(\left(\frac{d}{dt}y(t)\right)\left(t+\frac{\pi}{2}\right)+y(t)\right)^2\right)\sin\left(y(t)\left(t+\frac{\pi}{2}\right)\right)}{4} + 2\cos\left(y(t)\left(t+\frac{\pi}{2}\right.\right. \\
F_3 &= \frac{dF_2}{dt} \\
&= \frac{\partial F_2}{\partial t} + \frac{\partial F_2}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_2}{\partial \frac{d}{dt}y(t)}F_2 \\
&= \frac{\left(24\sin\left(y(t)\left(t+\frac{\pi}{2}\right)\right) + (-\pi^3 - 6\pi^2 t - 12\pi t^2 - 8t^3)\left(\frac{d}{dt}y(t)\right)^3 + (-6\pi^2 - 24\pi t - 24t^2)\,y(t)\left(\frac{d}{dt}y(t)\right)^{\cdots}\right.}{8}
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $t = 0$ and $y(0) = 1$ and $y'(0) = 1$ gives

$$\begin{aligned}
F_0 &= 1 \\
F_1 &= 0 \\
F_2 &= -\frac{1}{4}\pi^2 - \pi - 1 \\
F_3 &= -\frac{3}{4}\pi^2 - \frac{9}{2}\pi - 6
\end{aligned}$$

Substituting all the above in (7) and simplifying gives the solution as

$$y(t) = t + 1 + \frac{t^2}{2} - \frac{t^4\pi^2}{96} - \frac{t^4\pi}{24} - \frac{t^4}{24} - \frac{t^5\pi^2}{160} - \frac{3t^5\pi}{80} - \frac{t^5}{20} + O(t^5)$$

$$y(t) = t + 1 + \frac{t^2}{2} - \frac{t^4\pi^2}{96} - \frac{t^4\pi}{24} - \frac{t^4}{24} - \frac{t^5\pi^2}{160} - \frac{3t^5\pi}{80} - \frac{t^5}{20} + O(t^5)$$

Unable to also solve using normal power series since not linear ode. Not currently supported. Replacing t in the above with the original independent variable $x$using $t = x - \frac{\pi}{2}$ results in

$$y = x - \frac{\pi}{2} + 1 + \frac{\left(x - \frac{\pi}{2}\right)^2}{2} - \frac{\left(x - \frac{\pi}{2}\right)^4 \pi^2}{96} - \frac{\left(x - \frac{\pi}{2}\right)^4 \pi}{24} - \frac{\left(x - \frac{\pi}{2}\right)^4}{24} - \frac{\left(x - \frac{\pi}{2}\right)^5 \pi^2}{160} - \frac{3\left(x - \frac{\pi}{2}\right)^5 \pi}{80} - \frac{\left(x - \frac{\pi}{2}\right)^5}{20} + O\left(\left(x - \frac{\pi}{2}\right)^5\right)$$

Summary

The solution(s) found are the following

$$y = x - \frac{\pi}{2} + 1 + \frac{\left(x - \frac{\pi}{2}\right)^2}{2} - \frac{\left(x - \frac{\pi}{2}\right)^4 \pi^2}{96} - \frac{\left(x - \frac{\pi}{2}\right)^4 \pi}{24} - \frac{\left(x - \frac{\pi}{2}\right)^4}{24} - \frac{\left(x - \frac{\pi}{2}\right)^5 \pi^2}{160} - \frac{3\left(x - \frac{\pi}{2}\right)^5 \pi}{80} - \frac{\left(x - \frac{\pi}{2}\right)^5}{20} + O\left(\left(x - \frac{\pi}{2}\right)^5\right) \tag{1}$$

Verification of solutions

$$y = x - \frac{\pi}{2} + 1 + \frac{\left(x - \frac{\pi}{2}\right)^2}{2} - \frac{\left(x - \frac{\pi}{2}\right)^4 \pi^2}{96} - \frac{\left(x - \frac{\pi}{2}\right)^4 \pi}{24} - \frac{\left(x - \frac{\pi}{2}\right)^4}{24} - \frac{\left(x - \frac{\pi}{2}\right)^5 \pi^2}{160} - \frac{3\left(x - \frac{\pi}{2}\right)^5 \pi}{80} - \frac{\left(x - \frac{\pi}{2}\right)^5}{20} + O\left(\left(x - \frac{\pi}{2}\right)^5\right)$$

Verified OK.

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Taylor series method"**

Maple gives the following as the ode type

`[NONE]`

$$\boxed{y'' - \cos(yx) = 0}$$

With initial conditions

$$\left[y\left(\frac{\pi}{2}\right) = 1, y'\left(\frac{\pi}{2}\right) = 1\right]$$

With the expansion point for the power series method at $x = \frac{\pi}{2}$.

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - \frac{\pi}{2}$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\frac{d^2}{dt^2}y(t) = \cos\left(y(t)\left(t + \frac{\pi}{2}\right)\right)$$

With its expansion point and initial conditions now at $t=0$. With initial conditions now becoming

$$
\begin{aligned}
y(0) &= 1 \\
y'(0) &= 1
\end{aligned}
$$

The transformed ODE is now solved. Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$
y'' = f(x, y, y')
$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (1102) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (1103) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') && (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 && (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \tag{7}
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= \cos\left(y(t)\left(t+\frac{\pi}{2}\right)\right)\\
F_1 &= \frac{dF_0}{dt}\\
&= \frac{\partial F_0}{\partial t} + \frac{\partial F_0}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_0}{\partial \frac{d}{dt}y(t)}F_0\\
&= -\left(\left(\frac{d}{dt}y(t)\right)\left(t+\frac{\pi}{2}\right)+y(t)\right)\sin\left(y(t)\left(t+\frac{\pi}{2}\right)\right)\\
F_2 &= \frac{dF_1}{dt}\\
&= \frac{\partial F_1}{\partial t} + \frac{\partial F_1}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_1}{\partial \frac{d}{dt}y(t)}F_1\\
&= \frac{\left((-4t-2\pi)\sin\left(y(t)\left(t+\frac{\pi}{2}\right)\right)-4\left(\left(\frac{d}{dt}y(t)\right)\left(t+\frac{\pi}{2}\right)+y(t)\right)^2\right)\cos\left(y(t)\left(t+\frac{\pi}{2}\right)\right)}{4} - 2\left(\frac{d}{dt}y(t)\right)\sin\left(y\right.\\
F_3 &= \frac{dF_2}{dt}\\
&= \frac{\partial F_2}{\partial t} + \frac{\partial F_2}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_2}{\partial \frac{d}{dt}y(t)}F_2\\
&= \frac{\left(-24\cos\left(y(t)\left(t+\frac{\pi}{2}\right)\right)+(\pi^3+6\pi^2t+12\pi t^2+8t^3)\left(\frac{d}{dt}y(t)\right)^3+6(\pi^2+4\pi t+4t^2)\,y(t)\left(\frac{d}{dt}y(t)\right)^2+\right.}{8}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $t=0$ and $y(0)=1$ and $y'(0)=1$ gives

$$
\begin{aligned}
F_0 &= 0\\
F_1 &= -\frac{\pi}{2}-1\\
F_2 &= -2\\
F_3 &= \frac{1}{8}\pi^3+\pi^2+2\pi+1
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y(t) = t+1-\frac{t^3\pi}{12}-\frac{t^3}{6}-\frac{t^4}{12}+\frac{t^5\pi^3}{960}+\frac{t^5\pi^2}{120}+\frac{t^5\pi}{60}+\frac{t^5}{120}+O(t^5)
$$

$$
y(t) = t+1-\frac{t^3\pi}{12}-\frac{t^3}{6}-\frac{t^4}{12}+\frac{t^5\pi^3}{960}+\frac{t^5\pi^2}{120}+\frac{t^5\pi}{60}+\frac{t^5}{120}+O(t^5)
$$

Unable to also solve using normal power series since not linear ode. Not currently supported. Replacing t in the above with the original independent variable $x$susing $t = x - \frac{\pi}{2}$ results in

$$y = x - \frac{\pi}{2} + 1 - \frac{\left(x - \frac{\pi}{2}\right)^3 \pi}{12} - \frac{\left(x - \frac{\pi}{2}\right)^3}{6} - \frac{\left(x - \frac{\pi}{2}\right)^4}{12} + \frac{\left(x - \frac{\pi}{2}\right)^5 \pi^3}{960} + \frac{\left(x - \frac{\pi}{2}\right)^5 \pi^2}{120} + \frac{\left(x - \frac{\pi}{2}\right)^5 \pi}{60} + \frac{\left(x - \frac{\pi}{2}\right)^5}{120} + O\left(\left(x - \frac{\pi}{2}\right)^5\right)$$

Summary

The solution(s) found are the following

$$y = x - \frac{\pi}{2} + 1 - \frac{\left(x - \frac{\pi}{2}\right)^3 \pi}{12} - \frac{\left(x - \frac{\pi}{2}\right)^3}{6} - \frac{\left(x - \frac{\pi}{2}\right)^4}{12} + \frac{\left(x - \frac{\pi}{2}\right)^5 \pi^3}{960} + \frac{\left(x - \frac{\pi}{2}\right)^5 \pi^2}{120} + \frac{\left(x - \frac{\pi}{2}\right)^5 \pi}{60} + \frac{\left(x - \frac{\pi}{2}\right)^5}{120} + O\left(\left(x - \frac{\pi}{2}\right)^5\right) \tag{1}$$

Verification of solutions

$$y = x - \frac{\pi}{2} + 1 - \frac{\left(x - \frac{\pi}{2}\right)^3 \pi}{12} - \frac{\left(x - \frac{\pi}{2}\right)^3}{6} - \frac{\left(x - \frac{\pi}{2}\right)^4}{12} + \frac{\left(x - \frac{\pi}{2}\right)^5 \pi^3}{960} + \frac{\left(x - \frac{\pi}{2}\right)^5 \pi^2}{120} + \frac{\left(x - \frac{\pi}{2}\right)^5 \pi}{60} + \frac{\left(x - \frac{\pi}{2}\right)^5}{120} + O\left(\left(x - \frac{\pi}{2}\right)^5\right)$$

Verified OK.

Problem number: 1.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{2xy'' + 5y' + yx = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2xy'' + 5y' + yx = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{5}{2x}$$
$$q(x) = \frac{1}{2}$$

Table 636: Table $p(x), q(x)$ singularites.

$p(x) = \frac{5}{2x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{1}{2}$	
singularity	type

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2xy'' + 5y' + yx = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x + 5\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) x = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 5(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 5(n+r)\, a_n x^{n+r-1}\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r-1} a_n (n+r)(n+r-1) + 5(n+r)\, a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$2x^{-1+r} a_0 r(-1+r) + 5r a_0 x^{-1+r} = 0$$

Or

$$\left(2x^{-1+r} r(-1+r) + 5r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, x^{-1+r}(3+2r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 + 3r = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = -\frac{3}{2}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\, x^{-1+r}(3+2r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{3}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^n$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-\frac{3}{2}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$2a_n(n+r)(n+r-1) + 5a_n(n+r) + a_{n-2} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-2}}{2n^2 + 4nr + 2r^2 + 3n + 3r} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = -\frac{a_{n-2}}{n(2n+3)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{1}{2r^2 + 11r + 14}$$

Which for the root $r = 0$ becomes

$$a_2 = -\frac{1}{14}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{2r^2+11r+14}$	$-\frac{1}{14}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{2r^2+11r+14}$	$-\frac{1}{14}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{4r^4 + 60r^3 + 325r^2 + 750r + 616}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{616}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{2r^2+11r+14}$	$-\frac{1}{14}$
a_3	0	0
a_4	$\frac{1}{4r^4+60r^3+325r^2+750r+616}$	$\frac{1}{616}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{2r^2+11r+14}$	$-\frac{1}{14}$
a_3	0	0
a_4	$\frac{1}{4r^4+60r^3+325r^2+750r+616}$	$\frac{1}{616}$
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots \\
&= 1 - \frac{x^2}{14} + \frac{x^4}{616} + O(x^6)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$b_1 = 0$$

For $2 \leq n$ the recursive equation is

$$2b_n(n + r)(n + r - 1) + 5(n + r) b_n + b_{n-2} = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{b_{n-2}}{2n^2 + 4nr + 2r^2 + 3n + 3r} \tag{4}$$

Which for the root $r = -\frac{3}{2}$ becomes

$$b_n = -\frac{b_{n-2}}{n (2n - 3)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{3}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{1}{2r^2 + 11r + 14}$$

Which for the root $r = -\frac{3}{2}$ becomes

$$b_2 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{2r^2+11r+14}$	$-\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{2r^2+11r+14}$	$-\frac{1}{2}$
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{4r^4 + 60r^3 + 325r^2 + 750r + 616}$$

Which for the root $r = -\frac{3}{2}$ becomes

$$b_4 = \frac{1}{40}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{2r^2+11r+14}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{1}{4r^4+60r^3+325r^2+750r+616}$	$\frac{1}{40}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{2r^2+11r+14}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{1}{4r^4+60r^3+325r^2+750r+616}$	$\frac{1}{40}$
b_5	0	0

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= 1\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= \frac{1 - \frac{x^2}{2} + \frac{x^4}{40} + O(x^6)}{x^{\frac{3}{2}}}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 \left(1 - \frac{x^2}{14} + \frac{x^4}{616} + O(x^6)\right) + \frac{c_2 \left(1 - \frac{x^2}{2} + \frac{x^4}{40} + O(x^6)\right)}{x^{\frac{3}{2}}}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 \left(1 - \frac{x^2}{14} + \frac{x^4}{616} + O(x^6)\right) + \frac{c_2 \left(1 - \frac{x^2}{2} + \frac{x^4}{40} + O(x^6)\right)}{x^{\frac{3}{2}}}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \left(1 - \frac{x^2}{14} + \frac{x^4}{616} + O(x^6)\right) + \frac{c_2 \left(1 - \frac{x^2}{2} + \frac{x^4}{40} + O(x^6)\right)}{x^{\frac{3}{2}}} \tag{1}
$$

Verification of solutions

$$
y = c_1 \left(1 - \frac{x^2}{14} + \frac{x^4}{616} + O(x^6)\right) + \frac{c_2 \left(1 - \frac{x^2}{2} + \frac{x^4}{40} + O(x^6)\right)}{x^{\frac{3}{2}}}
$$

Verified OK.

23.1.1 Maple step by step solution

Let's solve

$2y''x + 5y' + yx = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

$y'' = -\frac{5y'}{2x} - \frac{y}{2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' + \frac{5y'}{2x} + \frac{y}{2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- Define functions

$\left[P_2(x) = \frac{5}{2x}, P_3(x) = \frac{1}{2}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

$\left(x \cdot P_2(x)\right)\Big|_{x=0} = \frac{5}{2}$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 0$

- $x = 0$is a regular singular point

Check to see if $x_0 = 0$ is a regular singular point

$x_0 = 0$

- Multiply by denominators

$2y''x + 5y' + yx = 0$

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x \cdot y$ to series expansion

$x \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+1}$

- Shift index using $k- >k - 1$

$x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^{k+r}$

- Convert y' to series expansion

$y' = \sum_{k=0}^{\infty} a_k(k + r)\, x^{k+r-1}$

- Shift index using $k- >k + 1$

$$y' = \sum_{k=-1}^{\infty} a_{k+1}(k+r+1)\, x^{k+r}$$

- Convert $x \cdot y''$ to series expansion

$$x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$$

- Shift index using $k->k+1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+r+1)\,(k+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(3+2r)\, x^{-1+r} + a_1(1+r)\,(5+2r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+r+1)\,(2k+5+2r) + a_{k-1}\right) x^{k+r}\right) =$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(3+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, -\frac{3}{2}\right\}$$

- Each term must be 0

$$a_1(1+r)\,(5+2r) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$2(k+r+1)\left(k+\frac{5}{2}+r\right) a_{k+1} + a_{k-1} = 0$$

- Shift index using $k->k+1$

$$2(k+2+r)\left(k+\frac{7}{2}+r\right) a_{k+2} + a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{a_k}{(k+2+r)(2k+7+2r)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{a_k}{(k+2)(2k+7)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k}{(k+2)(2k+7)}, 5a_1 = 0\right]$$

- Recursion relation for $r = -\frac{3}{2}$

$$a_{k+2} = -\frac{a_k}{\left(k+\frac{1}{2}\right)(2k+4)}$$

- Solution for $r = -\frac{3}{2}$

$$\left[y=\sum_{k=0}^{\infty} a_k x^{k-\frac{3}{2}}, a_{k+2}=-\frac{a_k}{\left(k+\frac{1}{2}\right)(2k+4)}, -a_1=0\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_k x^k\right)+\left(\sum_{k=0}^{\infty} b_k x^{k-\frac{3}{2}}\right), a_{k+2}=-\frac{a_k}{(k+2)(2k+7)}, 5a_1=0, b_{k+2}=-\frac{b_k}{\left(k+\frac{1}{2}\right)(2k+4)}, -b_1=0\right]$$

$$p(x) = -\frac{4}{3x\,(2+3x)}$$
$$q(x) = \frac{4}{3x\,(2+3x)}$$

Table 638: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{4}{3x(2+3x)}$	
singularity	type
$x = 0$	"regular"
$x = -\frac{2}{3}$	"regular"

$q(x) = \frac{4}{3x(2+3x)}$	
singularity	type
$x = 0$	"regular"
$x = -\frac{2}{3}$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $\left[0, -\frac{2}{3}, \infty\right]$

Irregular singular points : []

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$3x(2+3x)\, y'' - 4y' + 4y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$3x(2+3x)\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) - 4\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + 4\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 9x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 6x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-4(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 4a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 9x^{n+r} a_n (n+r)(n+r-1) = \sum_{n=1}^{\infty} 9a_{n-1}(n+r-1)(n+r-2)\, x^{n+r-1}$$

$$\sum_{n=0}^{\infty} 4a_n x^{n+r} = \sum_{n=1}^{\infty} 4a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=1}^{\infty} 9a_{n-1}(n+r-1)(n+r-2)\, x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 6x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-4(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} 4a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$6x^{n+r-1} a_n (n+r)(n+r-1) - 4(n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$6x^{-1+r} a_0 r(-1+r) - 4r a_0 x^{-1+r} = 0$$

Or

$$\left(6x^{-1+r} r(-1+r) - 4r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(6r^2 - 10r\right) x^{-1+r} = 0$$

Since the above is true for all x then the indicial equation becomes

$$6r^2 - 10r = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{5}{3}$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(6r^2 - 10r\right) x^{-1+r} = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{5}{3}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{5}{3}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^n$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$9a_{n-1}(n + r - 1)(n + r - 2) + 6a_n(n + r)(n + r - 1) - 4a_n(n + r) + 4a_{n-1} = 0 \quad (3)$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}(9n^2 + 18nr + 9r^2 - 27n - 27r + 22)}{2\left(3n^2 + 6nr + 3r^2 - 5n - 5r\right)} \quad (4)$$

Which for the root $r = \frac{5}{3}$ becomes

$$a_n = -\frac{a_{n-1}(9n^2 + 3n + 2)}{6n^2 + 10n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{5}{3}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{-9r^2 + 9r - 4}{6r^2 + 2r - 4}$$

Which for the root $r = \frac{5}{3}$ becomes

$$a_1 = -\frac{7}{8}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-9r^2+9r-4}{6r^2+2r-4}$	$-\frac{7}{8}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{81r^4 - 9r^2 + 16}{36r^4 + 96r^3 + 28r^2 - 48r - 16}$$

Which for the root $r = \frac{5}{3}$ becomes

$$a_2 = \frac{7}{8}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-9r^2+9r-4}{6r^2+2r-4}$	$-\frac{7}{8}$
a_2	$\frac{81r^4-9r^2+16}{36r^4+96r^3+28r^2-48r-16}$	$\frac{7}{8}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{-729r^6 - 2187r^5 - 1701r^4 + 243r^3 + 54r^2 - 432r - 352}{216r^6 + 1512r^5 + 3528r^4 + 2744r^3 - 672r^2 - 1568r - 384}$$

Which for the root $r = \frac{5}{3}$ becomes

$$a_3 = -\frac{23}{24}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-9r^2+9r-4}{6r^2+2r-4}$	$-\frac{7}{8}$
a_2	$\frac{81r^4-9r^2+16}{36r^4+96r^3+28r^2-48r-16}$	$\frac{7}{8}$
a_3	$\frac{-729r^6-2187r^5-1701r^4+243r^3+54r^2-432r-352}{216r^6+1512r^5+3528r^4+2744r^3-672r^2-1568r-384}$	$-\frac{23}{24}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{(9r^2 - 9r + 4)(9r^2 + 9r + 4)(9r^2 + 45r + 58)(9r^2 + 27r + 22)}{16(27r^6 + 189r^5 + 441r^4 + 343r^3 - 84r^2 - 196r - 48)(3r^2 + 19r + 28)}$$

Which for the root $r = \frac{5}{3}$ becomes

$$a_4 = \frac{1817}{1632}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-9r^2+9r-4}{6r^2+2r-4}$	$-\frac{7}{8}$
a_2	$\frac{81r^4-9r^2+16}{36r^4+96r^3+28r^2-48r-16}$	$\frac{7}{8}$
a_3	$\frac{-729r^6-2187r^5-1701r^4+243r^3+54r^2-432r-352}{216r^6+1512r^5+3528r^4+2744r^3-672r^2-1568r-384}$	$-\frac{23}{24}$
a_4	$\frac{(9r^2-9r+4)(9r^2+9r+4)(9r^2+45r+58)(9r^2+27r+22)}{16(27r^6+189r^5+441r^4+343r^3-84r^2-196r-48)(3r^2+19r+28)}$	$\frac{1817}{1632}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{(9r^2 - 9r + 4)(9r^2 + 9r + 4)(9r^2 + 45r + 58)(9r^2 + 27r + 22)(9r^2 + 63r + 112)}{32(27r^6 + 189r^5 + 441r^4 + 343r^3 - 84r^2 - 196r - 48)(3r^2 + 19r + 28)(3r^2 + 25r + 50)}$$

Which for the root $r = \frac{5}{3}$ becomes

$$a_5 = -\frac{219857}{163200}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-9r^2+9r-4}{6r^2+2r-4}$	$-\frac{7}{8}$
a_2	$\frac{81r^4-9r^2+16}{36r^4+96r^3+28r^2-48r-16}$	$\frac{7}{8}$
a_3	$\frac{-729r^6-2187r^5-1701r^4+243r^3+54r^2-432r-352}{216r^6+1512r^5+3528r^4+2744r^3-672r^2-1568r-384}$	$-\frac{23}{24}$
a_4	$\frac{(9r^2-9r+4)(9r^2+9r+4)(9r^2+45r+58)(9r^2+27r+22)}{16(27r^6+189r^5+441r^4+343r^3-84r^2-196r-48)(3r^2+19r+28)}$	$\frac{1817}{1632}$
a_5	$-\frac{(9r^2-9r+4)(9r^2+9r+4)(9r^2+45r+58)(9r^2+27r+22)(9r^2+63r+112)}{32(27r^6+189r^5+441r^4+343r^3-84r^2-196r-48)(3r^2+19r+28)(3r^2+25r+50)}$	$-\frac{219857}{163200}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{5}{3}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^{\frac{5}{3}}\left(1 - \frac{7x}{8} + \frac{7x^2}{8} - \frac{23x^3}{24} + \frac{1817x^4}{1632} - \frac{219857x^5}{163200} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$9b_{n-1}(n+r-1)(n+r-2) + 6b_n(n+r)(n+r-1) - 4(n+r)b_n + 4b_{n-1} = 0 \quad (3)$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{b_{n-1}(9n^2 + 18nr + 9r^2 - 27n - 27r + 22)}{2(3n^2 + 6nr + 3r^2 - 5n - 5r)} \quad (4)$$

Which for the root $r = 0$ becomes

$$b_n = -\frac{9b_{n-1}\left(n^2 - 3n + \frac{22}{9}\right)}{6n^2 - 10n} \quad (5)$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{-9r^2 + 9r - 4}{6r^2 + 2r - 4}$$

Which for the root $r = 0$ becomes

$$b_1 = 1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-9r^2+9r-4}{6r^2+2r-4}$	1

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{81r^4 - 9r^2 + 16}{36r^4 + 96r^3 + 28r^2 - 48r - 16}$$

Which for the root $r = 0$ becomes

$$b_2 = -1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-9r^2+9r-4}{6r^2+2r-4}$	1
b_2	$\frac{81r^4-9r^2+16}{36r^4+96r^3+28r^2-48r-16}$	-1

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{-729r^6 - 2187r^5 - 1701r^4 + 243r^3 + 54r^2 - 432r - 352}{216r^6 + 1512r^5 + 3528r^4 + 2744r^3 - 672r^2 - 1568r - 384}$$

Which for the root $r = 0$ becomes

$$b_3 = \frac{11}{12}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-9r^2+9r-4}{6r^2+2r-4}$	1
b_2	$\frac{81r^4-9r^2+16}{36r^4+96r^3+28r^2-48r-16}$	-1
b_3	$\frac{-729r^6-2187r^5-1701r^4+243r^3+54r^2-432r-352}{216r^6+1512r^5+3528r^4+2744r^3-672r^2-1568r-384}$	$\frac{11}{12}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{(9r^2-9r+4)(9r^2+9r+4)(9r^2+45r+58)(9r^2+27r+22)}{16(27r^6+189r^5+441r^4+343r^3-84r^2-196r-48)(3r^2+19r+28)}$$

Which for the root $r = 0$ becomes

$$b_4 = -\frac{319}{336}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-9r^2+9r-4}{6r^2+2r-4}$	1
b_2	$\frac{81r^4-9r^2+16}{36r^4+96r^3+28r^2-48r-16}$	-1
b_3	$\frac{-729r^6-2187r^5-1701r^4+243r^3+54r^2-432r-352}{216r^6+1512r^5+3528r^4+2744r^3-672r^2-1568r-384}$	$\frac{11}{12}$
b_4	$\frac{(9r^2-9r+4)(9r^2+9r+4)(9r^2+45r+58)(9r^2+27r+22)}{16(27r^6+189r^5+441r^4+343r^3-84r^2-196r-48)(3r^2+19r+28)}$	$-\frac{319}{336}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{(9r^2-9r+4)(9r^2+9r+4)(9r^2+45r+58)(9r^2+27r+22)(9r^2+63r+112)}{32(27r^6+189r^5+441r^4+343r^3-84r^2-196r-48)(3r^2+19r+28)(3r^2+25r+50)}$$

Which for the root $r = 0$ becomes

$$b_5 = \frac{319}{300}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-9r^2+9r-4}{6r^2+2r-4}$	1
b_2	$\frac{81r^4-9r^2+16}{36r^4+96r^3+28r^2-48r-16}$	-1
b_3	$\frac{-729r^6-2187r^5-1701r^4+243r^3+54r^2-432r-352}{216r^6+1512r^5+3528r^4+2744r^3-672r^2-1568r-384}$	$\frac{11}{12}$
b_4	$\frac{(9r^2-9r+4)(9r^2+9r+4)(9r^2+45r+58)(9r^2+27r+22)}{16(27r^6+189r^5+441r^4+343r^3-84r^2-196r-48)(3r^2+19r+28)}$	$-\frac{319}{336}$
b_5	$-\frac{(9r^2-9r+4)(9r^2+9r+4)(9r^2+45r+58)(9r^2+27r+22)(9r^2+63r+112)}{32(27r^6+189r^5+441r^4+343r^3-84r^2-196r-48)(3r^2+19r+28)(3r^2+25r+50)}$	$\frac{319}{300}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots \\
&= 1 + x - x^2 + \frac{11x^3}{12} - \frac{319x^4}{336} + \frac{319x^5}{300} + O(x^6)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{\frac{5}{3}} \left(1 - \frac{7x}{8} + \frac{7x^2}{8} - \frac{23x^3}{24} + \frac{1817x^4}{1632} - \frac{219857x^5}{163200} + O(x^6)\right) \\
&\quad + c_2 \left(1 + x - x^2 + \frac{11x^3}{12} - \frac{319x^4}{336} + \frac{319x^5}{300} + O(x^6)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{\frac{5}{3}} \left(1 - \frac{7x}{8} + \frac{7x^2}{8} - \frac{23x^3}{24} + \frac{1817x^4}{1632} - \frac{219857x^5}{163200} + O(x^6)\right) \\
&\quad + c_2 \left(1 + x - x^2 + \frac{11x^3}{12} - \frac{319x^4}{336} + \frac{319x^5}{300} + O(x^6)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = c_1 x^{\frac{5}{3}} \left(1 - \frac{7x}{8} + \frac{7x^2}{8} - \frac{23x^3}{24} + \frac{1817x^4}{1632} - \frac{219857x^5}{163200} + O(x^6)\right) \\
+ c_2 \left(1 + x - x^2 + \frac{11x^3}{12} - \frac{319x^4}{336} + \frac{319x^5}{300} + O(x^6)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$y = c_1 x^{\frac{5}{3}} \left(1 - \frac{7x}{8} + \frac{7x^2}{8} - \frac{23x^3}{24} + \frac{1817x^4}{1632} - \frac{219857x^5}{163200} + O(x^6)\right) + c_2 \left(1 + x - x^2 + \frac{11x^3}{12} - \frac{319x^4}{336} + \frac{319x^5}{300} + O(x^6)\right)$$

Verified OK.

23.2.1 Maple step by step solution

Let's solve

$3x(2+3x)\,y'' - 4y' + 4y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{4y}{3x(2+3x)} + \frac{4y'}{3x(2+3x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{4y'}{3x(2+3x)} + \frac{4y}{3x(2+3x)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = -\frac{4}{3x(2+3x)}, P_3(x) = \frac{4}{3x(2+3x)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\bigg|_{x=0} = -\frac{2}{3}$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $3x(2+3x)\,y'' - 4y' + 4y = 0$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

  ◦ Convert y' to series expansion

$$y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1}$$

  ◦ Shift index using $k->k+1$

$$y' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, x^{k+r}$$

  ◦ Convert $x^m \cdot y''$ to series expansion for $m = 1..2$

$$x^m \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

  ◦ Shift index using $k->k+2-m$

$$x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$2a_0r(-5+3r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} (2a_{k+1}(k+1+r)\,(3k-2+3r) + a_k(9k^2+18kr+9r^2-9k-9r+$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$2r(-5+3r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, \frac{5}{3}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$6(k+1+r)\left(k-\frac{2}{3}+r\right) a_{k+1} + 9\left(k^2+(2r-1)\,k+r^2-r+\frac{4}{9}\right) a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{(9k^2+18kr+9r^2-9k-9r+4)a_k}{2(k+1+r)(3k-2+3r)}$$

- Recursion relation for $r = 0$

$$a_{k+1} = -\frac{(9k^2-9k+4)a_k}{2(k+1)(3k-2)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = -\frac{(9k^2-9k+4)a_k}{2(k+1)(3k-2)}\right]$$

- Recursion relation for $r = \frac{5}{3}$

  $a_{k+1} = -\frac{(9k^2+21k+14)a_k}{2(k+\frac{8}{3})(3k+3)}$

- Solution for $r = \frac{5}{3}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{5}{3}}, a_{k+1} = -\frac{(9k^2+21k+14)a_k}{2(k+\frac{8}{3})(3k+3)}\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{5}{3}}\right), a_{k+1} = -\frac{(9k^2-9k+4)a_k}{2(k+1)(3k-2)}, b_{k+1} = -\frac{(9k^2+21k+14)b_k}{2(k+\frac{8}{3})(3k+3)}\right]$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 41, page 195
Problem number: 3.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2(x+4)\,y''+7xy'-y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(x^3+4x^2\right)y''+7xy'-y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=\frac{7}{x\,(x+4)}$$
$$q(x)=-\frac{1}{x^2\,(x+4)}$$

Table 640: Table $p(x), q(x)$ singularites.

$p(x) = \frac{7}{x(x+4)}$	
singularity	type
$x = -4$	"regular"
$x = 0$	"regular"

$q(x) = -\frac{1}{x^2(x+4)}$	
singularity	type
$x = -4$	"regular"
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-4, 0, \infty]$

Irregular singular points : $[]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2(x+4)\, y'' + 7xy' - y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2(x+4)\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + 7x\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 4x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 7x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1) = \sum_{n=1}^{\infty} a_{n-1}(n+r-1)(n+r-2)\, x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1)(n+r-2)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 4x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 7x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$4x^{n+r} a_n (n+r)(n+r-1) + 7x^{n+r} a_n (n+r) - a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$4x^r a_0 r(-1+r) + 7x^r a_0 r - a_0 x^r = 0$$

Or

$$\left(4x^r r(-1+r) + 7x^r r - x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(4r^2 + 3r - 1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$4r^2 + 3r - 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{4}$$
$$r_2 = -1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(4r^2 + 3r - 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{5}{4}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{4}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-1}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_{n-1}(n + r - 1)(n + r - 2) + 4a_n(n + r)(n + r - 1) + 7a_n(n + r) - a_n = 0 \quad (3)$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}(n + r - 1)(n + r - 2)}{4n^2 + 8nr + 4r^2 + 3n + 3r - 1} \quad (4)$$

Which for the root $r = \frac{1}{4}$ becomes

$$a_n = -\frac{a_{n-1}(16n^2 - 40n + 21)}{64n^2 + 80n} \quad (5)$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{4}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{r(-1+r)}{4r^2 + 11r + 6}$$

Which for the root $r = \frac{1}{4}$ becomes

$$a_1 = \frac{1}{48}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r(-1+r)}{4r^2+11r+6}$	$\frac{1}{48}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r^2(r^2 - 1)}{(4r^2 + 11r + 6)(4r^2 + 19r + 21)}$$

Which for the root $r = \frac{1}{4}$ becomes

$$a_2 = -\frac{5}{19968}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r(-1+r)}{4r^2+11r+6}$	$\frac{1}{48}$
a_2	$\frac{r^2(r^2-1)}{(4r^2+11r+6)(4r^2+19r+21)}$	$-\frac{5}{19968}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{(1+r)^2 r^2(-1+r)}{64r^5 + 784r^4 + 3644r^3 + 7931r^2 + 7905r + 2772}$$

Which for the root $r = \frac{1}{4}$ becomes

$$a_3 = \frac{25}{1810432}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r(-1+r)}{4r^2+11r+6}$	$\frac{1}{48}$
a_2	$\frac{r^2(r^2-1)}{(4r^2+11r+6)(4r^2+19r+21)}$	$-\frac{5}{19968}$
a_3	$-\frac{(1+r)^2 r^2(-1+r)}{64r^5+784r^4+3644r^3+7931r^2+7905r+2772}$	$\frac{25}{1810432}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{(2+r)(1+r)^2 r^2(-1+r)}{256r^6 + 4608r^5 + 32992r^4 + 119088r^3 + 225241r^2 + 206865r + 69300}$$

Which for the root $r = \frac{1}{4}$ becomes

$$a_4 = -\frac{75}{62390272}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r(-1+r)}{4r^2+11r+6}$	$\frac{1}{48}$
a_2	$\frac{r^2(r^2-1)}{(4r^2+11r+6)(4r^2+19r+21)}$	$-\frac{5}{19968}$
a_3	$-\frac{(1+r)^2 r^2(-1+r)}{64r^5+784r^4+3644r^3+7931r^2+7905r+2772}$	$\frac{25}{1810432}$
a_4	$\frac{(2+r)(1+r)^2 r^2(-1+r)}{256r^6+4608r^5+32992r^4+119088r^3+225241r^2+206865r+69300}$	$-\frac{75}{62390272}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{(3+r)(2+r)(1+r)^2 r^2(-1+r)}{1024r^7 + 25344r^6 + 257920r^5 + 1388640r^4 + 4228276r^3 + 7175751r^2 + 6146865r + 1975050}$$

Which for the root $r = \frac{1}{4}$ becomes

$$a_5 = \frac{39}{293601280}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r(-1+r)}{4r^2+11r+6}$	$\frac{1}{48}$
a_2	$\frac{r^2(r^2-1)}{(4r^2+11r+6)(4r^2+19r+21)}$	$-\frac{5}{19968}$
a_3	$-\frac{(1+r)^2 r^2(-1+r)}{64r^5+784r^4+3644r^3+7931r^2+7905r+2772}$	$\frac{25}{1810432}$
a_4	$\frac{(2+r)(1+r)^2 r^2(-1+r)}{256r^6+4608r^5+32992r^4+119088r^3+225241r^2+206865r+69300}$	$-\frac{75}{62390272}$
a_5	$-\frac{(3+r)(2+r)(1+r)^2 r^2(-1+r)}{1024r^7+25344r^6+257920r^5+1388640r^4+4228276r^3+7175751r^2+6146865r+1975050}$	$\frac{39}{293601280}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{1}{4}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^{\frac{1}{4}}\left(1 + \frac{x}{48} - \frac{5x^2}{19968} + \frac{25x^3}{1810432} - \frac{75x^4}{62390272} + \frac{39x^5}{293601280} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$b_{n-1}(n+r-1)(n+r-2) + 4b_n(n+r)(n+r-1) + 7b_n(n+r) - b_n = 0 \quad (3)$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{b_{n-1}(n+r-1)(n+r-2)}{4n^2+8nr+4r^2+3n+3r-1} \quad (4)$$

Which for the root $r = -1$ becomes

$$b_n = -\frac{b_{n-1}(n-2)(n-3)}{n(4n-5)} \quad (5)$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = -\frac{r(-1+r)}{4r^2 + 11r + 6}$$

Which for the root $r = -1$ becomes

$$b_1 = 2$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{r(-1+r)}{4r^2+11r+6}$	2

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{r^2(r^2-1)}{(4r^2+11r+6)(4r^2+19r+21)}$$

Which for the root $r = -1$ becomes

$$b_2 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{r(-1+r)}{4r^2+11r+6}$	2
b_2	$\frac{r^2(r^2-1)}{(4r^2+11r+6)(4r^2+19r+21)}$	0

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{(1+r)^2 r^2(-1+r)}{64r^5 + 784r^4 + 3644r^3 + 7931r^2 + 7905r + 2772}$$

Which for the root $r = -1$ becomes

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{r(-1+r)}{4r^2+11r+6}$	2
b_2	$\frac{r^2(r^2-1)}{(4r^2+11r+6)(4r^2+19r+21)}$	0
b_3	$-\frac{(1+r)^2 r^2(-1+r)}{64r^5+784r^4+3644r^3+7931r^2+7905r+2772}$	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{(2+r)(1+r)^2 r^2(-1+r)}{256r^6 + 4608r^5 + 32992r^4 + 119088r^3 + 225241r^2 + 206865r + 69300}$$

Which for the root $r = -1$ becomes

$$b_4 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{r(-1+r)}{4r^2+11r+6}$	2
b_2	$\frac{r^2(r^2-1)}{(4r^2+11r+6)(4r^2+19r+21)}$	0
b_3	$-\frac{(1+r)^2 r^2(-1+r)}{64r^5+784r^4+3644r^3+7931r^2+7905r+2772}$	0
b_4	$\frac{(2+r)(1+r)^2 r^2(-1+r)}{256r^6+4608r^5+32992r^4+119088r^3+225241r^2+206865r+69300}$	0

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{(3+r)(2+r)(1+r)^2 r^2(-1+r)}{1024r^7 + 25344r^6 + 257920r^5 + 1388640r^4 + 4228276r^3 + 7175751r^2 + 6146865r + 1975050}$$

Which for the root $r = -1$ becomes

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{r(-1+r)}{4r^2+11r+6}$	2
b_2	$\frac{r^2(r^2-1)}{(4r^2+11r+6)(4r^2+19r+21)}$	0
b_3	$-\frac{(1+r)^2 r^2(-1+r)}{64r^5+784r^4+3644r^3+7931r^2+7905r+2772}$	0
b_4	$\frac{(2+r)(1+r)^2 r^2(-1+r)}{256r^6+4608r^5+32992r^4+119088r^3+225241r^2+206865r+69300}$	0
b_5	$-\frac{(3+r)(2+r)(1+r)^2 r^2(-1+r)}{1024r^7+25344r^6+257920r^5+1388640r^4+4228276r^3+7175751r^2+6146865r+1975050}$	0

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x^{\frac{1}{4}}\left(b_0+b_1x+b_2x^2+b_3x^3+b_4x^4+b_5x^5+b_6x^6\dots\right) \\
&= \frac{1+2x+O(x^6)}{x}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1y_1(x)+c_2y_2(x) \\
&= c_1x^{\frac{1}{4}}\left(1+\frac{x}{48}-\frac{5x^2}{19968}+\frac{25x^3}{1810432}-\frac{75x^4}{62390272}+\frac{39x^5}{293601280}+O(x^6)\right) \\
&\quad+\frac{c_2(1+2x+O(x^6))}{x}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1x^{\frac{1}{4}}\left(1+\frac{x}{48}-\frac{5x^2}{19968}+\frac{25x^3}{1810432}-\frac{75x^4}{62390272}+\frac{39x^5}{293601280}+O(x^6)\right) \\
&\quad+\frac{c_2(1+2x+O(x^6))}{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = c_1x^{\frac{1}{4}}&\left(1+\frac{x}{48}-\frac{5x^2}{19968}+\frac{25x^3}{1810432}-\frac{75x^4}{62390272}+\frac{39x^5}{293601280}+O(x^6)\right) \\
&+\frac{c_2(1+2x+O(x^6))}{x}
\end{aligned} \tag{1}
$$

Verification of solutions

$$y = c_1 x^{\frac{1}{4}} \left(1 + \frac{x}{48} - \frac{5x^2}{19968} + \frac{25x^3}{1810432} - \frac{75x^4}{62390272} + \frac{39x^5}{293601280} + O(x^6)\right) + \frac{c_2(1 + 2x + O(x^6))}{x}$$

Verified OK.

23.3.1 Maple step by step solution

Let's solve

$x^2(x+4)\, y'' + 7xy' - y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{y}{x^2(x+4)} - \frac{7y'}{x(x+4)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{7y'}{x(x+4)} - \frac{y}{x^2(x+4)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{7}{x(x+4)}, P_3(x) = -\frac{1}{x^2(x+4)}\right]$

  ◦ $(x+4) \cdot P_2(x)$ is analytic at $x = -4$

    $\left((x+4) \cdot P_2(x)\right)\Big|_{x=-4} = -\frac{7}{4}$

  ◦ $(x+4)^2 \cdot P_3(x)$ is analytic at $x = -4$

    $\left((x+4)^2 \cdot P_3(x)\right)\Big|_{x=-4} = 0$

  ◦ $x = -4$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -4$

- Multiply by denominators

  $x^2(x+4)\, y'' + 7xy' - y = 0$

- Change variables using $x = u - 4$ so that the regular singular point is at $u = 0$

$$\left(u^{3}-8u^{2}+16u\right)\left(\frac{d^{2}}{du^{2}}y(u)\right)+\left(7u-28\right)\left(\frac{d}{du}y(u)\right)-y(u)=0$$

- Assume series solution for $y(u)$

$$y(u)=\sum_{k=0}^{\infty}a_{k}u^{k+r}$$

□ Rewrite ODE with series expansions

  - Convert $u^{m}\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

$$u^{m}\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_{k}(k+r)\,u^{k+r-1+m}$$

  - Shift index using $k->k+1-m$

$$u^{m}\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

  - Convert $u^{m}\cdot\left(\frac{d^{2}}{du^{2}}y(u)\right)$ to series expansion for $m=1..3$

$$u^{m}\cdot\left(\frac{d^{2}}{du^{2}}y(u)\right)=\sum_{k=0}^{\infty}a_{k}(k+r)\,(k+r-1)\,u^{k+r-2+m}$$

  - Shift index using $k->k+2-m$

$$u^{m}\cdot\left(\frac{d^{2}}{du^{2}}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$4a_{0}r(-11+4r)\,u^{-1+r}+\left(4a_{1}(1+r)\,(-7+4r)-a_{0}(8r^{2}-15r+1)\right)u^{r}+\left(\sum_{k=1}^{\infty}(4a_{k+1}(k+1+r)\right.$$

- a_{0}cannot be 0 by assumption, giving the indicial equation

$$4r(-11+4r)=0$$

- Values of r that satisfy the indicial equation

$$r\in\left\{0,\frac{11}{4}\right\}$$

- Each term must be 0

$$4a_{1}(1+r)\,(-7+4r)-a_{0}(8r^{2}-15r+1)=0$$

- Each term in the series must be 0, giving the recursion relation

$$\left(-8a_{k}+a_{k-1}+16a_{k+1}\right)k^{2}+\left(2(-8a_{k}+a_{k-1}+16a_{k+1})\,r+15a_{k}-3a_{k-1}-12a_{k+1}\right)k+(-8a_{k}+$$

- Shift index using $k->k+1$

$$\left(-8a_{k+1}+a_{k}+16a_{k+2}\right)(k+1)^{2}+\left(2(-8a_{k+1}+a_{k}+16a_{k+2})\,r+15a_{k+1}-3a_{k}-12a_{k+2}\right)(k+1$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} + 2kra_k - 16kra_{k+1} + r^2 a_k - 8r^2 a_{k+1} - ka_k - ka_{k+1} - ra_k - ra_{k+1} + 6a_{k+1}}{4(4k^2 + 8kr + 4r^2 + 5k + 5r - 6)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} - ka_k - ka_{k+1} + 6a_{k+1}}{4(4k^2 + 5k - 6)}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} - ka_k - ka_{k+1} + 6a_{k+1}}{4(4k^2 + 5k - 6)}, -28a_1 - a_0 = 0\right]$$

- Revert the change of variables $u = x + 4$

$$\left[y = \sum_{k=0}^{\infty} a_k (x+4)^k, a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} - ka_k - ka_{k+1} + 6a_{k+1}}{4(4k^2 + 5k - 6)}, -28a_1 - a_0 = 0\right]$$

- Recursion relation for $r = \frac{11}{4}$

$$a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} + \frac{9}{2}ka_k - 45ka_{k+1} + \frac{77}{16}a_k - \frac{229}{4}a_{k+1}}{4(4k^2 + 27k + 38)}$$

- Solution for $r = \frac{11}{4}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{11}{4}}, a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} + \frac{9}{2}ka_k - 45ka_{k+1} + \frac{77}{16}a_k - \frac{229}{4}a_{k+1}}{4(4k^2 + 27k + 38)}, 60a_1 - \frac{81a_0}{4} = 0\right]$$

- Revert the change of variables $u = x + 4$

$$\left[y = \sum_{k=0}^{\infty} a_k (x+4)^{k+\frac{11}{4}}, a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} + \frac{9}{2}ka_k - 45ka_{k+1} + \frac{77}{16}a_k - \frac{229}{4}a_{k+1}}{4(4k^2 + 27k + 38)}, 60a_1 - \frac{81a_0}{4} = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k (x+4)^k\right) + \left(\sum_{k=0}^{\infty} b_k (x+4)^{k+\frac{11}{4}}\right), a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} - ka_k - ka_{k+1} + 6a_{k+1}}{4(4k^2 + 5k - 6)}, -28a_1 - a$$

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{2x^2y'' + \left(-x^2+x\right)y' - y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2x^2y'' + \left(-x^2+x\right)y' - y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{x-1}{2x}$$
$$q(x) = -\frac{1}{2x^2}$$

Table 642: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x-1}{2x}$	
singularity	type
$x = 0$	"regular"

$q(x) = -\frac{1}{2x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2x^2y'' + (-x^2 + x)\, y' - y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2x^2 \left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + (-x^2 + x) \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)\right) = \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r} a_n (n+r)(n+r-1) + x^{n+r} a_n (n+r) - a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$2x^r a_0 r(-1+r) + x^r a_0 r - a_0 x^r = 0$$

Or

$$\left(2x^r r(-1+r) + x^r r - x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(2r^2 - r - 1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 - r - 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = -\frac{1}{2}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(2r^2 - r - 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{3}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{1+n}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-\frac{1}{2}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$2a_n(n+r)(n+r-1) - a_{n-1}(n+r-1) + a_n(n+r) - a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}}{2n+2r+1} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = \frac{a_{n-1}}{2n+3} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{1}{3 + 2r}$$

Which for the root $r = 1$ becomes

$$a_1 = \frac{1}{5}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{5}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{4r^2 + 16r + 15}$$

Which for the root $r = 1$ becomes

$$a_2 = \frac{1}{35}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{5}$
a_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{35}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{1}{8r^3 + 60r^2 + 142r + 105}$$

Which for the root $r = 1$ becomes

$$a_3 = \frac{1}{315}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{5}$
a_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{35}$
a_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{315}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{16r^4 + 192r^3 + 824r^2 + 1488r + 945}$$

Which for the root $r = 1$ becomes

$$a_4 = \frac{1}{3465}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{5}$
a_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{35}$
a_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{315}$
a_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{3465}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{1}{32r^5 + 560r^4 + 3760r^3 + 12040r^2 + 18258r + 10395}$$

Which for the root $r = 1$ becomes

$$a_5 = \frac{1}{45045}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{5}$
a_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{35}$
a_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{315}$
a_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{3465}$
a_5	$\frac{1}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	$\frac{1}{45045}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}y_1(x) &= x\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots\right)\\ &= x\left(1 + \frac{x}{5} + \frac{x^2}{35} + \frac{x^3}{315} + \frac{x^4}{3465} + \frac{x^5}{45045} + O(x^6)\right)\end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$2b_n(n+r)(n+r-1) - b_{n-1}(n+r-1) + b_n(n+r) - b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = \frac{b_{n-1}}{2n+2r+1} \tag{4}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_n = \frac{b_{n-1}}{2n} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{1}{3+2r}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_1 = \frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{1}{4r^2 + 16r + 15}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_2 = \frac{1}{8}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$
b_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{8}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{1}{8r^3 + 60r^2 + 142r + 105}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_3 = \frac{1}{48}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$
b_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{8}$
b_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{48}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{16r^4 + 192r^3 + 824r^2 + 1488r + 945}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_4 = \frac{1}{384}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$
b_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{8}$
b_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{48}$
b_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{384}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{1}{32r^5 + 560r^4 + 3760r^3 + 12040r^2 + 18258r + 10395}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_5 = \frac{1}{3840}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$
b_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{8}$
b_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{48}$
b_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{384}$
b_5	$\frac{1}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	$\frac{1}{3840}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= \frac{1 + \frac{x}{2} + \frac{x^2}{8} + \frac{x^3}{48} + \frac{x^4}{384} + \frac{x^5}{3840} + O(x^6)}{\sqrt{x}}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x \left(1 + \frac{x}{5} + \frac{x^2}{35} + \frac{x^3}{315} + \frac{x^4}{3465} + \frac{x^5}{45045} + O(x^6)\right) \\
&\quad + \frac{c_2 \left(1 + \frac{x}{2} + \frac{x^2}{8} + \frac{x^3}{48} + \frac{x^4}{384} + \frac{x^5}{3840} + O(x^6)\right)}{\sqrt{x}}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x \left(1 + \frac{x}{5} + \frac{x^2}{35} + \frac{x^3}{315} + \frac{x^4}{3465} + \frac{x^5}{45045} + O(x^6)\right) \\
&\quad + \frac{c_2 \left(1 + \frac{x}{2} + \frac{x^2}{8} + \frac{x^3}{48} + \frac{x^4}{384} + \frac{x^5}{3840} + O(x^6)\right)}{\sqrt{x}}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x \left(1 + \frac{x}{5} + \frac{x^2}{35} + \frac{x^3}{315} + \frac{x^4}{3465} + \frac{x^5}{45045} + O(x^6)\right) \\
&\quad + \frac{c_2 \left(1 + \frac{x}{2} + \frac{x^2}{8} + \frac{x^3}{48} + \frac{x^4}{384} + \frac{x^5}{3840} + O(x^6)\right)}{\sqrt{x}}
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 x \left(1 + \frac{x}{5} + \frac{x^2}{35} + \frac{x^3}{315} + \frac{x^4}{3465} + \frac{x^5}{45045} + O(x^6)\right) \\
&\quad + \frac{c_2 \left(1 + \frac{x}{2} + \frac{x^2}{8} + \frac{x^3}{48} + \frac{x^4}{384} + \frac{x^5}{3840} + O(x^6)\right)}{\sqrt{x}}
\end{aligned}
$$

Verified OK.

23.4.1 Maple step by step solution

Let's solve

$2x^2y'' + (-x^2 + x)\, y' - y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{y}{2x^2} + \frac{(x-1)y'}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{(x-1)y'}{2x} - \frac{y}{2x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = -\frac{x-1}{2x}, P_3(x) = -\frac{1}{2x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = \frac{1}{2}$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = -\frac{1}{2}$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2x^2y'' - x(x-1)\, y' - y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

  ◦ Shift index using $k- >k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^2 \cdot y''$ to series expansion

$$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(1+2r)\,(-1+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(2k+2r+1)\,(k+r-1) - a_{k-1}(k+r-1)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(1+2r)\,(-1+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{1, -\frac{1}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$2\left(\left(k+r+\frac{1}{2}\right) a_k - \frac{a_{k-1}}{2}\right)(k+r-1) = 0$$

- Shift index using $k- >k+1$

$$2\left(\left(k+\frac{3}{2}+r\right) a_{k+1} - \frac{a_k}{2}\right)(k+r) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{a_k}{2k+3+2r}$$

- Recursion relation for $r = 1$

$$a_{k+1} = \frac{a_k}{2k+5}$$

- Solution for $r = 1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+1} = \frac{a_k}{2k+5}\right]$$

- Recursion relation for $r = -\frac{1}{2}$

$$a_{k+1} = \frac{a_k}{2k+2}$$

- Solution for $r = -\frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+1} = \frac{a_k}{2k+2}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-\frac{1}{2}}\right), a_{k+1} = \frac{a_k}{2k+5}, b_{k+1} = \frac{b_k}{2k+2}\right]$$

Problem number: 5.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{2x^2y'' + 5xy' + y(x+1) = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2x^2y'' + 5xy' + y(x+1) = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{5}{2x}$$
$$q(x) = \frac{x+1}{2x^2}$$

Table 644: Table $p(x), q(x)$ singularites.

$p(x) = \frac{5}{2x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{x+1}{2x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2x^2y'' + 5xy' + y(x + 1) = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2x^2 \left(\sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2} \right) + 5x \left(\sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1} \right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r} \right) (x + 1) = 0 \tag{1}$$

Which simplifies to

$$
\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty} 5x^{n+r} a_n (n+r)\right) \tag{2A}
$$
$$
+\left(\sum_{n=0}^{\infty} x^{1+n+r} a_n\right)+\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right)=0
$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$
\sum_{n=0}^{\infty} x^{1+n+r} a_n = \sum_{n=1}^{\infty} a_{n-1} x^{n+r}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$
\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty} 5x^{n+r} a_n (n+r)\right) \tag{2B}
$$
$$
+\left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r}\right)+\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right)=0
$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$
2x^{n+r} a_n (n+r)(n+r-1)+5x^{n+r} a_n (n+r)+a_n x^{n+r}=0
$$

When $n=0$ the above becomes

$$
2x^r a_0 r(-1+r)+5x^r a_0 r+a_0 x^r=0
$$

Or

$$
\left(2x^r r(-1+r)+5x^r r+x^r\right) a_0=0
$$

Since $a_0 \neq 0$ then the above simplifies to

$$
\left(2r^2+3r+1\right) x^r=0
$$

Since the above is true for all x then the indicial equation becomes

$$
2r^2+3r+1=0
$$

Solving for r gives the roots of the indicial equation as

$$r_1 = -\frac{1}{2}$$
$$r_2 = -1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(2r^2 + 3r + 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n-\frac{1}{2}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-1}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$2a_n(n+r)(n+r-1) + 5a_n(n+r) + a_{n-1} + a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}}{2n^2 + 4nr + 2r^2 + 3n + 3r + 1} \tag{4}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$a_n = -\frac{a_{n-1}}{2n^2 + n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = -\frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{1}{2r^2 + 7r + 6}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$a_1 = -\frac{1}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+7r+6}$	$-\frac{1}{3}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{4r^4 + 36r^3 + 119r^2 + 171r + 90}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$a_2 = \frac{1}{30}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+7r+6}$	$-\frac{1}{3}$
a_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{30}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{1}{8r^6 + 132r^5 + 890r^4 + 3135r^3 + 6077r^2 + 6138r + 2520}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$a_3 = -\frac{1}{630}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+7r+6}$	$-\frac{1}{3}$
a_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{30}$
a_3	$-\frac{1}{8r^6+132r^5+890r^4+3135r^3+6077r^2+6138r+2520}$	$-\frac{1}{630}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{16r^8 + 416r^7 + 4648r^6 + 29120r^5 + 111769r^4 + 268814r^3 + 395127r^2 + 324090r + 113400}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$a_4 = \frac{1}{22680}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+7r+6}$	$-\frac{1}{3}$
a_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{30}$
a_3	$-\frac{1}{8r^6+132r^5+890r^4+3135r^3+6077r^2+6138r+2520}$	$-\frac{1}{630}$
a_4	$\frac{1}{16r^8+416r^7+4648r^6+29120r^5+111769r^4+268814r^3+395127r^2+324090r+113400}$	$\frac{1}{22680}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1}{(16r^8 + 416r^7 + 4648r^6 + 29120r^5 + 111769r^4 + 268814r^3 + 395127r^2 + 324090r + 113400)\,(2r^2 -}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$a_5 = -\frac{1}{1247400}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+7r+6}$	$-\frac{1}{3}$
a_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{30}$
a_3	$-\frac{1}{8r^6+132r^5+890r^4+3135r^3+6077r^2+6138r+2520}$	$-\frac{1}{630}$
a_4	$\frac{1}{16r^8+416r^7+4648r^6+29120r^5+111769r^4+268814r^3+395127r^2+324090r+113400}$	$\frac{1}{22680}$
a_5	$-\frac{1}{(16r^8+416r^7+4648r^6+29120r^5+111769r^4+268814r^3+395127r^2+324090r+113400)(2r^2+23r+66)}$	$-\frac{1}{1247400}$

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= \frac{1}{\sqrt{x}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\
&= \frac{1 - \frac{x}{3} + \frac{x^2}{30} - \frac{x^3}{630} + \frac{x^4}{22680} - \frac{x^5}{1247400} + O(x^6)}{\sqrt{x}}
\end{aligned}
$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$
2b_n(n+r)(n+r-1) + 5b_n(n+r) + b_{n-1} + b_n = 0 \tag{3}
$$

Solving for b_n from recursive equation (4) gives

$$
b_n = -\frac{b_{n-1}}{2n^2 + 4nr + 2r^2 + 3n + 3r + 1} \tag{4}
$$

Which for the root $r = -1$ becomes

$$
b_n = -\frac{b_{n-1}}{n(2n-1)} \tag{5}
$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = -\frac{1}{2r^2 + 7r + 6}$$

Which for the root $r = -1$ becomes

$$b_1 = -1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{2r^2+7r+6}$	-1

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{1}{4r^4 + 36r^3 + 119r^2 + 171r + 90}$$

Which for the root $r = -1$ becomes

$$b_2 = \frac{1}{6}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{2r^2+7r+6}$	-1
b_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{6}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{1}{8r^6 + 132r^5 + 890r^4 + 3135r^3 + 6077r^2 + 6138r + 2520}$$

Which for the root $r = -1$ becomes

$$b_3 = -\frac{1}{90}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{2r^2+7r+6}$	-1
b_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{6}$
b_3	$-\frac{1}{8r^6+132r^5+890r^4+3135r^3+6077r^2+6138r+2520}$	$-\frac{1}{90}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{16r^8 + 416r^7 + 4648r^6 + 29120r^5 + 111769r^4 + 268814r^3 + 395127r^2 + 324090r + 113400}$$

Which for the root $r = -1$ becomes

$$b_4 = \frac{1}{2520}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{2r^2+7r+6}$	-1
b_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{6}$
b_3	$-\frac{1}{8r^6+132r^5+890r^4+3135r^3+6077r^2+6138r+2520}$	$-\frac{1}{90}$
b_4	$\frac{1}{16r^8+416r^7+4648r^6+29120r^5+111769r^4+268814r^3+395127r^2+324090r+113400}$	$\frac{1}{2520}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{1}{(16r^8 + 416r^7 + 4648r^6 + 29120r^5 + 111769r^4 + 268814r^3 + 395127r^2 + 324090r + 113400)(2r^2 +}$$

Which for the root $r = -1$ becomes

$$b_5 = -\frac{1}{113400}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{2r^2+7r+6}$	-1
b_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{6}$
b_3	$-\frac{1}{8r^6+132r^5+890r^4+3135r^3+6077r^2+6138r+2520}$	$-\frac{1}{90}$
b_4	$\frac{1}{16r^8+416r^7+4648r^6+29120r^5+111769r^4+268814r^3+395127r^2+324090r+113400}$	$\frac{1}{2520}$
b_5	$-\frac{1}{(16r^8+416r^7+4648r^6+29120r^5+111769r^4+268814r^3+395127r^2+324090r+113400)(2r^2+23r+66)}$	$-\frac{1}{113400}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= \frac{1}{\sqrt{x}}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \ldots\right) \\
&= \frac{1 - x + \frac{x^2}{6} - \frac{x^3}{90} + \frac{x^4}{2520} - \frac{x^5}{113400} + O(x^6)}{x}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= \frac{c_1\left(1 - \frac{x}{3} + \frac{x^2}{30} - \frac{x^3}{630} + \frac{x^4}{22680} - \frac{x^5}{1247400} + O(x^6)\right)}{\sqrt{x}} \\
&\quad + \frac{c_2\left(1 - x + \frac{x^2}{6} - \frac{x^3}{90} + \frac{x^4}{2520} - \frac{x^5}{113400} + O(x^6)\right)}{x}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= \frac{c_1\left(1 - \frac{x}{3} + \frac{x^2}{30} - \frac{x^3}{630} + \frac{x^4}{22680} - \frac{x^5}{1247400} + O(x^6)\right)}{\sqrt{x}} \\
&\quad + \frac{c_2\left(1 - x + \frac{x^2}{6} - \frac{x^3}{90} + \frac{x^4}{2520} - \frac{x^5}{113400} + O(x^6)\right)}{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = \frac{c_1\left(1-\frac{x}{3}+\frac{x^2}{30}-\frac{x^3}{630}+\frac{x^4}{22680}-\frac{x^5}{1247400}+O(x^6)\right)}{\sqrt{x}} + \frac{c_2\left(1-x+\frac{x^2}{6}-\frac{x^3}{90}+\frac{x^4}{2520}-\frac{x^5}{113400}+O(x^6)\right)}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1\left(1-\frac{x}{3}+\frac{x^2}{30}-\frac{x^3}{630}+\frac{x^4}{22680}-\frac{x^5}{1247400}+O(x^6)\right)}{\sqrt{x}} + \frac{c_2\left(1-x+\frac{x^2}{6}-\frac{x^3}{90}+\frac{x^4}{2520}-\frac{x^5}{113400}+O(x^6)\right)}{x}$$

Verified OK.

23.5.1 Maple step by step solution

Let's solve

$2x^2y''+5xy'+y(x+1)=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{5y'}{2x}-\frac{(x+1)y}{2x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{5y'}{2x}+\frac{(x+1)y}{2x^2}=0$

☐ Check to see if $x_0=0$ is a regular singular point

- ∘ Define functions

  $\left[P_2(x)=\frac{5}{2x}, P_3(x)=\frac{x+1}{2x^2}\right]$

- ∘ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left.(x\cdot P_2(x))\right|_{x=0}=\frac{5}{2}$

- ∘ $x^2\cdot P_3(x)$ is analytic at $x=0$

$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = \frac{1}{2}$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2x^2y'' + 5xy' + y(x+1) = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..1$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- > k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$

- Convert $x^2 \cdot y''$ to series expansion

  $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)\,(1+2r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+1)\,(2k+2r+1) + a_{k-1}\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-1, -\frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $2(k+r+1)\left(k+r+\frac{1}{2}\right) a_k + a_{k-1} = 0$

- Shift index using $k->k+1$

  $2(k+2+r)\left(k+\frac{3}{2}+r\right)a_{k+1}+a_k=0$
- Recursion relation that defines series solution to ODE

  $a_{k+1}=-\frac{a_k}{(k+2+r)(2k+3+2r)}$
- Recursion relation for $r=-1$

  $a_{k+1}=-\frac{a_k}{(k+1)(2k+1)}$
- Solution for $r=-1$

  $\left[y=\sum_{k=0}^{\infty}a_k x^{k-1}, a_{k+1}=-\frac{a_k}{(k+1)(2k+1)}\right]$
- Recursion relation for $r=-\frac{1}{2}$

  $a_{k+1}=-\frac{a_k}{\left(k+\frac{3}{2}\right)(2k+2)}$
- Solution for $r=-\frac{1}{2}$

  $\left[y=\sum_{k=0}^{\infty}a_k x^{k-\frac{1}{2}}, a_{k+1}=-\frac{a_k}{\left(k+\frac{3}{2}\right)(2k+2)}\right]$
- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty}a_k x^{k-1}\right)+\left(\sum_{k=0}^{\infty}b_k x^{k-\frac{1}{2}}\right), a_{k+1}=-\frac{a_k}{(k+1)(2k+1)}, b_{k+1}=-\frac{b_k}{\left(k+\frac{3}{2}\right)(2k+2)}\right]$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 41, page 195
Problem number: 6.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{9x^2y'' + (2+3x)\,y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$9x^2y'' + (2+3x)\,y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$\begin{aligned} p(x) &= 0 \\ q(x) &= \frac{2+3x}{9x^2} \end{aligned}$$

Table 646: Table $p(x), q(x)$ singularites.

$p(x) = 0$	
singularity	type

$q(x) = \frac{2+3x}{9x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$9x^2y'' + (2 + 3x)\, y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$9x^2 \left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + (2+3x) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 9x^{n+r} a_n (n+r)\,(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 3x^{1+n+r} a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 3x^{1+n+r} a_n = \sum_{n=1}^{\infty} 3a_{n-1} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 9x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) + \left(\sum_{n=1}^{\infty} 3a_{n-1} x^{n+r}\right) = 0 \quad \text{(2B)}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$9x^{n+r} a_n (n+r)(n+r-1) + 2a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$9x^r a_0 r(-1+r) + 2a_0 x^r = 0$$

Or

$$\left(9x^r r(-1+r) + 2x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(9r^2 - 9r + 2\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$9r^2 - 9r + 2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{2}{3}$$
$$r_2 = \frac{1}{3}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(9r^2 - 9r + 2\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{3}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{2}{3}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n+\frac{1}{3}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$9a_n(n+r)(n+r-1) + 2a_n + 3a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{3a_{n-1}}{9n^2 + 18nr + 9r^2 - 9n - 9r + 2} \tag{4}$$

Which for the root $r = \frac{2}{3}$ becomes

$$a_n = -\frac{a_{n-1}}{3n^2 + n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{2}{3}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{3}{9r^2 + 9r + 2}$$

Which for the root $r = \frac{2}{3}$ becomes

$$a_1 = -\frac{1}{4}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{4}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{9}{(9r^2 + 9r + 2)(9r^2 + 27r + 20)}$$

Which for the root $r = \frac{2}{3}$ becomes

$$a_2 = \frac{1}{56}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{4}$
a_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{56}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{27}{(9r^2 + 9r + 2)(9r^2 + 27r + 20)(9r^2 + 45r + 56)}$$

Which for the root $r = \frac{2}{3}$ becomes

$$a_3 = -\frac{1}{1680}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{4}$
a_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{56}$
a_3	$-\frac{27}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)}$	$-\frac{1}{1680}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{81}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)}$$

Which for the root $r = \frac{2}{3}$ becomes

$$a_4 = \frac{1}{87360}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{4}$
a_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{56}$
a_3	$-\frac{27}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)}$	$-\frac{1}{1680}$
a_4	$\frac{81}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)}$	$\frac{1}{87360}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{243}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)(9r^2+81r+182)}$$

Which for the root $r = \frac{2}{3}$ becomes

$$a_5 = -\frac{1}{6988800}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{4}$
a_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{56}$
a_3	$-\frac{27}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)}$	$-\frac{1}{1680}$
a_4	$\frac{81}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)}$	$\frac{1}{87360}$
a_5	$-\frac{243}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)(9r^2+81r+182)}$	$-\frac{1}{6988800}$

Using the above table, then the solution $y_1(x)$ is

$$y_1(x) = x^{\frac{2}{3}}\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6\dots\right)$$
$$= x^{\frac{2}{3}}\left(1 - \frac{x}{4} + \frac{x^2}{56} - \frac{x^3}{1680} + \frac{x^4}{87360} - \frac{x^5}{6988800} + O(x^6)\right)$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$9b_n(n+r)(n+r-1) + 2b_n + 3b_{n-1} = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{3b_{n-1}}{9n^2 + 18nr + 9r^2 - 9n - 9r + 2} \tag{4}$$

Which for the root $r = \frac{1}{3}$ becomes

$$b_n = -\frac{b_{n-1}}{n(3n-1)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{1}{3}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = -\frac{3}{9r^2 + 9r + 2}$$

Which for the root $r = \frac{1}{3}$ becomes

$$b_1 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{2}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{9}{(9r^2 + 9r + 2)(9r^2 + 27r + 20)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$b_2 = \frac{1}{20}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{2}$
b_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{20}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{27}{(9r^2 + 9r + 2)(9r^2 + 27r + 20)(9r^2 + 45r + 56)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$b_3 = -\frac{1}{480}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{2}$
b_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{20}$
b_3	$-\frac{27}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)}$	$-\frac{1}{480}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{81}{(9r^2 + 9r + 2)(9r^2 + 27r + 20)(9r^2 + 45r + 56)(9r^2 + 63r + 110)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$b_4 = \frac{1}{21120}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{2}$
b_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{20}$
b_3	$-\frac{27}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)}$	$-\frac{1}{480}$
b_4	$\frac{81}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)}$	$\frac{1}{21120}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{243}{(9r^2 + 9r + 2)(9r^2 + 27r + 20)(9r^2 + 45r + 56)(9r^2 + 63r + 110)(9r^2 + 81r + 182)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$b_5 = -\frac{1}{1478400}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{2}$
b_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{20}$
b_3	$-\frac{27}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)}$	$-\frac{1}{480}$
b_4	$\frac{81}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)}$	$\frac{1}{21120}$
b_5	$-\frac{243}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)(9r^2+81r+182)}$	$-\frac{1}{1478400}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= x^{\frac{2}{3}}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\ &= x^{\frac{1}{3}}\left(1 - \frac{x}{2} + \frac{x^2}{20} - \frac{x^3}{480} + \frac{x^4}{21120} - \frac{x^5}{1478400} + O(x^6)\right) \end{aligned}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{\frac{2}{3}} \left(1 - \frac{x}{4} + \frac{x^2}{56} - \frac{x^3}{1680} + \frac{x^4}{87360} - \frac{x^5}{6988800} + O(x^6)\right) \\
&\quad + c_2 x^{\frac{1}{3}} \left(1 - \frac{x}{2} + \frac{x^2}{20} - \frac{x^3}{480} + \frac{x^4}{21120} - \frac{x^5}{1478400} + O(x^6)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{\frac{2}{3}} \left(1 - \frac{x}{4} + \frac{x^2}{56} - \frac{x^3}{1680} + \frac{x^4}{87360} - \frac{x^5}{6988800} + O(x^6)\right) \\
&\quad + c_2 x^{\frac{1}{3}} \left(1 - \frac{x}{2} + \frac{x^2}{20} - \frac{x^3}{480} + \frac{x^4}{21120} - \frac{x^5}{1478400} + O(x^6)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x^{\frac{2}{3}} \left(1 - \frac{x}{4} + \frac{x^2}{56} - \frac{x^3}{1680} + \frac{x^4}{87360} - \frac{x^5}{6988800} + O(x^6)\right) \\
&\quad + c_2 x^{\frac{1}{3}} \left(1 - \frac{x}{2} + \frac{x^2}{20} - \frac{x^3}{480} + \frac{x^4}{21120} - \frac{x^5}{1478400} + O(x^6)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 x^{\frac{2}{3}} \left(1 - \frac{x}{4} + \frac{x^2}{56} - \frac{x^3}{1680} + \frac{x^4}{87360} - \frac{x^5}{6988800} + O(x^6)\right) \\
&\quad + c_2 x^{\frac{1}{3}} \left(1 - \frac{x}{2} + \frac{x^2}{20} - \frac{x^3}{480} + \frac{x^4}{21120} - \frac{x^5}{1478400} + O(x^6)\right)
\end{aligned}
$$

Verified OK.

23.6.1 Maple step by step solution

Let's solve

$9x^2y'' + (2+3x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(2+3x)y}{9x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(2+3x)y}{9x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = 0, P_3(x) = \frac{2+3x}{9x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\bigg|_{x=0} = 0$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = \frac{2}{9}$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $9x^2y'' + (2+3x)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  ◦ Shift index using $k- >k - m$

$$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^2 \cdot y''$ to series expansion

$$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1) x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-1+3r)(-2+3r) x^r + \left(\sum_{k=1}^{\infty} \left(a_k(3k+3r-1)(3k+3r-2) + 3a_{k-1}\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(-1+3r)(-2+3r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{\frac{1}{3}, \frac{2}{3}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$9\left(k+r-\frac{1}{3}\right)\left(k+r-\frac{2}{3}\right) a_k + 3a_{k-1} = 0$$

- Shift index using $k->k+1$

$$9\left(k+\frac{2}{3}+r\right)\left(k+\frac{1}{3}+r\right) a_{k+1} + 3a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{3a_k}{(3k+2+3r)(3k+1+3r)}$$

- Recursion relation for $r = \frac{1}{3}$

$$a_{k+1} = -\frac{3a_k}{(3k+3)(3k+2)}$$

- Solution for $r = \frac{1}{3}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+1} = -\frac{3a_k}{(3k+3)(3k+2)}\right]$$

- Recursion relation for $r = \frac{2}{3}$

$$a_{k+1} = -\frac{3a_k}{(3k+4)(3k+3)}$$

- Solution for $r = \frac{2}{3}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{2}{3}}, a_{k+1} = -\frac{3a_k}{(3k+4)(3k+3)}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{2}{3}}\right), a_{k+1} = -\frac{3a_k}{(3k+3)(3k+2)}, b_{k+1} = -\frac{3b_k}{(3k+4)(3k+3)}\right]$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 41, page 195
Problem number: 7.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{\left(x^3+2x^2\right)y''-xy'+(1-x)\,y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(x^3+2x^2\right)y''-xy'+(1-x)\,y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=-\frac{1}{x\,(x+2)}$$
$$q(x)=-\frac{x-1}{x^2\,(x+2)}$$

Table 648: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{1}{x(x+2)}$	
singularity	type
$x = -2$	"regular"
$x = 0$	"regular"

$q(x) = -\frac{x-1}{x^2(x+2)}$	
singularity	type
$x = -2$	"regular"
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-2, 0, \infty]$

Irregular singular points : []

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$y''x^2(x+2) - xy' + (1-x)\,y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}\right) x^2(x+2) - x\left(\sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}\right) + (1-x)\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) \tag{2A}$$
$$+ \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n\right) = 0$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1) = \sum_{n=1}^{\infty} a_{n-1}(n+r-1)(n+r-2)\, x^{n+r}$$

$$\sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n\right) = \sum_{n=1}^{\infty} \left(-a_{n-1} x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1)(n+r-2)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) \tag{2B}$$
$$+ \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) + \sum_{n=1}^{\infty} \left(-a_{n-1} x^{n+r}\right) = 0$$

The indicial equation is obtained from $n = 0$. From Eq (2B) this gives

$$2x^{n+r} a_n (n+r)(n+r-1) - x^{n+r} a_n (n+r) + a_n x^{n+r} = 0$$

When $n = 0$ the above becomes

$$2x^r a_0 r(-1+r) - x^r a_0 r + a_0 x^r = 0$$

Or

$$\left(2x^r r(-1+r) - x^r r + x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(2r^2 - 3r + 1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 - 3r + 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = \frac{1}{2}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(2r^2 - 3r + 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n \right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n \right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{1+n}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n+\frac{1}{2}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_{n-1}(n + r - 1)(n + r - 2) + 2a_n(n + r)(n + r - 1) - a_n(n + r) + a_n - a_{n-1} = 0 \quad (3)$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}(n^2 + 2nr + r^2 - 3n - 3r + 1)}{2n^2 + 4nr + 2r^2 - 3n - 3r + 1} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = -\frac{a_{n-1}(n^2 - n - 1)}{2n^2 + n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{-r^2 + r + 1}{2r^2 + r}$$

Which for the root $r = 1$ becomes

$$a_1 = \frac{1}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{1}{3}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r^4 - 3r^2 + 1}{4r^4 + 12r^3 + 11r^2 + 3r}$$

Which for the root $r = 1$ becomes

$$a_2 = -\frac{1}{30}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{1}{3}$
a_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$-\frac{1}{30}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{-r^6 - 3r^5 + 2r^4 + 9r^3 + 2r^2 - 3r - 1}{r\,(4r^3 + 12r^2 + 11r + 3)\,(2r^2 + 9r + 10)}$$

Which for the root $r = 1$ becomes

$$a_3 = \frac{1}{126}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{1}{3}$
a_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$-\frac{1}{30}$
a_3	$\frac{-r^6-3r^5+2r^4+9r^3+2r^2-3r-1}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)}$	$\frac{1}{126}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{r^8 + 8r^7 + 18r^6 - 4r^5 - 57r^4 - 52r^3 + 6r^2 + 20r + 5}{r(4r^3 + 12r^2 + 11r + 3)(2r^2 + 9r + 10)(2r^2 + 13r + 21)}$$

Which for the root $r = 1$ becomes

$$a_4 = -\frac{11}{4536}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{1}{3}$
a_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$-\frac{1}{30}$
a_3	$\frac{-r^6-3r^5+2r^4+9r^3+2r^2-3r-1}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)}$	$\frac{1}{126}$
a_4	$\frac{r^8+8r^7+18r^6-4r^5-57r^4-52r^3+6r^2+20r+5}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)}$	$-\frac{11}{4536}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{(r^2 + 3r + 1)(r^2 + 5r + 5)(r^2 + 7r + 11)(r^2 + r - 1)(r^2 - r - 1)}{r(4r^3 + 12r^2 + 11r + 3)(2r^2 + 9r + 10)(2r^2 + 13r + 21)(2r^2 + 17r + 36)}$$

Which for the root $r = 1$ becomes

$$a_5 = \frac{19}{22680}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{1}{3}$
a_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$-\frac{1}{30}$
a_3	$\frac{-r^6-3r^5+2r^4+9r^3+2r^2-3r-1}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)}$	$\frac{1}{126}$
a_4	$\frac{r^8+8r^7+18r^6-4r^5-57r^4-52r^3+6r^2+20r+5}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)}$	$-\frac{11}{4536}$
a_5	$-\frac{(r^2+3r+1)(r^2+5r+5)(r^2+7r+11)(r^2+r-1)(r^2-r-1)}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)(2r^2+17r+36)}$	$\frac{19}{22680}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}y_1(x) &= x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right)\\ &= x\left(1 + \frac{x}{3} - \frac{x^2}{30} + \frac{x^3}{126} - \frac{11x^4}{4536} + \frac{19x^5}{22680} + O(x^6)\right)\end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$b_{n-1}(n+r-1)(n+r-2) + 2b_n(n+r)(n+r-1) - b_n(n+r) + b_n - b_{n-1} = 0 \quad (3)$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{b_{n-1}(n^2 + 2nr + r^2 - 3n - 3r + 1)}{2n^2 + 4nr + 2r^2 - 3n - 3r + 1} \quad (4)$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_n = -\frac{b_{n-1}(4n^2 - 8n - 1)}{8n^2 - 4n} \quad (5)$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{-r^2 + r + 1}{2r^2 + r}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_1 = \frac{5}{4}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{5}{4}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{r^4 - 3r^2 + 1}{4r^4 + 12r^3 + 11r^2 + 3r}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_2 = \frac{5}{96}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{5}{4}$
b_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$\frac{5}{96}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{-r^6 - 3r^5 + 2r^4 + 9r^3 + 2r^2 - 3r - 1}{r\left(4r^3 + 12r^2 + 11r + 3\right)\left(2r^2 + 9r + 10\right)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_3 = -\frac{11}{1152}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{5}{4}$
b_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$\frac{5}{96}$
b_3	$\frac{-r^6-3r^5+2r^4+9r^3+2r^2-3r-1}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)}$	$-\frac{11}{1152}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{r^8 + 8r^7 + 18r^6 - 4r^5 - 57r^4 - 52r^3 + 6r^2 + 20r + 5}{r(4r^3 + 12r^2 + 11r + 3)(2r^2 + 9r + 10)(2r^2 + 13r + 21)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_4 = \frac{341}{129024}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{5}{4}$
b_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$\frac{5}{96}$
b_3	$\frac{-r^6-3r^5+2r^4+9r^3+2r^2-3r-1}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)}$	$-\frac{11}{1152}$
b_4	$\frac{r^8+8r^7+18r^6-4r^5-57r^4-52r^3+6r^2+20r+5}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)}$	$\frac{341}{129024}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{(r^2 + 3r + 1)(r^2 + 5r + 5)(r^2 + 7r + 11)(r^2 + r - 1)(r^2 - r - 1)}{r(4r^3 + 12r^2 + 11r + 3)(2r^2 + 9r + 10)(2r^2 + 13r + 21)(2r^2 + 17r + 36)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_5 = -\frac{20119}{23224320}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{5}{4}$
b_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$\frac{5}{96}$
b_3	$\frac{-r^6-3r^5+2r^4+9r^3+2r^2-3r-1}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)}$	$-\frac{11}{1152}$
b_4	$\frac{r^8+8r^7+18r^6-4r^5-57r^4-52r^3+6r^2+20r+5}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)}$	$\frac{341}{129024}$
b_5	$-\frac{(r^2+3r+1)(r^2+5r+5)(r^2+7r+11)(r^2+r-1)(r^2-r-1)}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)(2r^2+17r+36)}$	$-\frac{20119}{23224320}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= x\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\ &= \sqrt{x}\left(1 + \frac{5x}{4} + \frac{5x^2}{96} - \frac{11x^3}{1152} + \frac{341x^4}{129024} - \frac{20119x^5}{23224320} + O(x^6)\right) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x\left(1 + \frac{x}{3} - \frac{x^2}{30} + \frac{x^3}{126} - \frac{11x^4}{4536} + \frac{19x^5}{22680} + O(x^6)\right) \\ &\quad + c_2\sqrt{x}\left(1 + \frac{5x}{4} + \frac{5x^2}{96} - \frac{11x^3}{1152} + \frac{341x^4}{129024} - \frac{20119x^5}{23224320} + O(x^6)\right) \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= c_1 x\left(1 + \frac{x}{3} - \frac{x^2}{30} + \frac{x^3}{126} - \frac{11x^4}{4536} + \frac{19x^5}{22680} + O(x^6)\right) \\ &\quad + c_2\sqrt{x}\left(1 + \frac{5x}{4} + \frac{5x^2}{96} - \frac{11x^3}{1152} + \frac{341x^4}{129024} - \frac{20119x^5}{23224320} + O(x^6)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = c_1 x\left(1 + \frac{x}{3} - \frac{x^2}{30} + \frac{x^3}{126} - \frac{11x^4}{4536} + \frac{19x^5}{22680} + O(x^6)\right) \\ + c_2\sqrt{x}\left(1 + \frac{5x}{4} + \frac{5x^2}{96} - \frac{11x^3}{1152} + \frac{341x^4}{129024} - \frac{20119x^5}{23224320} + O(x^6)\right) \end{aligned} \tag{1}$$

Verification of solutions

$$y = c_1 x \left(1+\frac{x}{3}-\frac{x^2}{30}+\frac{x^3}{126}-\frac{11x^4}{4536}+\frac{19x^5}{22680}+O(x^6)\right) + c_2\sqrt{x}\left(1+\frac{5x}{4}+\frac{5x^2}{96}-\frac{11x^3}{1152}+\frac{341x^4}{129024}-\frac{20119x^5}{23224320}+O(x^6)\right)$$

Verified OK.

