Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.1. Page 40
Problem number: 1.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{3y + y' = e^{-2t} + t}$$

1.1.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = 3$$
$$q(t) = e^{-2t} + t$$

Hence the ode is

$$3y + y' = e^{-2t} + t$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int 3dt} \\ &= e^{3t}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dt}(\mu y) &= (\mu)\left(e^{-2t}+t\right) \\ \frac{d}{dt}\left(e^{3t}y\right) &= \left(e^{3t}\right)\left(e^{-2t}+t\right) \\ d\left(e^{3t}y\right) &= \left(\left(e^{2t}t+1\right)e^{t}\right)\, dt\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{3t}y &= \int \left(e^{2t}t+1\right)e^{t}\, dt \\ e^{3t}y &= \frac{e^{3t}t}{3}-\frac{e^{3t}}{9}+e^{t}+c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{3t}$ results in

$$y = e^{-3t}\left(\frac{e^{3t}t}{3}-\frac{e^{3t}}{9}+e^{t}\right)+c_1 e^{-3t}$$

which simplifies to

$$y = \frac{t}{3}-\frac{1}{9}+e^{-2t}+c_1 e^{-3t}$$

Summary

The solution(s) found are the following

$$y = \frac{t}{3}-\frac{1}{9}+e^{-2t}+c_1 e^{-3t} \tag{1}$$

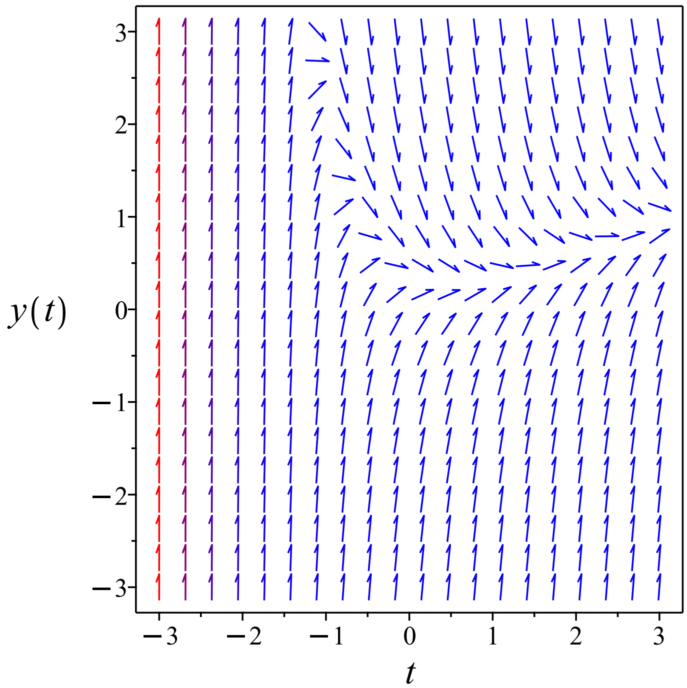

Figure 1: Slope field plot

Verification of solutions

$$y = \frac{t}{3} - \frac{1}{9} + e^{-2t} + c_1 e^{-3t}$$

Verified OK.

1.1.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -3y + e^{-2t} + t$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 1: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \mathrm{e}^{-3t}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{-3t}} dy \end{aligned}$$

Which results in

$$S = e^{3t} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y) S_y}{R_t + \omega(t,y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = -3y + e^{-2t} + t$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= 3\,e^{3t} y \\ S_y &= e^{3t} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = e^{t} + e^{3t} t \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = e^{R} + e^{3R} R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{e^{3R}R}{3} - \frac{e^{3R}}{9} + e^{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$e^{3t}y = \frac{e^{3t}t}{3} - \frac{e^{3t}}{9} + e^{t} + c_1$$

Which simplifies to

$$e^{3t}y = \frac{e^{3t}t}{3} - \frac{e^{3t}}{9} + e^{t} + c_1$$

Which gives

$$y = \frac{(3\,e^{3t}t - e^{3t} + 9\,e^{t} + 9c_1)\,e^{-3t}}{9}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -3y + e^{-2t} + t$ 	$R = t$ $S = e^{3t}y$	$\frac{dS}{dR} = e^{R} + e^{3R}R$ 
Summary

The solution(s) found are the following

$$y = \frac{(3\,e^{3t}t - e^{3t} + 9\,e^{t} + 9c_1)\,e^{-3t}}{9} \tag{1}$$

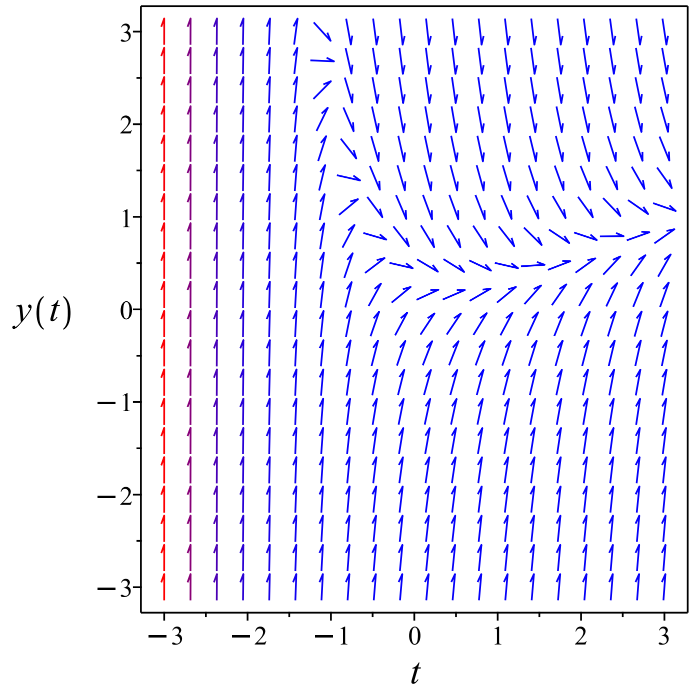

Figure 2: Slope field plot

Verification of solutions

$$y = \frac{(3\,e^{3t}t - e^{3t} + 9\,e^{t} + 9c_1)\,e^{-3t}}{9}$$

Verified OK.

1.1.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = \left(-3y + \mathrm{e}^{-2t} + t\right) \mathrm{d}t$$
$$\left(3y - \mathrm{e}^{-2t} - t\right) \mathrm{d}t + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(t, y) = 3y - \mathrm{e}^{-2t} - t$$
$$N(t, y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(3y - \mathrm{e}^{-2t} - t\right) \\ &= 3 \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(1) \\ &= 0 \end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\ &= 1((3) - (0)) \\ &= 3 \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}t} \\ &= e^{\int 3 \, \mathrm{d}t} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{3t} \\ &= \mathrm{e}^{3t} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{3t}\left(3y - \mathrm{e}^{-2t} - t\right) \\ &= -\left(1 + (-3y + t)\,\mathrm{e}^{2t}\right)\mathrm{e}^{t} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{3t}(1) \\ &= \mathrm{e}^{3t} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\ \left(-\left(1 + (-3y + t)\,\mathrm{e}^{2t}\right)\mathrm{e}^{t}\right) + \left(\mathrm{e}^{3t}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int \overline{M} \, \mathrm{d}t \\
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int -\left(1 + (-3y + t)\,\mathrm{e}^{2t}\right) \mathrm{e}^{t} \, \mathrm{d}t \\
\phi &= \frac{(-3t + 9y + 1)\,\mathrm{e}^{3t}}{9} - \mathrm{e}^{t} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = \mathrm{e}^{3t} + f'(y) \qquad (4)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{3t}$. Therefore equation (4) becomes

$$
\mathrm{e}^{3t} = \mathrm{e}^{3t} + f'(y) \qquad (5)
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = 0
$$

Therefore

$$
f(y) = c_1
$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$
\phi = \frac{(-3t + 9y + 1)\,\mathrm{e}^{3t}}{9} - \mathrm{e}^{t} + c_1
$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$
c_1 = \frac{(-3t + 9y + 1)\,\mathrm{e}^{3t}}{9} - \mathrm{e}^{t}
$$

The solution becomes

$$
y = \frac{(3\,\mathrm{e}^{3t} t - \mathrm{e}^{3t} + 9\,\mathrm{e}^{t} + 9c_1)\,\mathrm{e}^{-3t}}{9}
$$

Summary
The solution(s) found are the following

$$y = \frac{(3\,e^{3t}t - e^{3t} + 9\,e^{t} + 9c_1)\,e^{-3t}}{9} \tag{1}$$

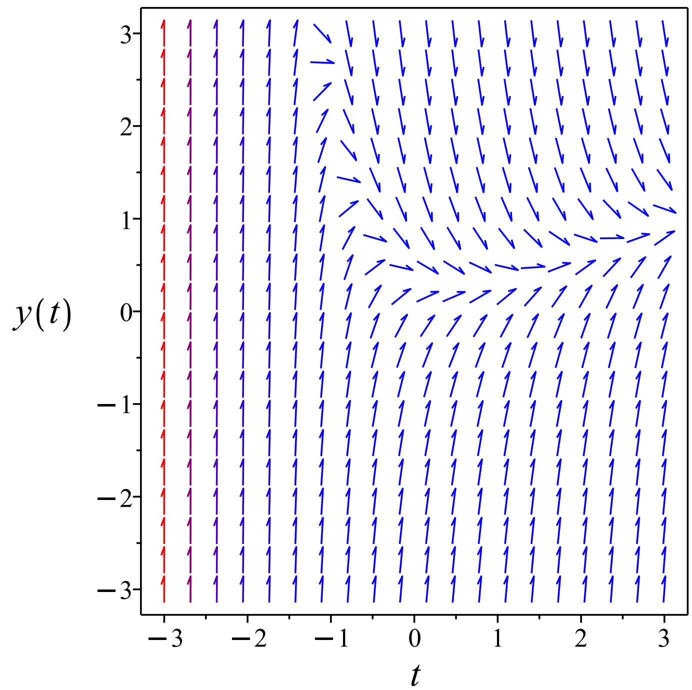

Figure 3: Slope field plot

Verification of solutions

$$y = \frac{(3\,e^{3t}t - e^{3t} + 9\,e^{t} + 9c_1)\,e^{-3t}}{9}$$

Verified OK.

1.1.4 Maple step by step solution

Let's solve

$3y + y' = e^{-2t} + t$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

$y' = -3y + e^{-2t} + t$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $3y + y' = e^{-2t} + t$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)(3y + y') = \mu(t)(e^{-2t} + t)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, y)$

  $\mu(t)(3y + y') = \mu'(t)\, y + \mu(t)\, y'$

- Isolate $\mu'(t)$

  $\mu'(t) = 3\mu(t)$

- Solve to find the integrating factor

  $\mu(t) = e^{3t}$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\, y)\right) dt = \int \mu(t)(e^{-2t} + t)\, dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\, y = \int \mu(t)(e^{-2t} + t)\, dt + c_1$

- Solve for y

  $y = \frac{\int \mu(t)(e^{-2t}+t)\, dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = e^{3t}$

  $y = \frac{\int (e^{-2t}+t)e^{3t}\, dt + c_1}{e^{3t}}$

- Evaluate the integrals on the rhs

  $y = \frac{\frac{(e^t)^3 t}{3} - \frac{(e^t)^3}{9} + e^t + c_1}{e^{3t}}$

- Simplify

  $y = \frac{(3\, e^{3t} t - e^{3t} + 9\, e^t + 9c_1)\, e^{-3t}}{9}$

1.2 problem 2

Internal problem ID [449]
Internal file name [`OUTPUT/449_Sunday_June_05_2022_01_41_40_AM_16129924/index.tex`]

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.1. Page 40
Problem number: 2.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{-2y + y' = e^{2t}t^2}$$

1.2.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = -2$$
$$q(t) = e^{2t}t^2$$

Hence the ode is

$$-2y + y' = e^{2t}t^2$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int (-2)dt} \\ &= e^{-2t}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dt}(\mu y) &= (\mu)\left(e^{2t}t^2\right) \\ \frac{d}{dt}\left(e^{-2t}y\right) &= \left(e^{-2t}\right)\left(e^{2t}t^2\right) \\ d\left(e^{-2t}y\right) &= t^2\, dt\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{-2t}y &= \int t^2\, dt \\ e^{-2t}y &= \frac{t^3}{3} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-2t}$ results in

$$y = \frac{e^{2t}t^3}{3} + c_1 e^{2t}$$

which simplifies to

$$y = e^{2t}\left(\frac{t^3}{3} + c_1\right)$$

Summary
The solution(s) found are the following

$$y = e^{2t}\left(\frac{t^3}{3} + c_1\right) \tag{1}$$

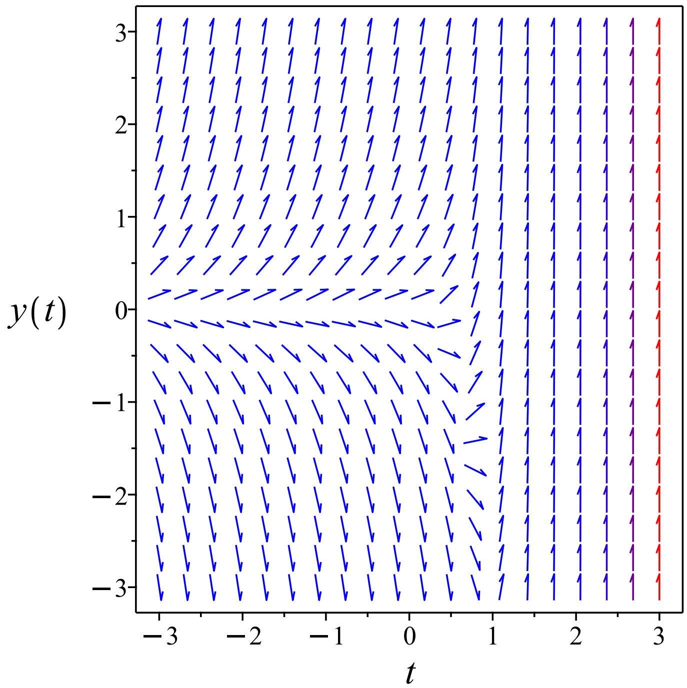

Figure 4: Slope field plot

Verification of solutions

$$y = e^{2t}\left(\frac{t^3}{3} + c_1\right)$$

Verified OK.