23.7.1 Maple step by step solution

Let's solve

$y''x^2(x+2)-xy'+(1-x)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{(x-1)y}{x^2(x+2)}+\frac{y'}{x(x+2)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{y'}{x(x+2)}-\frac{(x-1)y}{x^2(x+2)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=-\frac{1}{x(x+2)}, P_3(x)=-\frac{x-1}{x^2(x+2)}\right]$

  ◦ $(x+2)\cdot P_2(x)$ is analytic at $x=-2$

  $\left((x+2)\cdot P_2(x)\right)\Big|_{x=-2}=\frac{1}{2}$

  ◦ $(x+2)^2\cdot P_3(x)$ is analytic at $x=-2$

  $\left((x+2)^2\cdot P_3(x)\right)\Big|_{x=-2}=0$

  ◦ $x=-2$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-2$

- Multiply by denominators

  $y''x^2(x+2)-xy'+(1-x)\,y=0$

- Change variables using $x = u - 2$ so that the regular singular point is at $u = 0$

$$\left(u^{3}-4u^{2}+4u\right)\left(\frac{d^{2}}{d u^{2}}y(u)\right)+\left(-u+2\right)\left(\frac{d}{d u}y(u)\right)+\left(3-u\right)y(u)=0$$

- Assume series solution for $y(u)$

$$y(u)=\sum_{k=0}^{\infty}a_{k}u^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $u^{m}\cdot y(u)$ to series expansion for $m = 0..1$

$$u^{m}\cdot y(u)=\sum_{k=0}^{\infty}a_{k}u^{k+r+m}$$

- Shift index using $k->k-m$

$$u^{m}\cdot y(u)=\sum_{k=m}^{\infty}a_{k-m}u^{k+r}$$

- Convert $u^{m}\cdot\left(\frac{d}{d u}y(u)\right)$ to series expansion for $m = 0..1$

$$u^{m}\cdot\left(\frac{d}{d u}y(u)\right)=\sum_{k=0}^{\infty}a_{k}(k+r)\,u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$u^{m}\cdot\left(\frac{d}{d u}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

- Convert $u^{m}\cdot\left(\frac{d^{2}}{d u^{2}}y(u)\right)$ to series expansion for $m = 1..3$

$$u^{m}\cdot\left(\frac{d^{2}}{d u^{2}}y(u)\right)=\sum_{k=0}^{\infty}a_{k}(k+r)\,(k+r-1)\,u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^{m}\cdot\left(\frac{d^{2}}{d u^{2}}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$2a_{0}r(2r-1)\,u^{-1+r}+\left(2a_{1}(1+r)\,(1+2r)-a_{0}(4r^{2}-3r-3)\right)u^{r}+\left(\sum_{k=1}^{\infty}\left(2a_{k+1}(k+1+r)\,(2k+\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$2r(2r-1)=0$$

- Values of r that satisfy the indicial equation

$$r\in\left\{0,\frac{1}{2}\right\}$$

- Each term must be 0

$2a_1(1+r)(1+2r) - a_0(4r^2-3r-3) = 0$

- Each term in the series must be 0, giving the recursion relation

$(-4a_k + a_{k-1} + 4a_{k+1}) k^2 + ((-8a_k + 2a_{k-1} + 8a_{k+1}) r + 3a_k - 3a_{k-1} + 6a_{k+1}) k + (-4a_k + a_{k-}$

- Shift index using $k->k+1$

$(-4a_{k+1} + a_k + 4a_{k+2}) (k+1)^2 + ((-8a_{k+1} + 2a_k + 8a_{k+2}) r + 3a_{k+1} - 3a_k + 6a_{k+2}) (k+1) + ($

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} + 2kra_k - 8kra_{k+1} + r^2 a_k - 4r^2 a_{k+1} - ka_k - 5ka_{k+1} - ra_k - 5ra_{k+1} - a_k + 2a_{k+1}}{2(2k^2 + 4kr + 2r^2 + 7k + 7r + 6)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} - ka_k - 5ka_{k+1} - a_k + 2a_{k+1}}{2(2k^2 + 7k + 6)}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} - ka_k - 5ka_{k+1} - a_k + 2a_{k+1}}{2(2k^2 + 7k + 6)}, 2a_1 + 3a_0 = 0\right]$$

- Revert the change of variables $u = x + 2$

$$\left[y = \sum_{k=0}^{\infty} a_k (x+2)^k, a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} - ka_k - 5ka_{k+1} - a_k + 2a_{k+1}}{2(2k^2 + 7k + 6)}, 2a_1 + 3a_0 = 0\right]$$

- Recursion relation for $r = \frac{1}{2}$

$$a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} - 9ka_{k+1} - \frac{5}{4}a_k - \frac{3}{2}a_{k+1}}{2(2k^2 + 9k + 10)}$$

- Solution for $r = \frac{1}{2}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{1}{2}}, a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} - 9ka_{k+1} - \frac{5}{4}a_k - \frac{3}{2}a_{k+1}}{2(2k^2 + 9k + 10)}, 6a_1 + \frac{7a_0}{2} = 0\right]$$

- Revert the change of variables $u = x + 2$

$$\left[y = \sum_{k=0}^{\infty} a_k (x+2)^{k+\frac{1}{2}}, a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} - 9ka_{k+1} - \frac{5}{4}a_k - \frac{3}{2}a_{k+1}}{2(2k^2 + 9k + 10)}, 6a_1 + \frac{7a_0}{2} = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k (x+2)^k\right) + \left(\sum_{k=0}^{\infty} b_k (x+2)^{k+\frac{1}{2}}\right), a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} - ka_k - 5ka_{k+1} - a_k + 2a_{k+1}}{2(2k^2 + 7k + 6)}, 2a_1 + 3\right.$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 41, page 195
Problem number: 8.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{2x^2y'' - 3(x^2 + x)\,y' + (2 + 3x)\,y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2x^2y'' + (-3x^2 - 3x)\,y' + (2 + 3x)\,y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{3(x + 1)}{2x}$$
$$q(x) = \frac{2 + 3x}{2x^2}$$

Table 650: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{3(x+1)}{2x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{2+3x}{2x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2x^2y'' + (-3x^2 - 3x)\, y' + (2 + 3x)\, y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2x^2 \left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + (-3x^2 - 3x) \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + (2+3x) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-3x^{1+n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-3x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 3x^{1+n+r} a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-3x^{1+n+r} a_n (n+r)\right) = \sum_{n=1}^{\infty} \left(-3a_{n-1}(n+r-1)\, x^{n+r}\right)$$

$$\sum_{n=0}^{\infty} 3x^{1+n+r} a_n = \sum_{n=1}^{\infty} 3a_{n-1} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-3a_{n-1}(n+r-1)\, x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-3x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) + \left(\sum_{n=1}^{\infty} 3a_{n-1} x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r} a_n (n+r)(n+r-1) - 3x^{n+r} a_n (n+r) + 2a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$2x^r a_0 r(-1+r) - 3x^r a_0 r + 2a_0 x^r = 0$$

Or

$$\left(2x^r r(-1+r) - 3x^r r + 2x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(2r^2 - 5r + 2\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 - 5r + 2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 2$$
$$r_2 = \frac{1}{2}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(2r^2 - 5r + 2\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{3}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+2}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n+\frac{1}{2}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$2a_n(n+r)(n+r-1) - 3a_{n-1}(n+r-1) - 3a_n(n+r) + 2a_n + 3a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{3a_{n-1}}{2n+2r-1} \tag{4}$$

Which for the root $r = 2$ becomes

$$a_n = \frac{3a_{n-1}}{2n+3} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{3}{1 + 2r}$$

Which for the root $r = 2$ becomes

$$a_1 = \frac{3}{5}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{3}{1+2r}$	$\frac{3}{5}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{9}{4r^2 + 8r + 3}$$

Which for the root $r = 2$ becomes

$$a_2 = \frac{9}{35}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{3}{1+2r}$	$\frac{3}{5}$
a_2	$\frac{9}{4r^2+8r+3}$	$\frac{9}{35}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{27}{8r^3 + 36r^2 + 46r + 15}$$

Which for the root $r = 2$ becomes

$$a_3 = \frac{3}{35}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{3}{1+2r}$	$\frac{3}{5}$
a_2	$\frac{9}{4r^2+8r+3}$	$\frac{9}{35}$
a_3	$\frac{27}{8r^3+36r^2+46r+15}$	$\frac{3}{35}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{81}{16r^4 + 128r^3 + 344r^2 + 352r + 105}$$

Which for the root $r = 2$ becomes

$$a_4 = \frac{9}{385}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{3}{1+2r}$	$\frac{3}{5}$
a_2	$\frac{9}{4r^2+8r+3}$	$\frac{9}{35}$
a_3	$\frac{27}{8r^3+36r^2+46r+15}$	$\frac{3}{35}$
a_4	$\frac{81}{16r^4+128r^3+344r^2+352r+105}$	$\frac{9}{385}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{243}{32r^5 + 400r^4 + 1840r^3 + 3800r^2 + 3378r + 945}$$

Which for the root $r = 2$ becomes

$$a_5 = \frac{27}{5005}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{3}{1+2r}$	$\frac{3}{5}$
a_2	$\frac{9}{4r^2+8r+3}$	$\frac{9}{35}$
a_3	$\frac{27}{8r^3+36r^2+46r+15}$	$\frac{3}{35}$
a_4	$\frac{81}{16r^4+128r^3+344r^2+352r+105}$	$\frac{9}{385}$
a_5	$\frac{243}{32r^5+400r^4+1840r^3+3800r^2+3378r+945}$	$\frac{27}{5005}$

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= x^2(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots) \\
&= x^2\left(1 + \frac{3x}{5} + \frac{9x^2}{35} + \frac{3x^3}{35} + \frac{9x^4}{385} + \frac{27x^5}{5005} + O(x^6)\right)
\end{aligned}
$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$
2b_n(n+r)(n+r-1) - 3b_{n-1}(n+r-1) - 3b_n(n+r) + 2b_n + 3b_{n-1} = 0 \tag{3}
$$

Solving for b_n from recursive equation (4) gives

$$
b_n = \frac{3b_{n-1}}{2n+2r-1} \tag{4}
$$

Which for the root $r = \frac{1}{2}$ becomes

$$
b_n = \frac{3b_{n-1}}{2n} \tag{5}
$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$
b_1 = \frac{3}{1+2r}
$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_1 = \frac{3}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{3}{1+2r}$	$\frac{3}{2}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{9}{4r^2 + 8r + 3}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_2 = \frac{9}{8}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{3}{1+2r}$	$\frac{3}{2}$
b_2	$\frac{9}{4r^2+8r+3}$	$\frac{9}{8}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{27}{8r^3 + 36r^2 + 46r + 15}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_3 = \frac{9}{16}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{3}{1+2r}$	$\frac{3}{2}$
b_2	$\frac{9}{4r^2+8r+3}$	$\frac{9}{8}$
b_3	$\frac{27}{8r^3+36r^2+46r+15}$	$\frac{9}{16}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{81}{16r^4 + 128r^3 + 344r^2 + 352r + 105}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_4 = \frac{27}{128}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{3}{1+2r}$	$\frac{3}{2}$
b_2	$\frac{9}{4r^2+8r+3}$	$\frac{9}{8}$
b_3	$\frac{27}{8r^3+36r^2+46r+15}$	$\frac{9}{16}$
b_4	$\frac{81}{16r^4+128r^3+344r^2+352r+105}$	$\frac{27}{128}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{243}{32r^5 + 400r^4 + 1840r^3 + 3800r^2 + 3378r + 945}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_5 = \frac{81}{1280}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{3}{1+2r}$	$\frac{3}{2}$
b_2	$\frac{9}{4r^2+8r+3}$	$\frac{9}{8}$
b_3	$\frac{27}{8r^3+36r^2+46r+15}$	$\frac{9}{16}$
b_4	$\frac{81}{16r^4+128r^3+344r^2+352r+105}$	$\frac{27}{128}$
b_5	$\frac{243}{32r^5+400r^4+1840r^3+3800r^2+3378r+945}$	$\frac{81}{1280}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x^2\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= \sqrt{x}\left(1 + \frac{3x}{2} + \frac{9x^2}{8} + \frac{9x^3}{16} + \frac{27x^4}{128} + \frac{81x^5}{1280} + O(x^6)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^2\left(1 + \frac{3x}{5} + \frac{9x^2}{35} + \frac{3x^3}{35} + \frac{9x^4}{385} + \frac{27x^5}{5005} + O(x^6)\right) \\
&\quad + c_2\sqrt{x}\left(1 + \frac{3x}{2} + \frac{9x^2}{8} + \frac{9x^3}{16} + \frac{27x^4}{128} + \frac{81x^5}{1280} + O(x^6)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^2\left(1 + \frac{3x}{5} + \frac{9x^2}{35} + \frac{3x^3}{35} + \frac{9x^4}{385} + \frac{27x^5}{5005} + O(x^6)\right) \\
&\quad + c_2\sqrt{x}\left(1 + \frac{3x}{2} + \frac{9x^2}{8} + \frac{9x^3}{16} + \frac{27x^4}{128} + \frac{81x^5}{1280} + O(x^6)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x^2\left(1 + \frac{3x}{5} + \frac{9x^2}{35} + \frac{3x^3}{35} + \frac{9x^4}{385} + \frac{27x^5}{5005} + O(x^6)\right) \\
&\quad + c_2\sqrt{x}\left(1 + \frac{3x}{2} + \frac{9x^2}{8} + \frac{9x^3}{16} + \frac{27x^4}{128} + \frac{81x^5}{1280} + O(x^6)\right)
\end{aligned}
\tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 x^2\left(1 + \frac{3x}{5} + \frac{9x^2}{35} + \frac{3x^3}{35} + \frac{9x^4}{385} + \frac{27x^5}{5005} + O(x^6)\right) \\
&\quad + c_2\sqrt{x}\left(1 + \frac{3x}{2} + \frac{9x^2}{8} + \frac{9x^3}{16} + \frac{27x^4}{128} + \frac{81x^5}{1280} + O(x^6)\right)
\end{aligned}
$$

Verified OK.

23.8.1 Maple step by step solution

Let's solve

$2x^2y'' + (-3x^2 - 3x)\, y' + (2 + 3x)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{3(x+1)y'}{2x} - \frac{(2+3x)y}{2x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{3(x+1)y'}{2x} + \frac{(2+3x)y}{2x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = -\frac{3(x+1)}{2x}, P_3(x) = \frac{2+3x}{2x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\Big|_{x=0} = -\frac{3}{2}$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 1$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2x^2y'' - 3x(x + 1)\, y' + (2 + 3x)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

  $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

  $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$$

- Convert $x^2 \cdot y''$ to series expansion

  $$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(-1+2r)\,(-2+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(2k+2r-1)\,(k+r-2) - 3a_{k-1}(k+r-2)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$(-1+2r)\,(-2+r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{2, \frac{1}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

  $$2(k+r-2)\left(\left(k+r-\frac{1}{2}\right) a_k - \frac{3a_{k-1}}{2}\right) = 0$$

- Shift index using $k->k+1$

  $$2(k+r-1)\left(\left(k+\frac{1}{2}+r\right) a_{k+1} - \frac{3a_k}{2}\right) = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+1} = \frac{3a_k}{2k+1+2r}$$

- Recursion relation for $r = 2$

  $$a_{k+1} = \frac{3a_k}{2k+5}$$

- Solution for $r = 2$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+1} = \frac{3a_k}{2k+5}\right]$$

- Recursion relation for $r = \frac{1}{2}$

$a_{k+1} = \frac{3a_k}{2k+2}$

- Solution for $r = \frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = \frac{3a_k}{2k+2}\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+2}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+1} = \frac{3a_k}{2k+5}, b_{k+1} = \frac{3b_k}{2k+2}\right]$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 41, page 195
Problem number: 9.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{3x^2y'' + \left(-x^2+5x\right)y' + \left(2x^2-1\right)y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$3x^2y'' + \left(-x^2+5x\right)y' + \left(2x^2-1\right)y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$\begin{aligned} p(x) &= -\frac{x-5}{3x} \\ q(x) &= \frac{2x^2-1}{3x^2} \end{aligned}$$

Table 652: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x-5}{3x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{2x^2-1}{3x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$3x^2y'' + \left(-x^2 + 5x\right) y' + \left(2x^2 - 1\right) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$3x^2 \left(\sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}\right) + \left(-x^2 + 5x\right) \left(\sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}\right) + \left(2x^2 - 1\right) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 3x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 5x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 2x^{n+r+2} a_n\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)\right) = \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r}\right)$$

$$\sum_{n=0}^{\infty} 2x^{n+r+2} a_n = \sum_{n=2}^{\infty} 2a_{n-2} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 3x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 5x^{n+r} a_n (n+r)\right) + \left(\sum_{n=2}^{\infty} 2a_{n-2} x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$3x^{n+r} a_n (n+r)(n+r-1) + 5x^{n+r} a_n (n+r) - a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$3x^r a_0 r(-1+r) + 5x^r a_0 r - a_0 x^r = 0$$

Or

$$\left(3x^r r(-1+r) + 5x^r r - x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(3r^2 + 2r - 1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$3r^2 + 2r - 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{3}$$
$$r_2 = -1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(3r^2 + 2r - 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{4}{3}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{3}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-1}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = \frac{r}{3r^2 + 8r + 4}$$

For $2 \leq n$ the recursive equation is

$$3a_n(n + r)(n + r - 1) - a_{n-1}(n + r - 1) + 5a_n(n + r) + 2a_{n-2} - a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{n a_{n-1} + r a_{n-1} - 2a_{n-2} - a_{n-1}}{3n^2 + 6nr + 3r^2 + 2n + 2r - 1} \tag{4}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_n = \frac{3na_{n-1} - 6a_{n-2} - 2a_{n-1}}{9n^2 + 12n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{3}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{3r^2+8r+4}$	$\frac{1}{21}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{-5r^2 - 15r - 8}{(3r^2 + 8r + 4)(3r^2 + 14r + 15)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_2 = -\frac{61}{630}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{3r^2+8r+4}$	$\frac{1}{21}$
a_2	$\frac{-5r^2-15r-8}{(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{61}{630}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{-11r^3 - 53r^2 - 68r - 16}{(3r^2 + 20r + 32)(3r^2 + 8r + 4)(3r^2 + 14r + 15)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_3 = -\frac{607}{73710}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{3r^2+8r+4}$	$\frac{1}{21}$
a_2	$\frac{-5r^2-15r-8}{(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{61}{630}$
a_3	$\frac{-11r^3-53r^2-68r-16}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{607}{73710}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{19r^4 + 204r^3 + 741r^2 + 1060r + 464}{(3r^2 + 20r + 32)(3r^2 + 8r + 4)(3r^2 + 14r + 15)(3r^2 + 26r + 55)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_4 = \frac{2297}{884520}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{3r^2+8r+4}$	$\frac{1}{21}$
a_2	$\frac{-5r^2-15r-8}{(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{61}{630}$
a_3	$\frac{-11r^3-53r^2-68r-16}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{607}{73710}$
a_4	$\frac{19r^4+204r^3+741r^2+1060r+464}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)(3r^2+26r+55)}$	$\frac{2297}{884520}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{85r^5 + 1170r^4 + 5931r^3 + 13486r^2 + 13016r + 3616}{(3r^2 + 20r + 32)(3r^2 + 8r + 4)(3r^2 + 14r + 15)(3r^2 + 26r + 55)(3r^2 + 32r + 84)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_5 = \frac{14713}{50417640}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{3r^2+8r+4}$	$\frac{1}{21}$
a_2	$\frac{-5r^2-15r-8}{(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{61}{630}$
a_3	$\frac{-11r^3-53r^2-68r-16}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{607}{73710}$
a_4	$\frac{19r^4+204r^3+741r^2+1060r+464}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)(3r^2+26r+55)}$	$\frac{2297}{884520}$
a_5	$\frac{85r^5+1170r^4+5931r^3+13486r^2+13016r+3616}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)(3r^2+26r+55)(3r^2+32r+84)}$	$\frac{14713}{50417640}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{1}{3}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^{\frac{1}{3}}\left(1 + \frac{x}{21} - \frac{61x^2}{630} - \frac{607x^3}{73710} + \frac{2297x^4}{884520} + \frac{14713x^5}{50417640} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$b_1 = \frac{r}{3r^2 + 8r + 4}$$

For $2 \leq n$ the recursive equation is

$$3b_n(n+r)(n+r-1) - b_{n-1}(n+r-1) + 5b_n(n+r) + 2b_{n-2} - b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = \frac{nb_{n-1} + rb_{n-1} - 2b_{n-2} - b_{n-1}}{3n^2 + 6nr + 3r^2 + 2n + 2r - 1} \tag{4}$$

Which for the root $r = -1$ becomes

$$b_n = \frac{nb_{n-1} - 2b_{n-2} - 2b_{n-1}}{n(3n-4)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{3r^2+8r+4}$	1

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{-5r^2 - 15r - 8}{(3r^2 + 8r + 4)(3r^2 + 14r + 15)}$$

Which for the root $r = -1$ becomes

$$b_2 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{3r^2+8r+4}$	1
b_2	$\frac{-5r^2-15r-8}{(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{-11r^3 - 53r^2 - 68r - 16}{(3r^2 + 20r + 32)(3r^2 + 8r + 4)(3r^2 + 14r + 15)}$$

Which for the root $r = -1$ becomes

$$b_3 = -\frac{1}{6}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{3r^2+8r+4}$	1
b_2	$\frac{-5r^2-15r-8}{(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{1}{2}$
b_3	$\frac{-11r^3-53r^2-68r-16}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{1}{6}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{19r^4 + 204r^3 + 741r^2 + 1060r + 464}{(3r^2 + 20r + 32)(3r^2 + 8r + 4)(3r^2 + 14r + 15)(3r^2 + 26r + 55)}$$

Which for the root $r = -1$ becomes

$$b_4 = \frac{1}{48}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{3r^2+8r+4}$	1
b_2	$\frac{-5r^2-15r-8}{(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{1}{2}$
b_3	$\frac{-11r^3-53r^2-68r-16}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{1}{6}$
b_4	$\frac{19r^4+204r^3+741r^2+1060r+464}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)(3r^2+26r+55)}$	$\frac{1}{48}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{85r^5 + 1170r^4 + 5931r^3 + 13486r^2 + 13016r + 3616}{(3r^2 + 20r + 32)(3r^2 + 8r + 4)(3r^2 + 14r + 15)(3r^2 + 26r + 55)(3r^2 + 32r + 84)}$$

Which for the root $r = -1$ becomes

$$b_5 = \frac{19}{2640}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{3r^2+8r+4}$	1
b_2	$\frac{-5r^2-15r-8}{(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{1}{2}$
b_3	$\frac{-11r^3-53r^2-68r-16}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{1}{6}$
b_4	$\frac{19r^4+204r^3+741r^2+1060r+464}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)(3r^2+26r+55)}$	$\frac{1}{48}$
b_5	$\frac{85r^5+1170r^4+5931r^3+13486r^2+13016r+3616}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)(3r^2+26r+55)(3r^2+32r+84)}$	$\frac{19}{2640}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= x^{\frac{1}{3}}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\ &= \frac{1 + x - \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{48} + \frac{19x^5}{2640} + O(x^6)}{x} \end{aligned}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{\frac{1}{3}} \left(1 + \frac{x}{21} - \frac{61x^2}{630} - \frac{607x^3}{73710} + \frac{2297x^4}{884520} + \frac{14713x^5}{50417640} + O\left(x^6\right)\right) \\
&\quad + \frac{c_2 \left(1 + x - \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{48} + \frac{19x^5}{2640} + O(x^6)\right)}{x}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{\frac{1}{3}} \left(1 + \frac{x}{21} - \frac{61x^2}{630} - \frac{607x^3}{73710} + \frac{2297x^4}{884520} + \frac{14713x^5}{50417640} + O\left(x^6\right)\right) \\
&\quad + \frac{c_2 \left(1 + x - \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{48} + \frac{19x^5}{2640} + O(x^6)\right)}{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x^{\frac{1}{3}} \left(1 + \frac{x}{21} - \frac{61x^2}{630} - \frac{607x^3}{73710} + \frac{2297x^4}{884520} + \frac{14713x^5}{50417640} + O\left(x^6\right)\right) \\
&\quad + \frac{c_2 \left(1 + x - \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{48} + \frac{19x^5}{2640} + O(x^6)\right)}{x}
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 x^{\frac{1}{3}} \left(1 + \frac{x}{21} - \frac{61x^2}{630} - \frac{607x^3}{73710} + \frac{2297x^4}{884520} + \frac{14713x^5}{50417640} + O\left(x^6\right)\right) \\
&\quad + \frac{c_2 \left(1 + x - \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{48} + \frac{19x^5}{2640} + O(x^6)\right)}{x}
\end{aligned}
$$

Verified OK.

23.9.1 Maple step by step solution

Let's solve

$3x^2y'' + (-x^2 + 5x)\, y' + (2x^2 - 1)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{(x-5)y'}{3x} - \frac{(2x^2-1)y}{3x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{(x-5)y'}{3x} + \frac{(2x^2-1)y}{3x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- ○ Define functions

  $\left[P_2(x) = -\frac{x-5}{3x}, P_3(x) = \frac{2x^2-1}{3x^2}\right]$

- ○ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = \frac{5}{3}$

- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -\frac{1}{3}$

- ○ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $3x^2y'' - x(x-5)\, y' + (2x^2 - 1)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $x^{m}\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- Convert $x^{m}\cdot y'$ to series expansion for $m=1..2$

  $x^{m}\cdot y'=\sum_{k=0}^{\infty}a_{k}(k+r)\,x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $x^{m}\cdot y'=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^{2}\cdot y''$ to series expansion

  $x^{2}\cdot y''=\sum_{k=0}^{\infty}a_{k}(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_{0}(1+r)\,(-1+3r)\,x^{r}+(a_{1}(2+r)\,(2+3r)-a_{0}r)\,x^{1+r}+\left(\sum_{k=2}^{\infty}(a_{k}(k+r+1)\,(3k+3r-1)-a\right.$

- a_{0}cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(-1+3r)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{-1,\frac{1}{3}\right\}$

- Each term must be 0

  $a_{1}(2+r)\,(2+3r)-a_{0}r=0$

- Solve for the dependent coefficient(s)

  $a_{1}=\frac{a_{0}r}{3r^{2}+8r+4}$

- Each term in the series must be 0, giving the recursion relation

  $3\left(k+r-\frac{1}{3}\right)(k+r+1)\,a_{k}-a_{k-1}k-a_{k-1}r+2a_{k-2}+a_{k-1}=0$

- Shift index using $k->k+2$

  $3\left(k+\frac{5}{3}+r\right)(k+3+r)\,a_{k+2}-a_{k+1}(k+2)-a_{k+1}r+2a_{k}+a_{k+1}=0$

- Recursion relation that defines series solution to ODE

  $a_{k+2}=\frac{ka_{k+1}+a_{k+1}r-2a_{k}+a_{k+1}}{(3k+5+3r)(k+3+r)}$

- Recursion relation for $r=-1$

  $a_{k+2}=\frac{ka_{k+1}-2a_{k}}{(3k+2)(k+2)}$

- Solution for $r = -1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2} = \frac{k a_{k+1} - 2a_k}{(3k+2)(k+2)}, a_1 = a_0\right]$$

- Recursion relation for $r = \frac{1}{3}$

$$a_{k+2} = \frac{k a_{k+1} - 2a_k + \frac{4}{3} a_{k+1}}{(3k+6)\left(k+\frac{10}{3}\right)}$$

- Solution for $r = \frac{1}{3}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = \frac{k a_{k+1} - 2a_k + \frac{4}{3} a_{k+1}}{(3k+6)\left(k+\frac{10}{3}\right)}, a_1 = \frac{a_0}{21}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+2} = \frac{k a_{k+1} - 2a_k}{(3k+2)(k+2)}, a_1 = a_0, b_{k+2} = \frac{k b_{k+1} - 2b_k + \frac{4}{3} b_{k+1}}{(3k+6)\left(k+\frac{10}{3}\right)}, b_1 = \frac{b_0}{21}\right]$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 41, page 195
Problem number: 10.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{4x^2y'' + x(x^2-4)\,y' + 3y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$4x^2y'' + (x^3-4x)\,y' + 3y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{x^2-4}{4x}$$
$$q(x) = \frac{3}{4x^2}$$

Table 654: Table $p(x), q(x)$ singularites.

$p(x) = \frac{x^2-4}{4x}$	
singularity	type
$x = 0$	"regular"
$x = \infty$	"regular"
$x = -\infty$	"regular"

$q(x) = \frac{3}{4x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, \infty, -\infty]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$4x^2y'' + (x^3 - 4x) y' + 3y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$4x^2 \left(\sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}\right) + (x^3 - 4x) \left(\sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}\right) + 3\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} 4x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r+2} a_n (n+r)\right) \\
&+ \sum_{n=0}^{\infty} \left(-4x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 3a_n x^{n+r}\right) = 0
\end{aligned}
\tag{2A}
$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$
\sum_{n=0}^{\infty} x^{n+r+2} a_n (n+r) = \sum_{n=2}^{\infty} a_{n-2}(n+r-2)\, x^{n+r}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} 4x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=2}^{\infty} a_{n-2}(n+r-2)\, x^{n+r}\right) \\
&+ \sum_{n=0}^{\infty} \left(-4x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 3a_n x^{n+r}\right) = 0
\end{aligned}
\tag{2B}
$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$
4x^{n+r} a_n (n+r)(n+r-1) - 4x^{n+r} a_n (n+r) + 3a_n x^{n+r} = 0
$$

When $n=0$ the above becomes

$$
4x^r a_0 r(-1+r) - 4x^r a_0 r + 3a_0 x^r = 0
$$

Or

$$
\left(4x^r r(-1+r) - 4x^r r + 3x^r\right) a_0 = 0
$$

Since $a_0 \neq 0$ then the above simplifies to

$$
\left(4r^2 - 8r + 3\right) x^r = 0
$$

Since the above is true for all x then the indicial equation becomes

$$
4r^2 - 8r + 3 = 0
$$

Solving for r gives the roots of the indicial equation as

$$
\begin{aligned}
r_1 &= \frac{3}{2} \\
r_2 &= \frac{1}{2}
\end{aligned}
$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$
\left(4r^2 - 8r + 3\right) x^r = 0
$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 1$ is an integer, then we can construct two linearly independent solutions

$$
\begin{aligned}
y_1(x) &= x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right) \\
y_2(x) &= C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= x^{\frac{3}{2}} \left(\sum_{n=0}^{\infty} a_n x^n\right) \\
y_2(x) &= C y_1(x) \ln(x) + \sqrt{x} \left(\sum_{n=0}^{\infty} b_n x^n\right)
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+\frac{3}{2}} \\
y_2(x) &= C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+\frac{1}{2}}\right)
\end{aligned}
$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$
a_1 = 0
$$

For $2 \leq n$ the recursive equation is

$$
4a_n(n+r)(n+r-1) + a_{n-2}(n+r-2) - 4a_n(n+r) + 3a_n = 0 \tag{3}
$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-2}(n+r-2)}{4n^2+8nr+4r^2-8n-8r+3} \tag{4}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_n = -\frac{a_{n-2}(2n-1)}{8n\,(n+1)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{3}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{r}{4r^2+8r+3}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_2 = -\frac{1}{16}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{r}{4r^2+8r+3}$	$-\frac{1}{16}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{r}{4r^2+8r+3}$	$-\frac{1}{16}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{r(2+r)}{(4r^2+8r+3)(4r^2+24r+35)}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_4 = \frac{7}{2560}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{r}{4r^2+8r+3}$	$-\frac{1}{16}$
a_3	0	0
a_4	$\frac{r(2+r)}{(4r^2+8r+3)(4r^2+24r+35)}$	$\frac{7}{2560}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{r}{4r^2+8r+3}$	$-\frac{1}{16}$
a_3	0	0
a_4	$\frac{r(2+r)}{(4r^2+8r+3)(4r^2+24r+35)}$	$\frac{7}{2560}$
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= x^{\frac{3}{2}}(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots) \\
&= x^{\frac{3}{2}}\left(1 - \frac{x^2}{16} + \frac{7x^4}{2560} + O(x^6)\right)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 1$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_1(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned}
a_N &= a_1 \\
&= 0
\end{aligned}$$

Therefore

$$\begin{aligned}
\lim_{r\to r_2} 0 &= \lim_{r\to \frac{1}{2}} 0 \\
&= 0
\end{aligned}$$

The limit is 0. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$\begin{aligned}
y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\
&= \sum_{n=0}^{\infty} b_n x^{n+\frac{1}{2}}
\end{aligned}$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$b_1 = 0$$

For $2 \leq n$ the recursive equation is

$$4b_n(n + r)(n + r - 1) + b_{n-2}(n + r - 2) - 4b_n(n + r) + 3b_n = 0 \tag{4}$$

Which for for the root $r = \frac{1}{2}$ becomes

$$4b_n\left(n + \frac{1}{2}\right)\left(n - \frac{1}{2}\right) + b_{n-2}\left(n - \frac{3}{2}\right) - 4b_n\left(n + \frac{1}{2}\right) + 3b_n = 0 \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = -\frac{b_{n-2}(n + r - 2)}{4n^2 + 8nr + 4r^2 - 8n - 8r + 3} \tag{5}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_n = -\frac{b_{n-2}\left(n - \frac{3}{2}\right)}{4n^2 - 4n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{r}{4r^2 + 8r + 3}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_2 = -\frac{1}{16}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{r}{4r^2+8r+3}$	$-\frac{1}{16}$

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{r}{4r^2+8r+3}$	$-\frac{1}{16}$
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{r(2+r)}{(4r^2+8r+3)(4r^2+24r+35)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_4 = \frac{5}{1536}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{r}{4r^2+8r+3}$	$-\frac{1}{16}$
b_3	0	0
b_4	$\frac{r(2+r)}{(4r^2+8r+3)(4r^2+24r+35)}$	$\frac{5}{1536}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{r}{4r^2+8r+3}$	$-\frac{1}{16}$
b_3	0	0
b_4	$\frac{r(2+r)}{(4r^2+8r+3)(4r^2+24r+35)}$	$\frac{5}{1536}$
b_5	0	0

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x^{\frac{3}{2}}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= \sqrt{x}\left(1 - \frac{x^2}{16} + \frac{5x^4}{1536} + O(x^6)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{\frac{3}{2}}\left(1 - \frac{x^2}{16} + \frac{7x^4}{2560} + O(x^6)\right) + c_2\sqrt{x}\left(1 - \frac{x^2}{16} + \frac{5x^4}{1536} + O(x^6)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{\frac{3}{2}}\left(1 - \frac{x^2}{16} + \frac{7x^4}{2560} + O(x^6)\right) + c_2\sqrt{x}\left(1 - \frac{x^2}{16} + \frac{5x^4}{1536} + O(x^6)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x^{\frac{3}{2}}\left(1 - \frac{x^2}{16} + \frac{7x^4}{2560} + O(x^6)\right) + c_2\sqrt{x}\left(1 - \frac{x^2}{16} + \frac{5x^4}{1536} + O(x^6)\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 x^{\frac{3}{2}}\left(1 - \frac{x^2}{16} + \frac{7x^4}{2560} + O(x^6)\right) + c_2\sqrt{x}\left(1 - \frac{x^2}{16} + \frac{5x^4}{1536} + O(x^6)\right)
$$

Verified OK.

23.10.1 Maple step by step solution

Let's solve

$4x^2 y'' + (x^3 - 4x)\, y' + 3y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{3y}{4x^2} - \frac{(x^2-4)y'}{4x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$$y''+\frac{(x^2-4)y'}{4x}+\frac{3y}{4x^2}=0$$

☐ Check to see if $x_0=0$ is a regular singular point

- Define functions

$$\left[P_2(x)=\frac{x^2-4}{4x}, P_3(x)=\frac{3}{4x^2}\right]$$

- $x\cdot P_2(x)$ is analytic at $x=0$

$$\left(x\cdot P_2(x)\right)\bigg|_{x=0}=-1$$

- $x^2\cdot P_3(x)$ is analytic at $x=0$

$$\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=\frac{3}{4}$$

- $x=0$is a regular singular point

Check to see if $x_0=0$ is a regular singular point

$$x_0=0$$

- Multiply by denominators

$$4x^2y''+x(x^2-4)\,y'+3y=0$$

- Assume series solution for y

$$y=\sum_{k=0}^{\infty}a_kx^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m\cdot y'$ to series expansion for $m=1..3$

$$x^m\cdot y'=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$x^m\cdot y'=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$$

- Convert $x^2\cdot y''$ to series expansion

$$x^2\cdot y''=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-1+2r)\,(-3+2r)\,x^r+a_1(1+2r)\,(-1+2r)\,x^{1+r}+\left(\sum_{k=2}^{\infty}(a_k(2k+2r-1)\,(2k+2r-3)+a\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+2r)(-3+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{\frac{1}{2}, \frac{3}{2}\right\}$
- Each term must be 0

  $a_1(1+2r)(-1+2r) = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $4\left(k+r-\frac{3}{2}\right)\left(k+r-\frac{1}{2}\right)a_k + a_{k-2}(k-2+r) = 0$
- Shift index using $k- >k+2$

  $4\left(k+\frac{1}{2}+r\right)\left(k+\frac{3}{2}+r\right)a_{k+2} + a_k(k+r) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k(k+r)}{(2k+1+2r)(2k+3+2r)}$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -\frac{a_k\left(k+\frac{1}{2}\right)}{(2k+2)(2k+4)}$
- Solution for $r = \frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{a_k\left(k+\frac{1}{2}\right)}{(2k+2)(2k+4)}, a_1 = 0\right]$
- Recursion relation for $r = \frac{3}{2}$

  $a_{k+2} = -\frac{a_k\left(k+\frac{3}{2}\right)}{(2k+4)(2k+6)}$
- Solution for $r = \frac{3}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{3}{2}}, a_{k+2} = -\frac{a_k\left(k+\frac{3}{2}\right)}{(2k+4)(2k+6)}, a_1 = 0\right]$
- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{3}{2}}\right), a_{k+2} = -\frac{a_k\left(k+\frac{1}{2}\right)}{(2k+2)(2k+4)}, a_1 = 0, b_{k+2} = -\frac{b_k\left(k+\frac{3}{2}\right)}{(2k+4)(2k+6)}, b_1 = 0\right]$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 41, page 195
Problem number: 15.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{4x^2y'' - 3(x^2 + x)\, y' + 2y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$4x^2y'' + (-3x^2 - 3x)\, y' + 2y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{3(x+1)}{4x}$$
$$q(x) = \frac{1}{2x^2}$$

Table 656: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{3(x+1)}{4x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{1}{2x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$4x^2y'' + \left(-3x^2 - 3x\right) y' + 2y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$4x^2 \left(\sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}\right) + \left(-3x^2 - 3x\right) \left(\sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}\right) + 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 4x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-3x^{1+n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-3x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-3x^{1+n+r} a_n (n+r)\right) = \sum_{n=1}^{\infty} \left(-3a_{n-1}(n+r-1)\, x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 4x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-3a_{n-1}(n+r-1)\, x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-3x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n = 0$. From Eq (2B) this gives

$$4x^{n+r} a_n (n+r)(n+r-1) - 3x^{n+r} a_n (n+r) + 2a_n x^{n+r} = 0$$

When $n = 0$ the above becomes

$$4x^r a_0 r(-1+r) - 3x^r a_0 r + 2a_0 x^r = 0$$

Or

$$\left(4x^r r(-1+r) - 3x^r r + 2x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(4r^2 - 7r + 2\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$4r^2 - 7r + 2 = 0$$

Solving for r gives the roots of the indicial equation as

$$
\begin{aligned}
r_1 &= \frac{7}{8}+\frac{\sqrt{17}}{8} \\
r_2 &= \frac{7}{8}-\frac{\sqrt{17}}{8}
\end{aligned}
$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$
\left(4r^2-7r+2\right)x^r = 0
$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{\sqrt{17}}{4}$ is not an integer, then we can construct two linearly independent solutions

$$
\begin{aligned}
y_1(x) &= x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right) \\
y_2(x) &= x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+\frac{7}{8}+\frac{\sqrt{17}}{8}} \\
y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+\frac{7}{8}-\frac{\sqrt{17}}{8}}
\end{aligned}
$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$
4a_n(n+r)(n+r-1)-3a_{n-1}(n+r-1)-3a_n(n+r)+2a_n = 0 \tag{3}
$$

Solving for a_n from recursive equation (4) gives

$$
a_n = \frac{3a_{n-1}(n+r-1)}{4n^2+8nr+4r^2-7n-7r+2} \tag{4}
$$

Which for the root $r = \frac{7}{8}+\frac{\sqrt{17}}{8}$ becomes

$$
a_n = \frac{3a_{n-1}\left(8n-1+\sqrt{17}\right)}{8n\left(\sqrt{17}+4n\right)} \tag{5}
$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{7}{8} + \frac{\sqrt{17}}{8}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{3r}{4r^2 + r - 1}$$

Which for the root $r = \frac{7}{8} + \frac{\sqrt{17}}{8}$ becomes

$$a_1 = \frac{21 + 3\sqrt{17}}{32 + 8\sqrt{17}}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{3r}{4r^2+r-1}$	$\frac{21+3\sqrt{17}}{32+8\sqrt{17}}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{9r(1 + r)}{16r^4 + 40r^3 + 21r^2 - 5r - 4}$$

Which for the root $r = \frac{7}{8} + \frac{\sqrt{17}}{8}$ becomes

$$a_2 = \frac{9(7 + \sqrt{17})\left(15 + \sqrt{17}\right)}{128\left(4 + \sqrt{17}\right)\left(8 + \sqrt{17}\right)}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{3r}{4r^2+r-1}$	$\frac{21+3\sqrt{17}}{32+8\sqrt{17}}$
a_2	$\frac{9r(1+r)}{16r^4+40r^3+21r^2-5r-4}$	$\frac{9\left(7+\sqrt{17}\right)\left(15+\sqrt{17}\right)}{128\left(4+\sqrt{17}\right)\left(8+\sqrt{17}\right)}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{27r(1+r)(2+r)}{64r^6+432r^5+1036r^4+1017r^3+256r^2-153r-68}$$

Which for the root $r = \frac{7}{8} + \frac{\sqrt{17}}{8}$ becomes

$$a_3 = \frac{9(7+\sqrt{17})(15+\sqrt{17})(23+\sqrt{17})}{1024(49+12\sqrt{17})(12+\sqrt{17})}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{3r}{4r^2+r-1}$	$\frac{21+3\sqrt{17}}{32+8\sqrt{17}}$
a_2	$\frac{9r(1+r)}{16r^4+40r^3+21r^2-5r-4}$	$\frac{9(7+\sqrt{17})(15+\sqrt{17})}{128(4+\sqrt{17})(8+\sqrt{17})}$
a_3	$\frac{27r(1+r)(2+r)}{64r^6+432r^5+1036r^4+1017r^3+256r^2-153r-68}$	$\frac{9(7+\sqrt{17})(15+\sqrt{17})(23+\sqrt{17})}{1024(49+12\sqrt{17})(12+\sqrt{17})}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{81r(1+r)(2+r)(3+r)}{256r^8+3328r^7+17376r^6+46384r^5+65817r^4+44434r^3+5631r^2-7514r-2584}$$

Which for the root $r = \frac{7}{8} + \frac{\sqrt{17}}{8}$ becomes

$$a_4 = \frac{27(7+\sqrt{17})(15+\sqrt{17})(23+\sqrt{17})(31+\sqrt{17})}{32768(792+193\sqrt{17})(16+\sqrt{17})}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{3r}{4r^2+r-1}$	$\frac{21+3\sqrt{17}}{32+8\sqrt{17}}$
a_2	$\frac{9r(1+r)}{16r^4+40r^3+21r^2-5r-4}$	$\frac{9(7+\sqrt{17})(15+\sqrt{17})}{128(4+\sqrt{17})(8+\sqrt{17})}$
a_3	$\frac{27r(1+r)(2+r)}{64r^6+432r^5+1036r^4+1017r^3+256r^2-153r-68}$	$\frac{9(7+\sqrt{17})(15+\sqrt{17})(23+\sqrt{17})}{1024(49+12\sqrt{17})(12+\sqrt{17})}$
a_4	$\frac{81r(1+r)(2+r)(3+r)}{256r^8+3328r^7+17376r^6+46384r^5+65817r^4+44434r^3+5631r^2-7514r-2584}$	$\frac{27(7+\sqrt{17})(15+\sqrt{17})(23+\sqrt{17})(31+\sqrt{17})}{32768(792+193\sqrt{17})(16+\sqrt{17})}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{243r(1+r)(2+r)(3+r)(4+r)}{(256r^8 + 3328r^7 + 17376r^6 + 46384r^5 + 65817r^4 + 44434r^3 + 5631r^2 - 7514r - 2584)(4r^2 + 33r +$$

Which for the root $r = \frac{7}{8} + \frac{\sqrt{17}}{8}$ becomes

$$a_5 = \frac{81(7+\sqrt{17})(15+\sqrt{17})(23+\sqrt{17})(31+\sqrt{17})(39+\sqrt{17})}{1310720(15953+3880\sqrt{17})(20+\sqrt{17})}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{3r}{4r^2+r-1}$	$\frac{21+3\sqrt{17}}{32+8\sqrt{17}}$
a_2	$\frac{9r(1+r)}{16r^4+40r^3+21r^2-5r-4}$	$\frac{9(7+\sqrt{17})(15+\sqrt{17})}{128(4+\sqrt{17})(8+\sqrt{17})}$
a_3	$\frac{27r(1+r)(2+r)}{64r^6+432r^5+1036r^4+1017r^3+256r^2-153r-68}$	$\frac{9(7+\sqrt{17})(15+\sqrt{17})(23+\sqrt{17})}{1024(49+12\sqrt{17})(12+\sqrt{17})}$
a_4	$\frac{81r(1+r)(2+r)(3+r)}{256r^8+3328r^7+17376r^6+46384r^5+65817r^4+44434r^3+5631r^2-7514r-2584}$	$\frac{27(7+\sqrt{17})(15+\sqrt{17})(23+\sqrt{17})(31}{32768(792+193\sqrt{17})(16+\sqrt{17})}$
a_5	$\frac{243r(1+r)(2+r)(3+r)(4+r)}{(256r^8+3328r^7+17376r^6+46384r^5+65817r^4+44434r^3+5631r^2-7514r-2584)(4r^2+33r+67)}$	$\frac{81(7+\sqrt{17})(15+\sqrt{17})(23+\sqrt{17})(31}{1310720(15953+3880\sqrt{17})(2}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{7}{8}+\frac{\sqrt{17}}{8}}(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots) \\ &= x^{\frac{7}{8}+\frac{\sqrt{17}}{8}}\left(1 + \frac{(21+3\sqrt{17})x}{32+8\sqrt{17}} + \frac{9(7+\sqrt{17})(15+\sqrt{17})x^2}{128(4+\sqrt{17})(8+\sqrt{17})} + \frac{9(7+\sqrt{17})(15+\sqrt{17})(23+\sqrt{17})}{1024(49+12\sqrt{17})(12+\sqrt{17})}\right. \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$4b_n(n+r)(n+r-1) - 3b_{n-1}(n+r-1) - 3b_n(n+r) + 2b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = \frac{3b_{n-1}(n+r-1)}{4n^2 + 8nr + 4r^2 - 7n - 7r + 2} \tag{4}$$

Which for the root $r = \frac{7}{8} - \frac{\sqrt{17}}{8}$ becomes

$$b_n = \frac{3b_{n-1}\left(-8n+1+\sqrt{17}\right)}{8n\left(\sqrt{17}-4n\right)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{7}{8} - \frac{\sqrt{17}}{8}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{3r}{4r^2+r-1}$$

Which for the root $r = \frac{7}{8} - \frac{\sqrt{17}}{8}$ becomes

$$b_1 = \frac{-21+3\sqrt{17}}{-32+8\sqrt{17}}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{3r}{4r^2+r-1}$	$\frac{-21+3\sqrt{17}}{-32+8\sqrt{17}}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{9r(1+r)}{16r^4+40r^3+21r^2-5r-4}$$

Which for the root $r = \frac{7}{8} - \frac{\sqrt{17}}{8}$ becomes

$$b_2 = \frac{9\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)}{128\left(-4+\sqrt{17}\right)\left(-8+\sqrt{17}\right)}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{3r}{4r^2+r-1}$	$\frac{-21+3\sqrt{17}}{-32+8\sqrt{17}}$
b_2	$\frac{9r(1+r)}{16r^4+40r^3+21r^2-5r-4}$	$\frac{9\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)}{128\left(-4+\sqrt{17}\right)\left(-8+\sqrt{17}\right)}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{27r(1+r)(2+r)}{64r^6 + 432r^5 + 1036r^4 + 1017r^3 + 256r^2 - 153r - 68}$$

Which for the root $r = \frac{7}{8} - \frac{\sqrt{17}}{8}$ becomes

$$b_3 = -\frac{9\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-23+\sqrt{17}\right)}{1024\left(-49+12\sqrt{17}\right)\left(-12+\sqrt{17}\right)}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{3r}{4r^2+r-1}$	$\frac{-21+3\sqrt{17}}{-32+8\sqrt{17}}$
b_2	$\frac{9r(1+r)}{16r^4+40r^3+21r^2-5r-4}$	$\frac{9\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)}{128\left(-4+\sqrt{17}\right)\left(-8+\sqrt{17}\right)}$
b_3	$\frac{27r(1+r)(2+r)}{64r^6+432r^5+1036r^4+1017r^3+256r^2-153r-68}$	$-\frac{9\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-23+\sqrt{17}\right)}{1024\left(-49+12\sqrt{17}\right)\left(-12+\sqrt{17}\right)}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{81r(1+r)(2+r)(3+r)}{256r^8 + 3328r^7 + 17376r^6 + 46384r^5 + 65817r^4 + 44434r^3 + 5631r^2 - 7514r - 2584}$$

Which for the root $r = \frac{7}{8} - \frac{\sqrt{17}}{8}$ becomes

$$b_4 = \frac{27\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-23+\sqrt{17}\right)\left(-31+\sqrt{17}\right)}{32768\left(-792+193\sqrt{17}\right)\left(-16+\sqrt{17}\right)}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{3r}{4r^2+r-1}$	$\frac{-21+3\sqrt{17}}{-32+8\sqrt{17}}$
b_2	$\frac{9r(1+r)}{16r^4+40r^3+21r^2-5r-4}$	$\frac{9\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)}{128\left(-4+\sqrt{17}\right)\left(-8+\sqrt{17}\right)}$
b_3	$\frac{27r(1+r)(2+r)}{64r^6+432r^5+1036r^4+1017r^3+256r^2-153r-68}$	$-\frac{9\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-23+\sqrt{17}\right)}{1024\left(-49+12\sqrt{17}\right)\left(-12+\sqrt{17}\right)}$
b_4	$\frac{81r(1+r)(2+r)(3+r)}{256r^8+3328r^7+17376r^6+46384r^5+65817r^4+44434r^3+5631r^2-7514r-2584}$	$\frac{27\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-23+\sqrt{17}\right)\left(-31+\sqrt{17}\right)}{32768\left(-792+193\sqrt{17}\right)\left(-16+\sqrt{17}\right)}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{243r(1+r)(2+r)(3+r)(4+r)}{(256r^8+3328r^7+17376r^6+46384r^5+65817r^4+44434r^3+5631r^2-7514r-2584)(4r^2+33r+}$$

Which for the root $r = \frac{7}{8} - \frac{\sqrt{17}}{8}$ becomes

$$b_5 = -\frac{81\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-23+\sqrt{17}\right)\left(-31+\sqrt{17}\right)\left(-39+\sqrt{17}\right)}{1310720\left(-15953+3880\sqrt{17}\right)\left(-20+\sqrt{17}\right)}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{3r}{4r^2+r-1}$	$\frac{-21+3\sqrt{17}}{-32+8\sqrt{17}}$
b_2	$\frac{9r(1+r)}{16r^4+40r^3+21r^2-5r-4}$	$\frac{9\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)}{128\left(-4+\sqrt{17}\right)\left(-8+\sqrt{17}\right)}$
b_3	$\frac{27r(1+r)(2+r)}{64r^6+432r^5+1036r^4+1017r^3+256r^2-153r-68}$	$-\frac{9\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-23+\sqrt{1\right.}{1024\left(-49+12\sqrt{17}\right)\left(-12+\sqrt{17}\right)}$
b_4	$\frac{81r(1+r)(2+r)(3+r)}{256r^8+3328r^7+17376r^6+46384r^5+65817r^4+44434r^3+5631r^2-7514r-2584}$	$\frac{27\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-23+\sqrt{17}\right.}{32768\left(-792+193\sqrt{17}\right)\left(-16+\right.}$
b_5	$\frac{243r(1+r)(2+r)(3+r)(4+r)}{(256r^8+3328r^7+17376r^6+46384r^5+65817r^4+44434r^3+5631r^2-7514r-2584)(4r^2+33r+67)}$	$-\frac{81\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-23+\sqrt{\right.}{1310720\left(-15953+3880\sqrt{\right.}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x^{\frac{7}{8}+\frac{\sqrt{17}}{8}}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= x^{\frac{7}{8}-\frac{\sqrt{17}}{8}}\left(1 + \frac{\left(-21+3\sqrt{17}\right)x}{-32+8\sqrt{17}} + \frac{9\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)x^2}{128\left(-4+\sqrt{17}\right)\left(-8+\sqrt{17}\right)} - \frac{9\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-\right.}{1024\left(-49+12\sqrt{17}\right)\left(-1\right.}\right.
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{\frac{7}{8}+\frac{\sqrt{17}}{8}}\left(1 + \frac{\left(21+3\sqrt{17}\right)x}{32+8\sqrt{17}} + \frac{9\left(7+\sqrt{17}\right)\left(15+\sqrt{17}\right)x^2}{128\left(4+\sqrt{17}\right)\left(8+\sqrt{17}\right)}\right. \\
&\quad + \frac{9\left(7+\sqrt{17}\right)\left(15+\sqrt{17}\right)\left(23+\sqrt{17}\right)x^3}{1024\left(49+12\sqrt{17}\right)\left(12+\sqrt{17}\right)} \\
&\quad + \frac{27\left(7+\sqrt{17}\right)\left(15+\sqrt{17}\right)\left(23+\sqrt{17}\right)\left(31+\sqrt{17}\right)x^4}{32768\left(792+193\sqrt{17}\right)\left(16+\sqrt{17}\right)} \\
&\quad \left. + \frac{81\left(7+\sqrt{17}\right)\left(15+\sqrt{17}\right)\left(23+\sqrt{17}\right)\left(31+\sqrt{17}\right)\left(39+\sqrt{17}\right)x^5}{1310720\left(15953+3880\sqrt{17}\right)\left(20+\sqrt{17}\right)} + O\left(x^6\right)\right) \\
&\quad + c_2 x^{\frac{7}{8}-\frac{\sqrt{17}}{8}}\left(1 + \frac{\left(-21+3\sqrt{17}\right)x}{-32+8\sqrt{17}} + \frac{9\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)x^2}{128\left(-4+\sqrt{17}\right)\left(-8+\sqrt{17}\right)}\right. \\
&\quad - \frac{9\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-23+\sqrt{17}\right)x^3}{1024\left(-49+12\sqrt{17}\right)\left(-12+\sqrt{17}\right)} \\
&\quad + \frac{27\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-23+\sqrt{17}\right)\left(-31+\sqrt{17}\right)x^4}{32768\left(-792+193\sqrt{17}\right)\left(-16+\sqrt{17}\right)} \\
&\quad - \frac{81\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-23+\sqrt{17}\right)\left(-31+\sqrt{17}\right)\left(-39+\sqrt{17}\right)x^5}{1310720\left(-15953+3880\sqrt{17}\right)\left(-20+\sqrt{17}\right)} \\
&\quad \left. + O\left(x^6\right)\right)
\end{aligned}
$$

Hence the final solution is

$$
y = y_h
$$

$$
\begin{aligned}
&= c_1 x^{\frac{7}{8}+\frac{\sqrt{17}}{8}} \Bigg(1 + \frac{\left(21+3\sqrt{17}\right)x}{32+8\sqrt{17}} + \frac{9\left(7+\sqrt{17}\right)\left(15+\sqrt{17}\right)x^2}{128\left(4+\sqrt{17}\right)\left(8+\sqrt{17}\right)} \\
&\quad + \frac{9\left(7+\sqrt{17}\right)\left(15+\sqrt{17}\right)\left(23+\sqrt{17}\right)x^3}{1024\left(49+12\sqrt{17}\right)\left(12+\sqrt{17}\right)} \\
&\quad + \frac{27\left(7+\sqrt{17}\right)\left(15+\sqrt{17}\right)\left(23+\sqrt{17}\right)\left(31+\sqrt{17}\right)x^4}{32768\left(792+193\sqrt{17}\right)\left(16+\sqrt{17}\right)} \\
&\quad + \frac{81\left(7+\sqrt{17}\right)\left(15+\sqrt{17}\right)\left(23+\sqrt{17}\right)\left(31+\sqrt{17}\right)\left(39+\sqrt{17}\right)x^5}{1310720\left(15953+3880\sqrt{17}\right)\left(20+\sqrt{17}\right)} + O\left(x^6\right)\Bigg) \\
&\quad + c_2 x^{\frac{7}{8}-\frac{\sqrt{17}}{8}} \Bigg(1 + \frac{\left(-21+3\sqrt{17}\right)x}{-32+8\sqrt{17}} + \frac{9\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)x^2}{128\left(-4+\sqrt{17}\right)\left(-8+\sqrt{17}\right)} \\
&\quad - \frac{9\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-23+\sqrt{17}\right)x^3}{1024\left(-49+12\sqrt{17}\right)\left(-12+\sqrt{17}\right)} \\
&\quad + \frac{27\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-23+\sqrt{17}\right)\left(-31+\sqrt{17}\right)x^4}{32768\left(-792+193\sqrt{17}\right)\left(-16+\sqrt{17}\right)} \\
&\quad - \frac{81\left(-7+\sqrt{17}\right)\left(-15+\sqrt{17}\right)\left(-23+\sqrt{17}\right)\left(-31+\sqrt{17}\right)\left(-39+\sqrt{17}\right)x^5}{1310720\left(-15953+3880\sqrt{17}\right)\left(-20+\sqrt{17}\right)} \\
&\quad + O\left(x^6\right)\Bigg)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & c_1 x^{\frac{7}{8}+\frac{\sqrt{17}}{8}} \left(1+\frac{\left(21+3\sqrt{17}\right) x}{32+8\sqrt{17}}+\frac{9\left(7+\sqrt{17}\right) \left(15+\sqrt{17}\right) x^{2}}{128 \left(4+\sqrt{17}\right) \left(8+\sqrt{17}\right)}\right. \\
& +\frac{9\left(7+\sqrt{17}\right) \left(15+\sqrt{17}\right) \left(23+\sqrt{17}\right) x^{3}}{1024 \left(49+12\sqrt{17}\right) \left(12+\sqrt{17}\right)} \\
& +\frac{27\left(7+\sqrt{17}\right) \left(15+\sqrt{17}\right) \left(23+\sqrt{17}\right) \left(31+\sqrt{17}\right) x^{4}}{32768 \left(792+193\sqrt{17}\right) \left(16+\sqrt{17}\right)} \\

$$

Verification of solutions

$$
y = c_1 x^{\frac{7}{8}+\frac{\sqrt{17}}{8}} \left(1+\frac{\left(21+3\sqrt{17}\right) x}{32+8\sqrt{17}}+\frac{9\left(7+\sqrt{17}\right) \left(15+\sqrt{17}\right) x^{2}}{128 \left(4+\sqrt{17}\right) \left(8+\sqrt{17}\right)} + \frac{9\left(7+\sqrt{17}\right) \left(15+\sqrt{17}\right) \left(23+\sqrt{17}\right) x^{3}}{1024 \left(49+12\sqrt{17}\right) \left(12+\sqrt{17}\right)} + \frac{27\left(7+\sqrt{17}\right) \left(15+\sqrt{17}\right) \left(23+\sqrt{17}\right) \left(31+\sqrt{17}\right) x^{4}}{32768 \left(792+193\sqrt{17}\right) \left(16+\sqrt{17}\right)} + \frac{81\left(7+\sqrt{17}\right) \left(15+\sqrt{17}\right) \left(23+\sqrt{17}\right) \left(31+\sqrt{17}\right) \left(39+\sqrt{17}\right) x^{5}}{1310720 \left(15953+3880\sqrt{17}\right) \left(20+\sqrt{17}\right)}+O\left(x^{6}\right)\right) + c_2 x^{\frac{7}{8}-\frac{\sqrt{17}}{8}} \left(1+\frac{\left(-21+3\sqrt{17}\right) x}{-32+8\sqrt{17}}+\frac{9\left(-7+\sqrt{17}\right) \left(-15+\sqrt{17}\right) x^{2}}{128 \left(-4+\sqrt{17}\right) \left(-8+\sqrt{17}\right)} - \frac{9\left(-7+\sqrt{17}\right) \left(-15+\sqrt{17}\right) \left(-23+\sqrt{17}\right) x^{3}}{1024 \left(-49+12\sqrt{17}\right) \left(-12+\sqrt{17}\right)} + \frac{27\left(-7+\sqrt{17}\right) \left(-15+\sqrt{17}\right) \left(-23+\sqrt{17}\right) \left(-31+\sqrt{17}\right) x^{4}}{32768 \left(-792+193\sqrt{17}\right) \left(-16+\sqrt{17}\right)} - \frac{81\left(-7+\sqrt{17}\right) \left(-15+\sqrt{17}\right) \left(-23+\sqrt{17}\right) \left(-31+\sqrt{17}\right) \left(-39+\sqrt{17}\right) x^{5}}{1310720 \left(-15953+3880\sqrt{17}\right) \left(-20+\sqrt{17}\right)} + O\left(x^{6}\right)\right)
$$

Verified OK.

23.11.1 Maple step by step solution

Let's solve

$4x^2y'' + (-3x^2 - 3x)\, y' + 2y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y}{2x^2} + \frac{3(x+1)y'}{4x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{3(x+1)y'}{4x} + \frac{y}{2x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- Define functions

  $\left[P_2(x) = -\frac{3(x+1)}{4x}, P_3(x) = \frac{1}{2x^2}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\Big|_{x=0} = -\frac{3}{4}$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = \frac{1}{2}$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4x^2y'' - 3x(x+1)\,y' + 2y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k- >k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^2 \cdot y''$ to series expansion

  $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(4r^2 - 7r + 2)\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(4k^2 + 8kr + 4r^2 - 7k - 7r + 2) - 3a_{k-1}(k+r-1)\right)x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $4r^2 - 7r + 2 = 0$

- Values of r that satisfy the indicial equation

$r \in \left\{\frac{7}{8}-\frac{\sqrt{17}}{8}, \frac{7}{8}+\frac{\sqrt{17}}{8}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $(4k^2+(8r-7)k+4r^2-7r+2)a_k-3a_{k-1}(k+r-1)=0$

- Shift index using $k->k+1$

  $\left(4(k+1)^2+(8r-7)(k+1)+4r^2-7r+2\right)a_{k+1}-3a_k(k+r)=0$

- Recursion relation that defines series solution to ODE

  $a_{k+1}=\frac{3a_k(k+r)}{4k^2+8kr+4r^2+k+r-1}$

- Recursion relation for $r=\frac{7}{8}-\frac{\sqrt{17}}{8}$

  $a_{k+1}=\frac{3a_k\left(k+\frac{7}{8}-\frac{\sqrt{17}}{8}\right)}{4k^2+8k\left(\frac{7}{8}-\frac{\sqrt{17}}{8}\right)+4\left(\frac{7}{8}-\frac{\sqrt{17}}{8}\right)^2+k-\frac{1}{8}-\frac{\sqrt{17}}{8}}$

- Solution for $r=\frac{7}{8}-\frac{\sqrt{17}}{8}$

  $\left[y=\sum_{k=0}^{\infty}a_kx^{k+\frac{7}{8}-\frac{\sqrt{17}}{8}}, a_{k+1}=\frac{3a_k\left(k+\frac{7}{8}-\frac{\sqrt{17}}{8}\right)}{4k^2+8k\left(\frac{7}{8}-\frac{\sqrt{17}}{8}\right)+4\left(\frac{7}{8}-\frac{\sqrt{17}}{8}\right)^2+k-\frac{1}{8}-\frac{\sqrt{17}}{8}}\right]$

- Recursion relation for $r=\frac{7}{8}+\frac{\sqrt{17}}{8}$

  $a_{k+1}=\frac{3a_k\left(k+\frac{7}{8}+\frac{\sqrt{17}}{8}\right)}{4k^2+8k\left(\frac{7}{8}+\frac{\sqrt{17}}{8}\right)+4\left(\frac{7}{8}+\frac{\sqrt{17}}{8}\right)^2+k-\frac{1}{8}+\frac{\sqrt{17}}{8}}$

- Solution for $r=\frac{7}{8}+\frac{\sqrt{17}}{8}$

  $\left[y=\sum_{k=0}^{\infty}a_kx^{k+\frac{7}{8}+\frac{\sqrt{17}}{8}}, a_{k+1}=\frac{3a_k\left(k+\frac{7}{8}+\frac{\sqrt{17}}{8}\right)}{4k^2+8k\left(\frac{7}{8}+\frac{\sqrt{17}}{8}\right)+4\left(\frac{7}{8}+\frac{\sqrt{17}}{8}\right)^2+k-\frac{1}{8}+\frac{\sqrt{17}}{8}}\right]$

- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty}a_kx^{k+\frac{7}{8}-\frac{\sqrt{17}}{8}}\right)+\left(\sum_{k=0}^{\infty}b_kx^{k+\frac{7}{8}+\frac{\sqrt{17}}{8}}\right), a_{k+1}=\frac{3a_k\left(k+\frac{7}{8}-\frac{\sqrt{17}}{8}\right)}{4k^2+8k\left(\frac{7}{8}-\frac{\sqrt{17}}{8}\right)+4\left(\frac{7}{8}-\frac{\sqrt{17}}{8}\right)^2+k-\frac{1}{8}-\frac{\sqrt{17}}{8}}, b_{k+1}=\right.$

Problem number: 16.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{9x^2y'' + 9\left(-x^2 + x\right)y' + y(x-1) = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$9x^2y'' + \left(-9x^2 + 9x\right)y' + y(x-1) = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{x-1}{x}$$
$$q(x) = \frac{x-1}{9x^2}$$

Table 658: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x-1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{x-1}{9x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$9x^2y'' + (-9x^2 + 9x)\, y' + y(x - 1) = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r)\,(n + r - 1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$9x^2 \left(\sum_{n=0}^{\infty} (n + r)\,(n + r - 1)\, a_n x^{n+r-2}\right) + (-9x^2 + 9x) \left(\sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right)(x - 1) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 9x^{n+r} a_n (n+r) (n+r-1)\right) + \sum_{n=0}^{\infty} \left(-9x^{1+n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 9x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-9x^{1+n+r} a_n (n+r)\right) = \sum_{n=1}^{\infty} \left(-9a_{n-1} (n+r-1) x^{n+r}\right)$$

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n = \sum_{n=1}^{\infty} a_{n-1} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 9x^{n+r} a_n (n+r) (n+r-1)\right) + \sum_{n=1}^{\infty} \left(-9a_{n-1} (n+r-1) x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 9x^{n+r} a_n (n+r)\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$9x^{n+r} a_n (n+r) (n+r-1) + 9x^{n+r} a_n (n+r) - a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$9x^r a_0 r(-1+r) + 9x^r a_0 r - a_0 x^r = 0$$

Or

$$\left(9x^r r(-1+r) + 9x^r r - x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(9r^2 - 1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$9r^2 - 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{3}$$
$$r_2 = -\frac{1}{3}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$(9r^2 - 1)\, x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{2}{3}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n \right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n \right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{3}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-\frac{1}{3}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$9a_n(n+r)(n+r-1) - 9a_{n-1}(n+r-1) + 9a_n(n+r) + a_{n-1} - a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}(9n + 9r - 10)}{9n^2 + 18nr + 9r^2 - 1} \tag{4}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_n = \frac{9na_{n-1} - 7a_{n-1}}{9n^2 + 6n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{3}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{-1 + 9r}{9r^2 + 18r + 8}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_1 = \frac{2}{15}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+9r}{9r^2+18r+8}$	$\frac{2}{15}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{81r^2 + 63r - 8}{(9r^2 + 18r + 8)(9r^2 + 36r + 35)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_2 = \frac{11}{360}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+9r}{9r^2+18r+8}$	$\frac{2}{15}$
a_2	$\frac{81r^2+63r-8}{(9r^2+18r+8)(9r^2+36r+35)}$	$\frac{11}{360}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{729r^3 + 1944r^2 + 999r - 136}{(9r^2 + 18r + 8)(9r^2 + 36r + 35)(9r^2 + 54r + 80)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_3 = \frac{1}{162}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+9r}{9r^2+18r+8}$	$\frac{2}{15}$
a_2	$\frac{81r^2+63r-8}{(9r^2+18r+8)(9r^2+36r+35)}$	$\frac{11}{360}$
a_3	$\frac{729r^3+1944r^2+999r-136}{(9r^2+18r+8)(9r^2+36r+35)(9r^2+54r+80)}$	$\frac{1}{162}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{6561r^4 + 36450r^3 + 59535r^2 + 24750r - 3536}{(9r^2 + 18r + 8)(9r^2 + 36r + 35)(9r^2 + 54r + 80)(9r^2 + 72r + 143)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_4 = \frac{29}{27216}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+9r}{9r^2+18r+8}$	$\frac{2}{15}$
a_2	$\frac{81r^2+63r-8}{(9r^2+18r+8)(9r^2+36r+35)}$	$\frac{11}{360}$
a_3	$\frac{729r^3+1944r^2+999r-136}{(9r^2+18r+8)(9r^2+36r+35)(9r^2+54r+80)}$	$\frac{1}{162}$
a_4	$\frac{6561r^4+36450r^3+59535r^2+24750r-3536}{(9r^2+18r+8)(9r^2+36r+35)(9r^2+54r+80)(9r^2+72r+143)}$	$\frac{29}{27216}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{59049r^5 + 557685r^4 + 1811565r^3 + 2306475r^2 + 834426r - 123760}{(9r^2 + 18r + 8)(9r^2 + 36r + 35)(9r^2 + 54r + 80)(9r^2 + 72r + 143)(9r^2 + 90r + 224)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_5 = \frac{551}{3470040}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+9r}{9r^2+18r+8}$	$\frac{2}{15}$
a_2	$\frac{81r^2+63r-8}{(9r^2+18r+8)(9r^2+36r+35)}$	$\frac{11}{360}$
a_3	$\frac{729r^3+1944r^2+999r-136}{(9r^2+18r+8)(9r^2+36r+35)(9r^2+54r+80)}$	$\frac{1}{162}$
a_4	$\frac{6561r^4+36450r^3+59535r^2+24750r-3536}{(9r^2+18r+8)(9r^2+36r+35)(9r^2+54r+80)(9r^2+72r+143)}$	$\frac{29}{27216}$
a_5	$\frac{59049r^5+557685r^4+1811565r^3+2306475r^2+834426r-123760}{(9r^2+18r+8)(9r^2+36r+35)(9r^2+54r+80)(9r^2+72r+143)(9r^2+90r+224)}$	$\frac{551}{3470040}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{1}{3}}\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots\right) \\ &= x^{\frac{1}{3}}\left(1 + \frac{2x}{15} + \frac{11x^2}{360} + \frac{x^3}{162} + \frac{29x^4}{27216} + \frac{551x^5}{3470040} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$9b_n(n+r)(n+r-1) - 9b_{n-1}(n+r-1) + 9b_n(n+r) + b_{n-1} - b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = \frac{b_{n-1}(9n+9r-10)}{9n^2+18nr+9r^2-1} \tag{4}$$

Which for the root $r = -\frac{1}{3}$ becomes

$$b_n = \frac{9nb_{n-1} - 13b_{n-1}}{9n^2-6n} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{1}{3}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{-1 + 9r}{9r^2 + 18r + 8}$$

Which for the root $r = -\frac{1}{3}$ becomes

$$b_1 = -\frac{4}{3}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1+9r}{9r^2+18r+8}$	$-\frac{4}{3}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{81r^2 + 63r - 8}{(9r^2 + 18r + 8)(9r^2 + 36r + 35)}$$

Which for the root $r = -\frac{1}{3}$ becomes

$$b_2 = -\frac{5}{18}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1+9r}{9r^2+18r+8}$	$-\frac{4}{3}$
b_2	$\frac{81r^2+63r-8}{(9r^2+18r+8)(9r^2+36r+35)}$	$-\frac{5}{18}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{729r^3 + 1944r^2 + 999r - 136}{(9r^2 + 18r + 8)(9r^2 + 36r + 35)(9r^2 + 54r + 80)}$$

Which for the root $r = -\frac{1}{3}$ becomes

$$b_3 = -\frac{5}{81}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1+9r}{9r^2+18r+8}$	$-\frac{4}{3}$
b_2	$\frac{81r^2+63r-8}{(9r^2+18r+8)(9r^2+36r+35)}$	$-\frac{5}{18}$
b_3	$\frac{729r^3+1944r^2+999r-136}{(9r^2+18r+8)(9r^2+36r+35)(9r^2+54r+80)}$	$-\frac{5}{81}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{6561r^4 + 36450r^3 + 59535r^2 + 24750r - 3536}{(9r^2 + 18r + 8)(9r^2 + 36r + 35)(9r^2 + 54r + 80)(9r^2 + 72r + 143)}$$

Which for the root $r = -\frac{1}{3}$ becomes

$$b_4 = -\frac{23}{1944}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1+9r}{9r^2+18r+8}$	$-\frac{4}{3}$
b_2	$\frac{81r^2+63r-8}{(9r^2+18r+8)(9r^2+36r+35)}$	$-\frac{5}{18}$
b_3	$\frac{729r^3+1944r^2+999r-136}{(9r^2+18r+8)(9r^2+36r+35)(9r^2+54r+80)}$	$-\frac{5}{81}$
b_4	$\frac{6561r^4+36450r^3+59535r^2+24750r-3536}{(9r^2+18r+8)(9r^2+36r+35)(9r^2+54r+80)(9r^2+72r+143)}$	$-\frac{23}{1944}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{59049r^5 + 557685r^4 + 1811565r^3 + 2306475r^2 + 834426r - 123760}{(9r^2 + 18r + 8)(9r^2 + 36r + 35)(9r^2 + 54r + 80)(9r^2 + 72r + 143)(9r^2 + 90r + 224)}$$

Which for the root $r = -\frac{1}{3}$ becomes

$$b_5 = -\frac{92}{47385}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1+9r}{9r^2+18r+8}$	$-\frac{4}{3}$
b_2	$\frac{81r^2+63r-8}{(9r^2+18r+8)(9r^2+36r+35)}$	$-\frac{5}{18}$
b_3	$\frac{729r^3+1944r^2+999r-136}{(9r^2+18r+8)(9r^2+36r+35)(9r^2+54r+80)}$	$-\frac{5}{81}$
b_4	$\frac{6561r^4+36450r^3+59535r^2+24750r-3536}{(9r^2+18r+8)(9r^2+36r+35)(9r^2+54r+80)(9r^2+72r+143)}$	$-\frac{23}{1944}$
b_5	$\frac{59049r^5+557685r^4+1811565r^3+2306475r^2+834426r-123760}{(9r^2+18r+8)(9r^2+36r+35)(9r^2+54r+80)(9r^2+72r+143)(9r^2+90r+224)}$	$-\frac{92}{47385}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x^{\frac{1}{3}}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= \frac{1 - \frac{4x}{3} - \frac{5x^2}{18} - \frac{5x^3}{81} - \frac{23x^4}{1944} - \frac{92x^5}{47385} + O(x^6)}{x^{\frac{1}{3}}}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{\frac{1}{3}}\left(1 + \frac{2x}{15} + \frac{11x^2}{360} + \frac{x^3}{162} + \frac{29x^4}{27216} + \frac{551x^5}{3470040} + O(x^6)\right) \\
&\quad + \frac{c_2\left(1 - \frac{4x}{3} - \frac{5x^2}{18} - \frac{5x^3}{81} - \frac{23x^4}{1944} - \frac{92x^5}{47385} + O(x^6)\right)}{x^{\frac{1}{3}}}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{\frac{1}{3}}\left(1 + \frac{2x}{15} + \frac{11x^2}{360} + \frac{x^3}{162} + \frac{29x^4}{27216} + \frac{551x^5}{3470040} + O(x^6)\right) \\
&\quad + \frac{c_2\left(1 - \frac{4x}{3} - \frac{5x^2}{18} - \frac{5x^3}{81} - \frac{23x^4}{1944} - \frac{92x^5}{47385} + O(x^6)\right)}{x^{\frac{1}{3}}}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x^{\frac{1}{3}}\left(1 + \frac{2x}{15} + \frac{11x^2}{360} + \frac{x^3}{162} + \frac{29x^4}{27216} + \frac{551x^5}{3470040} + O(x^6)\right) \\
&\quad + \frac{c_2\left(1 - \frac{4x}{3} - \frac{5x^2}{18} - \frac{5x^3}{81} - \frac{23x^4}{1944} - \frac{92x^5}{47385} + O(x^6)\right)}{x^{\frac{1}{3}}}
\end{aligned}
\tag{1}
$$

Verification of solutions

$$y = c_1 x^{\frac{1}{3}}\left(1+\frac{2x}{15}+\frac{11x^2}{360}+\frac{x^3}{162}+\frac{29x^4}{27216}+\frac{551x^5}{3470040}+O(x^6)\right)$$
$$+\frac{c_2\left(1-\frac{4x}{3}-\frac{5x^2}{18}-\frac{5x^3}{81}-\frac{23x^4}{1944}-\frac{92x^5}{47385}+O(x^6)\right)}{x^{\frac{1}{3}}}$$

Verified OK.

23.12.1 Maple step by step solution

Let's solve

$9x^2y''+(-9x^2+9x)\,y'+y(x-1)=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{(x-1)y}{9x^2}+\frac{(x-1)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{(x-1)y'}{x}+\frac{(x-1)y}{9x^2}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=-\frac{x-1}{x}, P_3(x)=\frac{x-1}{9x^2}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

    $(x\cdot P_2(x))\Big|_{x=0}=1$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

    $(x^2\cdot P_3(x))\Big|_{x=0}=-\frac{1}{9}$

  ◦ $x=0$is a regular singular point

    Check to see if $x_0=0$ is a regular singular point

    $x_0=0$

- Multiply by denominators

  $9x^2y''-9x(x-1)\,y'+y(x-1)=0$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..1$

$$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k->k-m$

$$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$$

- Convert $x^2 \cdot y''$ to series expansion

$$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(1+3r)\,(-1+3r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(3k+3r+1)\,(3k+3r-1) - a_{k-1}(9k-10+9r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(1+3r)\,(-1+3r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{-\frac{1}{3}, \frac{1}{3}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$a_k(3k+3r+1)\,(3k+3r-1) - a_{k-1}(9k-10+9r) = 0$$

- Shift index using $k->k+1$

$$a_{k+1}(3k+4+3r)\,(3k+2+3r) - a_k(9k+9r-1) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{a_k(9k+9r-1)}{(3k+4+3r)(3k+2+3r)}$$

- Recursion relation for $r = -\frac{1}{3}$

$$a_{k+1} = \frac{a_k(9k-4)}{(3k+3)(3k+1)}$$

- Solution for $r = -\frac{1}{3}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{3}}, a_{k+1} = \frac{a_k(9k-4)}{(3k+3)(3k+1)}\right]$$

- Recursion relation for $r = \frac{1}{3}$

$$a_{k+1} = \frac{a_k(9k+2)}{(3k+5)(3k+3)}$$

- Solution for $r = \frac{1}{3}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+1} = \frac{a_k(9k+2)}{(3k+5)(3k+3)}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{3}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+1} = \frac{a_k(9k-4)}{(3k+3)(3k+1)}, b_{k+1} = \frac{b_k(9k+2)}{(3k+5)(3k+3)}\right]$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 41, page 195
Problem number: 17.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{4x^2(1-x)\,y''+3x(1+2x)\,y'-3y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(-4x^3+4x^2\right)y''+\left(6x^2+3x\right)y'-3y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=-\frac{3(1+2x)}{4x\,(x-1)}$$
$$q(x)=\frac{3}{4x^2\,(x-1)}$$

Table 660: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{3(1+2x)}{4x(x-1)}$	
singularity	type
$x = 0$	"regular"
$x = 1$	"regular"

$q(x) = \frac{3}{4x^2(x-1)}$	
singularity	type
$x = 0$	"regular"
$x = 1$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, 1, \infty]$

Irregular singular points : $[]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$-4y''x^2(x-1) + \left(6x^2 + 3x\right) y' - 3y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$-4\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x^2(x-1) + \left(6x^2+3x\right)\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) - 3\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\sum_{n=0}^{\infty}\left(-4x^{1+n+r}a_n(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty}4x^{n+r}a_n(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty}6x^{1+n+r}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}3x^{n+r}a_n(n+r)\right)+\sum_{n=0}^{\infty}\left(-3a_nx^{n+r}\right)=0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty}\left(-4x^{1+n+r}a_n(n+r)(n+r-1)\right)=\sum_{n=1}^{\infty}\left(-4a_{n-1}(n+r-1)(n+r-2)x^{n+r}\right)$$

$$\sum_{n=0}^{\infty}6x^{1+n+r}a_n(n+r)=\sum_{n=1}^{\infty}6a_{n-1}(n+r-1)x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\sum_{n=1}^{\infty}\left(-4a_{n-1}(n+r-1)(n+r-2)x^{n+r}\right)+\left(\sum_{n=0}^{\infty}4x^{n+r}a_n(n+r)(n+r-1)\right)+\left(\sum_{n=1}^{\infty}6a_{n-1}(n+r-1)x^{n+r}\right)+\left(\sum_{n=0}^{\infty}3x^{n+r}a_n(n+r)\right)+\sum_{n=0}^{\infty}\left(-3a_nx^{n+r}\right)=0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$4x^{n+r}a_n(n+r)(n+r-1)+3x^{n+r}a_n(n+r)-3a_nx^{n+r}=0$$

When $n=0$ the above becomes

$$4x^ra_0r(-1+r)+3x^ra_0r-3a_0x^r=0$$

Or

$$\left(4x^rr(-1+r)+3x^rr-3x^r\right)a_0=0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(4r^2 - r - 3\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$4r^2 - r - 3 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = -\frac{3}{4}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(4r^2 - r - 3\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{7}{4}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{1+n}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-\frac{3}{4}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$\begin{aligned} -4a_{n-1}(n+r-1)(n+r-2) + 4a_n(n+r)(n+r-1) \\ + 6a_{n-1}(n+r-1) + 3a_n(n+r) - 3a_n = 0 \end{aligned} \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{2(2n+2r-7)\, a_{n-1}}{4n+4r+3} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = \frac{(4n - 10)\, a_{n-1}}{4n + 7} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{4r - 10}{7 + 4r}$$

Which for the root $r = 1$ becomes

$$a_1 = -\frac{6}{11}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{4r-10}{7+4r}$	$-\frac{6}{11}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{16r^2 - 64r + 60}{16r^2 + 72r + 77}$$

Which for the root $r = 1$ becomes

$$a_2 = \frac{4}{55}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{4r-10}{7+4r}$	$-\frac{6}{11}$
a_2	$\frac{16r^2-64r+60}{16r^2+72r+77}$	$\frac{4}{55}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{64r^3 - 288r^2 + 368r - 120}{64r^3 + 528r^2 + 1388r + 1155}$$

Which for the root $r = 1$ becomes

$$a_3 = \frac{8}{1045}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{4r-10}{7+4r}$	$-\frac{6}{11}$
a_2	$\frac{16r^2-64r+60}{16r^2+72r+77}$	$\frac{4}{55}$
a_3	$\frac{64r^3-288r^2+368r-120}{64r^3+528r^2+1388r+1155}$	$\frac{8}{1045}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{256r^4 - 1024r^3 + 896r^2 + 256r - 240}{256r^4 + 3328r^3 + 15584r^2 + 30992r + 21945}$$

Which for the root $r = 1$ becomes

$$a_4 = \frac{48}{24035}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{4r-10}{7+4r}$	$-\frac{6}{11}$
a_2	$\frac{16r^2-64r+60}{16r^2+72r+77}$	$\frac{4}{55}$
a_3	$\frac{64r^3-288r^2+368r-120}{64r^3+528r^2+1388r+1155}$	$\frac{8}{1045}$
a_4	$\frac{256r^4-1024r^3+896r^2+256r-240}{256r^4+3328r^3+15584r^2+30992r+21945}$	$\frac{48}{24035}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{1024r^5 - 2560r^4 - 2560r^3 + 6400r^2 + 576r - 1440}{1024r^5 + 19200r^4 + 138880r^3 + 482400r^2 + 800596r + 504735}$$

Which for the root $r = 1$ becomes

$$a_5 = \frac{32}{43263}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{4r-10}{7+4r}$	$-\frac{6}{11}$
a_2	$\frac{16r^2-64r+60}{16r^2+72r+77}$	$\frac{4}{55}$
a_3	$\frac{64r^3-288r^2+368r-120}{64r^3+528r^2+1388r+1155}$	$\frac{8}{1045}$
a_4	$\frac{256r^4-1024r^3+896r^2+256r-240}{256r^4+3328r^3+15584r^2+30992r+21945}$	$\frac{48}{24035}$
a_5	$\frac{1024r^5-2560r^4-2560r^3+6400r^2+576r-1440}{1024r^5+19200r^4+138880r^3+482400r^2+800596r+504735}$	$\frac{32}{43263}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\
&= x\left(1 - \frac{6x}{11} + \frac{4x^2}{55} + \frac{8x^3}{1045} + \frac{48x^4}{24035} + \frac{32x^5}{43263} + O(x^6)\right)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$\begin{aligned}
&-4b_{n-1}(n+r-1)(n+r-2) + 4b_n(n+r)(n+r-1) \\
&+ 6b_{n-1}(n+r-1) + 3b_n(n+r) - 3b_n = 0
\end{aligned} \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = \frac{2(2n+2r-7)\, b_{n-1}}{4n+4r+3} \tag{4}$$

Which for the root $r = -\frac{3}{4}$ becomes

$$b_n = \frac{(4n-17)\, b_{n-1}}{4n} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{3}{4}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{4r - 10}{7 + 4r}$$

Which for the root $r = -\frac{3}{4}$ becomes

$$b_1 = -\frac{13}{4}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{4r-10}{7+4r}$	$-\frac{13}{4}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{16r^2 - 64r + 60}{16r^2 + 72r + 77}$$

Which for the root $r = -\frac{3}{4}$ becomes

$$b_2 = \frac{117}{32}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{4r-10}{7+4r}$	$-\frac{13}{4}$
b_2	$\frac{16r^2-64r+60}{16r^2+72r+77}$	$\frac{117}{32}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{64r^3 - 288r^2 + 368r - 120}{64r^3 + 528r^2 + 1388r + 1155}$$

Which for the root $r = -\frac{3}{4}$ becomes

$$b_3 = -\frac{195}{128}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{4r-10}{7+4r}$	$-\frac{13}{4}$
b_2	$\frac{16r^2-64r+60}{16r^2+72r+77}$	$\frac{117}{32}$
b_3	$\frac{64r^3-288r^2+368r-120}{64r^3+528r^2+1388r+1155}$	$-\frac{195}{128}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{256r^4 - 1024r^3 + 896r^2 + 256r - 240}{256r^4 + 3328r^3 + 15584r^2 + 30992r + 21945}$$

Which for the root $r = -\frac{3}{4}$ becomes

$$b_4 = \frac{195}{2048}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{4r-10}{7+4r}$	$-\frac{13}{4}$
b_2	$\frac{16r^2-64r+60}{16r^2+72r+77}$	$\frac{117}{32}$
b_3	$\frac{64r^3-288r^2+368r-120}{64r^3+528r^2+1388r+1155}$	$-\frac{195}{128}$
b_4	$\frac{256r^4-1024r^3+896r^2+256r-240}{256r^4+3328r^3+15584r^2+30992r+21945}$	$\frac{195}{2048}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{1024r^5 - 2560r^4 - 2560r^3 + 6400r^2 + 576r - 1440}{1024r^5 + 19200r^4 + 138880r^3 + 482400r^2 + 800596r + 504735}$$

Which for the root $r = -\frac{3}{4}$ becomes

$$b_5 = \frac{117}{8192}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{4r-10}{7+4r}$	$-\frac{13}{4}$
b_2	$\frac{16r^2-64r+60}{16r^2+72r+77}$	$\frac{117}{32}$
b_3	$\frac{64r^3-288r^2+368r-120}{64r^3+528r^2+1388r+1155}$	$-\frac{195}{128}$
b_4	$\frac{256r^4-1024r^3+896r^2+256r-240}{256r^4+3328r^3+15584r^2+30992r+21945}$	$\frac{195}{2048}$
b_5	$\frac{1024r^5-2560r^4-2560r^3+6400r^2+576r-1440}{1024r^5+19200r^4+138880r^3+482400r^2+800596r+504735}$	$\frac{117}{8192}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= \frac{1 - \frac{13x}{4} + \frac{117x^2}{32} - \frac{195x^3}{128} + \frac{195x^4}{2048} + \frac{117x^5}{8192} + O(x^6)}{x^{\frac{3}{4}}}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x\left(1 - \frac{6x}{11} + \frac{4x^2}{55} + \frac{8x^3}{1045} + \frac{48x^4}{24035} + \frac{32x^5}{43263} + O(x^6)\right) \\
&+ \frac{c_2\left(1 - \frac{13x}{4} + \frac{117x^2}{32} - \frac{195x^3}{128} + \frac{195x^4}{2048} + \frac{117x^5}{8192} + O(x^6)\right)}{x^{\frac{3}{4}}}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x\left(1 - \frac{6x}{11} + \frac{4x^2}{55} + \frac{8x^3}{1045} + \frac{48x^4}{24035} + \frac{32x^5}{43263} + O(x^6)\right) \\
&+ \frac{c_2\left(1 - \frac{13x}{4} + \frac{117x^2}{32} - \frac{195x^3}{128} + \frac{195x^4}{2048} + \frac{117x^5}{8192} + O(x^6)\right)}{x^{\frac{3}{4}}}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1 x \left(1-\frac{6x}{11}+\frac{4x^2}{55}+\frac{8x^3}{1045}+\frac{48x^4}{24035}+\frac{32x^5}{43263}+O(x^6)\right) + \frac{c_2\left(1-\frac{13x}{4}+\frac{117x^2}{32}-\frac{195x^3}{128}+\frac{195x^4}{2048}+\frac{117x^5}{8192}+O(x^6)\right)}{x^{\frac{3}{4}}} \tag{1}$$

Verification of solutions

$$y = c_1 x \left(1-\frac{6x}{11}+\frac{4x^2}{55}+\frac{8x^3}{1045}+\frac{48x^4}{24035}+\frac{32x^5}{43263}+O(x^6)\right) + \frac{c_2\left(1-\frac{13x}{4}+\frac{117x^2}{32}-\frac{195x^3}{128}+\frac{195x^4}{2048}+\frac{117x^5}{8192}+O(x^6)\right)}{x^{\frac{3}{4}}}$$

Verified OK.

23.13.1 Maple step by step solution

Let's solve

$-4y''x^2(x-1)+(6x^2+3x)\,y'-3y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{3y}{4x^2(x-1)}+\frac{3(1+2x)y'}{4x(x-1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{3(1+2x)y'}{4x(x-1)}+\frac{3y}{4x^2(x-1)}=0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x)=-\frac{3(1+2x)}{4x(x-1)}, P_3(x)=\frac{3}{4x^2(x-1)}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $(x\cdot P_2(x))\Big|_{x=0}=\frac{3}{4}$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

$\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = -\frac{3}{4}$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4y''x^2(x-1) - 3x(1+2x)\,y' + 3y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k- >k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^m \cdot y''$ to series expansion for $m = 2..3$

  $x^m \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

- Shift index using $k- >k+2-m$

  $x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $-a_0(3+4r)\,(-1+r)\,x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(4k+4r+3)\,(k+r-1) + 2a_{k-1}(k+r-1)\,(2k-7+2r)\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-(3+4r)\,(-1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{1, -\frac{3}{4}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $-4(k+r-1)\left(\left(-k-r+\frac{7}{2}\right)a_{k-1} + a_k\left(k+r+\frac{3}{4}\right)\right) = 0$

- Shift index using $k- >k+1$

  $-4(k+r)\left(\left(-k+\frac{5}{2}-r\right) a_{k}+a_{k+1}\left(k+\frac{7}{4}+r\right)\right)=0$
- Recursion relation that defines series solution to ODE

  $a_{k+1}=\frac{2(2k+2r-5)a_{k}}{4k+7+4r}$
- Recursion relation for $r=1$

  $a_{k+1}=\frac{2(2k-3)a_{k}}{4k+11}$
- Solution for $r=1$

  $\left[y=\sum_{k=0}^{\infty} a_{k} x^{k+1}, a_{k+1}=\frac{2(2k-3)a_{k}}{4k+11}\right]$
- Recursion relation for $r=-\frac{3}{4}$

  $a_{k+1}=\frac{2\left(2k-\frac{13}{2}\right)a_{k}}{4k+4}$
- Solution for $r=-\frac{3}{4}$

  $\left[y=\sum_{k=0}^{\infty} a_{k} x^{k-\frac{3}{4}}, a_{k+1}=\frac{2\left(2k-\frac{13}{2}\right)a_{k}}{4k+4}\right]$
- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty} a_{k} x^{k+1}\right)+\left(\sum_{k=0}^{\infty} b_{k} x^{k-\frac{3}{4}}\right), a_{k+1}=\frac{2(2k-3)a_{k}}{4k+11}, b_{k+1}=\frac{2\left(2k-\frac{13}{2}\right)b_{k}}{4k+4}\right]$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 41, page 195
Problem number: 18.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{2x^2(1-3x)\,y''+5xy'-2y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(-6x^3+2x^2\right)y''+5xy'-2y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=-\frac{5}{2x\,(3x-1)}$$
$$q(x)=\frac{1}{x^2\,(3x-1)}$$

Table 662: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{5}{2x(3x-1)}$	
singularity	type
$x = 0$	"regular"
$x = \frac{1}{3}$	"regular"

$q(x) = \frac{1}{x^2(3x-1)}$	
singularity	type
$x = 0$	"regular"
$x = \frac{1}{3}$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $\left[0, \frac{1}{3}, \infty\right]$

Irregular singular points : []

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$-2y''x^2(3x-1) + 5xy' - 2y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$
$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$-2\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x^2(3x-1) + 5x\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) - 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\sum_{n=0}^{\infty} \left(-6x^{1+n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 5x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-2a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-6x^{1+n+r} a_n (n+r)(n+r-1)\right) = \sum_{n=1}^{\infty} \left(-6a_{n-1}(n+r-1)(n+r-2)\, x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\sum_{n=1}^{\infty} \left(-6a_{n-1}(n+r-1)(n+r-2)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 5x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-2a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r} a_n (n+r)(n+r-1) + 5x^{n+r} a_n (n+r) - 2a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$2x^r a_0 r(-1+r) + 5x^r a_0 r - 2a_0 x^r = 0$$

Or

$$\left(2x^r r(-1+r) + 5x^r r - 2x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(2r^2 + 3r - 2\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 + 3r - 2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{2}$$
$$r_2 = -2$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(2r^2 + 3r - 2\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{5}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{2}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-2}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$-6a_{n-1}(n + r - 1)(n + r - 2) + 2a_n(n + r)(n + r - 1) + 5a_n(n + r) - 2a_n = 0 \quad (3)$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{6a_{n-1}(n + r - 1)(n + r - 2)}{2n^2 + 4nr + 2r^2 + 3n + 3r - 2} \quad (4)$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_n = \frac{3a_{n-1}(4n^2 - 8n + 3)}{4n^2 + 10n} \quad (5)$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{6r(-1+r)}{2r^2+7r+3}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_1 = -\frac{3}{14}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{6r(-1+r)}{2r^2+7r+3}$	$-\frac{3}{14}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{36r^4-36r^2}{4r^4+36r^3+107r^2+117r+36}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_2 = -\frac{3}{56}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{6r(-1+r)}{2r^2+7r+3}$	$-\frac{3}{14}$
a_2	$\frac{36r^4-36r^2}{4r^4+36r^3+107r^2+117r+36}$	$-\frac{3}{56}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{216r^2(-1+r)(1+r)^2(2+r)}{8r^6+132r^5+854r^4+2739r^3+4502r^2+3465r+900}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_3 = -\frac{45}{1232}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{6r(-1+r)}{2r^2+7r+3}$	$-\frac{3}{14}$
a_2	$\frac{36r^4-36r^2}{4r^4+36r^3+107r^2+117r+36}$	$-\frac{3}{56}$
a_3	$\frac{216r^2(-1+r)(1+r)^2(2+r)}{8r^6+132r^5+854r^4+2739r^3+4502r^2+3465r+900}$	$-\frac{45}{1232}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1296r^2(-1+r)(1+r)^2(2+r)^2}{16r^7+368r^6+3448r^5+16904r^4+46201r^3+68903r^2+50010r+12600}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_4 = -\frac{675}{18304}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{6r(-1+r)}{2r^2+7r+3}$	$-\frac{3}{14}$
a_2	$\frac{36r^4-36r^2}{4r^4+36r^3+107r^2+117r+36}$	$-\frac{3}{56}$
a_3	$\frac{216r^2(-1+r)(1+r)^2(2+r)}{8r^6+132r^5+854r^4+2739r^3+4502r^2+3465r+900}$	$-\frac{45}{1232}$
a_4	$\frac{1296r^2(-1+r)(1+r)^2(2+r)^2}{16r^7+368r^6+3448r^5+16904r^4+46201r^3+68903r^2+50010r+12600}$	$-\frac{675}{18304}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{7776(3+r)\,r^2(-1+r)(1+r)^2(2+r)^2}{32r^8+976r^7+12464r^6+86440r^5+352658r^4+854749r^3+1176456r^2+810495r+198450}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_5 = -\frac{1701}{36608}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{6r(-1+r)}{2r^2+7r+3}$	$-\frac{3}{14}$
a_2	$\frac{36r^4-36r^2}{4r^4+36r^3+107r^2+117r+36}$	$-\frac{3}{56}$
a_3	$\frac{216r^2(-1+r)(1+r)^2(2+r)}{8r^6+132r^5+854r^4+2739r^3+4502r^2+3465r+900}$	$-\frac{45}{1232}$
a_4	$\frac{1296r^2(-1+r)(1+r)^2(2+r)^2}{16r^7+368r^6+3448r^5+16904r^4+46201r^3+68903r^2+50010r+12600}$	$-\frac{675}{18304}$
a_5	$\frac{7776(3+r)r^2(-1+r)(1+r)^2(2+r)^2}{32r^8+976r^7+12464r^6+86440r^5+352658r^4+854749r^3+1176456r^2+810495r+198450}$	$-\frac{1701}{36608}$

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= \sqrt{x}\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots\right) \\
&= \sqrt{x}\left(1 - \frac{3x}{14} - \frac{3x^2}{56} - \frac{45x^3}{1232} - \frac{675x^4}{18304} - \frac{1701x^5}{36608} + O(x^6)\right)
\end{aligned}
$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$
-6b_{n-1}(n+r-1)(n+r-2) + 2b_n(n+r)(n+r-1) + 5b_n(n+r) - 2b_n = 0 \quad (3)
$$

Solving for b_n from recursive equation (4) gives

$$
b_n = \frac{6b_{n-1}(n+r-1)(n+r-2)}{2n^2+4nr+2r^2+3n+3r-2} \tag{4}
$$

Which for the root $r = -2$ becomes

$$
b_n = \frac{6b_{n-1}(n-3)(n-4)}{n(2n-5)} \tag{5}
$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -2$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{6r(-1+r)}{2r^2 + 7r + 3}$$

Which for the root $r = -2$ becomes

$$b_1 = -12$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{6r(-1+r)}{2r^2+7r+3}$	-12

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{36r^4 - 36r^2}{4r^4 + 36r^3 + 107r^2 + 117r + 36}$$

Which for the root $r = -2$ becomes

$$b_2 = 72$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{6r(-1+r)}{2r^2+7r+3}$	-12
b_2	$\frac{36r^4-36r^2}{4r^4+36r^3+107r^2+117r+36}$	72

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{216r^2(-1+r)(1+r)^2(2+r)}{8r^6 + 132r^5 + 854r^4 + 2739r^3 + 4502r^2 + 3465r + 900}$$

Which for the root $r = -2$ becomes

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{6r(-1+r)}{2r^2+7r+3}$	-12
b_2	$\frac{36r^4-36r^2}{4r^4+36r^3+107r^2+117r+36}$	72
b_3	$\frac{216r^2(-1+r)(1+r)^2(2+r)}{8r^6+132r^5+854r^4+2739r^3+4502r^2+3465r+900}$	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1296r^2(-1+r)\,(1+r)^2\,(2+r)^2}{16r^7+368r^6+3448r^5+16904r^4+46201r^3+68903r^2+50010r+12600}$$

Which for the root $r = -2$ becomes

$$b_4 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{6r(-1+r)}{2r^2+7r+3}$	-12
b_2	$\frac{36r^4-36r^2}{4r^4+36r^3+107r^2+117r+36}$	72
b_3	$\frac{216r^2(-1+r)(1+r)^2(2+r)}{8r^6+132r^5+854r^4+2739r^3+4502r^2+3465r+900}$	0
b_4	$\frac{1296r^2(-1+r)(1+r)^2(2+r)^2}{16r^7+368r^6+3448r^5+16904r^4+46201r^3+68903r^2+50010r+12600}$	0

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{7776(3+r)\,r^2(-1+r)\,(1+r)^2\,(2+r)^2}{32r^8+976r^7+12464r^6+86440r^5+352658r^4+854749r^3+1176456r^2+810495r+198450}$$

Which for the root $r = -2$ becomes

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{6r(-1+r)}{2r^2+7r+3}$	-12
b_2	$\frac{36r^4-36r^2}{4r^4+36r^3+107r^2+117r+36}$	72
b_3	$\frac{216r^2(-1+r)(1+r)^2(2+r)}{8r^6+132r^5+854r^4+2739r^3+4502r^2+3465r+900}$	0
b_4	$\frac{1296r^2(-1+r)(1+r)^2(2+r)^2}{16r^7+368r^6+3448r^5+16904r^4+46201r^3+68903r^2+50010r+12600}$	0
b_5	$\frac{7776(3+r)r^2(-1+r)(1+r)^2(2+r)^2}{32r^8+976r^7+12464r^6+86440r^5+352658r^4+854749r^3+1176456r^2+810495r+198450}$	0

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= \sqrt{x}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= \frac{1 - 12x + 72x^2 + O(x^6)}{x^2}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1\sqrt{x}\left(1-\frac{3x}{14}-\frac{3x^2}{56}-\frac{45x^3}{1232}-\frac{675x^4}{18304}-\frac{1701x^5}{36608}+O\left(x^6\right)\right)+\frac{c_2(1 - 12x + 72x^2 + O(x^6))}{x^2}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1\sqrt{x}\left(1-\frac{3x}{14}-\frac{3x^2}{56}-\frac{45x^3}{1232}-\frac{675x^4}{18304}-\frac{1701x^5}{36608}+O\left(x^6\right)\right)+\frac{c_2(1 - 12x + 72x^2 + O(x^6))}{x^2}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & c_1\sqrt{x}\left(1-\frac{3x}{14}-\frac{3x^2}{56}-\frac{45x^3}{1232}-\frac{675x^4}{18304}-\frac{1701x^5}{36608}+O\left(x^6\right)\right) \\
& + \frac{c_2(1 - 12x + 72x^2 + O(x^6))}{x^2}
\end{aligned} \tag{1}
$$

Verification of solutions

$$y = c_1\sqrt{x}\left(1-\frac{3x}{14}-\frac{3x^2}{56}-\frac{45x^3}{1232}-\frac{675x^4}{18304}-\frac{1701x^5}{36608}+O(x^6)\right) + \frac{c_2(1-12x+72x^2+O(x^6))}{x^2}$$

Verified OK.

23.14.1 Maple step by step solution

Let's solve

$-2y''x^2(3x-1)+5xy'-2y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{y}{x^2(3x-1)}+\frac{5y'}{2x(3x-1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{5y'}{2x(3x-1)}+\frac{y}{x^2(3x-1)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=-\frac{5}{2x(3x-1)}, P_3(x)=\frac{1}{x^2(3x-1)}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

    $(x\cdot P_2(x))\bigg|_{x=0}=\frac{5}{2}$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

    $(x^2\cdot P_3(x))\bigg|_{x=0}=-1$

  ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $2y''x^2(3x-1)-5xy'+2y=0$

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r}$

- Convert $x^m \cdot y''$ to series expansion for $m = 2..3$

  $x^m \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$

- Shift index using $k- >k+2-m$

  $x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $-a_0(2+r)\,(-1+2r)\, x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(k+r+2)\,(2k+2r-1) + 6a_{k-1}(k+r-1)\,(k-2+r)\right) x\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-(2+r)\,(-1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-2, \frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $6a_{k-1}(k+r-1)\,(k-2+r) - 2(k+r+2)\left(k+r-\frac{1}{2}\right) a_k = 0$

- Shift index using $k- >k+1$

  $6a_k(k+r)\,(k+r-1) - 2(k+3+r)\left(k+\frac{1}{2}+r\right) a_{k+1} = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{6a_k(k+r)(k+r-1)}{(k+3+r)(2k+1+2r)}$

- Recursion relation for $r = -2$; series terminates at $k = 2$

  $a_{k+1} = \frac{6a_k(k-2)(k-3)}{(k+1)(2k-3)}$

- Apply recursion relation for $k = 0$

  $a_1 = -12a_0$

- Apply recursion relation for $k = 1$

  $a_2 = -6a_1$

- Express in terms of a_0

  $a_2 = 72a_0$

- Terminating series solution of the ODE for $r = -2$. Use reduction of order to find the second

  $y = a_0 \cdot (1 - 12x + 72x^2)$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+1} = \frac{6a_k (k+\frac{1}{2})(k-\frac{1}{2})}{(k+\frac{7}{2})(2k+2)}$

- Solution for $r = \frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = \frac{6a_k (k+\frac{1}{2})(k-\frac{1}{2})}{(k+\frac{7}{2})(2k+2)}\right]$

- Combine solutions and rename parameters

  $\left[y = a_0 \cdot (1 - 12x + 72x^2) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), b_{k+1} = \frac{6b_k (k+\frac{1}{2})(k-\frac{1}{2})}{(k+\frac{7}{2})(2k+2)}\right]$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 41, page 195
Problem number: 19.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{4x^2(x+1)\,y''-5xy'+2y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(4x^3+4x^2\right)y''-5xy'+2y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=-\frac{5}{4x\,(x+1)}$$
$$q(x)=\frac{1}{2x^2\,(x+1)}$$

Table 664: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{5}{4x(x+1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

$q(x) = \frac{1}{2x^2(x+1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-1, 0, \infty]$

Irregular singular points : []

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$4x^2(x+1)\,y'' - 5xy' + 2y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$4x^2(x+1)\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) - 5x\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$
\left(\sum_{n=0}^{\infty} 4x^{1+n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 4x^{n+r} a_n (n+r)(n+r-1)\right) \\
+ \sum_{n=0}^{\infty} \left(-5x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) = 0 \tag{2A}
$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$
\sum_{n=0}^{\infty} 4x^{1+n+r} a_n (n+r)(n+r-1) = \sum_{n=1}^{\infty} 4a_{n-1}(n+r-1)(n+r-2)\, x^{n+r}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$
\left(\sum_{n=1}^{\infty} 4a_{n-1}(n+r-1)(n+r-2)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 4x^{n+r} a_n (n+r)(n+r-1)\right) \\
+ \sum_{n=0}^{\infty} \left(-5x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) = 0 \tag{2B}
$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$
4x^{n+r} a_n (n+r)(n+r-1) - 5x^{n+r} a_n (n+r) + 2a_n x^{n+r} = 0
$$

When $n=0$ the above becomes

$$
4x^r a_0 r(-1+r) - 5x^r a_0 r + 2a_0 x^r = 0
$$

Or

$$
\left(4x^r r(-1+r) - 5x^r r + 2x^r\right) a_0 = 0
$$

Since $a_0 \neq 0$ then the above simplifies to

$$
\left(4r^2 - 9r + 2\right) x^r = 0
$$

Since the above is true for all x then the indicial equation becomes

$$
4r^2 - 9r + 2 = 0
$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 2$$
$$r_2 = \frac{1}{4}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(4r^2 - 9r + 2\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{7}{4}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+2}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n+\frac{1}{4}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$4a_{n-1}(n + r - 1)(n + r - 2) + 4a_n(n + r)(n + r - 1) - 5a_n(n + r) + 2a_n = 0 \quad (3)$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{4(n + r - 1) a_{n-1}}{4n + 4r - 1} \tag{4}$$

Which for the root $r = 2$ becomes

$$a_n = -\frac{4(1 + n) a_{n-1}}{4n + 7} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{4r}{3+4r}$$

Which for the root $r = 2$ becomes

$$a_1 = -\frac{8}{11}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4r}{3+4r}$	$-\frac{8}{11}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{16r(1+r)}{16r^2+40r+21}$$

Which for the root $r = 2$ becomes

$$a_2 = \frac{32}{55}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4r}{3+4r}$	$-\frac{8}{11}$
a_2	$\frac{16r(1+r)}{16r^2+40r+21}$	$\frac{32}{55}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{64r(1+r)(2+r)}{64r^3+336r^2+524r+231}$$

Which for the root $r = 2$ becomes

$$a_3 = -\frac{512}{1045}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4r}{3+4r}$	$-\frac{8}{11}$
a_2	$\frac{16r(1+r)}{16r^2+40r+21}$	$\frac{32}{55}$
a_3	$-\frac{64r(1+r)(2+r)}{64r^3+336r^2+524r+231}$	$-\frac{512}{1045}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{256r(1+r)(2+r)(3+r)}{256r^4 + 2304r^3 + 7136r^2 + 8784r + 3465}$$

Which for the root $r = 2$ becomes

$$a_4 = \frac{2048}{4807}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4r}{3+4r}$	$-\frac{8}{11}$
a_2	$\frac{16r(1+r)}{16r^2+40r+21}$	$\frac{32}{55}$
a_3	$-\frac{64r(1+r)(2+r)}{64r^3+336r^2+524r+231}$	$-\frac{512}{1045}$
a_4	$\frac{256r(1+r)(2+r)(3+r)}{256r^4+2304r^3+7136r^2+8784r+3465}$	$\frac{2048}{4807}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1024(3+r)\,r(1+r)(2+r)(4+r)}{1024r^5 + 14080r^4 + 72320r^3 + 170720r^2 + 180756r + 65835}$$

Which for the root $r = 2$ becomes

$$a_5 = -\frac{16384}{43263}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4r}{3+4r}$	$-\frac{8}{11}$
a_2	$\frac{16r(1+r)}{16r^2+40r+21}$	$\frac{32}{55}$
a_3	$-\frac{64r(1+r)(2+r)}{64r^3+336r^2+524r+231}$	$-\frac{512}{1045}$
a_4	$\frac{256r(1+r)(2+r)(3+r)}{256r^4+2304r^3+7136r^2+8784r+3465}$	$\frac{2048}{4807}$
a_5	$-\frac{1024(3+r)r(1+r)(2+r)(4+r)}{1024r^5+14080r^4+72320r^3+170720r^2+180756r+65835}$	$-\frac{16384}{43263}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^2(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots) \\ &= x^2\left(1 - \frac{8x}{11} + \frac{32x^2}{55} - \frac{512x^3}{1045} + \frac{2048x^4}{4807} - \frac{16384x^5}{43263} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$4b_{n-1}(n+r-1)(n+r-2) + 4b_n(n+r)(n+r-1) - 5b_n(n+r) + 2b_n = 0 \quad (3)$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{4(n+r-1)\,b_{n-1}}{4n+4r-1} \quad (4)$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_n = -\frac{(4n-3)\,b_{n-1}}{4n} \quad (5)$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{1}{4}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = -\frac{4r}{3+4r}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_1 = -\frac{1}{4}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{4r}{3+4r}$	$-\frac{1}{4}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{16r(1+r)}{16r^2 + 40r + 21}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_2 = \frac{5}{32}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{4r}{3+4r}$	$-\frac{1}{4}$
b_2	$\frac{16r(1+r)}{16r^2+40r+21}$	$\frac{5}{32}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{64r(1+r)(2+r)}{64r^3 + 336r^2 + 524r + 231}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_3 = -\frac{15}{128}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{4r}{3+4r}$	$-\frac{1}{4}$
b_2	$\frac{16r(1+r)}{16r^2+40r+21}$	$\frac{5}{32}$
b_3	$-\frac{64r(1+r)(2+r)}{64r^3+336r^2+524r+231}$	$-\frac{15}{128}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{256r(1+r)(2+r)(3+r)}{256r^4 + 2304r^3 + 7136r^2 + 8784r + 3465}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_4 = \frac{195}{2048}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{4r}{3+4r}$	$-\frac{1}{4}$
b_2	$\frac{16r(1+r)}{16r^2+40r+21}$	$\frac{5}{32}$
b_3	$-\frac{64r(1+r)(2+r)}{64r^3+336r^2+524r+231}$	$-\frac{15}{128}$
b_4	$\frac{256r(1+r)(2+r)(3+r)}{256r^4+2304r^3+7136r^2+8784r+3465}$	$\frac{195}{2048}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{1024(3+r)r(1+r)(2+r)(4+r)}{1024r^5 + 14080r^4 + 72320r^3 + 170720r^2 + 180756r + 65835}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_5 = -\frac{663}{8192}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{4r}{3+4r}$	$-\frac{1}{4}$
b_2	$\frac{16r(1+r)}{16r^2+40r+21}$	$\frac{5}{32}$
b_3	$-\frac{64r(1+r)(2+r)}{64r^3+336r^2+524r+231}$	$-\frac{15}{128}$
b_4	$\frac{256r(1+r)(2+r)(3+r)}{256r^4+2304r^3+7136r^2+8784r+3465}$	$\frac{195}{2048}$
b_5	$-\frac{1024(3+r)r(1+r)(2+r)(4+r)}{1024r^5+14080r^4+72320r^3+170720r^2+180756r+65835}$	$-\frac{663}{8192}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x^2 \left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= x^{\frac{1}{4}} \left(1 - \frac{x}{4} + \frac{5x^2}{32} - \frac{15x^3}{128} + \frac{195x^4}{2048} - \frac{663x^5}{8192} + O(x^6)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^2 \left(1 - \frac{8x}{11} + \frac{32x^2}{55} - \frac{512x^3}{1045} + \frac{2048x^4}{4807} - \frac{16384x^5}{43263} + O(x^6)\right) \\
&+ c_2 x^{\frac{1}{4}} \left(1 - \frac{x}{4} + \frac{5x^2}{32} - \frac{15x^3}{128} + \frac{195x^4}{2048} - \frac{663x^5}{8192} + O(x^6)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^2 \left(1 - \frac{8x}{11} + \frac{32x^2}{55} - \frac{512x^3}{1045} + \frac{2048x^4}{4807} - \frac{16384x^5}{43263} + O(x^6)\right) \\
&+ c_2 x^{\frac{1}{4}} \left(1 - \frac{x}{4} + \frac{5x^2}{32} - \frac{15x^3}{128} + \frac{195x^4}{2048} - \frac{663x^5}{8192} + O(x^6)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = c_1 x^2 \left(1 - \frac{8x}{11} + \frac{32x^2}{55} - \frac{512x^3}{1045} + \frac{2048x^4}{4807} - \frac{16384x^5}{43263} + O(x^6)\right) \\
+ c_2 x^{\frac{1}{4}} \left(1 - \frac{x}{4} + \frac{5x^2}{32} - \frac{15x^3}{128} + \frac{195x^4}{2048} - \frac{663x^5}{8192} + O(x^6)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = c_1 x^2 \left(1 - \frac{8x}{11} + \frac{32x^2}{55} - \frac{512x^3}{1045} + \frac{2048x^4}{4807} - \frac{16384x^5}{43263} + O(x^6)\right) \\
+ c_2 x^{\frac{1}{4}} \left(1 - \frac{x}{4} + \frac{5x^2}{32} - \frac{15x^3}{128} + \frac{195x^4}{2048} - \frac{663x^5}{8192} + O(x^6)\right)
\end{aligned}
$$

Verified OK.

23.15.1 Maple step by step solution

Let's solve

$4x^2(x+1)\,y'' - 5xy' + 2y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{5y'}{4x(x+1)} - \frac{y}{2x^2(x+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{5y'}{4x(x+1)} + \frac{y}{2x^2(x+1)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = -\frac{5}{4x(x+1)}, P_3(x) = \frac{1}{2x^2(x+1)}\right]$

  ◦ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1} = \frac{5}{4}$

  ◦ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1} = 0$

  ◦ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $4x^2(x+1)\,y'' - 5xy' + 2y = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(4u^3 - 8u^2 + 4u)\left(\frac{d^2}{du^2}y(u)\right) + (-5u+5)\left(\frac{d}{du}y(u)\right) + 2y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..3$

  $$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

  $$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0 r(1+4r)\, u^{-1+r} + \left(a_1(1+r)\,(5+4r) - a_0(8r^2-3r-2)\right) u^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+1+r)\,(4k+5+\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$r(1+4r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{0, -\frac{1}{4}\right\}$$

- Each term must be 0

  $$a_1(1+r)\,(5+4r) - a_0(8r^2-3r-2) = 0$$

- Each term in the series must be 0, giving the recursion relation

  $$4(-2a_k + a_{k-1} + a_{k+1})\, k^2 + \left(8(-2a_k + a_{k-1} + a_{k+1})\, r + 3a_k - 12a_{k-1} + 9a_{k+1}\right) k + 4(-2a_k + a_k$$

- Shift index using $k- >k+1$

  $$4(-2a_{k+1} + a_k + a_{k+2})\,(k+1)^2 + \left(8(-2a_{k+1} + a_k + a_{k+2})\, r + 3a_{k+1} - 12a_k + 9a_{k+2}\right)(k+1) + 4$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2} = -\frac{4k^2a_k - 8k^2a_{k+1} + 8kra_k - 16kra_{k+1} + 4r^2a_k - 8r^2a_{k+1} - 4ka_k - 13ka_{k+1} - 4ra_k - 13ra_{k+1} - 3a_{k+1}}{4k^2 + 8kr + 4r^2 + 17k + 17r + 18}$$

- Recursion relation for $r = 0$

  $$a_{k+2} = -\frac{4k^2a_k - 8k^2a_{k+1} - 4ka_k - 13ka_{k+1} - 3a_{k+1}}{4k^2 + 17k + 18}$$

- Solution for $r = 0$

$$\left[y(u)=\sum_{k=0}^{\infty} a_k u^k, a_{k+2}=-\frac{4k^2a_k-8k^2a_{k+1}-4ka_k-13ka_{k+1}-3a_{k+1}}{4k^2+17k+18}, 5a_1+2a_0=0\right]$$

- Revert the change of variables $u=x+1$

$$\left[y=\sum_{k=0}^{\infty} a_k (x+1)^k, a_{k+2}=-\frac{4k^2a_k-8k^2a_{k+1}-4ka_k-13ka_{k+1}-3a_{k+1}}{4k^2+17k+18}, 5a_1+2a_0=0\right]$$

- Recursion relation for $r=-\frac{1}{4}$

$$a_{k+2}=-\frac{4k^2a_k-8k^2a_{k+1}-6ka_k-9ka_{k+1}+\frac{5}{4}a_k-\frac{1}{4}a_{k+1}}{4k^2+15k+14}$$

- Solution for $r=-\frac{1}{4}$

$$\left[y(u)=\sum_{k=0}^{\infty} a_k u^{k-\frac{1}{4}}, a_{k+2}=-\frac{4k^2a_k-8k^2a_{k+1}-6ka_k-9ka_{k+1}+\frac{5}{4}a_k-\frac{1}{4}a_{k+1}}{4k^2+15k+14}, 3a_1+\frac{3a_0}{4}=0\right]$$

- Revert the change of variables $u=x+1$

$$\left[y=\sum_{k=0}^{\infty} a_k (x+1)^{k-\frac{1}{4}}, a_{k+2}=-\frac{4k^2a_k-8k^2a_{k+1}-6ka_k-9ka_{k+1}+\frac{5}{4}a_k-\frac{1}{4}a_{k+1}}{4k^2+15k+14}, 3a_1+\frac{3a_0}{4}=0\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_k (x+1)^k\right)+\left(\sum_{k=0}^{\infty} b_k (x+1)^{k-\frac{1}{4}}\right), a_{k+2}=-\frac{4k^2a_k-8k^2a_{k+1}-4ka_k-13ka_{k+1}-3a_{k+1}}{4k^2+17k+18}, 5a_1+2a_0$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 41, page 195
Problem number: 20.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2(x+4)\, y''+x(x-1)\, y'+y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(x^3+4x^2\right) y''+\left(x^2-x\right) y'+y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=\frac{x-1}{x\,(x+4)}$$
$$q(x)=\frac{1}{x^2\,(x+4)}$$

Table 666: Table $p(x), q(x)$ singularites.

$p(x) = \frac{x-1}{x(x+4)}$	
singularity	type
$x = -4$	"regular"
$x = 0$	"regular"

$q(x) = \frac{1}{x^2(x+4)}$	
singularity	type
$x = -4$	"regular"
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-4, 0, \infty]$

Irregular singular points : []

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2(x+4)\, y'' + \left(x^2 - x\right) y' + y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2(x+4) \left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + \left(x^2 - x\right) \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 4x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1) = \sum_{n=1}^{\infty} a_{n-1}(n+r-1)(n+r-2) x^{n+r}$$

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r) = \sum_{n=1}^{\infty} a_{n-1}(n+r-1) x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1)(n+r-2) x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 4x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1) x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$4x^{n+r} a_n (n+r)(n+r-1) - x^{n+r} a_n (n+r) + a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$4x^r a_0 r(-1+r) - x^r a_0 r + a_0 x^r = 0$$

Or

$$\left(4x^r r(-1+r) - x^r r + x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(4r^2 - 5r + 1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$4r^2 - 5r + 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = \frac{1}{4}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(4r^2 - 5r + 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{3}{4}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{1+n}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n+\frac{1}{4}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$\begin{aligned} &a_{n-1}(n+r-1)(n+r-2) + 4a_n(n+r)(n+r-1) \\ &+ a_{n-1}(n+r-1) - a_n(n+r) + a_n = 0 \end{aligned} \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}(n+r-1)}{4n+4r-1} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = -\frac{a_{n-1}n}{4n+3} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{r}{3+4r}$$

Which for the root $r = 1$ becomes

$$a_1 = -\frac{1}{7}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r}{3+4r}$	$-\frac{1}{7}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r(1+r)}{16r^2 + 40r + 21}$$

Which for the root $r = 1$ becomes

$$a_2 = \frac{2}{77}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r}{3+4r}$	$-\frac{1}{7}$
a_2	$\frac{r(1+r)}{16r^2+40r+21}$	$\frac{2}{77}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{r(1+r)(2+r)}{64r^3 + 336r^2 + 524r + 231}$$

Which for the root $r = 1$ becomes

$$a_3 = -\frac{2}{385}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r}{3+4r}$	$-\frac{1}{7}$
a_2	$\frac{r(1+r)}{16r^2+40r+21}$	$\frac{2}{77}$
a_3	$-\frac{r(1+r)(2+r)}{64r^3+336r^2+524r+231}$	$-\frac{2}{385}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{r(1+r)(2+r)(3+r)}{256r^4 + 2304r^3 + 7136r^2 + 8784r + 3465}$$

Which for the root $r = 1$ becomes

$$a_4 = \frac{8}{7315}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r}{3+4r}$	$-\frac{1}{7}$
a_2	$\frac{r(1+r)}{16r^2+40r+21}$	$\frac{2}{77}$
a_3	$-\frac{r(1+r)(2+r)}{64r^3+336r^2+524r+231}$	$-\frac{2}{385}$
a_4	$\frac{r(1+r)(2+r)(3+r)}{256r^4+2304r^3+7136r^2+8784r+3465}$	$\frac{8}{7315}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{(3+r)\,r(1+r)(2+r)(4+r)}{1024r^5 + 14080r^4 + 72320r^3 + 170720r^2 + 180756r + 65835}$$

Which for the root $r = 1$ becomes

$$a_5 = -\frac{8}{33649}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r}{3+4r}$	$-\frac{1}{7}$
a_2	$\frac{r(1+r)}{16r^2+40r+21}$	$\frac{2}{77}$
a_3	$-\frac{r(1+r)(2+r)}{64r^3+336r^2+524r+231}$	$-\frac{2}{385}$
a_4	$\frac{r(1+r)(2+r)(3+r)}{256r^4+2304r^3+7136r^2+8784r+3465}$	$\frac{8}{7315}$
a_5	$-\frac{(3+r)r(1+r)(2+r)(4+r)}{1024r^5+14080r^4+72320r^3+170720r^2+180756r+65835}$	$-\frac{8}{33649}$

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\
&= x\left(1 - \frac{x}{7} + \frac{2x^2}{77} - \frac{2x^3}{385} + \frac{8x^4}{7315} - \frac{8x^5}{33649} + O(x^6)\right)
\end{aligned}
$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$
\begin{aligned}
&b_{n-1}(n+r-1)(n+r-2) + 4b_n(n+r)(n+r-1) \\
&+ b_{n-1}(n+r-1) - b_n(n+r) + b_n = 0
\end{aligned} \tag{3}
$$

Solving for b_n from recursive equation (4) gives

$$
b_n = -\frac{b_{n-1}(n+r-1)}{4n+4r-1} \tag{4}
$$

Which for the root $r = \frac{1}{4}$ becomes

$$
b_n = -\frac{b_{n-1}(4n-3)}{16n} \tag{5}
$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{1}{4}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = -\frac{r}{3+4r}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_1 = -\frac{1}{16}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{r}{3+4r}$	$-\frac{1}{16}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{r(1+r)}{16r^2+40r+21}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_2 = \frac{5}{512}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{r}{3+4r}$	$-\frac{1}{16}$
b_2	$\frac{r(1+r)}{16r^2+40r+21}$	$\frac{5}{512}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{r(1+r)(2+r)}{64r^3+336r^2+524r+231}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_3 = -\frac{15}{8192}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{r}{3+4r}$	$-\frac{1}{16}$
b_2	$\frac{r(1+r)}{16r^2+40r+21}$	$\frac{5}{512}$
b_3	$-\frac{r(1+r)(2+r)}{64r^3+336r^2+524r+231}$	$-\frac{15}{8192}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{r(1+r)(2+r)(3+r)}{256r^4 + 2304r^3 + 7136r^2 + 8784r + 3465}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_4 = \frac{195}{524288}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{r}{3+4r}$	$-\frac{1}{16}$
b_2	$\frac{r(1+r)}{16r^2+40r+21}$	$\frac{5}{512}$
b_3	$-\frac{r(1+r)(2+r)}{64r^3+336r^2+524r+231}$	$-\frac{15}{8192}$
b_4	$\frac{r(1+r)(2+r)(3+r)}{256r^4+2304r^3+7136r^2+8784r+3465}$	$\frac{195}{524288}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{(3+r)\,r(1+r)(2+r)(4+r)}{1024r^5 + 14080r^4 + 72320r^3 + 170720r^2 + 180756r + 65835}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_5 = -\frac{663}{8388608}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{r}{3+4r}$	$-\frac{1}{16}$
b_2	$\frac{r(1+r)}{16r^2+40r+21}$	$\frac{5}{512}$
b_3	$-\frac{r(1+r)(2+r)}{64r^3+336r^2+524r+231}$	$-\frac{15}{8192}$
b_4	$\frac{r(1+r)(2+r)(3+r)}{256r^4+2304r^3+7136r^2+8784r+3465}$	$\frac{195}{524288}$
b_5	$-\frac{(3+r)r(1+r)(2+r)(4+r)}{1024r^5+14080r^4+72320r^3+170720r^2+180756r+65835}$	$-\frac{663}{8388608}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x\left(b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6\dots\right) \\
&= x^{\frac{1}{4}}\left(1 - \frac{x}{16} + \frac{5x^2}{512} - \frac{15x^3}{8192} + \frac{195x^4}{524288} - \frac{663x^5}{8388608} + O(x^6)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1y_1(x) + c_2y_2(x) \\
&= c_1x\left(1 - \frac{x}{7} + \frac{2x^2}{77} - \frac{2x^3}{385} + \frac{8x^4}{7315} - \frac{8x^5}{33649} + O(x^6)\right) \\
&\quad + c_2x^{\frac{1}{4}}\left(1 - \frac{x}{16} + \frac{5x^2}{512} - \frac{15x^3}{8192} + \frac{195x^4}{524288} - \frac{663x^5}{8388608} + O(x^6)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1x\left(1 - \frac{x}{7} + \frac{2x^2}{77} - \frac{2x^3}{385} + \frac{8x^4}{7315} - \frac{8x^5}{33649} + O(x^6)\right) \\
&\quad + c_2x^{\frac{1}{4}}\left(1 - \frac{x}{16} + \frac{5x^2}{512} - \frac{15x^3}{8192} + \frac{195x^4}{524288} - \frac{663x^5}{8388608} + O(x^6)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = c_1x\left(1 - \frac{x}{7} + \frac{2x^2}{77} - \frac{2x^3}{385} + \frac{8x^4}{7315} - \frac{8x^5}{33649} + O(x^6)\right) \\
+ c_2x^{\frac{1}{4}}\left(1 - \frac{x}{16} + \frac{5x^2}{512} - \frac{15x^3}{8192} + \frac{195x^4}{524288} - \frac{663x^5}{8388608} + O(x^6)\right)
\end{aligned}
\tag{1}
$$

Verification of solutions

$$y = c_1 x \left(1-\frac{x}{7}+\frac{2x^2}{77}-\frac{2x^3}{385}+\frac{8x^4}{7315}-\frac{8x^5}{33649}+O\left(x^6\right)\right) + c_2 x^{\frac{1}{4}} \left(1-\frac{x}{16}+\frac{5x^2}{512}-\frac{15x^3}{8192}+\frac{195x^4}{524288}-\frac{663x^5}{8388608}+O\left(x^6\right)\right)$$

Verified OK.

23.16.1 Maple step by step solution

Let's solve

$x^2(x+4)\, y'' + (x^2 - x)\, y' + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y}{x^2(x+4)} - \frac{(x-1)y'}{x(x+4)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(x-1)y'}{x(x+4)} + \frac{y}{x^2(x+4)} = 0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x) = \frac{x-1}{x(x+4)}, P_3(x) = \frac{1}{x^2(x+4)}\right]$

- ◦ $(x+4)\cdot P_2(x)$ is analytic at $x=-4$

  $\left((x+4)\cdot P_2(x)\right)\Big|_{x=-4} = \frac{5}{4}$

- ◦ $(x+4)^2\cdot P_3(x)$ is analytic at $x=-4$

  $\left((x+4)^2\cdot P_3(x)\right)\Big|_{x=-4} = 0$

- ◦ $x=-4$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -4$

- Multiply by denominators

  $x^2(x+4)\, y'' + x(x-1)\, y' + y = 0$

- Change variables using $x = u - 4$ so that the regular singular point is at $u = 0$

$$\left(u^{3}-8u^{2}+16u\right)\left(\frac{d^{2}}{du^{2}}y(u)\right)+\left(u^{2}-9u+20\right)\left(\frac{d}{du}y(u)\right)+y(u)=0$$

- Assume series solution for $y(u)$

$$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$$

□ Rewrite ODE with series expansions

  - Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

$$u^m \cdot \left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$$

  - Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

  - Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..3$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$$

  - Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$4a_0r(1+4r)\,u^{-1+r}+\left(4a_1(1+r)\,(5+4r)-a_0\left(8r^2+r-1\right)\right)u^r+\left(\sum_{k=1}^{\infty}\left(4a_{k+1}(k+1+r)\,(4k+\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$4r(1+4r)=0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, -\frac{1}{4}\right\}$$

- Each term must be 0

$$4a_1(1+r)\,(5+4r)-a_0\left(8r^2+r-1\right)=0$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k-1}(k+r-1)^2+16\left(k+\frac{5}{4}+r\right)(k+1+r)\,a_{k+1}-a_k\left(8k^2+16kr+8r^2+k+r-1\right)=0$$

- Shift index using $k->k+1$

$$a_k(k+r)^2+16\left(k+\frac{9}{4}+r\right)(k+2+r)\,a_{k+2}-a_{k+1}\left(8(k+1)^2+16(k+1)\,r+8r^2+k+r\right)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} + 2kra_k - 16kra_{k+1} + r^2 a_k - 8r^2 a_{k+1} - 17ka_{k+1} - 17ra_{k+1} - 8a_{k+1}}{4(4k+9+4r)(k+2+r)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} - 17ka_{k+1} - 8a_{k+1}}{4(4k+9)(k+2)}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} - 17ka_{k+1} - 8a_{k+1}}{4(4k+9)(k+2)}, 20a_1 + a_0 = 0\right]$$

- Revert the change of variables $u = x + 4$

$$\left[y = \sum_{k=0}^{\infty} a_k (x+4)^k, a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} - 17ka_{k+1} - 8a_{k+1}}{4(4k+9)(k+2)}, 20a_1 + a_0 = 0\right]$$

- Recursion relation for $r = -\frac{1}{4}$

$$a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} - \frac{1}{2}ka_k - 13ka_{k+1} + \frac{1}{16}a_k - \frac{17}{4}a_{k+1}}{4(4k+8)\left(k+\frac{7}{4}\right)}$$

- Solution for $r = -\frac{1}{4}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{1}{4}}, a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} - \frac{1}{2}ka_k - 13ka_{k+1} + \frac{1}{16}a_k - \frac{17}{4}a_{k+1}}{4(4k+8)\left(k+\frac{7}{4}\right)}, 12a_1 + \frac{3a_0}{4} = 0\right]$$

- Revert the change of variables $u = x + 4$

$$\left[y = \sum_{k=0}^{\infty} a_k (x+4)^{k-\frac{1}{4}}, a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} - \frac{1}{2}ka_k - 13ka_{k+1} + \frac{1}{16}a_k - \frac{17}{4}a_{k+1}}{4(4k+8)\left(k+\frac{7}{4}\right)}, 12a_1 + \frac{3a_0}{4} = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k (x+4)^k\right) + \left(\sum_{k=0}^{\infty} b_k (x+4)^{k-\frac{1}{4}}\right), a_{k+2} = -\frac{k^2 a_k - 8k^2 a_{k+1} - 17ka_{k+1} - 8a_{k+1}}{4(4k+9)(k+2)}, 20a_1 + a_0 = 0$$

Section: Exercise 41, page 195
Problem number: 21.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(8-x)\,x^2y''+6xy'-y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(-x^3+8x^2\right)y''+6xy'-y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=-\frac{6}{x\,(-8+x)}$$
$$q(x)=\frac{1}{(-8+x)\,x^2}$$

Table 668: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{6}{x(-8+x)}$	
singularity	type
$x = 0$	"regular"
$x = 8$	"regular"

$q(x) = \frac{1}{(-8+x)x^2}$	
singularity	type
$x = 0$	"regular"
$x = 8$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, 8, \infty]$

Irregular singular points : $[]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$-y''(-8+x)\,x^2 + 6xy' - y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$
$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$-\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right)(-8+x)\,x^2 + 6x\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 8x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 6x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)(n+r-1)\right) = \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)(n+r-2)\, x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)(n+r-2)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 8x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 6x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$8x^{n+r} a_n (n+r)(n+r-1) + 6x^{n+r} a_n (n+r) - a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$8x^r a_0 r(-1+r) + 6x^r a_0 r - a_0 x^r = 0$$

Or

$$\left(8x^r r(-1+r) + 6x^r r - x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(8r^2 - 2r - 1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$8r^2 - 2r - 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{2}$$
$$r_2 = -\frac{1}{4}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(8r^2 - 2r - 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{3}{4}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{2}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-\frac{1}{4}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$-a_{n-1}(n+r-1)(n+r-2) + 8a_n(n+r)(n+r-1) + 6a_n(n+r) - a_n = 0 \quad (3)$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}(n+r-1)(n+r-2)}{8n^2 + 16nr + 8r^2 - 2n - 2r - 1} \quad (4)$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_n = \frac{a_{n-1}(2n-1)(2n-3)}{32n^2 + 24n} \quad (5)$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{r(-1+r)}{8r^2+14r+5}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_1 = -\frac{1}{56}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r(-1+r)}{8r^2+14r+5}$	$-\frac{1}{56}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r^2(r^2-1)}{(8r^2+14r+5)(8r^2+30r+27)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_2 = -\frac{3}{9856}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r(-1+r)}{8r^2+14r+5}$	$-\frac{1}{56}$
a_2	$\frac{r^2(r^2-1)}{(8r^2+14r+5)(8r^2+30r+27)}$	$-\frac{3}{9856}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{r^2(r^2-1)(r^2+3r+2)}{(8r^2+14r+5)(8r^2+30r+27)(8r^2+46r+65)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_3 = -\frac{1}{78848}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r(-1+r)}{8r^2+14r+5}$	$-\frac{1}{56}$
a_2	$\frac{r^2(r^2-1)}{(8r^2+14r+5)(8r^2+30r+27)}$	$-\frac{3}{9856}$
a_3	$\frac{r^2(r^2-1)(r^2+3r+2)}{(8r^2+14r+5)(8r^2+30r+27)(8r^2+46r+65)}$	$-\frac{1}{78848}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{(3+r)\,r^2(-1+r)\,(1+r)^2\,(2+r)^2}{(8r^2+14r+5)\,(8r^2+30r+27)\,(8r^2+46r+65)\,(8r^2+62r+119)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_4 = -\frac{5}{6848512}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r(-1+r)}{8r^2+14r+5}$	$-\frac{1}{56}$
a_2	$\frac{r^2(r^2-1)}{(8r^2+14r+5)(8r^2+30r+27)}$	$-\frac{3}{9856}$
a_3	$\frac{r^2(r^2-1)(r^2+3r+2)}{(8r^2+14r+5)(8r^2+30r+27)(8r^2+46r+65)}$	$-\frac{1}{78848}$
a_4	$\frac{(3+r)r^2(-1+r)(1+r)^2(2+r)^2}{(8r^2+14r+5)(8r^2+30r+27)(8r^2+46r+65)(8r^2+62r+119)}$	$-\frac{5}{6848512}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{(3+r)^2\,r^2(-1+r)\,(1+r)^2\,(2+r)^2\,(4+r)}{(8r^2+14r+5)\,(8r^2+30r+27)\,(8r^2+46r+65)\,(8r^2+62r+119)\,(8r^2+78r+189)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_5 = -\frac{63}{1260126208}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r(-1+r)}{8r^2+14r+5}$	$-\frac{1}{56}$
a_2	$\frac{r^2(r^2-1)}{(8r^2+14r+5)(8r^2+30r+27)}$	$-\frac{3}{9856}$
a_3	$\frac{r^2(r^2-1)(r^2+3r+2)}{(8r^2+14r+5)(8r^2+30r+27)(8r^2+46r+65)}$	$-\frac{1}{78848}$
a_4	$\frac{(3+r)r^2(-1+r)(1+r)^2(2+r)^2}{(8r^2+14r+5)(8r^2+30r+27)(8r^2+46r+65)(8r^2+62r+119)}$	$-\frac{5}{6848512}$
a_5	$\frac{(3+r)^2r^2(-1+r)(1+r)^2(2+r)^2(4+r)}{(8r^2+14r+5)(8r^2+30r+27)(8r^2+46r+65)(8r^2+62r+119)(8r^2+78r+189)}$	$-\frac{63}{1260126208}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= \sqrt{x}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\
&= \sqrt{x}\left(1 - \frac{x}{56} - \frac{3x^2}{9856} - \frac{x^3}{78848} - \frac{5x^4}{6848512} - \frac{63x^5}{1260126208} + O(x^6)\right)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$-b_{n-1}(n+r-1)(n+r-2) + 8b_n(n+r)(n+r-1) + 6b_n(n+r) - b_n = 0 \quad (3)$$

Solving for b_n from recursive equation (4) gives

$$b_n = \frac{b_{n-1}(n+r-1)(n+r-2)}{8n^2 + 16nr + 8r^2 - 2n - 2r - 1} \quad (4)$$

Which for the root $r = -\frac{1}{4}$ becomes

$$b_n = \frac{b_{n-1}(4n-5)(4n-9)}{128n^2 - 96n} \quad (5)$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{1}{4}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{r(-1+r)}{8r^2 + 14r + 5}$$

Which for the root $r = -\frac{1}{4}$ becomes

$$b_1 = \frac{5}{32}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r(-1+r)}{8r^2+14r+5}$	$\frac{5}{32}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{r^2(r^2-1)}{(8r^2+14r+5)(8r^2+30r+27)}$$

Which for the root $r = -\frac{1}{4}$ becomes

$$b_2 = -\frac{3}{2048}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r(-1+r)}{8r^2+14r+5}$	$\frac{5}{32}$
b_2	$\frac{r^2(r^2-1)}{(8r^2+14r+5)(8r^2+30r+27)}$	$-\frac{3}{2048}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{r^2(r^2-1)(r^2+3r+2)}{(8r^2+14r+5)(8r^2+30r+27)(8r^2+46r+65)}$$

Which for the root $r = -\frac{1}{4}$ becomes

$$b_3 = -\frac{7}{196608}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r(-1+r)}{8r^2+14r+5}$	$\frac{5}{32}$
b_2	$\frac{r^2(r^2-1)}{(8r^2+14r+5)(8r^2+30r+27)}$	$-\frac{3}{2048}$
b_3	$\frac{r^2(r^2-1)(r^2+3r+2)}{(8r^2+14r+5)(8r^2+30r+27)(8r^2+46r+65)}$	$-\frac{7}{196608}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{(3+r)\, r^2(-1+r)\,(1+r)^2\,(2+r)^2}{(8r^2+14r+5)\,(8r^2+30r+27)\,(8r^2+46r+65)\,(8r^2+62r+119)}$$

Which for the root $r = -\frac{1}{4}$ becomes

$$b_4 = -\frac{539}{327155712}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r(-1+r)}{8r^2+14r+5}$	$\frac{5}{32}$
b_2	$\frac{r^2(r^2-1)}{(8r^2+14r+5)(8r^2+30r+27)}$	$-\frac{3}{2048}$
b_3	$\frac{r^2(r^2-1)(r^2+3r+2)}{(8r^2+14r+5)(8r^2+30r+27)(8r^2+46r+65)}$	$-\frac{7}{196608}$
b_4	$\frac{(3+r)r^2(-1+r)(1+r)^2(2+r)^2}{(8r^2+14r+5)(8r^2+30r+27)(8r^2+46r+65)(8r^2+62r+119)}$	$-\frac{539}{327155712}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{(3+r)^2\, r^2(-1+r)\,(1+r)^2\,(2+r)^2\,(4+r)}{(8r^2+14r+5)\,(8r^2+30r+27)\,(8r^2+46r+65)\,(8r^2+62r+119)\,(8r^2+78r+189)}$$

Which for the root $r = -\frac{1}{4}$ becomes

$$b_5 = -\frac{5929}{59324235776}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r(-1+r)}{8r^2+14r+5}$	$\frac{5}{32}$
b_2	$\frac{r^2(r^2-1)}{(8r^2+14r+5)(8r^2+30r+27)}$	$-\frac{3}{2048}$
b_3	$\frac{r^2(r^2-1)(r^2+3r+2)}{(8r^2+14r+5)(8r^2+30r+27)(8r^2+46r+65)}$	$-\frac{7}{196608}$
b_4	$\frac{(3+r)r^2(-1+r)(1+r)^2(2+r)^2}{(8r^2+14r+5)(8r^2+30r+27)(8r^2+46r+65)(8r^2+62r+119)}$	$-\frac{539}{327155712}$
b_5	$\frac{(3+r)^2r^2(-1+r)(1+r)^2(2+r)^2(4+r)}{(8r^2+14r+5)(8r^2+30r+27)(8r^2+46r+65)(8r^2+62r+119)(8r^2+78r+189)}$	$-\frac{5929}{59324235776}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned}
y_2(x) &= \sqrt{x}\left(b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 \dots\right) \\
&= \frac{1 + \frac{5x}{32} - \frac{3x^2}{2048} - \frac{7x^3}{196608} - \frac{539x^4}{327155712} - \frac{5929x^5}{59324235776} + O(x^6)}{x^{\frac{1}{4}}}
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= c_1y_1(x) + c_2y_2(x) \\
&= c_1\sqrt{x}\left(1 - \frac{x}{56} - \frac{3x^2}{9856} - \frac{x^3}{78848} - \frac{5x^4}{6848512} - \frac{63x^5}{1260126208} + O(x^6)\right) \\
&+ \frac{c_2\left(1 + \frac{5x}{32} - \frac{3x^2}{2048} - \frac{7x^3}{196608} - \frac{539x^4}{327155712} - \frac{5929x^5}{59324235776} + O(x^6)\right)}{x^{\frac{1}{4}}}
\end{aligned}$$

Hence the final solution is

$$\begin{aligned}
y &= y_h \\
&= c_1\sqrt{x}\left(1 - \frac{x}{56} - \frac{3x^2}{9856} - \frac{x^3}{78848} - \frac{5x^4}{6848512} - \frac{63x^5}{1260126208} + O(x^6)\right) \\
&+ \frac{c_2\left(1 + \frac{5x}{32} - \frac{3x^2}{2048} - \frac{7x^3}{196608} - \frac{539x^4}{327155712} - \frac{5929x^5}{59324235776} + O(x^6)\right)}{x^{\frac{1}{4}}}
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1\sqrt{x}\left(1-\frac{x}{56}-\frac{3x^2}{9856}-\frac{x^3}{78848}-\frac{5x^4}{6848512}-\frac{63x^5}{1260126208}+O(x^6)\right) + \frac{c_2\left(1+\frac{5x}{32}-\frac{3x^2}{2048}-\frac{7x^3}{196608}-\frac{539x^4}{327155712}-\frac{5929x^5}{59324235776}+O(x^6)\right)}{x^{\frac{1}{4}}} \tag{1}$$

Verification of solutions

$$y = c_1\sqrt{x}\left(1-\frac{x}{56}-\frac{3x^2}{9856}-\frac{x^3}{78848}-\frac{5x^4}{6848512}-\frac{63x^5}{1260126208}+O(x^6)\right) + \frac{c_2\left(1+\frac{5x}{32}-\frac{3x^2}{2048}-\frac{7x^3}{196608}-\frac{539x^4}{327155712}-\frac{5929x^5}{59324235776}+O(x^6)\right)}{x^{\frac{1}{4}}}$$

Verified OK.

23.17.1 Maple step by step solution

Let's solve

$-y''(-8+x)\,x^2+6xy'-y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{y}{(-8+x)x^2}+\frac{6y'}{x(-8+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{6y'}{x(-8+x)}+\frac{y}{(-8+x)x^2}=0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x)=-\frac{6}{x(-8+x)},P_3(x)=\frac{1}{(-8+x)x^2}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $(x\cdot P_2(x))\bigg|_{x=0}=\frac{3}{4}$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

$$\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = -\frac{1}{8}$$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''(-8+x)\, x^2 - 6xy' + y = 0$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

- ☐ Rewrite ODE with series expansions

  - Convert $x \cdot y'$ to series expansion

    $$x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$$

  - Convert $x^m \cdot y''$ to series expansion for $m = 2..3$

    $$x^m \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-2+m}$$

  - Shift index using $k- >k+2-m$

    $$x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$-a_0(1+4r)\,(-1+2r)\, x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(4k+4r+1)\,(2k+2r-1) + a_{k-1}(k+r-1)\,(k-2+r)\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-(1+4r)\,(-1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-\frac{1}{4}, \frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $a_{k-1}(k+r-1)\,(k-2+r) - 8a_k\left(k+r+\frac{1}{4}\right)\left(k+r-\frac{1}{2}\right) = 0$

- Shift index using $k- >k+1$

  $a_k(k+r)\,(k+r-1) - 8a_{k+1}\left(k+\frac{5}{4}+r\right)\left(k+\frac{1}{2}+r\right) = 0$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{a_k(k+r)(k+r-1)}{(4k+5+4r)(2k+1+2r)}$$

- Recursion relation for $r = -\frac{1}{4}$

$$a_{k+1} = \frac{a_k\left(k-\frac{1}{4}\right)\left(k-\frac{5}{4}\right)}{(4k+4)\left(2k+\frac{1}{2}\right)}$$

- Solution for $r = -\frac{1}{4}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{4}}, a_{k+1} = \frac{a_k\left(k-\frac{1}{4}\right)\left(k-\frac{5}{4}\right)}{(4k+4)\left(2k+\frac{1}{2}\right)}\right]$$

- Recursion relation for $r = \frac{1}{2}$

$$a_{k+1} = \frac{a_k\left(k+\frac{1}{2}\right)\left(k-\frac{1}{2}\right)}{(4k+7)(2k+2)}$$

- Solution for $r = \frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = \frac{a_k\left(k+\frac{1}{2}\right)\left(k-\frac{1}{2}\right)}{(4k+7)(2k+2)}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{4}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+1} = \frac{a_k\left(k-\frac{1}{4}\right)\left(k-\frac{5}{4}\right)}{(4k+4)\left(2k+\frac{1}{2}\right)}, b_{k+1} = \frac{b_k\left(k+\frac{1}{2}\right)\left(k-\frac{1}{2}\right)}{(4k+7)(2k+2)}\right]$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 41, page 195
Problem number: 22.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{2x^2y'' + x(x^2+1)\,y' - y(x+1) = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2x^2y'' + (x^3+x)\,y' + (-x-1)\,y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{x^2+1}{2x}$$
$$q(x) = -\frac{x+1}{2x^2}$$

Table 670: Table $p(x), q(x)$ singularites.

$p(x) = \frac{x^2+1}{2x}$	
singularity	type
$x = 0$	"regular"
$x = \infty$	"regular"
$x = -\infty$	"regular"

$q(x) = -\frac{x+1}{2x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, \infty, -\infty]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2x^2y'' + \left(x^3 + x\right) y' + (-x - 1) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2x^2 \left(\sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}\right) + \left(x^3 + x\right) \left(\sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}\right) + (-x - 1) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r+2} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n (n+r) = \sum_{n=2}^{\infty} a_{n-2}(n+r-2)\, x^{n+r}$$

$$\sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n\right) = \sum_{n=1}^{\infty} \left(-a_{n-1} x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=2}^{\infty} a_{n-2}(n+r-2)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \sum_{n=1}^{\infty} \left(-a_{n-1} x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n = 0$. From Eq (2B) this gives

$$2x^{n+r} a_n (n+r)(n+r-1) + x^{n+r} a_n (n+r) - a_n x^{n+r} = 0$$

When $n = 0$ the above becomes

$$2x^r a_0 r(-1+r) + x^r a_0 r - a_0 x^r = 0$$

Or

$$\left(2x^r r(-1+r) + x^r r - x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(2r^2 - r - 1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 - r - 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = -\frac{1}{2}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(2r^2 - r - 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{3}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{1+n}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-\frac{1}{2}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = \frac{1}{r(2r+3)}$$

For $2 \leq n$ the recursive equation is

$$2a_n(n+r)(n+r-1) + a_{n-2}(n+r-2) + a_n(n+r) - a_{n-1} - a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{n a_{n-2} + r a_{n-2} - 2a_{n-2} - a_{n-1}}{2n^2 + 4nr + 2r^2 - n - r - 1} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = \frac{-n a_{n-2} + a_{n-2} + a_{n-1}}{n\,(2n+3)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r(2r+3)}$	$\frac{1}{5}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{-2r^2 - r + 1}{4r^3 + 16r^2 + 15r}$$

Which for the root $r = 1$ becomes

$$a_2 = -\frac{2}{35}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r(2r+3)}$	$\frac{1}{5}$
a_2	$\frac{-2r^2-r+1}{4r^3+16r^2+15r}$	$-\frac{2}{35}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{4(1+r)^2}{8r^5 + 76r^4 + 262r^3 + 389r^2 + 210r}$$

Which for the root $r = 1$ becomes

$$a_3 = -\frac{16}{945}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r(2r+3)}$	$\frac{1}{5}$
a_2	$\frac{-2r^2-r+1}{4r^3+16r^2+15r}$	$-\frac{2}{35}$
a_3	$-\frac{4(1+r)^2}{8r^5+76r^4+262r^3+389r^2+210r}$	$-\frac{16}{945}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{4r^5 + 32r^4 + 85r^3 + 73r^2 - 16r - 32}{(2r^2 + 15r + 27)\, r\, (8r^4 + 76r^3 + 262r^2 + 389r + 210)}$$

Which for the root $r = 1$ becomes

$$a_4 = \frac{73}{20790}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r(2r+3)}$	$\frac{1}{5}$
a_2	$\frac{-2r^2-r+1}{4r^3+16r^2+15r}$	$-\frac{2}{35}$
a_3	$-\frac{4(1+r)^2}{8r^5+76r^4+262r^3+389r^2+210r}$	$-\frac{16}{945}$
a_4	$\frac{4r^5+32r^4+85r^3+73r^2-16r-32}{(2r^2+15r+27)r(8r^4+76r^3+262r^2+389r+210)}$	$\frac{73}{20790}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{12r^5 + 132r^4 + 549r^3 + 1057r^2 + 920r + 292}{(2r^2 + 15r + 27)\, r\, (8r^4 + 76r^3 + 262r^2 + 389r + 210)\, (2r^2 + 19r + 44)}$$

Which for the root $r = 1$ becomes

$$a_5 = \frac{1481}{1351350}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r(2r+3)}$	$\frac{1}{5}$
a_2	$\frac{-2r^2-r+1}{4r^3+16r^2+15r}$	$-\frac{2}{35}$
a_3	$-\frac{4(1+r)^2}{8r^5+76r^4+262r^3+389r^2+210r}$	$-\frac{16}{945}$
a_4	$\frac{4r^5+32r^4+85r^3+73r^2-16r-32}{(2r^2+15r+27)r(8r^4+76r^3+262r^2+389r+210)}$	$\frac{73}{20790}$
a_5	$\frac{12r^5+132r^4+549r^3+1057r^2+920r+292}{(2r^2+15r+27)r(8r^4+76r^3+262r^2+389r+210)(2r^2+19r+44)}$	$\frac{1481}{1351350}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}y_1(x) &= x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right)\\ &= x\left(1 + \frac{x}{5} - \frac{2x^2}{35} - \frac{16x^3}{945} + \frac{73x^4}{20790} + \frac{1481x^5}{1351350} + O(x^6)\right)\end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$b_1 = \frac{1}{r(2r+3)}$$

For $2 \leq n$ the recursive equation is

$$2b_n(n+r)(n+r-1) + b_{n-2}(n+r-2) + b_n(n+r) - b_{n-1} - b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{nb_{n-2} + rb_{n-2} - 2b_{n-2} - b_{n-1}}{2n^2 + 4nr + 2r^2 - n - r - 1} \tag{4}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_n = \frac{-2nb_{n-2} + 5b_{n-2} + 2b_{n-1}}{4n^2 - 6n} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{r(2r+3)}$	-1

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{-2r^2 - r + 1}{4r^3 + 16r^2 + 15r}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_2 = -\frac{1}{4}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{r(2r+3)}$	-1
b_2	$\frac{-2r^2-r+1}{4r^3+16r^2+15r}$	$-\frac{1}{4}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{4(1+r)^2}{8r^5 + 76r^4 + 262r^3 + 389r^2 + 210r}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_3 = \frac{1}{36}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{r(2r+3)}$	-1
b_2	$\frac{-2r^2-r+1}{4r^3+16r^2+15r}$	$-\frac{1}{4}$
b_3	$-\frac{4(1+r)^2}{8r^5+76r^4+262r^3+389r^2+210r}$	$\frac{1}{36}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{4r^5 + 32r^4 + 85r^3 + 73r^2 - 16r - 32}{(2r^2 + 15r + 27)\, r\, (8r^4 + 76r^3 + 262r^2 + 389r + 210)}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_4 = \frac{29}{1440}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{r(2r+3)}$	-1
b_2	$\frac{-2r^2-r+1}{4r^3+16r^2+15r}$	$-\frac{1}{4}$
b_3	$-\frac{4(1+r)^2}{8r^5+76r^4+262r^3+389r^2+210r}$	$\frac{1}{36}$
b_4	$\frac{4r^5+32r^4+85r^3+73r^2-16r-32}{(2r^2+15r+27)r(8r^4+76r^3+262r^2+389r+210)}$	$\frac{29}{1440}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{12r^5 + 132r^4 + 549r^3 + 1057r^2 + 920r + 292}{(2r^2 + 15r + 27)\, r\, (8r^4 + 76r^3 + 262r^2 + 389r + 210)\, (2r^2 + 19r + 44)}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_5 = -\frac{71}{50400}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{r(2r+3)}$	-1
b_2	$\frac{-2r^2-r+1}{4r^3+16r^2+15r}$	$-\frac{1}{4}$
b_3	$-\frac{4(1+r)^2}{8r^5+76r^4+262r^3+389r^2+210r}$	$\frac{1}{36}$
b_4	$\frac{4r^5+32r^4+85r^3+73r^2-16r-32}{(2r^2+15r+27)r(8r^4+76r^3+262r^2+389r+210)}$	$\frac{29}{1440}$
b_5	$\frac{12r^5+132r^4+549r^3+1057r^2+920r+292}{(2r^2+15r+27)r(8r^4+76r^3+262r^2+389r+210)(2r^2+19r+44)}$	$-\frac{71}{50400}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= x\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\ &= \frac{1 - x - \frac{x^2}{4} + \frac{x^3}{36} + \frac{29x^4}{1440} - \frac{71x^5}{50400} + O(x^6)}{\sqrt{x}} \end{aligned}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x \left(1+\frac{x}{5}-\frac{2x^2}{35}-\frac{16x^3}{945}+\frac{73x^4}{20790}+\frac{1481x^5}{1351350}+O(x^6)\right) \\
&+ \frac{c_2 \left(1-x-\frac{x^2}{4}+\frac{x^3}{36}+\frac{29x^4}{1440}-\frac{71x^5}{50400}+O(x^6)\right)}{\sqrt{x}}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x \left(1+\frac{x}{5}-\frac{2x^2}{35}-\frac{16x^3}{945}+\frac{73x^4}{20790}+\frac{1481x^5}{1351350}+O(x^6)\right) \\
&+ \frac{c_2 \left(1-x-\frac{x^2}{4}+\frac{x^3}{36}+\frac{29x^4}{1440}-\frac{71x^5}{50400}+O(x^6)\right)}{\sqrt{x}}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x \left(1+\frac{x}{5}-\frac{2x^2}{35}-\frac{16x^3}{945}+\frac{73x^4}{20790}+\frac{1481x^5}{1351350}+O(x^6)\right) \\
&+ \frac{c_2 \left(1-x-\frac{x^2}{4}+\frac{x^3}{36}+\frac{29x^4}{1440}-\frac{71x^5}{50400}+O(x^6)\right)}{\sqrt{x}}
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 x \left(1+\frac{x}{5}-\frac{2x^2}{35}-\frac{16x^3}{945}+\frac{73x^4}{20790}+\frac{1481x^5}{1351350}+O(x^6)\right) \\
&+ \frac{c_2 \left(1-x-\frac{x^2}{4}+\frac{x^3}{36}+\frac{29x^4}{1440}-\frac{71x^5}{50400}+O(x^6)\right)}{\sqrt{x}}
\end{aligned}
$$

Verified OK.