1.2.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = 2y + e^{2t}t^2$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2\xi_y - \omega_t\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 4: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= e^{2t}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{2t}} dy \end{aligned}$$

Which results in

$$S = e^{-2t} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y) S_y}{R_t + \omega(t,y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = 2y + e^{2t} t^2$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= -2\, e^{-2t} y \\ S_y &= e^{-2t} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = t^2 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R^2$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^3}{3} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$e^{-2t}y = \frac{t^3}{3} + c_1$$

Which simplifies to

$$e^{-2t}y = \frac{t^3}{3} + c_1$$

Which gives

$$y = \frac{e^{2t}(t^3 + 3c_1)}{3}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = 2y + e^{2t}t^2$ 	$R = t$ $S = e^{-2t}y$	$\frac{dS}{dR} = R^2$ 
Summary

The solution(s) found are the following

$$y = \frac{e^{2t}(t^3 + 3c_1)}{3} \tag{1}$$

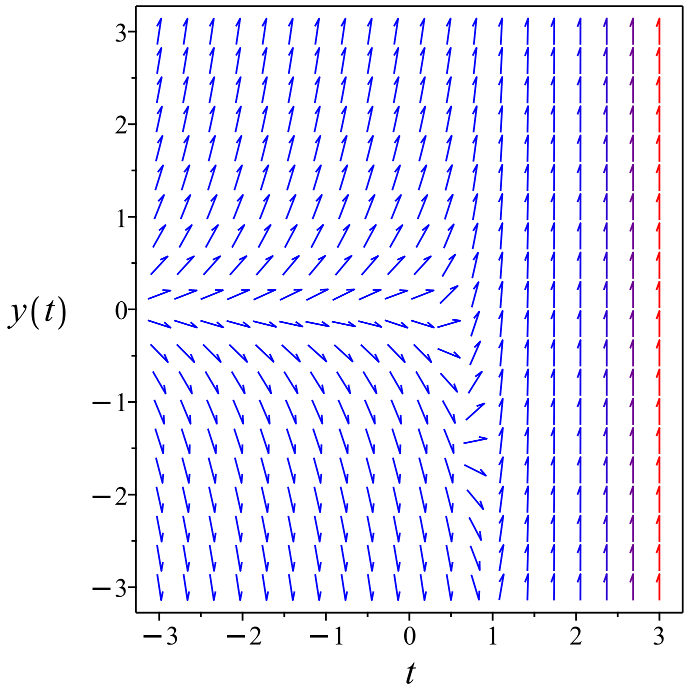

Figure 5: Slope field plot

Verification of solutions

$$y = \frac{e^{2t}(t^3 + 3c_1)}{3}$$

Verified OK.

1.2.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y) \, \mathrm{d}t + N(t, y) \, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned} \mathrm{d}y &= \left(2y + \mathrm{e}^{2t} t^2\right) \mathrm{d}t \\ \left(-2y - \mathrm{e}^{2t} t^2\right) \mathrm{d}t + \mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(t, y) = -2y - \mathrm{e}^{2t} t^2$$
$$N(t, y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-2y - \mathrm{e}^{2t} t^2\right) \\ &= -2 \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(1) \\ &= 0 \end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right)\\ &= 1((-2) - (0))\\ &= -2\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}t}\\ &= e^{\int -2\,\mathrm{d}t}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-2t}\\ &= \mathrm{e}^{-2t}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \mathrm{e}^{-2t}\left(-2y - \mathrm{e}^{2t}t^2\right)\\ &= -2\,\mathrm{e}^{-2t}y - t^2\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \mathrm{e}^{-2t}(1)\\ &= \mathrm{e}^{-2t}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0\\ \left(-2\,\mathrm{e}^{-2t}y - t^2\right) + \left(\mathrm{e}^{-2t}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int \overline{M} \, \mathrm{d}t$$

$$\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int -2\,\mathrm{e}^{-2t} y - t^2 \, \mathrm{d}t$$

$$\phi = -\frac{t^3}{3} + \mathrm{e}^{-2t} y + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{-2t} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-2t}$. Therefore equation (4) becomes

$$\mathrm{e}^{-2t} = \mathrm{e}^{-2t} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{t^3}{3} + \mathrm{e}^{-2t} y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{t^3}{3} + \mathrm{e}^{-2t} y$$

The solution becomes

$$y = \frac{\mathrm{e}^{2t}(t^3 + 3c_1)}{3}$$

Summary

The solution(s) found are the following

$$y = \frac{e^{2t}(t^3 + 3c_1)}{3} \tag{1}$$

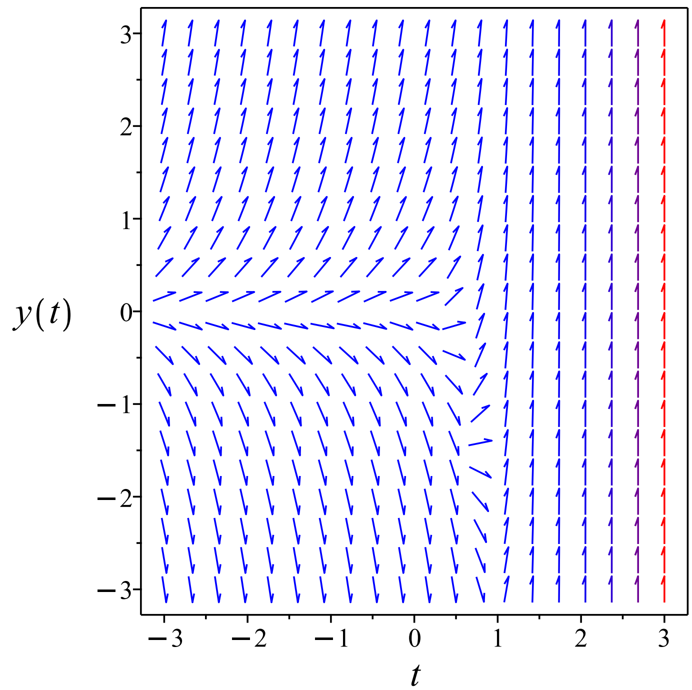

Figure 6: Slope field plot

Verification of solutions

$$y = \frac{e^{2t}(t^3 + 3c_1)}{3}$$

Verified OK.

1.2.4 Maple step by step solution

Let's solve

$-2y + y' = e^{2t}t^2$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

$y' = 2y + e^{2t}t^2$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $-2y + y' = e^{2t}t^2$
- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(-2y + y'\right) = \mu(t)\, e^{2t}t^2$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, y)$

  $\mu(t)\left(-2y + y'\right) = \mu'(t)\, y + \mu(t)\, y'$
- Isolate $\mu'(t)$

  $\mu'(t) = -2\mu(t)$
- Solve to find the integrating factor

  $\mu(t) = e^{-2t}$
- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\, y)\right) dt = \int \mu(t)\, e^{2t}t^2 dt + c_1$
- Evaluate the integral on the lhs

  $\mu(t)\, y = \int \mu(t)\, e^{2t}t^2 dt + c_1$
- Solve for y

  $y = \frac{\int \mu(t) e^{2t}t^2 dt + c_1}{\mu(t)}$
- Substitute $\mu(t) = e^{-2t}$

  $y = \frac{\int e^{2t}t^2 e^{-2t} dt + c_1}{e^{-2t}}$
- Evaluate the integrals on the rhs

  $y = \frac{\frac{t^3}{3} + c_1}{e^{-2t}}$
- Simplify

  $y = \frac{e^{2t}(t^3 + 3c_1)}{3}$

Problem number: 3.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y + y' = 1 + t\,\mathrm{e}^{-t}}$$

1.3.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = 1$$
$$q(t) = 1 + t\,\mathrm{e}^{-t}$$

Hence the ode is

$$y + y' = 1 + t\,\mathrm{e}^{-t}$$

The integrating factor μ is

$$\mu = e^{\int 1dt} \\ = e^{t}$$

The ode becomes

$$\frac{d}{dt}(\mu y) = (\mu)\left(1 + t\,e^{-t}\right)$$
$$\frac{d}{dt}\left(y\,e^{t}\right) = \left(e^{t}\right)\left(1 + t\,e^{-t}\right)$$
$$d\left(y\,e^{t}\right) = \left(e^{t} + t\right)\,dt$$

Integrating gives

$$y\,e^{t} = \int e^{t} + t\,dt$$
$$y\,e^{t} = \frac{t^2}{2} + e^{t} + c_1$$

Dividing both sides by the integrating factor $\mu = e^{t}$ results in

$$y = e^{-t}\left(\frac{t^2}{2} + e^{t}\right) + c_1 e^{-t}$$

which simplifies to

$$y = 1 + \frac{(t^2 + 2c_1)\,e^{-t}}{2}$$

Summary

The solution(s) found are the following

$$y = 1 + \frac{(t^2 + 2c_1)\,e^{-t}}{2} \tag{1}$$

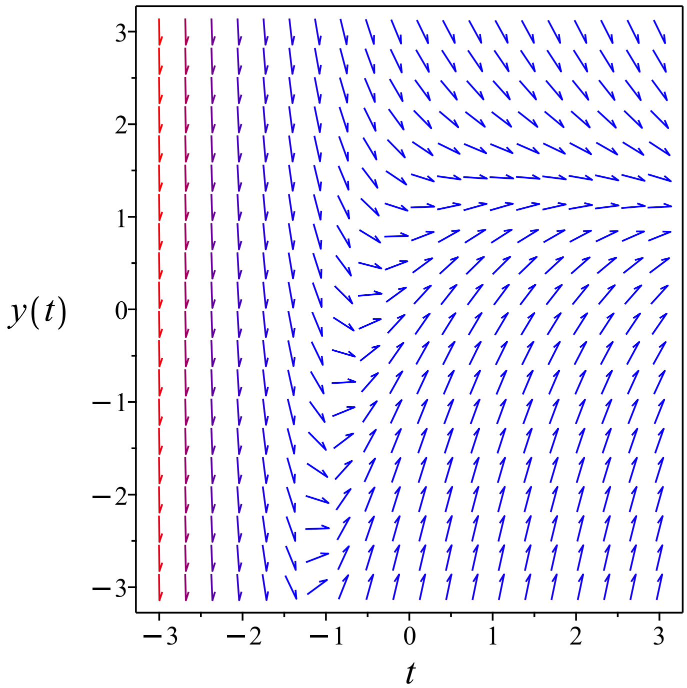

Figure 7: Slope field plot

Verification of solutions

$$y = 1 + \frac{(t^2 + 2c_1)\,\mathrm{e}^{-t}}{2}$$

Verified OK.

1.3.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= -\left(y\,\mathrm{e}^{t} - \mathrm{e}^{t} - t\right)\mathrm{e}^{-t} \\ y' &= \omega(t, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 7: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \mathrm{e}^{-t}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{-t}} dy \end{aligned}$$

Which results in

$$S = y\,\mathrm{e}^{t}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = -\left(y\,\mathrm{e}^{t} - \mathrm{e}^{t} - t\right) \mathrm{e}^{-t}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= y\,\mathrm{e}^{t} \\ S_y &= \mathrm{e}^{t} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \mathrm{e}^{t} + t \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \mathrm{e}^{R} + R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^2}{2} + e^R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$y\,e^t = \frac{t^2}{2} + e^t + c_1$$

Which simplifies to

$$y\,e^t = \frac{t^2}{2} + e^t + c_1$$

Which gives

$$y = \frac{(t^2 + 2\,e^t + 2c_1)\,e^{-t}}{2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in t, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>
<tr><td>$\frac{dy}{dt} = -(y\,e^t - e^t - t)\,e^{-t}$
</td><td>$R = t$
$S = y\,e^t$</td><td>$\frac{dS}{dR} = e^R + R$
</td></tr>
</table>

Summary
The solution(s) found are the following

$$y = \frac{(t^2 + 2\,e^t + 2c_1)\,e^{-t}}{2} \tag{1}$$

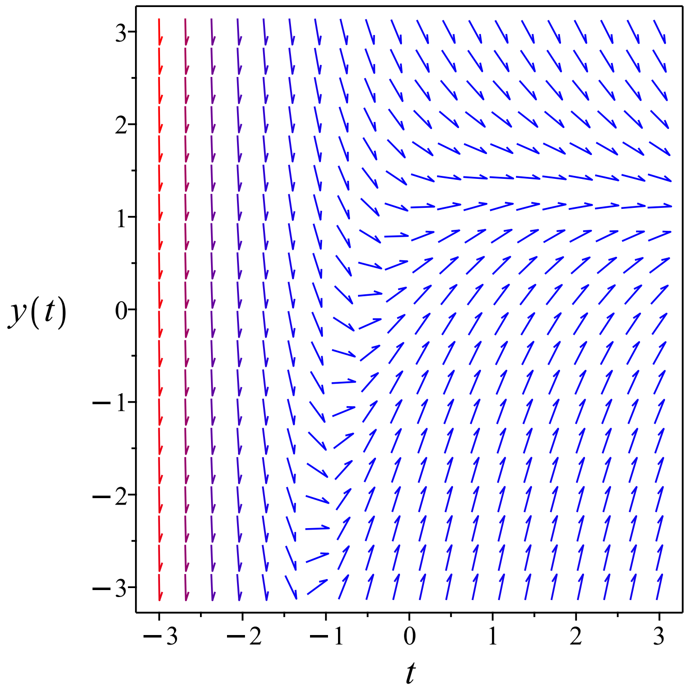

Figure 8: Slope field plot

<u>Verification of solutions</u>

$$y = \frac{(t^2 + 2\,e^t + 2c_1)\,e^{-t}}{2}$$

Verified OK.

1.3.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t + N(t,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(\mathrm{e}^t)\,\mathrm{d}y &= \left(-y\,\mathrm{e}^t + \mathrm{e}^t + t\right)\mathrm{d}t\\ \left(y\,\mathrm{e}^t - \mathrm{e}^t - t\right)\mathrm{d}t + (\mathrm{e}^t)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t,y) &= y\,\mathrm{e}^t - \mathrm{e}^t - t\\ N(t,y) &= \mathrm{e}^t\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(y\,\mathrm{e}^t - \mathrm{e}^t - t\right)\\ &= \mathrm{e}^t\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(\mathrm{e}^t)\\ &= \mathrm{e}^t\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(t, y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial t} &= M \qquad (1) \\
\frac{\partial \phi}{\partial y} &= N \qquad (2)
\end{aligned}
$$

Integrating (1) w.r.t. t gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int M \, \mathrm{d}t \\
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int y \, \mathrm{e}^t - \mathrm{e}^t - t \, \mathrm{d}t \\
\phi &= \mathrm{e}^t (y-1) - \frac{t^2}{2} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = \mathrm{e}^t + f'(y) \qquad (4)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^t$. Therefore equation (4) becomes

$$
\mathrm{e}^t = \mathrm{e}^t + f'(y) \qquad (5)
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = 0
$$

Therefore

$$
f(y) = c_1
$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$
\phi = \mathrm{e}^t (y-1) - \frac{t^2}{2} + c_1
$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$
c_1 = \mathrm{e}^t (y-1) - \frac{t^2}{2}
$$

The solution becomes

$$y = \frac{(t^2 + 2\,e^t + 2c_1)\,e^{-t}}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{(t^2 + 2\,e^t + 2c_1)\,e^{-t}}{2} \tag{1}$$

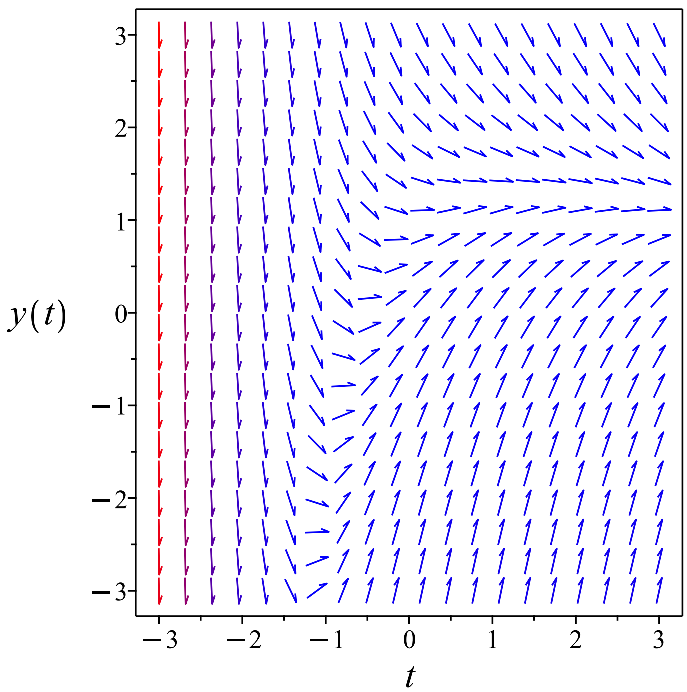

Figure 9: Slope field plot

Verification of solutions

$$y = \frac{(t^2 + 2\,e^t + 2c_1)\,e^{-t}}{2}$$

Verified OK.

1.3.4 Maple step by step solution

Let's solve

$y + y' = 1 + \frac{t}{e^t}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -y + \frac{e^t + t}{e^t}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y + y' = \frac{e^t + t}{e^t}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\,(y + y') = \frac{\mu(t)(e^t + t)}{e^t}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

  $\mu(t)\,(y + y') = \mu'(t)\,y + \mu(t)\,y'$

- Isolate $\mu'(t)$

  $\mu'(t) = \mu(t)$

- Solve to find the integrating factor

  $\mu(t) = (e^t)^2\,e^{-t}$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\,y)\right) dt = \int \frac{\mu(t)(e^t + t)}{e^t} dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\,y = \int \frac{\mu(t)(e^t + t)}{e^t} dt + c_1$

- Solve for y

  $y = \frac{\int \frac{\mu(t)\left(e^t + t\right)}{e^t} dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = (e^t)^2\,e^{-t}$

  $y = \frac{\int e^t e^{-t}(e^t + t)dt + c_1}{(e^t)^2 e^{-t}}$

- Evaluate the integrals on the rhs

  $y = \frac{\frac{t^2}{2} + e^t + c_1}{(e^t)^2 e^{-t}}$

- Simplify

  $y = 1 + \frac{(t^2+2c_1)e^{-t}}{2}$

1.4 problem 4

Internal problem ID [451]
Internal file name [`OUTPUT/451_Sunday_June_05_2022_01_41_42_AM_48741648/index.tex`]

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.1. Page 40
Problem number: 4.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{\frac{y}{t} + y' = 3\cos(2t)}$$

1.4.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \frac{1}{t}$$
$$q(t) = 3\cos(2t)$$

Hence the ode is

$$\frac{y}{t} + y' = 3\cos(2t)$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int \frac{1}{t}dt} \\
&= t
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dt}(\mu y) &= (\mu)\left(3\cos(2t)\right) \\
\frac{d}{dt}(ty) &= (t)\left(3\cos(2t)\right) \\
d(ty) &= (3\cos(2t)\,t)\; dt
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
ty &= \int 3\cos(2t)\,t\, dt \\
ty &= \frac{3\cos(2t)}{4} + \frac{3\sin(2t)\,t}{2} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = t$ results in

$$
y = \frac{\frac{3\cos(2t)}{4} + \frac{3\sin(2t)t}{2}}{t} + \frac{c_1}{t}
$$

which simplifies to

$$
y = \frac{6\sin(2t)\,t + 3\cos(2t) + 4c_1}{4t}
$$

Summary

The solution(s) found are the following

$$
y = \frac{6\sin(2t)\,t + 3\cos(2t) + 4c_1}{4t} \tag{1}
$$

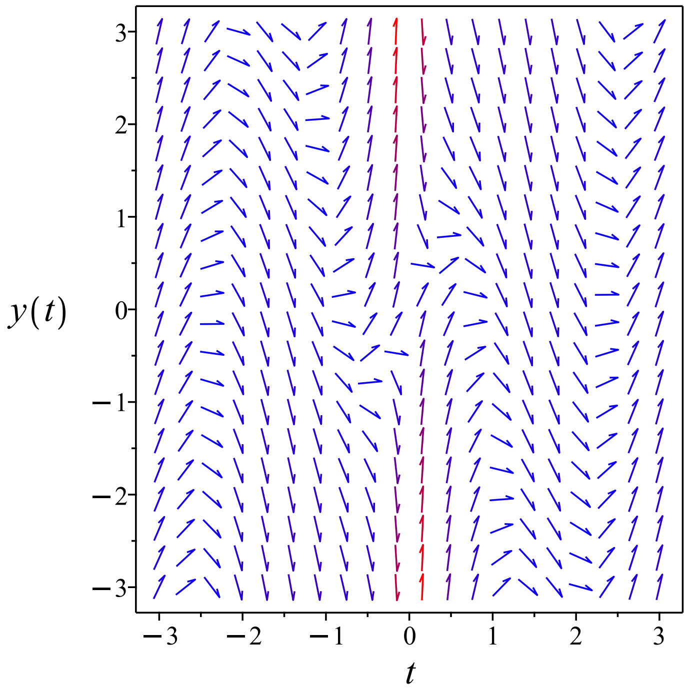

Figure 10: Slope field plot

Verification of solutions

$$y = \frac{6\sin(2t)\,t + 3\cos(2t) + 4c_1}{4t}$$

Verified OK.

1.4.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{-y + 3\cos(2t)\,t}{t}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2\xi_y - \omega_t\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 10: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \frac{1}{t}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{t}} dy \end{aligned}$$

Which results in

$$S = ty$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = \frac{-y + 3\cos(2t)\, t}{t}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= y \\ S_y &= t \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 3\cos(2t)\, t \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 3\cos(2R)\, R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{3\cos(2R)}{4} + \frac{3\sin(2R)\,R}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$yt = \frac{3\cos(2t)}{4} + \frac{3\sin(2t)\,t}{2} + c_1$$

Which simplifies to

$$yt = \frac{3\cos(2t)}{4} + \frac{3\sin(2t)\,t}{2} + c_1$$

Which gives

$$y = \frac{6\sin(2t)\,t + 3\cos(2t) + 4c_1}{4t}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = \frac{-y+3\cos(2t)t}{t}$ 	$R = t$ $S = ty$	$\frac{dS}{dR} = 3\cos(2R)\,R$ 
Summary

The solution(s) found are the following

$$y = \frac{6\sin(2t)\,t + 3\cos(2t) + 4c_1}{4t} \tag{1}$$

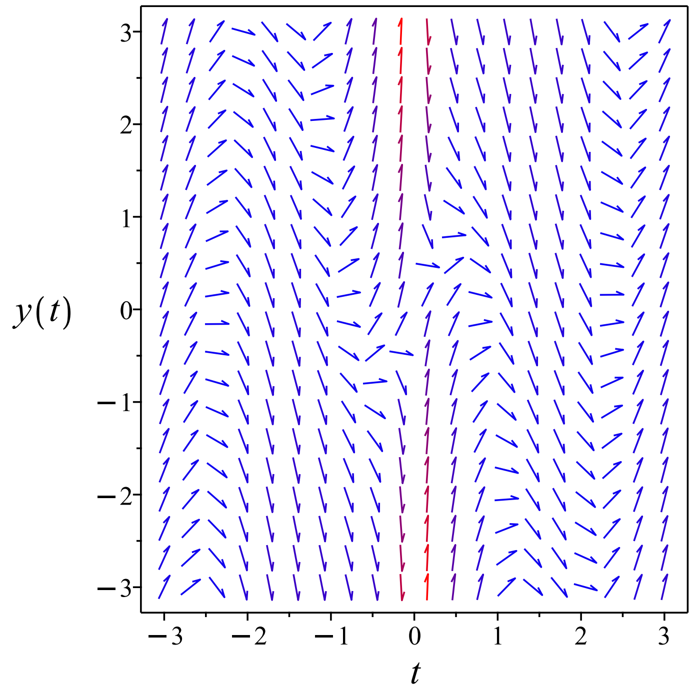

Figure 11: Slope field plot

Verification of solutions

$$y = \frac{6 \sin (2t) t + 3 \cos (2t) + 4c_1}{4t}$$

Verified OK.

1.4.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t + N(t,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(t)\,\mathrm{d}y &= (-y + 3\cos(2t)\,t)\,\mathrm{d}t\\ (y - 3\cos(2t)\,t)\,\mathrm{d}t + (t)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t,y) &= y - 3\cos(2t)\,t\\ N(t,y) &= t\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(y - 3\cos(2t)\,t)\\ &= 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(t)\\ &= 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int M \, \mathrm{d}t$$
$$\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int y - 3\cos(2t) \, t \, \mathrm{d}t$$
$$\phi = ty - \frac{3\cos(2t)}{4} - \frac{3\sin(2t)\, t}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = t + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = t$. Therefore equation (4) becomes

$$t = t + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = ty - \frac{3\cos(2t)}{4} - \frac{3\sin(2t)\, t}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = ty - \frac{3\cos(2t)}{4} - \frac{3\sin(2t)\, t}{2}$$

The solution becomes

$$y = \frac{6 \sin(2t) t + 3 \cos(2t) + 4c_1}{4t}$$

Summary

The solution(s) found are the following

$$y = \frac{6 \sin(2t) t + 3 \cos(2t) + 4c_1}{4t} \tag{1}$$

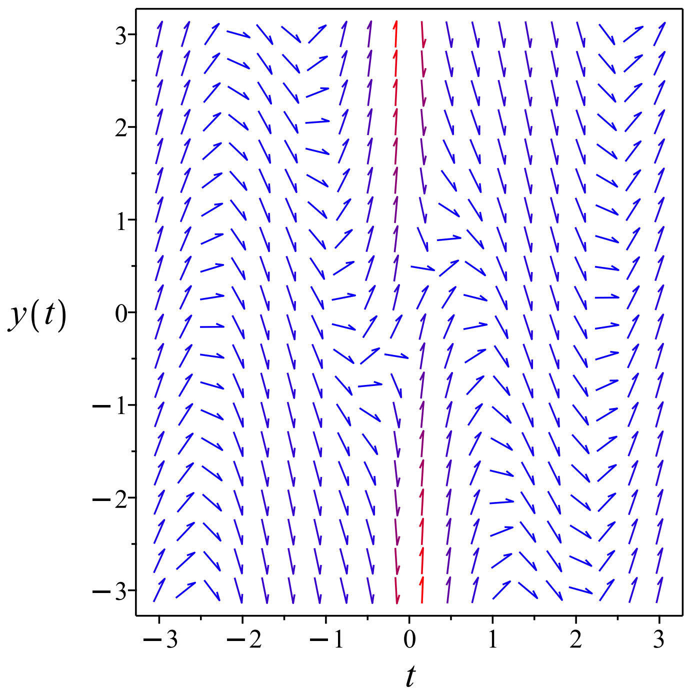

Figure 12: Slope field plot

Verification of solutions

$$y = \frac{6 \sin(2t) t + 3 \cos(2t) + 4c_1}{4t}$$

Verified OK.

1.4.4 Maple step by step solution

Let's solve

$\frac{y}{t}+y'=3\cos(2t)$

- Highest derivative means the order of the ODE is 1

y'

- Isolate the derivative

$y'=-\frac{y}{t}+3\cos(2t)$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

$\frac{y}{t}+y'=3\cos(2t)$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

$\mu(t)\left(\frac{y}{t}+y'\right)=3\mu(t)\cos(2t)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

$\mu(t)\left(\frac{y}{t}+y'\right)=\mu'(t)\,y+\mu(t)\,y'$

- Isolate $\mu'(t)$

$\mu'(t)=\frac{\mu(t)}{t}$

- Solve to find the integrating factor

$\mu(t)=t$

- Integrate both sides with respect to t

$\int\left(\frac{d}{dt}(\mu(t)\,y)\right)dt=\int 3\mu(t)\cos(2t)\,dt+c_1$

- Evaluate the integral on the lhs

$\mu(t)\,y=\int 3\mu(t)\cos(2t)\,dt+c_1$

- Solve for y

$y=\frac{\int 3\mu(t)\cos(2t)dt+c_1}{\mu(t)}$

- Substitute $\mu(t)=t$

$y=\frac{\int 3\cos(2t)t dt+c_1}{t}$

- Evaluate the integrals on the rhs

$y=\frac{\frac{3\cos(2t)}{4}+\frac{3\sin(2t)t}{2}+c_1}{t}$

- Simplify

$$y = \frac{6\sin(2t)t+3\cos(2t)+4c_1}{4t}$$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{-2y + y' = 3\,\mathrm{e}^{t}}$$

1.5.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = -2$$
$$q(t) = 3\,\mathrm{e}^{t}$$

Hence the ode is

$$-2y + y' = 3\,\mathrm{e}^{t}$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int (-2)dt} \\ &= \mathrm{e}^{-2t}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}(\mu y) &= (\mu)\left(3\,\mathrm{e}^{t}\right) \\ \frac{\mathrm{d}}{\mathrm{d}t}\left(\mathrm{e}^{-2t} y\right) &= \left(\mathrm{e}^{-2t}\right)\left(3\,\mathrm{e}^{t}\right) \\ \mathrm{d}\left(\mathrm{e}^{-2t} y\right) &= \left(3\,\mathrm{e}^{-t}\right)\,\mathrm{d}t\end{aligned}$$

Integrating gives

$$\begin{aligned}\mathrm{e}^{-2t} y &= \int 3\,\mathrm{e}^{-t}\,\mathrm{d}t \\ \mathrm{e}^{-2t} y &= -3\,\mathrm{e}^{-t} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-2t}$ results in

$$y = -3\,\mathrm{e}^{2t}\mathrm{e}^{-t} + c_1 \mathrm{e}^{2t}$$

which simplifies to

$$y = -3\,\mathrm{e}^{t} + c_1 \mathrm{e}^{2t}$$

Summary

The solution(s) found are the following

$$y = -3\,\mathrm{e}^{t} + c_1 \mathrm{e}^{2t} \tag{1}$$

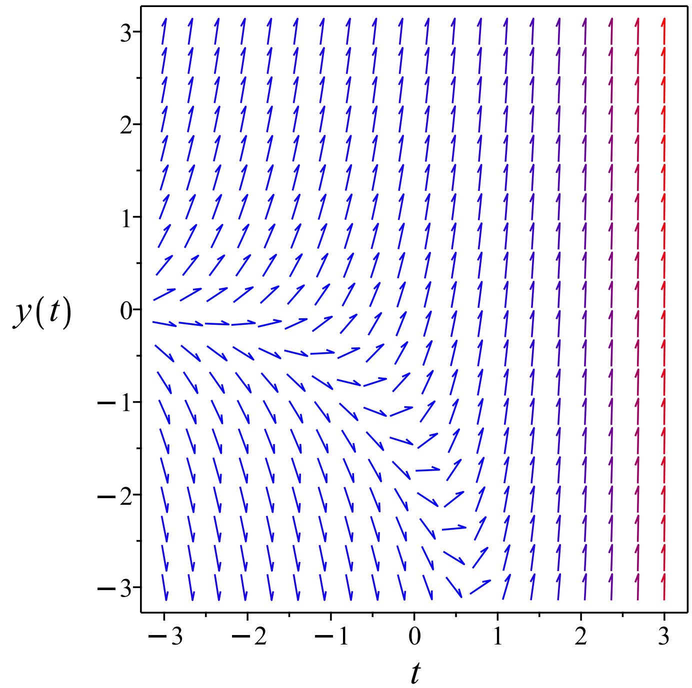

Figure 13: Slope field plot

Verification of solutions

$$y = -3\,e^{t} + c_1 e^{2t}$$

Verified OK.