23.18.1 Maple step by step solution

Let's solve

$2x^2y'' + (x^3 + x)\, y' + (-x - 1)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{(x+1)y}{2x^2} - \frac{(x^2+1)y'}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(x^2+1)y'}{2x} - \frac{(x+1)y}{2x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{x^2+1}{2x}, P_3(x) = -\frac{x+1}{2x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = \frac{1}{2}$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = -\frac{1}{2}$

  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $2x^2y'' + x(x^2 + 1)\, y' + (-x - 1)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $x^m \cdot y=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot y'$ to series expansion for $m=1..3$

  $x^m \cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $x^m \cdot y'=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^2 \cdot y''$ to series expansion

  $x^2 \cdot y''=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+2r)\,(-1+r)\, x^r+(a_1(3+2r)\, r-a_0)\, x^{1+r}+\left(\sum_{k=2}^{\infty} (a_k(2k+2r+1)\,(k+r-1)-a_{k-1}+a\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+2r)\,(-1+r)=0$

- Values of r that satisfy the indicial equation

  $r \in \left\{1, -\frac{1}{2}\right\}$

- Each term must be 0

  $a_1(3+2r)\, r-a_0=0$

- Solve for the dependent coefficient(s)

  $a_1=\frac{a_0}{r(3+2r)}$

- Each term in the series must be 0, giving the recursion relation

  $2\left(k+r+\frac{1}{2}\right)\,(k+r-1)\, a_k+a_{k-2}k+a_{k-2}r-2a_{k-2}-a_{k-1}=0$

- Shift index using $k->k+2$

  $2\left(k+\frac{5}{2}+r\right)\,(k+1+r)\, a_{k+2}+a_k(k+2)+r a_k-2a_k-a_{k+1}=0$

- Recursion relation that defines series solution to ODE

  $a_{k+2}=-\frac{k a_k+r a_k-a_{k+1}}{(2k+5+2r)(k+1+r)}$

- Recursion relation for $r=1$

  $a_{k+2}=-\frac{k a_k+a_k-a_{k+1}}{(2k+7)(k+2)}$

- Solution for $r = 1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{k a_k + a_k - a_{k+1}}{(2k+7)(k+2)}, a_1 = \frac{a_0}{5}\right]$$

- Recursion relation for $r = -\frac{1}{2}$

$$a_{k+2} = -\frac{k a_k - \frac{1}{2} a_k - a_{k+1}}{(2k+4)\left(k+\frac{1}{2}\right)}$$

- Solution for $r = -\frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = -\frac{k a_k - \frac{1}{2} a_k - a_{k+1}}{(2k+4)\left(k+\frac{1}{2}\right)}, a_1 = -a_0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-\frac{1}{2}}\right), a_{k+2} = -\frac{k a_k + a_k - a_{k+1}}{(2k+7)(k+2)}, a_1 = \frac{a_0}{5}, b_{k+2} = -\frac{k b_k - \frac{1}{2} b_k - b_{k+1}}{(2k+4)\left(k+\frac{1}{2}\right)}, b_1 = -$$

Section: Exercise 41, page 195
Problem number: 23.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{2x^2y'' - xy' + (x^2 + 1)\, y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2x^2y'' - xy' + (x^2 + 1)\, y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{1}{2x}$$
$$q(x) = \frac{x^2 + 1}{2x^2}$$

Table 672: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{1}{2x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{x^2+1}{2x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2x^2y'' - xy' + \left(x^2 + 1\right) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2x^2 \left(\sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2} \right) - x \left(\sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1} \right) + \left(x^2 + 1\right) \left(\sum_{n=0}^{\infty} a_n x^{n+r} \right) = 0 \tag{1}$$

Which simplifies to

$$
\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r+2} a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}
$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$
\sum_{n=0}^{\infty} x^{n+r+2} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$
\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2B}
$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$
2x^{n+r} a_n (n+r)(n+r-1) - x^{n+r} a_n (n+r) + a_n x^{n+r} = 0
$$

When $n=0$ the above becomes

$$
2x^r a_0 r(-1+r) - x^r a_0 r + a_0 x^r = 0
$$

Or

$$
\left(2x^r r(-1+r) - x^r r + x^r\right) a_0 = 0
$$

Since $a_0 \neq 0$ then the above simplifies to

$$
\left(2r^2 - 3r + 1\right) x^r = 0
$$

Since the above is true for all x then the indicial equation becomes

$$
2r^2 - 3r + 1 = 0
$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = \frac{1}{2}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(2r^2 - 3r + 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+1}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n+\frac{1}{2}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$2a_n(n+r)(n+r-1) - a_n(n+r) + a_{n-2} + a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-2}}{2n^2 + 4nr + 2r^2 - 3n - 3r + 1} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = -\frac{a_{n-2}}{2n^2 + n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{1}{2r^2 + 5r + 3}$$

Which for the root $r = 1$ becomes

$$a_2 = -\frac{1}{10}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{2r^2+5r+3}$	$-\frac{1}{10}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{2r^2+5r+3}$	$-\frac{1}{10}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{4r^4 + 36r^3 + 113r^2 + 144r + 63}$$

Which for the root $r = 1$ becomes

$$a_4 = \frac{1}{360}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{2r^2+5r+3}$	$-\frac{1}{10}$
a_3	0	0
a_4	$\frac{1}{4r^4+36r^3+113r^2+144r+63}$	$\frac{1}{360}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{2r^2+5r+3}$	$-\frac{1}{10}$
a_3	0	0
a_4	$\frac{1}{4r^4+36r^3+113r^2+144r+63}$	$\frac{1}{360}$
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x\left(1 - \frac{x^2}{10} + \frac{x^4}{360} + O\left(x^6\right)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$b_1 = 0$$

For $2 \leq n$ the recursive equation is

$$2b_n(n+r)(n+r-1) - b_n(n+r) + b_{n-2} + b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{b_{n-2}}{2n^2 + 4nr + 2r^2 - 3n - 3r + 1} \tag{4}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_n = -\frac{b_{n-2}}{n(2n-1)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{1}{2r^2 + 5r + 3}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_2 = -\frac{1}{6}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{2r^2+5r+3}$	$-\frac{1}{6}$

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{2r^2+5r+3}$	$-\frac{1}{6}$
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{4r^4 + 36r^3 + 113r^2 + 144r + 63}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_4 = \frac{1}{168}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{2r^2+5r+3}$	$-\frac{1}{6}$
b_3	0	0
b_4	$\frac{1}{4r^4+36r^3+113r^2+144r+63}$	$\frac{1}{168}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{2r^2+5r+3}$	$-\frac{1}{6}$
b_3	0	0
b_4	$\frac{1}{4r^4+36r^3+113r^2+144r+63}$	$\frac{1}{168}$
b_5	0	0

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= \sqrt{x}\left(1 - \frac{x^2}{6} + \frac{x^4}{168} + O(x^6)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x\left(1 - \frac{x^2}{10} + \frac{x^4}{360} + O(x^6)\right) + c_2\sqrt{x}\left(1 - \frac{x^2}{6} + \frac{x^4}{168} + O(x^6)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x\left(1 - \frac{x^2}{10} + \frac{x^4}{360} + O(x^6)\right) + c_2\sqrt{x}\left(1 - \frac{x^2}{6} + \frac{x^4}{168} + O(x^6)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x\left(1 - \frac{x^2}{10} + \frac{x^4}{360} + O(x^6)\right) + c_2\sqrt{x}\left(1 - \frac{x^2}{6} + \frac{x^4}{168} + O(x^6)\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 x\left(1 - \frac{x^2}{10} + \frac{x^4}{360} + O(x^6)\right) + c_2\sqrt{x}\left(1 - \frac{x^2}{6} + \frac{x^4}{168} + O(x^6)\right)
$$

Verified OK.

23.19.1 Maple step by step solution

Let's solve

$2x^2y'' - xy' + (x^2+1)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(x^2+1)y}{2x^2} + \frac{y'}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{y'}{2x} + \frac{(x^2+1)y}{2x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -\frac{1}{2x}, P_3(x) = \frac{x^2+1}{2x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\bigg|_{x=0} = -\frac{1}{2}$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\bigg|_{x=0} = \frac{1}{2}$

  ◦ $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $2x^2y'' - xy' + (x^2+1)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  ◦ Shift index using $k- >k - m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  ◦ Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$

  ◦ Convert $x^2 \cdot y''$ to series expansion

    $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

Rewrite ODE with series expansions

$$a_0(-1+2r)(-1+r)\,x^r + a_1(1+2r)\,r\,x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(2k+2r-1)(k+r-1) + a_{k-2}\right) x^{k+r}\right) =$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+2r)(-1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{1, \frac{1}{2}\right\}$

- Each term must be 0

  $a_1(1+2r)\,r = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $2(k+r-1)\left(k+r-\frac{1}{2}\right)a_k + a_{k-2} = 0$

- Shift index using $k->k+2$

  $2(k+1+r)\left(k+\frac{3}{2}+r\right)a_{k+2} + a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k}{(k+1+r)(2k+3+2r)}$

- Recursion relation for $r = 1$

  $a_{k+2} = -\frac{a_k}{(k+2)(2k+5)}$

- Solution for $r = 1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k}{(k+2)(2k+5)}, a_1 = 0\right]$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -\frac{a_k}{\left(k+\frac{3}{2}\right)(2k+4)}$

- Solution for $r = \frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{a_k}{\left(k+\frac{3}{2}\right)(2k+4)}, a_1 = 0\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+2} = -\frac{a_k}{(k+2)(2k+5)}, a_1 = 0, b_{k+2} = -\frac{b_k}{\left(k+\frac{3}{2}\right)(2k+4)}, b_1 = 0\right]$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 41, page 195
Problem number: 24.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{3x^2y'' + 2xy' + \left(x^2 - 2\right) y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$3x^2y'' + 2xy' + \left(x^2 - 2\right) y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{2}{3x}$$
$$q(x) = \frac{x^2 - 2}{3x^2}$$

Table 674: Table $p(x), q(x)$ singularites.

$p(x) = \frac{2}{3x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{x^2-2}{3x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$3x^2y'' + 2xy' + \left(x^2 - 2\right) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$3x^2 \left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + 2x \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \left(x^2 - 2\right) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 3x^{n+r} a_n(n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2x^{n+r} a_n(n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r+2} a_n\right) + \sum_{n=0}^{\infty} \left(-2a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 3x^{n+r} a_n(n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2x^{n+r} a_n(n+r)\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-2a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$3x^{n+r} a_n(n+r)(n+r-1) + 2x^{n+r} a_n(n+r) - 2a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$3x^r a_0 r(-1+r) + 2x^r a_0 r - 2a_0 x^r = 0$$

Or

$$\left(3x^r r(-1+r) + 2x^r r - 2x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(3r^2 - r - 2\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$3r^2 - r - 2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = -\frac{2}{3}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(3r^2 - r - 2\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{5}{3}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+1}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-\frac{2}{3}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$3a_n(n + r)(n + r - 1) + 2a_n(n + r) + a_{n-2} - 2a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-2}}{3n^2 + 6nr + 3r^2 - n - r - 2} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = -\frac{a_{n-2}}{n(3n + 5)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{1}{3r^2 + 11r + 8}$$

Which for the root $r = 1$ becomes

$$a_2 = -\frac{1}{22}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{3r^2+11r+8}$	$-\frac{1}{22}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{3r^2+11r+8}$	$-\frac{1}{22}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{9r^4 + 102r^3 + 403r^2 + 646r + 336}$$

Which for the root $r = 1$ becomes

$$a_4 = \frac{1}{1496}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{3r^2+11r+8}$	$-\frac{1}{22}$
a_3	0	0
a_4	$\frac{1}{9r^4+102r^3+403r^2+646r+336}$	$\frac{1}{1496}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{3r^2+11r+8}$	$-\frac{1}{22}$
a_3	0	0
a_4	$\frac{1}{9r^4+102r^3+403r^2+646r+336}$	$\frac{1}{1496}$
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x\left(1 - \frac{x^2}{22} + \frac{x^4}{1496} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$b_1 = 0$$

For $2 \leq n$ the recursive equation is

$$3b_n(n+r)(n+r-1) + 2b_n(n+r) + b_{n-2} - 2b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{b_{n-2}}{3n^2 + 6nr + 3r^2 - n - r - 2} \tag{4}$$

Which for the root $r = -\frac{2}{3}$ becomes

$$b_n = -\frac{b_{n-2}}{n(3n-5)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{2}{3}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{1}{3r^2 + 11r + 8}$$

Which for the root $r = -\frac{2}{3}$ becomes

$$b_2 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{3r^2+11r+8}$	$-\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{3r^2+11r+8}$	$-\frac{1}{2}$
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{9r^4 + 102r^3 + 403r^2 + 646r + 336}$$

Which for the root $r = -\frac{2}{3}$ becomes

$$b_4 = \frac{1}{56}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{3r^2+11r+8}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{1}{9r^4+102r^3+403r^2+646r+336}$	$\frac{1}{56}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{3r^2+11r+8}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{1}{9r^4+102r^3+403r^2+646r+336}$	$\frac{1}{56}$
b_5	0	0

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= \frac{1 - \frac{x^2}{2} + \frac{x^4}{56} + O(x^6)}{x^{\frac{2}{3}}}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x\left(1 - \frac{x^2}{22} + \frac{x^4}{1496} + O(x^6)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{56} + O(x^6)\right)}{x^{\frac{2}{3}}}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x\left(1 - \frac{x^2}{22} + \frac{x^4}{1496} + O(x^6)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{56} + O(x^6)\right)}{x^{\frac{2}{3}}}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x\left(1 - \frac{x^2}{22} + \frac{x^4}{1496} + O(x^6)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{56} + O(x^6)\right)}{x^{\frac{2}{3}}} \tag{1}
$$

Verification of solutions

$$
y = c_1 x\left(1 - \frac{x^2}{22} + \frac{x^4}{1496} + O(x^6)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{56} + O(x^6)\right)}{x^{\frac{2}{3}}}
$$

Verified OK.

23.20.1 Maple step by step solution

Let's solve

$3x^2y'' + 2xy' + (x^2 - 2)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

$y'' = -\frac{(x^2-2)y}{3x^2} - \frac{2y'}{3x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{2y'}{3x} + \frac{(x^2-2)y}{3x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- ○ Define functions

  $\left[P_2(x) = \frac{2}{3x}, P_3(x) = \frac{x^2-2}{3x^2}\right]$

- ○ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\bigg|_{x=0} = \frac{2}{3}$

- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = -\frac{2}{3}$

- ○ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $3x^2y'' + 2xy' + (x^2 - 2)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- ○ Shift index using $k- > k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- ○ Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r}$

- ○ Convert $x^2 \cdot y''$ to series expansion

$$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(2+3r)(-1+r)\, x^r + a_1(5+3r)\, r\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(3k+3r+2)(k+r-1) + a_{k-2}\right) x^{k+r}\right) =$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(2+3r)(-1+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{1, -\frac{2}{3}\right\}$$

- Each term must be 0

$$a_1(5+3r)\, r = 0$$

- Solve for the dependent coefficient(s)

$$a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$3\left(k+r+\frac{2}{3}\right)(k+r-1)\, a_k + a_{k-2} = 0$$

- Shift index using $k- >k+2$

$$3\left(k+\frac{8}{3}+r\right)(k+1+r)\, a_{k+2} + a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{a_k}{(3k+8+3r)(k+1+r)}$$

- Recursion relation for $r = 1$

$$a_{k+2} = -\frac{a_k}{(3k+11)(k+2)}$$

- Solution for $r = 1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k}{(3k+11)(k+2)}, a_1 = 0\right]$$

- Recursion relation for $r = -\frac{2}{3}$

$$a_{k+2} = -\frac{a_k}{(3k+6)\left(k+\frac{1}{3}\right)}$$

- Solution for $r = -\frac{2}{3}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{2}{3}}, a_{k+2} = -\frac{a_k}{(3k+6)\left(k+\frac{1}{3}\right)}, a_1 = 0\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}a_k x^{k+1}\right)+\left(\sum_{k=0}^{\infty}b_k x^{k-\frac{2}{3}}\right), a_{k+2}=-\frac{a_k}{(3k+11)(k+2)}, a_1=0, b_{k+2}=-\frac{b_k}{(3k+6)\left(k+\frac{1}{3}\right)}, b_1=0\right]$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 41, page 195
Problem number: 25.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Irregular singular point"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

Unable to solve or complete the solution.

$$\boxed{x^3(x^2+3)\,y''+5xy'-y(x+1)=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$(x^5+3x^3)\,y''+5xy'+(-x-1)\,y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$\begin{aligned}p(x)&=\frac{5}{x^2\,(x^2+3)}\\ q(x)&=-\frac{x+1}{x^3\,(x^2+3)}\end{aligned}$$

Table 676: Table $p(x), q(x)$ singularites.

$p(x) = \frac{5}{x^2(x^2+3)}$	
singularity	type
$x = 0$	"irregular"
$x = -i\sqrt{3}$	"regular"
$x = i\sqrt{3}$	"regular"

$q(x) = -\frac{x+1}{x^3(x^2+3)}$	
singularity	type
$x = 0$	"irregular"
$x = -i\sqrt{3}$	"regular"
$x = i\sqrt{3}$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-i\sqrt{3}, i\sqrt{3}, \infty]$

Irregular singular points : $[0]$

Since $x = 0$ is not an ordinary point, then we will now check if it is a regular singular point. Unable to solve since $x = 0$ is not regular singular point. Terminating.

Verification of solutions N/A

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 41, page 195
Problem number: 26.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{2xy'' - \left(x^3+1\right)y' + y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2xy'' + \left(-x^3-1\right)y' + y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{x^3+1}{2x}$$
$$q(x) = \frac{1}{2x}$$

Table 677: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x^3+1}{2x}$	
singularity	type
$x = 0$	"regular"
$x = \infty$	"regular"
$x = -\infty$	"regular"

$q(x) = \frac{1}{2x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, \infty, -\infty]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2xy'' + (-x^3 - 1)\, y' + y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x + (-x^3 - 1)\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r+2} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{n+r+2} a_n (n+r)\right) = \sum_{n=3}^{\infty} \left(-a_{n-3}(n+r-3)\, x^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty} a_n x^{n+r} = \sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=3}^{\infty} \left(-a_{n-3}(n+r-3)\, x^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r-1} a_n (n+r)(n+r-1) - (n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$2x^{-1+r} a_0 r(-1+r) - r a_0 x^{-1+r} = 0$$

Or

$$\left(2x^{-1+r} r(-1+r) - r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, x^{-1+r}(-3+2r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 - 3r = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{3}{2}$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\, x^{-1+r}(-3+2r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{3}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{3}{2}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^n$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = -\frac{1}{2r^2 + r - 1}$$

Substituting $n = 2$ in Eq. (2B) gives

$$a_2 = \frac{1}{4r^4 + 12r^3 + 7r^2 - 3r - 2}$$

For $3 \leq n$ the recursive equation is

$$2a_n(n+r)(n+r-1) - a_{n-3}(n+r-3) - a_n(n+r) + a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{n a_{n-3} + r a_{n-3} - 3a_{n-3} - a_{n-1}}{2n^2 + 4nr + 2r^2 - 3n - 3r} \tag{4}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_n = \frac{2n a_{n-3} - 3a_{n-3} - 2a_{n-1}}{4n^2 + 6n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{3}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+r-1}$	$-\frac{1}{5}$
a_2	$\frac{1}{4r^4+12r^3+7r^2-3r-2}$	$\frac{1}{70}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{4r^5 + 12r^4 + 7r^3 - 3r^2 - 2r - 1}{8r^6 + 60r^5 + 158r^4 + 165r^3 + 32r^2 - 45r - 18}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_3 = \frac{52}{945}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+r-1}$	$-\frac{1}{5}$
a_2	$\frac{1}{4r^4+12r^3+7r^2-3r-2}$	$\frac{1}{70}$
a_3	$\frac{4r^5+12r^4+7r^3-3r^2-2r-1}{8r^6+60r^5+158r^4+165r^3+32r^2-45r-18}$	$\frac{52}{945}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{-8r^5 - 44r^4 - 102r^3 - 127r^2 - 79r - 17}{16r^8 + 224r^7 + 1256r^6 + 3584r^5 + 5369r^4 + 3626r^3 + 19r^2 - 1134r - 360}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_4 = -\frac{1049}{83160}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+r-1}$	$-\frac{1}{5}$
a_2	$\frac{1}{4r^4+12r^3+7r^2-3r-2}$	$\frac{1}{70}$
a_3	$\frac{4r^5+12r^4+7r^3-3r^2-2r-1}{8r^6+60r^5+158r^4+165r^3+32r^2-45r-18}$	$\frac{52}{945}$
a_4	$\frac{-8r^5-44r^4-102r^3-127r^2-79r-17}{16r^8+224r^7+1256r^6+3584r^5+5369r^4+3626r^3+19r^2-1134r-360}$	$-\frac{1049}{83160}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{12r^5 + 96r^4 + 365r^3 + 774r^2 + 853r + 377}{32r^{10} + 720r^9 + 6880r^8 + 36360r^7 + 115626r^6 + 223965r^5 + 249595r^4 + 124965r^3 - 19333r^2 - 458}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_5 = \frac{5207}{5405400}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+r-1}$	$-\frac{1}{5}$
a_2	$\frac{1}{4r^4+12r^3+7r^2-3r-2}$	$\frac{1}{70}$
a_3	$\frac{4r^5+12r^4+7r^3-3r^2-2r-1}{8r^6+60r^5+158r^4+165r^3+32r^2-45r-18}$	$\frac{52}{945}$
a_4	$\frac{-8r^5-44r^4-102r^3-127r^2-79r-17}{16r^8+224r^7+1256r^6+3584r^5+5369r^4+3626r^3+19r^2-1134r-360}$	$-\frac{1049}{83160}$
a_5	$\frac{12r^5+96r^4+365r^3+774r^2+853r+377}{32r^{10}+720r^9+6880r^8+36360r^7+115626r^6+223965r^5+249595r^4+124965r^3-19333r^2-45810r-12600}$	$\frac{5207}{5405400}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{3}{2}}\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots\right) \\ &= x^{\frac{3}{2}}\left(1 - \frac{x}{5} + \frac{x^2}{70} + \frac{52x^3}{945} - \frac{1049x^4}{83160} + \frac{5207x^5}{5405400} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$b_1 = -\frac{1}{2r^2 + r - 1}$$

Substituting $n = 2$ in Eq. (2B) gives

$$b_2 = \frac{1}{4r^4 + 12r^3 + 7r^2 - 3r - 2}$$

For $3 \leq n$ the recursive equation is

$$2b_n(n+r)(n+r-1) - b_{n-3}(n+r-3) - (n+r)b_n + b_{n-1} = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = \frac{nb_{n-3} + rb_{n-3} - 3b_{n-3} - b_{n-1}}{2n^2 + 4nr + 2r^2 - 3n - 3r} \tag{4}$$

Which for the root $r = 0$ becomes

$$b_n = \frac{(n-3)b_{n-3} - b_{n-1}}{n(2n-3)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{2r^2+r-1}$	1
b_2	$\frac{1}{4r^4+12r^3+7r^2-3r-2}$	$-\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{4r^5 + 12r^4 + 7r^3 - 3r^2 - 2r - 1}{8r^6 + 60r^5 + 158r^4 + 165r^3 + 32r^2 - 45r - 18}$$

Which for the root $r = 0$ becomes

$$b_3 = \frac{1}{18}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{2r^2+r-1}$	1
b_2	$\frac{1}{4r^4+12r^3+7r^2-3r-2}$	$-\frac{1}{2}$
b_3	$\frac{4r^5+12r^4+7r^3-3r^2-2r-1}{8r^6+60r^5+158r^4+165r^3+32r^2-45r-18}$	$\frac{1}{18}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{-8r^5 - 44r^4 - 102r^3 - 127r^2 - 79r - 17}{16r^8 + 224r^7 + 1256r^6 + 3584r^5 + 5369r^4 + 3626r^3 + 19r^2 - 1134r - 360}$$

Which for the root $r = 0$ becomes

$$b_4 = \frac{17}{360}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{2r^2+r-1}$	1
b_2	$\frac{1}{4r^4+12r^3+7r^2-3r-2}$	$-\frac{1}{2}$
b_3	$\frac{4r^5+12r^4+7r^3-3r^2-2r-1}{8r^6+60r^5+158r^4+165r^3+32r^2-45r-18}$	$\frac{1}{18}$
b_4	$\frac{-8r^5-44r^4-102r^3-127r^2-79r-17}{16r^8+224r^7+1256r^6+3584r^5+5369r^4+3626r^3+19r^2-1134r-360}$	$\frac{17}{360}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{12r^5 + 96r^4 + 365r^3 + 774r^2 + 853r + 377}{32r^{10} + 720r^9 + 6880r^8 + 36360r^7 + 115626r^6 + 223965r^5 + 249595r^4 + 124965r^3 - 19333r^2 - 458}$$

Which for the root $r = 0$ becomes

$$b_5 = -\frac{377}{12600}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{2r^2+r-1}$	1
b_2	$\frac{1}{4r^4+12r^3+7r^2-3r-2}$	$-\frac{1}{2}$
b_3	$\frac{4r^5+12r^4+7r^3-3r^2-2r-1}{8r^6+60r^5+158r^4+165r^3+32r^2-45r-18}$	$\frac{1}{18}$
b_4	$\frac{-8r^5-44r^4-102r^3-127r^2-79r-17}{16r^8+224r^7+1256r^6+3584r^5+5369r^4+3626r^3+19r^2-1134r-360}$	$\frac{17}{360}$
b_5	$\frac{12r^5+96r^4+365r^3+774r^2+853r+377}{32r^{10}+720r^9+6880r^8+36360r^7+115626r^6+223965r^5+249595r^4+124965r^3-19333r^2-45810r-12600}$	$-\frac{377}{12600}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots \\
&= 1 + x - \frac{x^2}{2} + \frac{x^3}{18} + \frac{17x^4}{360} - \frac{377x^5}{12600} + O(x^6)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{\frac{3}{2}} \left(1 - \frac{x}{5} + \frac{x^2}{70} + \frac{52x^3}{945} - \frac{1049x^4}{83160} + \frac{5207x^5}{5405400} + O(x^6)\right) \\
&+ c_2 \left(1 + x - \frac{x^2}{2} + \frac{x^3}{18} + \frac{17x^4}{360} - \frac{377x^5}{12600} + O(x^6)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{\frac{3}{2}} \left(1 - \frac{x}{5} + \frac{x^2}{70} + \frac{52x^3}{945} - \frac{1049x^4}{83160} + \frac{5207x^5}{5405400} + O(x^6)\right) \\
&+ c_2 \left(1 + x - \frac{x^2}{2} + \frac{x^3}{18} + \frac{17x^4}{360} - \frac{377x^5}{12600} + O(x^6)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = c_1 x^{\frac{3}{2}} \left(1 - \frac{x}{5} + \frac{x^2}{70} + \frac{52x^3}{945} - \frac{1049x^4}{83160} + \frac{5207x^5}{5405400} + O(x^6)\right) \\
+ c_2 \left(1 + x - \frac{x^2}{2} + \frac{x^3}{18} + \frac{17x^4}{360} - \frac{377x^5}{12600} + O(x^6)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$y = c_1 x^{\frac{3}{2}} \left(1 - \frac{x}{5} + \frac{x^2}{70} + \frac{52x^3}{945} - \frac{1049x^4}{83160} + \frac{5207x^5}{5405400} + O(x^6)\right) + c_2 \left(1 + x - \frac{x^2}{2} + \frac{x^3}{18} + \frac{17x^4}{360} - \frac{377x^5}{12600} + O(x^6)\right)$$

Verified OK.

23.22.1 Maple step by step solution

Let's solve

$2y''x + (-x^3 - 1) y' + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y}{2x} + \frac{(x^3+1)y'}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{(x^3+1)y'}{2x} + \frac{y}{2x} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -\frac{x^3+1}{2x}, P_3(x) = \frac{1}{2x}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\Big|_{x=0} = -\frac{1}{2}$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\Big|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2y''x + (-x^3 - 1) y' + y = 0$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y'$ to series expansion for $m = 0..3$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$$

- Convert $x \cdot y''$ to series expansion

$$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$$

- Shift index using $k- >k+1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1} (k+1+r)\,(k+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-3+2r)\, x^{-1+r} + (a_1(1+r)\,(-1+2r) + a_0)\, x^r + (a_2(2+r)\,(1+2r) + a_1)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_{k+\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-3+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, \frac{3}{2}\right\}$$

- The coefficients of each power of x must be 0

$$[a_1(1+r)\,(-1+2r) + a_0 = 0, a_2(2+r)\,(1+2r) + a_1 = 0]$$

- Solve for the dependent coefficient(s)

$$\left\{a_1 = -\frac{a_0}{2r^2+r-1}, a_2 = \frac{a_0}{4r^4+12r^3+7r^2-3r-2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)\,(2k-1+2r) + a_k - a_{k-2}(k-2+r) = 0$$

- Shift index using $k- >k+2$

$$a_{k+3}(k+3+r)\,(2k+3+2r) + a_{k+2} - a_k(k+r) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+3} = \frac{k a_k + r a_k - a_{k+2}}{(k+3+r)(2k+3+2r)}$$

- Recursion relation for $r = 0$

  $a_{k+3} = \frac{k a_k - a_{k+2}}{(k+3)(2k+3)}$

- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = \frac{k a_k - a_{k+2}}{(k+3)(2k+3)}, a_1 = a_0, a_2 = -\frac{a_0}{2}\right]$

- Recursion relation for $r = \frac{3}{2}$

  $a_{k+3} = \frac{k a_k + \frac{3}{2} a_k - a_{k+2}}{\left(k+\frac{9}{2}\right)(2k+6)}$

- Solution for $r = \frac{3}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{3}{2}}, a_{k+3} = \frac{k a_k + \frac{3}{2} a_k - a_{k+2}}{\left(k+\frac{9}{2}\right)(2k+6)}, a_1 = -\frac{a_0}{5}, a_2 = \frac{a_0}{70}\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{3}{2}}\right), a_{k+3} = \frac{k a_k - a_{k+2}}{(k+3)(2k+3)}, a_1 = a_0, a_2 = -\frac{a_0}{2}, b_{k+3} = \frac{k b_k + \frac{3}{2} b_k - b_{k+2}}{\left(k+\frac{9}{2}\right)(2k+6)}, b_1\right.$

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{xy'' + y' + 2y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$xy'' + y' + 2y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{2}{x}$$

Table 679: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{2}{x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$xy'' + y' + 2y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x + \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)\,(n+r-1)\right) + \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2a_n x^{n+r} = \sum_{n=1}^{\infty} 2a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} 2a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r-1} a_n (n+r)(n+r-1) + (n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$x^{-1+r} a_0 r(-1+r) + r a_0 x^{-1+r} = 0$$

Or

$$\left(x^{-1+r} r(-1+r) + r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$x^{-1+r} r^2 = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$x^{-1+r} r^2 = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + a_n(n+r) + 2a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{2a_{n-1}}{n^2 + 2nr + r^2} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = -\frac{2a_{n-1}}{n^2} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{2}{(r+1)^2}$$

Which for the root $r = 0$ becomes

$$a_1 = -2$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2}{(r+1)^2}$	-2

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{4}{(r+1)^2 (2+r)^2}$$

Which for the root $r = 0$ becomes

$$a_2 = 1$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2}{(r+1)^2}$	-2
a_2	$\frac{4}{(r+1)^2(2+r)^2}$	1

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{8}{(r+1)^2 (2+r)^2 (r+3)^2}$$

Which for the root $r = 0$ becomes

$$a_3 = -\frac{2}{9}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2}{(r+1)^2}$	-2
a_2	$\frac{4}{(r+1)^2(2+r)^2}$	1
a_3	$-\frac{8}{(r+1)^2(2+r)^2(r+3)^2}$	$-\frac{2}{9}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{16}{(r+1)^2 (2+r)^2 (r+3)^2 (r+4)^2}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{36}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2}{(r+1)^2}$	-2
a_2	$\frac{4}{(r+1)^2(2+r)^2}$	1
a_3	$-\frac{8}{(r+1)^2(2+r)^2(r+3)^2}$	$-\frac{2}{9}$
a_4	$\frac{16}{(r+1)^2(2+r)^2(r+3)^2(r+4)^2}$	$\frac{1}{36}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{32}{(r+1)^2 (2+r)^2 (r+3)^2 (r+4)^2 (r+5)^2}$$

Which for the root $r = 0$ becomes

$$a_5 = -\frac{1}{450}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2}{(r+1)^2}$	-2
a_2	$\frac{4}{(r+1)^2(2+r)^2}$	1
a_3	$-\frac{8}{(r+1)^2(2+r)^2(r+3)^2}$	$-\frac{2}{9}$
a_4	$\frac{16}{(r+1)^2(2+r)^2(r+3)^2(r+4)^2}$	$\frac{1}{36}$
a_5	$-\frac{32}{(r+1)^2(2+r)^2(r+3)^2(r+4)^2(r+5)^2}$	$-\frac{1}{450}$

Using the above table, then the first solution $y_1(x)$ becomes

$$\begin{aligned} y_1(x) &= a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots \\ &= x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O(x^6) \end{aligned}$$

Now the second solution is found. The second solution is given by

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)$$

Where b_n is found using

$$b_n = \frac{d}{dr} a_{n,r}$$

And the above is then evaluated at $r = 0$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr} a_{n,r}$	$b_n(r = 0)$
b_0	1	1	N/A since b_n starts from 1	N/A
b_1	$-\frac{2}{(r+1)^2}$	-2	$\frac{4}{(r+1)^3}$	4
b_2	$\frac{4}{(r+1)^2 (2+r)^2}$	1	$\frac{-24-16r}{(r+1)^3 (2+r)^3}$	-3
b_3	$-\frac{8}{(r+1)^2 (2+r)^2 (r+3)^2}$	$-\frac{2}{9}$	$\frac{48r^2+192r+176}{(r+1)^3 (2+r)^3 (r+3)^3}$	$\frac{22}{27}$
b_4	$\frac{16}{(r+1)^2 (2+r)^2 (r+3)^2 (r+4)^2}$	$\frac{1}{36}$	$-\frac{64(2r^3+15r^2+35r+25)}{(r+1)^3 (2+r)^3 (r+3)^3 (r+4)^3}$	$-\frac{25}{216}$
b_5	$-\frac{32}{(r+1)^2 (2+r)^2 (r+3)^2 (r+4)^2 (r+5)^2}$	$-\frac{1}{450}$	$\frac{320r^4+3840r^3+16320r^2+28800r+17536}{(r+1)^3 (2+r)^3 (r+3)^3 (r+4)^3 (r+5)^3}$	$\frac{137}{13500}$

The above table gives all values of b_n needed. Hence the second solution is

$$\begin{aligned} y_2(x) &= y_1(x) \ln(x) + b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 \dots \\ &= \left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O(x^6)\right) \ln(x) - 3x^2 + 4x + \frac{22x^3}{27} - \frac{25x^4}{216} + \frac{137x^5}{13500} \\ &\quad + O(x^6) \end{aligned}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 \left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O(x^6)\right) \\
&\quad + c_2 \left(\left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O(x^6)\right) \ln(x) - 3x^2 + 4x + \frac{22x^3}{27} \right. \\
&\quad \left. - \frac{25x^4}{216} + \frac{137x^5}{13500} + O(x^6)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 \left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O(x^6)\right) \\
&\quad + c_2 \left(\left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O(x^6)\right) \ln(x) - 3x^2 + 4x + \frac{22x^3}{27} - \frac{25x^4}{216} \right. \\
&\quad \left. + \frac{137x^5}{13500} + O(x^6)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 \left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O(x^6)\right) \\
&\quad + c_2 \left(\left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O(x^6)\right) \ln(x) - 3x^2 + 4x + \frac{22x^3}{27} \right. \\
&\quad \left. - \frac{25x^4}{216} + \frac{137x^5}{13500} + O(x^6)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 \left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O(x^6)\right) \\
&\quad + c_2 \left(\left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O(x^6)\right) \ln(x) - 3x^2 + 4x + \frac{22x^3}{27} - \frac{25x^4}{216} \right. \\
&\quad \left. + \frac{137x^5}{13500} + O(x^6)\right)
\end{aligned}
$$

Verified OK.

24.1.1 Maple step by step solution

Let's solve

$y''x + y' + 2y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{2y}{x} - \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + \frac{2y}{x} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{1}{x}, P_3(x) = \frac{2}{x}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = 1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x + y' + 2y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  ◦ Convert y' to series expansion

  $y' = \sum_{k=0}^{\infty} a_k(k + r)\, x^{k+r-1}$

  ◦ Shift index using $k- >k + 1$

$$y' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, x^{k+r}$$

- ○ Convert $x \cdot y''$ to series expansion

$$x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$$

- ○ Shift index using $k->k+1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r^2 x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)^2 + 2a_k\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = 0$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1)^2 + 2a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{2a_k}{(k+1)^2}$$

- Recursion relation for $r = 0$

$$a_{k+1} = -\frac{2a_k}{(k+1)^2}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = -\frac{2a_k}{(k+1)^2}\right]$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 42, page 206
Problem number: 2.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy'' + y' + 2yx = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$xy'' + y' + 2yx = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = 2$$

Table 681: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = 2$	
singularity	type

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$xy'' + y' + 2yx = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x + \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) x = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)\,(n+r-1)\right) + \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 2x^{1+n+r} a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2x^{1+n+r}a_n = \sum_{n=2}^{\infty} 2a_{n-2}x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} x^{n+r-1}a_n(n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} (n+r)a_n x^{n+r-1}\right) + \left(\sum_{n=2}^{\infty} 2a_{n-2}x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r-1}a_n(n+r)(n+r-1) + (n+r)a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$x^{-1+r}a_0 r(-1+r) + r a_0 x^{-1+r} = 0$$

Or

$$\left(x^{-1+r}r(-1+r) + r\,x^{-1+r}\right)a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$x^{-1+r}r^2 = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$x^{-1+r}r^2 = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + a_n(n+r) + 2a_{n-2} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{2a_{n-2}}{n^2 + 2nr + r^2} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = -\frac{2a_{n-2}}{n^2} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{2}{(2+r)^2}$$

Which for the root $r = 0$ becomes

$$a_2 = -\frac{1}{2}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{2}{(2+r)^2}$	$-\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{2}{(2+r)^2}$	$-\frac{1}{2}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{4}{(2+r)^2 (r+4)^2}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{16}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{2}{(2+r)^2}$	$-\frac{1}{2}$
a_3	0	0
a_4	$\frac{4}{(2+r)^2(r+4)^2}$	$\frac{1}{16}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{2}{(2+r)^2}$	$-\frac{1}{2}$
a_3	0	0
a_4	$\frac{4}{(2+r)^2(r+4)^2}$	$\frac{1}{16}$
a_5	0	0

Using the above table, then the first solution $y_1(x)$ becomes

$$\begin{aligned}
y_1(x) &= a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots \\
&= 1 - \frac{x^2}{2} + \frac{x^4}{16} + O(x^6)
\end{aligned}$$

Now the second solution is found. The second solution is given by

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)$$

Where b_n is found using

$$b_n = \frac{d}{dr} a_{n,r}$$

And the above is then evaluated at $r = 0$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr}a_{n,r}$	$b_n(r=0)$
b_0	1	1	N/A since b_n starts from 1	N/A
b_1	0	0	0	0
b_2	$-\frac{2}{(2+r)^2}$	$-\frac{1}{2}$	$\frac{4}{(2+r)^3}$	$\frac{1}{2}$
b_3	0	0	0	0
b_4	$\frac{4}{(2+r)^2(r+4)^2}$	$\frac{1}{16}$	$\frac{-16r-48}{(2+r)^3(r+4)^3}$	$-\frac{3}{32}$
b_5	0	0	0	0

The above table gives all values of b_n needed. Hence the second solution is

$$\begin{aligned} y_2(x) &= y_1(x)\ln(x) + b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6\dots \\ &= \left(1 - \frac{x^2}{2} + \frac{x^4}{16} + O(x^6)\right)\ln(x) + \frac{x^2}{2} - \frac{3x^4}{32} + O(x^6) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1y_1(x) + c_2y_2(x) \\ &= c_1\left(1-\frac{x^2}{2}+\frac{x^4}{16}+O(x^6)\right)+c_2\left(\left(1-\frac{x^2}{2}+\frac{x^4}{16}+O(x^6)\right)\ln(x)+\frac{x^2}{2}-\frac{3x^4}{32}+O(x^6)\right) \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= c_1\left(1-\frac{x^2}{2}+\frac{x^4}{16}+O(x^6)\right)+c_2\left(\left(1-\frac{x^2}{2}+\frac{x^4}{16}+O(x^6)\right)\ln(x)+\frac{x^2}{2}-\frac{3x^4}{32}+O(x^6)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = c_1&\left(1 - \frac{x^2}{2} + \frac{x^4}{16} + O(x^6)\right) \\ &+ c_2\left(\left(1 - \frac{x^2}{2} + \frac{x^4}{16} + O(x^6)\right)\ln(x) + \frac{x^2}{2} - \frac{3x^4}{32} + O(x^6)\right) \end{aligned} \tag{1}$$

Verification of solutions

$$y = c_1\left(1-\frac{x^2}{2}+\frac{x^4}{16}+O(x^6)\right)+c_2\left(\left(1-\frac{x^2}{2}+\frac{x^4}{16}+O(x^6)\right)\ln(x)+\frac{x^2}{2}-\frac{3x^4}{32}+O(x^6)\right)$$

Verified OK.

24.2.1 Maple step by step solution

Let's solve

$y''x + y' + 2yx = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y'}{x} - 2y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + 2y = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{1}{x}, P_3(x) = 2\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 1$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 0$

  - $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x + y' + 2yx = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions
  - Convert $x \cdot y$ to series expansion

    $$x \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+1}$$
  - Shift index using $k->k-1$

    $$x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^{k+r}$$
  - Convert y' to series expansion

    $$y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1}$$
  - Shift index using $k->k+1$

    $$y' = \sum_{k=-1}^{\infty} a_{k+1}(k+r+1)\, x^{k+r}$$
  - Convert $x \cdot y''$ to series expansion

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 42, page 206
Problem number: 3.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - 3xy' + 4y(x+1) = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' - 3xy' + (4x + 4)\, y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{3}{x}$$
$$q(x) = \frac{4x + 4}{x^2}$$

Table 683: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{3}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{4x+4}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' - 3xy' + (4x + 4)\, y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\begin{aligned} & x^2 \left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) \\ & - 3x \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + (4x+4) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \end{aligned} \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-3x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 4x^{1+n+r} a_n\right) + \left(\sum_{n=0}^{\infty} 4a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 4x^{1+n+r} a_n = \sum_{n=1}^{\infty} 4a_{n-1} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-3x^{n+r} a_n (n+r)\right) + \left(\sum_{n=1}^{\infty} 4a_{n-1} x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 4a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n = 0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - 3x^{n+r} a_n (n+r) + 4a_n x^{n+r} = 0$$

When $n = 0$ the above becomes

$$x^r a_0 r(-1+r) - 3x^r a_0 r + 4a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - 3x^r r + 4x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$(r-2)^2 x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$(r-2)^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 2$$
$$r_2 = 2$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$(r-2)^2 x^r = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. Using the value of the indicial root found earlier, $r = 2$, Eqs (1A,1B) become

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+2}$$
$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+2}\right)$$

We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - 3a_n(n+r) + 4a_{n-1} + 4a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{4a_{n-1}}{n^2 + 2nr + r^2 - 4n - 4r + 4} \tag{4}$$

Which for the root $r = 2$ becomes

$$a_n = -\frac{4a_{n-1}}{n^2} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{4}{(-1+r)^2}$$

Which for the root $r = 2$ becomes

$$a_1 = -4$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{(-1+r)^2}$	-4

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{16}{(-1+r)^2 r^2}$$

Which for the root $r = 2$ becomes

$$a_2 = 4$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{(-1+r)^2}$	-4
a_2	$\frac{16}{(-1+r)^2 r^2}$	4

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{64}{(-1+r)^2 r^2 (r+1)^2}$$

Which for the root $r = 2$ becomes

$$a_3 = -\frac{16}{9}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{(-1+r)^2}$	-4
a_2	$\frac{16}{(-1+r)^2 r^2}$	4
a_3	$-\frac{64}{(-1+r)^2 r^2 (r+1)^2}$	$-\frac{16}{9}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{256}{(-1+r)^2 r^2 (r+1)^2 (2+r)^2}$$

Which for the root $r = 2$ becomes

$$a_4 = \frac{4}{9}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{(-1+r)^2}$	-4
a_2	$\frac{16}{(-1+r)^2 r^2}$	4
a_3	$-\frac{64}{(-1+r)^2 r^2 (r+1)^2}$	$-\frac{16}{9}$
a_4	$\frac{256}{(-1+r)^2 r^2 (r+1)^2 (2+r)^2}$	$\frac{4}{9}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1024}{(-1+r)^2 r^2 (r+1)^2 (2+r)^2 (r+3)^2}$$

Which for the root $r = 2$ becomes

$$a_5 = -\frac{16}{225}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{(-1+r)^2}$	-4
a_2	$\frac{16}{(-1+r)^2 r^2}$	4
a_3	$-\frac{64}{(-1+r)^2 r^2 (r+1)^2}$	$-\frac{16}{9}$
a_4	$\frac{256}{(-1+r)^2 r^2 (r+1)^2 (2+r)^2}$	$\frac{4}{9}$
a_5	$-\frac{1024}{(-1+r)^2 r^2 (r+1)^2 (2+r)^2 (r+3)^2}$	$-\frac{16}{225}$

Using the above table, then the first solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^2 \left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^2 \left(4x^2 - 4x + 1 - \frac{16x^3}{9} + \frac{4x^4}{9} - \frac{16x^5}{225} + O(x^6)\right) \end{aligned}$$

Now the second solution is found. The second solution is given by

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)$$

Where b_n is found using

$$b_n = \frac{d}{dr} a_{n,r}$$

And the above is then evaluated at $r = 2$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr}a_{n,r}$	$b_n(r = 2)$
b_0	1	1	N/A since b_n starts from 1	N/A
b_1	$-\frac{4}{(-1+r)^2}$	-4	$\frac{8}{(-1+r)^3}$	8
b_2	$\frac{16}{(-1+r)^2 r^2}$	4	$\frac{-64r+32}{(-1+r)^3 r^3}$	-12
b_3	$-\frac{64}{(-1+r)^2 r^2 (r+1)^2}$	$-\frac{16}{9}$	$\frac{384r^2-128}{(-1+r)^3 r^3 (r+1)^3}$	$\frac{176}{27}$
b_4	$\frac{256}{(-1+r)^2 r^2 (r+1)^2 (2+r)^2}$	$\frac{4}{9}$	$\frac{-2048r^3-3072r^2+1024r+1024}{(-1+r)^3 r^3 (r+1)^3 (2+r)^3}$	$-\frac{50}{27}$
b_5	$-\frac{1024}{(-1+r)^2 r^2 (r+1)^2 (2+r)^2 (r+3)^2}$	$-\frac{16}{225}$	$\frac{10240r^4+40960r^3+30720r^2-20480r-12288}{(-1+r)^3 r^3 (r+1)^3 (2+r)^3 (r+3)^3}$	$\frac{1096}{3375}$

The above table gives all values of b_n needed. Hence the second solution is

$$
\begin{aligned}
y_2(x) &= y_1(x)\ln(x) + b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \ldots \\
&= x^2\left(4x^2 - 4x + 1 - \frac{16x^3}{9} + \frac{4x^4}{9} - \frac{16x^5}{225} + O(x^6)\right)\ln(x) \\
&\quad + x^2\left(-12x^2 + 8x + \frac{176x^3}{27} - \frac{50x^4}{27} + \frac{1096x^5}{3375} + O(x^6)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^2\left(4x^2 - 4x + 1 - \frac{16x^3}{9} + \frac{4x^4}{9} - \frac{16x^5}{225} + O(x^6)\right) \\
&\quad + c_2\left(x^2\left(4x^2 - 4x + 1 - \frac{16x^3}{9} + \frac{4x^4}{9} - \frac{16x^5}{225} + O(x^6)\right)\ln(x)\right. \\
&\quad \left. + x^2\left(-12x^2 + 8x + \frac{176x^3}{27} - \frac{50x^4}{27} + \frac{1096x^5}{3375} + O(x^6)\right)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^2\left(4x^2 - 4x + 1 - \frac{16x^3}{9} + \frac{4x^4}{9} - \frac{16x^5}{225} + O(x^6)\right) \\
&\quad + c_2\left(x^2\left(4x^2 - 4x + 1 - \frac{16x^3}{9} + \frac{4x^4}{9} - \frac{16x^5}{225} + O(x^6)\right)\ln(x)\right. \\
&\quad \left. + x^2\left(-12x^2 + 8x + \frac{176x^3}{27} - \frac{50x^4}{27} + \frac{1096x^5}{3375} + O(x^6)\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & c_1 x^2 \left(4x^2-4x+1-\frac{16x^3}{9}+\frac{4x^4}{9}-\frac{16x^5}{225}+O\left(x^6\right)\right) \\
& + c_2 \left(x^2 \left(4x^2-4x+1-\frac{16x^3}{9}+\frac{4x^4}{9}-\frac{16x^5}{225}+O\left(x^6\right)\right) \ln\left(x\right)\right. \\
& \left. + x^2 \left(-12x^2+8x+\frac{176x^3}{27}-\frac{50x^4}{27}+\frac{1096x^5}{3375}+O\left(x^6\right)\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & c_1 x^2 \left(4x^2-4x+1-\frac{16x^3}{9}+\frac{4x^4}{9}-\frac{16x^5}{225}+O\left(x^6\right)\right) \\
& + c_2 \left(x^2 \left(4x^2-4x+1-\frac{16x^3}{9}+\frac{4x^4}{9}-\frac{16x^5}{225}+O\left(x^6\right)\right) \ln\left(x\right)\right. \\
& \left. + x^2 \left(-12x^2+8x+\frac{176x^3}{27}-\frac{50x^4}{27}+\frac{1096x^5}{3375}+O\left(x^6\right)\right)\right)
\end{aligned}
$$

Verified OK.

24.3.1 Maple step by step solution

Let's solve

$x^2y''-3xy'+(4x+4)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{3y'}{x}-\frac{4(x+1)y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{3y'}{x}+\frac{4(x+1)y}{x^2}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=-\frac{3}{x}, P_3(x)=\frac{4(x+1)}{x^2}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

    $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=-3$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 4$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2 y'' - 3xy' + (4x + 4)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k- > k - m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r}$

  - Convert $x^2 \cdot y''$ to series expansion

    $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k + r)\,(k + r - 1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 (-2 + r)^2 x^r + \left(\sum_{k=1}^{\infty} \left(a_k (k + r - 2)^2 + 4a_{k-1}\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2 + r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = 2$

- Each term in the series must be 0, giving the recursion relation

$$a_k(k+r-2)^2+4a_{k-1}=0$$

- Shift index using $k->k+1$

$$a_{k+1}(k+r-1)^2+4a_k=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=-\frac{4a_k}{(k+r-1)^2}$$

- Recursion relation for $r=2$

$$a_{k+1}=-\frac{4a_k}{(k+1)^2}$$

- Solution for $r=2$

$$\left[y=\sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+1}=-\frac{4a_k}{(k+1)^2}\right]$$

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2y'' - x(x+1)\,y' + y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + \left(-x^2 - x\right)y' + y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{x+1}{x}$$
$$q(x) = \frac{1}{x^2}$$

Table 685: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x+1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{1}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' + \left(-x^2 - x\right)y' + y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + \left(-x^2 - x\right)\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)\right) = \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - x^{n+r} a_n (n+r) + a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - x^r a_0 r + a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - x^r r + x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$(-1+r)^2 x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$(-1+r)^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = 1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$(-1+r)^2 x^r = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. Using the value of the indicial root found earlier, $r = 1$, Eqs (1A,1B) become

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{1+n}$$
$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{1+n}\right)$$

We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - a_{n-1}(n+r-1) - a_n(n+r) + a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}}{n+r-1} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = \frac{a_{n-1}}{n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{1}{r}$$

Which for the root $r = 1$ becomes

$$a_1 = 1$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r}$	1

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{r(1+r)}$$

Which for the root $r = 1$ becomes

$$a_2 = \frac{1}{2}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r}$	1
a_2	$\frac{1}{r(1+r)}$	$\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{1}{(2+r) r (1+r)}$$

Which for the root $r = 1$ becomes

$$a_3 = \frac{1}{6}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r}$	1
a_2	$\frac{1}{r(1+r)}$	$\frac{1}{2}$
a_3	$\frac{1}{(2+r)r(1+r)}$	$\frac{1}{6}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{(3+r)(2+r) r (1+r)}$$

Which for the root $r = 1$ becomes

$$a_4 = \frac{1}{24}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r}$	1
a_2	$\frac{1}{r(1+r)}$	$\frac{1}{2}$
a_3	$\frac{1}{(2+r)r(1+r)}$	$\frac{1}{6}$
a_4	$\frac{1}{(3+r)(2+r)r(1+r)}$	$\frac{1}{24}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{1}{(4+r)(3+r)(2+r) r (1+r)}$$

Which for the root $r = 1$ becomes

$$a_5 = \frac{1}{120}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r}$	1
a_2	$\frac{1}{r(1+r)}$	$\frac{1}{2}$
a_3	$\frac{1}{(2+r)r(1+r)}$	$\frac{1}{6}$
a_4	$\frac{1}{(3+r)(2+r)r(1+r)}$	$\frac{1}{24}$
a_5	$\frac{1}{(4+r)(3+r)(2+r)r(1+r)}$	$\frac{1}{120}$

Using the above table, then the first solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x\left(x + 1 + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)\right) \end{aligned}$$

Now the second solution is found. The second solution is given by

$$y_2(x) = y_1(x)\ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)$$

Where b_n is found using

$$b_n = \frac{d}{dr} a_{n,r}$$

And the above is then evaluated at $r = 1$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr} a_{n,r}$	$b_n(r=1)$
b_0	1	1	N/A since b_n starts from 1	N/A
b_1	$\frac{1}{r}$	1	$-\frac{1}{r^2}$	-1
b_2	$\frac{1}{r(1+r)}$	$\frac{1}{2}$	$\frac{-1-2r}{r^2(1+r)^2}$	$-\frac{3}{4}$
b_3	$\frac{1}{(2+r)r(1+r)}$	$\frac{1}{6}$	$\frac{-3r^2-6r-2}{(2+r)^2 r^2 (1+r)^2}$	$-\frac{11}{36}$
b_4	$\frac{1}{(3+r)(2+r)r(1+r)}$	$\frac{1}{24}$	$\frac{-4r^3-18r^2-22r-6}{(3+r)^2(2+r)^2 r^2 (1+r)^2}$	$-\frac{25}{288}$
b_5	$\frac{1}{(4+r)(3+r)(2+r)r(1+r)}$	$\frac{1}{120}$	$\frac{-5r^4-40r^3-105r^2-100r-24}{(4+r)^2(3+r)^2(2+r)^2 r^2 (1+r)^2}$	$-\frac{137}{7200}$

The above table gives all values of b_n needed. Hence the second solution is

$$\begin{aligned}
y_2(x) &= y_1(x)\ln(x) + b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6\dots \\
&= x\left(x + 1 + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)\right)\ln(x) \\
&\quad + x\left(-x - \frac{3x^2}{4} - \frac{11x^3}{36} - \frac{25x^4}{288} - \frac{137x^5}{7200} + O(x^6)\right)
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= c_1y_1(x) + c_2y_2(x) \\
&= c_1x\left(x + 1 + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)\right) \\
&\quad + c_2\left(x\left(x + 1 + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)\right)\ln(x)\right. \\
&\qquad \left. + x\left(-x - \frac{3x^2}{4} - \frac{11x^3}{36} - \frac{25x^4}{288} - \frac{137x^5}{7200} + O(x^6)\right)\right)
\end{aligned}$$

Hence the final solution is

$$\begin{aligned}
y &= y_h \\
&= c_1x\left(x + 1 + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)\right) \\
&\quad + c_2\left(x\left(x + 1 + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)\right)\ln(x)\right. \\
&\qquad \left. + x\left(-x - \frac{3x^2}{4} - \frac{11x^3}{36} - \frac{25x^4}{288} - \frac{137x^5}{7200} + O(x^6)\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned}
y &= c_1x\left(x + 1 + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)\right) \\
&\quad + c_2\left(x\left(x + 1 + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)\right)\ln(x)\right. \\
&\qquad \left. + x\left(-x - \frac{3x^2}{4} - \frac{11x^3}{36} - \frac{25x^4}{288} - \frac{137x^5}{7200} + O(x^6)\right)\right)
\end{aligned} \tag{1}$$

Verification of solutions

$$
\begin{aligned}
y = c_1 x \left(x+1+\frac{x^2}{2}+\frac{x^3}{6}+\frac{x^4}{24}+\frac{x^5}{120}+O(x^6)\right) \\
+ c_2 \left(x \left(x+1+\frac{x^2}{2}+\frac{x^3}{6}+\frac{x^4}{24}+\frac{x^5}{120}+O(x^6)\right) \ln(x) \right. \\
\left. + x \left(-x-\frac{3x^2}{4}-\frac{11x^3}{36}-\frac{25x^4}{288}-\frac{137x^5}{7200}+O(x^6)\right)\right)
\end{aligned}
$$

Verified OK.

24.4.1 Maple step by step solution

Let's solve

$x^2y''+(-x^2-x)\,y'+y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{y}{x^2}+\frac{(x+1)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{(x+1)y'}{x}+\frac{y}{x^2}=0$

□ Check to see if $x_0=0$ is a regular singular point

  - Define functions

    $\left[P_2(x)=-\frac{x+1}{x}, P_3(x)=\frac{1}{x^2}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left.(x\cdot P_2(x))\right|_{x=0}=-1$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left.(x^2\cdot P_3(x))\right|_{x=0}=1$

  - $x=0$is a regular singular point

    Check to see if $x_0=0$ is a regular singular point

    $x_0=0$

- Multiply by denominators

$$x^2 y'' - x(x+1)\, y' + y = 0$$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

  - Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

  - Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$$

  - Convert $x^2 \cdot y''$ to series expansion

$$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-1+r)^2 x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r-1)^2 - a_{k-1}(k+r-1)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(-1+r)^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = 1$$

- Each term in the series must be 0, giving the recursion relation

$$(k+r-1)\left(a_k(k+r-1) - a_{k-1}\right) = 0$$

- Shift index using $k->k+1$

$$(k+r)\left(a_{k+1}(k+r) - a_k\right) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{a_k}{k+r}$$

- Recursion relation for $r = 1$

$$a_{k+1} = \frac{a_k}{k+1}$$

- Solution for $r = 1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+1} = \frac{a_k}{k+1}\right]$$

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2y'' - x(2x+3)\,y' + 4y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + \left(-2x^2 - 3x\right) y' + 4y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{2x+3}{x}$$
$$q(x) = \frac{4}{x^2}$$

Table 687: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{2x+3}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{4}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' + (-2x^2 - 3x)\, y' + 4y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2 \left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + (-2x^2 - 3x) \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + 4\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-2x^{1+n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-3x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 4a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-2x^{1+n+r} a_n (n+r)\right) = \sum_{n=1}^{\infty} \left(-2a_{n-1}(n+r-1) x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-2a_{n-1}(n+r-1) x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-3x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 4a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - 3x^{n+r} a_n (n+r) + 4a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - 3x^r a_0 r + 4a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - 3x^r r + 4x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$(r-2)^2 x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$(r-2)^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 2$$
$$r_2 = 2$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$(r-2)^2 x^r = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. Using the value of the indicial root found earlier, $r = 2$, Eqs (1A,1B) become

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+2}$$
$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+2}\right)$$

We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - 2a_{n-1}(n+r-1) - 3a_n(n+r) + 4a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{2a_{n-1}(n+r-1)}{n^2 + 2nr + r^2 - 4n - 4r + 4} \tag{4}$$

Which for the root $r = 2$ becomes

$$a_n = \frac{2a_{n-1}(1+n)}{n^2} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{2r}{(-1+r)^2}$$

Which for the root $r = 2$ becomes

$$a_1 = 4$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2r}{(-1+r)^2}$	4

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{4+4r}{r(-1+r)^2}$$

Which for the root $r = 2$ becomes

$$a_2 = 6$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2r}{(-1+r)^2}$	4
a_2	$\frac{4+4r}{r(-1+r)^2}$	6

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{16 + 8r}{(1 + r)\, r\, (-1 + r)^2}$$

Which for the root $r = 2$ becomes

$$a_3 = \frac{16}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2r}{(-1+r)^2}$	4
a_2	$\frac{4+4r}{r(-1+r)^2}$	6
a_3	$\frac{16+8r}{(1+r)r(-1+r)^2}$	$\frac{16}{3}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{48 + 16r}{(2 + r)\,(1 + r)\, r\, (-1 + r)^2}$$

Which for the root $r = 2$ becomes

$$a_4 = \frac{10}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2r}{(-1+r)^2}$	4
a_2	$\frac{4+4r}{r(-1+r)^2}$	6
a_3	$\frac{16+8r}{(1+r)r(-1+r)^2}$	$\frac{16}{3}$
a_4	$\frac{48+16r}{(2+r)(1+r)r(-1+r)^2}$	$\frac{10}{3}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{128 + 32r}{(3 + r)\,(2 + r)\,(1 + r)\, r\, (-1 + r)^2}$$

Which for the root $r = 2$ becomes

$$a_5 = \frac{8}{5}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2r}{(-1+r)^2}$	4
a_2	$\frac{4+4r}{r(-1+r)^2}$	6
a_3	$\frac{16+8r}{(1+r)r(-1+r)^2}$	$\frac{16}{3}$
a_4	$\frac{48+16r}{(2+r)(1+r)r(-1+r)^2}$	$\frac{10}{3}$
a_5	$\frac{128+32r}{(3+r)(2+r)(1+r)r(-1+r)^2}$	$\frac{8}{5}$

Using the above table, then the first solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= x^2 \left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\
&= x^2 \left(6x^2 + 4x + 1 + \frac{16x^3}{3} + \frac{10x^4}{3} + \frac{8x^5}{5} + O(x^6)\right)
\end{aligned}$$

Now the second solution is found. The second solution is given by

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)$$

Where b_n is found using

$$b_n = \frac{d}{dr} a_{n,r}$$

And the above is then evaluated at $r = 2$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr}a_{n,r}$	$b_n(r=2)$
b_0	1	1	N/A since b_n starts from 1	N/A
b_1	$\frac{2r}{(-1+r)^2}$	4	$\frac{-2r-2}{(-1+r)^3}$	-6
b_2	$\frac{4+4r}{r(-1+r)^2}$	6	$\frac{-8r^2-12r+4}{r^2(-1+r)^3}$	-13
b_3	$\frac{16+8r}{(1+r)r(-1+r)^2}$	$\frac{16}{3}$	$\frac{-24r^3-72r^2-16r+16}{(1+r)^2r^2(-1+r)^3}$	$-\frac{124}{9}$
b_4	$\frac{48+16r}{(2+r)(1+r)r(-1+r)^2}$	$\frac{10}{3}$	$\frac{-64r^4-352r^3-448r^2+96}{(2+r)^2(1+r)^2r^2(-1+r)^3}$	$-\frac{173}{18}$
b_5	$\frac{128+32r}{(3+r)(2+r)(1+r)r(-1+r)^2}$	$\frac{8}{5}$	$-\frac{32(5r^5+45r^4+125r^3+105r^2-16r-24)}{(3+r)^2(2+r)^2(1+r)^2r^2(-1+r)^3}$	$-\frac{374}{75}$

The above table gives all values of b_n needed. Hence the second solution is

$$
\begin{aligned}
y_2(x) &= y_1(x)\ln(x) + b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6\ldots \\
&= x^2\left(6x^2 + 4x + 1 + \frac{16x^3}{3} + \frac{10x^4}{3} + \frac{8x^5}{5} + O(x^6)\right)\ln(x) \\
&\quad + x^2\left(-13x^2 - 6x - \frac{124x^3}{9} - \frac{173x^4}{18} - \frac{374x^5}{75} + O(x^6)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1y_1(x) + c_2y_2(x) \\
&= c_1x^2\left(6x^2 + 4x + 1 + \frac{16x^3}{3} + \frac{10x^4}{3} + \frac{8x^5}{5} + O(x^6)\right) \\
&\quad + c_2\Bigg(x^2\left(6x^2 + 4x + 1 + \frac{16x^3}{3} + \frac{10x^4}{3} + \frac{8x^5}{5} + O(x^6)\right)\ln(x) \\
&\quad + x^2\left(-13x^2 - 6x - \frac{124x^3}{9} - \frac{173x^4}{18} - \frac{374x^5}{75} + O(x^6)\right)\Bigg)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1x^2\left(6x^2 + 4x + 1 + \frac{16x^3}{3} + \frac{10x^4}{3} + \frac{8x^5}{5} + O(x^6)\right) \\
&\quad + c_2\Bigg(x^2\left(6x^2 + 4x + 1 + \frac{16x^3}{3} + \frac{10x^4}{3} + \frac{8x^5}{5} + O(x^6)\right)\ln(x) \\
&\quad + x^2\left(-13x^2 - 6x - \frac{124x^3}{9} - \frac{173x^4}{18} - \frac{374x^5}{75} + O(x^6)\right)\Bigg)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = c_1 x^2 \left(6x^2+4x+1+\frac{16x^3}{3}+\frac{10x^4}{3}+\frac{8x^5}{5}+O(x^6)\right) \\
+ c_2 \left(x^2 \left(6x^2+4x+1+\frac{16x^3}{3}+\frac{10x^4}{3}+\frac{8x^5}{5}+O(x^6)\right) \ln(x) \right. \\
\left. + x^2 \left(-13x^2-6x-\frac{124x^3}{9}-\frac{173x^4}{18}-\frac{374x^5}{75}+O(x^6)\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = c_1 x^2 \left(6x^2+4x+1+\frac{16x^3}{3}+\frac{10x^4}{3}+\frac{8x^5}{5}+O(x^6)\right) \\
+ c_2 \left(x^2 \left(6x^2+4x+1+\frac{16x^3}{3}+\frac{10x^4}{3}+\frac{8x^5}{5}+O(x^6)\right) \ln(x) \right. \\
\left. + x^2 \left(-13x^2-6x-\frac{124x^3}{9}-\frac{173x^4}{18}-\frac{374x^5}{75}+O(x^6)\right)\right)
\end{aligned}
$$

Verified OK.

24.5.1 Maple step by step solution

Let's solve

$x^2 y'' + (-2x^2-3x)\, y' + 4y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{4y}{x^2} + \frac{(2x+3)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{(2x+3)y'}{x} + \frac{4y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -\frac{2x+3}{x}, P_3(x) = \frac{4}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = -3$

- $x^2 \cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 4$

- $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2 y'' - x(2x+3)\,y' + 4y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^2 \cdot y''$ to series expansion

  $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-2+r)^2\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r-2)^2 - 2a_{k-1}(k+r-1)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2+r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r=2$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r-2)^2 - 2a_{k-1}(k+r-1) = 0$

- Shift index using $k->k+1$

  $a_{k+1}(k+r-1)^2 - 2a_k(k+r) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{2a_k(k+r)}{(k+r-1)^2}$

- Recursion relation for $r = 2$

  $a_{k+1} = \frac{2a_k(k+2)}{(k+1)^2}$

- Solution for $r = 2$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+1} = \frac{2a_k(k+2)}{(k+1)^2}\right]$

Problem number: 6.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2(-x^2+1)\,y''-5xy'+9y=0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$(-x^4+x^2)\,y''-5xy'+9y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=\frac{5}{x\,(x^2-1)}$$
$$q(x)=-\frac{9}{x^2\,(x^2-1)}$$

Table 689: Table $p(x), q(x)$ singularites.

$p(x) = \frac{5}{x(x^2-1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"
$x = 1$	"regular"

$q(x) = -\frac{9}{x^2(x^2-1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"
$x = 1$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-1, 0, 1, \infty]$

Irregular singular points : $[]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$-y''x^2(x^2-1) - 5xy' + 9y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$-\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x^2(x^2-1) - 5x\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + 9\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\sum_{n=0}^{\infty}\left(-x^{n+r+2}a_n(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)(n+r-1)\right)$$
$$+\sum_{n=0}^{\infty}\left(-5x^{n+r}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}9a_nx^{n+r}\right)=0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty}\left(-x^{n+r+2}a_n(n+r)(n+r-1)\right)=\sum_{n=2}^{\infty}\left(-a_{n-2}(n+r-2)(n-3+r)x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\sum_{n=2}^{\infty}\left(-a_{n-2}(n+r-2)(n-3+r)x^{n+r}\right)+\left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)(n+r-1)\right)$$
$$+\sum_{n=0}^{\infty}\left(-5x^{n+r}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}9a_nx^{n+r}\right)=0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r}a_n(n+r)(n+r-1)-5x^{n+r}a_n(n+r)+9a_nx^{n+r}=0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r)-5x^r a_0 r+9a_0x^r=0$$

Or

$$\left(x^r r(-1+r)-5x^r r+9x^r\right)a_0=0$$

Since $a_0\neq 0$ then the above simplifies to

$$(r-3)^2 x^r=0$$

Since the above is true for all x then the indicial equation becomes

$$(r-3)^2=0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 3$$
$$r_2 = 3$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$(r-3)^2 x^r = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. Using the value of the indicial root found earlier, $r = 3$, Eqs (1A,1B) become

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+3}$$
$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+3}\right)$$

We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$-a_{n-2}(n+r-2)(n-3+r) + a_n(n+r)(n+r-1) - 5a_n(n+r) + 9a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{(n + r - 2)\, a_{n-2}}{n - 3 + r} \tag{4}$$

Which for the root $r = 3$ becomes

$$a_n = \frac{(n + 1)\, a_{n-2}}{n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 3$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r}{-1 + r}$$

Which for the root $r = 3$ becomes

$$a_2 = \frac{3}{2}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{r}{-1+r}$	$\frac{3}{2}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{r}{-1+r}$	$\frac{3}{2}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{r(2+r)}{r^2 - 1}$$

Which for the root $r = 3$ becomes

$$a_4 = \frac{15}{8}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{r}{-1+r}$	$\frac{3}{2}$
a_3	0	0
a_4	$\frac{r(2+r)}{r^2-1}$	$\frac{15}{8}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{r}{-1+r}$	$\frac{3}{2}$
a_3	0	0
a_4	$\frac{r(2+r)}{r^2-1}$	$\frac{15}{8}$
a_5	0	0

Using the above table, then the first solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^3 \left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^3 \left(1 + \frac{3x^2}{2} + \frac{15x^4}{8} + O(x^6)\right) \end{aligned}$$

Now the second solution is found. The second solution is given by

$$y_2(x) = y_1(x)\ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)$$

Where b_n is found using

$$b_n = \frac{d}{dr}a_{n,r}$$

And the above is then evaluated at $r = 3$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr}a_{n,r}$	$b_n(r=3)$
b_0	1	1	N/A since b_n starts from 1	N/A
b_1	0	0	0	0
b_2	$\frac{r}{-1+r}$	$\frac{3}{2}$	$-\frac{1}{(-1+r)^2}$	$-\frac{1}{4}$
b_3	0	0	0	0
b_4	$\frac{r(2+r)}{r^2-1}$	$\frac{15}{8}$	$\frac{-2r^2-2r-2}{(r^2-1)^2}$	$-\frac{13}{32}$
b_5	0	0	0	0

The above table gives all values of b_n needed. Hence the second solution is

$$\begin{aligned} y_2(x) &= y_1(x)\ln(x) + b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots \\ &= x^3\left(1 + \frac{3x^2}{2} + \frac{15x^4}{8} + O(x^6)\right)\ln(x) + x^3\left(-\frac{x^2}{4} - \frac{13x^4}{32} + O(x^6)\right) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^3\left(1 + \frac{3x^2}{2} + \frac{15x^4}{8} + O(x^6)\right) \\ &\quad + c_2\left(x^3\left(1 + \frac{3x^2}{2} + \frac{15x^4}{8} + O(x^6)\right)\ln(x) + x^3\left(-\frac{x^2}{4} - \frac{13x^4}{32} + O(x^6)\right)\right) \end{aligned}$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^3\left(1+\frac{3x^2}{2}+\frac{15x^4}{8}+O(x^6)\right) \\
&\quad + c_2\left(x^3\left(1+\frac{3x^2}{2}+\frac{15x^4}{8}+O(x^6)\right)\ln(x)+x^3\left(-\frac{x^2}{4}-\frac{13x^4}{32}+O(x^6)\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = c_1 x^3\left(1+\frac{3x^2}{2}+\frac{15x^4}{8}+O(x^6)\right) \\
+ c_2\left(x^3\left(1+\frac{3x^2}{2}+\frac{15x^4}{8}+O(x^6)\right)\ln(x)+x^3\left(-\frac{x^2}{4}-\frac{13x^4}{32}+O(x^6)\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = c_1 x^3\left(1+\frac{3x^2}{2}+\frac{15x^4}{8}+O(x^6)\right) \\
+ c_2\left(x^3\left(1+\frac{3x^2}{2}+\frac{15x^4}{8}+O(x^6)\right)\ln(x)+x^3\left(-\frac{x^2}{4}-\frac{13x^4}{32}+O(x^6)\right)\right)
\end{aligned}
$$

Verified OK.

24.6.1 Maple step by step solution

Let's solve

$-y''x^2(x^2-1)-5xy'+9y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{9y}{x^2(x^2-1)}-\frac{5y'}{x(x^2-1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{5y'}{x(x^2-1)}-\frac{9y}{x^2(x^2-1)}=0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

$\left[P_2(x) = \frac{5}{x(x^2-1)}, P_3(x) = -\frac{9}{x^2(x^2-1)}\right]$

- $(x+1) \cdot P_2(x)$ is analytic at $x = -1$

  $\left((x+1) \cdot P_2(x)\right)\bigg|_{x=-1} = \frac{5}{2}$

- $(x+1)^2 \cdot P_3(x)$ is analytic at $x = -1$

  $\left((x+1)^2 \cdot P_3(x)\right)\bigg|_{x=-1} = 0$

- $x = -1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $y''x^2(x^2-1) + 5xy' - 9y = 0$

- Change variables using $x = u - 1$ so that the regular singular point is at $u = 0$

  $(u^4 - 4u^3 + 5u^2 - 2u)\left(\frac{d^2}{du^2}y(u)\right) + (5u - 5)\left(\frac{d}{du}y(u)\right) - 9y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..4$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

$-a_0 r(3+2r)\, u^{-1+r} + (-a_1(1+r)(5+2r) + a_0(5r^2-9))\, u^r + (-a_2(2+r)(7+2r) + a_1(5r^2+$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-r(3+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{0, -\frac{3}{2}\}$
- The coefficients of each power of u must be 0

  $[-a_1(1+r)(5+2r) + a_0(5r^2-9) = 0, -a_2(2+r)(7+2r) + a_1(5r^2+10r-4) - 4a_0 r(-1+r)$
- Solve for the dependent coefficient(s)

  $\left\{a_1 = \frac{a_0(5r^2-9)}{2r^2+7r+5}, a_2 = \frac{a_0(17r^4+30r^3-57r^2-70r+36)}{4r^4+36r^3+115r^2+153r+70}\right\}$
- Each term in the series must be 0, giving the recursion relation

  $(5a_k + a_{k-2} - 4a_{k-1} - 2a_{k+1})\, k^2 + (2(5a_k + a_{k-2} - 4a_{k-1} - 2a_{k+1})\, r - 5a_{k-2} + 12a_{k-1} - 7a_{k+1})$
- Shift index using $k- >k+2$

  $(5a_{k+2} + a_k - 4a_{k+1} - 2a_{k+3})\,(k+2)^2 + (2(5a_{k+2} + a_k - 4a_{k+1} - 2a_{k+3})\, r - 5a_k + 12a_{k+1} - 7a_k$
- Recursion relation that defines series solution to ODE

  $a_{k+3} = \frac{k^2 a_k - 4k^2 a_{k+1} + 5k^2 a_{k+2} + 2kr a_k - 8kr a_{k+1} + 10kr a_{k+2} + r^2 a_k - 4r^2 a_{k+1} + 5r^2 a_{k+2} - k a_k - 4k a_{k+1} + 20k a_{k+2} - r a_k - 4r a_{k+}}{2k^2+4kr+2r^2+15k+15r+27}$
- Recursion relation for $r = 0$

  $a_{k+3} = \frac{k^2 a_k - 4k^2 a_{k+1} + 5k^2 a_{k+2} - k a_k - 4k a_{k+1} + 20k a_{k+2} + 11a_{k+2}}{2k^2+15k+27}$
- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+3} = \frac{k^2 a_k - 4k^2 a_{k+1} + 5k^2 a_{k+2} - k a_k - 4k a_{k+1} + 20k a_{k+2} + 11a_{k+2}}{2k^2+15k+27}, a_1 = -\frac{9a_0}{5}, a_2 = \frac{18a_0}{35}\right]$
- Revert the change of variables $u = x+1$

  $\left[y = \sum_{k=0}^{\infty} a_k (x+1)^k, a_{k+3} = \frac{k^2 a_k - 4k^2 a_{k+1} + 5k^2 a_{k+2} - k a_k - 4k a_{k+1} + 20k a_{k+2} + 11a_{k+2}}{2k^2+15k+27}, a_1 = -\frac{9a_0}{5}, a_2 = \frac{18a_0}{35}\right]$
- Recursion relation for $r = -\frac{3}{2}$

  $a_{k+3} = \frac{k^2 a_k - 4k^2 a_{k+1} + 5k^2 a_{k+2} - 4k a_k + 8k a_{k+1} + 5k a_{k+2} + \frac{15}{4} a_k - 3a_{k+1} - \frac{31}{4} a_{k+2}}{2k^2+9k+9}$
- Solution for $r = -\frac{3}{2}$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{3}{2}}, a_{k+3} = \frac{k^2 a_k - 4k^2 a_{k+1} + 5k^2 a_{k+2} - 4k a_k + 8k a_{k+1} + 5k a_{k+2} + \frac{15}{4} a_k - 3a_{k+1} - \frac{31}{4} a_{k+2}}{2k^2+9k+9}, a_1 = -\frac{9a_0}{4}, a\right.$
- Revert the change of variables $u = x+1$

$$\left[y=\sum_{k=0}^{\infty} a_k (x+1)^{k-\frac{3}{2}}, a_{k+3}=\frac{k^2 a_k-4k^2 a_{k+1}+5k^2 a_{k+2}-4k a_k+8k a_{k+1}+5k a_{k+2}+\frac{15}{4} a_k-3a_{k+1}-\frac{31}{4} a_{k+2}}{2k^2+9k+9}, a_1=-\frac{9}{}\right.$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_k (x+1)^k\right)+\left(\sum_{k=0}^{\infty} b_k (x+1)^{k-\frac{3}{2}}\right), a_{k+3}=\frac{k^2 a_k-4k^2 a_{k+1}+5k^2 a_{k+2}-k a_k-4k a_{k+1}+20k a_{k+2}+11a}{2k^2+15k+27}\right.$$

Problem number: 7.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + x(x^2 - 1)\, y' + (-x^2 + 1)\, y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + (x^3 - x)\, y' + (-x^2 + 1)\, y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{x^2 - 1}{x}$$
$$q(x) = -\frac{x^2 - 1}{x^2}$$

Table 691: Table $p(x), q(x)$ singularites.