1.5.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= 2y + 3\,e^{t} \\ y' &= \omega(t, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 13: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t,y) &= 0 \\
\eta(t,y) &= \mathrm{e}^{2t}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{2t}} dy \end{aligned}$$

Which results in

$$S = e^{-2t} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y) S_y}{R_t + \omega(t,y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = 2y + 3\,e^t$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= -2\,e^{-2t} y \\ S_y &= e^{-2t} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 3\,e^{-t} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 3\,e^{-R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -3\,\mathrm{e}^{-R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\mathrm{e}^{-2t} y = -3\,\mathrm{e}^{-t} + c_1$$

Which simplifies to

$$\mathrm{e}^{-2t} y = -3\,\mathrm{e}^{-t} + c_1$$

Which gives

$$y = -\left(3\,\mathrm{e}^{-t} - c_1\right) \mathrm{e}^{2t}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in t, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>
<tr><td>$\frac{dy}{dt} = 2y + 3\,\mathrm{e}^{t}$
</td><td>$R = t$
$S = \mathrm{e}^{-2t} y$</td><td>$\frac{dS}{dR} = 3\,\mathrm{e}^{-R}$
</td></tr>
</table>

Summary

The solution(s) found are the following

$$y = -\left(3\,\mathrm{e}^{-t} - c_1\right) \mathrm{e}^{2t} \tag{1}$$

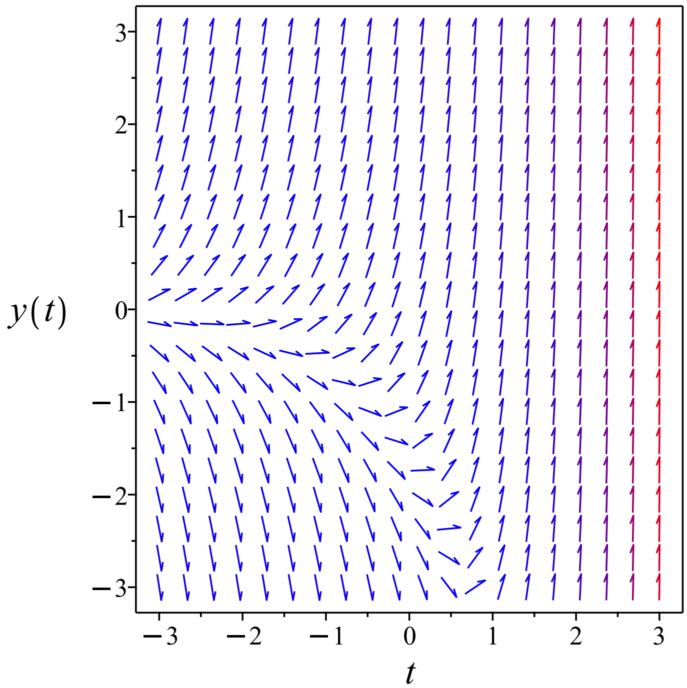

Figure 14: Slope field plot

Verification of solutions

$$y = -\left(3\,\mathrm{e}^{-t} - c_1\right)\mathrm{e}^{2t}$$

Verified OK.

1.5.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\,\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(t, y)\, \mathrm{d}t + N(t, y)\, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\mathrm{d}y &= \left(2y + 3\,\mathrm{e}^{t}\right) \mathrm{d}t \\
\left(-2y - 3\,\mathrm{e}^{t}\right) \mathrm{d}t + \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(t, y) &= -2y - 3\,\mathrm{e}^{t} \\
N(t, y) &= 1
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-2y - 3\,\mathrm{e}^{t}\right) \\
&= -2
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(1) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\ &= 1((-2) - (0)) \\ &= -2 \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}t} \\ &= e^{\int -2 \, \mathrm{d}t} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-2t} \\ &= \mathrm{e}^{-2t} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{-2t}\left(-2y - 3\,\mathrm{e}^{t}\right) \\ &= \left(-2y - 3\,\mathrm{e}^{t}\right)\mathrm{e}^{-2t} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{-2t}(1) \\ &= \mathrm{e}^{-2t} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\ \left(\left(-2y - 3\,\mathrm{e}^{t}\right)\mathrm{e}^{-2t}\right) + \left(\mathrm{e}^{-2t}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \,\mathrm{d}t = \int \overline{M} \,\mathrm{d}t$$

$$\int \frac{\partial \phi}{\partial t} \,\mathrm{d}t = \int \left(-2y - 3\,\mathrm{e}^{t}\right) \mathrm{e}^{-2t} \,\mathrm{d}t$$

$$\phi = 3\,\mathrm{e}^{-t} + \mathrm{e}^{-2t} y + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{-2t} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-2t}$. Therefore equation (4) becomes

$$\mathrm{e}^{-2t} = \mathrm{e}^{-2t} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = 3\,\mathrm{e}^{-t} + \mathrm{e}^{-2t} y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = 3\,\mathrm{e}^{-t} + \mathrm{e}^{-2t} y$$

The solution becomes

$$y = -\left(3\,\mathrm{e}^{-t} - c_1\right) \mathrm{e}^{2t}$$

Summary

The solution(s) found are the following

$$y = -\left(3\,\mathrm{e}^{-t} - c_1\right) \mathrm{e}^{2t} \tag{1}$$

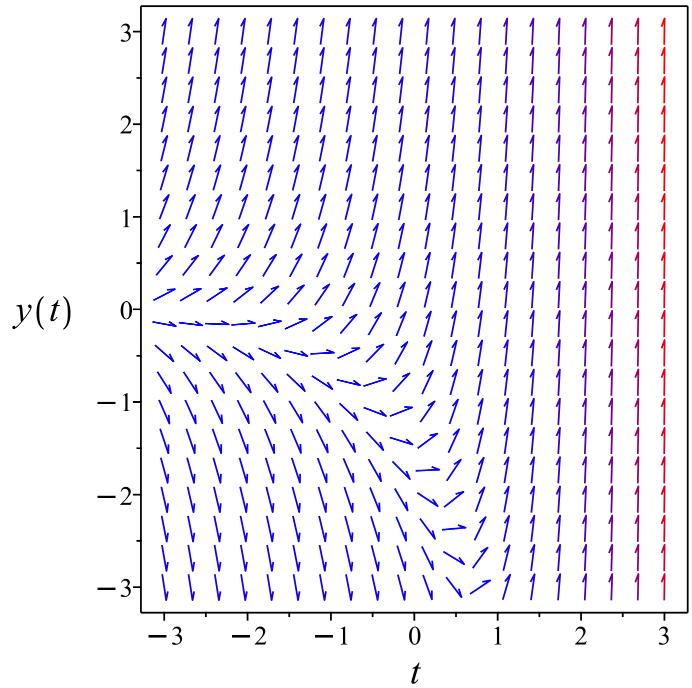

Figure 15: Slope field plot

Verification of solutions

$$y = -\left(3\,\mathrm{e}^{-t} - c_1\right)\mathrm{e}^{2t}$$

Verified OK.

1.5.4 Maple step by step solution

Let's solve

$-2y + y' = 3\,\mathrm{e}^{t}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = 2y + 3\,\mathrm{e}^{t}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $-2y + y' = 3\,\mathrm{e}^{t}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(-2y + y'\right) = 3\mu(t)\,\mathrm{e}^{t}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, y)$

  $\mu(t)\,(-2y+y') = \mu'(t)\, y + \mu(t)\, y'$
- Isolate $\mu'(t)$

  $\mu'(t) = -2\mu(t)$
- Solve to find the integrating factor

  $\mu(t) = \mathrm{e}^{-2t}$
- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\, y)\right) dt = \int 3\mu(t)\, \mathrm{e}^{t} dt + c_1$
- Evaluate the integral on the lhs

  $\mu(t)\, y = \int 3\mu(t)\, \mathrm{e}^{t} dt + c_1$
- Solve for y

  $y = \frac{\int 3\mu(t)\mathrm{e}^{t} dt + c_1}{\mu(t)}$
- Substitute $\mu(t) = \mathrm{e}^{-2t}$

  $y = \frac{\int 3\,\mathrm{e}^{t}\mathrm{e}^{-2t} dt + c_1}{\mathrm{e}^{-2t}}$
- Evaluate the integrals on the rhs

  $y = \frac{-3\,\mathrm{e}^{-t} + c_1}{\mathrm{e}^{-2t}}$
- Simplify

  $y = -3\,\mathrm{e}^{t} + c_1 \mathrm{e}^{2t}$

Problem number: 6.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{2y + ty' = \sin(t)}$$

1.6.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \frac{2}{t}$$
$$q(t) = \frac{\sin(t)}{t}$$

Hence the ode is

$$y' + \frac{2y}{t} = \frac{\sin(t)}{t}$$

The integrating factor μ is

$$\mu = e^{\int \frac{2}{t}dt}$$
$$= t^2$$

The ode becomes

$$\frac{d}{dt}(\mu y) = (\mu)\left(\frac{\sin(t)}{t}\right)$$
$$\frac{d}{dt}(t^2 y) = (t^2)\left(\frac{\sin(t)}{t}\right)$$
$$d(t^2 y) = (t \sin(t))\ dt$$

Integrating gives

$$t^2 y = \int t \sin(t)\ dt$$
$$t^2 y = -t\cos(t) + \sin(t) + c_1$$

Dividing both sides by the integrating factor $\mu = t^2$ results in

$$y = \frac{-t\cos(t) + \sin(t)}{t^2} + \frac{c_1}{t^2}$$

which simplifies to

$$y = \frac{-t\cos(t) + \sin(t) + c_1}{t^2}$$

Summary

The solution(s) found are the following

$$y = \frac{-t\cos(t) + \sin(t) + c_1}{t^2} \tag{1}$$

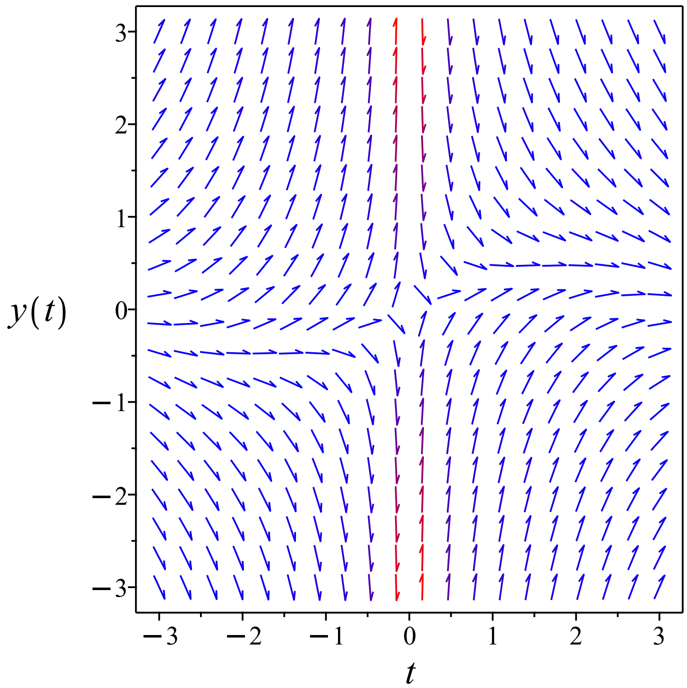

Figure 16: Slope field plot

Verification of solutions

$$y = \frac{-t\cos(t) + \sin(t) + c_1}{t^2}$$

Verified OK.

1.6.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{-2y + \sin(t)}{t}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 16: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(t,y) &= 0 \\ \eta(t,y) &= \frac{1}{t^2} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{t^2}} dy \end{aligned}$$

Which results in

$$S = t^2 y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y) S_y}{R_t + \omega(t,y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = \frac{-2y + \sin(t)}{t}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= 2ty \\ S_y &= t^2 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = t \sin(t) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R \sin(R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -R\cos(R) + \sin(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$yt^2 = -t\cos(t) + \sin(t) + c_1$$

Which simplifies to

$$yt^2 = -t\cos(t) + \sin(t) + c_1$$

Which gives

$$y = \frac{-t\cos(t) + \sin(t) + c_1}{t^2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = \frac{-2y+\sin(t)}{t}$ 	$R = t$ $S = t^2 y$	$\frac{dS}{dR} = R\sin(R)$ 
Summary

The solution(s) found are the following

$$y = \frac{-t\cos(t) + \sin(t) + c_1}{t^2} \tag{1}$$

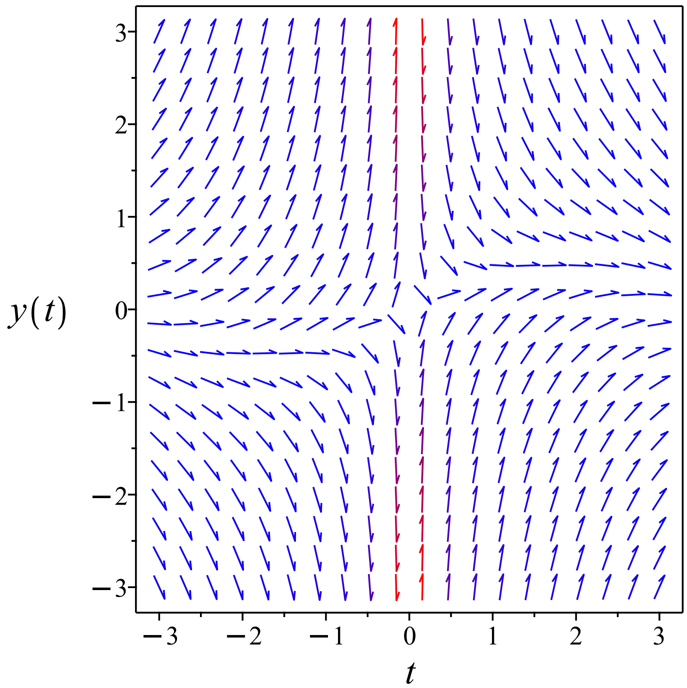

Figure 17: Slope field plot

Verification of solutions

$$y = \frac{-t\cos(t) + \sin(t) + c_1}{t^2}$$

Verified OK.

1.6.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}
(t)\,\mathrm{d}y &= (-2y + \sin(t))\,\mathrm{d}t \\
(2y - \sin(t))\,\mathrm{d}t + (t)\,\mathrm{d}y &= 0 \qquad (2A)
\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(t, y) &= 2y - \sin(t) \\
N(t, y) &= t
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(2y - \sin(t)) \\
&= 2
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(t) \\
&= 1
\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\ &= \frac{1}{t}((2) - (1)) \\ &= \frac{1}{t} \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}t} \\ &= e^{\int \frac{1}{t} \, \mathrm{d}t} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{\ln(t)} \\ &= t \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= t(2y - \sin(t)) \\ &= (2y - \sin(t))\, t \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= t(t) \\ &= t^2 \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N} \frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\ ((2y - \sin(t))\, t) + (t^2) \frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t}\, \mathrm{d}t = \int \overline{M}\, \mathrm{d}t$$
$$\int \frac{\partial \phi}{\partial t}\, \mathrm{d}t = \int (2y - \sin(t))\, t\, \mathrm{d}t$$
$$\phi = t^2 y + t\cos(t) - \sin(t) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = t^2 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = t^2$. Therefore equation (4) becomes

$$t^2 = t^2 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = t^2 y + t\cos(t) - \sin(t) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = t^2 y + t\cos(t) - \sin(t)$$

The solution becomes

$$y = \frac{-t\cos(t) + \sin(t) + c_1}{t^2}$$

Summary

The solution(s) found are the following

$$y = \frac{-t\cos(t) + \sin(t) + c_1}{t^2} \tag{1}$$

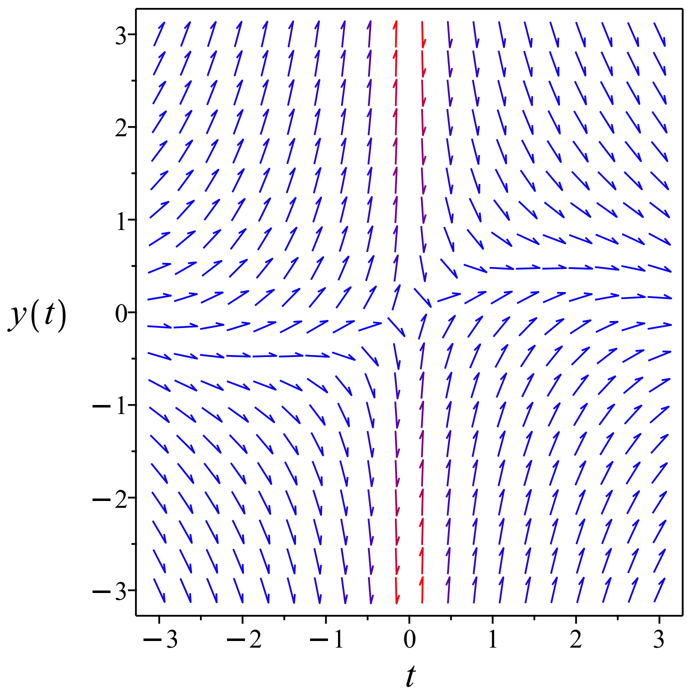

Figure 18: Slope field plot

Verification of solutions

$$y = \frac{-t\cos(t) + \sin(t) + c_1}{t^2}$$

Verified OK.

1.6.4 Maple step by step solution

Let's solve

$2y + ty' = \sin(t)$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{2y}{t} + \frac{\sin(t)}{t}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{2y}{t} = \frac{\sin(t)}{t}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(y' + \frac{2y}{t}\right) = \frac{\mu(t)\sin(t)}{t}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, y)$

  $\mu(t)\left(y' + \frac{2y}{t}\right) = \mu'(t)\, y + \mu(t)\, y'$

- Isolate $\mu'(t)$

  $\mu'(t) = \frac{2\mu(t)}{t}$

- Solve to find the integrating factor

  $\mu(t) = t^2$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\, y)\right) dt = \int \frac{\mu(t)\sin(t)}{t} dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\, y = \int \frac{\mu(t)\sin(t)}{t} dt + c_1$

- Solve for y

  $y = \frac{\int \frac{\mu(t)\sin(t)}{t} dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = t^2$

  $y = \frac{\int t\sin(t) dt + c_1}{t^2}$

- Evaluate the integrals on the rhs

  $y = \frac{-t\cos(t) + \sin(t) + c_1}{t^2}$

Problem number: 7.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_linear]
```

$$\boxed{2yt + y' = 2t\,\mathrm{e}^{-t^2}}$$

1.7.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = 2t$$
$$q(t) = 2t\,\mathrm{e}^{-t^2}$$

Hence the ode is

$$2yt + y' = 2t\,\mathrm{e}^{-t^2}$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int 2t dt} \\
&= e^{t^2}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dt}(\mu y) &= (\mu)\left(2t\,e^{-t^2}\right) \\
\frac{d}{dt}\left(y\,e^{t^2}\right) &= \left(e^{t^2}\right)\left(2t\,e^{-t^2}\right) \\
d\left(y\,e^{t^2}\right) &= (2t)\ dt
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
y\,e^{t^2} &= \int 2t\,dt \\
y\,e^{t^2} &= t^2 + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{t^2}$ results in

$$
y = t^2 e^{-t^2} + c_1 e^{-t^2}
$$

which simplifies to

$$
y = e^{-t^2}\left(t^2 + c_1\right)
$$

Summary

The solution(s) found are the following

$$
y = e^{-t^2}\left(t^2 + c_1\right) \tag{1}
$$

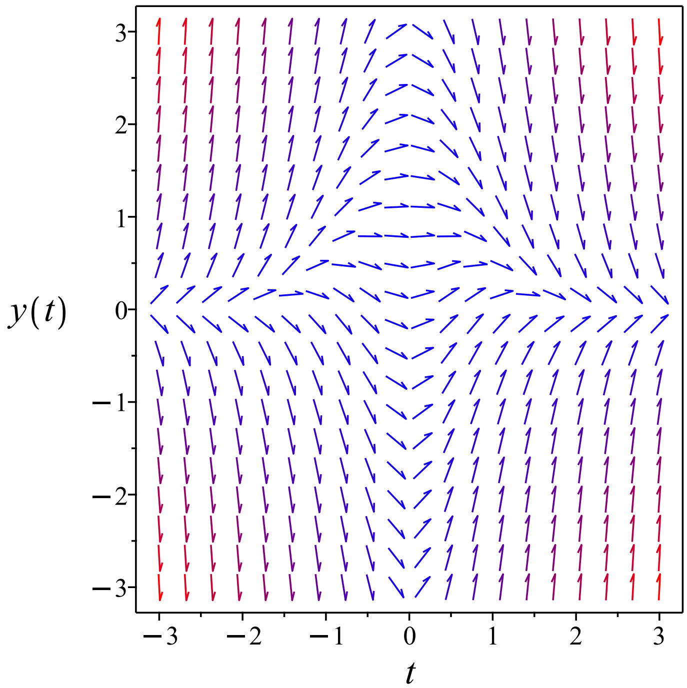

Figure 19: Slope field plot

Verification of solutions

$$y = e^{-t^2}\left(t^2 + c_1\right)$$

1.7.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -2t\left(y\, e^{t^2} - 1\right) e^{-t^2}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 19: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(t, y) &= 0 \\ \eta(t, y) &= \mathrm{e}^{-t^2} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{-t^2}} dy \end{aligned}$$

Which results in

$$S = y\,\mathrm{e}^{t^2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y)S_y}{R_t + \omega(t,y)R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = -2t\left(y\,\mathrm{e}^{t^2} - 1\right)\mathrm{e}^{-t^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= 2ty\,\mathrm{e}^{t^2} \\ S_y &= \mathrm{e}^{t^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 2t \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 2R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = R^2 + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$y\,\mathrm{e}^{t^2} = t^2 + c_1$$

Which simplifies to

$$y\,\mathrm{e}^{t^2} = t^2 + c_1$$

Which gives

$$y = \mathrm{e}^{-t^2}\left(t^2 + c_1\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -2t\left(y\,\mathrm{e}^{t^2} - 1\right)\mathrm{e}^{-t^2}$ 	$R = t$ $S = y\,\mathrm{e}^{t^2}$	$\frac{dS}{dR} = 2R$ 
Summary
The solution(s) found are the following

$$y = \mathrm{e}^{-t^2}\left(t^2 + c_1\right) \tag{1}$$

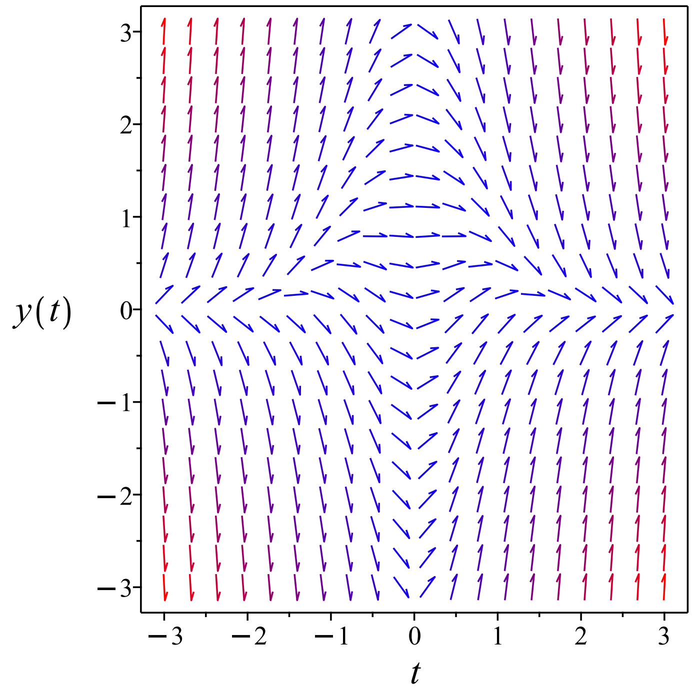

Figure 20: Slope field plot

Verification of solutions

$$y = e^{-t^2}\left(t^2 + c_1\right)$$

1.7.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\mathrm{e}^{t^2}\right)\mathrm{d}y &= \left(-2t\left(y\,\mathrm{e}^{t^2} - 1\right)\right)\mathrm{d}t\\ \left(2t\left(y\,\mathrm{e}^{t^2} - 1\right)\right)\mathrm{d}t + \left(\mathrm{e}^{t^2}\right)\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t, y) &= 2t\left(y\,\mathrm{e}^{t^2} - 1\right)\\ N(t, y) &= \mathrm{e}^{t^2}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(2t\left(y\,\mathrm{e}^{t^2} - 1\right)\right)\\ &= 2t\,\mathrm{e}^{t^2}\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}\left(\mathrm{e}^{t^2}\right)\\ &= 2t\,\mathrm{e}^{t^2}\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. t gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial t}\,\mathrm{d}t &= \int M\,\mathrm{d}t\\ \int \frac{\partial \phi}{\partial t}\,\mathrm{d}t &= \int 2t\left(y\,\mathrm{e}^{t^2} - 1\right)\mathrm{d}t\end{aligned}$$
$$\phi = -t^2 + y\,\mathrm{e}^{t^2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{t^2} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{t^2}$. Therefore equation (4) becomes

$$\mathrm{e}^{t^2} = \mathrm{e}^{t^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -t^2 + y\,\mathrm{e}^{t^2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -t^2 + y\,\mathrm{e}^{t^2}$$

The solution becomes

$$y = \mathrm{e}^{-t^2}\left(t^2 + c_1\right)$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-t^2}\left(t^2 + c_1\right) \tag{1}$$

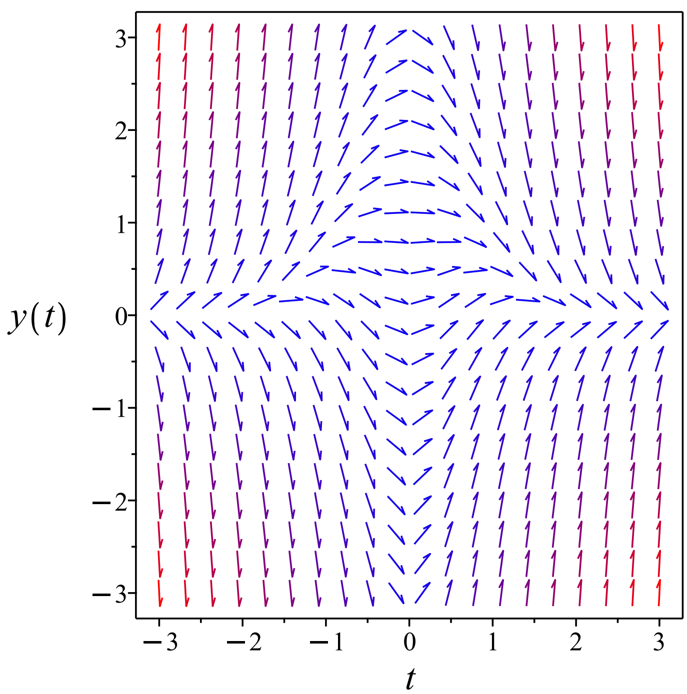

Figure 21: Slope field plot

Verification of solutions

$$y = \mathrm{e}^{-t^2}\left(t^2 + c_1\right)$$

Verified OK.

1.7.4 Maple step by step solution

Let's solve

$2yt + y' = \frac{2t}{e^{t^2}}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -2yt + \frac{2t}{e^{t^2}}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $2yt + y' = \frac{2t}{e^{t^2}}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\,(2yt + y') = \frac{2\mu(t)t}{e^{t^2}}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

  $\mu(t)\,(2yt + y') = \mu'(t)\,y + \mu(t)\,y'$

- Isolate $\mu'(t)$

  $\mu'(t) = 2\mu(t)\,t$

- Solve to find the integrating factor

  $\mu(t) = \left(e^{t^2}\right)^2 e^{-t^2}$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\,y)\right) dt = \int \frac{2\mu(t)t}{e^{t^2}} dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\,y = \int \frac{2\mu(t)t}{e^{t^2}} dt + c_1$

- Solve for y

  $y = \frac{\int \frac{2\mu(t)t}{e^{t^2}} dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = \left(e^{t^2}\right)^2 e^{-t^2}$

  $y = \frac{\int 2t\,e^{-t^2} e^{t^2} dt + c_1}{\left(e^{t^2}\right)^2 e^{-t^2}}$

- Evaluate the integrals on the rhs

$$y = \frac{t^2+c_1}{\left(e^{t^2}\right)^2 e^{-t^2}}$$

- Simplify

$$y = e^{-t^2}(t^2 + c_1)$$

Problem number: 8.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{4yt + \left(t^2+1\right)y' = \frac{1}{\left(t^2+1\right)^2}}$$

1.8.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \frac{4t}{t^2+1}$$
$$q(t) = \frac{1}{\left(t^2+1\right)^3}$$

Hence the ode is

$$y' + \frac{4yt}{t^2+1} = \frac{1}{\left(t^2+1\right)^3}$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int \frac{4t}{t^2+1}dt} \\ &= \left(t^2+1\right)^2\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}(\mu y) &= (\mu)\left(\frac{1}{\left(t^2+1\right)^3}\right) \\ \frac{\mathrm{d}}{\mathrm{d}t}\left(\left(t^2+1\right)^2 y\right) &= \left(\left(t^2+1\right)^2\right)\left(\frac{1}{\left(t^2+1\right)^3}\right) \\ \mathrm{d}\left(\left(t^2+1\right)^2 y\right) &= \frac{1}{t^2+1}\,\mathrm{d}t\end{aligned}$$

Integrating gives

$$\begin{aligned}\left(t^2+1\right)^2 y &= \int \frac{1}{t^2+1}\,\mathrm{d}t \\ \left(t^2+1\right)^2 y &= \arctan(t) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \left(t^2+1\right)^2$ results in

$$y = \frac{\arctan(t)}{\left(t^2+1\right)^2} + \frac{c_1}{\left(t^2+1\right)^2}$$

which simplifies to

$$y = \frac{\arctan(t) + c_1}{\left(t^2+1\right)^2}$$

Summary

The solution(s) found are the following

$$y = \frac{\arctan(t) + c_1}{\left(t^2+1\right)^2} \tag{1}$$

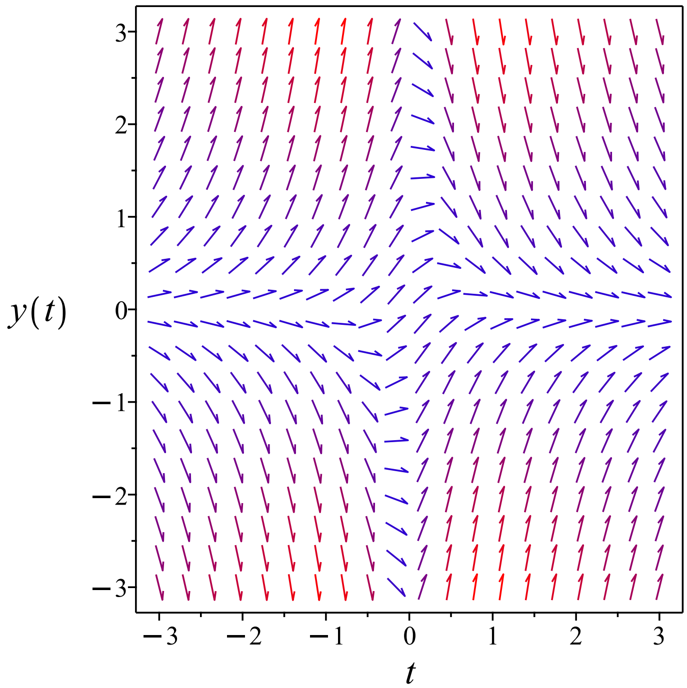

Figure 22: Slope field plot

Verification of solutions

$$y = \frac{\arctan(t) + c_1}{(t^2+1)^2}$$

Verified OK.

1.8.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{4t^5 y + 8t^3 y + 4ty - 1}{(t^2+1)^3}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 22: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \frac{1}{(t^2 + 1)^2}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{(t^2+1)^2}} dy \end{aligned}$$

Which results in