$p(x) = \frac{x^2-1}{x}$	
singularity	type
$x = 0$	"regular"
$x = \infty$	"regular"
$x = -\infty$	"regular"

$q(x) = -\frac{x^2-1}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, \infty, -\infty]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' + (x^3 - x)\, y' + (-x^2 + 1)\, y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r)\, (n + r - 1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2 \left(\sum_{n=0}^{\infty} (n + r)\, (n + r - 1)\, a_n x^{n+r-2}\right) + (x^3 - x) \left(\sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}\right) + (-x^2 + 1) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r+2} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r+2} a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n (n+r) = \sum_{n=2}^{\infty} a_{n-2} (n+r-2)\, x^{n+r}$$

$$\sum_{n=0}^{\infty} \left(-x^{n+r+2} a_n\right) = \sum_{n=2}^{\infty} \left(-a_{n-2} x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=2}^{\infty} a_{n-2} (n+r-2)\, x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \sum_{n=2}^{\infty} \left(-a_{n-2} x^{n+r}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - x^{n+r} a_n (n+r) + a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - x^r a_0 r + a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - x^r r + x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$(-1+r)^2 x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$(-1+r)^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = 1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$(-1+r)^2 x^r = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. Using the value of the indicial root found earlier, $r = 1$, Eqs (1A,1B) become

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+1}$$
$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+1}\right)$$

We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1)+a_{n-2}(n+r-2)-a_n(n+r)-a_{n-2}+a_n=0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n=-\frac{a_{n-2}(n+r-3)}{n^2+2nr+r^2-2n-2r+1} \tag{4}$$

Which for the root $r=1$ becomes

$$a_n=-\frac{a_{n-2}(n-2)}{n^2} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r=1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n=2$, using the above recursive equation gives

$$a_2=\frac{1-r}{(1+r)^2}$$

Which for the root $r=1$ becomes

$$a_2=0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{1-r}{(1+r)^2}$	0

For $n=3$, using the above recursive equation gives

$$a_3=0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{1-r}{(1+r)^2}$	0
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{-1+r}{(1+r)(r+3)^2}$$

Which for the root $r = 1$ becomes

$$a_4 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{1-r}{(1+r)^2}$	0
a_3	0	0
a_4	$\frac{-1+r}{(1+r)(r+3)^2}$	0

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{1-r}{(1+r)^2}$	0
a_3	0	0
a_4	$\frac{-1+r}{(1+r)(r+3)^2}$	0
a_5	0	0

Using the above table, then the first solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= x\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots\right) \\
&= x\left(1 + O(x^6)\right)
\end{aligned}
$$

Now the second solution is found. The second solution is given by

$$
y_2(x) = y_1(x)\ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)
$$

Where b_n is found using

$$
b_n = \frac{d}{dr} a_{n,r}
$$

And the above is then evaluated at $r = 1$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr} a_{n,r}$	$b_n(r=1)$
b_0	1	1	N/A since b_n starts from 1	N/A
b_1	0	0	0	0
b_2	$\frac{1-r}{(1+r)^2}$	0	$\frac{r-3}{(1+r)^3}$	$-\frac{1}{4}$
b_3	0	0	0	0
b_4	$\frac{-1+r}{(1+r)(r+3)^2}$	0	$\frac{-2r^2+2r+8}{(1+r)^2(r+3)^3}$	$\frac{1}{32}$
b_5	0	0	0	0

The above table gives all values of b_n needed. Hence the second solution is

$$
\begin{aligned}
y_2(x) &= y_1(x)\ln(x) + b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 \dots \\
&= x\left(1 + O(x^6)\right)\ln(x) + x\left(-\frac{x^2}{4} + \frac{x^4}{32} + O(x^6)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1y_1(x) + c_2y_2(x) \\
&= c_1x\left(1 + O(x^6)\right) + c_2\left(x\left(1 + O(x^6)\right)\ln(x) + x\left(-\frac{x^2}{4} + \frac{x^4}{32} + O(x^6)\right)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x(1+O(x^6)) + c_2\left(x(1+O(x^6))\ln(x) + x\left(-\frac{x^2}{4}+\frac{x^4}{32}+O(x^6)\right)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 x(1+O(x^6)) + c_2\left(x(1+O(x^6))\ln(x) + x\left(-\frac{x^2}{4}+\frac{x^4}{32}+O(x^6)\right)\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 x(1+O(x^6)) + c_2\left(x(1+O(x^6))\ln(x) + x\left(-\frac{x^2}{4}+\frac{x^4}{32}+O(x^6)\right)\right)
$$

Verified OK.

  $y'' = \frac{(x^2-1)y}{x^2} - \frac{(x^2-1)y'}{x}$
- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear
  $y'' + \frac{(x^2-1)y'}{x} - \frac{(x^2-1)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(x) = \frac{x^2-1}{x}, P_3(x) = -\frac{x^2-1}{x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
    $\left.(x \cdot P_2(x))\right|_{x=0} = -1$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$$(x^2 \cdot P_3(x))\bigg|_{x=0} = 1$$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2y'' + x(x^2-1)\,y' + (-x^2+1)\,y = 0$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k-m$

  $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

  $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

  $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$$

- Convert $x^2 \cdot y''$ to series expansion

  $$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(-1+r)^2\,x^r + a_1r^2x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)^2 + a_{k-2}(k-3+r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = 1$

- Each term must be 0

  $a_1r^2 = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $a_k(k + r - 1)^2 + a_{k-2}(k - 3 + r) = 0$
- Shift index using $k- >k + 2$

  $a_{k+2}(k + 1 + r)^2 + a_k(k + r - 1) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k(k+r-1)}{(k+1+r)^2}$
- Recursion relation for $r = 1$

  $a_{k+2} = -\frac{a_k k}{(k+2)^2}$
- Solution for $r = 1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k k}{(k+2)^2}, a_1 = 0\right]$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 42, page 206
Problem number: 8.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2y''+x(2x-1)\,y'+x(x-1)\,y=0}$$

With the expansion point for the power series method at $x = 0$.

The ODE is

$$x^2y''+\left(2x^2-x\right)y'+\left(x^2-x\right)y=0$$

Or

$$x(y''x+2xy'+yx-y'-y)=0$$

For $x \neq 0$ the above simplifies to

$$y''x+(2x-1)\,y'+y(x-1)=0$$

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y''+\left(2x^2-x\right)y'+\left(x^2-x\right)y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$
\begin{aligned}
p(x) &= \frac{2x-1}{x} \\
q(x) &= \frac{x-1}{x}
\end{aligned}
$$

Table 693: Table $p(x), q(x)$ singularites.

$p(x) = \frac{2x-1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{x-1}{x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$
x^2y'' + (2x^2 - x)\, y' + (x^2 - x)\, y = 0
$$

Let the solution be represented as Frobenius power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^{n+r}
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1} \\
y'' &= \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$x^2\left(\sum_{n=0}^{\infty}(n+r)(n+r-1)\,a_n x^{n+r-2}\right) + (2x^2-x)\left(\sum_{n=0}^{\infty}(n+r)\,a_n x^{n+r-1}\right) + (x^2-x)\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty}2x^{1+n+r}a_n(n+r)\right) + \sum_{n=0}^{\infty}\left(-x^{n+r}a_n(n+r)\right) + \left(\sum_{n=0}^{\infty}x^{n+r+2}a_n\right) + \sum_{n=0}^{\infty}\left(-x^{1+n+r}a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty}2x^{1+n+r}a_n(n+r) = \sum_{n=1}^{\infty}2a_{n-1}(n+r-1)\,x^{n+r}$$

$$\sum_{n=0}^{\infty}x^{n+r+2}a_n = \sum_{n=2}^{\infty}a_{n-2}x^{n+r}$$

$$\sum_{n=0}^{\infty}\left(-x^{1+n+r}a_n\right) = \sum_{n=1}^{\infty}\left(-a_{n-1}x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)(n+r-1)\right) + \left(\sum_{n=1}^{\infty}2a_{n-1}(n+r-1)\,x^{n+r}\right) + \sum_{n=0}^{\infty}\left(-x^{n+r}a_n(n+r)\right) + \left(\sum_{n=2}^{\infty}a_{n-2}x^{n+r}\right) + \sum_{n=1}^{\infty}\left(-a_{n-1}x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n = 0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - x^{n+r} a_n (n+r) = 0$$

When $n = 0$ the above becomes

$$x^r a_0 r(-1+r) - x^r a_0 r = 0$$

Or

$$(x^r r(-1+r) - x^r r)\, a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$x^r r(-2+r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$r(-2+r) = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 2$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$x^r r(-2+r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 2$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x^2 \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$
\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+2} \\
y_2(x) &= C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)
\end{aligned}
$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$
a_1 = \frac{-2r+1}{r^2-1}
$$

For $2 \leq n$ the recursive equation is

$$
a_n(n+r)(n+r-1) + 2a_{n-1}(n+r-1) - a_n(n+r) + a_{n-2} - a_{n-1} = 0 \tag{3}
$$

Solving for a_n from recursive equation (4) gives

$$
a_n = -\frac{2na_{n-1} + 2ra_{n-1} + a_{n-2} - 3a_{n-1}}{n^2 + 2nr + r^2 - 2n - 2r} \tag{4}
$$

Which for the root $r = 2$ becomes

$$
a_n = \frac{-2na_{n-1} - a_{n-2} - a_{n-1}}{n(n+2)} \tag{5}
$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2r+1}{r^2-1}$	-1

For $n = 2$, using the above recursive equation gives

$$
a_2 = \frac{3r}{(r^2-1)(r+2)}
$$

Which for the root $r = 2$ becomes

$$
a_2 = \frac{1}{2}
$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2r+1}{r^2-1}$	-1
a_2	$\frac{3r}{(r^2-1)(r+2)}$	$\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{-4r - 2}{(r + 3)(1 + r)(r + 2)(-1 + r)}$$

Which for the root $r = 2$ becomes

$$a_3 = -\frac{1}{6}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2r+1}{r^2-1}$	-1
a_2	$\frac{3r}{(r^2-1)(r+2)}$	$\frac{1}{2}$
a_3	$\frac{-4r-2}{(r+3)(1+r)(r+2)(-1+r)}$	$-\frac{1}{6}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{5}{(r + 4)(r + 2)(-1 + r)(r + 3)}$$

Which for the root $r = 2$ becomes

$$a_4 = \frac{1}{24}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2r+1}{r^2-1}$	-1
a_2	$\frac{3r}{(r^2-1)(r+2)}$	$\frac{1}{2}$
a_3	$\frac{-4r-2}{(r+3)(1+r)(r+2)(-1+r)}$	$-\frac{1}{6}$
a_4	$\frac{5}{(r+4)(r+2)(-1+r)(r+3)}$	$\frac{1}{24}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{-6r - 9}{(r^2 + 8r + 15)(r + 2)(r + 4)(r^2 - 1)}$$

Which for the root $r = 2$ becomes

$$a_5 = -\frac{1}{120}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2r+1}{r^2-1}$	-1
a_2	$\frac{3r}{(r^2-1)(r+2)}$	$\frac{1}{2}$
a_3	$\frac{-4r-2}{(r+3)(1+r)(r+2)(-1+r)}$	$-\frac{1}{6}$
a_4	$\frac{5}{(r+4)(r+2)(-1+r)(r+3)}$	$\frac{1}{24}$
a_5	$\frac{-6r-9}{(r^2+8r+15)(r+2)(r+4)(r^2-1)}$	$-\frac{1}{120}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^2(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots) \\ &= x^2\left(1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 2$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \to r_2} a_2(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_2 \\ &= \frac{3r}{(r^2 - 1)(r + 2)} \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r \to r_2} \frac{3r}{(r^2 - 1)(r + 2)} &= \lim_{r \to 0} \frac{3r}{(r^2 - 1)(r + 2)} \\ &= 0 \end{aligned}$$

The limit is 0. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$\begin{aligned} y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\ &= \sum_{n=0}^{\infty} b_n x^n \end{aligned}$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$b_1 = -\frac{2r - 1}{r^2 - 1}$$

For $2 \leq n$ the recursive equation is

$$b_n(n+r)(n+r-1) + 2b_{n-1}(n+r-1) - b_n(n+r) + b_{n-2} - b_{n-1} = 0 \tag{4}$$

Which for for the root $r = 0$ becomes

$$b_n n(n-1) + 2b_{n-1}(n-1) - b_n n + b_{n-2} - b_{n-1} = 0 \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = -\frac{2nb_{n-1} + 2rb_{n-1} + b_{n-2} - 3b_{n-1}}{n^2 + 2nr + r^2 - 2n - 2r} \tag{5}$$

Which for the root $r = 0$ becomes

$$b_n = -\frac{2nb_{n-1} + b_{n-2} - 3b_{n-1}}{n^2 - 2n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-2r+1}{r^2-1}$	-1

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{3r}{(r^2 - 1)(r + 2)}$$

Which for the root $r = 0$ becomes

$$b_2 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-2r+1}{r^2-1}$	-1
b_2	$\frac{3r}{(r^2-1)(r+2)}$	0

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{2(2r+1)}{(r^2+4r+3)(r+2)(-1+r)}$$

Which for the root $r = 0$ becomes

$$b_3 = \frac{1}{3}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-2r+1}{r^2-1}$	-1
b_2	$\frac{3r}{(r^2-1)(r+2)}$	0
b_3	$\frac{-4r-2}{(r+3)(1+r)(r+2)(-1+r)}$	$\frac{1}{3}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{5}{(r^2+6r+8)(-1+r)(r+3)}$$

Which for the root $r = 0$ becomes

$$b_4 = -\frac{5}{24}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-2r+1}{r^2-1}$	-1
b_2	$\frac{3r}{(r^2-1)(r+2)}$	0
b_3	$\frac{-4r-2}{(r+3)(1+r)(r+2)(-1+r)}$	$\frac{1}{3}$
b_4	$\frac{5}{(r+4)(r+2)(-1+r)(r+3)}$	$-\frac{5}{24}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{3(2r+3)}{(r^2+8r+15)(1+r)(-1+r)(r+2)(r+4)}$$

Which for the root $r = 0$ becomes

$$b_5 = \frac{3}{40}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-2r+1}{r^2-1}$	-1
b_2	$\frac{3r}{(r^2-1)(r+2)}$	0
b_3	$\frac{-4r-2}{(r+3)(1+r)(r+2)(-1+r)}$	$\frac{1}{3}$
b_4	$\frac{5}{(r+4)(r+2)(-1+r)(r+3)}$	$-\frac{5}{24}$
b_5	$\frac{-6r-9}{(r^2+8r+15)(r+2)(r+4)(r^2-1)}$	$\frac{3}{40}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots \\ &= 1 - x + \frac{x^3}{3} - \frac{5x^4}{24} + \frac{3x^5}{40} + O(x^6) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^2 \left(1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + O(x^6)\right) + c_2 \left(1 - x + \frac{x^3}{3} - \frac{5x^4}{24} + \frac{3x^5}{40} + O(x^6)\right) \end{aligned}$$

Hence the final solution is

$$y = y_h$$

$$= c_1 x^2 \left(1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + O(x^6)\right) + c_2 \left(1 - x + \frac{x^3}{3} - \frac{5x^4}{24} + \frac{3x^5}{40} + O(x^6)\right)$$

Summary

The solution(s) found are the following

$$y = c_1 x^2 \left(1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + O(x^6)\right) + c_2 \left(1 - x + \frac{x^3}{3} - \frac{5x^4}{24} + \frac{3x^5}{40} + O(x^6)\right) \tag{1}$$

Verification of solutions

$$y = c_1 x^2 \left(1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + O(x^6)\right) + c_2 \left(1 - x + \frac{x^3}{3} - \frac{5x^4}{24} + \frac{3x^5}{40} + O(x^6)\right)$$

Verified OK.

24.8.1 Maple step by step solution

Let's solve

$x^2 y'' + (2x^2 - x) y' + (x^2 - x) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(x-1)y}{x} - \frac{(2x-1)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(2x-1)y'}{x} + \frac{(x-1)y}{x} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{2x-1}{x}, P_3(x) = \frac{x-1}{x}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = -1$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 0$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x + (2x-1)\, y' + y(x-1) = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k- >k - m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

  - Shift index using $k- >k + 1 - m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

  - Convert $x \cdot y''$ to series expansion

    $x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$

  - Shift index using $k- >k + 1$

    $x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(-2+r)\, x^{-1+r} + \left(a_1(1+r)\,(-1+r) + a_0(-1+2r)\right) x^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+1+r)\,(k+r-1)\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$

- Each term must be 0

  $a_1(1+r)(-1+r) + a_0(-1+2r) = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)(k+r-1) + a_k(2k+2r-1) + a_{k-1} = 0$

- Shift index using $k->k+1$

  $a_{k+2}(k+2+r)(k+r) + a_{k+1}(2k+1+2r) + a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{2ka_{k+1}+2ra_{k+1}+a_k+a_{k+1}}{(k+2+r)(k+r)}$

- Recursion relation for $r = 0$

  $a_{k+2} = -\frac{2ka_{k+1}+a_k+a_{k+1}}{(k+2)k}$

- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 0$

  $a_{k+2} = -\frac{2ka_{k+1}+a_k+a_{k+1}}{(k+2)k}$

- Recursion relation for $r = 2$

  $a_{k+2} = -\frac{2ka_{k+1}+a_k+5a_{k+1}}{(k+4)(k+2)}$

- Solution for $r = 2$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = -\frac{2ka_{k+1}+a_k+5a_{k+1}}{(k+4)(k+2)}, 3a_1 + 3a_0 = 0\right]$

Problem number: 9.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2 y'' - y' x^2 + \left(x^2 - 2\right) y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2 y'' - y' x^2 + \left(x^2 - 2\right) y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x) y' + q(x) y = 0$$

Where

$$\begin{aligned} p(x) &= -1 \\ q(x) &= \frac{x^2 - 2}{x^2} \end{aligned}$$

Table 695: Table $p(x), q(x)$ singularites.

$p(x) = -1$	
singularity	type

$q(x) = \frac{x^2-2}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2 y'' - y' x^2 + \left(x^2 - 2\right) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2 \left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) - \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) x^2 + \left(x^2 - 2\right) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r+2} a_n\right) + \sum_{n=0}^{\infty} \left(-2 a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)\right) = \sum_{n=1}^{\infty} \left(-a_{n-1} (n+r-1) x^{n+r}\right)$$

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-a_{n-1} (n+r-1) x^{n+r}\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-2 a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - 2 a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - 2 a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - 2x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2 - r - 2\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - r - 2 = 0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned} r_1 &= 2 \\ r_2 &= -1 \end{aligned}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$(r^2 - r - 2) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 3$ is an integer, then we can construct two linearly independent solutions

$$\begin{aligned} y_1(x) &= x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right) \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= x^2 \left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x} \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+2} \\ y_2(x) &= C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-1}\right) \end{aligned}$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = \frac{r}{r^2 + r - 2}$$

For $2 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - a_{n-1}(n+r-1) + a_{n-2} - 2a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{n a_{n-1} + r a_{n-1} - a_{n-2} - a_{n-1}}{n^2 + 2nr + r^2 - n - r - 2} \tag{4}$$

Which for the root $r = 2$ becomes

$$a_n = \frac{n a_{n-1} - a_{n-2} + a_{n-1}}{n(n+3)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{2}{(r^2+r-2)\, r\, (r+3)}$$

Which for the root $r = 2$ becomes

$$a_2 = \frac{1}{20}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
a_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{20}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{-r^2 - 2r + 4}{(r+4)(r^2+r-2)\, r\, (r+3)}$$

Which for the root $r = 2$ becomes

$$a_3 = -\frac{1}{60}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
a_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{20}$
a_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$-\frac{1}{60}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{-r^2 - 3r + 2}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$$

Which for the root $r = 2$ becomes

$$a_4 = -\frac{1}{210}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
a_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{20}$
a_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$-\frac{1}{60}$
a_4	$\frac{-r^2-3r+2}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$-\frac{1}{210}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{4}{(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+5)}$$

Which for the root $r = 2$ becomes

$$a_5 = -\frac{1}{3360}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
a_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{20}$
a_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$-\frac{1}{60}$
a_4	$\frac{-r^2-3r+2}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$-\frac{1}{210}$
a_5	$-\frac{4}{(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+5)}$	$-\frac{1}{3360}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= x^2\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\
&= x^2\left(1 + \frac{x}{2} + \frac{x^2}{20} - \frac{x^3}{60} - \frac{x^4}{210} - \frac{x^5}{3360} + O\left(x^6\right)\right)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 3$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_3(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned}
a_N &= a_3 \\
&= \frac{-r^2 - 2r + 4}{(r+4)\left(r^2 + r - 2\right) r \left(r+3\right)}
\end{aligned}$$

Therefore

$$\begin{aligned}
\lim_{r\to r_2} \frac{-r^2 - 2r + 4}{(r+4)\left(r^2 + r - 2\right) r \left(r+3\right)} &= \lim_{r\to -1} \frac{-r^2 - 2r + 4}{(r+4)\left(r^2 + r - 2\right) r \left(r+3\right)} \\
&= \frac{5}{12}
\end{aligned}$$

The limit is $\frac{5}{12}$. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$\begin{aligned}
y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\
&= \sum_{n=0}^{\infty} b_n x^{n-1}
\end{aligned}$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$b_1 = \frac{r}{r^2 + r - 2}$$

For $2 \leq n$ the recursive equation is

$$b_n(n + r)(n + r - 1) - b_{n-1}(n + r - 1) + b_{n-2} - 2b_n = 0 \tag{4}$$

Which for for the root $r = -1$ becomes

$$b_n(n - 1)(n - 2) - b_{n-1}(n - 2) + b_{n-2} - 2b_n = 0 \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = \frac{nb_{n-1} + rb_{n-1} - b_{n-2} - b_{n-1}}{n^2 + 2nr + r^2 - n - r - 2} \tag{5}$$

Which for the root $r = -1$ becomes

$$b_n = \frac{nb_{n-1} - b_{n-2} - 2b_{n-1}}{n^2 - 3n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{2}{(r^2 + r - 2) r (r + 3)}$$

Which for the root $r = -1$ becomes

$$b_2 = \frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
b_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{r^2 + 2r - 4}{(r+4)(r^2+r-2)\, r\, (r+3)}$$

Which for the root $r = -1$ becomes

$$b_3 = \frac{5}{12}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
b_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{2}$
b_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$\frac{5}{12}$

For $n = 4$, using the above recursive equation gives

$$b_4 = -\frac{r^2 + 3r - 2}{(r^2+7r+10)(r+3)\, r\, (-1+r)(r+4)}$$

Which for the root $r = -1$ becomes

$$b_4 = \frac{1}{12}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
b_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{2}$
b_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$\frac{5}{12}$
b_4	$\frac{-r^2-3r+2}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$\frac{1}{12}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{4}{(r^2 + 9r + 18)\, r\, (r^2 + r - 2)\, (r + 4)\, (r + 5)}$$

Which for the root $r = -1$ becomes

$$b_5 = -\frac{1}{60}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
b_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{2}$
b_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$\frac{5}{12}$
b_4	$\frac{-r^2-3r+2}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$\frac{1}{12}$
b_5	$-\frac{4}{(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+5)}$	$-\frac{1}{60}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned}
y_2(x) &= x^2 \left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= \frac{1 + \frac{x}{2} + \frac{x^2}{2} + \frac{5x^3}{12} + \frac{x^4}{12} - \frac{x^5}{60} + O(x^6)}{x}
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^2 \left(1 + \frac{x}{2} + \frac{x^2}{20} - \frac{x^3}{60} - \frac{x^4}{210} - \frac{x^5}{3360} + O(x^6)\right) \\
&\quad + \frac{c_2 \left(1 + \frac{x}{2} + \frac{x^2}{2} + \frac{5x^3}{12} + \frac{x^4}{12} - \frac{x^5}{60} + O(x^6)\right)}{x}
\end{aligned}$$

Hence the final solution is

$$\begin{aligned}
y &= y_h \\
&= c_1 x^2 \left(1 + \frac{x}{2} + \frac{x^2}{20} - \frac{x^3}{60} - \frac{x^4}{210} - \frac{x^5}{3360} + O(x^6)\right) \\
&\quad + \frac{c_2 \left(1 + \frac{x}{2} + \frac{x^2}{2} + \frac{5x^3}{12} + \frac{x^4}{12} - \frac{x^5}{60} + O(x^6)\right)}{x}
\end{aligned}$$

Summary
The solution(s) found are the following

$$
y = c_1 x^2 \left(1+\frac{x}{2}+\frac{x^2}{20}-\frac{x^3}{60}-\frac{x^4}{210}-\frac{x^5}{3360}+O(x^6)\right) + \frac{c_2\left(1+\frac{x}{2}+\frac{x^2}{2}+\frac{5x^3}{12}+\frac{x^4}{12}-\frac{x^5}{60}+O(x^6)\right)}{x} \tag{1}
$$

Verification of solutions

$$
y = c_1 x^2 \left(1+\frac{x}{2}+\frac{x^2}{20}-\frac{x^3}{60}-\frac{x^4}{210}-\frac{x^5}{3360}+O(x^6)\right) + \frac{c_2\left(1+\frac{x}{2}+\frac{x^2}{2}+\frac{5x^3}{12}+\frac{x^4}{12}-\frac{x^5}{60}+O(x^6)\right)}{x}
$$

Verified OK.

24.9.1 Maple step by step solution

Let's solve

$x^2 y'' - y' x^2 + (x^2-2)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = y' - \frac{(x^2-2)y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - y' + \frac{(x^2-2)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- ◦ Define functions

  $\left[P_2(x) = -1, P_3(x) = \frac{x^2-2}{x^2}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = 0$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = -2$

- $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2y''-y'x^2+(x^2-2)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m\cdot y$ to series expansion for $m=0..2$

  $x^m\cdot y=\sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $x^m\cdot y=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^2\cdot y'$ to series expansion

  $x^2\cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r+1}$

- Shift index using $k->k-1$

  $x^2\cdot y'=\sum_{k=1}^{\infty} a_{k-1}(k-1+r)\,x^{k+r}$

- Convert $x^2\cdot y''$ to series expansion

  $x^2\cdot y''=\sum_{k=0}^{\infty} a_k(k+r)\,(k-1+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)\,(-2+r)\,x^r+(a_1(2+r)\,(-1+r)-a_0r)\,x^{1+r}+\left(\sum_{k=2}^{\infty}(a_k(k+r+1)\,(k+r-2)-a_{k-1}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(-2+r)=0$

- Values of r that satisfy the indicial equation

  $r\in\{-1,2\}$

- Each term must be 0

$$a_1(2+r)(-1+r)-a_0r=0$$

- Solve for the dependent coefficient(s)

$$a_1=\frac{a_0r}{r^2+r-2}$$

- Each term in the series must be 0, giving the recursion relation

$$a_k(k+r+1)(k+r-2)-a_{k-1}k-a_{k-1}r+a_{k-2}+a_{k-1}=0$$

- Shift index using $k->k+2$

$$a_{k+2}(k+3+r)(k+r)-a_{k+1}(k+2)-a_{k+1}r+a_k+a_{k+1}=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2}=\frac{ka_{k+1}+a_{k+1}r-a_k+a_{k+1}}{(k+3+r)(k+r)}$$

- Recursion relation for $r=-1$

$$a_{k+2}=\frac{ka_{k+1}-a_k}{(k+2)(k-1)}$$

- Series not valid for $r=-1$, division by 0 in the recursion relation at $k=1$

$$a_{k+2}=\frac{ka_{k+1}-a_k}{(k+2)(k-1)}$$

- Recursion relation for $r=2$

$$a_{k+2}=\frac{ka_{k+1}-a_k+3a_{k+1}}{(k+5)(k+2)}$$

- Solution for $r=2$

$$\left[y=\sum_{k=0}^{\infty}a_kx^{k+2},a_{k+2}=\frac{ka_{k+1}-a_k+3a_{k+1}}{(k+5)(k+2)},a_1=\frac{a_0}{2}\right]$$

Problem number: 10.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + 2y'x^2 - (3x^2 + 2)\, y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + 2y'x^2 + (-3x^2 - 2)\, y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = 2$$
$$q(x) = -\frac{3x^2 + 2}{x^2}$$

Table 697: Table $p(x), q(x)$ singularites.

$p(x) = 2$	
singularity	type

$q(x) = -\frac{3x^2+2}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' + 2y'x^2 + \left(-3x^2 - 2\right) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2 \left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + 2\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) x^2 + \left(-3x^2 - 2\right) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2x^{1+n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-3x^{n+r+2} a_n\right) + \sum_{n=0}^{\infty} \left(-2a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2x^{1+n+r} a_n (n+r) = \sum_{n=1}^{\infty} 2a_{n-1}(n+r-1)\, x^{n+r}$$

$$\sum_{n=0}^{\infty} \left(-3x^{n+r+2} a_n\right) = \sum_{n=2}^{\infty} \left(-3a_{n-2} x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=1}^{\infty} 2a_{n-1}(n+r-1)\, x^{n+r}\right) + \sum_{n=2}^{\infty} \left(-3a_{n-2} x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-2a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - 2a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - 2a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - 2x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2 - r - 2\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - r - 2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 2$$
$$r_2 = -1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2 - r - 2\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 3$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x^2 \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+2}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-1}\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = -\frac{2r}{r^2 + r - 2}$$

For $2 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + 2a_{n-1}(n+r-1) - 3a_{n-2} - 2a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{2na_{n-1} + 2ra_{n-1} - 3a_{n-2} - 2a_{n-1}}{n^2 + 2nr + r^2 - n - r - 2} \tag{4}$$

Which for the root $r = 2$ becomes

$$a_n = \frac{-2na_{n-1} + 3a_{n-2} - 2a_{n-1}}{n(n+3)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2r}{r^2+r-2}$	-1

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{7r^2 + 7r - 6}{(r^2 + r - 2)\, r\, (r+3)}$$

Which for the root $r = 2$ becomes

$$a_2 = \frac{9}{10}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2r}{r^2+r-2}$	-1
a_2	$\frac{7r^2+7r-6}{(r^2+r-2)r(r+3)}$	$\frac{9}{10}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{-20r^2 - 40r + 24}{(r+4)(r^2 + r - 2)\, r\, (r+3)}$$

Which for the root $r = 2$ becomes

$$a_3 = -\frac{17}{30}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2r}{r^2+r-2}$	-1
a_2	$\frac{7r^2+7r-6}{(r^2+r-2)r(r+3)}$	$\frac{9}{10}$
a_3	$\frac{-20r^2-40r+24}{(r+4)(r^2+r-2)r(r+3)}$	$-\frac{17}{30}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{61r^2 + 183r - 108}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$$

Which for the root $r = 2$ becomes

$$a_4 = \frac{251}{840}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2r}{r^2+r-2}$	-1
a_2	$\frac{7r^2+7r-6}{(r^2+r-2)r(r+3)}$	$\frac{9}{10}$
a_3	$\frac{-20r^2-40r+24}{(r+4)(r^2+r-2)r(r+3)}$	$-\frac{17}{30}$
a_4	$\frac{61r^2+183r-108}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$\frac{251}{840}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{-182r^2 - 728r + 408}{(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+5)}$$

Which for the root $r = 2$ becomes

$$a_5 = -\frac{37}{280}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2r}{r^2+r-2}$	-1
a_2	$\frac{7r^2+7r-6}{(r^2+r-2)r(r+3)}$	$\frac{9}{10}$
a_3	$\frac{-20r^2-40r+24}{(r+4)(r^2+r-2)r(r+3)}$	$-\frac{17}{30}$
a_4	$\frac{61r^2+183r-108}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$\frac{251}{840}$
a_5	$\frac{-182r^2-728r+408}{(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+5)}$	$-\frac{37}{280}$

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= x^2\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\
&= x^2\left(1 - x + \frac{9x^2}{10} - \frac{17x^3}{30} + \frac{251x^4}{840} - \frac{37x^5}{280} + O(x^6)\right)
\end{aligned}
$$

Now the second solution $y_2(x)$ is found. Let

$$
r_1 - r_2 = N
$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 3$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \to r_2} a_3(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$
\begin{aligned}
a_N &= a_3 \\
&= \frac{-20r^2 - 40r + 24}{(r+4)(r^2+r-2)\, r\, (r+3)}
\end{aligned}
$$

Therefore

$$
\begin{aligned}
\lim_{r \to r_2} \frac{-20r^2 - 40r + 24}{(r+4)(r^2+r-2)\, r\, (r+3)} &= \lim_{r \to -1} \frac{-20r^2 - 40r + 24}{(r+4)(r^2+r-2)\, r\, (r+3)} \\
&= \frac{11}{3}
\end{aligned}
$$

The limit is $\frac{11}{3}$. Since the limit exists then the log term is not needed and we can set

$C = 0$. Therefore the second solution has the form

$$
\begin{aligned}
y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\
&= \sum_{n=0}^{\infty} b_n x^{n-1}
\end{aligned}
$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$
b_1 = -\frac{2r}{r^2 + r - 2}
$$

For $2 \leq n$ the recursive equation is

$$
b_n(n+r)(n+r-1) + 2b_{n-1}(n+r-1) - 3b_{n-2} - 2b_n = 0 \tag{4}
$$

Which for for the root $r = -1$ becomes

$$
b_n(n-1)(n-2) + 2b_{n-1}(n-2) - 3b_{n-2} - 2b_n = 0 \tag{4A}
$$

Solving for b_n from the recursive equation (4) gives

$$
b_n = -\frac{2nb_{n-1} + 2rb_{n-1} - 3b_{n-2} - 2b_{n-1}}{n^2 + 2nr + r^2 - n - r - 2} \tag{5}
$$

Which for the root $r = -1$ becomes

$$
b_n = -\frac{2nb_{n-1} - 3b_{n-2} - 4b_{n-1}}{n^2 - 3n} \tag{6}
$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{2r}{r^2+r-2}$	-1

For $n = 2$, using the above recursive equation gives

$$
b_2 = \frac{7r^2 + 7r - 6}{(r^2 + r - 2)\, r\, (r+3)}
$$

Which for the root $r = -1$ becomes

$$b_2 = -\frac{3}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{2r}{r^2+r-2}$	-1
b_2	$\frac{7r^2+7r-6}{(r^2+r-2)r(r+3)}$	$-\frac{3}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{4(5r^2 + 10r - 6)}{(r+4)(r^2+r-2)\,r\,(r+3)}$$

Which for the root $r = -1$ becomes

$$b_3 = \frac{11}{3}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{2r}{r^2+r-2}$	-1
b_2	$\frac{7r^2+7r-6}{(r^2+r-2)r(r+3)}$	$-\frac{3}{2}$
b_3	$\frac{-20r^2-40r+24}{(r+4)(r^2+r-2)r(r+3)}$	$\frac{11}{3}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{61r^2 + 183r - 108}{(r^2+7r+10)(r+3)\,r\,(-1+r)(r+4)}$$

Which for the root $r = -1$ becomes

$$b_4 = -\frac{115}{24}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{2r}{r^2+r-2}$	-1
b_2	$\frac{7r^2+7r-6}{(r^2+r-2)r(r+3)}$	$-\frac{3}{2}$
b_3	$\frac{-20r^2-40r+24}{(r+4)(r^2+r-2)r(r+3)}$	$\frac{11}{3}$
b_4	$\frac{61r^2+183r-108}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$-\frac{115}{24}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{2(91r^2 + 364r - 204)}{(r^2 + 9r + 18)\, r\, (r^2 + r - 2)\, (r + 4)\, (r + 5)}$$

Which for the root $r = -1$ becomes

$$b_5 = \frac{159}{40}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{2r}{r^2+r-2}$	-1
b_2	$\frac{7r^2+7r-6}{(r^2+r-2)r(r+3)}$	$-\frac{3}{2}$
b_3	$\frac{-20r^2-40r+24}{(r+4)(r^2+r-2)r(r+3)}$	$\frac{11}{3}$
b_4	$\frac{61r^2+183r-108}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$-\frac{115}{24}$
b_5	$\frac{-182r^2-728r+408}{(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+5)}$	$\frac{159}{40}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= x^2 \left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\ &= \frac{1 - x - \frac{3x^2}{2} + \frac{11x^3}{3} - \frac{115x^4}{24} + \frac{159x^5}{40} + O(x^6)}{x} \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}y_h(x) &= c_1 y_1(x) + c_2 y_2(x)\\ &= c_1 x^2 \left(1 - x + \frac{9x^2}{10} - \frac{17x^3}{30} + \frac{251x^4}{840} - \frac{37x^5}{280} + O(x^6)\right)\\ &\quad + \frac{c_2 \left(1 - x - \frac{3x^2}{2} + \frac{11x^3}{3} - \frac{115x^4}{24} + \frac{159x^5}{40} + O(x^6)\right)}{x}\end{aligned}$$

Hence the final solution is

$$\begin{aligned}y &= y_h\\ &= c_1 x^2 \left(1 - x + \frac{9x^2}{10} - \frac{17x^3}{30} + \frac{251x^4}{840} - \frac{37x^5}{280} + O(x^6)\right)\\ &\quad + \frac{c_2 \left(1 - x - \frac{3x^2}{2} + \frac{11x^3}{3} - \frac{115x^4}{24} + \frac{159x^5}{40} + O(x^6)\right)}{x}\end{aligned}$$

Summary
The solution(s) found are the following

$$\begin{aligned}y &= c_1 x^2 \left(1 - x + \frac{9x^2}{10} - \frac{17x^3}{30} + \frac{251x^4}{840} - \frac{37x^5}{280} + O(x^6)\right)\\ &\quad + \frac{c_2 \left(1 - x - \frac{3x^2}{2} + \frac{11x^3}{3} - \frac{115x^4}{24} + \frac{159x^5}{40} + O(x^6)\right)}{x}\end{aligned} \tag{1}$$

Verification of solutions

$$\begin{aligned}y &= c_1 x^2 \left(1 - x + \frac{9x^2}{10} - \frac{17x^3}{30} + \frac{251x^4}{840} - \frac{37x^5}{280} + O(x^6)\right)\\ &\quad + \frac{c_2 \left(1 - x - \frac{3x^2}{2} + \frac{11x^3}{3} - \frac{115x^4}{24} + \frac{159x^5}{40} + O(x^6)\right)}{x}\end{aligned}$$

Verified OK.

24.10.1 Maple step by step solution

Let's solve

$x^2y'' + 2y'x^2 + (-3x^2 - 2)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{(3x^2+2)y}{x^2} - 2y'$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + 2y' - \frac{(3x^2+2)y}{x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = 2, P_3(x) = -\frac{3x^2+2}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\bigg|_{x=0} = 0$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = -2$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2y'' + 2y'x^2 + (-3x^2 - 2)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
- Convert $x^2 \cdot y'$ to series expansion

  $x^2 \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r+1}$
- Shift index using $k->k-1$

  $x^2 \cdot y' = \sum_{k=1}^{\infty} a_{k-1}(k-1+r)\, x^{k+r}$
- Convert $x^2 \cdot y''$ to series expansion

  $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k-1+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)\,(-2+r)\, x^r + (a_1(2+r)\,(-1+r) + 2a_0 r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r+1)\,(k+r-2) + 2a_k\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(-2+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{-1, 2\}$
- Each term must be 0

  $a_1(2+r)\,(-1+r) + 2a_0 r = 0$
- Solve for the dependent coefficient(s)

  $a_1 = -\frac{2a_0 r}{r^2+r-2}$
- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+1)\,(k+r-2) + 2a_{k-1}k + 2a_{k-1}r - 3a_{k-2} - 2a_{k-1} = 0$
- Shift index using $k->k+2$

  $a_{k+2}(k+3+r)\,(k+r) + 2a_{k+1}(k+2) + 2a_{k+1}r - 3a_k - 2a_{k+1} = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{2ka_{k+1}+2a_{k+1}r-3a_k+2a_{k+1}}{(k+3+r)(k+r)}$
- Recursion relation for $r = -1$

  $a_{k+2} = -\frac{2ka_{k+1}-3a_k}{(k+2)(k-1)}$

- Series not valid for $r=-1$, division by 0 in the recursion relation at $k=1$

$a_{k+2}=-\frac{2ka_{k+1}-3a_k}{(k+2)(k-1)}$

- Recursion relation for $r=2$

$a_{k+2}=-\frac{2ka_{k+1}-3a_k+6a_{k+1}}{(k+5)(k+2)}$

- Solution for $r=2$

$$\left[y=\sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2}=-\frac{2ka_{k+1}-3a_k+6a_{k+1}}{(k+5)(k+2)}, a_1=-a_0\right]$$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 42, page 206
Problem number: 11.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2(1-x)\,y''+x(x+1)\,y'-9y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(-x^3+x^2\right)y''+\left(x^2+x\right)y'-9y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=-\frac{x+1}{x\,(x-1)}$$
$$q(x)=\frac{9}{x^2\,(x-1)}$$

Table 699: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x+1}{x(x-1)}$	
singularity	type
$x = 0$	"regular"
$x = 1$	"regular"

$q(x) = \frac{9}{x^2(x-1)}$	
singularity	type
$x = 0$	"regular"
$x = 1$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, 1, \infty]$

Irregular singular points : $[]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$-y''x^2(x-1) + (x^2 + x)\, y' - 9y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$-\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x^2(x-1) + (x^2 + x)\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) - 9\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-9 a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)(n+r-1)\right) = \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)(n+r-2)\, x^{n+r}\right)$$

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r) = \sum_{n=1}^{\infty} a_{n-1}(n+r-1)\, x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)(n+r-2)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-9 a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) + x^{n+r} a_n (n+r) - 9 a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) + x^r a_0 r - 9 a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) + x^r r - 9 x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2 - 9\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - 9 = 0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned} r_1 &= 3 \\ r_2 &= -3 \end{aligned}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2 - 9\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 6$ is an integer, then we can construct two linearly independent solutions

$$\begin{aligned} y_1(x) &= x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right) \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= x^3 \left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x^3} \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+3} \\ y_2(x) &= C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-3}\right) \end{aligned}$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$-a_{n-1}(n+r-1)(n+r-2) + a_n(n+r)(n+r-1) + a_{n-1}(n+r-1) + a_n(n+r) - 9a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}(n+r-1)}{n+r+3} \tag{4}$$

Which for the root $r = 3$ becomes

$$a_n = \frac{a_{n-1}(n+2)}{n+6} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 3$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{r}{4+r}$$

Which for the root $r = 3$ becomes

$$a_1 = \frac{3}{7}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{4+r}$	$\frac{3}{7}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{(1+r)\,r}{(4+r)\,(5+r)}$$

Which for the root $r = 3$ becomes

$$a_2 = \frac{3}{14}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{4+r}$	$\frac{3}{7}$
a_2	$\frac{(1+r)r}{(4+r)(5+r)}$	$\frac{3}{14}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{(1+r)\, r(2+r)}{(4+r)\,(5+r)\,(6+r)}$$

Which for the root $r = 3$ becomes

$$a_3 = \frac{5}{42}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{4+r}$	$\frac{3}{7}$
a_2	$\frac{(1+r)r}{(4+r)(5+r)}$	$\frac{3}{14}$
a_3	$\frac{(1+r)r(2+r)}{(4+r)(5+r)(6+r)}$	$\frac{5}{42}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{(1+r)\, r(2+r)\,(r+3)}{(4+r)\,(5+r)\,(6+r)\,(7+r)}$$

Which for the root $r = 3$ becomes

$$a_4 = \frac{1}{14}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{4+r}$	$\frac{3}{7}$
a_2	$\frac{(1+r)r}{(4+r)(5+r)}$	$\frac{3}{14}$
a_3	$\frac{(1+r)r(2+r)}{(4+r)(5+r)(6+r)}$	$\frac{5}{42}$
a_4	$\frac{(1+r)r(2+r)(r+3)}{(4+r)(5+r)(6+r)(7+r)}$	$\frac{1}{14}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{(r+3)\, r(1+r)\,(2+r)}{(7+r)\,(6+r)\,(5+r)\,(8+r)}$$

Which for the root $r = 3$ becomes

$$a_5 = \frac{1}{22}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{4+r}$	$\frac{3}{7}$
a_2	$\frac{(1+r)r}{(4+r)(5+r)}$	$\frac{3}{14}$
a_3	$\frac{(1+r)r(2+r)}{(4+r)(5+r)(6+r)}$	$\frac{5}{42}$
a_4	$\frac{(1+r)r(2+r)(r+3)}{(4+r)(5+r)(6+r)(7+r)}$	$\frac{1}{14}$
a_5	$\frac{(r+3)r(1+r)(2+r)}{(7+r)(6+r)(5+r)(8+r)}$	$\frac{1}{22}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{(r+3)\,(1+r)\, r(2+r)}{(8+r)\,(7+r)\,(6+r)\,(9+r)}$$

Which for the root $r = 3$ becomes

$$a_6 = \frac{1}{33}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{4+r}$	$\frac{3}{7}$
a_2	$\frac{(1+r)r}{(4+r)(5+r)}$	$\frac{3}{14}$
a_3	$\frac{(1+r)r(2+r)}{(4+r)(5+r)(6+r)}$	$\frac{5}{42}$
a_4	$\frac{(1+r)r(2+r)(r+3)}{(4+r)(5+r)(6+r)(7+r)}$	$\frac{1}{14}$
a_5	$\frac{(r+3)r(1+r)(2+r)}{(7+r)(6+r)(5+r)(8+r)}$	$\frac{1}{22}$
a_6	$\frac{(r+3)(1+r)r(2+r)}{(8+r)(7+r)(6+r)(9+r)}$	$\frac{1}{33}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= x^3\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 + a_7x^7 \dots\right)\\
&= x^3\left(1 + \frac{3x}{7} + \frac{3x^2}{14} + \frac{5x^3}{42} + \frac{x^4}{14} + \frac{x^5}{22} + \frac{x^6}{33} + O(x^7)\right)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 6$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_6(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned}
a_N &= a_6\\
&= \frac{(r+3)(1+r)\,r(2+r)}{(8+r)(7+r)(6+r)(9+r)}
\end{aligned}$$

Therefore

$$\begin{aligned}
\lim_{r\to r_2} \frac{(r+3)(1+r)\,r(2+r)}{(8+r)(7+r)(6+r)(9+r)} &= \lim_{r\to -3} \frac{(r+3)(1+r)\,r(2+r)}{(8+r)(7+r)(6+r)(9+r)}\\
&= 0
\end{aligned}$$

The limit is 0. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$\begin{aligned}
y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r}\\
&= \sum_{n=0}^{\infty} b_n x^{n-3}
\end{aligned}$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$\begin{aligned}
&-b_{n-1}(n+r-1)(n+r-2) + b_n(n+r)(n+r-1)\\
&+ b_{n-1}(n+r-1) + b_n(n+r) - 9b_n = 0
\end{aligned} \tag{4}$$

Which for for the root $r = -3$ becomes

$$-b_{n-1}(n-4)(n-5) + b_n(n-3)(n-4) + b_{n-1}(n-4) + b_n(n-3) - 9b_n = 0 \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = \frac{b_{n-1}(n+r-1)}{n+r+3} \tag{5}$$

Which for the root $r = -3$ becomes

$$b_n = \frac{b_{n-1}(n-4)}{n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -3$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{r}{4+r}$$

Which for the root $r = -3$ becomes

$$b_1 = -3$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{4+r}$	-3

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{(1+r)\,r}{(4+r)\,(5+r)}$$

Which for the root $r = -3$ becomes

$$b_2 = 3$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{4+r}$	-3
b_2	$\frac{(1+r)r}{(4+r)(5+r)}$	3

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{(1+r)\, r(2+r)}{(4+r)\,(5+r)\,(6+r)}$$

Which for the root $r = -3$ becomes

$$b_3 = -1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{4+r}$	-3
b_2	$\frac{(1+r)r}{(4+r)(5+r)}$	3
b_3	$\frac{(1+r)r(2+r)}{(4+r)(5+r)(6+r)}$	-1

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{(1+r)\, r(2+r)\,(r+3)}{(4+r)\,(5+r)\,(6+r)\,(7+r)}$$

Which for the root $r = -3$ becomes

$$b_4 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{4+r}$	-3
b_2	$\frac{(1+r)r}{(4+r)(5+r)}$	3
b_3	$\frac{(1+r)r(2+r)}{(4+r)(5+r)(6+r)}$	-1
b_4	$\frac{(1+r)r(2+r)(r+3)}{(4+r)(5+r)(6+r)(7+r)}$	0

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{(r+3)\, r(1+r)\,(2+r)}{(7+r)\,(6+r)\,(5+r)\,(8+r)}$$

Which for the root $r = -3$ becomes

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{4+r}$	-3
b_2	$\frac{(1+r)r}{(4+r)(5+r)}$	3
b_3	$\frac{(1+r)r(2+r)}{(4+r)(5+r)(6+r)}$	-1
b_4	$\frac{(1+r)r(2+r)(r+3)}{(4+r)(5+r)(6+r)(7+r)}$	0
b_5	$\frac{(r+3)r(1+r)(2+r)}{(7+r)(6+r)(5+r)(8+r)}$	0

For $n = 6$, using the above recursive equation gives

$$b_6 = \frac{(r+3)\,(1+r)\, r(2+r)}{(8+r)\,(7+r)\,(6+r)\,(9+r)}$$

Which for the root $r = -3$ becomes

$$b_6 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{4+r}$	-3
b_2	$\frac{(1+r)r}{(4+r)(5+r)}$	3
b_3	$\frac{(1+r)r(2+r)}{(4+r)(5+r)(6+r)}$	-1
b_4	$\frac{(1+r)r(2+r)(r+3)}{(4+r)(5+r)(6+r)(7+r)}$	0
b_5	$\frac{(r+3)r(1+r)(2+r)}{(7+r)(6+r)(5+r)(8+r)}$	0
b_6	$\frac{(r+3)(1+r)r(2+r)}{(8+r)(7+r)(6+r)(9+r)}$	0

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x^3\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 \dots\right) \\
&= \frac{1 - 3x + 3x^2 - x^3 + O(x^7)}{x^3}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^3\left(1+\frac{3x}{7}+\frac{3x^2}{14}+\frac{5x^3}{42}+\frac{x^4}{14}+\frac{x^5}{22}+\frac{x^6}{33}+O(x^7)\right)+\frac{c_2(1-3x+3x^2-x^3+O(x^7))}{x^3}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^3\left(1+\frac{3x}{7}+\frac{3x^2}{14}+\frac{5x^3}{42}+\frac{x^4}{14}+\frac{x^5}{22}+\frac{x^6}{33}+O(x^7)\right)+\frac{c_2(1-3x+3x^2-x^3+O(x^7))}{x^3}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = c_1 x^3\left(1+\frac{3x}{7}+\frac{3x^2}{14}+\frac{5x^3}{42}+\frac{x^4}{14}+\frac{x^5}{22}+\frac{x^6}{33}+O(x^7)\right) \\
+\frac{c_2(1-3x+3x^2-x^3+O(x^7))}{x^3}
\end{aligned} \tag{1}
$$

Verification of solutions

$$
y = c_1 x^3\left(1+\frac{3x}{7}+\frac{3x^2}{14}+\frac{5x^3}{42}+\frac{x^4}{14}+\frac{x^5}{22}+\frac{x^6}{33}+O(x^7)\right)+\frac{c_2(1-3x+3x^2-x^3+O(x^7))}{x^3}
$$

Verified OK.

24.11.1 Maple step by step solution

Let's solve

$-y'' x^2(x-1) + (x^2+x)\, y' - 9y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

$y'' = -\frac{9y}{x^2(x-1)} + \frac{(x+1)y'}{x(x-1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' - \frac{(x+1)y'}{x(x-1)} + \frac{9y}{x^2(x-1)} = 0$

☐ Check to see if x_0 is a regular singular point

- ○ Define functions

$\left[P_2(x) = -\frac{x+1}{x(x-1)}, P_3(x) = \frac{9}{x^2(x-1)}\right]$

- ○ $x \cdot P_2(x)$ is analytic at $x = 0$

$\left(x \cdot P_2(x)\right)\bigg|_{x=0} = 1$

- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = -9$

- ○ $x = 0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0 = 0$

- Multiply by denominators

$y''x^2(x-1) - x(x+1)\,y' + 9y = 0$

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- ○ Shift index using $k- >k+1-m$

$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ○ Convert $x^m \cdot y''$ to series expansion for $m = 2..3$

$x^m \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

- ○ Shift index using $k- >k+2-m$

$$x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$-a_0(3+r)(-3+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(k+r+3)(k+r-3) + a_{k-1}(k+r-1)(k+r-3)\right) x^{k+r}\right)$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-(3+r)(-3+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{-3, 3\}$
- Each term in the series must be 0, giving the recursion relation

  $-((-k-r+1)\, a_{k-1} + a_k(k+r+3))(k+r-3) = 0$
- Shift index using $k- >k+1$

  $-((-k-r)\, a_k + a_{k+1}(k+4+r))(k+r-2) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{(k+r)a_k}{k+4+r}$
- Recursion relation for $r = -3$; series terminates at $k = 3$

  $a_{k+1} = \frac{(k-3)a_k}{k+1}$
- Apply recursion relation for $k = 0$

  $a_1 = -3a_0$
- Apply recursion relation for $k = 1$

  $a_2 = -a_1$
- Express in terms of a_0

  $a_2 = 3a_0$
- Apply recursion relation for $k = 2$

  $a_3 = -\frac{a_2}{3}$
- Express in terms of a_0

  $a_3 = -a_0$
- Terminating series solution of the ODE for $r = -3$. Use reduction of order to find the second

  $y = a_0 \cdot (1 - 3x + 3x^2 - x^3)$
- Recursion relation for $r = 3$

$a_{k+1} = \frac{(k+3)a_k}{k+7}$

- Solution for $r = 3$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+1} = \frac{(k+3)a_k}{k+7}\right]$$

- Combine solutions and rename parameters

$$\left[y = a_0 \cdot (1 - 3x + 3x^2 - x^3) + \left(\sum_{k=0}^{\infty} b_k x^{k+3}\right), b_{k+1} = \frac{(k+3)b_k}{k+7}\right]$$

Problem number: 12.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{\left(-x^2+x\right) y''-3y'+2y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(-x^2+x\right) y''-3y'+2y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$\begin{aligned} p(x) &= \frac{3}{x\left(x-1\right)} \\ q(x) &= -\frac{2}{x\left(x-1\right)} \end{aligned}$$

Table 701: Table $p(x), q(x)$ singularites.

$p(x) = \frac{3}{x(x-1)}$	
singularity	type
$x = 0$	"regular"
$x = 1$	"regular"

$q(x) = -\frac{2}{x(x-1)}$	
singularity	type
$x = 0$	"regular"
$x = 1$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, 1, \infty]$

Irregular singular points : $[]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$-y''x(x-1) - 3y' + 2y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$-\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x(x-1) - 3\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-3(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)(n+r-1)\right) = \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)(n+r-2) x^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty} 2a_n x^{n+r} = \sum_{n=1}^{\infty} 2a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)(n+r-2) x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-3(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} 2a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r-1} a_n (n+r)(n+r-1) - 3(n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$x^{-1+r} a_0 r(-1+r) - 3r a_0 x^{-1+r} = 0$$

Or

$$\left(x^{-1+r} r(-1+r) - 3r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, x^{-1+r}(-4+r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$r(-4+r) = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 4$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\,x^{-1+r}(-4+r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 4$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x^4\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+4}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$-a_{n-1}(n+r-1)(n+r-2) + a_n(n+r)(n+r-1) - 3a_n(n+r) + 2a_{n-1} = 0 \quad (3)$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{(n+r-3)\, a_{n-1}}{n-4+r} \tag{4}$$

Which for the root $r = 4$ becomes

$$a_n = \frac{(n+1)\, a_{n-1}}{n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 4$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{-2+r}{r-3}$$

Which for the root $r = 4$ becomes

$$a_1 = 2$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+r}{r-3}$	2

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{-1+r}{r-3}$$

Which for the root $r = 4$ becomes

$$a_2 = 3$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+r}{r-3}$	2
a_2	$\frac{-1+r}{r-3}$	3

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{r}{r - 3}$$

Which for the root $r = 4$ becomes

$$a_3 = 4$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+r}{r-3}$	2
a_2	$\frac{-1+r}{r-3}$	3
a_3	$\frac{r}{r-3}$	4

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1 + r}{r - 3}$$

Which for the root $r = 4$ becomes

$$a_4 = 5$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+r}{r-3}$	2
a_2	$\frac{-1+r}{r-3}$	3
a_3	$\frac{r}{r-3}$	4
a_4	$\frac{1+r}{r-3}$	5

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{2 + r}{r - 3}$$

Which for the root $r = 4$ becomes

$$a_5 = 6$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+r}{r-3}$	2
a_2	$\frac{-1+r}{r-3}$	3
a_3	$\frac{r}{r-3}$	4
a_4	$\frac{1+r}{r-3}$	5
a_5	$\frac{2+r}{r-3}$	6

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^4\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots\right) \\ &= x^4\left(1 + 2x + 3x^2 + 4x^3 + 5x^4 + 6x^5 + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 4$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_4(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_4 \\ &= \frac{1+r}{r-3} \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r\to r_2} \frac{1+r}{r-3} &= \lim_{r\to 0} \frac{1+r}{r-3} \\ &= -\frac{1}{3} \end{aligned}$$

The limit is $-\frac{1}{3}$. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$\begin{aligned} y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\ &= \sum_{n=0}^{\infty} b_n x^n \end{aligned}$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$-b_{n-1}(n+r-1)(n+r-2) + b_n(n+r)(n+r-1) - 3(n+r)b_n + 2b_{n-1} = 0 \quad (4)$$

Which for for the root $r = 0$ becomes

$$-b_{n-1}(n-1)(n-2) + b_n n(n-1) - 3nb_n + 2b_{n-1} = 0 \quad (4A)$$

Solving for b_n from the recursive equation (4) gives

$$b_n = \frac{(n+r-3)\,b_{n-1}}{n-4+r} \quad (5)$$

Which for the root $r = 0$ becomes

$$b_n = \frac{(n-3)\,b_{n-1}}{n-4} \quad (6)$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{-2+r}{r-3}$$

Which for the root $r = 0$ becomes

$$b_1 = \frac{2}{3}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-2+r}{r-3}$	$\frac{2}{3}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{-1+r}{r-3}$$

Which for the root $r = 0$ becomes

$$b_2 = \frac{1}{3}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-2+r}{r-3}$	$\frac{2}{3}$
b_2	$\frac{-1+r}{r-3}$	$\frac{1}{3}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{r}{r-3}$$

Which for the root $r = 0$ becomes

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-2+r}{r-3}$	$\frac{2}{3}$
b_2	$\frac{-1+r}{r-3}$	$\frac{1}{3}$
b_3	$\frac{r}{r-3}$	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1+r}{r-3}$$

Which for the root $r = 0$ becomes

$$b_4 = -\frac{1}{3}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-2+r}{r-3}$	$\frac{2}{3}$
b_2	$\frac{-1+r}{r-3}$	$\frac{1}{3}$
b_3	$\frac{r}{r-3}$	0
b_4	$\frac{1+r}{r-3}$	$-\frac{1}{3}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{2+r}{r-3}$$

Which for the root $r = 0$ becomes

$$b_5 = -\frac{2}{3}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-2+r}{r-3}$	$\frac{2}{3}$
b_2	$\frac{-1+r}{r-3}$	$\frac{1}{3}$
b_3	$\frac{r}{r-3}$	0
b_4	$\frac{1+r}{r-3}$	$-\frac{1}{3}$
b_5	$\frac{2+r}{r-3}$	$-\frac{2}{3}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots \\ &= 1 + \frac{2x}{3} + \frac{x^2}{3} - \frac{x^4}{3} - \frac{2x^5}{3} + O(x^6) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^4 \left(1+2x+3x^2+4x^3+5x^4+6x^5+O(x^6)\right)+c_2\left(1+\frac{2x}{3}+\frac{x^2}{3}-\frac{x^4}{3}-\frac{2x^5}{3}+O(x^6)\right) \end{aligned}$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^4 \left(1+2x+3x^2+4x^3+5x^4+6x^5+O(x^6)\right)+c_2\left(1+\frac{2x}{3}+\frac{x^2}{3}-\frac{x^4}{3}-\frac{2x^5}{3}+O(x^6)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & c_1 x^4 \left(1+2x+3x^2+4x^3+5x^4+6x^5+O(x^6)\right) \\
& + c_2\left(1+\frac{2x}{3}+\frac{x^2}{3}-\frac{x^4}{3}-\frac{2x^5}{3}+O(x^6)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
y = c_1 x^4 \left(1+2x+3x^2+4x^3+5x^4+6x^5+O(x^6)\right)+c_2\left(1+\frac{2x}{3}+\frac{x^2}{3}-\frac{x^4}{3}-\frac{2x^5}{3}+O(x^6)\right)
$$

Verified OK.

24.12.1 Maple step by step solution

Let's solve

$-y''x(x-1)-3y'+2y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{2y}{x(x-1)}-\frac{3y'}{x(x-1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{3y'}{x(x-1)}-\frac{2y}{x(x-1)}=0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{3}{x(x-1)}, P_3(x)=-\frac{2}{x(x-1)}\right]$

  - $x \cdot P_2(x)$ is analytic at $x=0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0}=-3$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 0$$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $$y''x(x-1) + 3y' - 2y = 0$$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

- ☐ Rewrite ODE with series expansions

  - Convert y' to series expansion

    $$y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1}$$

  - Shift index using $k->k+1$

    $$y' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, x^{k+r}$$

  - Convert $x^m \cdot y''$ to series expansion for $m = 1..2$

    $$x^m \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, x^{k+r-2+m}$$

  - Shift index using $k->k+2-m$

    $$x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$-a_0 r(-4+r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-a_{k+1}(k+1+r)(k-3+r) + a_k(k+1+r)(k+r-2)\right) x^{k+r}\right) =$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$-r(-4+r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \{0, 4\}$$

- Each term in the series must be 0, giving the recursion relation

$$((-k-r+3)\,a_{k+1}+a_k(k+r-2))\,(k+1+r)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=\frac{a_k(k+r-2)}{k-3+r}$$

- Recursion relation for $r=0$; series terminates at $k=2$

$$a_{k+1}=\frac{a_k(k-2)}{k-3}$$

- Apply recursion relation for $k=0$

$$a_1=\frac{2a_0}{3}$$

- Apply recursion relation for $k=1$

$$a_2=\frac{a_1}{2}$$

- Express in terms of a_0

$$a_2=\frac{a_0}{3}$$

- Terminating series solution of the ODE for $r=0$. Use reduction of order to find the second li

$$y=a_0\cdot\left(1+\frac{2}{3}x+\frac{1}{3}x^2\right)$$

- Recursion relation for $r=4$

$$a_{k+1}=\frac{a_k(k+2)}{k+1}$$

- Solution for $r=4$

$$\left[y=\sum_{k=0}^{\infty}a_k x^{k+4}, a_{k+1}=\frac{a_k(k+2)}{k+1}\right]$$

- Combine solutions and rename parameters

$$\left[y=a_0\cdot\left(1+\frac{2}{3}x+\frac{1}{3}x^2\right)+\left(\sum_{k=0}^{\infty}b_k x^{k+4}\right), b_{k+1}=\frac{b_k(k+2)}{k+1}\right]$$

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2 y'' + x(x-7)\,y' + (x+12)\,y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2 y'' + \left(x^2 - 7x\right) y' + (x+12)\,y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{x-7}{x}$$
$$q(x) = \frac{x+12}{x^2}$$

Table 703: Table $p(x), q(x)$ singularites.

$p(x) = \frac{x-7}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{x+12}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' + (x^2 - 7x)\, y' + (x + 12)\, y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r)\, (n + r - 1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2 \left(\sum_{n=0}^{\infty} (n + r)\, (n + r - 1)\, a_n x^{n+r-2} \right) + (x^2 - 7x) \left(\sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1} \right) + (x + 12) \left(\sum_{n=0}^{\infty} a_n x^{n+r} \right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-7x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n\right) + \left(\sum_{n=0}^{\infty} 12 a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r) = \sum_{n=1}^{\infty} a_{n-1} (n+r-1)\, x^{n+r}$$

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n = \sum_{n=1}^{\infty} a_{n-1} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=1}^{\infty} a_{n-1} (n+r-1)\, x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-7x^{n+r} a_n (n+r)\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 12 a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - 7x^{n+r} a_n (n+r) + 12 a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - 7x^r a_0 r + 12 a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - 7x^r r + 12x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$(r-2)(r-6)\, x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$(r-2)(r-6)=0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned} r_1 &= 6 \\ r_2 &= 2 \end{aligned}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$(r-2)(r-6)x^r=0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 4$ is an integer, then we can construct two linearly independent solutions

$$\begin{aligned} y_1(x) &= x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= C y_1(x)\ln(x) + x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right) \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= x^{6}\left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= C y_1(x)\ln(x) + x^{2}\left(\sum_{n=0}^{\infty} b_n x^n\right) \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+6} \\ y_2(x) &= C y_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+2}\right) \end{aligned}$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + a_{n-1}(n+r-1) - 7a_n(n+r) + a_{n-1} + 12a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}(n+r)}{n^2+2nr+r^2-8n-8r+12} \tag{4}$$

Which for the root $r = 6$ becomes

$$a_n = -\frac{a_{n-1}(n+6)}{n\,(n+4)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 6$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{-1-r}{r^2-6r+5}$$

Which for the root $r = 6$ becomes

$$a_1 = -\frac{7}{5}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1-r}{r^2-6r+5}$	$-\frac{7}{5}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r^2+3r+2}{(-1+r)\,(r-5)\,r\,(r-4)}$$

Which for the root $r = 6$ becomes

$$a_2 = \frac{14}{15}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1-r}{r^2-6r+5}$	$-\frac{7}{5}$
a_2	$\frac{r^2+3r+2}{(-1+r)(r-5)r(r-4)}$	$\frac{14}{15}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{(2+r)(3+r)}{(r-3)(r-4)r(r-5)(-1+r)}$$

Which for the root $r = 6$ becomes

$$a_3 = -\frac{2}{5}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1-r}{r^2-6r+5}$	$-\frac{7}{5}$
a_2	$\frac{r^2+3r+2}{(-1+r)(r-5)r(r-4)}$	$\frac{14}{15}$
a_3	$-\frac{(2+r)(3+r)}{(r-3)(r-4)r(r-5)(-1+r)}$	$-\frac{2}{5}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{(4+r)(3+r)}{(r-2)(r-3)(r-4)r(r-5)(-1+r)}$$

Which for the root $r = 6$ becomes

$$a_4 = \frac{1}{8}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1-r}{r^2-6r+5}$	$-\frac{7}{5}$
a_2	$\frac{r^2+3r+2}{(-1+r)(r-5)r(r-4)}$	$\frac{14}{15}$
a_3	$-\frac{(2+r)(3+r)}{(r-3)(r-4)r(r-5)(-1+r)}$	$-\frac{2}{5}$
a_4	$\frac{(4+r)(3+r)}{(r-2)(r-3)(r-4)r(r-5)(-1+r)}$	$\frac{1}{8}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{(5+r)(4+r)}{(-1+r)^2(r-2)(r-3)(r-4)r(r-5)}$$

Which for the root $r = 6$ becomes

$$a_5 = -\frac{11}{360}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1-r}{r^2-6r+5}$	$-\frac{7}{5}$
a_2	$\frac{r^2+3r+2}{(-1+r)(r-5)r(r-4)}$	$\frac{14}{15}$
a_3	$-\frac{(2+r)(3+r)}{(r-3)(r-4)r(r-5)(-1+r)}$	$-\frac{2}{5}$
a_4	$\frac{(4+r)(3+r)}{(r-2)(r-3)(r-4)r(r-5)(-1+r)}$	$\frac{1}{8}$
a_5	$-\frac{(5+r)(4+r)}{(-1+r)^2(r-2)(r-3)(r-4)r(r-5)}$	$-\frac{11}{360}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^6\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^6\left(1 - \frac{7x}{5} + \frac{14x^2}{15} - \frac{2x^3}{5} + \frac{x^4}{8} - \frac{11x^5}{360} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 4$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_4(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_4 \\ &= \frac{(4+r)(3+r)}{(r-2)(r-3)(r-4)r(r-5)(-1+r)} \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r\to r_2} \frac{(4+r)(3+r)}{(r-2)(r-3)(r-4)r(r-5)(-1+r)} &= \lim_{r\to 2} \frac{(4+r)(3+r)}{(r-2)(r-3)(r-4)r(r-5)(-1+r)} \\ &= \mathit{undefined} \end{aligned}$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Therefore

$$\begin{aligned}
\frac{d}{dx}y_2(x) &= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) \\
&= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n(n+r_2)\right) \\
\frac{d^2}{dx^2}y_2(x) &= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} \\
&\quad + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right) \\
&= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n(n+r_2)(-1+n+r_2)\right)
\end{aligned}$$

Substituting these back into the given ode $x^2y'' + (x^2 - 7x)\,y' + (x+12)\,y = 0$ gives

$$\begin{aligned}
&x^2\Bigg(Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} \\
&+ \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\Bigg) \\
&+ (x^2 - 7x)\left(Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right)\right) \\
&+ (x+12)\left(Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)\right) = 0
\end{aligned}$$

Which can be written as

$$\left(\left(\left(x^{2} y_{1}''(x)+\left(x^{2}-7 x\right) y_{1}'(x)+(x+12) y_{1}(x)\right) \ln (x)+x^{2}\left(\frac{2 y_{1}'(x)}{x}-\frac{y_{1}(x)}{x^{2}}\right)\right.\right.$$
$$\left.+\frac{\left(x^{2}-7 x\right) y_{1}(x)}{x}\right) C+x^{2}\left(\sum_{n=0}^{\infty}\left(\frac{b_{n} x^{n+r_{2}}\left(n+r_{2}\right)^{2}}{x^{2}}-\frac{b_{n} x^{n+r_{2}}\left(n+r_{2}\right)}{x^{2}}\right)\right) \tag{7}$$
$$+\left(x^{2}-7 x\right)\left(\sum_{n=0}^{\infty} \frac{b_{n} x^{n+r_{2}}\left(n+r_{2}\right)}{x}\right)+(x+12)\left(\sum_{n=0}^{\infty} b_{n} x^{n+r_{2}}\right)=0$$

But since $y_1(x)$ is a solution to the ode, then

$$x^{2} y_{1}''(x)+\left(x^{2}-7 x\right) y_{1}'(x)+(x+12) y_{1}(x)=0$$

Eq (7) simplifes to

$$\left(x^{2}\left(\frac{2 y_{1}'(x)}{x}-\frac{y_{1}(x)}{x^{2}}\right)+\frac{\left(x^{2}-7 x\right) y_{1}(x)}{x}\right) C$$
$$+x^{2}\left(\sum_{n=0}^{\infty}\left(\frac{b_{n} x^{n+r_{2}}\left(n+r_{2}\right)^{2}}{x^{2}}-\frac{b_{n} x^{n+r_{2}}\left(n+r_{2}\right)}{x^{2}}\right)\right) \tag{8}$$
$$+\left(x^{2}-7 x\right)\left(\sum_{n=0}^{\infty} \frac{b_{n} x^{n+r_{2}}\left(n+r_{2}\right)}{x}\right)+(x+12)\left(\sum_{n=0}^{\infty} b_{n} x^{n+r_{2}}\right)=0$$

Substituting $y_1 = \sum_{n=0}^{\infty} a_n x^{n+r_1}$ into the above gives

$$\left(2\left(\sum_{n=0}^{\infty} x^{-1+n+r_{1}} a_{n}\left(n+r_{1}\right)\right) x+(-8+x)\left(\sum_{n=0}^{\infty} a_{n} x^{n+r_{1}}\right)\right) C$$
$$+\left(\sum_{n=0}^{\infty} x^{-2+n+r_{2}} b_{n}\left(n+r_{2}\right)\left(-1+n+r_{2}\right)\right) x^{2} \tag{9}$$
$$+\left(x^{2}-7 x\right)\left(\sum_{n=0}^{\infty} x^{-1+n+r_{2}} b_{n}\left(n+r_{2}\right)\right)+(x+12)\left(\sum_{n=0}^{\infty} b_{n} x^{n+r_{2}}\right)=0$$

Since $r_1 = 6$ and $r_2 = 2$ then the above becomes

$$\left(2\left(\sum_{n=0}^{\infty} x^{5+n} a_n (n+6)\right) x + (-8+x)\left(\sum_{n=0}^{\infty} a_n x^{n+6}\right)\right) C + \left(\sum_{n=0}^{\infty} x^n b_n (n+2)(1+n)\right) x^2 + (x^2 - 7x)\left(\sum_{n=0}^{\infty} x^{1+n} b_n (n+2)\right) + (x+12)\left(\sum_{n=0}^{\infty} b_n x^{n+2}\right) = 0 \tag{10}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2C\, x^{n+6} a_n (n+6)\right) + \sum_{n=0}^{\infty} \left(-8C\, x^{n+6} a_n\right) + \left(\sum_{n=0}^{\infty} C\, x^{n+7} a_n\right) + \left(\sum_{n=0}^{\infty} x^{n+2} b_n (n^2+3n+2)\right) + \left(\sum_{n=0}^{\infty} x^{n+3} b_n (n+2)\right) + \sum_{n=0}^{\infty} \left(-7x^{n+2} b_n (n+2)\right) + \left(\sum_{n=0}^{\infty} x^{n+3} b_n\right) + \left(\sum_{n=0}^{\infty} 12 b_n x^{n+2}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+2$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+2} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2C\, x^{n+6} a_n (n+6) = \sum_{n=4}^{\infty} 2C a_{n-4} (n+2)\, x^{n+2}$$

$$\sum_{n=0}^{\infty} \left(-8C\, x^{n+6} a_n\right) = \sum_{n=4}^{\infty} \left(-8C a_{n-4} x^{n+2}\right)$$

$$\sum_{n=0}^{\infty} C\, x^{n+7} a_n = \sum_{n=5}^{\infty} C a_{n-5} x^{n+2}$$

$$\sum_{n=0}^{\infty} x^{n+3} b_n (n+2) = \sum_{n=1}^{\infty} b_{n-1} (1+n)\, x^{n+2}$$

$$\sum_{n=0}^{\infty} x^{n+3} b_n = \sum_{n=1}^{\infty} b_{n-1} x^{n+2}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+2$.

$$
\begin{aligned}
&\left(\sum_{n=4}^{\infty} 2 C a_{n-4}(n+2)\, x^{n+2}\right)+\sum_{n=4}^{\infty}\left(-8 C a_{n-4} x^{n+2}\right)+\left(\sum_{n=5}^{\infty} C a_{n-5} x^{n+2}\right) \\
&+\left(\sum_{n=0}^{\infty} x^{n+2} b_{n}\left(n^{2}+3 n+2\right)\right)+\left(\sum_{n=1}^{\infty} b_{n-1}(1+n)\, x^{n+2}\right) \\
&+\sum_{n=0}^{\infty}\left(-7 x^{n+2} b_{n}(n+2)\right)+\left(\sum_{n=1}^{\infty} b_{n-1} x^{n+2}\right)+\left(\sum_{n=0}^{\infty} 12 b_{n} x^{n+2}\right)=0
\end{aligned} \tag{2B}
$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0=1$. For $n=1$, Eq (2B) gives

$$-3b_1+3b_0=0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-3b_1+3=0$$

Solving the above for b_1 gives

$$b_1=1$$

For $n=2$, Eq (2B) gives

$$-4b_2+4b_1=0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-4b_2+4=0$$

Solving the above for b_2 gives

$$b_2=1$$

For $n=3$, Eq (2B) gives

$$-3b_3+5b_2=0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-3b_3+5=0$$

Solving the above for b_3 gives

$$b_3=\frac{5}{3}$$

For $n = N$, where $N = 4$ which is the difference between the two roots, we are free to choose $b_4 = 0$. Hence for $n = 4$, Eq (2B) gives

$$4C + 10 = 0$$

Which is solved for C. Solving for C gives

$$C = -\frac{5}{2}$$

For $n = 5$, Eq (2B) gives

$$(a_0 + 6a_1) C + 7b_4 + 5b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$\frac{37}{2} + 5b_5 = 0$$

Solving the above for b_5 gives

$$b_5 = -\frac{37}{10}$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = -\frac{5}{2}$ and all b_n, then the second solution becomes

$$y_2(x) = -\frac{5}{2}\left(x^6\left(1 - \frac{7x}{5} + \frac{14x^2}{15} - \frac{2x^3}{5} + \frac{x^4}{8} - \frac{11x^5}{360} + O(x^6)\right)\right)\ln(x) + x^2\left(1 + x + x^2 + \frac{5x^3}{3} - \frac{37x^5}{10} + O(x^6)\right)$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^6\left(1 - \frac{7x}{5} + \frac{14x^2}{15} - \frac{2x^3}{5} + \frac{x^4}{8} - \frac{11x^5}{360} + O(x^6)\right) \\ &+ c_2\left(-\frac{5}{2}\left(x^6\left(1 - \frac{7x}{5} + \frac{14x^2}{15} - \frac{2x^3}{5} + \frac{x^4}{8} - \frac{11x^5}{360} + O(x^6)\right)\right)\ln(x) \right. \\ &\left. + x^2\left(1 + x + x^2 + \frac{5x^3}{3} - \frac{37x^5}{10} + O(x^6)\right)\right) \end{aligned}$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^6 \left(1 - \frac{7x}{5} + \frac{14x^2}{15} - \frac{2x^3}{5} + \frac{x^4}{8} - \frac{11x^5}{360} + O(x^6)\right) \\
&+ c_2 \left(-\frac{5x^6 \left(1 - \frac{7x}{5} + \frac{14x^2}{15} - \frac{2x^3}{5} + \frac{x^4}{8} - \frac{11x^5}{360} + O(x^6)\right) \ln(x)}{2} \right. \\
&\left. + x^2 \left(1 + x + x^2 + \frac{5x^3}{3} - \frac{37x^5}{10} + O(x^6)\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x^6 \left(1 - \frac{7x}{5} + \frac{14x^2}{15} - \frac{2x^3}{5} + \frac{x^4}{8} - \frac{11x^5}{360} + O(x^6)\right) \\
&+ c_2 \left(-\frac{5x^6 \left(1 - \frac{7x}{5} + \frac{14x^2}{15} - \frac{2x^3}{5} + \frac{x^4}{8} - \frac{11x^5}{360} + O(x^6)\right) \ln(x)}{2} \right. \\
&\left. + x^2 \left(1 + x + x^2 + \frac{5x^3}{3} - \frac{37x^5}{10} + O(x^6)\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 x^6 \left(1 - \frac{7x}{5} + \frac{14x^2}{15} - \frac{2x^3}{5} + \frac{x^4}{8} - \frac{11x^5}{360} + O(x^6)\right) \\
&+ c_2 \left(-\frac{5x^6 \left(1 - \frac{7x}{5} + \frac{14x^2}{15} - \frac{2x^3}{5} + \frac{x^4}{8} - \frac{11x^5}{360} + O(x^6)\right) \ln(x)}{2} \right. \\
&\left. + x^2 \left(1 + x + x^2 + \frac{5x^3}{3} - \frac{37x^5}{10} + O(x^6)\right)\right)
\end{aligned}
$$

Verified OK.

24.13.1 Maple step by step solution

Let's solve

$x^2y'' + (x^2 - 7x)\,y' + (x + 12)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(x+12)y}{x^2} - \frac{(x-7)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(x-7)y'}{x} + \frac{(x+12)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{x-7}{x}, P_3(x) = \frac{x+12}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = -7$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 12$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2y'' + x(x - 7)\,y' + (x + 12)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  ◦ Shift index using $k- >k - m$

$$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^2 \cdot y''$ to series expansion

$$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-2+r)\,(-6+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r-2)\,(k+r-6) + a_{k-1}(k+r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(-2+r)\,(-6+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{2, 6\}$$

- Each term in the series must be 0, giving the recursion relation

$$a_k(k+r-2)\,(k+r-6) + a_{k-1}(k+r) = 0$$

- Shift index using $k->k+1$

$$a_{k+1}(k+r-1)\,(k-5+r) + a_k(k+r+1) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{a_k(k+r+1)}{(k+r-1)(k-5+r)}$$

- Recursion relation for $r = 2$

$$a_{k+1} = -\frac{a_k(k+3)}{(k+1)(k-3)}$$

- Series not valid for $r = 2$, division by 0 in the recursion relation at $k = 3$

$$a_{k+1} = -\frac{a_k(k+3)}{(k+1)(k-3)}$$

- Recursion relation for $r = 6$

$$a_{k+1} = -\frac{a_k(k+7)}{(k+5)(k+1)}$$

- Solution for $r = 6$

$$\left[y=\sum_{k=0}^{\infty} a_k x^{k+6}, a_{k+1}=-\frac{a_k(k+7)}{(k+5)(k+1)}\right]$$

Problem number: 14.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2(x+1)\,y''+x(x-4)\,y'+4y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(x^3+x^2\right)y''+\left(x^2-4x\right)y'+4y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=\frac{x-4}{x\,(x+1)}$$
$$q(x)=\frac{4}{x^2\,(x+1)}$$

Table 705: Table $p(x), q(x)$ singularites.