$$S = (t^2 + 1)^2 y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = -\frac{4t^5 y + 8t^3 y + 4ty - 1}{(t^2 + 1)^3}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= 4(t^2 + 1) yt \\ S_y &= (t^2 + 1)^2 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{t^2 + 1} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R^2 + 1}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \arctan(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\left(t^2+1\right)^2 y = \arctan(t) + c_1$$

Which simplifies to

$$\left(t^2+1\right)^2 y = \arctan(t) + c_1$$

Which gives

$$y = \frac{\arctan(t) + c_1}{\left(t^2+1\right)^2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{4t^5y+8t^3y+4ty-1}{(t^2+1)^3}$ 	$R = t$ $S = \left(t^2+1\right)^2 y$	$\frac{dS}{dR} = \frac{1}{R^2+1}$ 
Summary
The solution(s) found are the following

$$y = \frac{\arctan(t) + c_1}{(t^2 + 1)^2} \tag{1}$$

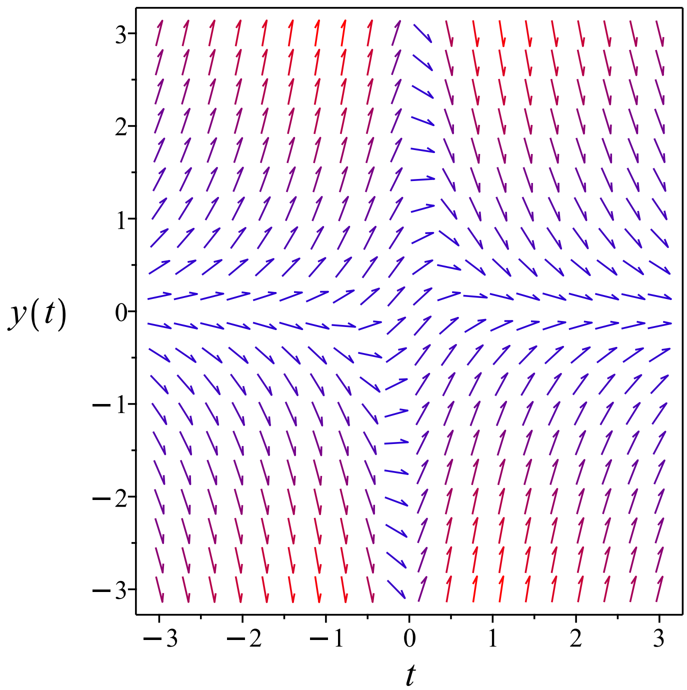

Figure 23: Slope field plot

Verification of solutions

$$y = \frac{\arctan(t) + c_1}{(t^2 + 1)^2}$$

Verified OK.

1.8.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the

ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x}&=M\\ \frac{\partial \phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t+N(t,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(t^2+1)\,\mathrm{d}y&=\left(-4ty+\frac{1}{(t^2+1)^2}\right)\mathrm{d}t\\ \left(4ty-\frac{1}{(t^2+1)^2}\right)\mathrm{d}t+(t^2+1)\,\mathrm{d}y&=0 \qquad \text{(2A)}\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t,y)&=4ty-\frac{1}{(t^2+1)^2}\\ N(t,y)&=t^2+1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial t}$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(4ty - \frac{1}{\left(t^2+1\right)^2}\right) \\
&= 4t
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}\left(t^2+1\right) \\
&= 2t
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\
&= \frac{1}{t^2+1}((4t) - (2t)) \\
&= \frac{2t}{t^2+1}
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}t} \\
&= e^{\int \frac{2t}{t^2+1} \, \mathrm{d}t}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{\ln(t^2+1)} \\
&= t^2+1
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= t^2+1\left(4ty - \frac{1}{\left(t^2+1\right)^2}\right) \\
&= \left(4ty - \frac{1}{\left(t^2+1\right)^2}\right)\left(t^2+1\right)
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= t^2 + 1\left(t^2 + 1\right) \\
&= \left(t^2 + 1\right)^2
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\
\left(\left(4ty - \frac{1}{\left(t^2+1\right)^2}\right)\left(t^2+1\right)\right) + \left(\left(t^2+1\right)^2\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$
\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. t gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial t}\,\mathrm{d}t &= \int \overline{M}\,\mathrm{d}t \\
\int \frac{\partial \phi}{\partial t}\,\mathrm{d}t &= \int \left(4ty - \frac{1}{\left(t^2+1\right)^2}\right)\left(t^2+1\right)\mathrm{d}t
\end{aligned}
$$

$$
\phi = t^4 y + 2t^2 y - \arctan(t) + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = t^4 + 2t^2 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \left(t^2+1\right)^2$. Therefore equation (4) becomes

$$
\left(t^2+1\right)^2 = t^4 + 2t^2 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = 1
$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (1)\,\mathrm{d}y$$
$$f(y) = y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = t^4 y + 2t^2 y - \arctan(t) + y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = t^4 y + 2t^2 y - \arctan(t) + y$$

Summary
The solution(s) found are the following

$$y t^4 + 2y t^2 - \arctan(t) + y = c_1 \tag{1}$$

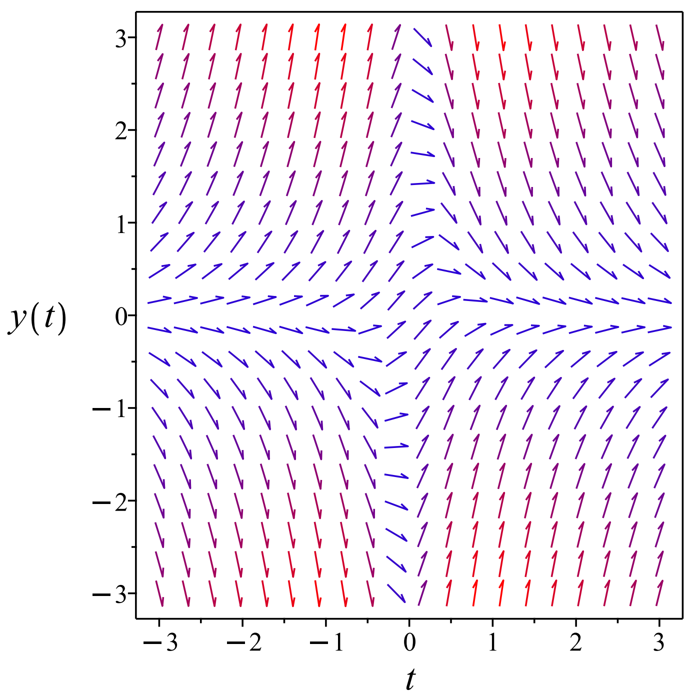

Figure 24: Slope field plot

Verification of solutions

$$yt^4 + 2yt^2 - \arctan(t) + y = c_1$$

Verified OK.

1.8.4 Maple step by step solution

Let's solve

$4yt + (t^2+1)\,y' = \frac{1}{(t^2+1)^2}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{4yt}{t^2+1} + \frac{1}{(t^2+1)^3}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{4yt}{t^2+1} = \frac{1}{(t^2+1)^3}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(y' + \frac{4yt}{t^2+1}\right) = \frac{\mu(t)}{(t^2+1)^3}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

  $\mu(t)\left(y' + \frac{4yt}{t^2+1}\right) = \mu'(t)\,y + \mu(t)\,y'$

- Isolate $\mu'(t)$

  $\mu'(t) = \frac{4\mu(t)t}{t^2+1}$

- Solve to find the integrating factor

  $\mu(t) = (t^2+1)^2$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\,y)\right) dt = \int \frac{\mu(t)}{(t^2+1)^3} dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\,y = \int \frac{\mu(t)}{(t^2+1)^3} dt + c_1$

- Solve for y

  $y = \frac{\int \frac{\mu(t)}{(t^2+1)^3} dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = (t^2+1)^2$

  $y = \frac{\int \frac{1}{t^2+1}dt + c_1}{(t^2+1)^2}$

- Evaluate the integrals on the rhs

  $y = \frac{\arctan(t)+c_1}{(t^2+1)^2}$

Internal file name [`OUTPUT/456_Sunday_June_05_2022_01_41_46_AM_4296471/index.tex`]

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.1. Page 40
Problem number: 9.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y + 2y' = 3t}$$

1.9.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \frac{1}{2}$$
$$q(t) = \frac{3t}{2}$$

Hence the ode is

$$y' + \frac{y}{2} = \frac{3t}{2}$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int \frac{1}{2}dt} \\
&= e^{\frac{t}{2}}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dt}(\mu y) &= (\mu)\left(\frac{3t}{2}\right) \\
\frac{d}{dt}\left(e^{\frac{t}{2}} y\right) &= \left(e^{\frac{t}{2}}\right)\left(\frac{3t}{2}\right) \\
d\left(e^{\frac{t}{2}} y\right) &= \left(\frac{3t\, e^{\frac{t}{2}}}{2}\right) dt
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
e^{\frac{t}{2}} y &= \int \frac{3t\, e^{\frac{t}{2}}}{2}\, dt \\
e^{\frac{t}{2}} y &= 3(t-2)\, e^{\frac{t}{2}} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{\frac{t}{2}}$ results in

$$
y = 3\, e^{-\frac{t}{2}}(t-2)\, e^{\frac{t}{2}} + c_1 e^{-\frac{t}{2}}
$$

which simplifies to

$$
y = 3t - 6 + c_1 e^{-\frac{t}{2}}
$$

Summary

The solution(s) found are the following

$$
y = 3t - 6 + c_1 e^{-\frac{t}{2}} \tag{1}
$$

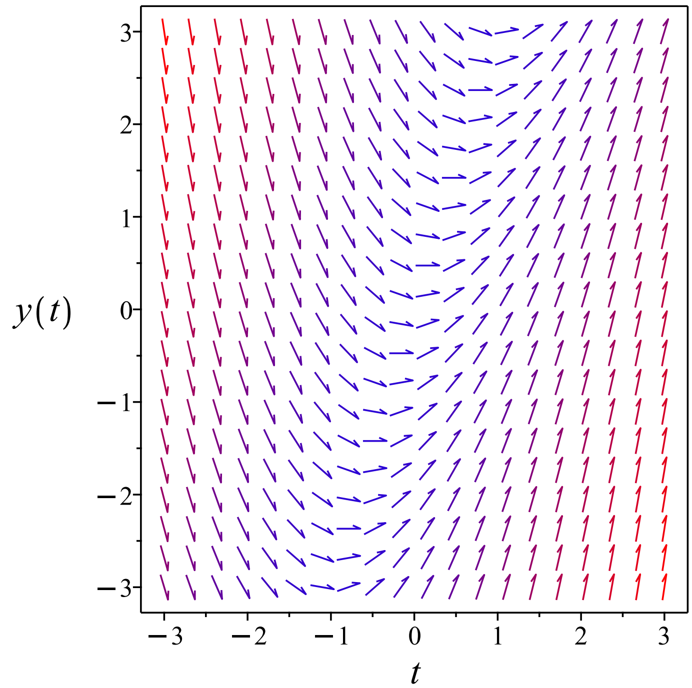

Figure 25: Slope field plot

Verification of solutions

$$y = 3t - 6 + c_1 e^{-\frac{t}{2}}$$

Verified OK.

1.9.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{y}{2} + \frac{3t}{2}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 25: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \mathrm{e}^{-\frac{t}{2}}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{-\frac{t}{2}}} dy \end{aligned}$$

Which results in

$$S = e^{\frac{t}{2}} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = -\frac{y}{2} + \frac{3t}{2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= \frac{e^{\frac{t}{2}} y}{2} \\ S_y &= e^{\frac{t}{2}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{3t\, e^{\frac{t}{2}}}{2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{3R\, e^{\frac{R}{2}}}{2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = 3(R-2)\,\mathrm{e}^{\frac{R}{2}} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\mathrm{e}^{\frac{t}{2}} y = 3(t-2)\,\mathrm{e}^{\frac{t}{2}} + c_1$$

Which simplifies to

$$(-3t + y + 6)\,\mathrm{e}^{\frac{t}{2}} - c_1 = 0$$

Which gives

$$y = \left(3t\,\mathrm{e}^{\frac{t}{2}} - 6\,\mathrm{e}^{\frac{t}{2}} + c_1\right)\mathrm{e}^{-\frac{t}{2}}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{y}{2} + \frac{3t}{2}$ 	$R = t$ $S = \mathrm{e}^{\frac{t}{2}} y$	$\frac{dS}{dR} = \frac{3R\,\mathrm{e}^{\frac{R}{2}}}{2}$ 
Summary

The solution(s) found are the following

$$y = \left(3t\,\mathrm{e}^{\frac{t}{2}} - 6\,\mathrm{e}^{\frac{t}{2}} + c_1\right)\mathrm{e}^{-\frac{t}{2}} \tag{1}$$

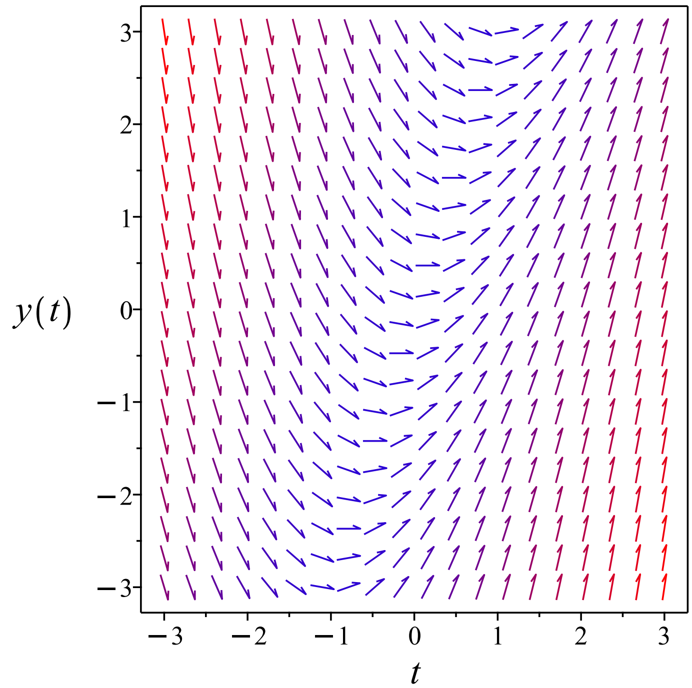

Figure 26: Slope field plot

<u>Verification of solutions</u>

$$y = \left(3t\,e^{\frac{t}{2}} - 6\,e^{\frac{t}{2}} + c_1\right) e^{-\frac{t}{2}}$$

Verified OK.

1.9.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(t, y) \, \mathrm{d}t + N(t, y) \, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
(2) \, \mathrm{d}y &= (-y + 3t) \, \mathrm{d}t \\
(y - 3t) \, \mathrm{d}t + (2) \, \mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(t, y) &= y - 3t \\
N(t, y) &= 2
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(y - 3t) \\
&= 1
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(2) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\ &= \frac{1}{2}((1) - (0)) \\ &= \frac{1}{2} \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}t} \\ &= e^{\int \frac{1}{2} \, \mathrm{d}t} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{\frac{t}{2}} \\ &= \mathrm{e}^{\frac{t}{2}} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{\frac{t}{2}}(y - 3t) \\ &= (y - 3t)\,\mathrm{e}^{\frac{t}{2}} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{\frac{t}{2}}(2) \\ &= 2\,\mathrm{e}^{\frac{t}{2}} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\ \left((y - 3t)\,\mathrm{e}^{\frac{t}{2}}\right) + \left(2\,\mathrm{e}^{\frac{t}{2}}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(t,y)$

$$\frac{\partial\phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\begin{aligned}
\int \frac{\partial\phi}{\partial t}\,\mathrm{d}t &= \int \overline{M}\,\mathrm{d}t \\
\int \frac{\partial\phi}{\partial t}\,\mathrm{d}t &= \int (y-3t)\,\mathrm{e}^{\frac{t}{2}}\,\mathrm{d}t
\end{aligned}$$

$$\phi = (-6t + 2y + 12)\,\mathrm{e}^{\frac{t}{2}} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial\phi}{\partial y} = 2\,\mathrm{e}^{\frac{t}{2}} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = 2\,\mathrm{e}^{\frac{t}{2}}$. Therefore equation (4) becomes

$$2\,\mathrm{e}^{\frac{t}{2}} = 2\,\mathrm{e}^{\frac{t}{2}} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = (-6t + 2y + 12)\,\mathrm{e}^{\frac{t}{2}} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = (-6t + 2y + 12)\,\mathrm{e}^{\frac{t}{2}}$$

The solution becomes

$$y = \frac{\left(6t\,e^{\frac{t}{2}} - 12\,e^{\frac{t}{2}} + c_1\right) e^{-\frac{t}{2}}}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(6t\,e^{\frac{t}{2}} - 12\,e^{\frac{t}{2}} + c_1\right) e^{-\frac{t}{2}}}{2} \tag{1}$$

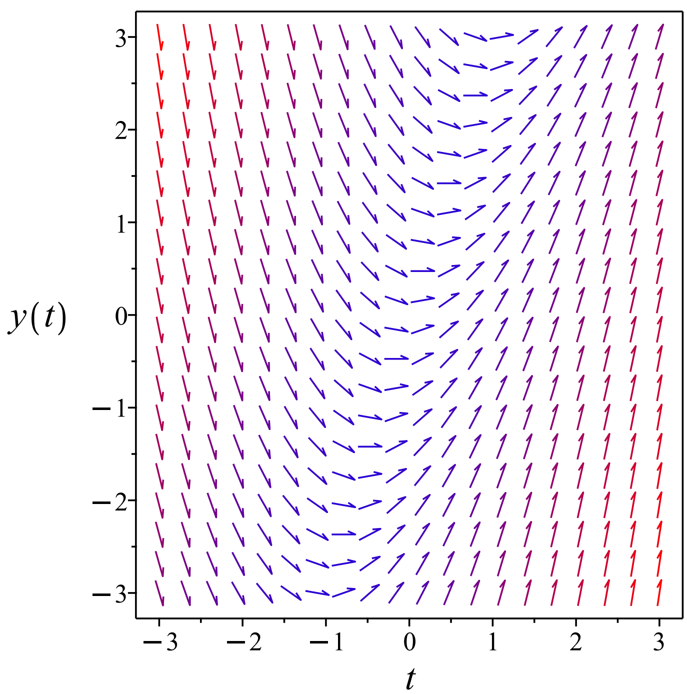

Figure 27: Slope field plot

Verification of solutions

$$y = \frac{\left(6t\,e^{\frac{t}{2}} - 12\,e^{\frac{t}{2}} + c_1\right) e^{-\frac{t}{2}}}{2}$$

Verified OK.

1.9.4 Maple step by step solution

Let's solve

$y + 2y' = 3t$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{y}{2} + \frac{3t}{2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{y}{2} = \frac{3t}{2}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(y' + \frac{y}{2}\right) = \frac{3\mu(t)t}{2}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

  $\mu(t)\left(y' + \frac{y}{2}\right) = \mu'(t)\,y + \mu(t)\,y'$

- Isolate $\mu'(t)$

  $\mu'(t) = \frac{\mu(t)}{2}$

- Solve to find the integrating factor

  $\mu(t) = \mathrm{e}^{\frac{t}{2}}$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\,y)\right) dt = \int \frac{3\mu(t)t}{2} dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\,y = \int \frac{3\mu(t)t}{2} dt + c_1$

- Solve for y

  $y = \frac{\int \frac{3\mu(t)t}{2} dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = \mathrm{e}^{\frac{t}{2}}$

  $y = \frac{\int \frac{3t\,\mathrm{e}^{\frac{t}{2}}}{2} dt + c_1}{\mathrm{e}^{\frac{t}{2}}}$

- Evaluate the integrals on the rhs

  $y = \frac{3(t-2)\mathrm{e}^{\frac{t}{2}} + c_1}{\mathrm{e}^{\frac{t}{2}}}$

- Simplify

$$y = 3t - 6 + c_1 e^{-\frac{t}{2}}$$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "homogeneousTypeD2", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{ty' - y = t^2 e^{-t}}$$

1.10.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = -\frac{1}{t}$$
$$q(t) = t\,e^{-t}$$

Hence the ode is

$$y' - \frac{y}{t} = t\,e^{-t}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{1}{t}dt} \\ &= \frac{1}{t}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dt}(\mu y) &= (\mu)\left(t\,e^{-t}\right) \\ \frac{d}{dt}\left(\frac{y}{t}\right) &= \left(\frac{1}{t}\right)\left(t\,e^{-t}\right) \\ d\left(\frac{y}{t}\right) &= e^{-t}\,dt\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{y}{t} &= \int e^{-t}\,dt \\ \frac{y}{t} &= -e^{-t} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{t}$ results in

$$y = -t\,e^{-t} + c_1 t$$

which simplifies to

$$y = t\left(-e^{-t} + c_1\right)$$

Summary

The solution(s) found are the following

$$y = t\left(-e^{-t} + c_1\right) \tag{1}$$

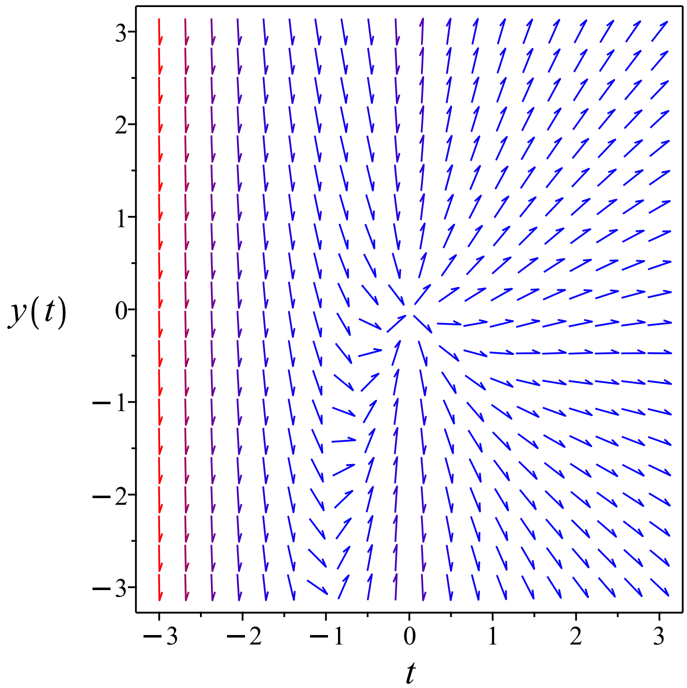

Figure 28: Slope field plot

Verification of solutions

$$y = t\left(-e^{-t} + c_1\right)$$

Verified OK.

1.10.2 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(t)\, t$ on the above ode results in new ode in $u(t)$

$$t(u'(t)\, t + u(t)) - u(t)\, t = t^2 e^{-t}$$

Integrating both sides gives

$$\begin{aligned} u(t) &= \int e^{-t}\, dt \\ &= -e^{-t} + c_2 \end{aligned}$$

Therefore the solution y is

$$\begin{aligned} y &= ut \\ &= t\left(-e^{-t} + c_2\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = t\left(-\mathrm{e}^{-t} + c_2\right) \tag{1}$$

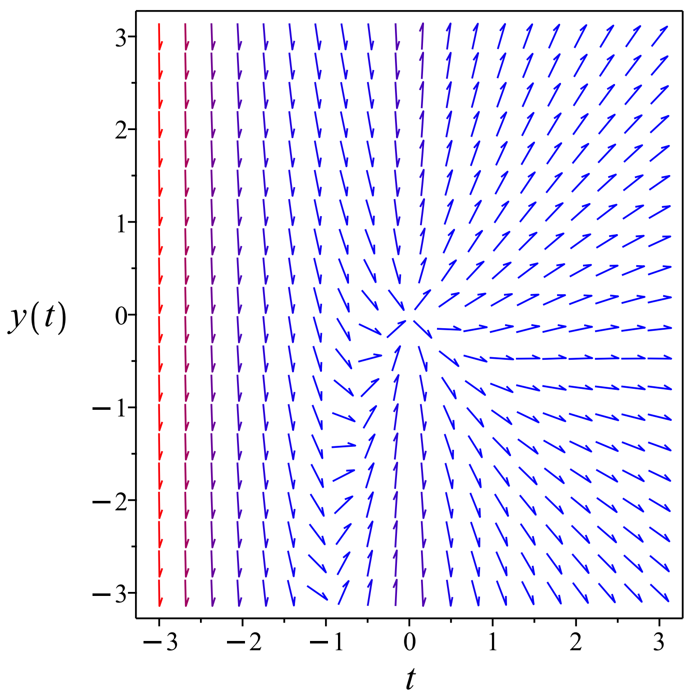

Figure 29: Slope field plot

Verification of solutions

$$y = t\left(-\mathrm{e}^{-t} + c_2\right)$$

Verified OK.

1.10.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{(y\,\mathrm{e}^{t} + t^2)\,\mathrm{e}^{-t}}{t}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 28: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x) dx - h(x)}}{g(x)}$	$\frac{f(x) e^{-\int b f(x) dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= t
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{t} dy \end{aligned}$$

Which results in

$$S = \frac{y}{t}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = \frac{(y\,\mathrm{e}^t + t^2)\,\mathrm{e}^{-t}}{t}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= -\frac{y}{t^2} \\ S_y &= \frac{1}{t} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \mathrm{e}^{-t} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \mathrm{e}^{-R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\mathrm{e}^{-R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\frac{y}{t} = -\mathrm{e}^{-t} + c_1$$

Which simplifies to

$$\frac{y}{t} = -\mathrm{e}^{-t} + c_1$$

Which gives

$$y = -t(\mathrm{e}^{-t} - c_1)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = \frac{(y\,\mathrm{e}^{t}+t^2)\mathrm{e}^{-t}}{t}$ 	$R = t$ $S = \frac{y}{t}$	$\frac{dS}{dR} = \mathrm{e}^{-R}$ 
Summary
The solution(s) found are the following

$$y = -t(\mathrm{e}^{-t} - c_1) \tag{1}$$

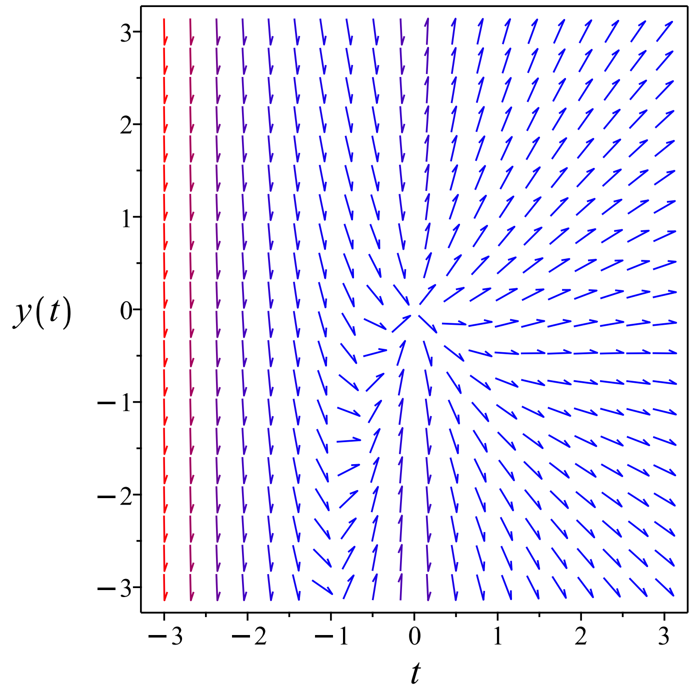

Figure 30: Slope field plot

Verification of solutions

$$
y = -t\left(e^{-t} - c_1\right)
$$

1.10.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$
M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}
$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$
\frac{d}{dx}\phi(x, y) = 0
$$

Hence

$$
\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}
$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(t)\,\mathrm{d}y &= \left(t^2 \mathrm{e}^{-t} + y\right) \mathrm{d}t\\ \left(-t^2 \mathrm{e}^{-t} - y\right) \mathrm{d}t + (t)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t, y) &= -t^2 \mathrm{e}^{-t} - y\\ N(t, y) &= t\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-t^2 \mathrm{e}^{-t} - y\right)\\ &= -1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(t)\\ &= 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\
&= \frac{1}{t}((-1) - (1)) \\
&= -\frac{2}{t}
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}t} \\
&= e^{\int -\frac{2}{t} \, \mathrm{d}t}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-2\ln(t)} \\
&= \frac{1}{t^2}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \frac{1}{t^2}\left(-t^2 \mathrm{e}^{-t} - y\right) \\
&= \frac{-t^2 \mathrm{e}^{-t} - y}{t^2}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{t^2}(t) \\
&= \frac{1}{t}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\
\left(\frac{-t^2 \mathrm{e}^{-t} - y}{t^2}\right) + \left(\frac{1}{t}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(t,y)$

$$\frac{\partial\phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial\phi}{\partial t}\, \mathrm{d}t = \int \overline{M}\, \mathrm{d}t$$

$$\int \frac{\partial\phi}{\partial t}\, \mathrm{d}t = \int \frac{-t^2 \mathrm{e}^{-t} - y}{t^2}\, \mathrm{d}t$$

$$\phi = \frac{t\,\mathrm{e}^{-t} + y}{t} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial\phi}{\partial y} = \frac{1}{t} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = \frac{1}{t}$. Therefore equation (4) becomes

$$\frac{1}{t} = \frac{1}{t} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{t\,\mathrm{e}^{-t} + y}{t} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{t\,\mathrm{e}^{-t} + y}{t}$$