$p(x) = \frac{x-4}{x(x+1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

$q(x) = \frac{4}{x^2(x+1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-1, 0, \infty]$

Irregular singular points : $[]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2(x+1)\, y'' + \left(x^2 - 4x\right) y' + 4y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2(x+1) \left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + \left(x^2 - 4x\right) \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + 4\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) \tag{2A}$$
$$+ \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-4x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 4a_n x^{n+r}\right) = 0$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1) = \sum_{n=1}^{\infty} a_{n-1} (n+r-1)(n+r-2) x^{n+r}$$

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r) = \sum_{n=1}^{\infty} a_{n-1} (n+r-1) x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=1}^{\infty} a_{n-1} (n+r-1)(n+r-2) x^{n+r}\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) \tag{2B}$$
$$+ \left(\sum_{n=1}^{\infty} a_{n-1} (n+r-1) x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-4x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 4a_n x^{n+r}\right) = 0$$

The indicial equation is obtained from $n = 0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - 4x^{n+r} a_n (n+r) + 4a_n x^{n+r} = 0$$

When $n = 0$ the above becomes

$$x^r a_0 r(-1+r) - 4x^r a_0 r + 4a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - 4x^r r + 4x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2 - 5r + 4\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - 5r + 4 = 0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned} r_1 &= 4 \\ r_2 &= 1 \end{aligned}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2 - 5r + 4\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 3$ is an integer, then we can construct two linearly independent solutions

$$\begin{aligned} y_1(x) &= x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right) \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= x^4 \left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= C y_1(x) \ln(x) + x \left(\sum_{n=0}^{\infty} b_n x^n\right) \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+4} \\ y_2(x) &= C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{1+n}\right) \end{aligned}$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$\begin{aligned} &a_{n-1}(n + r - 1)(n + r - 2) + a_n(n + r)(n + r - 1) \\ &+ a_{n-1}(n + r - 1) - 4a_n(n + r) + 4a_n = 0 \end{aligned} \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}(n+r-1)}{n+r-4} \tag{4}$$

Which for the root $r = 4$ becomes

$$a_n = -\frac{a_{n-1}(n+3)}{n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 4$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{r}{-3+r}$$

Which for the root $r = 4$ becomes

$$a_1 = -4$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r}{-3+r}$	-4

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r(1+r)}{(-3+r)(-2+r)}$$

Which for the root $r = 4$ becomes

$$a_2 = 10$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r}{-3+r}$	-4
a_2	$\frac{r(1+r)}{(-3+r)(-2+r)}$	10

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{(2+r)\, r(1+r)}{(-3+r)\,(-2+r)\,(-1+r)}$$

Which for the root $r = 4$ becomes

$$a_3 = -20$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r}{-3+r}$	-4
a_2	$\frac{r(1+r)}{(-3+r)(-2+r)}$	10
a_3	$-\frac{(2+r)r(1+r)}{(-3+r)(-2+r)(-1+r)}$	-20

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{(3+r)\,(1+r)\,(2+r)}{(-3+r)\,(-2+r)\,(-1+r)}$$

Which for the root $r = 4$ becomes

$$a_4 = 35$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r}{-3+r}$	-4
a_2	$\frac{r(1+r)}{(-3+r)(-2+r)}$	10
a_3	$-\frac{(2+r)r(1+r)}{(-3+r)(-2+r)(-1+r)}$	-20
a_4	$\frac{(3+r)(1+r)(2+r)}{(-3+r)(-2+r)(-1+r)}$	35

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{(3+r)\,(2+r)\,(4+r)}{(-3+r)\,(-2+r)\,(-1+r)}$$

Which for the root $r = 4$ becomes

$$a_5 = -56$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r}{-3+r}$	-4
a_2	$\frac{r(1+r)}{(-3+r)(-2+r)}$	10
a_3	$-\frac{(2+r)r(1+r)}{(-3+r)(-2+r)(-1+r)}$	-20
a_4	$\frac{(3+r)(1+r)(2+r)}{(-3+r)(-2+r)(-1+r)}$	35
a_5	$-\frac{(3+r)(2+r)(4+r)}{(-3+r)(-2+r)(-1+r)}$	-56

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^4\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots\right) \\ &= x^4\left(1 - 4x + 10x^2 - 20x^3 + 35x^4 - 56x^5 + O\left(x^6\right)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 3$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \to r_2} a_3(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_3 \\ &= -\frac{(2+r)\, r(1+r)}{(-3+r)\,(-2+r)\,(-1+r)} \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r \to r_2} -\frac{(2+r)\, r(1+r)}{(-3+r)\,(-2+r)\,(-1+r)} &= \lim_{r \to 1} -\frac{(2+r)\, r(1+r)}{(-3+r)\,(-2+r)\,(-1+r)} \\ &= \mathit{undefined} \end{aligned}$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Therefore

$$\begin{aligned}\frac{d}{dx}y_2(x) &= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right)\\ &= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n(n+r_2)\right)\\ \frac{d^2}{dx^2}y_2(x) &= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2}\\ &\quad+ \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\\ &= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n(n+r_2)(-1+n+r_2)\right)\end{aligned}$$

Substituting these back into the given ode $x^2(x+1)\,y'' + (x^2-4x)\,y' + 4y = 0$ gives

$$\begin{aligned}&x^2(x+1)\left(Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2}\right.\\ &\left.+ \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)\\ &+ (x^2-4x)\left(Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)\right)\\ &+ 4Cy_1(x)\ln(x) + 4\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0\end{aligned}$$

Which can be written as

$$\begin{aligned}&\left(\left(x^2(x+1)\,y_1''(x)+\left(x^2-4x\right)y_1'(x)+4y_1(x)\right)\ln\left(x\right)\right.\\&+x^2(x+1)\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)+\frac{\left(x^2-4x\right)y_1(x)}{x}\Bigg)\,C\\&+x^2(x+1)\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)\\&+\left(x^2-4x\right)\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)+4\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0\end{aligned}\tag{7}$$

But since $y_1(x)$ is a solution to the ode, then

$$x^2(x+1)\,y_1''(x)+\left(x^2-4x\right)y_1'(x)+4y_1(x)=0$$

Eq (7) simplifes to

$$\begin{aligned}&\left(x^2(x+1)\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)+\frac{\left(x^2-4x\right)y_1(x)}{x}\right)C\\&+x^2(x+1)\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)\\&+\left(x^2-4x\right)\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)+4\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0\end{aligned}\tag{8}$$

Substituting $y_1=\sum_{n=0}^{\infty}a_n x^{n+r_1}$ into the above gives

$$\begin{aligned}&\left(2x(x+1)\left(\sum_{n=0}^{\infty}x^{-1+n+r_1}a_n(n+r_1)\right)-5\left(\sum_{n=0}^{\infty}a_n x^{n+r_1}\right)\right)C\\&+x^2(x+1)\left(\sum_{n=0}^{\infty}x^{-2+n+r_2}b_n(n+r_2)\,(-1+n+r_2)\right)\\&+\left(x^2-4x\right)\left(\sum_{n=0}^{\infty}x^{-1+n+r_2}b_n(n+r_2)\right)+4\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0\end{aligned}\tag{9}$$

Since $r_1 = 4$ and $r_2 = 1$ then the above becomes

$$\begin{aligned} &\left(2x(x+1)\left(\sum_{n=0}^{\infty} x^{n+3} a_n (n+4)\right) - 5\left(\sum_{n=0}^{\infty} a_n x^{n+4}\right)\right) C \\ &+ x^2(x+1)\left(\sum_{n=0}^{\infty} x^{n-1} b_n (1+n)\, n\right) \\ &+ \left(x^2-4x\right)\left(\sum_{n=0}^{\infty} x^n b_n (1+n)\right) + 4\left(\sum_{n=0}^{\infty} b_n x^{1+n}\right) = 0 \end{aligned} \tag{10}$$

Which simplifies to

$$\begin{aligned} &\left(\sum_{n=0}^{\infty} 2C\, x^{n+5} a_n (n+4)\right) + \left(\sum_{n=0}^{\infty} 2C\, x^{n+4} a_n (n+4)\right) + \sum_{n=0}^{\infty} \left(-5C a_n x^{n+4}\right) \\ &+ \left(\sum_{n=0}^{\infty} n\, x^{n+2} b_n (1+n)\right) + \left(\sum_{n=0}^{\infty} n\, x^{1+n} b_n (1+n)\right) \\ &+ \left(\sum_{n=0}^{\infty} x^{n+2} b_n (1+n)\right) + \sum_{n=0}^{\infty} \left(-4x^{1+n} b_n (1+n)\right) + \left(\sum_{n=0}^{\infty} 4 b_n x^{1+n}\right) = 0 \end{aligned} \tag{2A}$$

The next step is to make all powers of x be $1+n$ in each summation term. Going over each summation term above with power of x in it which is not already x^{1+n} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2C\, x^{n+5} a_n (n+4) = \sum_{n=4}^{\infty} 2C a_{-4+n} n\, x^{1+n}$$

$$\sum_{n=0}^{\infty} 2C\, x^{n+4} a_n (n+4) = \sum_{n=3}^{\infty} 2C a_{n-3} (1+n)\, x^{1+n}$$

$$\sum_{n=0}^{\infty} \left(-5C a_n x^{n+4}\right) = \sum_{n=3}^{\infty} \left(-5C a_{n-3} x^{1+n}\right)$$

$$\sum_{n=0}^{\infty} n\, x^{n+2} b_n (1+n) = \sum_{n=1}^{\infty} (n-1)\, b_{n-1} n\, x^{1+n}$$

$$\sum_{n=0}^{\infty} x^{n+2} b_n (1+n) = \sum_{n=1}^{\infty} b_{n-1} n\, x^{1+n}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $1+n$.

$$\left(\sum_{n=4}^{\infty} 2C a_{-4+n} n\, x^{1+n}\right) + \left(\sum_{n=3}^{\infty} 2C a_{n-3}(1+n)\, x^{1+n}\right) + \sum_{n=3}^{\infty} \left(-5C a_{n-3} x^{1+n}\right) + \left(\sum_{n=1}^{\infty} (n-1)\, b_{n-1} n\, x^{1+n}\right) + \left(\sum_{n=0}^{\infty} n\, x^{1+n} b_n (1+n)\right) + \left(\sum_{n=1}^{\infty} b_{n-1} n\, x^{1+n}\right) + \sum_{n=0}^{\infty} \left(-4x^{1+n} b_n (1+n)\right) + \left(\sum_{n=0}^{\infty} 4 b_n x^{1+n}\right) = 0 \tag{2B}$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0 = 1$. For $n=1$, Eq (2B) gives

$$-2b_1 + b_0 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-2b_1 + 1 = 0$$

Solving the above for b_1 gives

$$b_1 = \frac{1}{2}$$

For $n=2$, Eq (2B) gives

$$4b_1 - 2b_2 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$2 - 2b_2 = 0$$

Solving the above for b_2 gives

$$b_2 = 1$$

For $n=N$, where $N=3$ which is the difference between the two roots, we are free to choose $b_3 = 0$. Hence for $n=3$, Eq (2B) gives

$$3C + 9 = 0$$

Which is solved for C. Solving for C gives

$$C = -3$$

For $n=4$, Eq (2B) gives

$$(8a_0 + 5a_1)\, C + 16b_3 + 4b_4 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$36+4b_4=0$$

Solving the above for b_4 gives

$$b_4=-9$$

For $n=5$, Eq (2B) gives

$$(10a_1+7a_2)\,C+25b_4+10b_5=0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-315+10b_5=0$$

Solving the above for b_5 gives

$$b_5=\frac{63}{2}$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x)=Cy_1(x)\ln(x)+\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)$$

Using the above value found for $C=-3$ and all b_n, then the second solution becomes

$$\begin{aligned}y_2(x)&=(-3)\left(x^4\left(1-4x+10x^2-20x^3+35x^4-56x^5+O\left(x^6\right)\right)\right)\ln(x)\\&\quad+x\left(1+\frac{x}{2}+x^2-9x^4+\frac{63x^5}{2}+O\left(x^6\right)\right)\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}y_h(x)&=c_1y_1(x)+c_2y_2(x)\\&=c_1x^4\left(1-4x+10x^2-20x^3+35x^4-56x^5+O\left(x^6\right)\right)\\&\quad+c_2\Bigg((-3)\left(x^4\left(1-4x+10x^2-20x^3+35x^4-56x^5+O\left(x^6\right)\right)\right)\ln(x)\\&\quad+x\left(1+\frac{x}{2}+x^2-9x^4+\frac{63x^5}{2}+O\left(x^6\right)\right)\Bigg)\end{aligned}$$

Hence the final solution is

$$\begin{aligned}y&=y_h\\&=c_1x^4\left(1-4x+10x^2-20x^3+35x^4-56x^5+O\left(x^6\right)\right)\\&\quad+c_2\Bigg(-3x^4\left(1-4x+10x^2-20x^3+35x^4-56x^5+O\left(x^6\right)\right)\ln(x)\\&\quad+x\left(1+\frac{x}{2}+x^2-9x^4+\frac{63x^5}{2}+O\left(x^6\right)\right)\Bigg)\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 x^4 \left(1-4x+10x^2-20x^3+35x^4-56x^5+O(x^6)\right) + c_2 \left(-3x^4 \left(1-4x+10x^2-20x^3+35x^4-56x^5+O(x^6)\right) \ln(x) + x\left(1+\frac{x}{2}+x^2-9x^4+\frac{63x^5}{2}+O(x^6)\right)\right) \tag{1}$$

Verification of solutions

$$y = c_1 x^4 \left(1-4x+10x^2-20x^3+35x^4-56x^5+O(x^6)\right) + c_2 \left(-3x^4 \left(1-4x+10x^2-20x^3+35x^4-56x^5+O(x^6)\right) \ln(x) + x\left(1+\frac{x}{2}+x^2-9x^4+\frac{63x^5}{2}+O(x^6)\right)\right)$$

Verified OK.

24.14.1 Maple step by step solution

Let's solve

$x^2(x+1)\,y''+(x^2-4x)\,y'+4y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{4y}{x^2(x+1)}-\frac{(x-4)y'}{x(x+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{(x-4)y'}{x(x+1)}+\frac{4y}{x^2(x+1)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{x-4}{x(x+1)}, P_3(x)=\frac{4}{x^2(x+1)}\right]$

  ◦ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

  $\left.\left((x+1)\cdot P_2(x)\right)\right|_{x=-1}=5$

  ◦ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

$$\left((x+1)^2 \cdot P_3(x)\right)\bigg|_{x=-1} = 0$$

- $x = -1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $x^2(x+1)\, y'' + x(x-4)\, y' + 4y = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u = 0$

  $(u^3 - 2u^2 + u)\left(\frac{d^2}{du^2}y(u)\right) + (u^2 - 6u + 5)\left(\frac{d}{du}y(u)\right) + 4y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..3$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(4+r)\, u^{-1+r} + \left(a_1(1+r)\,(5+r) - 2a_0(r^2+2r-2)\right) u^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+1+r)\,(k+5+r)\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(4+r) = 0$

- Values of r that satisfy the indicial equation

$r \in \{-4, 0\}$

- Each term must be 0

  $a_1(1+r)(5+r) - 2a_0(r^2+2r-2) = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_{k-1}(k+r-1)^2 + a_{k+1}(k+1+r)(k+5+r) - 2(k^2+(2r+2)k+r^2+2r-2)a_k = 0$

- Shift index using $k- >k+1$

  $a_k(k+r)^2 + a_{k+2}(k+2+r)(k+6+r) - 2\left((k+1)^2+(2r+2)(k+1)+r^2+2r-2\right)a_{k+1} = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{k^2a_k-2k^2a_{k+1}+2kra_k-4kra_{k+1}+r^2a_k-2r^2a_{k+1}-8ka_{k+1}-8ra_{k+1}-2a_{k+1}}{(k+2+r)(k+6+r)}$

- Recursion relation for $r = -4$

  $a_{k+2} = -\frac{k^2a_k-2k^2a_{k+1}-8ka_k+8ka_{k+1}+16a_k-2a_{k+1}}{(k-2)(k+2)}$

- Series not valid for $r = -4$, division by 0 in the recursion relation at $k = 2$

  $a_{k+2} = -\frac{k^2a_k-2k^2a_{k+1}-8ka_k+8ka_{k+1}+16a_k-2a_{k+1}}{(k-2)(k+2)}$

- Recursion relation for $r = 0$

  $a_{k+2} = -\frac{k^2a_k-2k^2a_{k+1}-8ka_{k+1}-2a_{k+1}}{(k+2)(k+6)}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{k^2a_k-2k^2a_{k+1}-8ka_{k+1}-2a_{k+1}}{(k+2)(k+6)}, 5a_1+4a_0 = 0\right]$

- Revert the change of variables $u = x+1$

  $\left[y = \sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+2} = -\frac{k^2a_k-2k^2a_{k+1}-8ka_{k+1}-2a_{k+1}}{(k+2)(k+6)}, 5a_1+4a_0 = 0\right]$

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 42, page 206
Problem number: 15.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2y'' + x(-x^2+3)\,y' - 3y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + (-x^3+3x)\,y' - 3y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{x^2-3}{x}$$
$$q(x) = -\frac{3}{x^2}$$

Table 707: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x^2-3}{x}$	
singularity	type
$x = 0$	"regular"
$x = \infty$	"regular"
$x = -\infty$	"regular"

$q(x) = -\frac{3}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, \infty, -\infty]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2 y'' + \left(-x^3 + 3x\right) y' - 3y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2 \left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) + \left(-x^3 + 3x\right) \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) - 3\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r+2} a_n(n+r)\right) + \left(\sum_{n=0}^{\infty} 3x^{n+r} a_n(n+r)\right) + \sum_{n=0}^{\infty} \left(-3a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{n+r+2} a_n(n+r)\right) = \sum_{n=2}^{\infty} \left(-a_{n-2}(n+r-2)\, x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right) + \sum_{n=2}^{\infty} \left(-a_{n-2}(n+r-2)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 3x^{n+r} a_n(n+r)\right) + \sum_{n=0}^{\infty} \left(-3a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n(n+r)(n+r-1) + 3x^{n+r} a_n(n+r) - 3a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) + 3x^r a_0 r - 3a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) + 3x^r r - 3x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2 + 2r - 3\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 + 2r - 3 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = -3$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2 + 2r - 3\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 4$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x^3}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+1}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-3}\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n + r)(n + r - 1) - a_{n-2}(n + r - 2) + 3a_n(n + r) - 3a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-2}(n+r-2)}{n^2+2nr+r^2+2n+2r-3} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = \frac{a_{n-2}(n-1)}{n(n+4)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r}{r^2+6r+5}$$

Which for the root $r = 1$ becomes

$$a_2 = \frac{1}{12}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{r}{r^2+6r+5}$	$\frac{1}{12}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{r}{r^2+6r+5}$	$\frac{1}{12}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{r(2+r)}{(r^2+6r+5)(r^2+10r+21)}$$

Which for the root $r = 1$ becomes

$$a_4 = \frac{1}{128}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{r}{r^2+6r+5}$	$\frac{1}{12}$
a_3	0	0
a_4	$\frac{r(2+r)}{(r^2+6r+5)(r^2+10r+21)}$	$\frac{1}{128}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{r}{r^2+6r+5}$	$\frac{1}{12}$
a_3	0	0
a_4	$\frac{r(2+r)}{(r^2+6r+5)(r^2+10r+21)}$	$\frac{1}{128}$
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x\left(1 + \frac{x^2}{12} + \frac{x^4}{128} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 4$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \to r_2} a_4(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_4 \\ &= \frac{r(2+r)}{(r^2+6r+5)(r^2+10r+21)} \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r \to r_2} \frac{r(2+r)}{(r^2+6r+5)(r^2+10r+21)} &= \lim_{r \to -3} \frac{r(2+r)}{(r^2+6r+5)(r^2+10r+21)} \\ &= \textit{undefined} \end{aligned}$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Therefore

$$\begin{aligned} \frac{d}{dx} y_2(x) &= C y_1'(x) \ln(x) + \frac{C y_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) \\ &= C y_1'(x) \ln(x) + \frac{C y_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n (n+r_2)\right) \\ \frac{d^2}{dx^2} y_2(x) &= C y_1''(x) \ln(x) + \frac{2C y_1'(x)}{x} - \frac{C y_1(x)}{x^2} \\ &\quad + \sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right) \\ &= C y_1''(x) \ln(x) + \frac{2C y_1'(x)}{x} - \frac{C y_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n (n+r_2)(-1+n+r_2)\right) \end{aligned}$$

Substituting these back into the given ode $x^2y''+(-x^3+3x)\,y'-3y=0$ gives

$$x^2\left(Cy_1''(x)\ln(x)+\frac{2Cy_1'(x)}{x}-\frac{Cy_1(x)}{x^2}+\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)+(-x^3+3x)\left(Cy_1'(x)\ln(x)+\frac{Cy_1(x)}{x}+\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)\right)-3Cy_1(x)\ln(x)-3\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0$$

Which can be written as

$$\left(\left(x^2y_1''(x)+(-x^3+3x)\,y_1'(x)-3y_1(x)\right)\ln(x)+x^2\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)+\frac{(-x^3+3x)\,y_1(x)}{x}\right)C+x^2\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)+(-x^3+3x)\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)-3\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0 \tag{7}$$

But since $y_1(x)$ is a solution to the ode, then

$$x^2y_1''(x)+(-x^3+3x)\,y_1'(x)-3y_1(x)=0$$

Eq (7) simplifes to

$$\left(x^2\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)+\frac{(-x^3+3x)\,y_1(x)}{x}\right)C+x^2\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)+(-x^3+3x)\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)-3\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0 \tag{8}$$

Substituting $y_1 = \sum_{n=0}^{\infty} a_n x^{n+r_1}$ into the above gives

$$\left(2\left(\sum_{n=0}^{\infty} x^{-1+n+r_1} a_n(n+r_1)\right) x + \left(-x^2+2\right)\left(\sum_{n=0}^{\infty} a_n x^{n+r_1}\right)\right) C \\ + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n(n+r_2)\left(-1+n+r_2\right)\right) x^2 \\ + \left(-x^3+3x\right)\left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n(n+r_2)\right) - 3\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0 \tag{9}$$

Since $r_1 = 1$ and $r_2 = -3$ then the above becomes

$$\left(2\left(\sum_{n=0}^{\infty} x^{n} a_n(n+1)\right) x + \left(-x^2+2\right)\left(\sum_{n=0}^{\infty} a_n x^{n+1}\right)\right) C \\ + \left(\sum_{n=0}^{\infty} x^{-5+n} b_n(n-3)\left(-4+n\right)\right) x^2 \\ + \left(-x^3+3x\right)\left(\sum_{n=0}^{\infty} x^{-4+n} b_n(n-3)\right) - 3\left(\sum_{n=0}^{\infty} b_n x^{n-3}\right) = 0 \tag{10}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2C\, x^{n+1} a_n(n+1)\right) + \sum_{n=0}^{\infty}\left(-C\, x^{n+3} a_n\right) + \left(\sum_{n=0}^{\infty} 2C\, x^{n+1} a_n\right) \\ + \left(\sum_{n=0}^{\infty} x^{n-3} b_n(-4+n)\left(n-3\right)\right) + \sum_{n=0}^{\infty}\left(-x^{n-1} b_n(n-3)\right) \\ + \left(\sum_{n=0}^{\infty} 3x^{n-3} b_n(n-3)\right) + \sum_{n=0}^{\infty}\left(-3b_n x^{n-3}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n-3$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n-3} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2C\, x^{n+1} a_n(n+1) = \sum_{n=4}^{\infty} 2C a_{-4+n}(n-3)\, x^{n-3}$$

$$\sum_{n=0}^{\infty} \left(-C\, x^{n+3} a_n\right) = \sum_{n=6}^{\infty} \left(-C a_{n-6} x^{n-3}\right)$$

$$\sum_{n=0}^{\infty} 2C\, x^{n+1} a_n = \sum_{n=4}^{\infty} 2C a_{-4+n} x^{n-3}$$

$$\sum_{n=0}^{\infty} \left(-x^{n-1} b_n(n-3)\right) = \sum_{n=2}^{\infty} \left(-b_{n-2}(-5+n)\, x^{n-3}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n-3$.

$$\begin{aligned}&\left(\sum_{n=4}^{\infty} 2C a_{-4+n}(n-3)\, x^{n-3}\right) + \sum_{n=6}^{\infty} \left(-C a_{n-6} x^{n-3}\right) + \left(\sum_{n=4}^{\infty} 2C a_{-4+n} x^{n-3}\right) \\ &+ \left(\sum_{n=0}^{\infty} x^{n-3} b_n(-4+n)\,(n-3)\right) + \sum_{n=2}^{\infty} \left(-b_{n-2}(-5+n)\, x^{n-3}\right) \\ &+ \left(\sum_{n=0}^{\infty} 3x^{n-3} b_n(n-3)\right) + \sum_{n=0}^{\infty} \left(-3b_n x^{n-3}\right) = 0\end{aligned} \tag{2B}$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0 = 1$. For $n=1$, Eq (2B) gives

$$-3b_1 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-3b_1 = 0$$

Solving the above for b_1 gives

$$b_1 = 0$$

For $n=2$, Eq (2B) gives

$$-4b_2 + 3b_0 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-4b_2 + 3 = 0$$

Solving the above for b_2 gives

$$b_2 = \frac{3}{4}$$

For $n = 3$, Eq (2B) gives

$$2b_1 - 3b_3 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-3b_3 = 0$$

Solving the above for b_3 gives

$$b_3 = 0$$

For $n = N$, where $N = 4$ which is the difference between the two roots, we are free to choose $b_4 = 0$. Hence for $n = 4$, Eq (2B) gives

$$4C + \frac{3}{4} = 0$$

Which is solved for C. Solving for C gives

$$C = -\frac{3}{16}$$

For $n = 5$, Eq (2B) gives

$$6Ca_1 + 5b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$5b_5 = 0$$

Solving the above for b_5 gives

$$b_5 = 0$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = -\frac{3}{16}$ and all b_n, then the second solution becomes

$$y_2(x) = -\frac{3}{16}\left(x\left(1 + \frac{x^2}{12} + \frac{x^4}{128} + O(x^6)\right)\right)\ln(x) + \frac{1 + \frac{3x^2}{4} + O(x^6)}{x^3}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x \left(1 + \frac{x^2}{12} + \frac{x^4}{128} + O\left(x^6\right)\right) \\
&\quad + c_2 \left(-\frac{3}{16}\left(x\left(1 + \frac{x^2}{12} + \frac{x^4}{128} + O\left(x^6\right)\right)\right)\ln\left(x\right) + \frac{1 + \frac{3x^2}{4} + O(x^6)}{x^3}\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x \left(1 + \frac{x^2}{12} + \frac{x^4}{128} + O\left(x^6\right)\right) \\
&\quad + c_2 \left(-\frac{3x\left(1 + \frac{x^2}{12} + \frac{x^4}{128} + O(x^6)\right)\ln\left(x\right)}{16} + \frac{1 + \frac{3x^2}{4} + O(x^6)}{x^3}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x \left(1 + \frac{x^2}{12} + \frac{x^4}{128} + O\left(x^6\right)\right) \\
&\quad + c_2 \left(-\frac{3x\left(1 + \frac{x^2}{12} + \frac{x^4}{128} + O(x^6)\right)\ln\left(x\right)}{16} + \frac{1 + \frac{3x^2}{4} + O(x^6)}{x^3}\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 x \left(1 + \frac{x^2}{12} + \frac{x^4}{128} + O\left(x^6\right)\right) \\
&\quad + c_2 \left(-\frac{3x\left(1 + \frac{x^2}{12} + \frac{x^4}{128} + O(x^6)\right)\ln\left(x\right)}{16} + \frac{1 + \frac{3x^2}{4} + O(x^6)}{x^3}\right)
\end{aligned}
$$

Verified OK.

24.15.1 Maple step by step solution

Let's solve

$x^2y'' + (-x^3 + 3x)\, y' - 3y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{3y}{x^2} + \frac{(x^2-3)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{(x^2-3)y'}{x} - \frac{3y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -\frac{x^2-3}{x}, P_3(x) = -\frac{3}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\Big|_{x=0} = 3$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\Big|_{x=0} = -3$

  ◦ $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $x^2y'' - x(x^2 - 3)\, y' - 3y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k + r)\, x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $x^{m}\cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^{2}\cdot y''$ to series expansion

  $x^{2}\cdot y'' = \sum_{k=0}^{\infty} a_{k}(k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_{0}(3+r)\,(-1+r)\, x^{r} + a_{1}(4+r)\, r\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_{k}(k+r+3)\,(k+r-1) - a_{k-2}(k-2+r)\right) x^{k-}\right.$

- a_{0}cannot be 0 by assumption, giving the indicial equation

  $(3+r)\,(-1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-3, 1\}$

- Each term must be 0

  $a_{1}(4+r)\, r = 0$

- Solve for the dependent coefficient(s)

  $a_{1} = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_{k}(k+r+3)\,(k+r-1) - a_{k-2}(k-2+r) = 0$

- Shift index using $k->k+2$

  $a_{k+2}(k+5+r)\,(k+1+r) - a_{k}(k+r) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{a_{k}(k+r)}{(k+5+r)(k+1+r)}$

- Recursion relation for $r=-3$

  $a_{k+2} = \frac{a_{k}(k-3)}{(k+2)(k-2)}$

- Series not valid for $r=-3$, division by 0 in the recursion relation at $k=2$

  $a_{k+2} = \frac{a_{k}(k-3)}{(k+2)(k-2)}$

- Recursion relation for $r=1$

  $a_{k+2} = \frac{a_{k}(k+1)}{(k+6)(k+2)}$

- Solution for $r=1$

$$\left[y=\sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2}=\frac{a_k(k+1)}{(k+6)(k+2)}, a_1=0\right]$$

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y''x + 3y' - y = x}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$y''x + 3y' - y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{3}{x}$$
$$q(x) = -\frac{1}{x}$$

Table 709: Table $p(x), q(x)$ singularites.

$p(x) = \frac{3}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = -\frac{1}{x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$y''x + 3y' - y = x$$

Since this is an inhomogeneous, then let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ode $y''x+3y'-y = 0$, and y_p is a particular solution to the inhomogeneous ode.which is found using the balance equation generated from indicial equation

First, we solve for y_h Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x + 3\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)\,(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 3(n+r)\, a_n x^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = \sum_{n=1}^{\infty} \left(-a_{n-1} x^{n+r-1}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 3(n+r) a_n x^{n+r-1}\right) + \sum_{n=1}^{\infty} \left(-a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r-1} a_n (n+r)(n+r-1) + 3(n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$x^{-1+r} a_0 r(-1+r) + 3r a_0 x^{-1+r} = 0$$

Or

$$\left(x^{-1+r} r(-1+r) + 3r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, x^{-1+r}(2+r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$r(2+r) = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = -2$$

The corresponding balance equation is found by replacing r by m and a by c to avoid confusing terms between particular solution and the homogeneous solution. Hence the balance equation is

$$\left(x^{-1+m} m(-1+m) + 3m\, x^{-1+m}\right) c_0 = x$$

This equation will used later to find the particular solution.

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\,x^{-1+r}(2+r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 2$ is an integer, then we can construct two linearly independent solutions

$$\begin{aligned} y_1(x) &= x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= C y_1(x)\ln(x) + x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right) \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= \sum_{n=0}^{\infty} a_n x^n \\ y_2(x) &= C y_1(x)\ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x^2} \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= \sum_{n=0}^{\infty} a_n x^n \\ y_2(x) &= C y_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-2}\right) \end{aligned}$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + 3a_n(n+r) - a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}}{n^2 + 2nr + r^2 + 2n + 2r} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = \frac{a_{n-1}}{n\,(n+2)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{1}{r^2 + 4r + 3}$$

Which for the root $r = 0$ becomes

$$a_1 = \frac{1}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r^2+4r+3}$	$\frac{1}{3}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{r^4 + 10r^3 + 35r^2 + 50r + 24}$$

Which for the root $r = 0$ becomes

$$a_2 = \frac{1}{24}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r^2+4r+3}$	$\frac{1}{3}$
a_2	$\frac{1}{r^4+10r^3+35r^2+50r+24}$	$\frac{1}{24}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{1}{\left(r+3\right)^2 \left(r+1\right) \left(r+4\right) \left(2+r\right) \left(r+5\right)}$$

Which for the root $r = 0$ becomes

$$a_3 = \frac{1}{360}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r^2+4r+3}$	$\frac{1}{3}$
a_2	$\frac{1}{r^4+10r^3+35r^2+50r+24}$	$\frac{1}{24}$
a_3	$\frac{1}{(r+3)^2(r+1)(r+4)(2+r)(r+5)}$	$\frac{1}{360}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{\left(r+3\right)^2 \left(r+1\right) \left(r+4\right)^2 \left(2+r\right) \left(r+5\right) \left(r+6\right)}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{8640}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r^2+4r+3}$	$\frac{1}{3}$
a_2	$\frac{1}{r^4+10r^3+35r^2+50r+24}$	$\frac{1}{24}$
a_3	$\frac{1}{(r+3)^2(r+1)(r+4)(2+r)(r+5)}$	$\frac{1}{360}$
a_4	$\frac{1}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)(r+6)}$	$\frac{1}{8640}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{1}{\left(r+3\right)^2 \left(r+1\right) \left(r+4\right)^2 \left(2+r\right) \left(r+5\right)^2 \left(r+6\right) \left(7+r\right)}$$

Which for the root $r = 0$ becomes

$$a_5 = \frac{1}{302400}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r^2+4r+3}$	$\frac{1}{3}$
a_2	$\frac{1}{r^4+10r^3+35r^2+50r+24}$	$\frac{1}{24}$
a_3	$\frac{1}{(r+3)^2(r+1)(r+4)(2+r)(r+5)}$	$\frac{1}{360}$
a_4	$\frac{1}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)(r+6)}$	$\frac{1}{8640}$
a_5	$\frac{1}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)^2(r+6)(7+r)}$	$\frac{1}{302400}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}y_1(x) &= a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \ldots \\ &= 1 + \frac{x}{3} + \frac{x^2}{24} + \frac{x^3}{360} + \frac{x^4}{8640} + \frac{x^5}{302400} + O\left(x^6\right)\end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 2$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \to r_2} a_2(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned}a_N &= a_2 \\ &= \frac{1}{r^4 + 10r^3 + 35r^2 + 50r + 24}\end{aligned}$$

Therefore

$$\begin{aligned}\lim_{r \to r_2} \frac{1}{r^4 + 10r^3 + 35r^2 + 50r + 24} &= \lim_{r \to -2} \frac{1}{r^4 + 10r^3 + 35r^2 + 50r + 24} \\ &= \mathit{undefined}\end{aligned}$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Therefore

$$
\begin{aligned}
\frac{d}{dx}y_2(x) &= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) \\
&= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n (n+r_2)\right) \\
\frac{d^2}{dx^2}y_2(x) &= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} \\
&\quad + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right) \\
&= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n (n+r_2)(-1+n+r_2)\right)
\end{aligned}
$$

Substituting these back into the given ode $y''x + 3y' - y = 0$ gives

$$
\begin{aligned}
&\left(Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2}\right. \\
&\left. + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x + 3Cy_1'(x)\ln(x) \\
&+ \frac{3Cy_1(x)}{x} + 3\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right) - Cy_1(x)\ln(x) - \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0
\end{aligned}
$$

Which can be written as

$$
\begin{aligned}
&\left((y_1''(x)\,x - y_1(x) + 3y_1'(x))\ln(x) + \left(\frac{2y_1'(x)}{x} - \frac{y_1(x)}{x^2}\right)x + \frac{3y_1(x)}{x}\right)C \\
&+ \left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x \\
&+ 3\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right) - \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0
\end{aligned} \tag{7}
$$

But since $y_1(x)$ is a solution to the ode, then

$$
y_1''(x)\,x - y_1(x) + 3y_1'(x) = 0
$$

Eq (7) simplifes to

$$\left(\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)x+\frac{3y_1(x)}{x}\right)C + \left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x + 3\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)-\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0 \tag{8}$$

Substituting $y_1=\sum_{n=0}^{\infty}a_n x^{n+r_1}$ into the above gives

$$\frac{\left(2\left(\sum_{n=0}^{\infty}x^{-1+n+r_1}a_n(n+r_1)\right)x+2\left(\sum_{n=0}^{\infty}a_n x^{n+r_1}\right)\right)C}{x} + \frac{\left(\sum_{n=0}^{\infty}x^{-2+n+r_2}b_n(n+r_2)(-1+n+r_2)\right)x^2-\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)x+3\left(\sum_{n=0}^{\infty}x^{-1+n+r_2}b_n(n+r_2)\right)x}{x} = 0 \tag{9}$$

Since $r_1=0$ and $r_2=-2$ then the above becomes

$$\frac{\left(2\left(\sum_{n=0}^{\infty}x^{n-1}a_n n\right)x+2\left(\sum_{n=0}^{\infty}a_n x^{n}\right)\right)C}{x} + \frac{\left(\sum_{n=0}^{\infty}x^{-4+n}b_n(n-2)(-3+n)\right)x^2-\left(\sum_{n=0}^{\infty}b_n x^{n-2}\right)x+3\left(\sum_{n=0}^{\infty}x^{-3+n}b_n(n-2)\right)x}{x}=0 \tag{10}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty}2C\,x^{n-1}a_n n\right)+\left(\sum_{n=0}^{\infty}2C\,x^{n-1}a_n\right)+\left(\sum_{n=0}^{\infty}x^{-3+n}b_n\left(n^2-5n+6\right)\right) + \sum_{n=0}^{\infty}\left(-b_n x^{n-2}\right)+\left(\sum_{n=0}^{\infty}3x^{-3+n}b_n(n-2)\right)=0 \tag{2A}$$

The next step is to make all powers of x be $-3+n$ in each summation term. Going over each summation term above with power of x in it which is not already x^{-3+n} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2C\, x^{n-1} a_n n = \sum_{n=2}^{\infty} 2C(n-2)\, a_{n-2} x^{-3+n}$$

$$\sum_{n=0}^{\infty} 2C\, x^{n-1} a_n = \sum_{n=2}^{\infty} 2C a_{n-2} x^{-3+n}$$

$$\sum_{n=0}^{\infty} \left(-b_n x^{n-2}\right) = \sum_{n=1}^{\infty} \left(-b_{n-1} x^{-3+n}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $-3+n$.

$$\left(\sum_{n=2}^{\infty} 2C(n-2)\, a_{n-2} x^{-3+n}\right) + \left(\sum_{n=2}^{\infty} 2C a_{n-2} x^{-3+n}\right) + \left(\sum_{n=0}^{\infty} x^{-3+n} b_n \left(n^2-5n+6\right)\right) + \sum_{n=1}^{\infty} \left(-b_{n-1} x^{-3+n}\right) + \left(\sum_{n=0}^{\infty} 3x^{-3+n} b_n (n-2)\right) = 0 \tag{2B}$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0=1$. For $n=1$, Eq (2B) gives

$$-b_1 - b_0 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-b_1 - 1 = 0$$

Solving the above for b_1 gives

$$b_1 = -1$$

For $n=N$, where $N=2$ which is the difference between the two roots, we are free to choose $b_2=0$. Hence for $n=2$, Eq (2B) gives

$$2C + 1 = 0$$

Which is solved for C. Solving for C gives

$$C = -\frac{1}{2}$$

For $n = 3$, Eq (2B) gives

$$4Ca_1 - b_2 + 3b_3 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$3b_3 - \frac{2}{3} = 0$$

Solving the above for b_3 gives

$$b_3 = \frac{2}{9}$$

For $n = 4$, Eq (2B) gives

$$6Ca_2 - b_3 + 8b_4 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$8b_4 - \frac{25}{72} = 0$$

Solving the above for b_4 gives

$$b_4 = \frac{25}{576}$$

For $n = 5$, Eq (2B) gives

$$8Ca_3 - b_4 + 15b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$15b_5 - \frac{157}{2880} = 0$$

Solving the above for b_5 gives

$$b_5 = \frac{157}{43200}$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = -\frac{1}{2}$ and all b_n, then the second solution becomes

$$y_2(x) = -\frac{1}{2}\left(1 + \frac{x}{3} + \frac{x^2}{24} + \frac{x^3}{360} + \frac{x^4}{8640} + \frac{x^5}{302400} + O(x^6)\right)\ln(x) + \frac{1 - x + \frac{2x^3}{9} + \frac{25x^4}{576} + \frac{157x^5}{43200} + O(x^6)}{x^2}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 \left(1 + \frac{x}{3} + \frac{x^2}{24} + \frac{x^3}{360} + \frac{x^4}{8640} + \frac{x^5}{302400} + O(x^6)\right) \\
&+ c_2 \left(-\frac{1}{2}\left(1 + \frac{x}{3} + \frac{x^2}{24} + \frac{x^3}{360} + \frac{x^4}{8640} + \frac{x^5}{302400} + O(x^6)\right) \ln(x) \right. \\
&\left. + \frac{1 - x + \frac{2x^3}{9} + \frac{25x^4}{576} + \frac{157x^5}{43200} + O(x^6)}{x^2}\right)
\end{aligned}
$$

The particular solution is found by solving for c, m the balance equation

$$
\left(x^{-1+m} m(-1+m) + 3m\, x^{-1+m}\right) c_0 = F
$$

Where $F(x)$ is the RHS of the ode. If $F(x)$ has more than one term, then this is done for each term one at a time and then all the particular solutions are added. The function $F(x)$ will be converted to series if needed. in order to solve for c_n, m for each term, the same recursive relation used to find $y_h(x)$ is used to find c_n, m which is used to find the particular solution $\sum_{n=0} c_n x^{n+m}$ by replacing a_n by c_n and r by m.

The following are the values of a_n found in terms of the indicial root r.

$$
\boxed{
\begin{aligned}
a_1 &= \frac{a_0}{r^2+4r+3} \\
a_2 &= \frac{a_0}{(r^2+4r+3)(r^2+6r+8)} \\
a_3 &= \frac{a_0}{(r+3)^2 (r+1)(r+4)(2+r)(r+5)} \\
a_4 &= \frac{a_0}{(r+3)^2 (r+1)(r+4)^2 (2+r)(r+5)(r+6)} \\
a_5 &= \frac{a_0}{(r+3)^2 (r+1)(r+4)^2 (2+r)(r+5)^2 (r+6)(7+r)}
\end{aligned}
}
$$

Now we determine the particular solution y_p associated with $F = x$ by solving the balance equation

$$
\left(x^{-1+m} m(-1+m) + 3m\, x^{-1+m}\right) c_0 = x
$$

For c_0 and x. This results in

$$
\begin{aligned}
c_0 &= \frac{1}{8} \\
m &= 2
\end{aligned}
$$

The particular solution is therefore

$$\begin{aligned} y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\ &= \sum_{n=0}^{\infty} c_n x^{n+2} \end{aligned}$$

Where in the above $c_0 = \frac{1}{8}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 2$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{8}$ and $r = m$ or $r = 2$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$$\boxed{\begin{aligned} c_0 &= \frac{1}{8} \\ c_1 &= \frac{1}{120} \\ c_2 &= \frac{1}{2880} \\ c_3 &= \frac{1}{100800} \\ c_4 &= \frac{1}{4838400} \\ c_5 &= \frac{1}{304819200} \end{aligned}}$$

The particular solution is now found using

$$\begin{aligned} y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\ &= x^2 \sum_{n=0}^{\infty} c_n x^n \end{aligned}$$

Using the values found above for c_n into the above sum gives

$$\begin{aligned} y_p &= x^2 \left(\frac{1}{8} + \frac{1}{120} x + \frac{1}{2880} x^2 + \frac{1}{100800} x^3 + \frac{1}{4838400} x^4 + \frac{1}{304819200} x^5 \right) \\ &= \frac{1}{8} x^2 + \frac{1}{120} x^3 + \frac{1}{2880} x^4 + \frac{1}{100800} x^5 + \frac{1}{4838400} x^6 + \frac{1}{304819200} x^7 \end{aligned}$$

Adding all the above particular solution(s) gives

$$y_p = \frac{x^2}{8}+\frac{x^3}{120}+\frac{x^4}{2880}+\frac{x^5}{100800}+\frac{x^6}{4838400}+\frac{x^7}{304819200}+O(x^6)$$

Truncating the particular solution to the order of series requested gives

$$y_p = \frac{x^2}{8}+\frac{x^3}{120}+\frac{x^4}{2880}+\frac{x^5}{100800}+O(x^6)$$

Hence the final solution is

$y = y_h + y_p$

$$= \frac{x^2}{8}+\frac{x^3}{120}+\frac{x^4}{2880}+\frac{x^5}{100800}+O(x^6)+c_1\left(1+\frac{x}{3}+\frac{x^2}{24}+\frac{x^3}{360}+\frac{x^4}{8640}+\frac{x^5}{302400}+O(x^6)\right) + c_2\left(\left(-\frac{1}{2}-\frac{x}{6}-\frac{x^2}{48}-\frac{x^3}{720}-\frac{x^4}{17280}-\frac{x^5}{604800}-\frac{O(x^6)}{2}\right)\ln(x) + \frac{1-x+\frac{2x^3}{9}+\frac{25x^4}{576}+\frac{157x^5}{43200}+O(x^6)}{x^2}\right)$$

Summary

The solution(s) found are the following

$$y = \frac{x^2}{8}+\frac{x^3}{120}+\frac{x^4}{2880}+\frac{x^5}{100800}+O(x^6) + c_1\left(1+\frac{x}{3}+\frac{x^2}{24}+\frac{x^3}{360}+\frac{x^4}{8640}+\frac{x^5}{302400}+O(x^6)\right) + c_2\left(\left(-\frac{1}{2}-\frac{x}{6}-\frac{x^2}{48}-\frac{x^3}{720}-\frac{x^4}{17280}-\frac{x^5}{604800}-\frac{O(x^6)}{2}\right)\ln(x) + \frac{1-x+\frac{2x^3}{9}+\frac{25x^4}{576}+\frac{157x^5}{43200}+O(x^6)}{x^2}\right) \tag{1}$$

Verification of solutions

$$y = \frac{x^2}{8}+\frac{x^3}{120}+\frac{x^4}{2880}+\frac{x^5}{100800}+O(x^6)+c_1\left(1+\frac{x}{3}+\frac{x^2}{24}+\frac{x^3}{360}+\frac{x^4}{8640}+\frac{x^5}{302400}+O(x^6)\right) + c_2\left(\left(-\frac{1}{2}-\frac{x}{6}-\frac{x^2}{48}-\frac{x^3}{720}-\frac{x^4}{17280}-\frac{x^5}{604800}-\frac{O(x^6)}{2}\right)\ln(x) + \frac{1-x+\frac{2x^3}{9}+\frac{25x^4}{576}+\frac{157x^5}{43200}+O(x^6)}{x^2}\right)$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 43, page 209
Problem number: 1.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y''x + 3y' - y = x}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$y''x + 3y' - y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{3}{x}$$
$$q(x) = -\frac{1}{x}$$

Table 710: Table $p(x), q(x)$ singularites.

$p(x) = \frac{3}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = -\frac{1}{x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$y''x + 3y' - y = x$$

Since this is an inhomogeneous, then let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ode $y''x+3y'-y = 0$, and y_p is a particular solution to the inhomogeneous ode.which is found using the balance equation generated from indicial equation

First, we solve for y_h Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x + 3\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 3(n+r) a_n x^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty}\left(-a_n x^{n+r}\right) = \sum_{n=1}^{\infty}\left(-a_{n-1} x^{n+r-1}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 3(n+r) a_n x^{n+r-1}\right) + \sum_{n=1}^{\infty}\left(-a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r-1} a_n (n+r)(n+r-1) + 3(n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$x^{-1+r} a_0 r(-1+r) + 3r a_0 x^{-1+r} = 0$$

Or

$$\left(x^{-1+r} r(-1+r) + 3r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, x^{-1+r}(2+r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$r(2+r) = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = -2$$

The corresponding balance equation is found by replacing r by m and a by c to avoid confusing terms between particular solution and the homogeneous solution. Hence the balance equation is

$$\left(x^{-1+m} m(-1+m) + 3m\, x^{-1+m}\right) c_0 = x$$

This equation will used later to find the particular solution.

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\,x^{-1+r}(2+r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 2$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x)\ln(x) + x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^n$$
$$y_2(x) = C y_1(x)\ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x^2}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^n$$
$$y_2(x) = C y_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-2}\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + 3a_n(n+r) - a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}}{n^2 + 2nr + r^2 + 2n + 2r} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = \frac{a_{n-1}}{n(n+2)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{1}{r^2 + 4r + 3}$$

Which for the root $r = 0$ becomes

$$a_1 = \frac{1}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r^2+4r+3}$	$\frac{1}{3}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{r^4 + 10r^3 + 35r^2 + 50r + 24}$$

Which for the root $r = 0$ becomes

$$a_2 = \frac{1}{24}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r^2+4r+3}$	$\frac{1}{3}$
a_2	$\frac{1}{r^4+10r^3+35r^2+50r+24}$	$\frac{1}{24}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{1}{\left(r+3\right)^2 \left(r+1\right) \left(r+4\right) \left(2+r\right) \left(r+5\right)}$$

Which for the root $r = 0$ becomes

$$a_3 = \frac{1}{360}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r^2+4r+3}$	$\frac{1}{3}$
a_2	$\frac{1}{r^4+10r^3+35r^2+50r+24}$	$\frac{1}{24}$
a_3	$\frac{1}{(r+3)^2(r+1)(r+4)(2+r)(r+5)}$	$\frac{1}{360}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{(r+3)^2 (r+1) (r+4)^2 (2+r) (r+5) (r+6)}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{8640}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r^2+4r+3}$	$\frac{1}{3}$
a_2	$\frac{1}{r^4+10r^3+35r^2+50r+24}$	$\frac{1}{24}$
a_3	$\frac{1}{(r+3)^2(r+1)(r+4)(2+r)(r+5)}$	$\frac{1}{360}$
a_4	$\frac{1}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)(r+6)}$	$\frac{1}{8640}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{1}{(r+3)^2 (r+1) (r+4)^2 (2+r) (r+5)^2 (r+6) (7+r)}$$

Which for the root $r = 0$ becomes

$$a_5 = \frac{1}{302400}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r^2+4r+3}$	$\frac{1}{3}$
a_2	$\frac{1}{r^4+10r^3+35r^2+50r+24}$	$\frac{1}{24}$
a_3	$\frac{1}{(r+3)^2(r+1)(r+4)(2+r)(r+5)}$	$\frac{1}{360}$
a_4	$\frac{1}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)(r+6)}$	$\frac{1}{8640}$
a_5	$\frac{1}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)^2(r+6)(7+r)}$	$\frac{1}{302400}$

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots \\
&= 1 + \frac{x}{3} + \frac{x^2}{24} + \frac{x^3}{360} + \frac{x^4}{8640} + \frac{x^5}{302400} + O(x^6)
\end{aligned}
$$

Now the second solution $y_2(x)$ is found. Let

$$
r_1 - r_2 = N
$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 2$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \rightarrow r_2} a_2(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$
\begin{aligned}
a_N &= a_2 \\
&= \frac{1}{r^4 + 10r^3 + 35r^2 + 50r + 24}
\end{aligned}
$$

Therefore

$$
\begin{aligned}
\lim_{r \rightarrow r_2} \frac{1}{r^4 + 10r^3 + 35r^2 + 50r + 24} &= \lim_{r \rightarrow -2} \frac{1}{r^4 + 10r^3 + 35r^2 + 50r + 24} \\
&= \textit{undefined}
\end{aligned}
$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$
y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2} \right)
$$

Therefore

$$
\begin{aligned}
\frac{d}{dx}y_2(x) &= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) \\
&= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n(n+r_2)\right) \\
\frac{d^2}{dx^2}y_2(x) &= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} \\
&\quad + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right) \\
&= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n(n+r_2)(-1+n+r_2)\right)
\end{aligned}
$$

Substituting these back into the given ode $y''x + 3y' - y = 0$ gives

$$
\begin{aligned}
&\left(Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2}\right. \\
&\left. + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right) x + 3Cy_1'(x)\ln(x) \\
&+ \frac{3Cy_1(x)}{x} + 3\left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) - Cy_1(x)\ln(x) - \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0
\end{aligned}
$$

Which can be written as

$$
\begin{aligned}
&\left(\left(y_1''(x)\,x - y_1(x) + 3y_1'(x)\right)\ln(x) + \left(\frac{2y_1'(x)}{x} - \frac{y_1(x)}{x^2}\right)x + \frac{3y_1(x)}{x}\right)C \\
&+ \left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x \\
&+ 3\left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) - \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0
\end{aligned} \tag{7}
$$

But since $y_1(x)$ is a solution to the ode, then

$$
y_1''(x)\,x - y_1(x) + 3y_1'(x) = 0
$$

Eq (7) simplifes to

$$\left(\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)x+\frac{3y_1(x)}{x}\right)C \\ +\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x \\ +3\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)-\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0 \tag{8}$$

Substituting $y_1=\sum_{n=0}^{\infty}a_n x^{n+r_1}$ into the above gives

$$\frac{\left(2\left(\sum_{n=0}^{\infty}x^{-1+n+r_1}a_n(n+r_1)\right)x+2\left(\sum_{n=0}^{\infty}a_n x^{n+r_1}\right)\right)C}{x} \\ +\frac{\left(\sum_{n=0}^{\infty}x^{-2+n+r_2}b_n(n+r_2)(-1+n+r_2)\right)x^2+3\left(\sum_{n=0}^{\infty}x^{-1+n+r_2}b_n(n+r_2)\right)x-\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)x}{x} \\ =0 \tag{9}$$

Since $r_1=0$ and $r_2=-2$ then the above becomes

$$\frac{\left(2\left(\sum_{n=0}^{\infty}x^{n-1}a_n n\right)x+2\left(\sum_{n=0}^{\infty}a_n x^{n}\right)\right)C}{x} \\ +\frac{\left(\sum_{n=0}^{\infty}x^{-4+n}b_n(n-2)(-3+n)\right)x^2+3\left(\sum_{n=0}^{\infty}x^{-3+n}b_n(n-2)\right)x-\left(\sum_{n=0}^{\infty}b_n x^{n-2}\right)x}{x}=0 \tag{10}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty}2C\,x^{n-1}a_n n\right)+\left(\sum_{n=0}^{\infty}2C\,x^{n-1}a_n\right)+\left(\sum_{n=0}^{\infty}x^{-3+n}b_n\left(n^2-5n+6\right)\right) \\ +\left(\sum_{n=0}^{\infty}3x^{-3+n}b_n(n-2)\right)+\sum_{n=0}^{\infty}\left(-b_n x^{n-2}\right)=0 \tag{2A}$$

The next step is to make all powers of x be $-3+n$ in each summation term. Going over each summation term above with power of x in it which is not already x^{-3+n} and adjusting the power and the corresponding index gives

$$\begin{aligned}
\sum_{n=0}^{\infty} 2C\, x^{n-1} a_n n &= \sum_{n=2}^{\infty} 2C(n-2)\, a_{n-2} x^{-3+n} \\
\sum_{n=0}^{\infty} 2C\, x^{n-1} a_n &= \sum_{n=2}^{\infty} 2C a_{n-2} x^{-3+n} \\
\sum_{n=0}^{\infty} \left(-b_n x^{n-2}\right) &= \sum_{n=1}^{\infty} \left(-b_{n-1} x^{-3+n}\right)
\end{aligned}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $-3+n$.

$$\begin{aligned}
&\left(\sum_{n=2}^{\infty} 2C(n-2)\, a_{n-2} x^{-3+n}\right) + \left(\sum_{n=2}^{\infty} 2C a_{n-2} x^{-3+n}\right) \\
&+ \left(\sum_{n=0}^{\infty} x^{-3+n} b_n \left(n^2-5n+6\right)\right) \\
&+ \left(\sum_{n=0}^{\infty} 3x^{-3+n} b_n (n-2)\right) + \sum_{n=1}^{\infty} \left(-b_{n-1} x^{-3+n}\right) = 0
\end{aligned} \tag{2B}$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0=1$. For $n=1$, Eq (2B) gives

$$-b_1 - b_0 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-b_1 - 1 = 0$$

Solving the above for b_1 gives

$$b_1 = -1$$

For $n=N$, where $N=2$ which is the difference between the two roots, we are free to choose $b_2=0$. Hence for $n=2$, Eq (2B) gives

$$2C + 1 = 0$$

Which is solved for C. Solving for C gives

$$C = -\frac{1}{2}$$

For $n = 3$, Eq (2B) gives

$$4Ca_1 - b_2 + 3b_3 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$3b_3 - \frac{2}{3} = 0$$

Solving the above for b_3 gives

$$b_3 = \frac{2}{9}$$

For $n = 4$, Eq (2B) gives

$$6Ca_2 - b_3 + 8b_4 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$8b_4 - \frac{25}{72} = 0$$

Solving the above for b_4 gives

$$b_4 = \frac{25}{576}$$

For $n = 5$, Eq (2B) gives

$$8Ca_3 - b_4 + 15b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$15b_5 - \frac{157}{2880} = 0$$

Solving the above for b_5 gives

$$b_5 = \frac{157}{43200}$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = -\frac{1}{2}$ and all b_n, then the second solution becomes

$$y_2(x) = -\frac{1}{2}\left(1 + \frac{x}{3} + \frac{x^2}{24} + \frac{x^3}{360} + \frac{x^4}{8640} + \frac{x^5}{302400} + O(x^6)\right)\ln(x) + \frac{1 - x + \frac{2x^3}{9} + \frac{25x^4}{576} + \frac{157x^5}{43200} + O(x^6)}{x^2}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1\left(1+\frac{x}{3}+\frac{x^2}{24}+\frac{x^3}{360}+\frac{x^4}{8640}+\frac{x^5}{302400}+O(x^6)\right) \\
&\quad + c_2\left(-\frac{1}{2}\left(1+\frac{x}{3}+\frac{x^2}{24}+\frac{x^3}{360}+\frac{x^4}{8640}+\frac{x^5}{302400}+O(x^6)\right)\ln(x)\right. \\
&\quad \left. + \frac{1-x+\frac{2x^3}{9}+\frac{25x^4}{576}+\frac{157x^5}{43200}+O(x^6)}{x^2}\right)
\end{aligned}
$$

The particular solution is found by solving for c, m the balance equation

$$
\left(x^{-1+m} m(-1+m) + 3m\, x^{-1+m}\right) c_0 = F
$$

Where $F(x)$ is the RHS of the ode. If $F(x)$ has more than one term, then this is done for each term one at a time and then all the particular solutions are added. The function $F(x)$ will be converted to series if needed. in order to solve for c_n, m for each term, the same recursive relation used to find $y_h(x)$ is used to find c_n, m which is used to find the particular solution $\sum_{n=0} c_n x^{n+m}$ by replacing a_n by c_n and r by m.

The following are the values of a_n found in terms of the indicial root r.

$$
\boxed{
\begin{aligned}
a_1 &= \frac{a_0}{r^2+4r+3} \\
a_2 &= \frac{a_0}{(r^2+4r+3)(r^2+6r+8)} \\
a_3 &= \frac{a_0}{(r+3)^2 (r+1)(r+4)(2+r)(r+5)} \\
a_4 &= \frac{a_0}{(r+3)^2 (r+1)(r+4)^2 (2+r)(r+5)(r+6)} \\
a_5 &= \frac{a_0}{(r+3)^2 (r+1)(r+4)^2 (2+r)(r+5)^2 (r+6)(7+r)}
\end{aligned}
}
$$

Now we determine the particular solution y_p associated with $F = x$ by solving the balance equation

$$
\left(x^{-1+m} m(-1+m) + 3m\, x^{-1+m}\right) c_0 = x
$$

For c_0 and x. This results in

$$
\begin{aligned}
c_0 &= \frac{1}{8} \\
m &= 2
\end{aligned}
$$

The particular solution is therefore

$$
\begin{aligned}
y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\
&= \sum_{n=0}^{\infty} c_n x^{n+2}
\end{aligned}
$$

Where in the above $c_0 = \frac{1}{8}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 2$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{8}$ and $r = m$ or $r = 2$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$$
\boxed{
\begin{aligned}
c_0 &= \frac{1}{8} \\
c_1 &= \frac{1}{120} \\
c_2 &= \frac{1}{2880} \\
c_3 &= \frac{1}{100800} \\
c_4 &= \frac{1}{4838400} \\
c_5 &= \frac{1}{304819200}
\end{aligned}
}
$$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\
&= x^2 \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x^2 \left(\frac{1}{8} + \frac{1}{120} x + \frac{1}{2880} x^2 + \frac{1}{100800} x^3 + \frac{1}{4838400} x^4 + \frac{1}{304819200} x^5\right) \\
&= \frac{1}{8} x^2 + \frac{1}{120} x^3 + \frac{1}{2880} x^4 + \frac{1}{100800} x^5 + \frac{1}{4838400} x^6 + \frac{1}{304819200} x^7
\end{aligned}
$$

Adding all the above particular solution(s) gives

$$y_p = \frac{x^2}{8}+\frac{x^3}{120}+\frac{x^4}{2880}+\frac{x^5}{100800}+\frac{x^6}{4838400}+\frac{x^7}{304819200}+O\left(x^6\right)$$

Truncating the particular solution to the order of series requested gives

$$y_p = \frac{x^2}{8}+\frac{x^3}{120}+\frac{x^4}{2880}+\frac{x^5}{100800}+O\left(x^6\right)$$

Hence the final solution is

$y = y_h + y_p$

$$= \frac{x^2}{8}+\frac{x^3}{120}+\frac{x^4}{2880}+\frac{x^5}{100800}+O\left(x^6\right)+c_1\left(1+\frac{x}{3}+\frac{x^2}{24}+\frac{x^3}{360}+\frac{x^4}{8640}+\frac{x^5}{302400}+O\left(x^6\right)\right) + c_2\left(\left(-\frac{1}{2}-\frac{x}{6}-\frac{x^2}{48}-\frac{x^3}{720}-\frac{x^4}{17280}-\frac{x^5}{604800}-\frac{O(x^6)}{2}\right)\ln\left(x\right) + \frac{1-x+\frac{2x^3}{9}+\frac{25x^4}{576}+\frac{157x^5}{43200}+O(x^6)}{x^2}\right)$$

Summary

The solution(s) found are the following

$$y = \frac{x^2}{8}+\frac{x^3}{120}+\frac{x^4}{2880}+\frac{x^5}{100800}+O\left(x^6\right) + c_1\left(1+\frac{x}{3}+\frac{x^2}{24}+\frac{x^3}{360}+\frac{x^4}{8640}+\frac{x^5}{302400}+O\left(x^6\right)\right) + c_2\left(\left(-\frac{1}{2}-\frac{x}{6}-\frac{x^2}{48}-\frac{x^3}{720}-\frac{x^4}{17280}-\frac{x^5}{604800}-\frac{O(x^6)}{2}\right)\ln\left(x\right) + \frac{1-x+\frac{2x^3}{9}+\frac{25x^4}{576}+\frac{157x^5}{43200}+O(x^6)}{x^2}\right) \tag{1}$$

Verification of solutions

$$y = \frac{x^2}{8}+\frac{x^3}{120}+\frac{x^4}{2880}+\frac{x^5}{100800}+O\left(x^6\right)+c_1\left(1+\frac{x}{3}+\frac{x^2}{24}+\frac{x^3}{360}+\frac{x^4}{8640}+\frac{x^5}{302400}+O\left(x^6\right)\right) + c_2\left(\left(-\frac{1}{2}-\frac{x}{6}-\frac{x^2}{48}-\frac{x^3}{720}-\frac{x^4}{17280}-\frac{x^5}{604800}-\frac{O(x^6)}{2}\right)\ln\left(x\right) + \frac{1-x+\frac{2x^3}{9}+\frac{25x^4}{576}+\frac{157x^5}{43200}+O(x^6)}{x^2}\right)$$

Verified OK.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y''x + y' - 2yx = x^2}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$y''x + y' - 2yx = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = -2$$

Table 711: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = -2$	
singularity	type

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$y''x + y' - 2yx = x^2$$

Since this is an inhomogeneous, then let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ode $y''x + y' - 2yx = 0$, and y_p is a particular solution to the inhomogeneous ode.which is found using the balance equation generated from indicial equation

First, we solve for y_h Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x + \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) - 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) x = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)\,(n+r-1)\right) + \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-2x^{1+n+r} a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-2x^{1+n+r} a_n\right) = \sum_{n=2}^{\infty} \left(-2a_{n-2} x^{n+r-1}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r) (n+r-1)\right) + \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \sum_{n=2}^{\infty} \left(-2a_{n-2} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r-1} a_n (n+r) (n+r-1) + (n+r)\, a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$x^{-1+r} a_0 r(-1+r) + r a_0 x^{-1+r} = 0$$

Or

$$\left(x^{-1+r} r(-1+r) + r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$x^{-1+r} r^2 = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = 0$$

The corresponding balance equation is found by replacing r by m and a by c to avoid confusing terms between particular solution and the homogeneous solution. Hence the balance equation is

$$\left(x^{-1+m} m(-1+m) + m\, x^{-1+m}\right) c_0 = x^2$$

This equation will used later to find the particular solution.

Since $a_0 \neq 0$ then the indicial equation becomes

$$x^{-1+r} r^2 = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + a_n(n+r) - 2a_{n-2} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{2a_{n-2}}{n^2 + 2nr + r^2} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = \frac{2a_{n-2}}{n^2} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{2}{(2+r)^2}$$

Which for the root $r = 0$ becomes

$$a_2 = \frac{1}{2}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{2}{(2+r)^2}$	$\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{2}{(2+r)^2}$	$\frac{1}{2}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{4}{(2+r)^2 (r+4)^2}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{16}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{2}{(2+r)^2}$	$\frac{1}{2}$
a_3	0	0
a_4	$\frac{4}{(2+r)^2(r+4)^2}$	$\frac{1}{16}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{2}{(2+r)^2}$	$\frac{1}{2}$
a_3	0	0
a_4	$\frac{4}{(2+r)^2(r+4)^2}$	$\frac{1}{16}$
a_5	0	0

Using the above table, then the first solution $y_1(x)$ becomes

$$\begin{aligned} y_1(x) &= a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots \\ &= 1 + \frac{x^2}{2} + \frac{x^4}{16} + O(x^6) \end{aligned}$$

Now the second solution is found. The second solution is given by

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)$$

Where b_n is found using

$$b_n = \frac{d}{dr} a_{n,r}$$

And the above is then evaluated at $r = 0$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr} a_{n,r}$	$b_n(r = 0)$
b_0	1	1	N/A since b_n starts from 1	N/A
b_1	0	0	0	0
b_2	$\frac{2}{(2+r)^2}$	$\frac{1}{2}$	$-\frac{4}{(2+r)^3}$	$-\frac{1}{2}$
b_3	0	0	0	0
b_4	$\frac{4}{(2+r)^2 (r+4)^2}$	$\frac{1}{16}$	$\frac{-16r-48}{(2+r)^3 (r+4)^3}$	$-\frac{3}{32}$
b_5	0	0	0	0

The above table gives all values of b_n needed. Hence the second solution is

$$\begin{aligned}
y_2(x) &= y_1(x) \ln(x) + b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots \\
&= \left(1 + \frac{x^2}{2} + \frac{x^4}{16} + O(x^6)\right) \ln(x) - \frac{x^2}{2} - \frac{3x^4}{32} + O(x^6)
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 \left(1 + \frac{x^2}{2} + \frac{x^4}{16} + O(x^6)\right) + c_2 \left(\left(1 + \frac{x^2}{2} + \frac{x^4}{16} + O(x^6)\right) \ln(x) - \frac{x^2}{2} - \frac{3x^4}{32} + O(x^6)\right)
\end{aligned}$$

The particular solution is found by solving for c, m the balance equation

$$\left(x^{-1+m} m(-1+m) + m\, x^{-1+m}\right) c_0 = F$$

Where $F(x)$ is the RHS of the ode. If $F(x)$ has more than one term, then this is done for each term one at a time and then all the particular solutions are added. The function $F(x)$ will be converted to series if needed. in order to solve for c_n, m for each term, the same recursive relation used to find $y_h(x)$ is used to find c_n, m which is used to find the particular solution $\sum_{n=0} c_n x^{n+m}$ by replacing a_n by c_n and r by m.

The following are the values of a_n found in terms of the indicial root r.

$$
\begin{array}{|l|}
\hline
a_1 = 0 \\
a_2 = \frac{2a_0}{(2+r)^2} \\
a_3 = 0 \\
a_4 = \frac{4a_0}{(2+r)^2 (r+4)^2} \\
a_5 = 0 \\
\hline
\end{array}
$$

Now we determine the particular solution y_p associated with $F = x^2$ by solving the balance equation

$$
\left(x^{-1+m} m(-1+m) + m\, x^{-1+m}\right) c_0 = x^2
$$

For c_0 and x. This results in

$$
c_0 = \frac{1}{9}
$$
$$
m = 3
$$

The particular solution is therefore

$$
y_p = \sum_{n=0}^{\infty} c_n x^{n+m}
$$
$$
= \sum_{n=0}^{\infty} c_n x^{n+3}
$$

Where in the above $c_0 = \frac{1}{9}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 3$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{9}$ and $r = m$ or $r = 3$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$$
\begin{array}{|l|}
\hline
c_0 = \frac{1}{9} \\
c_1 = 0 \\
c_2 = \frac{2}{225} \\
c_3 = 0 \\
c_4 = \frac{4}{11025} \\
c_5 = 0 \\
\hline
\end{array}
$$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\
&= x^3 \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x^3 \left(\frac{1}{9} + \frac{2}{225} x^2 + \frac{4}{11025} x^4\right) \\
&= \frac{1}{9} x^3 + \frac{2}{225} x^5 + \frac{4}{11025} x^7
\end{aligned}
$$

Adding all the above particular solution(s) gives

$$
y_p = \frac{x^3}{9} + \frac{2x^5}{225} + \frac{4x^7}{11025} + O\left(x^6\right)
$$

Truncating the particular solution to the order of series requested gives

$$
y_p = \frac{x^3}{9} + \frac{2x^5}{225} + O\left(x^6\right)
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \frac{x^3}{9} + \frac{2x^5}{225} + O\left(x^6\right) + c_1 \left(1 + \frac{x^2}{2} + \frac{x^4}{16} + O\left(x^6\right)\right) \\
&\quad + c_2 \left(\left(1 + \frac{x^2}{2} + \frac{x^4}{16} + O\left(x^6\right)\right) \ln\left(x\right) - \frac{x^2}{2} - \frac{3x^4}{32} + O\left(x^6\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = \frac{x^3}{9} + \frac{2x^5}{225} + O\left(x^6\right) + c_1 \left(1 + \frac{x^2}{2} + \frac{x^4}{16} + O\left(x^6\right)\right) \\
+ c_2 \left(\left(1 + \frac{x^2}{2} + \frac{x^4}{16} + O\left(x^6\right)\right) \ln\left(x\right) - \frac{x^2}{2} - \frac{3x^4}{32} + O\left(x^6\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$y = \frac{x^3}{9} + \frac{2x^5}{225} + O(x^6) + c_1\left(1 + \frac{x^2}{2} + \frac{x^4}{16} + O(x^6)\right) + c_2\left(\left(1 + \frac{x^2}{2} + \frac{x^4}{16} + O(x^6)\right)\ln(x) - \frac{x^2}{2} - \frac{3x^4}{32} + O(x^6)\right)$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 43, page 209
Problem number: 3.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y''x - xy' + y = x^3}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$y''x - xy' + y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -1$$
$$q(x) = \frac{1}{x}$$

Table 712: Table $p(x), q(x)$ singularites.

$p(x) = -1$	
singularity	type

$q(x) = \frac{1}{x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$y''x - xy' + y = x^3$$

Since this is an inhomogeneous, then let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ode $y''x - xy' + y = 0$, and y_p is a particular solution to the inhomogeneous ode.which is found using the balance equation generated from indicial equation

First, we solve for y_h Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x - x\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \quad \text{(2A)}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{n+r} a_n(n+r)\right) = \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty} a_n x^{n+r} = \sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n(n+r)\,(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n = 0$. From Eq (2B) this gives

$$x^{n+r-1} a_n(n+r)\,(n+r-1) = 0$$

When $n = 0$ the above becomes

$$x^{-1+r} a_0 r(-1+r) = 0$$

Or

$$x^{-1+r} a_0 r(-1+r) = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$x^{-1+r} r(-1+r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$r(-1+r) = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = 0$$

The corresponding balance equation is found by replacing r by m and a by c to avoid confusing terms between particular solution and the homogeneous solution. Hence the balance equation is

$$x^{-1+m} c_0 m(-1+m) = x^3$$

This equation will used later to find the particular solution.

Since $a_0 \neq 0$ then the indicial equation becomes

$$x^{-1+r} r(-1+r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 1$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+1}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - a_{n-1}(n+r-1) + a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}(n+r-2)}{(n+r)(n+r-1)} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = \frac{a_{n-1}(n-1)}{(n+1)\, n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{-1+r}{(1+r)\, r}$$

Which for the root $r = 1$ becomes

$$a_1 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+r}{(1+r)r}$	0

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{-1+r}{(1+r)^2\, (2+r)}$$

Which for the root $r = 1$ becomes

$$a_2 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+r}{(1+r)r}$	0
a_2	$\frac{-1+r}{(1+r)^2(2+r)}$	0

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{-1+r}{(1+r)(2+r)^2(3+r)}$$

Which for the root $r = 1$ becomes

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+r}{(1+r)r}$	0
a_2	$\frac{-1+r}{(1+r)^2(2+r)}$	0
a_3	$\frac{-1+r}{(1+r)(2+r)^2(3+r)}$	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{-1+r}{(1+r)(2+r)(3+r)^2(4+r)}$$

Which for the root $r = 1$ becomes

$$a_4 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+r}{(1+r)r}$	0
a_2	$\frac{-1+r}{(1+r)^2(2+r)}$	0
a_3	$\frac{-1+r}{(1+r)(2+r)^2(3+r)}$	0
a_4	$\frac{-1+r}{(1+r)(2+r)(3+r)^2(4+r)}$	0

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{-1+r}{(1+r)(2+r)(3+r)(4+r)^2(5+r)}$$

Which for the root $r = 1$ becomes

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+r}{(1+r)r}$	0
a_2	$\frac{-1+r}{(1+r)^2(2+r)}$	0
a_3	$\frac{-1+r}{(1+r)(2+r)^2(3+r)}$	0
a_4	$\frac{-1+r}{(1+r)(2+r)(3+r)^2(4+r)}$	0
a_5	$\frac{-1+r}{(1+r)(2+r)(3+r)(4+r)^2(5+r)}$	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x\left(1 + O\left(x^6\right)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 1$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \to r_2} a_1(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_1 \\ &= \frac{-1 + r}{(1 + r) r} \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r \to r_2} \frac{-1 + r}{(1 + r) r} &= \lim_{r \to 0} \frac{-1 + r}{(1 + r) r} \\ &= \textit{undefined} \end{aligned}$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n + r_2}\right)$$

Therefore

$$
\begin{aligned}
\frac{d}{dx}y_2(x) &= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) \\
&= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n (n+r_2)\right) \\
\frac{d^2}{dx^2}y_2(x) &= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} \\
&\quad + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right) \\
&= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n (n+r_2)(-1+n+r_2)\right)
\end{aligned}
$$

Substituting these back into the given ode $y''x - xy' + y = 0$ gives

$$
\begin{aligned}
&\left(Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2}\right. \\
&\left.+ \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right) x \\
&- x\left(Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right)\right) \\
&+ Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0
\end{aligned}
$$

Which can be written as

$$
\begin{aligned}
&\left((-y_1'(x)\,x + y_1''(x)\,x + y_1(x))\ln(x) + \left(\frac{2y_1'(x)}{x} - \frac{y_1(x)}{x^2}\right)x - y_1(x)\right)C \\
&+ \left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x \\
&- x\left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0
\end{aligned}
\tag{7}
$$

But since $y_1(x)$ is a solution to the ode, then

$$-y_1'(x)\,x + y_1''(x)\,x + y_1(x) = 0$$

Eq (7) simplifes to

$$\begin{aligned}
&\left(\left(\frac{2y_1'(x)}{x} - \frac{y_1(x)}{x^2}\right)x - y_1(x)\right)C \\
&+ \left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x \\
&- x\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0
\end{aligned} \tag{8}$$

Substituting $y_1 = \sum_{n=0}^{\infty} a_n x^{n+r_1}$ into the above gives

$$\begin{aligned}
&\frac{\left(2\left(\sum_{n=0}^{\infty} x^{-1+n+r_1}a_n(n+r_1)\right)x - (x+1)\left(\sum_{n=0}^{\infty} a_n x^{n+r_1}\right)\right)C}{x} \\
&+ \frac{\left(\sum_{n=0}^{\infty} x^{-2+n+r_2}b_n(n+r_2)(-1+n+r_2)\right)x^2 - \left(\sum_{n=0}^{\infty} x^{-1+n+r_2}b_n(n+r_2)\right)x^2 + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)x}{x} \\
&= 0
\end{aligned} \tag{9}$$

Since $r_1 = 1$ and $r_2 = 0$ then the above becomes

$$\begin{aligned}
&\frac{\left(2\left(\sum_{n=0}^{\infty} x^n a_n(n+1)\right)x - (x+1)\left(\sum_{n=0}^{\infty} a_n x^{n+1}\right)\right)C}{x} \\
&+ \frac{\left(\sum_{n=0}^{\infty} x^{-2+n}b_n n(n-1)\right)x^2 - \left(\sum_{n=0}^{\infty} x^{n-1}b_n n\right)x^2 + \left(\sum_{n=0}^{\infty} b_n x^n\right)x}{x} = 0
\end{aligned} \tag{10}$$

Which simplifies to

$$\begin{aligned}
&\left(\sum_{n=0}^{\infty} 2C\,x^n a_n(n+1)\right) + \sum_{n=0}^{\infty}\left(-C\,x^{n+1}a_n\right) + \sum_{n=0}^{\infty}\left(-Ca_n x^n\right) \\
&+ \left(\sum_{n=0}^{\infty} n\,x^{n-1}b_n(n-1)\right) + \sum_{n=0}^{\infty}\left(-x^n b_n n\right) + \left(\sum_{n=0}^{\infty} b_n x^n\right) = 0
\end{aligned} \tag{2A}$$

The next step is to make all powers of x be $n-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2C\, x^n a_n (n+1) = \sum_{n=1}^{\infty} 2C a_{n-1} n\, x^{n-1}$$

$$\sum_{n=0}^{\infty} \left(-C\, x^{n+1} a_n\right) = \sum_{n=2}^{\infty} \left(-C a_{-2+n} x^{n-1}\right)$$

$$\sum_{n=0}^{\infty} \left(-C a_n x^n\right) = \sum_{n=1}^{\infty} \left(-C a_{n-1} x^{n-1}\right)$$

$$\sum_{n=0}^{\infty} \left(-x^n b_n n\right) = \sum_{n=1}^{\infty} \left(-(n-1)\, b_{n-1} x^{n-1}\right)$$

$$\sum_{n=0}^{\infty} b_n x^n = \sum_{n=1}^{\infty} b_{n-1} x^{n-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n-1$.

$$\left(\sum_{n=1}^{\infty} 2C a_{n-1} n\, x^{n-1}\right) + \sum_{n=2}^{\infty} \left(-C a_{-2+n} x^{n-1}\right) + \sum_{n=1}^{\infty} \left(-C a_{n-1} x^{n-1}\right) + \left(\sum_{n=0}^{\infty} n\, x^{n-1} b_n (n-1)\right) + \sum_{n=1}^{\infty} \left(-(n-1)\, b_{n-1} x^{n-1}\right) + \left(\sum_{n=1}^{\infty} b_{n-1} x^{n-1}\right) = 0 \tag{2B}$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0 = 1$. For $n = N$, where $N = 1$ which is the difference between the two roots, we are free to choose $b_1 = 0$. Hence for $n = 1$, Eq (2B) gives

$$C + 1 = 0$$

Which is solved for C. Solving for C gives

$$C = -1$$

For $n = 2$, Eq (2B) gives

$$(-a_0 + 3a_1)\, C + 2b_2 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$1 + 2b_2 = 0$$

Solving the above for b_2 gives

$$b_2 = -\frac{1}{2}$$

For $n = 3$, Eq (2B) gives

$$(-a_1 + 5a_2)\, C - b_2 + 6b_3 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$\frac{1}{2} + 6b_3 = 0$$

Solving the above for b_3 gives

$$b_3 = -\frac{1}{12}$$

For $n = 4$, Eq (2B) gives

$$(-a_2 + 7a_3)\, C - 2b_3 + 12b_4 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$\frac{1}{6} + 12b_4 = 0$$

Solving the above for b_4 gives

$$b_4 = -\frac{1}{72}$$

For $n = 5$, Eq (2B) gives

$$(-a_3 + 9a_4)\, C - 3b_4 + 20b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$\frac{1}{24} + 20b_5 = 0$$

Solving the above for b_5 gives

$$b_5 = -\frac{1}{480}$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = -1$ and all b_n, then the second solution becomes

$$y_2(x) = (-1)\left(x\left(1+O\left(x^6\right)\right)\right)\ln(x) + 1 - \frac{x^2}{2} - \frac{x^3}{12} - \frac{x^4}{72} - \frac{x^5}{480} + O\left(x^6\right)$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x\left(1+O\left(x^6\right)\right) + c_2\left((-1)\left(x\left(1+O\left(x^6\right)\right)\right)\ln(x) + 1 - \frac{x^2}{2} - \frac{x^3}{12} - \frac{x^4}{72} - \frac{x^5}{480} + O\left(x^6\right)\right) \end{aligned}$$

The particular solution is found by solving for c, m the balance equation

$$x^{-1+m} c_0 m(-1+m) = F$$

Where $F(x)$ is the RHS of the ode. If $F(x)$ has more than one term, then this is done for each term one at a time and then all the particular solutions are added. The function $F(x)$ will be converted to series if needed. in order to solve for c_n, m for each term, the same recursive relation used to find $y_h(x)$ is used to find c_n, m which is used to find the particular solution $\sum_{n=0} c_n x^{n+m}$ by replacing a_n by c_n and r by m.

The following are the values of a_n found in terms of the indicial root r.

$$\begin{aligned} a_1 &= \frac{a_0(-1+r)}{(1+r)r} \\ a_2 &= \frac{a_0(-1+r)}{(1+r)^2(2+r)} \\ a_3 &= \frac{a_0(-1+r)}{(1+r)(2+r)^2(3+r)} \\ a_4 &= \frac{a_0(-1+r)}{(1+r)(2+r)(3+r)^2(4+r)} \\ a_5 &= \frac{a_0(-1+r)}{(1+r)(2+r)(3+r)(4+r)^2(5+r)} \end{aligned}$$

Now we determine the particular solution y_p associated with $F = x^3$ by solving the balance equation

$$x^{-1+m} c_0 m(-1+m) = x^3$$

For c_0 and x. This results in

$$\begin{aligned} c_0 &= \frac{1}{12} \\ m &= 4 \end{aligned}$$

The particular solution is therefore

$$
\begin{aligned}
y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\
&= \sum_{n=0}^{\infty} c_n x^{n+4}
\end{aligned}
$$

Where in the above $c_0 = \frac{1}{12}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 4$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{12}$ and $r = m$ or $r = 4$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = \frac{1}{12}$
$c_1 = \frac{1}{80}$
$c_2 = \frac{1}{600}$
$c_3 = \frac{1}{5040}$
$c_4 = \frac{1}{47040}$
$c_5 = \frac{1}{483840}$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\
&= x^4 \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x^4 \left(\frac{1}{12} + \frac{1}{80}x + \frac{1}{600}x^2 + \frac{1}{5040}x^3 + \frac{1}{47040}x^4 + \frac{1}{483840}x^5\right) \\
&= \frac{1}{12}x^4 + \frac{1}{80}x^5 + \frac{1}{600}x^6 + \frac{1}{5040}x^7 + \frac{1}{47040}x^8 + \frac{1}{483840}x^9
\end{aligned}
$$

Adding all the above particular solution(s) gives

$$y_p = \frac{x^4}{12} + \frac{x^5}{80} + \frac{x^6}{600} + \frac{x^7}{5040} + \frac{x^8}{47040} + \frac{x^9}{483840} + O(x^6)$$

Truncating the particular solution to the order of series requested gives

$$y_p = \frac{x^4}{12} + \frac{x^5}{80} + O(x^6)$$

Hence the final solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \frac{x^4}{12} + \frac{x^5}{80} + O(x^6) + c_1 x(1 + O(x^6)) \\ &\quad + c_2\left(-x(1 + O(x^6))\ln(x) + 1 - \frac{x^2}{2} - \frac{x^3}{12} - \frac{x^4}{72} - \frac{x^5}{480} + O(x^6)\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$\begin{aligned} y &= \frac{x^4}{12} + \frac{x^5}{80} + O(x^6) + c_1 x(1 + O(x^6)) \\ &\quad + c_2\left(-x(1 + O(x^6))\ln(x) + 1 - \frac{x^2}{2} - \frac{x^3}{12} - \frac{x^4}{72} - \frac{x^5}{480} + O(x^6)\right) \end{aligned} \tag{1}$$

Verification of solutions

$$\begin{aligned} y &= \frac{x^4}{12} + \frac{x^5}{80} + O(x^6) + c_1 x(1 + O(x^6)) \\ &\quad + c_2\left(-x(1 + O(x^6))\ln(x) + 1 - \frac{x^2}{2} - \frac{x^3}{12} - \frac{x^4}{72} - \frac{x^5}{480} + O(x^6)\right) \end{aligned}$$

Verified OK.

Problem number: 4.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second_order_change_of_variable_on_y_method_2", "second order series method. Taylor series method", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(1-2x)\,y''+4xy'-4y=x^2-x}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y_0'$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0)+(x-x_0)\,y'(x_0)+\frac{(x-x_0)^2}{2}y''(x_0)+\frac{(x-x_0)^3}{3!}y'''(x_0)+\cdots \\
&= y_0+xy_0'+\frac{x^2}{2}\,f|_{x_0,y_0,y_0'}+\frac{x^3}{3!}\,f'|_{x_0,y_0,y_0'}+\cdots \\
&= y_0+xy_0'+\sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)\,!}\,\frac{d^nf}{dx^n}\bigg|_{x_0,y_0,y_0'}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{1145}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{1146}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') && (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 && (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n \big|_{x_0, y_0, y_0'} \tag{7}
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$\begin{aligned}
F_0 &= \frac{4xy' - x^2 - 4y + x}{2x - 1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{8xy' - 2x^2 - 8y + 1}{2x - 1} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{16xy' - 4x^2 - 16y + 2}{2x - 1} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{32xy' - 8x^2 - 32y + 4}{2x - 1} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{64xy' - 16x^2 - 64y + 8}{2x - 1}
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$\begin{aligned}
F_0 &= 4y(0) \\
F_1 &= 8y(0) - 1 \\
F_2 &= 16y(0) - 2 \\
F_3 &= 32y(0) - 4 \\
F_4 &= 64y(0) - 8
\end{aligned}$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = \left(1 + 2x^2 + \frac{4}{3}x^3 + \frac{2}{3}x^4 + \frac{4}{15}x^5 + \frac{4}{45}x^6\right) y(0) + xy'(0) - \frac{x^3}{6} - \frac{x^4}{12} - \frac{x^5}{30} - \frac{x^6}{90} + O(x^6)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$(1-2x)\,y'' + 4xy' - 4y = x^2 - x$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}$$

Substituting the above back into the ode gives

$$(1-2x)\left(\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}\right) + 4x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - 4\left(\sum_{n=0}^{\infty} a_n x^n\right) = x^2 - x \quad (1)$$

Expanding $x^2 - x$ as Taylor series around $x = 0$ and keeping only the first 6 terms gives

$$\begin{aligned} x^2 - x &= x^2 - x + \dots \\ &= x^2 - x \end{aligned}$$

Hence the ODE in Eq (1) becomes

$$(1-2x)\left(\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}\right) + 4x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - 4\left(\sum_{n=0}^{\infty} a_n x^n\right) = x^2 - x$$

Which simplifies to

$$\sum_{n=2}^{\infty} \left(-2n\, x^{n-1} a_n (n-1)\right) + \left(\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} 4n a_n x^n\right) + \sum_{n=0}^{\infty} \left(-4a_n x^n\right) \quad (2)$$
$$= x^2 - x$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=2}^{\infty}\left(-2n\,x^{n-1}a_n(n-1)\right) &= \sum_{n=1}^{\infty}\left(-2(n+1)\,a_{n+1}n\,x^n\right) \\
\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2} &= \sum_{n=0}^{\infty}(n+2)\,a_{n+2}(n+1)\,x^n
\end{aligned}
$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$
\begin{aligned}
\sum_{n=1}^{\infty}\left(-2(n+1)\,a_{n+1}n\,x^n\right) + \left(\sum_{n=0}^{\infty}(n+2)\,a_{n+2}(n+1)\,x^n\right) \\
+ \left(\sum_{n=1}^{\infty}4na_n x^n\right) + \sum_{n=0}^{\infty}\left(-4a_n x^n\right) = x^2 - x
\end{aligned} \tag{3}
$$

$n = 0$ gives

$$
2a_2 - 4a_0 = 0
$$

$$
a_2 = 2a_0
$$

For $1 \leq n$, the recurrence equation is

$$
\left(-2(n+1)\,a_{n+1}n + (n+2)\,a_{n+2}(n+1) + 4na_n - 4a_n\right)x^n = x^2 - x \tag{4}
$$

For $n = 1$ the recurrence equation gives

$$
\begin{aligned}
(-4a_2 + 6a_3)\,x &= -x \\
-4a_2 + 6a_3 &= -1
\end{aligned}
$$

Which after substituting the earlier terms found becomes

$$
a_3 = -\frac{1}{6} + \frac{4a_0}{3}
$$

For $n = 2$ the recurrence equation gives

$$(-12a_3 + 12a_4 + 4a_2) x^2 = x^2$$
$$-12a_3 + 12a_4 + 4a_2 = 1$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{1}{12} + \frac{2a_0}{3}$$

For $n = 3$ the recurrence equation gives

$$(-24a_4 + 20a_5 + 8a_3) x^3 = 0$$
$$-24a_4 + 20a_5 + 8a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{1}{30} + \frac{4a_0}{15}$$

For $n = 4$ the recurrence equation gives

$$(-40a_5 + 30a_6 + 12a_4) x^4 = 0$$
$$-40a_5 + 30a_6 + 12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{1}{90} + \frac{4a_0}{45}$$

For $n = 5$ the recurrence equation gives

$$(-60a_6 + 42a_7 + 16a_5) x^5 = 0$$
$$-60a_6 + 42a_7 + 16a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{1}{315} + \frac{8a_0}{315}$$

And so on. Therefore the solution is

$$y = \sum_{n=0}^{\infty} a_n x^n$$
$$= a_3x^3 + a_2x^2 + a_1x + a_0 + \dots$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1x + 2a_0x^2 + \left(-\frac{1}{6} + \frac{4a_0}{3}\right)x^3 + \left(-\frac{1}{12} + \frac{2a_0}{3}\right)x^4 + \left(-\frac{1}{30} + \frac{4a_0}{15}\right)x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + 2x^2 + \frac{4}{3}x^3 + \frac{2}{3}x^4 + \frac{4}{15}x^5\right)a_0 + a_1x - \frac{x^3}{6} - \frac{x^4}{12} - \frac{x^5}{30} + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 + 2x^2 + \frac{4}{3}x^3 + \frac{2}{3}x^4 + \frac{4}{15}x^5\right)c_1 + c_2x - \frac{x^3}{6} - \frac{x^4}{12} - \frac{x^5}{30} + O(x^6)$$

Summary

The solution(s) found are the following

$$y = \left(1 + 2x^2 + \frac{4}{3}x^3 + \frac{2}{3}x^4 + \frac{4}{15}x^5 + \frac{4}{45}x^6\right)y(0) + xy'(0) - \frac{x^3}{6} - \frac{x^4}{12} - \frac{x^5}{30} - \frac{x^6}{90} + O(x^6) \tag{1}$$

$$y = \left(1 + 2x^2 + \frac{4}{3}x^3 + \frac{2}{3}x^4 + \frac{4}{15}x^5\right)c_1 + c_2x - \frac{x^3}{6} - \frac{x^4}{12} - \frac{x^5}{30} + O(x^6) \tag{2}$$

Verification of solutions

$$y = \left(1 + 2x^2 + \frac{4}{3}x^3 + \frac{2}{3}x^4 + \frac{4}{15}x^5 + \frac{4}{45}x^6\right)y(0) + xy'(0) - \frac{x^3}{6} - \frac{x^4}{12} - \frac{x^5}{30} - \frac{x^6}{90} + O(x^6)$$

Verified OK.

$$y = \left(1 + 2x^2 + \frac{4}{3}x^3 + \frac{2}{3}x^4 + \frac{4}{15}x^5\right)c_1 + c_2x - \frac{x^3}{6} - \frac{x^4}{12} - \frac{x^5}{30} + O(x^6)$$

Verified OK.

Problem number: 5.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Complex roots"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{x^2y'' + xy' + (x+12)\,y = x^2 + x}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + xy' + (x+12)\,y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{x+12}{x^2}$$

Table 713: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{x+12}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' + xy' + (x + 12)\,y = x^2 + x$$

Since this is an inhomogeneous, then let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ode $x^2y'' + xy' + (x + 12)\,y = 0$, and y_p is a particular solution to the inhomogeneous ode.which is found using the balance equation generated from indicial equation

First, we solve for y_h Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r)\,(n + r - 1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$
\begin{aligned}
&x^2\left(\sum_{n=0}^{\infty}(n+r)(n+r-1)\,a_n x^{n+r-2}\right) \\
&+x\left(\sum_{n=0}^{\infty}(n+r)\,a_n x^{n+r-1}\right)+(x+12)\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right)=0
\end{aligned} \tag{1}
$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)\right) \\
&+\left(\sum_{n=0}^{\infty}x^{1+n+r}a_n\right)+\left(\sum_{n=0}^{\infty}12a_n x^{n+r}\right)=0
\end{aligned} \tag{2A}
$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$
\sum_{n=0}^{\infty}x^{1+n+r}a_n=\sum_{n=1}^{\infty}a_{n-1}x^{n+r}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)\right) \\
&+\left(\sum_{n=1}^{\infty}a_{n-1}x^{n+r}\right)+\left(\sum_{n=0}^{\infty}12a_n x^{n+r}\right)=0
\end{aligned} \tag{2B}
$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$
x^{n+r}a_n(n+r)(n+r-1)+x^{n+r}a_n(n+r)+12a_n x^{n+r}=0
$$

When $n=0$ the above becomes

$$
x^r a_0 r(-1+r)+x^r a_0 r+12a_0 x^r=0
$$

Or

$$\left(x^{r} r(-1+r)+x^{r} r+12 x^{r}\right) a_{0}=0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^{2}+12\right) x^{r}=0$$

Since the above is true for all x then the indicial equation becomes

$$r^{2}+12=0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned} r_{1} &= 2 i \sqrt{3} \\ r_{2} &= -2 i \sqrt{3} \end{aligned}$$

The corresponding balance equation is found by replacing r by m and a by c to avoid confusing terms between particular solution and the homogeneous solution. Hence the balance equation is

$$\left(x^{m} m(-1+m)+x^{m} m+12 x^{m}\right) c_{0}=x^{2}+x$$

This equation will used later to find the particular solution.

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^{2}+12\right) x^{r}=0$$

Solving for r gives the roots of the indicial equation as Since the roots are complex conjugates, then two linearly independent solutions can be constructed using

$$\begin{aligned} y_{1}(x) &= x^{r_{1}}\left(\sum_{n=0}^{\infty} a_{n} x^{n}\right) \\ y_{2}(x) &= x^{r_{2}}\left(\sum_{n=0}^{\infty} b_{n} x^{n}\right) \end{aligned}$$

Or

$$\begin{aligned} y_{1}(x) &= \sum_{n=0}^{\infty} a_{n} x^{n+2 i \sqrt{3}} \\ y_{2}(x) &= \sum_{n=0}^{\infty} b_{n} x^{n-2 i \sqrt{3}} \end{aligned}$$

$y_1(x)$ is found first. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + a_n(n+r) + a_{n-1} + 12a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}}{n^2 + 2nr + r^2 + 12} \tag{4}$$

Which for the root $r = 2i\sqrt{3}$ becomes

$$a_n = -\frac{a_{n-1}}{n^2 + 4in\sqrt{3}} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2i\sqrt{3}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{1}{r^2 + 2r + 13}$$

Which for the root $r = 2i\sqrt{3}$ becomes

$$a_1 = \frac{1}{-1 - 4i\sqrt{3}}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+2r+13}$	$\frac{1}{-1-4i\sqrt{3}}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{(r^2 + 2r + 13)(r^2 + 4r + 16)}$$

Which for the root $r = 2i\sqrt{3}$ becomes

$$a_2 = -\frac{1}{4\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+2r+13}$	$\frac{1}{-1-4i\sqrt{3}}$
a_2	$\frac{1}{(r^2+2r+13)(r^2+4r+16)}$	$-\frac{1}{4\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{1}{(r^2+2r+13)(r^2+4r+16)(r^2+6r+21)}$$

Which for the root $r = 2i\sqrt{3}$ becomes

$$a_3 = \frac{1}{48\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(i\sqrt{3}+\frac{3}{4}\right)}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+2r+13}$	$\frac{1}{-1-4i\sqrt{3}}$
a_2	$\frac{1}{(r^2+2r+13)(r^2+4r+16)}$	$-\frac{1}{4\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)}$
a_3	$-\frac{1}{(r^2+2r+13)(r^2+4r+16)(r^2+6r+21)}$	$\frac{1}{48\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(i\sqrt{3}+\frac{3}{4}\right)}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{(r^2+2r+13)(r^2+4r+16)(r^2+6r+21)(r^2+8r+28)}$$

Which for the root $r = 2i\sqrt{3}$ becomes

$$a_4 = \frac{1}{192\left(-4\sqrt{3}+3i\right)\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(i-\sqrt{3}\right)}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+2r+13}$	$\frac{1}{-1-4i\sqrt{3}}$
a_2	$\frac{1}{(r^2+2r+13)(r^2+4r+16)}$	$-\frac{1}{4\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)}$
a_3	$-\frac{1}{(r^2+2r+13)(r^2+4r+16)(r^2+6r+21)}$	$\frac{1}{48\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(i\sqrt{3}+\frac{3}{4}\right)}$
a_4	$\frac{1}{(r^2+2r+13)(r^2+4r+16)(r^2+6r+21)(r^2+8r+28)}$	$\frac{1}{192\left(-4\sqrt{3}+3i\right)\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(i-\sqrt{3}\right)}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1}{(r^2+2r+13)(r^2+4r+16)(r^2+6r+21)(r^2+8r+28)(r^2+10r+37)}$$

Which for the root $r = 2i\sqrt{3}$ becomes

$$a_5 = \frac{1}{15360\left(\sqrt{3}-\frac{3i}{4}\right)\left(-i+4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(-i+\sqrt{3}\right)\left(i\sqrt{3}+\frac{5}{4}\right)}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+2r+13}$	$\frac{1}{-1-4i\sqrt{3}}$
a_2	$\frac{1}{(r^2+2r+13)(r^2+4r+16)}$	$-\frac{1}{4\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)}$
a_3	$-\frac{1}{(r^2+2r+13)(r^2+4r+16)(r^2+6r+21)}$	$\frac{1}{48\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(i\sqrt{3}+\frac{3}{4}\right)}$
a_4	$\frac{1}{(r^2+2r+13)(r^2+4r+16)(r^2+6r+21)(r^2+8r+28)}$	$\frac{1}{192\left(-4\sqrt{3}+3i\right)\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(i-\sqrt{3}\right)}$
a_5	$-\frac{1}{(r^2+2r+13)(r^2+4r+16)(r^2+6r+21)(r^2+8r+28)(r^2+10r+37)}$	$\frac{1}{15360\left(\sqrt{3}-\frac{3i}{4}\right)\left(-i+4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(-i+\sqrt{3}\right)\left(i\sqrt{3}+\frac{5}{4}\right)}$

Using the above table, then the solution $y_1(x)$ is

$$y_1(x) = x^{2i\sqrt{3}}\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots\right)$$

$$= x^{2i\sqrt{3}} \left(1 + \frac{x}{-1 - 4i\sqrt{3}} - \frac{x^2}{4\left(i - 4\sqrt{3}\right)\left(-2\sqrt{3} + i\right)} + \frac{x^3}{48\left(i - 4\sqrt{3}\right)\left(-2\sqrt{3} + i\right)\left(i\sqrt{3} + \frac{3}{4}\right)} + \frac{x^4}{192\left(-4\sqrt{3} + 3i\right)\left(i - 4\sqrt{3}\right)\left(-2\sqrt{3} + i\right)\left(i - \sqrt{3}\right)} + \frac{x^5}{15360\left(\sqrt{3} - \frac{3i}{4}\right)\left(-i + 4\sqrt{3}\right)\left(-2\sqrt{3} + i\right)\left(-i + \sqrt{3}\right)\left(i\sqrt{3} + \frac{5}{4}\right)} + O(x^6)\right)$$

The second solution $y_2(x)$ is found by taking the complex conjugate of $y_1(x)$ which gives

$$y_2(x) = x^{-2i\sqrt{3}} \left(1 + \frac{x}{-1 + 4i\sqrt{3}} - \frac{x^2}{4\left(-i - 4\sqrt{3}\right)\left(-2\sqrt{3} - i\right)} + \frac{x^3}{48\left(-i - 4\sqrt{3}\right)\left(-2\sqrt{3} - i\right)\left(-i\sqrt{3} + \frac{3}{4}\right)} + \frac{x^4}{192\left(-4\sqrt{3} - 3i\right)\left(-i - 4\sqrt{3}\right)\left(-2\sqrt{3} - i\right)\left(-i - \sqrt{3}\right)} + \frac{x^5}{15360\left(\sqrt{3} + \frac{3i}{4}\right)\left(i + 4\sqrt{3}\right)\left(-2\sqrt{3} - i\right)\left(\sqrt{3} + i\right)\left(-i\sqrt{3} + \frac{5}{4}\right)} + O(x^6)\right)$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 y_1(x) + c_2 y_2(x)$$

$$
\begin{aligned}
&= c_1 x^{2i\sqrt{3}}\left(1+\frac{x}{-1-4i\sqrt{3}}-\frac{x^2}{4\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)}\right.\\
&\quad+\frac{x^3}{48\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(i\sqrt{3}+\frac{3}{4}\right)}\\
&\quad+\frac{x^4}{192\left(-4\sqrt{3}+3i\right)\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(i-\sqrt{3}\right)}\\
&\quad\left.+\frac{x^5}{15360\left(\sqrt{3}-\frac{3i}{4}\right)\left(-i+4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(-i+\sqrt{3}\right)\left(i\sqrt{3}+\frac{5}{4}\right)}+O\left(x^6\right)\right)\\
&\quad+c_2 x^{-2i\sqrt{3}}\left(1+\frac{x}{-1+4i\sqrt{3}}-\frac{x^2}{4\left(-i-4\sqrt{3}\right)\left(-2\sqrt{3}-i\right)}\right.\\
&\quad+\frac{x^3}{48\left(-i-4\sqrt{3}\right)\left(-2\sqrt{3}-i\right)\left(-i\sqrt{3}+\frac{3}{4}\right)}\\
&\quad+\frac{x^4}{192\left(-4\sqrt{3}-3i\right)\left(-i-4\sqrt{3}\right)\left(-2\sqrt{3}-i\right)\left(-i-\sqrt{3}\right)}\\
&\quad\left.+\frac{x^5}{15360\left(\sqrt{3}+\frac{3i}{4}\right)\left(i+4\sqrt{3}\right)\left(-2\sqrt{3}-i\right)\left(\sqrt{3}+i\right)\left(-i\sqrt{3}+\frac{5}{4}\right)}+O\left(x^6\right)\right)
\end{aligned}
$$

The particular solution is found by solving for c, m the balance equation

$$
\left(x^m m(-1+m)+x^m m+12x^m\right)c_0=F
$$

Where $F(x)$ is the RHS of the ode. If $F(x)$ has more than one term, then this is done for each term one at a time and then all the particular solutions are added. The function $F(x)$ will be converted to series if needed. in order to solve for c_n, m for each term, the same recursive relation used to find $y_h(x)$ is used to find c_n, m which is used to find the particular solution $\sum_{n=0} c_n x^{n+m}$ by replacing a_n by c_n and r by m.

The following are the values of a_n found in terms of the indicial root r.

$$
\begin{aligned}
a_1 &= -\frac{a_0}{r^2+2r+13}\\
a_2 &= \frac{a_0}{(r^2+2r+13)(r^2+4r+16)}\\
a_3 &= -\frac{a_0}{(r^2+2r+13)(r^2+4r+16)(r^2+6r+21)}\\
a_4 &= \frac{a_0}{(r^2+2r+13)(r^2+4r+16)(r^2+6r+21)(r^2+8r+28)}\\
a_5 &= -\frac{a_0}{(r^2+2r+13)(r^2+4r+16)(r^2+6r+21)(r^2+8r+28)(r^2+10r+37)}
\end{aligned}
$$

Since the $F = x^2 + x$ has more than one term then we find a particular solution for each term and add the result to find the particular solution to the ode.

Now we determine the particular solution y_p associated with $F = x^2$ by solving the balance equation

$$\left(x^m m(-1+m) + x^m m + 12x^m\right) c_0 = x^2$$

For c_0 and x. This results in

$$c_0 = \frac{1}{16}$$
$$m = 2$$

The particular solution is therefore

$$y_p = \sum_{n=0}^{\infty} c_n x^{n+m}$$
$$= \sum_{n=0}^{\infty} c_n x^{n+2}$$

Where in the above $c_0 = \frac{1}{16}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 2$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{16}$ and $r = m$ or $r = 2$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = \frac{1}{16}$
$c_1 = -\frac{1}{336}$
$c_2 = \frac{1}{9408}$
$c_3 = -\frac{1}{348096}$
$c_4 = \frac{1}{16708608}$
$c_5 = -\frac{1}{1019225088}$

The particular solution is now found using

$$y_p = x^m \sum_{n=0}^{\infty} c_n x^n$$

$$= x^2 \sum_{n=0}^{\infty} c_n x^n$$

Using the values found above for c_n into the above sum gives

$$\begin{aligned} y_p &= x^2\left(\frac{1}{16}-\frac{1}{336}x+\frac{1}{9408}x^2-\frac{1}{348096}x^3+\frac{1}{16708608}x^4-\frac{1}{1019225088}x^5\right) \\ &= \frac{1}{16}x^2-\frac{1}{336}x^3+\frac{1}{9408}x^4-\frac{1}{348096}x^5+\frac{1}{16708608}x^6-\frac{1}{1019225088}x^7 \end{aligned}$$

Now we determine the particular solution y_p associated with $F = x$ by solving the balance equation

$$(x^m m(-1+m)+x^m m+12x^m)\, c_0 = x$$

For c_0 and x. This results in

$$\begin{aligned} c_0 &= \frac{1}{13} \\ m &= 1 \end{aligned}$$

The particular solution is therefore

$$\begin{aligned} y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\ &= \sum_{n=0}^{\infty} c_n x^{n+1} \end{aligned}$$

Where in the above $c_0 = \frac{1}{13}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 1$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{13}$ and $r = m$ or $r = 1$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = \frac{1}{13}$
$c_1 = -\frac{1}{208}$
$c_2 = \frac{1}{4368}$
$c_3 = -\frac{1}{122304}$
$c_4 = \frac{1}{4525248}$
$c_5 = -\frac{1}{217211904}$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\
&= x \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x \left(\frac{1}{13} - \frac{1}{208}x + \frac{1}{4368}x^2 - \frac{1}{122304}x^3 + \frac{1}{4525248}x^4 - \frac{1}{217211904}x^5\right) \\
&= \frac{1}{13}x - \frac{1}{208}x^2 + \frac{1}{4368}x^3 - \frac{1}{122304}x^4 + \frac{1}{4525248}x^5 - \frac{1}{217211904}x^6
\end{aligned}
$$

Adding all the above particular solution(s) gives

$$
y_p = \frac{x}{13} + \frac{3x^2}{52} - \frac{x^3}{364} + \frac{x^4}{10192} - \frac{x^5}{377104} + \frac{x^6}{18100992} - \frac{x^7}{1019225088} + O\left(x^6\right)
$$

Truncating the particular solution to the order of series requested gives

$$
y_p = \frac{x}{13} + \frac{3x^2}{52} - \frac{x^3}{364} + \frac{x^4}{10192} - \frac{x^5}{377104} + O\left(x^6\right)
$$

Hence the final solution is

$$
y = y_h + y_p
$$

$$
\begin{aligned}
&= \frac{x}{13} + \frac{3x^2}{52} - \frac{x^3}{364} + \frac{x^4}{10192} - \frac{x^5}{377104} + O\left(x^6\right) + c_1 x^{2i\sqrt{3}} \left(1 + \frac{x}{-1 - 4i\sqrt{3}}\right. \\
&\quad - \frac{x^2}{4\left(i - 4\sqrt{3}\right)\left(-2\sqrt{3} + i\right)} + \frac{x^3}{48\left(i - 4\sqrt{3}\right)\left(-2\sqrt{3} + i\right)\left(i\sqrt{3} + \frac{3}{4}\right)} \\
&\quad + \frac{x^4}{192\left(-4\sqrt{3} + 3i\right)\left(i - 4\sqrt{3}\right)\left(-2\sqrt{3} + i\right)\left(i - \sqrt{3}\right)} \\
&\quad \left. + \frac{x^5}{15360\left(\sqrt{3} - \frac{3i}{4}\right)\left(-i + 4\sqrt{3}\right)\left(-2\sqrt{3} + i\right)\left(-i + \sqrt{3}\right)\left(i\sqrt{3} + \frac{5}{4}\right)} + O\left(x^6\right)\right) \\
&\quad + c_2 x^{-2i\sqrt{3}} \left(1 + \frac{x}{-1 + 4i\sqrt{3}} - \frac{x^2}{4\left(-i - 4\sqrt{3}\right)\left(-2\sqrt{3} - i\right)}\right. \\
&\quad + \frac{x^3}{48\left(-i - 4\sqrt{3}\right)\left(-2\sqrt{3} - i\right)\left(-i\sqrt{3} + \frac{3}{4}\right)} \\
&\quad + \frac{x^4}{192\left(-4\sqrt{3} - 3i\right)\left(-i - 4\sqrt{3}\right)\left(-2\sqrt{3} - i\right)\left(-i - \sqrt{3}\right)} \\
&\quad \left. + \frac{x^5}{15360\left(\sqrt{3} + \frac{3i}{4}\right)\left(i + 4\sqrt{3}\right)\left(-2\sqrt{3} - i\right)\left(\sqrt{3} + i\right)\left(-i\sqrt{3} + \frac{5}{4}\right)} + O\left(x^6\right)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
\begin{aligned}
y = {} & \frac{x}{13}+\frac{3x^{2}}{52}-\frac{x^{3}}{364}+\frac{x^{4}}{10192}-\frac{x^{5}}{377104}+O\left(x^{6}\right)+c_{1} x^{2 i \sqrt{3}} \left(1+\frac{x}{-1-4 i \sqrt{3}} \right. \\
& -\frac{x^{2}}{4\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)}+\frac{x^{3}}{48\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(i\sqrt{3}+\frac{3}{4}\right)} \\
& +\frac{x^{4}}{192\left(-4\sqrt{3}+3i\right)\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(i-\sqrt{3}\right)} \\
& \left. +\frac{x^{5}}{15360\left(\sqrt{3}-\frac{3i}{4}\right)\left(-i+4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(-i+\sqrt{3}\right)\left(i\sqrt{3}+\frac{5}{4}\right)}+O\left(x^{6}\right)\right) \\
& +c_{2} x^{-2 i \sqrt{3}} \left(1+\frac{x}{-1+4 i \sqrt{3}}-\frac{x^{2}}{4\left(-i-4\sqrt{3}\right)\left(-2\sqrt{3}-i\right)} \right. \\
& +\frac{x^{3}}{48\left(-i-4\sqrt{3}\right)\left(-2\sqrt{3}-i\right)\left(-i\sqrt{3}+\frac{3}{4}\right)} \\
& +\frac{x^{4}}{192\left(-4\sqrt{3}-3i\right)\left(-i-4\sqrt{3}\right)\left(-2\sqrt{3}-i\right)\left(-i-\sqrt{3}\right)} \\
& \left. +\frac{x^{5}}{15360\left(\sqrt{3}+\frac{3i}{4}\right)\left(i+4\sqrt{3}\right)\left(-2\sqrt{3}-i\right)\left(\sqrt{3}+i\right)\left(-i\sqrt{3}+\frac{5}{4}\right)}+O\left(x^{6}\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & \frac{x}{13}+\frac{3x^2}{52}-\frac{x^3}{364}+\frac{x^4}{10192}-\frac{x^5}{377104}+O(x^6)+c_1 x^{2i\sqrt{3}}\left(1+\frac{x}{-1-4i\sqrt{3}}\right. \\
& -\frac{x^2}{4\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)}+\frac{x^3}{48\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(i\sqrt{3}+\frac{3}{4}\right)} \\
& +\frac{x^4}{192\left(-4\sqrt{3}+3i\right)\left(i-4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(i-\sqrt{3}\right)} \\
& \left.+\frac{x^5}{15360\left(\sqrt{3}-\frac{3i}{4}\right)\left(-i+4\sqrt{3}\right)\left(-2\sqrt{3}+i\right)\left(-i+\sqrt{3}\right)\left(i\sqrt{3}+\frac{5}{4}\right)}+O(x^6)\right) \\

Problem number: 6.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{x^2(x+1)\,y''+x\left(x^2+3\right)y'+y=-2x^2+x}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(x^3+x^2\right)y''+\left(x^3+3x\right)y'+y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=\frac{x^2+3}{x\,(x+1)}$$
$$q(x)=\frac{1}{x^2\,(x+1)}$$

Table 714: Table $p(x), q(x)$ singularites.

$p(x) = \frac{x^2+3}{x(x+1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

$q(x) = \frac{1}{x^2(x+1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-1, 0]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2(x+1)\, y'' + \left(x^3 + 3x\right) y' + y = -2x^2 + x$$

Since this is an inhomogeneous, then let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ode $x^2(x+1)\, y'' + \left(x^3 + 3x\right) y' + y = 0$, and y_p is a particular solution to the inhomogeneous ode.which is found using the balance equation generated from indicial equation

First, we solve for y_h Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$
\begin{aligned}
&x^2(x+1)\left(\sum_{n=0}^{\infty}(n+r)(n+r-1)\,a_n x^{n+r-2}\right) \\
&+ \left(x^3+3x\right)\left(\sum_{n=0}^{\infty}(n+r)\,a_n x^{n+r-1}\right)+\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right)=0
\end{aligned} \tag{1}
$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty}x^{1+n+r}a_n(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)(n+r-1)\right) \\
&+\left(\sum_{n=0}^{\infty}x^{n+r+2}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}3x^{n+r}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right)=0
\end{aligned} \tag{2A}
$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=0}^{\infty}x^{1+n+r}a_n(n+r)(n+r-1) &= \sum_{n=1}^{\infty}a_{n-1}(n+r-1)(n+r-2)\,x^{n+r} \\
\sum_{n=0}^{\infty}x^{n+r+2}a_n(n+r) &= \sum_{n=2}^{\infty}a_{n-2}(n+r-2)\,x^{n+r}
\end{aligned}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$
\begin{aligned}
&\left(\sum_{n=1}^{\infty}a_{n-1}(n+r-1)(n+r-2)\,x^{n+r}\right)+\left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)(n+r-1)\right) \\
&+\left(\sum_{n=2}^{\infty}a_{n-2}(n+r-2)\,x^{n+r}\right)+\left(\sum_{n=0}^{\infty}3x^{n+r}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right)=0
\end{aligned} \tag{2B}
$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$
x^{n+r}a_n(n+r)(n+r-1)+3x^{n+r}a_n(n+r)+a_n x^{n+r}=0
$$

When $n = 0$ the above becomes

$$x^r a_0 r(-1+r) + 3x^r a_0 r + a_0 x^r = 0$$

Or

$$(x^r r(-1+r) + 3x^r r + x^r) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$(r+1)^2 x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$(r+1)^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = -1$$
$$r_2 = -1$$

The corresponding balance equation is found by replacing r by m and a by c to avoid confusing terms between particular solution and the homogeneous solution. Hence the balance equation is

$$(x^m m(-1+m) + 3x^m m + x^m) c_0 = -2x^2 + x$$

This equation will used later to find the particular solution.

Since $a_0 \neq 0$ then the indicial equation becomes

$$(r+1)^2 x^r = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. Using the value of the indicial root found earlier, $r = -1$, Eqs (1A,1B) become

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n-1}$$
$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n-1}\right)$$

We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = -\frac{r(-1+r)}{(2+r)^2}$$

For $2 \leq n$ the recursive equation is

$$a_{n-1}(n+r-1)(n+r-2) + a_n(n+r)(n+r-1) + a_{n-2}(n+r-2) + 3a_n(n+r) + a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{n^2 a_{n-1} + 2nr a_{n-1} + r^2 a_{n-1} + n a_{n-2} - 3n a_{n-1} + r a_{n-2} - 3r a_{n-1} - 2a_{n-2} + 2a_{n-1}}{n^2 + 2nr + r^2 + 2n + 2r + 1} \tag{4}$$

Which for the root $r = -1$ becomes

$$a_n = -\frac{(n-3)\left((n-2)\, a_{n-1} + a_{n-2}\right)}{n^2} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r(-1+r)}{(2+r)^2}$	-2

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r(r^3 - r^2 - 5r - 4)}{(2 + r)^2 (r + 3)^2}$$

Which for the root $r = -1$ becomes

$$a_2 = \frac{1}{4}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r(-1+r)}{(2+r)^2}$	-2
a_2	$\frac{r(r^3-r^2-5r-4)}{(2+r)^2(r+3)^2}$	$\frac{1}{4}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{r(r + 1)(r^4 - 12r^2 - 17r + 1)}{(2 + r)^2 (r + 3)^2 (r + 4)^2}$$

Which for the root $r = -1$ becomes

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r(-1+r)}{(2+r)^2}$	-2
a_2	$\frac{r(r^3-r^2-5r-4)}{(2+r)^2(r+3)^2}$	$\frac{1}{4}$
a_3	$-\frac{r(r+1)(r^4-12r^2-17r+1)}{(2+r)^2(r+3)^2(r+4)^2}$	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{(r^6 + 3r^5 - 16r^4 - 68r^3 - 43r^2 + 65r + 67)\, r}{(r + 5)^2 (r + 4)^2 (r + 3)^2 (2 + r)}$$

Which for the root $r = -1$ becomes

$$a_4 = -\frac{1}{64}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r(-1+r)}{(2+r)^2}$	-2
a_2	$\frac{r(r^3-r^2-5r-4)}{(2+r)^2(r+3)^2}$	$\frac{1}{4}$
a_3	$-\frac{r(r+1)(r^4-12r^2-17r+1)}{(2+r)^2(r+3)^2(r+4)^2}$	0
a_4	$\frac{(r^6+3r^5-16r^4-68r^3-43r^2+65r+67)r}{(r+5)^2(r+4)^2(r+3)^2(2+r)}$	$-\frac{1}{64}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{(r^8 + 8r^7 - r^6 - 163r^5 - 455r^4 - 131r^3 + 997r^2 + 1312r + 511)\,r}{(r+6)^2\,(2+r)^2\,(r+3)\,(r+4)^2\,(r+5)^2}$$

Which for the root $r = -1$ becomes

$$a_5 = \frac{3}{800}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r(-1+r)}{(2+r)^2}$	-2
a_2	$\frac{r(r^3-r^2-5r-4)}{(2+r)^2(r+3)^2}$	$\frac{1}{4}$
a_3	$-\frac{r(r+1)(r^4-12r^2-17r+1)}{(2+r)^2(r+3)^2(r+4)^2}$	0
a_4	$\frac{(r^6+3r^5-16r^4-68r^3-43r^2+65r+67)r}{(r+5)^2(r+4)^2(r+3)^2(2+r)}$	$-\frac{1}{64}$
a_5	$-\frac{(r^8+8r^7-r^6-163r^5-455r^4-131r^3+997r^2+1312r+511)r}{(r+6)^2(2+r)^2(r+3)(r+4)^2(r+5)^2}$	$\frac{3}{800}$

Using the above table, then the first solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= \frac{1}{x}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\
&= \frac{1 - 2x + \frac{x^2}{4} - \frac{x^4}{64} + \frac{3x^5}{800} + O(x^6)}{x}
\end{aligned}
$$

Now the second solution is found. The second solution is given by

$$
y_2(x) = y_1(x)\ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)
$$

Where b_n is found using

$$
b_n = \frac{d}{dr} a_{n,r}
$$

And the above is then evaluated at $r = -1$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr} a_{n,r}$
b_0	1	1	N/A since b_n starts from 1
b_1	$-\frac{r(-1+r)}{(2+r)^2}$	-2	$\frac{-5r+2}{(2+r)^3}$
b_2	$\frac{r(r^3-r^2-5r-4)}{(2+r)^2(r+3)^2}$	$\frac{1}{4}$	$\frac{11r^4+29r^3-6r^2-40r-24}{(2+r)^3(r+3)^3}$
b_3	$-\frac{r(r+1)(r^4-12r^2-17r+1)}{(2+r)^2(r+3)^2(r+4)^2}$	0	$\frac{-17r^7-137r^6-309r^5+179r^4+1623r^3+2115r^2+794r-24}{(2+r)^3(r+3)^3(r+4)^3}$
b_4	$\frac{(r^6+3r^5-16r^4-68r^3-43r^2+65r+67)r}{(r+5)^2(r+4)^2(r+3)^2(2+r)}$	$-\frac{1}{64}$	$\frac{23r^9+328r^8+1633r^7+2240r^6-8423r^5-36854r^4-51903r^3-227\cdots}{(r+5)^3(r+4)^3(r+3)^3(2+r)^2}$
b_5	$-\frac{(r^8+8r^7-r^6-163r^5-455r^4-131r^3+997r^2+1312r+511)r}{(r+6)^2(2+r)^2(r+3)(r+4)^2(r+5)^2}$	$\frac{3}{800}$	$\frac{-29r^{12}-707r^{11}-6972r^{10}-33562r^9-59772r^8+166668r^7+1175\cdots}{(r+6)^3(2+r\cdots}$

The above table gives all values of b_n needed. Hence the second solution is

$$
\begin{aligned}
y_2(x) &= y_1(x)\ln(x) + b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots \\
&= \frac{\left(1 - 2x + \frac{x^2}{4} - \frac{x^4}{64} + \frac{3x^5}{800} + O(x^6)\right)\ln(x)}{x} + \frac{-x^2 + 7x + \frac{7x^3}{36} + \frac{35x^4}{1152} - \frac{191x^5}{9000} + O(x^6)}{x}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= \frac{c_1 \left(1 - 2x + \frac{x^2}{4} - \frac{x^4}{64} + \frac{3x^5}{800} + O(x^6)\right)}{x} \\
&\quad + c_2 \left(\frac{\left(1 - 2x + \frac{x^2}{4} - \frac{x^4}{64} + \frac{3x^5}{800} + O(x^6)\right) \ln(x)}{x} \right. \\
&\quad \left. + \frac{-x^2 + 7x + \frac{7x^3}{36} + \frac{35x^4}{1152} - \frac{191x^5}{9000} + O(x^6)}{x}\right)
\end{aligned}
$$

The particular solution is found by solving for c, m the balance equation

$$
(x^m m(-1+m) + 3x^m m + x^m)\, c_0 = F
$$

Where $F(x)$ is the RHS of the ode. If $F(x)$ has more than one term, then this is done for each term one at a time and then all the particular solutions are added. The function $F(x)$ will be converted to series if needed. in order to solve for c_n, m for each term, the same recursive relation used to find $y_h(x)$ is used to find c_n, m which is used to find the particular solution $\sum_{n=0} c_n x^{n+m}$ by replacing a_n by c_n and r by m.

The following are the values of a_n found in terms of the indicial root r.

$$
\begin{aligned}
a_1 &= -\frac{a_0 r(-1+r)}{(2+r)^2} \\
a_2 &= \frac{a_0 r(r^3 - r^2 - 5r - 4)}{(2+r)^2 (r+3)^2} \\
a_3 &= -\frac{a_0 r(r+1)(r^4 - 12r^2 - 17r + 1)}{(2+r)^2 (r+3)^2 (r+4)^2} \\
a_4 &= \frac{(r^6 + 3r^5 - 16r^4 - 68r^3 - 43r^2 + 65r + 67) a_0 r}{(r+5)^2 (r+4)^2 (r+3)^2 (2+r)} \\
a_5 &= -\frac{(r^8 + 8r^7 - r^6 - 163r^5 - 455r^4 - 131r^3 + 997r^2 + 1312r + 511) a_0 r}{(r+6)^2 (2+r)^2 (r+3)(r+4)^2 (r+5)^2}
\end{aligned}
$$

Since the $F = -2x^2 + x$ has more than one term then we find a particular solution for each term and add the result to find the particular solution to the ode.

Now we determine the particular solution y_p associated with $F = -2x^2$ by solving the balance equation

$$
(x^m m(-1+m) + 3x^m m + x^m)\, c_0 = -2x^2
$$

For c_0 and x. This results in

$$
\begin{aligned}
c_0 &= -\frac{2}{9} \\
m &= 2
\end{aligned}
$$

The particular solution is therefore

$$
\begin{aligned}
y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\
&= \sum_{n=0}^{\infty} c_n x^{n+2}
\end{aligned}
$$

Where in the above $c_0 = -\frac{2}{9}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 2$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = -\frac{2}{9}$ and $r = m$ or $r = 2$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = -\frac{2}{9}$
$c_1 = \frac{1}{36}$
$c_2 = \frac{1}{90}$
$c_3 = -\frac{13}{2160}$
$c_4 = \frac{41}{26460}$
$c_5 = -\frac{347}{1354752}$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\
&= x^2 \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
y_p = x^2 \left(-\frac{2}{9} + \frac{1}{36} x + \frac{1}{90} x^2 - \frac{13}{2160} x^3 + \frac{41}{26460} x^4 - \frac{347}{1354752} x^5 \right)
$$

$$= -\frac{2}{9}x^2 + \frac{1}{36}x^3 + \frac{1}{90}x^4 - \frac{13}{2160}x^5 + \frac{41}{26460}x^6 - \frac{347}{1354752}x^7$$

Now we determine the particular solution y_p associated with $F = x$ by solving the balance equation

$$(x^m m(-1+m) + 3x^m m + x^m)\, c_0 = x$$

For c_0 and x. This results in

$$c_0 = \frac{1}{4}$$
$$m = 1$$

The particular solution is therefore

$$y_p = \sum_{n=0}^{\infty} c_n x^{n+m}$$
$$= \sum_{n=0}^{\infty} c_n x^{n+1}$$

Where in the above $c_0 = \frac{1}{4}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 1$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{4}$ and $r = m$ or $r = 1$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = \frac{1}{4}$
$c_1 = 0$
$c_2 = -\frac{1}{64}$
$c_3 = \frac{3}{800}$
$c_4 = \frac{1}{19200}$
$c_5 = -\frac{11}{33600}$

The particular solution is now found using

$$y_p = x^m \sum_{n=0}^{\infty} c_n x^n$$
$$= x \sum_{n=0}^{\infty} c_n x^n$$

Using the values found above for c_n into the above sum gives

$$y_p = x\left(\frac{1}{4} - \frac{1}{64}x^2 + \frac{3}{800}x^3 + \frac{1}{19200}x^4 - \frac{11}{33600}x^5\right)$$
$$= \frac{1}{4}x - \frac{1}{64}x^3 + \frac{3}{800}x^4 + \frac{1}{19200}x^5 - \frac{11}{33600}x^6$$

Adding all the above particular solution(s) gives

$$y_p = \frac{x}{4} - \frac{2x^2}{9} + \frac{7x^3}{576} + \frac{107x^4}{7200} - \frac{1031x^5}{172800} + \frac{2587x^6}{2116800} - \frac{347x^7}{1354752} + O(x^6)$$

Truncating the particular solution to the order of series requested gives

$$y_p = \frac{x}{4} - \frac{2x^2}{9} + \frac{7x^3}{576} + \frac{107x^4}{7200} - \frac{1031x^5}{172800} + O(x^6)$$

Hence the final solution is

$y = y_h + y_p$

$$= \frac{x}{4} - \frac{2x^2}{9} + \frac{7x^3}{576} + \frac{107x^4}{7200} - \frac{1031x^5}{172800} + O(x^6) + \frac{c_1\left(1 - 2x + \frac{x^2}{4} - \frac{x^4}{64} + \frac{3x^5}{800} + O(x^6)\right)}{x} + c_2\left(\frac{\left(1 - 2x + \frac{x^2}{4} - \frac{x^4}{64} + \frac{3x^5}{800} + O(x^6)\right)\ln(x)}{x} + \frac{-x^2 + 7x + \frac{7x^3}{36} + \frac{35x^4}{1152} - \frac{191x^5}{9000} + O(x^6)}{x}\right)$$

Summary

The solution(s) found are the following

$$y = \frac{x}{4} - \frac{2x^2}{9} + \frac{7x^3}{576} + \frac{107x^4}{7200} - \frac{1031x^5}{172800} + O(x^6) + \frac{c_1\left(1 - 2x + \frac{x^2}{4} - \frac{x^4}{64} + \frac{3x^5}{800} + O(x^6)\right)}{x} + c_2\left(\frac{\left(1 - 2x + \frac{x^2}{4} - \frac{x^4}{64} + \frac{3x^5}{800} + O(x^6)\right)\ln(x)}{x} + \frac{-x^2 + 7x + \frac{7x^3}{36} + \frac{35x^4}{1152} - \frac{191x^5}{9000} + O(x^6)}{x}\right) \tag{1}$$

Verification of solutions

$$
\begin{aligned}
y = {} & \frac{x}{4}-\frac{2x^{2}}{9}+\frac{7x^{3}}{576}+\frac{107x^{4}}{7200}-\frac{1031x^{5}}{172800}+O\left(x^{6}\right)+\frac{c_{1}\left(1-2x+\frac{x^{2}}{4}-\frac{x^{4}}{64}+\frac{3x^{5}}{800}+O(x^{6})\right)}{x} \\
& + c_{2}\left(\frac{\left(1-2x+\frac{x^{2}}{4}-\frac{x^{4}}{64}+\frac{3x^{5}}{800}+O(x^{6})\right)\ln\left(x\right)}{x}\right. \\
& \left. + \frac{-x^{2}+7x+\frac{7x^{3}}{36}+\frac{35x^{4}}{1152}-\frac{191x^{5}}{9000}+O(x^{6})}{x}\right)
\end{aligned}
$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 43, page 209
Problem number: 7.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{3x^2(x+1)\,y''+x(5-x)\,y'+\left(2x^2-1\right)y=-x^3+x}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(3x^3+3x^2\right)y''+\left(-x^2+5x\right)y'+\left(2x^2-1\right)y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$\begin{aligned} p(x) &= -\frac{x-5}{3x\,(x+1)} \\ q(x) &= \frac{2x^2-1}{3x^2\,(x+1)} \end{aligned}$$

Table 715: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x-5}{3x(x+1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

$q(x) = \frac{2x^2-1}{3x^2(x+1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-1, 0]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$3x^2(x+1)\,y'' + (-x^2+5x)\,y' + (2x^2-1)\,y = -x^3 + x$$

Since this is an inhomogeneous, then let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ode $3x^2(x+1)\,y'' + (-x^2+5x)\,y' + (2x^2-1)\,y = 0$, and y_p is a particular solution to the inhomogeneous ode.which is found using the balance equation generated from indicial equation

First, we solve for y_h Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$
\begin{aligned}
&3x^2(x+1)\left(\sum_{n=0}^{\infty}(n+r)\,(n+r-1)\,a_n x^{n+r-2}\right) \\
&+\left(-x^2+5x\right)\left(\sum_{n=0}^{\infty}(n+r)\,a_n x^{n+r-1}\right)+\left(2x^2-1\right)\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right)=0
\end{aligned}
\tag{1}
$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty}3x^{1+n+r}a_n(n+r)\,(n+r-1)\right)+\left(\sum_{n=0}^{\infty}3x^{n+r}a_n(n+r)\,(n+r-1)\right) \\
&+\sum_{n=0}^{\infty}\left(-x^{1+n+r}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}5x^{n+r}a_n(n+r)\right) \\
&+\left(\sum_{n=0}^{\infty}2x^{n+r+2}a_n\right)+\sum_{n=0}^{\infty}\left(-a_n x^{n+r}\right)=0
\end{aligned}
\tag{2A}
$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=0}^{\infty}3x^{1+n+r}a_n(n+r)\,(n+r-1) &= \sum_{n=1}^{\infty}3a_{n-1}(n+r-1)\,(n+r-2)\,x^{n+r} \\
\sum_{n=0}^{\infty}\left(-x^{1+n+r}a_n(n+r)\right) &= \sum_{n=1}^{\infty}\left(-a_{n-1}(n+r-1)\,x^{n+r}\right) \\
\sum_{n=0}^{\infty}2x^{n+r+2}a_n &= \sum_{n=2}^{\infty}2a_{n-2}x^{n+r}
\end{aligned}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=1}^{\infty} 3a_{n-1}(n+r-1)(n+r-2)x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 3x^{n+r}a_n(n+r)(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 5x^{n+r}a_n(n+r)\right) + \left(\sum_{n=2}^{\infty} 2a_{n-2}x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$3x^{n+r}a_n(n+r)(n+r-1) + 5x^{n+r}a_n(n+r) - a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$3x^r a_0 r(-1+r) + 5x^r a_0 r - a_0 x^r = 0$$

Or

$$(3x^r r(-1+r) + 5x^r r - x^r)\, a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(3r^2 + 2r - 1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$3r^2 + 2r - 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{3}$$
$$r_2 = -1$$

The corresponding balance equation is found by replacing r by m and a by c to avoid confusing terms between particular solution and the homogeneous solution. Hence the balance equation is

$$(3x^m m(-1+m) + 5x^m m - x^m)\, c_0 = -x^3 + x$$

This equation will used later to find the particular solution.

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(3r^2 + 2r - 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{4}{3}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n \right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n \right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{3}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-1}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = \frac{-3r^2 + 4r}{3r^2 + 8r + 4}$$

For $2 \leq n$ the recursive equation is

$$\begin{aligned} 3a_{n-1}(n + r - 1) (n + r - 2) + 3a_n(n + r) (n + r - 1) \\ - a_{n-1}(n + r - 1) + 5a_n(n + r) + 2a_{n-2} - a_n = 0 \end{aligned} \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{3n^2 a_{n-1} + 6nr a_{n-1} + 3r^2 a_{n-1} - 10n a_{n-1} - 10r a_{n-1} + 2a_{n-2} + 7a_{n-1}}{3n^2 + 6nr + 3r^2 + 2n + 2r - 1} \tag{4}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_n = \frac{-3n^2 a_{n-1} + 8n a_{n-1} - 2a_{n-2} - 4a_{n-1}}{n\,(3n + 4)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{3}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3r^2+4r}{3r^2+8r+4}$	$\frac{1}{7}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{9r^4 - 6r^3 - 17r^2 - 12r - 8}{9r^4 + 66r^3 + 169r^2 + 176r + 60}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_2 = -\frac{1}{10}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3r^2+4r}{3r^2+8r+4}$	$\frac{1}{7}$
a_2	$\frac{9r^4-6r^3-17r^2-12r-8}{9r^4+66r^3+169r^2+176r+60}$	$-\frac{1}{10}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{-27r^6 - 54r^5 + 81r^4 + 256r^3 + 166r^2 - 8r + 32}{(3r^2 + 20r + 32)(3r^2 + 8r + 4)(3r^2 + 14r + 15)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_3 = \frac{29}{2730}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3r^2+4r}{3r^2+8r+4}$	$\frac{1}{7}$
a_2	$\frac{9r^4-6r^3-17r^2-12r-8}{9r^4+66r^3+169r^2+176r+60}$	$-\frac{1}{10}$
a_3	$\frac{-27r^6-54r^5+81r^4+256r^3+166r^2-8r+32}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)}$	$\frac{29}{2730}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{81r^8 + 540r^7 + 864r^6 - 1416r^5 - 5531r^4 - 5004r^3 - 858r^2 + 760r + 32}{(3r^2 + 26r + 55)(9r^4 + 66r^3 + 169r^2 + 176r + 60)(3r^2 + 20r + 32)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_4 = -\frac{17}{87360}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3r^2+4r}{3r^2+8r+4}$	$\frac{1}{7}$
a_2	$\frac{9r^4-6r^3-17r^2-12r-8}{9r^4+66r^3+169r^2+176r+60}$	$-\frac{1}{10}$
a_3	$\frac{-27r^6-54r^5+81r^4+256r^3+166r^2-8r+32}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)}$	$\frac{29}{2730}$
a_4	$\frac{81r^8+540r^7+864r^6-1416r^5-5531r^4-5004r^3-858r^2+760r+32}{(3r^2+26r+55)(9r^4+66r^3+169r^2+176r+60)(3r^2+20r+32)}$	$-\frac{17}{87360}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{-243r^{10} - 3240r^9 - 15822r^8 - 28584r^7 + 22557r^6 + 171136r^5 + 256428r^4 + 138264r^3 - 5876r^2 - 2}{(3r^2 + 32r + 84)(3r^2 + 26r + 55)(9r^4 + 66r^3 + 169r^2 + 176r + 60)(3r^2 + 20r + 32)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_5 = -\frac{1193}{8299200}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3r^2+4r}{3r^2+8r+4}$	$\frac{1}{7}$
a_2	$\frac{9r^4-6r^3-17r^2-12r-8}{9r^4+66r^3+169r^2+176r+60}$	$-\frac{1}{10}$
a_3	$\frac{-27r^6-54r^5+81r^4+256r^3+166r^2-8r+32}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)}$	$\frac{29}{2730}$
a_4	$\frac{81r^8+540r^7+864r^6-1416r^5-5531r^4-5004r^3-858r^2+760r+32}{(3r^2+26r+55)(9r^4+66r^3+169r^2+176r+60)(3r^2+20r+32)}$	$-\frac{17}{87360}$
a_5	$\frac{-243r^{10}-3240r^9-15822r^8-28584r^7+22557r^6+171136r^5+256428r^4+138264r^3-5876r^2-25744r-4544}{(3r^2+32r+84)(3r^2+26r+55)(9r^4+66r^3+169r^2+176r+60)(3r^2+20r+32)}$	$-\frac{1193}{8299200}$

Using the above table, then the solution $y_1(x)$ is

$$y_1(x) = x^{\frac{1}{3}}(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots)$$
$$= x^{\frac{1}{3}}\left(1 + \frac{x}{7} - \frac{x^2}{10} + \frac{29x^3}{2730} - \frac{17x^4}{87360} - \frac{1193x^5}{8299200} + O(x^6)\right)$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$b_1 = \frac{-3r^2 + 4r}{3r^2 + 8r + 4}$$

For $2 \leq n$ the recursive equation is

$$3b_{n-1}(n + r - 1)(n + r - 2) + 3b_n(n + r)(n + r - 1) - b_{n-1}(n + r - 1) + 5b_n(n + r) + 2b_{n-2} - b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{3n^2b_{n-1} + 6nrb_{n-1} + 3r^2b_{n-1} - 10nb_{n-1} - 10rb_{n-1} + 2b_{n-2} + 7b_{n-1}}{3n^2 + 6nr + 3r^2 + 2n + 2r - 1} \tag{4}$$

Which for the root $r = -1$ becomes

$$b_n = \frac{-3n^2b_{n-1} + 16nb_{n-1} - 2b_{n-2} - 20b_{n-1}}{n(3n - 4)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-3r^2+4r}{3r^2+8r+4}$	7

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{9r^4 - 6r^3 - 17r^2 - 12r - 8}{9r^4 + 66r^3 + 169r^2 + 176r + 60}$$

Which for the root $r = -1$ becomes

$$b_2 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-3r^2+4r}{3r^2+8r+4}$	7
b_2	$\frac{9r^4-6r^3-17r^2-12r-8}{9r^4+66r^3+169r^2+176r+60}$	$-\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{-27r^6 - 54r^5 + 81r^4 + 256r^3 + 166r^2 - 8r + 32}{(3r^2 + 20r + 32)(3r^2 + 8r + 4)(3r^2 + 14r + 15)}$$

Which for the root $r = -1$ becomes

$$b_3 = -\frac{29}{30}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-3r^2+4r}{3r^2+8r+4}$	7
b_2	$\frac{9r^4-6r^3-17r^2-12r-8}{9r^4+66r^3+169r^2+176r+60}$	$-\frac{1}{2}$
b_3	$\frac{-27r^6-54r^5+81r^4+256r^3+166r^2-8r+32}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{29}{30}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{81r^8 + 540r^7 + 864r^6 - 1416r^5 - 5531r^4 - 5004r^3 - 858r^2 + 760r + 32}{(3r^2 + 26r + 55)(9r^4 + 66r^3 + 169r^2 + 176r + 60)(3r^2 + 20r + 32)}$$

Which for the root $r = -1$ becomes

$$b_4 = \frac{73}{480}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-3r^2+4r}{3r^2+8r+4}$	7
b_2	$\frac{9r^4-6r^3-17r^2-12r-8}{9r^4+66r^3+169r^2+176r+60}$	$-\frac{1}{2}$
b_3	$\frac{-27r^6-54r^5+81r^4+256r^3+166r^2-8r+32}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{29}{30}$
b_4	$\frac{81r^8+540r^7+864r^6-1416r^5-5531r^4-5004r^3-858r^2+760r+32}{(3r^2+26r+55)(9r^4+66r^3+169r^2+176r+60)(3r^2+20r+32)}$	$\frac{73}{480}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{-243r^{10} - 3240r^9 - 15822r^8 - 28584r^7 + 22557r^6 + 171136r^5 + 256428r^4 + 138264r^3 - 5876r^2 - 2}{(3r^2 + 32r + 84)(3r^2 + 26r + 55)(9r^4 + 66r^3 + 169r^2 + 176r + 60)(3r^2 + 20r + 32)}$$

Which for the root $r = -1$ becomes

$$b_5 = -\frac{167}{26400}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-3r^2+4r}{3r^2+8r+4}$	7
b_2	$\frac{9r^4-6r^3-17r^2-12r-8}{9r^4+66r^3+169r^2+176r+60}$	$-\frac{1}{2}$
b_3	$\frac{-27r^6-54r^5+81r^4+256r^3+166r^2-8r+32}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)}$	$-\frac{29}{30}$
b_4	$\frac{81r^8+540r^7+864r^6-1416r^5-5531r^4-5004r^3-858r^2+760r+32}{(3r^2+26r+55)(9r^4+66r^3+169r^2+176r+60)(3r^2+20r+32)}$	$\frac{73}{480}$
b_5	$\frac{-243r^{10}-3240r^9-15822r^8-28584r^7+22557r^6+171136r^5+256428r^4+138264r^3-5876r^2-25744r-4544}{(3r^2+32r+84)(3r^2+26r+55)(9r^4+66r^3+169r^2+176r+60)(3r^2+20r+32)}$	$-\frac{167}{26400}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= x^{\frac{1}{3}}\left(b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 \dots\right) \\ &= \frac{1 + 7x - \frac{x^2}{2} - \frac{29x^3}{30} + \frac{73x^4}{480} - \frac{167x^5}{26400} + O(x^6)}{x} \end{aligned}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{\frac{1}{3}} \left(1 + \frac{x}{7} - \frac{x^2}{10} + \frac{29x^3}{2730} - \frac{17x^4}{87360} - \frac{1193x^5}{8299200} + O(x^6)\right) \\
&\quad + \frac{c_2 \left(1 + 7x - \frac{x^2}{2} - \frac{29x^3}{30} + \frac{73x^4}{480} - \frac{167x^5}{26400} + O(x^6)\right)}{x}
\end{aligned}
$$

The particular solution is found by solving for c, m the balance equation

$$
(3x^m m(-1+m) + 5x^m m - x^m)\, c_0 = F
$$

Where $F(x)$ is the RHS of the ode. If $F(x)$ has more than one term, then this is done for each term one at a time and then all the particular solutions are added. The function $F(x)$ will be converted to series if needed. in order to solve for c_n, m for each term, the same recursive relation used to find $y_h(x)$ is used to find c_n, m which is used to find the particular solution $\sum_{n=0} c_n x^{n+m}$ by replacing a_n by c_n and r by m.

The following are the values of a_n found in terms of the indicial root r.

$$
\begin{aligned}
a_1 &= \frac{a_0(-3r^2+4r)}{3r^2+8r+4} \\
a_2 &= \frac{a_0(9r^4-6r^3-17r^2-12r-8)}{9r^4+66r^3+169r^2+176r+60} \\
a_3 &= -\frac{(27r^6+54r^5-81r^4-256r^3-166r^2+8r-32)a_0}{(3r^2+20r+32)(3r^2+8r+4)(3r^2+14r+15)} \\
a_4 &= \frac{a_0(81r^8+540r^7+864r^6-1416r^5-5531r^4-5004r^3-858r^2+760r+32)}{(3r^2+26r+55)(9r^4+66r^3+169r^2+176r+60)(3r^2+20r+32)} \\
a_5 &= -\frac{a_0(243r^{10}+3240r^9+15822r^8+28584r^7-22557r^6-171136r^5-256428r^4-138264r^3+5876r^2+25744r+4544)}{(3r^2+32r+84)(3r^2+26r+55)(9r^4+66r^3+169r^2+176r+60)(3r^2+20r+32)}
\end{aligned}
$$

Since the $F = -x^3 + x$ has more than one term then we find a particular solution for each term and add the result to find the particular solution to the ode.

Now we determine the particular solution y_p associated with $F = -x^3$ by solving the balance equation

$$
(3x^m m(-1+m) + 5x^m m - x^m)\, c_0 = -x^3
$$

For c_0 and x. This results in

$$
\begin{aligned}
c_0 &= -\frac{1}{32} \\
m &= 3
\end{aligned}
$$

The particular solution is therefore

$$
\begin{aligned}
y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\
&= \sum_{n=0}^{\infty} c_n x^{n+3}
\end{aligned}
$$

Where in the above $c_0 = -\frac{1}{32}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 3$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = -\frac{1}{32}$ and $r = m$ or $r = 3$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = -\frac{1}{32}$
$c_1 = \frac{3}{352}$
$c_2 = -\frac{37}{14784}$
$c_3 = \frac{1783}{1759296}$
$c_4 = -\frac{10069}{20106240}$
$c_5 = \frac{8102197}{29133941760}$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\
&= x^3 \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x^3 \left(-\frac{1}{32} + \frac{3}{352} x - \frac{37}{14784} x^2 + \frac{1783}{1759296} x^3 - \frac{10069}{20106240} x^4 + \frac{8102197}{29133941760} x^5 \right) \\
&= -\frac{1}{32} x^3 + \frac{3}{352} x^4 - \frac{37}{14784} x^5 + \frac{1783}{1759296} x^6 - \frac{10069}{20106240} x^7 + \frac{8102197}{29133941760} x^8
\end{aligned}
$$

Now we determine the particular solution y_p associated with $F = x$ by solving the balance equation

$$\left(3x^m m(-1+m)+5x^m m - x^m\right) c_0 = x$$

For c_0 and x. This results in

$$\begin{aligned} c_0 &= \frac{1}{4} \\ m &= 1 \end{aligned}$$

The particular solution is therefore

$$\begin{aligned} y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\ &= \sum_{n=0}^{\infty} c_n x^{n+1} \end{aligned}$$

Where in the above $c_0 = \frac{1}{4}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 1$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{4}$ and $r = m$ or $r = 1$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = \frac{1}{4}$
$c_1 = \frac{1}{60}$
$c_2 = -\frac{17}{960}$
$c_3 = \frac{223}{52800}$
$c_4 = -\frac{2633}{2217600}$
$c_5 = \frac{126083}{263894400}$

The particular solution is now found using

$$\begin{aligned} y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\ &= x \sum_{n=0}^{\infty} c_n x^n \end{aligned}$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x\left(\frac{1}{4}+\frac{1}{60}x-\frac{17}{960}x^2+\frac{223}{52800}x^3-\frac{2633}{2217600}x^4+\frac{126083}{263894400}x^5\right) \\
&= \frac{1}{4}x+\frac{1}{60}x^2-\frac{17}{960}x^3+\frac{223}{52800}x^4-\frac{2633}{2217600}x^5+\frac{126083}{263894400}x^6
\end{aligned}
$$

Adding all the above particular solution(s) gives

$$
y_p = \frac{x}{4}+\frac{x^2}{60}-\frac{47x^3}{960}+\frac{673x^4}{52800}-\frac{1169x^5}{316800}+\frac{3307x^6}{2217600}-\frac{10069x^7}{20106240}+\frac{8102197x^8}{29133941760}+O\left(x^6\right)
$$

Truncating the particular solution to the order of series requested gives

$$
y_p = \frac{x}{4}+\frac{x^2}{60}-\frac{47x^3}{960}+\frac{673x^4}{52800}-\frac{1169x^5}{316800}+O\left(x^6\right)
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \frac{x}{4}+\frac{x^2}{60}-\frac{47x^3}{960}+\frac{673x^4}{52800}-\frac{1169x^5}{316800}+O\left(x^6\right) \\
&\quad + c_1 x^{\frac{1}{3}}\left(1+\frac{x}{7}-\frac{x^2}{10}+\frac{29x^3}{2730}-\frac{17x^4}{87360}-\frac{1193x^5}{8299200}+O\left(x^6\right)\right) \\
&\quad + \frac{c_2\left(1+7x-\frac{x^2}{2}-\frac{29x^3}{30}+\frac{73x^4}{480}-\frac{167x^5}{26400}+O(x^6)\right)}{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= \frac{x}{4}+\frac{x^2}{60}-\frac{47x^3}{960}+\frac{673x^4}{52800}-\frac{1169x^5}{316800}+O\left(x^6\right) \\
&\quad + c_1 x^{\frac{1}{3}}\left(1+\frac{x}{7}-\frac{x^2}{10}+\frac{29x^3}{2730}-\frac{17x^4}{87360}-\frac{1193x^5}{8299200}+O\left(x^6\right)\right) \\
&\quad + \frac{c_2\left(1+7x-\frac{x^2}{2}-\frac{29x^3}{30}+\frac{73x^4}{480}-\frac{167x^5}{26400}+O(x^6)\right)}{x}
\end{aligned}
\tag{1}
$$

Verification of solutions

$$y = \frac{x}{4}+\frac{x^2}{60}-\frac{47x^3}{960}+\frac{673x^4}{52800}-\frac{1169x^5}{316800}+O(x^6) + c_1 x^{\frac{1}{3}}\left(1+\frac{x}{7}-\frac{x^2}{10}+\frac{29x^3}{2730}-\frac{17x^4}{87360}-\frac{1193x^5}{8299200}+O(x^6)\right) + \frac{c_2\left(1+7x-\frac{x^2}{2}-\frac{29x^3}{30}+\frac{73x^4}{480}-\frac{167x^5}{26400}+O(x^6)\right)}{x}$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 43, page 209
Problem number: 8.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{9x^2y'' + (2+3x)\,y = x^4 + x^2}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$9x^2y'' + (2+3x)\,y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = 0$$
$$q(x) = \frac{2+3x}{9x^2}$$

Table 716: Table $p(x), q(x)$ singularites.

$p(x) = 0$	
singularity	type

$q(x) = \frac{2+3x}{9x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$9x^2y'' + (2 + 3x)\, y = x^4 + x^2$$

Since this is an inhomogeneous, then let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ode $9x^2y'' + (2 + 3x)\, y = 0$, and y_p is a particular solution to the inhomogeneous ode.which is found using the balance equation generated from indicial equation

First, we solve for y_h Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r)\, (n + r - 1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$9x^2 \left(\sum_{n=0}^{\infty} (n + r)\, (n + r - 1)\, a_n x^{n+r-2}\right) + (2 + 3x) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 9x^{n+r} a_n (n + r)\, (n + r - 1)\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 3x^{1+n+r} a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 3x^{1+n+r} a_n = \sum_{n=1}^{\infty} 3a_{n-1} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 9x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) + \left(\sum_{n=1}^{\infty} 3a_{n-1} x^{n+r}\right) = 0 \quad \text{(2B)}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$9x^{n+r} a_n (n+r)(n+r-1) + 2a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$9x^r a_0 r(-1+r) + 2a_0 x^r = 0$$

Or

$$(9x^r r(-1+r) + 2x^r)\, a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$(9r^2 - 9r + 2)\, x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$9r^2 - 9r + 2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{2}{3}$$
$$r_2 = \frac{1}{3}$$

The corresponding balance equation is found by replacing r by m and a by c to avoid confusing terms between particular solution and the homogeneous solution. Hence the balance equation is

$$(9x^m m(-1+m) + 2x^m)\, c_0 = x^4 + x^2$$

This equation will used later to find the particular solution.

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(9r^2 - 9r + 2\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{3}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n \right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n \right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{2}{3}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n+\frac{1}{3}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$9a_n(n + r)(n + r - 1) + 2a_n + 3a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{3a_{n-1}}{9n^2 + 18nr + 9r^2 - 9n - 9r + 2} \tag{4}$$

Which for the root $r = \frac{2}{3}$ becomes

$$a_n = -\frac{a_{n-1}}{3n^2 + n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{2}{3}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{3}{9r^2 + 9r + 2}$$

Which for the root $r = \frac{2}{3}$ becomes

$$a_1 = -\frac{1}{4}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{4}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{9}{(9r^2 + 9r + 2)(9r^2 + 27r + 20)}$$

Which for the root $r = \frac{2}{3}$ becomes

$$a_2 = \frac{1}{56}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{4}$
a_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{56}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{27}{(9r^2 + 9r + 2)(9r^2 + 27r + 20)(9r^2 + 45r + 56)}$$

Which for the root $r = \frac{2}{3}$ becomes

$$a_3 = -\frac{1}{1680}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{4}$
a_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{56}$
a_3	$-\frac{27}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)}$	$-\frac{1}{1680}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{81}{(9r^2 + 9r + 2)(9r^2 + 27r + 20)(9r^2 + 45r + 56)(9r^2 + 63r + 110)}$$

Which for the root $r = \frac{2}{3}$ becomes

$$a_4 = \frac{1}{87360}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{4}$
a_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{56}$
a_3	$-\frac{27}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)}$	$-\frac{1}{1680}$
a_4	$\frac{81}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)}$	$\frac{1}{87360}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{243}{(9r^2 + 9r + 2)(9r^2 + 27r + 20)(9r^2 + 45r + 56)(9r^2 + 63r + 110)(9r^2 + 81r + 182)}$$

Which for the root $r = \frac{2}{3}$ becomes

$$a_5 = -\frac{1}{6988800}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{4}$
a_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{56}$
a_3	$-\frac{27}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)}$	$-\frac{1}{1680}$
a_4	$\frac{81}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)}$	$\frac{1}{87360}$
a_5	$-\frac{243}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)(9r^2+81r+182)}$	$-\frac{1}{6988800}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{2}{3}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^{\frac{2}{3}}\left(1 - \frac{x}{4} + \frac{x^2}{56} - \frac{x^3}{1680} + \frac{x^4}{87360} - \frac{x^5}{6988800} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$9b_n(n+r)(n+r-1) + 2b_n + 3b_{n-1} = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{3b_{n-1}}{9n^2 + 18nr + 9r^2 - 9n - 9r + 2} \tag{4}$$

Which for the root $r = \frac{1}{3}$ becomes

$$b_n = -\frac{b_{n-1}}{n(3n-1)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{1}{3}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = -\frac{3}{9r^2 + 9r + 2}$$

Which for the root $r = \frac{1}{3}$ becomes

$$b_1 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{2}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{9}{(9r^2 + 9r + 2)(9r^2 + 27r + 20)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$b_2 = \frac{1}{20}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{2}$
b_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{20}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{27}{(9r^2 + 9r + 2)(9r^2 + 27r + 20)(9r^2 + 45r + 56)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$b_3 = -\frac{1}{480}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{2}$
b_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{20}$
b_3	$-\frac{27}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)}$	$-\frac{1}{480}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{81}{(9r^2 + 9r + 2)(9r^2 + 27r + 20)(9r^2 + 45r + 56)(9r^2 + 63r + 110)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$b_4 = \frac{1}{21120}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{2}$
b_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{20}$
b_3	$-\frac{27}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)}$	$-\frac{1}{480}$
b_4	$\frac{81}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)}$	$\frac{1}{21120}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{243}{(9r^2 + 9r + 2)(9r^2 + 27r + 20)(9r^2 + 45r + 56)(9r^2 + 63r + 110)(9r^2 + 81r + 182)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$b_5 = -\frac{1}{1478400}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{3}{9r^2+9r+2}$	$-\frac{1}{2}$
b_2	$\frac{9}{(9r^2+9r+2)(9r^2+27r+20)}$	$\frac{1}{20}$
b_3	$-\frac{27}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)}$	$-\frac{1}{480}$
b_4	$\frac{81}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)}$	$\frac{1}{21120}$
b_5	$-\frac{243}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)(9r^2+81r+182)}$	$-\frac{1}{1478400}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x^{\frac{2}{3}}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= x^{\frac{1}{3}}\left(1 - \frac{x}{2} + \frac{x^2}{20} - \frac{x^3}{480} + \frac{x^4}{21120} - \frac{x^5}{1478400} + O\left(x^6\right)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{\frac{2}{3}}\left(1 - \frac{x}{4} + \frac{x^2}{56} - \frac{x^3}{1680} + \frac{x^4}{87360} - \frac{x^5}{6988800} + O\left(x^6\right)\right) \\
&\quad + c_2 x^{\frac{1}{3}}\left(1 - \frac{x}{2} + \frac{x^2}{20} - \frac{x^3}{480} + \frac{x^4}{21120} - \frac{x^5}{1478400} + O\left(x^6\right)\right)
\end{aligned}
$$

The particular solution is found by solving for c, m the balance equation

$$
\left(9x^m m(-1+m) + 2x^m\right) c_0 = F
$$

Where $F(x)$ is the RHS of the ode. If $F(x)$ has more than one term, then this is done for each term one at a time and then all the particular solutions are added. The function $F(x)$ will be converted to series if needed. in order to solve for c_n, m for each term, the same recursive relation used to find $y_h(x)$ is used to find c_n, m which is used to find the particular solution $\sum_{n=0} c_n x^{n+m}$ by replacing a_n by c_n and r by m.

The following are the values of a_n found in terms of the indicial root r.

$$
\begin{aligned}
a_1 &= -\frac{3a_0}{9r^2+9r+2} \\
a_2 &= \frac{9a_0}{(9r^2+9r+2)(9r^2+27r+20)} \\
a_3 &= -\frac{27a_0}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)} \\
a_4 &= \frac{81a_0}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)} \\
a_5 &= -\frac{243a_0}{(9r^2+9r+2)(9r^2+27r+20)(9r^2+45r+56)(9r^2+63r+110)(9r^2+81r+182)}
\end{aligned}
$$

Since the $F = x^4 + x^2$ has more than one term then we find a particular solution for each term and add the result to find the particular solution to the ode.

Now we determine the particular solution y_p associated with $F = x^4$ by solving the balance equation

$$
\left(9x^m m(-1+m) + 2x^m\right) c_0 = x^4
$$

For c_0 and x. This results in

$$c_0 = \frac{1}{110}$$
$$m = 4$$

The particular solution is therefore

$$\begin{aligned} y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\ &= \sum_{n=0}^{\infty} c_n x^{n+4} \end{aligned}$$

Where in the above $c_0 = \frac{1}{110}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 4$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{110}$ and $r = m$ or $r = 4$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = \frac{1}{110}$
$c_1 = -\frac{3}{20020}$
$c_2 = \frac{9}{5445440}$
$c_3 = -\frac{27}{2069267200}$
$c_4 = \frac{81}{1047049203200}$
$c_5 = -\frac{243}{680581982080000}$

The particular solution is now found using

$$\begin{aligned} y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\ &= x^4 \sum_{n=0}^{\infty} c_n x^n \end{aligned}$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x^4\left(\frac{1}{110} - \frac{3}{20020}x + \frac{9}{5445440}x^2 - \frac{27}{2069267200}x^3 + \frac{81}{1047049203200}x^4 \right.\\
&\quad \left. - \frac{243}{680581982080000}x^5\right) \\
&= \frac{1}{110}x^4 - \frac{3}{20020}x^5 + \frac{9}{5445440}x^6 - \frac{27}{2069267200}x^7 \\
&\quad + \frac{81}{1047049203200}x^8 - \frac{243}{680581982080000}x^9
\end{aligned}
$$

Now we determine the particular solution y_p associated with $F = x^2$ by solving the balance equation

$$
\left(9x^m m(-1+m) + 2x^m\right) c_0 = x^2
$$

For c_0 and x. This results in

$$
\begin{aligned}
c_0 &= \frac{1}{20} \\
m &= 2
\end{aligned}
$$

The particular solution is therefore

$$
\begin{aligned}
y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\
&= \sum_{n=0}^{\infty} c_n x^{n+2}
\end{aligned}
$$

Where in the above $c_0 = \frac{1}{20}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 2$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{20}$ and $r = m$ or $r = 2$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$$
\begin{aligned}
c_0 &= \frac{1}{20}\\
c_1 &= -\frac{3}{1120}\\
c_2 &= \frac{9}{123200}\\
c_3 &= -\frac{27}{22422400}\\
c_4 &= \frac{81}{6098892800}\\
c_5 &= -\frac{243}{2317579264000}
\end{aligned}
$$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n\\
&= x^2 \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x^2 \left(\frac{1}{20} - \frac{3}{1120}x + \frac{9}{123200}x^2 - \frac{27}{22422400}x^3 + \frac{81}{6098892800}x^4 - \frac{243}{2317579264000}x^5\right)\\
&= \frac{1}{20}x^2 - \frac{3}{1120}x^3 + \frac{9}{123200}x^4 - \frac{27}{22422400}x^5 + \frac{81}{6098892800}x^6 - \frac{243}{2317579264000}x^7
\end{aligned}
$$

Adding all the above particular solution(s) gives

$$
\begin{aligned}
y_p = {} & \frac{x^2}{20} - \frac{3x^3}{1120} + \frac{1129x^4}{123200} - \frac{3387x^5}{22422400} + \frac{10161x^6}{6098892800}\\
& - \frac{30483x^7}{2317579264000} + \frac{81x^8}{1047049203200} - \frac{243x^9}{680581982080000} + O\left(x^6\right)
\end{aligned}
$$

Truncating the particular solution to the order of series requested gives

$$
y_p = \frac{x^2}{20} - \frac{3x^3}{1120} + \frac{1129x^4}{123200} - \frac{3387x^5}{22422400} + O\left(x^6\right)
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \frac{x^2}{20} - \frac{3x^3}{1120} + \frac{1129x^4}{123200} - \frac{3387x^5}{22422400} + O(x^6) \\
&\quad + c_1 x^{\frac{2}{3}} \left(1 - \frac{x}{4} + \frac{x^2}{56} - \frac{x^3}{1680} + \frac{x^4}{87360} - \frac{x^5}{6988800} + O(x^6)\right) \\
&\quad + c_2 x^{\frac{1}{3}} \left(1 - \frac{x}{2} + \frac{x^2}{20} - \frac{x^3}{480} + \frac{x^4}{21120} - \frac{x^5}{1478400} + O(x^6)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= \frac{x^2}{20} - \frac{3x^3}{1120} + \frac{1129x^4}{123200} - \frac{3387x^5}{22422400} + O(x^6) \\
&\quad + c_1 x^{\frac{2}{3}} \left(1 - \frac{x}{4} + \frac{x^2}{56} - \frac{x^3}{1680} + \frac{x^4}{87360} - \frac{x^5}{6988800} + O(x^6)\right) \\
&\quad + c_2 x^{\frac{1}{3}} \left(1 - \frac{x}{2} + \frac{x^2}{20} - \frac{x^3}{480} + \frac{x^4}{21120} - \frac{x^5}{1478400} + O(x^6)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= \frac{x^2}{20} - \frac{3x^3}{1120} + \frac{1129x^4}{123200} - \frac{3387x^5}{22422400} + O(x^6) \\
&\quad + c_1 x^{\frac{2}{3}} \left(1 - \frac{x}{4} + \frac{x^2}{56} - \frac{x^3}{1680} + \frac{x^4}{87360} - \frac{x^5}{6988800} + O(x^6)\right) \\
&\quad + c_2 x^{\frac{1}{3}} \left(1 - \frac{x}{2} + \frac{x^2}{20} - \frac{x^3}{480} + \frac{x^4}{21120} - \frac{x^5}{1478400} + O(x^6)\right)
\end{aligned}
$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 43, page 209
Problem number: 9.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Complex roots"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{9x^2y'' + 10xy' + y = x - 1}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$9x^2y'' + 10xy' + y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{10}{9x}$$
$$q(x) = \frac{1}{9x^2}$$

Table 717: Table $p(x), q(x)$ singularites.

$p(x) = \frac{10}{9x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{1}{9x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, \infty]$

Irregular singular points : []

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$9x^2y'' + 10xy' + y = x - 1$$

Since this is an inhomogeneous, then let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ode $9x^2y'' + 10xy' + y = 0$, and y_p is a particular solution to the inhomogeneous ode.which is found using the balance equation generated from indicial equation

First, we solve for y_h Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$9x^2 \left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) + 10x \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 9x^{n+r} a_n (n+r) (n+r-1)\right) + \left(\sum_{n=0}^{\infty} 10x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \quad \text{(2A)}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 9x^{n+r} a_n (n+r) (n+r-1)\right) + \left(\sum_{n=0}^{\infty} 10x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \quad \text{(2B)}$$

The indicial equation is obtained from $n = 0$. From Eq (2B) this gives

$$9x^{n+r} a_n (n+r) (n+r-1) + 10x^{n+r} a_n (n+r) + a_n x^{n+r} = 0$$

When $n = 0$ the above becomes

$$9x^r a_0 r(-1+r) + 10x^r a_0 r + a_0 x^r = 0$$

Or

$$(9x^r r(-1+r) + 10x^r r + x^r) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(9r^2 + r + 1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$9r^2 + r + 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = -\frac{1}{18} + \frac{i\sqrt{35}}{18}$$
$$r_2 = -\frac{1}{18} - \frac{i\sqrt{35}}{18}$$

The corresponding balance equation is found by replacing r by m and a by c to avoid confusing terms between particular solution and the homogeneous solution. Hence the balance equation is

$$(9x^m m(-1+m) + 10x^m m + x^m) c_0 = x - 1$$

This equation will used later to find the particular solution.

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(9r^2+r+1\right)x^r = 0$$

Solving for r gives the roots of the indicial equation as Since the roots are complex conjugates, then two linearly independent solutions can be constructed using

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n-\frac{1}{18}+\frac{i\sqrt{35}}{18}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-\frac{1}{18}-\frac{i\sqrt{35}}{18}}$$

$y_1(x)$ is found first. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $0 \leq n$ the recursive equation is

$$9a_n(n+r)(n+r-1) + 10a_n(n+r) + a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = 0 \tag{4}$$

Which for the root $r = -\frac{1}{18} + \frac{i\sqrt{35}}{18}$ becomes

$$a_n = 0 \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = -\frac{1}{18} + \frac{i\sqrt{35}}{18}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{-\frac{1}{18}+\frac{i\sqrt{35}}{18}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^{-\frac{1}{18}+\frac{i\sqrt{35}}{18}}\left(1 + O(x^6)\right) \end{aligned}$$

The second solution $y_2(x)$ is found by taking the complex conjugate of $y_1(x)$ which gives

$$y_2(x) = x^{-\frac{1}{18}-\frac{i\sqrt{35}}{18}}\left(1 + O(x^6)\right)$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^{-\frac{1}{18}+\frac{i\sqrt{35}}{18}}\left(1 + O(x^6)\right) + c_2 x^{-\frac{1}{18}-\frac{i\sqrt{35}}{18}}\left(1 + O(x^6)\right) \end{aligned}$$

The particular solution is found by solving for c, m the balance equation

$$\left(9x^m m(-1+m) + 10x^m m + x^m\right) c_0 = F$$

Where $F(x)$ is the RHS of the ode. If $F(x)$ has more than one term, then this is done for each term one at a time and then all the particular solutions are added. The function $F(x)$ will be converted to series if needed. in order to solve for c_n, m for each term, the same recursive relation used to find $y_h(x)$ is used to find c_n, m which is used to find the particular solution $\sum_{n=0} c_n x^{n+m}$ by replacing a_n by c_n and r by m.

The following are the values of a_n found in terms of the indicial root r.

$$\boxed{\begin{aligned} a_1 &= 0 \\ a_2 &= 0 \\ a_3 &= 0 \\ a_4 &= 0 \\ a_5 &= 0 \end{aligned}}$$

Since the $F = x - 1$ has more than one term then we find a particular solution for each term and add the result to find the particular solution to the ode.

Now we determine the particular solution y_p associated with $F = x$ by solving the balance equation

$$\left(9x^m m(-1+m) + 10x^m m + x^m\right) c_0 = x$$

For c_0 and x. This results in

$$\begin{aligned} c_0 &= \frac{1}{11} \\ m &= 1 \end{aligned}$$

The particular solution is therefore

$$\begin{aligned} y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\ &= \sum_{n=0}^{\infty} c_n x^{n+1} \end{aligned}$$

Where in the above $c_0 = \frac{1}{11}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 1$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{11}$ and $r = m$ or $r = 1$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = \frac{1}{11}$
$c_1 = 0$
$c_2 = 0$
$c_3 = 0$
$c_4 = 0$
$c_5 = 0$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\
&= x \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x \left(\frac{1}{11}\right) \\
&= \frac{x}{11}
\end{aligned}
$$

Now we determine the particular solution y_p associated with $F = -1$ by solving the balance equation

$$
(9x^m m(-1+m) + 10x^m m + x^m)\, c_0 = -1
$$

For c_0 and x. This results in

$$
\begin{aligned}
c_0 &= -1 \\
m &= 0
\end{aligned}
$$

The particular solution is therefore

$$
\begin{aligned}
y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\
&= \sum_{n=0}^{\infty} c_n x^{n+0}
\end{aligned}
$$

Where in the above $c_0 = -1$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 0$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = -1$ and $r = m$ or $r = 0$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = -1$
$c_1 = 0$
$c_2 = 0$
$c_3 = 0$
$c_4 = 0$
$c_5 = 0$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\
&= 1 \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= 1(-1) \\
&= -1
\end{aligned}
$$

Adding all the above particular solution(s) gives

$$
y_p = -1 + \frac{x}{11} + O(x^6)
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= -1 + \frac{x}{11} + O(x^6) + c_1 x^{-\frac{1}{18}+\frac{i\sqrt{35}}{18}} \left(1 + O(x^6)\right) + c_2 x^{-\frac{1}{18}-\frac{i\sqrt{35}}{18}} \left(1 + O(x^6)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$y = -1+\frac{x}{11}+O\left(x^{6}\right)+c_{1} x^{-\frac{1}{18}+\frac{i \sqrt{35}}{18}} \left(1+O\left(x^{6}\right)\right)+c_{2} x^{-\frac{1}{18}-\frac{i \sqrt{35}}{18}} \left(1+O\left(x^{6}\right)\right) \tag{1}$$

Verification of solutions

$$y = -1+\frac{x}{11}+O\left(x^{6}\right)+c_{1} x^{-\frac{1}{18}+\frac{i \sqrt{35}}{18}} \left(1+O\left(x^{6}\right)\right)+c_{2} x^{-\frac{1}{18}-\frac{i \sqrt{35}}{18}} \left(1+O\left(x^{6}\right)\right)$$

Verified OK.

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{2x^2y'' + \left(-x^2+x\right)y' - y = x^3+1}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2x^2y'' + \left(-x^2+x\right)y' - y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$\begin{aligned} p(x) &= -\frac{x-1}{2x} \\ q(x) &= -\frac{1}{2x^2} \end{aligned}$$

Table 718: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x-1}{2x}$	
singularity	type
$x = 0$	"regular"

$q(x) = -\frac{1}{2x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2x^2y'' + (-x^2 + x)\,y' - y = x^3 + 1$$

Since this is an inhomogeneous, then let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ode $2x^2y'' + (-x^2 + x)\,y' - y = 0$, and y_p is a particular solution to the inhomogeneous ode.which is found using the balance equation generated from indicial equation

First, we solve for y_h Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$
\begin{aligned}
2x^2\left(\sum_{n=0}^{\infty}(n+r)\,(n+r-1)\,a_n x^{n+r-2}\right)& \\
+\left(-x^2+x\right)\left(\sum_{n=0}^{\infty}(n+r)\,a_n x^{n+r-1}\right)-\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right)&=0
\end{aligned} \tag{1}
$$

Which simplifies to

$$
\begin{aligned}
\left(\sum_{n=0}^{\infty}2x^{n+r}a_n(n+r)\,(n+r-1)\right)+\sum_{n\,=0}^{\infty}\left(-x^{1+n+r}a_n(n+r)\right)& \\
+\left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)\right)+\sum_{n\,=0}^{\infty}\left(-a_n x^{n+r}\right)&=0
\end{aligned} \tag{2A}
$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$
\sum_{n\,=0}^{\infty}\left(-x^{1+n+r}a_n(n+r)\right)=\sum_{n=1}^{\infty}\left(-a_{n-1}(n+r-1)\,x^{n+r}\right)
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$
\begin{aligned}
\left(\sum_{n=0}^{\infty}2x^{n+r}a_n(n+r)\,(n+r-1)\right)+\sum_{n\,=1}^{\infty}\left(-a_{n-1}(n+r-1)\,x^{n+r}\right)& \\
+\left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)\right)+\sum_{n\,=0}^{\infty}\left(-a_n x^{n+r}\right)&=0
\end{aligned} \tag{2B}
$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$
2x^{n+r}a_n(n+r)\,(n+r-1)+x^{n+r}a_n(n+r)-a_n x^{n+r}=0
$$

When $n=0$ the above becomes

$$
2x^r a_0 r(-1+r)+x^r a_0 r-a_0 x^r=0
$$

Or

$$\left(2x^r r(-1+r)+x^r r-x^r\right)a_0=0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(2r^2-r-1\right)x^r=0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2-r-1=0$$

Solving for r gives the roots of the indicial equation as

$$r_1=1$$
$$r_2=-\frac{1}{2}$$

The corresponding balance equation is found by replacing r by m and a by c to avoid confusing terms between particular solution and the homogeneous solution. Hence the balance equation is

$$\left(2x^m m(-1+m)+x^m m-x^m\right)c_0=x^3+1$$

This equation will used later to find the particular solution.

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(2r^2-r-1\right)x^r=0$$

Solving for r gives the roots of the indicial equation as Since $r_1-r_2=\frac{3}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x)=x^{r_1}\left(\sum_{n=0}^{\infty}a_n x^n\right)$$
$$y_2(x)=x^{r_2}\left(\sum_{n=0}^{\infty}b_n x^n\right)$$

Or

$$y_1(x)=\sum_{n=0}^{\infty}a_n x^{1+n}$$
$$y_2(x)=\sum_{n=0}^{\infty}b_n x^{n-\frac{1}{2}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$2a_n(n+r)(n+r-1) - a_{n-1}(n+r-1) + a_n(n+r) - a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}}{2n+2r+1} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = \frac{a_{n-1}}{2n+3} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{1}{3+2r}$$

Which for the root $r = 1$ becomes

$$a_1 = \frac{1}{5}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{5}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{4r^2+16r+15}$$

Which for the root $r = 1$ becomes

$$a_2 = \frac{1}{35}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{5}$
a_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{35}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{1}{8r^3 + 60r^2 + 142r + 105}$$

Which for the root $r = 1$ becomes

$$a_3 = \frac{1}{315}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{5}$
a_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{35}$
a_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{315}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{16r^4 + 192r^3 + 824r^2 + 1488r + 945}$$

Which for the root $r = 1$ becomes

$$a_4 = \frac{1}{3465}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{5}$
a_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{35}$
a_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{315}$
a_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{3465}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{1}{32r^5 + 560r^4 + 3760r^3 + 12040r^2 + 18258r + 10395}$$

Which for the root $r = 1$ becomes

$$a_5 = \frac{1}{45045}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{5}$
a_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{35}$
a_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{315}$
a_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{3465}$
a_5	$\frac{1}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	$\frac{1}{45045}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x\left(1 + \frac{x}{5} + \frac{x^2}{35} + \frac{x^3}{315} + \frac{x^4}{3465} + \frac{x^5}{45045} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$2b_n(n+r)(n+r-1) - b_{n-1}(n+r-1) + b_n(n+r) - b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = \frac{b_{n-1}}{2n + 2r + 1} \tag{4}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_n = \frac{b_{n-1}}{2n} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{1}{3 + 2r}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_1 = \frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{1}{4r^2 + 16r + 15}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_2 = \frac{1}{8}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$
b_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{8}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{1}{8r^3 + 60r^2 + 142r + 105}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_3 = \frac{1}{48}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$
b_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{8}$
b_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{48}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{16r^4 + 192r^3 + 824r^2 + 1488r + 945}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_4 = \frac{1}{384}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$
b_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{8}$
b_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{48}$
b_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{384}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{1}{32r^5 + 560r^4 + 3760r^3 + 12040r^2 + 18258r + 10395}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_5 = \frac{1}{3840}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$
b_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{8}$
b_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{48}$
b_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{384}$
b_5	$\frac{1}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	$\frac{1}{3840}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= \frac{1 + \frac{x}{2} + \frac{x^2}{8} + \frac{x^3}{48} + \frac{x^4}{384} + \frac{x^5}{3840} + O(x^6)}{\sqrt{x}}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x\left(1 + \frac{x}{5} + \frac{x^2}{35} + \frac{x^3}{315} + \frac{x^4}{3465} + \frac{x^5}{45045} + O(x^6)\right) \\
&\quad + \frac{c_2\left(1 + \frac{x}{2} + \frac{x^2}{8} + \frac{x^3}{48} + \frac{x^4}{384} + \frac{x^5}{3840} + O(x^6)\right)}{\sqrt{x}}
\end{aligned}
$$

The particular solution is found by solving for c, m the balance equation

$$
\left(2x^m m(-1+m) + x^m m - x^m\right) c_0 = F
$$

Where $F(x)$ is the RHS of the ode. If $F(x)$ has more than one term, then this is done for each term one at a time and then all the particular solutions are added. The function $F(x)$ will be converted to series if needed. in order to solve for c_n, m for each term, the same recursive relation used to find $y_h(x)$ is used to find c_n, m which is used to find the particular solution $\sum_{n=0} c_n x^{n+m}$ by replacing a_n by c_n and r by m.

The following are the values of a_n found in terms of the indicial root r.

$$
\begin{aligned}
a_1 &= \frac{a_0}{3+2r} \\
a_2 &= \frac{a_0}{4r^2+16r+15} \\
a_3 &= \frac{a_0}{8r^3+60r^2+142r+105} \\
a_4 &= \frac{a_0}{16r^4+192r^3+824r^2+1488r+945} \\
a_5 &= \frac{a_0}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}
\end{aligned}
$$

Since the $F = x^3 + 1$ has more than one term then we find a particular solution for each term and add the result to find the particular solution to the ode.

Now we determine the particular solution y_p associated with $F = x^3$ by solving the balance equation

$$
(2x^m m(-1+m) + x^m m - x^m) c_0 = x^3
$$

For c_0 and x. This results in

$$
\begin{aligned}
c_0 &= \frac{1}{14} \\
m &= 3
\end{aligned}
$$

The particular solution is therefore

$$
\begin{aligned}
y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\
&= \sum_{n=0}^{\infty} c_n x^{n+3}
\end{aligned}
$$

Where in the above $c_0 = \frac{1}{14}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 3$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{14}$ and $r = m$ or $r = 3$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$$
\boxed{
\begin{aligned}
c_0 &= \frac{1}{14} \\
c_1 &= \frac{1}{126} \\
c_2 &= \frac{1}{1386} \\
c_3 &= \frac{1}{18018} \\
c_4 &= \frac{1}{270270} \\
c_5 &= \frac{1}{4594590}
\end{aligned}
}
$$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\
&= x^3 \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x^3 \left(\frac{1}{14} + \frac{1}{126}x + \frac{1}{1386}x^2 + \frac{1}{18018}x^3 + \frac{1}{270270}x^4 + \frac{1}{4594590}x^5\right) \\
&= \frac{1}{14}x^3 + \frac{1}{126}x^4 + \frac{1}{1386}x^5 + \frac{1}{18018}x^6 + \frac{1}{270270}x^7 + \frac{1}{4594590}x^8
\end{aligned}
$$

Now we determine the particular solution y_p associated with $F = 1$ by solving the balance equation

$$
\left(2x^m m(-1+m) + x^m m - x^m\right) c_0 = 1
$$

For c_0 and x. This results in

$$
\begin{aligned}
c_0 &= -1 \\
m &= 0
\end{aligned}
$$

The particular solution is therefore

$$
\begin{aligned}
y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\
&= \sum_{n=0}^{\infty} c_n x^{n+0}
\end{aligned}
$$

Where in the above $c_0 = -1$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 0$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = -1$ and $r = m$ or $r = 0$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = -1$
$c_1 = -\frac{1}{3}$
$c_2 = -\frac{1}{15}$
$c_3 = -\frac{1}{105}$
$c_4 = -\frac{1}{945}$
$c_5 = -\frac{1}{10395}$

The particular solution is now found using

$$\begin{aligned} y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\ &= 1 \sum_{n=0}^{\infty} c_n x^n \end{aligned}$$

Using the values found above for c_n into the above sum gives

$$\begin{aligned} y_p &= 1\left(-1 - \frac{1}{3}x - \frac{1}{15}x^2 - \frac{1}{105}x^3 - \frac{1}{945}x^4 - \frac{1}{10395}x^5\right) \\ &= -1 - \frac{1}{3}x - \frac{1}{15}x^2 - \frac{1}{105}x^3 - \frac{1}{945}x^4 - \frac{1}{10395}x^5 \end{aligned}$$

Adding all the above particular solution(s) gives

$$y_p = -1 - \frac{x}{3} - \frac{x^2}{15} + \frac{13x^3}{210} + \frac{13x^4}{1890} + \frac{13x^5}{20790} + \frac{x^6}{18018} + \frac{x^7}{270270} + \frac{x^8}{4594590} + O(x^6)$$

Truncating the particular solution to the order of series requested gives

$$y_p = -1 - \frac{x}{3} - \frac{x^2}{15} + \frac{13x^3}{210} + \frac{13x^4}{1890} + \frac{13x^5}{20790} + O(x^6)$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= -1 - \frac{x}{3} - \frac{x^2}{15} + \frac{13x^3}{210} + \frac{13x^4}{1890} + \frac{13x^5}{20790} + O\left(x^6\right) \\
&\quad + c_1 x \left(1 + \frac{x}{5} + \frac{x^2}{35} + \frac{x^3}{315} + \frac{x^4}{3465} + \frac{x^5}{45045} + O\left(x^6\right)\right) \\
&\quad + \frac{c_2 \left(1 + \frac{x}{2} + \frac{x^2}{8} + \frac{x^3}{48} + \frac{x^4}{384} + \frac{x^5}{3840} + O(x^6)\right)}{\sqrt{x}}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= -1 - \frac{x}{3} - \frac{x^2}{15} + \frac{13x^3}{210} + \frac{13x^4}{1890} + \frac{13x^5}{20790} + O\left(x^6\right) \\
&\quad + c_1 x \left(1 + \frac{x}{5} + \frac{x^2}{35} + \frac{x^3}{315} + \frac{x^4}{3465} + \frac{x^5}{45045} + O\left(x^6\right)\right) \\
&\quad + \frac{c_2 \left(1 + \frac{x}{2} + \frac{x^2}{8} + \frac{x^3}{48} + \frac{x^4}{384} + \frac{x^5}{3840} + O(x^6)\right)}{\sqrt{x}}
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= -1 - \frac{x}{3} - \frac{x^2}{15} + \frac{13x^3}{210} + \frac{13x^4}{1890} + \frac{13x^5}{20790} + O\left(x^6\right) \\
&\quad + c_1 x \left(1 + \frac{x}{5} + \frac{x^2}{35} + \frac{x^3}{315} + \frac{x^4}{3465} + \frac{x^5}{45045} + O\left(x^6\right)\right) \\
&\quad + \frac{c_2 \left(1 + \frac{x}{2} + \frac{x^2}{8} + \frac{x^3}{48} + \frac{x^4}{384} + \frac{x^5}{3840} + O(x^6)\right)}{\sqrt{x}}
\end{aligned}
$$

Verified OK.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second_order_change_of_variable_on_y_method_2", "second order series method. Taylor series method", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{\left(-x^{2}+1\right) y''+2xy'-2y=6\left(-x^{2}+1\right)^{2}}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0,y_0,y'_0} + \frac{x^3}{3!} f'|_{x_0,y_0,y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left.\frac{d^n f}{dx^n}\right|_{x_0,y_0,y'_0}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{1154}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{1155}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}F_n|_{x_0,y_0,y_0'} \qquad (7)$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= \frac{-6x^4 + 2xy' + 12x^2 - 2y - 6}{x^2 - 1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= -24x \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= -24 \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= 0 \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= 0
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= 2y(0) + 6 \\
F_1 &= 0 \\
F_2 &= -24 \\
F_3 &= 0 \\
F_4 &= 0
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(x^2 + 1\right) y(0) - x^4 + xy'(0) + 3x^2 + O\left(x^6\right)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$
\left(-x^2 + 1\right) y'' + 2xy' - 2y = 6x^4 - 12x^2 + 6
$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}$$

Substituting the above back into the ode gives

$$(-x^2+1)\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + 2x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - 2\left(\sum_{n=0}^{\infty} a_n x^n\right) = 6x^4 - 12x^2 + 6 \tag{1}$$

Expanding $6x^4 - 12x^2 + 6$ as Taylor series around $x = 0$ and keeping only the first 6 terms gives

$$\begin{aligned} 6x^4 - 12x^2 + 6 &= 6x^4 - 12x^2 + 6 + \dots \\ &= 6x^4 - 12x^2 + 6 \end{aligned}$$

Hence the ODE in Eq (1) becomes

$$(-x^2+1)\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + 2x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - 2\left(\sum_{n=0}^{\infty} a_n x^n\right) = 6x^4 - 12x^2 + 6$$

Which simplifies to

$$\sum_{n=2}^{\infty} \left(-x^n a_n n(n-1)\right) + \left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} 2n a_n x^n\right) + \sum_{n=0}^{\infty} (-2a_n x^n) \tag{2}$$
$$= 6x^4 - 12x^2 + 6$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\sum_{n=2}^{\infty} (-x^n a_n n(n-1)) + \left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \left(\sum_{n=1}^{\infty} 2n a_n x^n\right) + \sum_{n=0}^{\infty} (-2a_n x^n) = 6x^4 - 12x^2 + 6 \tag{3}$$

$n = 0$ gives

$$(2a_2 - 2a_0)\, x^0 = 6$$
$$2a_2 - 2a_0 = 6$$

$$a_2 = a_0 + 3$$

For $2 \leq n$, the recurrence equation is

$$(-n a_n(n-1) + (n+2)\, a_{n+2}(n+1) + 2n a_n - 2a_n)\, x^n = 6x^4 - 12x^2 + 6 \tag{4}$$

For $n = 2$ the recurrence equation gives

$$(12a_4)\, x^2 = -12x^2$$
$$12a_4 = -12$$

Which after substituting the earlier terms found becomes

$$a_4 = -1$$

For $n = 3$ the recurrence equation gives

$$(-2a_3 + 20a_5)\, x^3 = 0$$
$$-2a_3 + 20a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = 0$$

For $n = 4$ the recurrence equation gives

$$(-6a_4 + 30a_6)\, x^4 = 6x^4$$
$$-6a_4 + 30a_6 = 6$$

Which after substituting the earlier terms found becomes

$$a_6 = 0$$

For $n = 5$ the recurrence equation gives

$$(-12a_5 + 42a_7)\, x^5 = 0$$
$$-12a_5 + 42a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = 0$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + (a_0 + 3)\, x^2 - x^4 + \dots$$

Collecting terms, the solution becomes

$$y = \left(x^2 + 1\right) a_0 - x^4 + 3x^2 + a_1 x + O\left(x^6\right) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(x^2 + 1\right) c_1 - x^4 + 3x^2 + c_2 x + O\left(x^6\right)$$

Summary

The solution(s) found are the following

$$y = \left(x^2 + 1\right) y(0) - x^4 + xy'(0) + 3x^2 + O\left(x^6\right) \tag{1}$$
$$y = \left(x^2 + 1\right) c_1 - x^4 + 3x^2 + c_2 x + O\left(x^6\right) \tag{2}$$

Verification of solutions

$$y = (x^2 + 1)\, y(0) - x^4 + xy'(0) + 3x^2 + O(x^6)$$

Verified OK.

$$y = (x^2 + 1)\, c_1 - x^4 + 3x^2 + c_2 x + O(x^6)$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 43, page 209
Problem number: 12.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{\left(x^2+2x\right)y''-(2+2x)\,y'+2y=x^2(x+2)^2}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(x^2+2x\right)y''+(-2-2x)\,y'+2y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=-\frac{2(x+1)}{x\,(x+2)}$$
$$q(x)=\frac{2}{x\,(x+2)}$$

Table 719: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{2(x+1)}{x(x+2)}$	
singularity	type
$x = -2$	"regular"
$x = 0$	"regular"

$q(x) = \frac{2}{x(x+2)}$	
singularity	type
$x = -2$	"regular"
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-2, 0, \infty]$

Irregular singular points : []

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$y''x(x+2) + (-2-2x)\,y' + 2y = x^2(x+2)^2$$

Since this is an inhomogeneous, then let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ode $y''x(x+2) + (-2-2x)\,y' + 2y = 0$, and y_p is a particular solution to the inhomogeneous ode.which is found using the balance equation generated from indicial equation

First, we solve for y_h Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty}(n+r)(n+r-1)\,a_n x^{n+r-2}\right)x(x+2) \\ +(-2-2x)\left(\sum_{n=0}^{\infty}(n+r)\,a_n x^{n+r-1}\right)+2\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right)=0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty}2x^{n+r-1}a_n(n+r)(n+r-1)\right) \\ +\sum_{n=0}^{\infty}\left(-2x^{n+r}a_n(n+r)\right)+\sum_{n=0}^{\infty}\left(-2(n+r)\,a_n x^{n+r-1}\right)+\left(\sum_{n=0}^{\infty}2a_n x^{n+r}\right)=0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)(n+r-1)=\sum_{n=1}^{\infty}a_{n-1}(n+r-1)(n+r-2)\,x^{n+r-1}$$

$$\sum_{n=0}^{\infty}\left(-2x^{n+r}a_n(n+r)\right)=\sum_{n=1}^{\infty}\left(-2a_{n-1}(n+r-1)\,x^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty}2a_n x^{n+r}=\sum_{n=1}^{\infty}2a_{n-1}x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=1}^{\infty}a_{n-1}(n+r-1)(n+r-2)\,x^{n+r-1}\right) \\ +\left(\sum_{n=0}^{\infty}2x^{n+r-1}a_n(n+r)(n+r-1)\right)+\sum_{n=1}^{\infty}\left(-2a_{n-1}(n+r-1)\,x^{n+r-1}\right) \\ +\sum_{n=0}^{\infty}\left(-2(n+r)\,a_n x^{n+r-1}\right)+\left(\sum_{n=1}^{\infty}2a_{n-1}x^{n+r-1}\right)=0 \tag{2B}$$

The indicial equation is obtained from $n = 0$. From Eq (2B) this gives

$$2x^{n+r-1}a_n(n+r)\,(n+r-1) - 2(n+r)\,a_n x^{n+r-1} = 0$$

When $n = 0$ the above becomes

$$2x^{-1+r}a_0 r(-1+r) - 2r a_0 x^{-1+r} = 0$$

Or

$$\left(2x^{-1+r}r(-1+r) - 2r\,x^{-1+r}\right)a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$2r\,x^{-1+r}(-2+r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r(-2+r) = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 2$$
$$r_2 = 0$$

The corresponding balance equation is found by replacing r by m and a by c to avoid confusing terms between particular solution and the homogeneous solution. Hence the balance equation is

$$\left(2x^{-1+m}m(-1+m) - 2m\,x^{-1+m}\right)c_0 = x^2(x+2)^2$$

This equation will used later to find the particular solution.

Since $a_0 \neq 0$ then the indicial equation becomes

$$2r\,x^{-1+r}(-2+r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 2$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x)\ln(x) + x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$
\begin{aligned}
y_1(x) &= x^2 \left(\sum_{n=0}^{\infty} a_n x^n\right) \\
y_2(x) &= C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+2} \\
y_2(x) &= C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)
\end{aligned}
$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$
\begin{aligned}
& a_{n-1}(n+r-1)(n+r-2) + 2a_n(n+r)(n+r-1) \\
& - 2a_{n-1}(n+r-1) - 2a_n(n+r) + 2a_{n-1} = 0
\end{aligned} \tag{3}
$$

Solving for a_n from recursive equation (4) gives

$$
a_n = -\frac{(n+r-3)\, a_{n-1}}{2(n+r)} \tag{4}
$$

Which for the root $r = 2$ becomes

$$
a_n = -\frac{(n-1)\, a_{n-1}}{2n+4} \tag{5}
$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$
a_1 = \frac{2-r}{2+2r}
$$

Which for the root $r = 2$ becomes

$$a_1 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2-r}{2+2r}$	0

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r^2 - 3r + 2}{4(1+r)(2+r)}$$

Which for the root $r = 2$ becomes

$$a_2 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2-r}{2+2r}$	0
a_2	$\frac{r^2-3r+2}{4(1+r)(2+r)}$	0

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{(r^2 - 3r + 2)\, r}{8(2+r)(3+r)(1+r)}$$

Which for the root $r = 2$ becomes

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2-r}{2+2r}$	0
a_2	$\frac{r^2-3r+2}{4(1+r)(2+r)}$	0
a_3	$-\frac{(r^2-3r+2)r}{8(2+r)(3+r)(1+r)}$	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{(r^2 - 3r + 2) r}{16 (3 + r) (4 + r) (2 + r)}$$

Which for the root $r = 2$ becomes

$$a_4 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2-r}{2+2r}$	0
a_2	$\frac{r^2-3r+2}{4(1+r)(2+r)}$	0
a_3	$-\frac{(r^2-3r+2)r}{8(2+r)(3+r)(1+r)}$	0
a_4	$\frac{(r^2-3r+2)r}{16(3+r)(4+r)(2+r)}$	0

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{(r^2 - 3r + 2) r}{32 (4 + r) (3 + r) (5 + r)}$$

Which for the root $r = 2$ becomes

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2-r}{2+2r}$	0
a_2	$\frac{r^2-3r+2}{4(1+r)(2+r)}$	0
a_3	$-\frac{(r^2-3r+2)r}{8(2+r)(3+r)(1+r)}$	0
a_4	$\frac{(r^2-3r+2)r}{16(3+r)(4+r)(2+r)}$	0
a_5	$-\frac{(r^2-3r+2)r}{32(4+r)(3+r)(5+r)}$	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^2 \left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^2 \left(1 + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 2$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \to r_2} a_2(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_2 \\ &= \frac{r^2 - 3r + 2}{4(1+r)(2+r)} \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r \to r_2} \frac{r^2 - 3r + 2}{4(1+r)(2+r)} &= \lim_{r \to 0} \frac{r^2 - 3r + 2}{4(1+r)(2+r)} \\ &= \frac{1}{4} \end{aligned}$$

The limit is $\frac{1}{4}$. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$\begin{aligned} y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\ &= \sum_{n=0}^{\infty} b_n x^n \end{aligned}$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$\begin{aligned} & b_{n-1}(n+r-1)(n+r-2) + 2b_n(n+r)(n+r-1) \\ & - 2b_{n-1}(n+r-1) - 2(n+r) b_n + 2b_{n-1} = 0 \end{aligned} \tag{4}$$

Which for for the root $r = 0$ becomes

$$b_{n-1}(n-1)(n-2) + 2b_n n(n-1) - 2b_{n-1}(n-1) - 2nb_n + 2b_{n-1} = 0 \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = -\frac{(n+r-3)\, b_{n-1}}{2\,(n+r)} \tag{5}$$

Which for the root $r = 0$ becomes

$$b_n = -\frac{(n-3)\, b_{n-1}}{2n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = -\frac{-2+r}{2\,(1+r)}$$

Which for the root $r = 0$ becomes

$$b_1 = 1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2-r}{2+2r}$	1

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{r^2 - 3r + 2}{4\,(1+r)\,(2+r)}$$

Which for the root $r = 0$ becomes

$$b_2 = \frac{1}{4}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2-r}{2+2r}$	1
b_2	$\frac{r^2-3r+2}{4(1+r)(2+r)}$	$\frac{1}{4}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{(r^2 - 3r + 2)\, r}{8\,(2 + r)\,(3 + r)\,(1 + r)}$$

Which for the root $r = 0$ becomes

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2-r}{2+2r}$	1
b_2	$\frac{r^2-3r+2}{4(1+r)(2+r)}$	$\frac{1}{4}$
b_3	$-\frac{(r^2-3r+2)r}{8(2+r)(3+r)(1+r)}$	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{(r^2 - 3r + 2)\, r}{16\,(3 + r)\,(4 + r)\,(2 + r)}$$

Which for the root $r = 0$ becomes

$$b_4 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2-r}{2+2r}$	1
b_2	$\frac{r^2-3r+2}{4(1+r)(2+r)}$	$\frac{1}{4}$
b_3	$-\frac{(r^2-3r+2)r}{8(2+r)(3+r)(1+r)}$	0
b_4	$\frac{(r^2-3r+2)r}{16(3+r)(4+r)(2+r)}$	0

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{(r^2 - 3r + 2)\, r}{32\,(4 + r)\,(3 + r)\,(5 + r)}$$

Which for the root $r = 0$ becomes

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2-r}{2+2r}$	1
b_2	$\frac{r^2-3r+2}{4(1+r)(2+r)}$	$\frac{1}{4}$
b_3	$-\frac{(r^2-3r+2)r}{8(2+r)(3+r)(1+r)}$	0
b_4	$\frac{(r^2-3r+2)r}{16(3+r)(4+r)(2+r)}$	0
b_5	$-\frac{(r^2-3r+2)r}{32(4+r)(3+r)(5+r)}$	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots \\ &= 1 + x + \frac{x^2}{4} + O(x^6) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^2 (1 + O(x^6)) + c_2 \left(1 + x + \frac{x^2}{4} + O(x^6)\right) \end{aligned}$$

The particular solution is found by solving for c, m the balance equation

$$\left(2x^{-1+m} m(-1+m) - 2m\, x^{-1+m}\right) c_0 = F$$

Where $F(x)$ is the RHS of the ode. If $F(x)$ has more than one term, then this is done for each term one at a time and then all the particular solutions are added. The function $F(x)$ will be converted to series if needed. in order to solve for c_n, m for each term, the same recursive relation used to find $y_h(x)$ is used to find c_n, m which is used to find the particular solution $\sum_{n=0} c_n x^{n+m}$ by replacing a_n by c_n and r by m.

The following are the values of a_n found in terms of the indicial root r.

$$
\begin{array}{|l|}
\hline
a_1 = -\frac{(-2+r)a_0}{2+2r} \\
a_2 = \frac{(-1+r)(-2+r)a_0}{4(1+r)(2+r)} \\
a_3 = -\frac{r(-1+r)(-2+r)a_0}{8(1+r)(2+r)(3+r)} \\
a_4 = \frac{r(-1+r)(-2+r)a_0}{16(2+r)(3+r)(4+r)} \\
a_5 = -\frac{r(-1+r)(-2+r)a_0}{32(3+r)(4+r)(5+r)} \\
\hline
\end{array}
$$

Expanding the rhs of the ode $x^2(x+2)^2$ in series gives

$$
x^2(x+2)^2 = x^4 + 4x^3 + 4x^2
$$

Since the $F = x^4 + 4x^3 + 4x^2$ has more than one term then we find a particular solution for each term and add the result to find the particular solution to the ode.

Now we determine the particular solution y_p associated with $F = x^4$ by solving the balance equation

$$
\left(2x^{-1+m}m(-1+m) - 2m\, x^{-1+m}\right) c_0 = x^4
$$

For c_0 and x. This results in

$$
\begin{aligned}
c_0 &= \frac{1}{30} \\
m &= 5
\end{aligned}
$$

The particular solution is therefore

$$
\begin{aligned}
y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\
&= \sum_{n=0}^{\infty} c_n x^{n+5}
\end{aligned}
$$

Where in the above $c_0 = \frac{1}{30}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 5$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{30}$ and $r = m$ or $r = 5$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$$
\boxed{
\begin{aligned}
c_0 &= \tfrac{1}{30} \\
c_1 &= -\tfrac{1}{120} \\
c_2 &= \tfrac{1}{420} \\
c_3 &= -\tfrac{1}{1344} \\
c_4 &= \tfrac{1}{4032} \\
c_5 &= -\tfrac{1}{11520}
\end{aligned}
}
$$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\
&= x^5 \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x^5 \left(\frac{1}{30} - \frac{1}{120}x + \frac{1}{420}x^2 - \frac{1}{1344}x^3 + \frac{1}{4032}x^4 - \frac{1}{11520}x^5\right) \\
&= \frac{1}{30}x^5 - \frac{1}{120}x^6 + \frac{1}{420}x^7 - \frac{1}{1344}x^8 + \frac{1}{4032}x^9 - \frac{1}{11520}x^{10}
\end{aligned}
$$

Now we determine the particular solution y_p associated with $F = 4x^3$ by solving the balance equation

$$
\left(2x^{-1+m} m(-1+m) - 2m\, x^{-1+m}\right) c_0 = 4x^3
$$

For c_0 and x. This results in

$$
\begin{aligned}
c_0 &= \frac{1}{4} \\
m &= 4
\end{aligned}
$$

The particular solution is therefore

$$
\begin{aligned}
y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\
&= \sum_{n=0}^{\infty} c_n x^{n+4}
\end{aligned}
$$

Where in the above $c_0 = \frac{1}{4}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 4$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{4}$ and $r = m$ or $r = 4$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = \frac{1}{4}$
$c_1 = -\frac{1}{20}$
$c_2 = \frac{1}{80}$
$c_3 = -\frac{1}{280}$
$c_4 = \frac{1}{896}$
$c_5 = -\frac{1}{2688}$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\
&= x^4 \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x^4 \left(\frac{1}{4} - \frac{1}{20}x + \frac{1}{80}x^2 - \frac{1}{280}x^3 + \frac{1}{896}x^4 - \frac{1}{2688}x^5\right) \\
&= \frac{1}{4}x^4 - \frac{1}{20}x^5 + \frac{1}{80}x^6 - \frac{1}{280}x^7 + \frac{1}{896}x^8 - \frac{1}{2688}x^9
\end{aligned}
$$

Now we determine the particular solution y_p associated with $F = 4x^2$ by solving the balance equation

$$
\left(2x^{-1+m} m(-1+m) - 2m\, x^{-1+m}\right) c_0 = 4x^2
$$

For c_0 and x. This results in

$$
\begin{aligned}
c_0 &= \frac{2}{3} \\
m &= 3
\end{aligned}
$$

The particular solution is therefore

$$
\begin{aligned}
y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\
&= \sum_{n=0}^{\infty} c_n x^{n+3}
\end{aligned}
$$

Where in the above $c_0 = \frac{2}{3}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 3$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{2}{3}$ and $r = m$ or $r = 3$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = \frac{2}{3}$
$c_1 = -\frac{1}{12}$
$c_2 = \frac{1}{60}$
$c_3 = -\frac{1}{240}$
$c_4 = \frac{1}{840}$
$c_5 = -\frac{1}{2688}$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\
&= x^3 \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x^3 \left(\frac{2}{3} - \frac{1}{12}x + \frac{1}{60}x^2 - \frac{1}{240}x^3 + \frac{1}{840}x^4 - \frac{1}{2688}x^5\right) \\
&= \frac{2}{3}x^3 - \frac{1}{12}x^4 + \frac{1}{60}x^5 - \frac{1}{240}x^6 + \frac{1}{840}x^7 - \frac{1}{2688}x^8
\end{aligned}
$$

Adding all the above particular solution(s) gives

$$y_p = \frac{2x^3}{3} + \frac{x^4}{6} - \frac{x^9}{8064} - \frac{x^{10}}{11520} + O(x^6)$$

Truncating the particular solution to the order of series requested gives

$$y_p = \frac{2x^3}{3} + \frac{x^4}{6} + O(x^6)$$

Hence the final solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \frac{2x^3}{3} + \frac{x^4}{6} + O(x^6) + c_1 x^2 (1 + O(x^6)) + c_2 \left(1 + x + \frac{x^2}{4} + O(x^6)\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{2x^3}{3} + \frac{x^4}{6} + O(x^6) + c_1 x^2 (1 + O(x^6)) + c_2 \left(1 + x + \frac{x^2}{4} + O(x^6)\right) \tag{1}$$

Verification of solutions

$$y = \frac{2x^3}{3} + \frac{x^4}{6} + O(x^6) + c_1 x^2 (1 + O(x^6)) + c_2 \left(1 + x + \frac{x^2}{4} + O(x^6)\right)$$

Verified OK.

Problem number: 13.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{2x^2y'' + 5xy' + y(x+1) = x(x^2+x+1)}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2x^2y'' + 5xy' + y(x+1) = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{5}{2x}$$
$$q(x) = \frac{x+1}{2x^2}$$

Table 720: Table $p(x), q(x)$ singularites.

$p(x) = \frac{5}{2x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{x+1}{2x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2x^2y'' + 5xy' + y(x + 1) = x^3 + x^2 + x$$

Since this is an inhomogeneous, then let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ode $2x^2y'' + 5xy' + y(x + 1) = 0$, and y_p is a particular solution to the inhomogeneous ode.which is found using the balance equation generated from indicial equation

First, we solve for y_h Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2x^2\left(\sum_{n=0}^{\infty}(n+r)(n+r-1)\,a_n x^{n+r-2}\right)\\ +5x\left(\sum_{n=0}^{\infty}(n+r)\,a_n x^{n+r-1}\right)+\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right)(x+1)=0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty}2x^{n+r}a_n(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty}5x^{n+r}a_n(n+r)\right)\\ +\left(\sum_{n=0}^{\infty}x^{1+n+r}a_n\right)+\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right)=0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty}x^{1+n+r}a_n=\sum_{n=1}^{\infty}a_{n-1}x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty}2x^{n+r}a_n(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty}5x^{n+r}a_n(n+r)\right)\\ +\left(\sum_{n=1}^{\infty}a_{n-1}x^{n+r}\right)+\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right)=0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r}a_n(n+r)(n+r-1)+5x^{n+r}a_n(n+r)+a_n x^{n+r}=0$$

When $n=0$ the above becomes

$$2x^r a_0 r(-1+r)+5x^r a_0 r+a_0 x^r=0$$

Or

$$\left(2x^r r(-1+r)+5x^r r+x^r\right) a_0=0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(2r^2+3r+1\right) x^r=0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2+3r+1=0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned} r_1 &= -\frac{1}{2} \\ r_2 &= -1 \end{aligned}$$

The corresponding balance equation is found by replacing r by m and a by c to avoid confusing terms between particular solution and the homogeneous solution. Hence the balance equation is

$$\left(2x^m m(-1+m)+5x^m m+x^m\right) c_0=x^3+x^2+x$$

This equation will used later to find the particular solution.

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(2r^2+3r+1\right) x^r=0$$

Solving for r gives the roots of the indicial equation as Since $r_1-r_2=\frac{1}{2}$ is not an integer, then we can construct two linearly independent solutions

$$\begin{aligned} y_1(x) &= x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right) \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n-\frac{1}{2}} \\ y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n-1} \end{aligned}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$2a_n(n+r)(n+r-1) + 5a_n(n+r) + a_{n-1} + a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}}{2n^2 + 4nr + 2r^2 + 3n + 3r + 1} \tag{4}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$a_n = -\frac{a_{n-1}}{2n^2 + n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = -\frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{1}{2r^2 + 7r + 6}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$a_1 = -\frac{1}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+7r+6}$	$-\frac{1}{3}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{4r^4 + 36r^3 + 119r^2 + 171r + 90}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$a_2 = \frac{1}{30}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+7r+6}$	$-\frac{1}{3}$
a_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{30}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{1}{8r^6 + 132r^5 + 890r^4 + 3135r^3 + 6077r^2 + 6138r + 2520}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$a_3 = -\frac{1}{630}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+7r+6}$	$-\frac{1}{3}$
a_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{30}$
a_3	$-\frac{1}{8r^6+132r^5+890r^4+3135r^3+6077r^2+6138r+2520}$	$-\frac{1}{630}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{16r^8 + 416r^7 + 4648r^6 + 29120r^5 + 111769r^4 + 268814r^3 + 395127r^2 + 324090r + 113400}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$a_4 = \frac{1}{22680}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+7r+6}$	$-\frac{1}{3}$
a_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{30}$
a_3	$-\frac{1}{8r^6+132r^5+890r^4+3135r^3+6077r^2+6138r+2520}$	$-\frac{1}{630}$
a_4	$\frac{1}{16r^8+416r^7+4648r^6+29120r^5+111769r^4+268814r^3+395127r^2+324090r+113400}$	$\frac{1}{22680}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1}{(16r^8 + 416r^7 + 4648r^6 + 29120r^5 + 111769r^4 + 268814r^3 + 395127r^2 + 324090r + 113400)\,(2r^2 +$$

Which for the root $r = -\frac{1}{2}$ becomes

$$a_5 = -\frac{1}{1247400}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+7r+6}$	$-\frac{1}{3}$
a_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{30}$
a_3	$-\frac{1}{8r^6+132r^5+890r^4+3135r^3+6077r^2+6138r+2520}$	$-\frac{1}{630}$
a_4	$\frac{1}{16r^8+416r^7+4648r^6+29120r^5+111769r^4+268814r^3+395127r^2+324090r+113400}$	$\frac{1}{22680}$
a_5	$-\frac{1}{(16r^8+416r^7+4648r^6+29120r^5+111769r^4+268814r^3+395127r^2+324090r+113400)(2r^2+23r+66)}$	$-\frac{1}{1247400}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= \frac{1}{\sqrt{x}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= \frac{1 - \frac{x}{3} + \frac{x^2}{30} - \frac{x^3}{630} + \frac{x^4}{22680} - \frac{x^5}{1247400} + O(x^6)}{\sqrt{x}} \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$2b_n(n+r)(n+r-1) + 5b_n(n+r) + b_{n-1} + b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{b_{n-1}}{2n^2 + 4nr + 2r^2 + 3n + 3r + 1} \tag{4}$$

Which for the root $r = -1$ becomes

$$b_n = -\frac{b_{n-1}}{n(2n-1)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = -\frac{1}{2r^2 + 7r + 6}$$

Which for the root $r = -1$ becomes

$$b_1 = -1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{2r^2+7r+6}$	-1

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{1}{4r^4 + 36r^3 + 119r^2 + 171r + 90}$$

Which for the root $r = -1$ becomes

$$b_2 = \frac{1}{6}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{2r^2+7r+6}$	-1
b_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{6}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{1}{8r^6 + 132r^5 + 890r^4 + 3135r^3 + 6077r^2 + 6138r + 2520}$$

Which for the root $r = -1$ becomes

$$b_3 = -\frac{1}{90}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{2r^2+7r+6}$	-1
b_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{6}$
b_3	$-\frac{1}{8r^6+132r^5+890r^4+3135r^3+6077r^2+6138r+2520}$	$-\frac{1}{90}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{16r^8 + 416r^7 + 4648r^6 + 29120r^5 + 111769r^4 + 268814r^3 + 395127r^2 + 324090r + 113400}$$

Which for the root $r = -1$ becomes

$$b_4 = \frac{1}{2520}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{2r^2+7r+6}$	-1
b_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{6}$
b_3	$-\frac{1}{8r^6+132r^5+890r^4+3135r^3+6077r^2+6138r+2520}$	$-\frac{1}{90}$
b_4	$\frac{1}{16r^8+416r^7+4648r^6+29120r^5+111769r^4+268814r^3+395127r^2+324090r+113400}$	$\frac{1}{2520}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{1}{(16r^8 + 416r^7 + 4648r^6 + 29120r^5 + 111769r^4 + 268814r^3 + 395127r^2 + 324090r + 113400)\,(2r^2 +}$$

Which for the root $r = -1$ becomes

$$b_5 = -\frac{1}{113400}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{2r^2+7r+6}$	-1
b_2	$\frac{1}{4r^4+36r^3+119r^2+171r+90}$	$\frac{1}{6}$
b_3	$-\frac{1}{8r^6+132r^5+890r^4+3135r^3+6077r^2+6138r+2520}$	$-\frac{1}{90}$
b_4	$\frac{1}{16r^8+416r^7+4648r^6+29120r^5+111769r^4+268814r^3+395127r^2+324090r+113400}$	$\frac{1}{2520}$
b_5	$-\frac{1}{(16r^8+416r^7+4648r^6+29120r^5+111769r^4+268814r^3+395127r^2+324090r+113400)(2r^2+23r+66)}$	$-\frac{1}{113400}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= \frac{1}{\sqrt{x}}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\ &= \frac{1 - x + \frac{x^2}{6} - \frac{x^3}{90} + \frac{x^4}{2520} - \frac{x^5}{113400} + O(x^6)}{x} \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= \frac{c_1\left(1 - \frac{x}{3} + \frac{x^2}{30} - \frac{x^3}{630} + \frac{x^4}{22680} - \frac{x^5}{1247400} + O(x^6)\right)}{\sqrt{x}} \\ &\quad + \frac{c_2\left(1 - x + \frac{x^2}{6} - \frac{x^3}{90} + \frac{x^4}{2520} - \frac{x^5}{113400} + O(x^6)\right)}{x} \end{aligned}$$

The particular solution is found by solving for c, m the balance equation

$$\left(2x^m m(-1+m) + 5x^m m + x^m\right) c_0 = F$$

Where $F(x)$ is the RHS of the ode. If $F(x)$ has more than one term, then this is done for each term one at a time and then all the particular solutions are added. The function $F(x)$ will be converted to series if needed. in order to solve for c_n, m for each term, the same recursive relation used to find $y_h(x)$ is used to find c_n, m which is used to find the particular solution $\sum_{n=0} c_n x^{n+m}$ by replacing a_n by c_n and r by m.

The following are the values of a_n found in terms of the indicial root r.

$$
\begin{aligned}
a_1 &= -\frac{a_0}{2r^2+7r+6} \\
a_2 &= \frac{a_0}{(2r^2+7r+6)(2r^2+11r+15)} \\
a_3 &= -\frac{a_0}{(2r^2+7r+6)(2r^2+11r+15)(2r^2+15r+28)} \\
a_4 &= \frac{a_0}{(2r^2+7r+6)(2r^2+11r+15)(2r^2+15r+28)(2r^2+19r+45)} \\
a_5 &= -\frac{a_0}{(2r^2+7r+6)(2r^2+11r+15)(2r^2+15r+28)(2r^2+19r+45)(2r^2+23r+66)}
\end{aligned}
$$

Since the $F = x^3 + x^2 + x$ has more than one term then we find a particular solution for each term and add the result to find the particular solution to the ode.

Now we determine the particular solution y_p associated with $F = x^3$ by solving the balance equation

$$
(2x^m m(-1+m) + 5x^m m + x^m) c_0 = x^3
$$

For c_0 and x. This results in

$$
\begin{aligned}
c_0 &= \frac{1}{28} \\
m &= 3
\end{aligned}
$$

The particular solution is therefore

$$
\begin{aligned}
y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\
&= \sum_{n=0}^{\infty} c_n x^{n+3}
\end{aligned}
$$

Where in the above $c_0 = \frac{1}{28}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 3$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{28}$ and $r = m$ or $r = 3$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$$
\boxed{\begin{aligned}
c_0 &= \tfrac{1}{28}\\
c_1 &= -\tfrac{1}{1260}\\
c_2 &= \tfrac{1}{83160}\\
c_3 &= -\tfrac{1}{7567560}\\
c_4 &= \tfrac{1}{908107200}\\
c_5 &= -\tfrac{1}{138940401600}
\end{aligned}}
$$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n\\
&= x^3 \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x^3 \left(\frac{1}{28} - \frac{1}{1260}x + \frac{1}{83160}x^2 - \frac{1}{7567560}x^3 + \frac{1}{908107200}x^4 - \frac{1}{138940401600}x^5\right)\\
&= \frac{1}{28}x^3 - \frac{1}{1260}x^4 + \frac{1}{83160}x^5 - \frac{1}{7567560}x^6 + \frac{1}{908107200}x^7 - \frac{1}{138940401600}x^8
\end{aligned}
$$

Now we determine the particular solution y_p associated with $F = x^2$ by solving the balance equation

$$
(2x^m m(-1+m) + 5x^m m + x^m)\, c_0 = x^2
$$

For c_0 and x. This results in

$$
\begin{aligned}
c_0 &= \frac{1}{15}\\
m &= 2
\end{aligned}
$$

The particular solution is therefore

$$
\begin{aligned}
y_p &= \sum_{n=0}^{\infty} c_n x^{n+m}\\
&= \sum_{n=0}^{\infty} c_n x^{n+2}
\end{aligned}
$$

Where in the above $c_0 = \frac{1}{15}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 2$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{15}$ and $r = m$ or $r = 2$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = \frac{1}{15}$
$c_1 = -\frac{1}{420}$
$c_2 = \frac{1}{18900}$
$c_3 = -\frac{1}{1247400}$
$c_4 = \frac{1}{113513400}$
$c_5 = -\frac{1}{13621608000}$

The particular solution is now found using

$$\begin{aligned} y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\ &= x^2 \sum_{n=0}^{\infty} c_n x^n \end{aligned}$$

Using the values found above for c_n into the above sum gives

$$\begin{aligned} y_p &= x^2 \left(\frac{1}{15} - \frac{1}{420}x + \frac{1}{18900}x^2 - \frac{1}{1247400}x^3 + \frac{1}{113513400}x^4 - \frac{1}{13621608000}x^5 \right) \\ &= \frac{1}{15}x^2 - \frac{1}{420}x^3 + \frac{1}{18900}x^4 - \frac{1}{1247400}x^5 + \frac{1}{113513400}x^6 - \frac{1}{13621608000}x^7 \end{aligned}$$

Now we determine the particular solution y_p associated with $F = x$ by solving the balance equation

$$(2x^m m(-1+m) + 5x^m m + x^m)\, c_0 = x$$

For c_0 and x. This results in

$$\begin{aligned} c_0 &= \frac{1}{6} \\ m &= 1 \end{aligned}$$

The particular solution is therefore

$$y_p = \sum_{n=0}^{\infty} c_n x^{n+m}$$
$$= \sum_{n=0}^{\infty} c_n x^{n+1}$$

Where in the above $c_0 = \frac{1}{6}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 1$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{6}$ and $r = m$ or $r = 1$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = \frac{1}{6}$
$c_1 = -\frac{1}{90}$
$c_2 = \frac{1}{2520}$
$c_3 = -\frac{1}{113400}$
$c_4 = \frac{1}{7484400}$
$c_5 = -\frac{1}{681080400}$

The particular solution is now found using

$$y_p = x^m \sum_{n=0}^{\infty} c_n x^n$$
$$= x \sum_{n=0}^{\infty} c_n x^n$$

Using the values found above for c_n into the above sum gives

$$y_p = x\left(\frac{1}{6} - \frac{1}{90}x + \frac{1}{2520}x^2 - \frac{1}{113400}x^3 + \frac{1}{7484400}x^4 - \frac{1}{681080400}x^5\right)$$
$$= \frac{1}{6}x - \frac{1}{90}x^2 + \frac{1}{2520}x^3 - \frac{1}{113400}x^4 + \frac{1}{7484400}x^5 - \frac{1}{681080400}x^6$$

Adding all the above particular solution(s) gives

$$y_p = \frac{x}{6}+\frac{x^2}{18}+\frac{17x^3}{504}-\frac{17x^4}{22680}+\frac{17x^5}{1496880}-\frac{17x^6}{136216080} + \frac{x^7}{972972000}-\frac{x^8}{138940401600}+O(x^6)$$

Truncating the particular solution to the order of series requested gives

$$y_p = \frac{x}{6}+\frac{x^2}{18}+\frac{17x^3}{504}-\frac{17x^4}{22680}+\frac{17x^5}{1496880}+O(x^6)$$

Hence the final solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \frac{x}{6}+\frac{x^2}{18}+\frac{17x^3}{504}-\frac{17x^4}{22680}+\frac{17x^5}{1496880}+O(x^6) \\ &+ \frac{c_1\left(1-\frac{x}{3}+\frac{x^2}{30}-\frac{x^3}{630}+\frac{x^4}{22680}-\frac{x^5}{1247400}+O(x^6)\right)}{\sqrt{x}} \\ &+ \frac{c_2\left(1-x+\frac{x^2}{6}-\frac{x^3}{90}+\frac{x^4}{2520}-\frac{x^5}{113400}+O(x^6)\right)}{x} \end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y &= \frac{x}{6}+\frac{x^2}{18}+\frac{17x^3}{504}-\frac{17x^4}{22680}+\frac{17x^5}{1496880}+O(x^6) \\ &+ \frac{c_1\left(1-\frac{x}{3}+\frac{x^2}{30}-\frac{x^3}{630}+\frac{x^4}{22680}-\frac{x^5}{1247400}+O(x^6)\right)}{\sqrt{x}} \\ &+ \frac{c_2\left(1-x+\frac{x^2}{6}-\frac{x^3}{90}+\frac{x^4}{2520}-\frac{x^5}{113400}+O(x^6)\right)}{x} \end{aligned} \tag{1}$$

Verification of solutions

$$\begin{aligned} y &= \frac{x}{6}+\frac{x^2}{18}+\frac{17x^3}{504}-\frac{17x^4}{22680}+\frac{17x^5}{1496880}+O(x^6) \\ &+ \frac{c_1\left(1-\frac{x}{3}+\frac{x^2}{30}-\frac{x^3}{630}+\frac{x^4}{22680}-\frac{x^5}{1247400}+O(x^6)\right)}{\sqrt{x}} \\ &+ \frac{c_2\left(1-x+\frac{x^2}{6}-\frac{x^3}{90}+\frac{x^4}{2520}-\frac{x^5}{113400}+O(x^6)\right)}{x} \end{aligned}$$

Verified OK.

Book: Differential Equations by Alfred L. Nelson, Karl W. Folley, Max Coral. 3rd ed. DC heath. Boston. 1964
Section: Exercise 43, page 209
Problem number: 14.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{(x^3+2x^2)\,y''-xy'+(1-x)\,y=x^2(x+1)^2}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$(x^3+2x^2)\,y''-xy'+(1-x)\,y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=-\frac{1}{x\,(x+2)}$$
$$q(x)=-\frac{x-1}{x^2\,(x+2)}$$

Table 721: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{1}{x(x+2)}$	
singularity	type
$x = -2$	"regular"
$x = 0$	"regular"

$q(x) = -\frac{x-1}{x^2(x+2)}$	
singularity	type
$x = -2$	"regular"
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-2, 0, \infty]$

Irregular singular points : []

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$y''x^2(x+2) - xy' + (1-x)\,y = x^2(x+1)^2$$

Since this is an inhomogeneous, then let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ode $y''x^2(x+2) - xy' + (1-x)\,y = 0$, and y_p is a particular solution to the inhomogeneous ode.which is found using the balance equation generated from indicial equation

First, we solve for y_h Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty}(n+r)(n+r-1)a_n x^{n+r-2}\right)x^2(x+2) - x\left(\sum_{n=0}^{\infty}(n+r)a_n x^{n+r-1}\right) + (1-x)\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty}x^{1+n+r}a_n(n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty}2x^{n+r}a_n(n+r)(n+r-1)\right) + \sum_{n=0}^{\infty}\left(-x^{n+r}a_n(n+r)\right) + \left(\sum_{n=0}^{\infty}a_n x^{n+r}\right) + \sum_{n=0}^{\infty}\left(-x^{1+n+r}a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty}x^{1+n+r}a_n(n+r)(n+r-1) = \sum_{n=1}^{\infty}a_{n-1}(n+r-1)(n+r-2)x^{n+r}$$

$$\sum_{n=0}^{\infty}\left(-x^{1+n+r}a_n\right) = \sum_{n=1}^{\infty}\left(-a_{n-1}x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=1}^{\infty}a_{n-1}(n+r-1)(n+r-2)x^{n+r}\right) + \left(\sum_{n=0}^{\infty}2x^{n+r}a_n(n+r)(n+r-1)\right) + \sum_{n=0}^{\infty}\left(-x^{n+r}a_n(n+r)\right) + \left(\sum_{n=0}^{\infty}a_n x^{n+r}\right) + \sum_{n=1}^{\infty}\left(-a_{n-1}x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n = 0$. From Eq (2B) this gives

$$2x^{n+r}a_n(n+r)(n+r-1) - x^{n+r}a_n(n+r) + a_n x^{n+r} = 0$$

When $n = 0$ the above becomes

$$2x^r a_0 r(-1+r) - x^r a_0 r + a_0 x^r = 0$$

Or

$$(2x^r r(-1+r) - x^r r + x^r)\, a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(2r^2 - 3r + 1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 - 3r + 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = \frac{1}{2}$$

The corresponding balance equation is found by replacing r by m and a by c to avoid confusing terms between particular solution and the homogeneous solution. Hence the balance equation is

$$(2x^m m(-1+m) - x^m m + x^m)\, c_0 = x^2(x+1)^2$$

This equation will used later to find the particular solution.

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(2r^2 - 3r + 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{1+n}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n+\frac{1}{2}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_{n-1}(n+r-1)(n+r-2) + 2a_n(n+r)(n+r-1) - a_n(n+r) + a_n - a_{n-1} = 0 \quad (3)$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}(n^2 + 2nr + r^2 - 3n - 3r + 1)}{2n^2 + 4nr + 2r^2 - 3n - 3r + 1} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = -\frac{a_{n-1}(n^2 - n - 1)}{2n^2 + n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{-r^2 + r + 1}{2r^2 + r}$$

Which for the root $r = 1$ becomes

$$a_1 = \frac{1}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{1}{3}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r^4 - 3r^2 + 1}{4r^4 + 12r^3 + 11r^2 + 3r}$$

Which for the root $r = 1$ becomes

$$a_2 = -\frac{1}{30}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{1}{3}$
a_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$-\frac{1}{30}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{-r^6 - 3r^5 + 2r^4 + 9r^3 + 2r^2 - 3r - 1}{r (4r^3 + 12r^2 + 11r + 3) (2r^2 + 9r + 10)}$$

Which for the root $r = 1$ becomes

$$a_3 = \frac{1}{126}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{1}{3}$
a_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$-\frac{1}{30}$
a_3	$\frac{-r^6-3r^5+2r^4+9r^3+2r^2-3r-1}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)}$	$\frac{1}{126}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{r^8 + 8r^7 + 18r^6 - 4r^5 - 57r^4 - 52r^3 + 6r^2 + 20r + 5}{r (4r^3 + 12r^2 + 11r + 3) (2r^2 + 9r + 10) (2r^2 + 13r + 21)}$$

Which for the root $r = 1$ becomes

$$a_4 = -\frac{11}{4536}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{1}{3}$
a_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$-\frac{1}{30}$
a_3	$\frac{-r^6-3r^5+2r^4+9r^3+2r^2-3r-1}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)}$	$\frac{1}{126}$
a_4	$\frac{r^8+8r^7+18r^6-4r^5-57r^4-52r^3+6r^2+20r+5}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)}$	$-\frac{11}{4536}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{(r^2+3r+1)(r^2+5r+5)(r^2+7r+11)(r^2+r-1)(r^2-r-1)}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)(2r^2+17r+36)}$$

Which for the root $r = 1$ becomes

$$a_5 = \frac{19}{22680}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{1}{3}$
a_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$-\frac{1}{30}$
a_3	$\frac{-r^6-3r^5+2r^4+9r^3+2r^2-3r-1}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)}$	$\frac{1}{126}$
a_4	$\frac{r^8+8r^7+18r^6-4r^5-57r^4-52r^3+6r^2+20r+5}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)}$	$-\frac{11}{4536}$
a_5	$-\frac{(r^2+3r+1)(r^2+5r+5)(r^2+7r+11)(r^2+r-1)(r^2-r-1)}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)(2r^2+17r+36)}$	$\frac{19}{22680}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\
&= x\left(1 + \frac{x}{3} - \frac{x^2}{30} + \frac{x^3}{126} - \frac{11x^4}{4536} + \frac{19x^5}{22680} + O(x^6)\right)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$b_{n-1}(n+r-1)(n+r-2) + 2b_n(n+r)(n+r-1) - b_n(n+r) + b_n - b_{n-1} = 0 \quad (3)$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{b_{n-1}(n^2+2nr+r^2-3n-3r+1)}{2n^2+4nr+2r^2-3n-3r+1} \tag{4}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_n = -\frac{b_{n-1}(4n^2-8n-1)}{8n^2-4n} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{-r^2+r+1}{2r^2+r}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_1 = \frac{5}{4}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{5}{4}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_2 = \frac{5}{96}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{5}{4}$
b_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$\frac{5}{96}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{-r^6 - 3r^5 + 2r^4 + 9r^3 + 2r^2 - 3r - 1}{r\left(4r^3 + 12r^2 + 11r + 3\right)\left(2r^2 + 9r + 10\right)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_3 = -\frac{11}{1152}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{5}{4}$
b_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$\frac{5}{96}$
b_3	$\frac{-r^6-3r^5+2r^4+9r^3+2r^2-3r-1}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)}$	$-\frac{11}{1152}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{r^8 + 8r^7 + 18r^6 - 4r^5 - 57r^4 - 52r^3 + 6r^2 + 20r + 5}{r\left(4r^3 + 12r^2 + 11r + 3\right)\left(2r^2 + 9r + 10\right)\left(2r^2 + 13r + 21\right)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_4 = \frac{341}{129024}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{5}{4}$
b_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$\frac{5}{96}$
b_3	$\frac{-r^6-3r^5+2r^4+9r^3+2r^2-3r-1}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)}$	$-\frac{11}{1152}$
b_4	$\frac{r^8+8r^7+18r^6-4r^5-57r^4-52r^3+6r^2+20r+5}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)}$	$\frac{341}{129024}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{(r^2+3r+1)(r^2+5r+5)(r^2+7r+11)(r^2+r-1)(r^2-r-1)}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)(2r^2+17r+36)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$b_5 = -\frac{20119}{23224320}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-r^2+r+1}{2r^2+r}$	$\frac{5}{4}$
b_2	$\frac{r^4-3r^2+1}{4r^4+12r^3+11r^2+3r}$	$\frac{5}{96}$
b_3	$\frac{-r^6-3r^5+2r^4+9r^3+2r^2-3r-1}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)}$	$-\frac{11}{1152}$
b_4	$\frac{r^8+8r^7+18r^6-4r^5-57r^4-52r^3+6r^2+20r+5}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)}$	$\frac{341}{129024}$
b_5	$-\frac{(r^2+3r+1)(r^2+5r+5)(r^2+7r+11)(r^2+r-1)(r^2-r-1)}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)(2r^2+17r+36)}$	$-\frac{20119}{23224320}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= x\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\ &= \sqrt{x}\left(1 + \frac{5x}{4} + \frac{5x^2}{96} - \frac{11x^3}{1152} + \frac{341x^4}{129024} - \frac{20119x^5}{23224320} + O(x^6)\right) \end{aligned}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x \left(1+\frac{x}{3}-\frac{x^2}{30}+\frac{x^3}{126}-\frac{11x^4}{4536}+\frac{19x^5}{22680}+O(x^6)\right) \\
&\quad + c_2\sqrt{x}\left(1+\frac{5x}{4}+\frac{5x^2}{96}-\frac{11x^3}{1152}+\frac{341x^4}{129024}-\frac{20119x^5}{23224320}+O(x^6)\right)
\end{aligned}
$$

The particular solution is found by solving for c, m the balance equation

$$
(2x^m m(-1+m) - x^m m + x^m)\, c_0 = F
$$

Where $F(x)$ is the RHS of the ode. If $F(x)$ has more than one term, then this is done for each term one at a time and then all the particular solutions are added. The function $F(x)$ will be converted to series if needed. in order to solve for c_n, m for each term, the same recursive relation used to find $y_h(x)$ is used to find c_n, m which is used to find the particular solution $\sum_{n=0} c_n x^{n+m}$ by replacing a_n by c_n and r by m.

The following are the values of a_n found in terms of the indicial root r.

$$
\begin{aligned}
a_1 &= -\frac{a_0(r^2-r-1)}{2r^2+r} \\
a_2 &= \frac{a_0(r^2-r-1)(r^2+r-1)}{4r^4+12r^3+11r^2+3r} \\
a_3 &= -\frac{a_0(r^2-r-1)(r^2+r-1)(r^2+3r+1)}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)} \\
a_4 &= \frac{a_0(r^2-r-1)(r^2+r-1)(r^2+3r+1)(r^2+5r+5)}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)} \\
a_5 &= -\frac{a_0(r^2-r-1)(r^2+r-1)(r^2+3r+1)(r^2+5r+5)(r^2+7r+11)}{r(4r^3+12r^2+11r+3)(2r^2+9r+10)(2r^2+13r+21)(2r^2+17r+36)}
\end{aligned}
$$

Expanding the rhs of the ode $x^2(x+1)^2$ in series gives

$$
x^2(x+1)^2 = x^4 + 2x^3 + x^2
$$

Since the $F = x^4 + 2x^3 + x^2$ has more than one term then we find a particular solution for each term and add the result to find the particular solution to the ode.

Now we determine the particular solution y_p associated with $F = x^4$ by solving the balance equation

$$
(2x^m m(-1+m) - x^m m + x^m)\, c_0 = x^4
$$

For c_0 and x. This results in

$$\begin{aligned} c_0 &= \frac{1}{21} \\ m &= 4 \end{aligned}$$

The particular solution is therefore

$$\begin{aligned} y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\ &= \sum_{n=0}^{\infty} c_n x^{n+4} \end{aligned}$$

Where in the above $c_0 = \frac{1}{21}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 4$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{21}$ and $r = m$ or $r = 4$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$$\begin{aligned} c_0 &= \frac{1}{21} \\ c_1 &= -\frac{11}{756} \\ c_2 &= \frac{19}{3780} \\ c_3 &= -\frac{551}{294840} \\ c_4 &= \frac{22591}{30958200} \\ c_5 &= -\frac{248501}{842063040} \end{aligned}$$

The particular solution is now found using

$$\begin{aligned} y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\ &= x^4 \sum_{n=0}^{\infty} c_n x^n \end{aligned}$$

Using the values found above for c_n into the above sum gives

$$y_p = x^4 \left(\frac{1}{21} - \frac{11}{756} x + \frac{19}{3780} x^2 - \frac{551}{294840} x^3 + \frac{22591}{30958200} x^4 - \frac{248501}{842063040} x^5 \right)$$

$$
= \frac{1}{21}x^4 - \frac{11}{756}x^5 + \frac{19}{3780}x^6 - \frac{551}{294840}x^7 + \frac{22591}{30958200}x^8 - \frac{248501}{842063040}x^9
$$

Now we determine the particular solution y_p associated with $F = 2x^3$ by solving the balance equation

$$
\left(2x^m m(-1+m) - x^m m + x^m\right) c_0 = 2x^3
$$

For c_0 and x. This results in

$$
c_0 = \frac{1}{5}
$$
$$
m = 3
$$

The particular solution is therefore

$$
\begin{aligned}
y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\
&= \sum_{n=0}^{\infty} c_n x^{n+3}
\end{aligned}
$$

Where in the above $c_0 = \frac{1}{5}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 3$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{5}$ and $r = m$ or $r = 3$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = \frac{1}{5}$
$c_1 = -\frac{1}{21}$
$c_2 = \frac{11}{756}$
$c_3 = -\frac{19}{3780}$
$c_4 = \frac{551}{294840}$
$c_5 = -\frac{22591}{30958200}$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\
&= x^3 \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x^3\left(\frac{1}{5}-\frac{1}{21}x+\frac{11}{756}x^2-\frac{19}{3780}x^3+\frac{551}{294840}x^4-\frac{22591}{30958200}x^5\right)\\
&= \frac{1}{5}x^3-\frac{1}{21}x^4+\frac{11}{756}x^5-\frac{19}{3780}x^6+\frac{551}{294840}x^7-\frac{22591}{30958200}x^8
\end{aligned}
$$

Now we determine the particular solution y_p associated with $F = x^2$ by solving the balance equation

$$
(2x^m m(-1+m) - x^m m + x^m)\, c_0 = x^2
$$

For c_0 and x. This results in

$$
\begin{aligned}
c_0 &= \frac{1}{3}\\
m &= 2
\end{aligned}
$$

The particular solution is therefore

$$
\begin{aligned}
y_p &= \sum_{n=0}^{\infty} c_n x^{n+m}\\
&= \sum_{n=0}^{\infty} c_n x^{n+2}
\end{aligned}
$$

Where in the above $c_0 = \frac{1}{3}$.

The remaining c_n values are found using the same recurrence relation given in the earlier table which was used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 2$ in place of the root of the indicial equation used to find the homogeneous solution. By letting $a_0 = c_0$ or $a_0 = \frac{1}{3}$ and $r = m$ or $r = 2$. The following table gives the resulting c_n values. These values will be used to find the particular solution. Values of c_n found not defined when doing the substitution will be discarded and not used

$c_0 = \frac{1}{3}$
$c_1 = -\frac{1}{30}$
$c_2 = \frac{1}{126}$
$c_3 = -\frac{11}{4536}$
$c_4 = \frac{19}{22680}$
$c_5 = -\frac{551}{1769040}$

The particular solution is now found using

$$
\begin{aligned}
y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\
&= x^2 \sum_{n=0}^{\infty} c_n x^n
\end{aligned}
$$

Using the values found above for c_n into the above sum gives

$$
\begin{aligned}
y_p &= x^2 \left(\frac{1}{3} - \frac{1}{30}x + \frac{1}{126}x^2 - \frac{11}{4536}x^3 + \frac{19}{22680}x^4 - \frac{551}{1769040}x^5\right) \\
&= \frac{1}{3}x^2 - \frac{1}{30}x^3 + \frac{1}{126}x^4 - \frac{11}{4536}x^5 + \frac{19}{22680}x^6 - \frac{551}{1769040}x^7
\end{aligned}
$$

Adding all the above particular solution(s) gives

$$
y_p = \frac{x^2}{3} + \frac{x^3}{6} + \frac{x^4}{126} - \frac{11x^5}{4536} + \frac{19x^6}{22680} - \frac{551x^7}{1769040} - \frac{248501x^9}{842063040} + O(x^6)
$$

Truncating the particular solution to the order of series requested gives

$$
y_p = \frac{x^2}{3} + \frac{x^3}{6} + \frac{x^4}{126} - \frac{11x^5}{4536} + O(x^6)
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \frac{x^2}{3} + \frac{x^3}{6} + \frac{x^4}{126} - \frac{11x^5}{4536} + O(x^6) + c_1 x \left(1 + \frac{x}{3} - \frac{x^2}{30} + \frac{x^3}{126} - \frac{11x^4}{4536} + \frac{19x^5}{22680} + O(x^6)\right) \\
&\quad + c_2 \sqrt{x} \left(1 + \frac{5x}{4} + \frac{5x^2}{96} - \frac{11x^3}{1152} + \frac{341x^4}{129024} - \frac{20119x^5}{23224320} + O(x^6)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & \frac{x^2}{3} + \frac{x^3}{6} + \frac{x^4}{126} - \frac{11x^5}{4536} + O(x^6) + c_1 x \left(1 + \frac{x}{3} - \frac{x^2}{30} + \frac{x^3}{126} - \frac{11x^4}{4536} + \frac{19x^5}{22680} + O(x^6)\right) \\
& + c_2 \sqrt{x} \left(1 + \frac{5x}{4} + \frac{5x^2}{96} - \frac{11x^3}{1152} + \frac{341x^4}{129024} - \frac{20119x^5}{23224320} + O(x^6)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$y = \frac{x^2}{3}+\frac{x^3}{6}+\frac{x^4}{126}-\frac{11x^5}{4536}+O(x^6)+c_1x\left(1+\frac{x}{3}-\frac{x^2}{30}+\frac{x^3}{126}-\frac{11x^4}{4536}+\frac{19x^5}{22680}+O(x^6)\right)$$
$$+c_2\sqrt{x}\left(1+\frac{5x}{4}+\frac{5x^2}{96}-\frac{11x^3}{1152}+\frac{341x^4}{129024}-\frac{20119x^5}{23224320}+O(x^6)\right)$$

Verified OK.