The solution becomes

$$y = -t\left(\mathrm{e}^{-t} - c_1\right)$$

Summary

The solution(s) found are the following

$$y = -t\left(\mathrm{e}^{-t} - c_1\right) \tag{1}$$

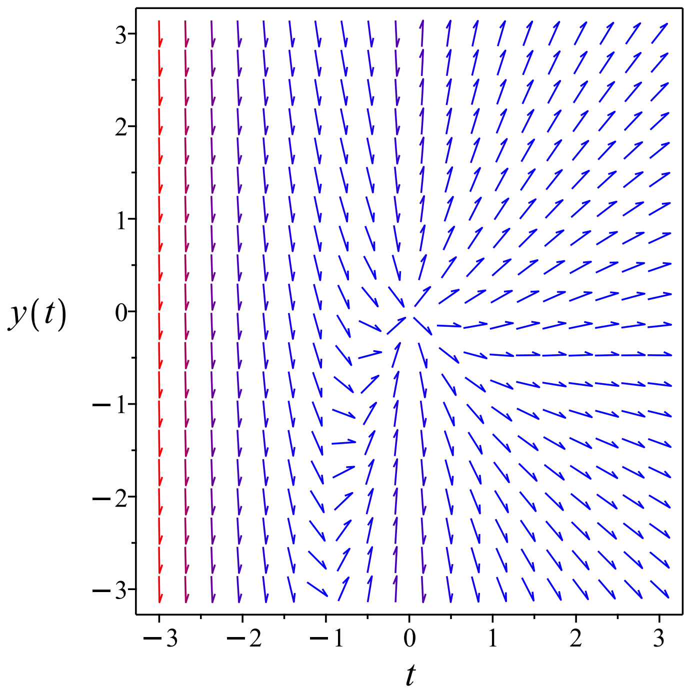

Figure 31: Slope field plot

Verification of solutions

$$y = -t\left(\mathrm{e}^{-t} - c_1\right)$$

Verified OK.

1.10.5 Maple step by step solution

Let's solve

$ty' - y = \frac{t^2}{e^t}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \frac{y}{t} + \frac{t}{e^t}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - \frac{y}{t} = \frac{t}{e^t}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(y' - \frac{y}{t}\right) = \frac{\mu(t)t}{e^t}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

  $\mu(t)\left(y' - \frac{y}{t}\right) = \mu'(t)\,y + \mu(t)\,y'$

- Isolate $\mu'(t)$

  $\mu'(t) = -\frac{\mu(t)}{t}$

- Solve to find the integrating factor

  $\mu(t) = \frac{e^{-t}e^t}{t}$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\,y)\right) dt = \int \frac{\mu(t)t}{e^t} dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\,y = \int \frac{\mu(t)t}{e^t} dt + c_1$

- Solve for y

  $y = \frac{\int \frac{\mu(t)t}{e^t} dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = \frac{e^{-t}e^t}{t}$

  $y = \frac{t\left(\int e^{-t} dt + c_1\right)}{e^{-t}e^t}$

- Evaluate the integrals on the rhs

  $y = \frac{t\left(-e^{-t} + c_1\right)}{e^{-t}e^t}$

- Simplify

$$y = t(-e^{-t} + c_1)$$

Problem number: 11.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y + y' = 5\sin(2t)}$$

1.11.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = 1$$
$$q(t) = 5\sin(2t)$$

Hence the ode is

$$y + y' = 5\sin(2t)$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int 1dt} \\ &= \mathrm{e}^{t}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}(\mu y) &= (\mu)\,(5\sin(2t)) \\ \frac{\mathrm{d}}{\mathrm{d}t}\left(y\,\mathrm{e}^{t}\right) &= \left(\mathrm{e}^{t}\right)(5\sin(2t)) \\ \mathrm{d}\left(y\,\mathrm{e}^{t}\right) &= \left(5\,\mathrm{e}^{t}\sin(2t)\right)\,\mathrm{d}t\end{aligned}$$

Integrating gives

$$\begin{aligned}y\,\mathrm{e}^{t} &= \int 5\,\mathrm{e}^{t}\sin(2t)\,\mathrm{d}t \\ y\,\mathrm{e}^{t} &= -2\,\mathrm{e}^{t}\cos(2t) + \mathrm{e}^{t}\sin(2t) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{t}$ results in

$$y = \mathrm{e}^{-t}\left(-2\,\mathrm{e}^{t}\cos(2t) + \mathrm{e}^{t}\sin(2t)\right) + c_1\mathrm{e}^{-t}$$

which simplifies to

$$y = \sin(2t) - 2\cos(2t) + c_1\mathrm{e}^{-t}$$

Summary

The solution(s) found are the following

$$y = \sin(2t) - 2\cos(2t) + c_1\mathrm{e}^{-t} \tag{1}$$

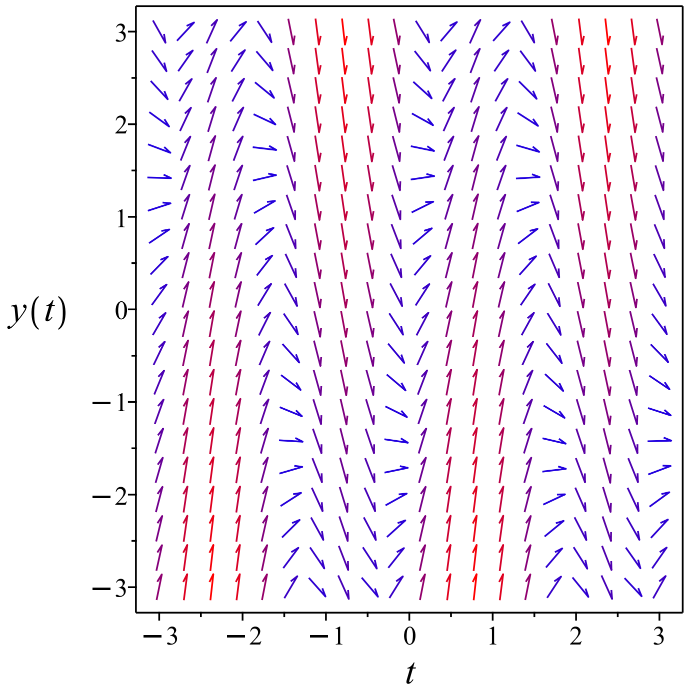

Figure 32: Slope field plot

Verification of solutions

$$y = \sin(2t) - 2\cos(2t) + c_1 e^{-t}$$

Verified OK.

1.11.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -y + 5\sin(2t)$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 31: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(t, y) &= 0 \\ \eta(t, y) &= e^{-t} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{-t}} dy \end{aligned}$$

Which results in

$$S = y\,e^{t}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = -y + 5\sin(2t)$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= y\,e^{t} \\ S_y &= e^{t} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 5\,e^{t}\sin(2t) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 5\,e^{R}\sin(2R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 - e^R(2\cos(2R) - \sin(2R)) \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$y\,e^t = c_1 - e^t(2\cos(2t) - \sin(2t))$$

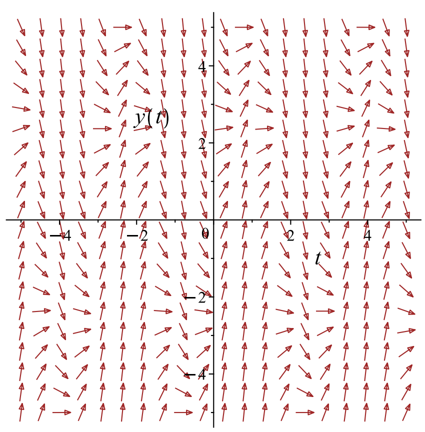
Which simplifies to

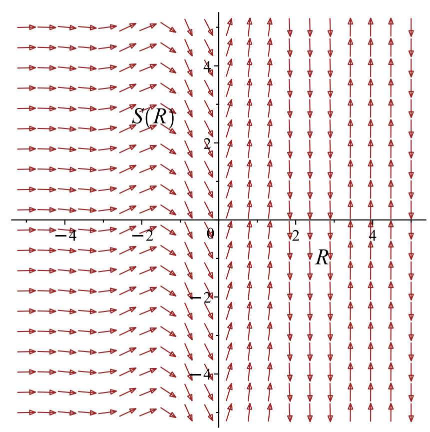
$$y\,e^t = c_1 - e^t(2\cos(2t) - \sin(2t))$$

Which gives

$$y = e^{-t}\left(e^t \sin(2t) - 2\,e^t \cos(2t) + c_1\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in t, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>
<tr><td>$\frac{dy}{dt} = -y + 5\sin(2t)$


</td><td>$R = t$
$S = y\,e^t$</td><td>$\frac{dS}{dR} = 5\,e^R \sin(2R)$


</td></tr>
</table>

Summary
The solution(s) found are the following

$$y = e^{-t}\left(e^t \sin(2t) - 2\,e^t \cos(2t) + c_1\right) \tag{1}$$

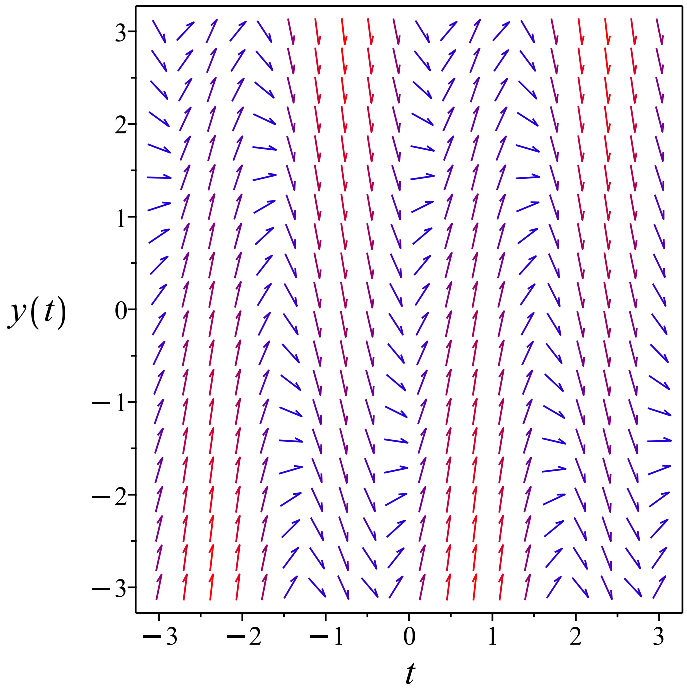


Figure 33: Slope field plot

Verification of solutions

$$y = e^{-t}\left(e^t \sin(2t) - 2\,e^t \cos(2t) + c_1\right)$$

Verified OK.

1.11.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\mathrm{d}y &= (-y + 5\sin(2t))\,\mathrm{d}t \\ (y - 5\sin(2t))\,\mathrm{d}t + \mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t, y) &= y - 5\sin(2t) \\ N(t, y) &= 1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(y - 5\sin(2t)) \\ &= 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(1) \\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\ &= 1((1) - (0)) \\ &= 1 \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}t} \\ &= e^{\int 1 \, \mathrm{d}t} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{t} \\ &= \mathrm{e}^{t} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{t}(y - 5\sin(2t)) \\ &= (y - 5\sin(2t))\,\mathrm{e}^{t} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{t}(1) \\ &= \mathrm{e}^{t} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\ \left((y - 5\sin(2t))\,\mathrm{e}^{t}\right) + \left(\mathrm{e}^{t}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int \overline{M} \, \mathrm{d}t$$

$$\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int (y - 5\sin(2t)) \, \mathrm{e}^{t} \, \mathrm{d}t$$

$$\phi = \mathrm{e}^{t}(y + 2\cos(2t) - \sin(2t)) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{t} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{t}$. Therefore equation (4) becomes

$$\mathrm{e}^{t} = \mathrm{e}^{t} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \mathrm{e}^{t}(y + 2\cos(2t) - \sin(2t)) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \mathrm{e}^{t}(y + 2\cos(2t) - \sin(2t))$$

The solution becomes

$$y = \mathrm{e}^{-t}\left(\mathrm{e}^{t}\sin(2t) - 2\,\mathrm{e}^{t}\cos(2t) + c_1\right)$$

Summary
The solution(s) found are the following

$$y = e^{-t}\left(e^{t} \sin(2t) - 2 e^{t} \cos(2t) + c_1\right) \tag{1}$$

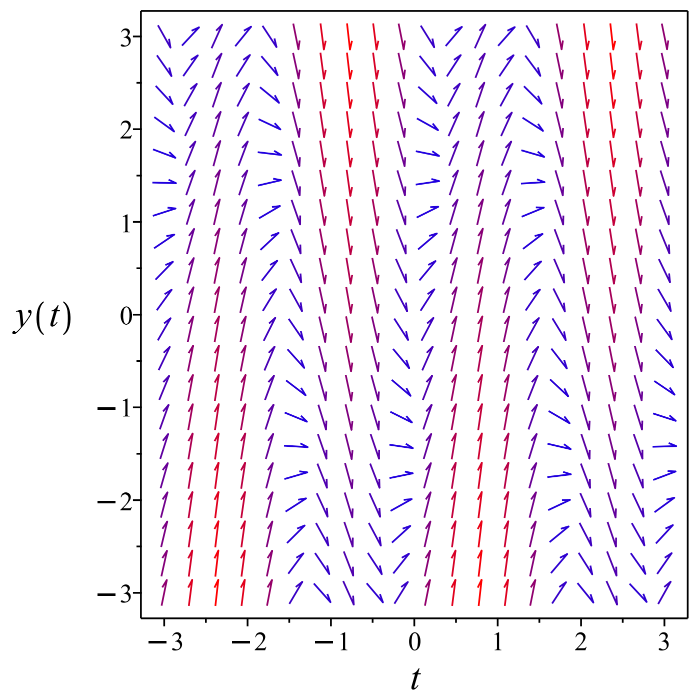

Figure 34: Slope field plot

Verification of solutions

$$y = e^{-t}\left(e^{t} \sin(2t) - 2 e^{t} \cos(2t) + c_1\right)$$

Verified OK.

1.11.4 Maple step by step solution

Let's solve

$y + y' = 5\sin(2t)$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -y + 5\sin(2t)$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y + y' = 5 \sin(2t)$
- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)(y + y') = 5\mu(t) \sin(2t)$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t) y)$

  $\mu(t)(y + y') = \mu'(t) y + \mu(t) y'$
- Isolate $\mu'(t)$

  $\mu'(t) = \mu(t)$
- Solve to find the integrating factor

  $\mu(t) = \mathrm{e}^{t}$
- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t) y)\right) dt = \int 5\mu(t) \sin(2t) dt + c_1$
- Evaluate the integral on the lhs

  $\mu(t) y = \int 5\mu(t) \sin(2t) dt + c_1$
- Solve for y

  $y = \frac{\int 5\mu(t) \sin(2t)dt + c_1}{\mu(t)}$
- Substitute $\mu(t) = \mathrm{e}^{t}$

  $y = \frac{\int 5\,\mathrm{e}^{t} \sin(2t)dt + c_1}{\mathrm{e}^{t}}$
- Evaluate the integrals on the rhs

  $y = \frac{\mathrm{e}^{t} \sin(2t) - 2\,\mathrm{e}^{t} \cos(2t) + c_1}{\mathrm{e}^{t}}$
- Simplify

  $y = \sin(2t) - 2\cos(2t) + c_1 \mathrm{e}^{-t}$

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.1. Page 40
Problem number: 12.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y + 2y' = 3t^2}$$

1.12.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \frac{1}{2}$$
$$q(t) = \frac{3t^2}{2}$$

Hence the ode is

$$y' + \frac{y}{2} = \frac{3t^2}{2}$$

The integrating factor μ is

$$\mu = e^{\int \frac{1}{2}dt}$$
$$= e^{\frac{t}{2}}$$

The ode becomes

$$\frac{d}{dt}(\mu y) = (\mu)\left(\frac{3t^2}{2}\right)$$
$$\frac{d}{dt}\left(e^{\frac{t}{2}}y\right) = \left(e^{\frac{t}{2}}\right)\left(\frac{3t^2}{2}\right)$$
$$d\left(e^{\frac{t}{2}}y\right) = \left(\frac{3t^2e^{\frac{t}{2}}}{2}\right) dt$$

Integrating gives

$$e^{\frac{t}{2}}y = \int \frac{3t^2e^{\frac{t}{2}}}{2} dt$$
$$e^{\frac{t}{2}}y = 3(t^2 - 4t + 8) e^{\frac{t}{2}} + c_1$$

Dividing both sides by the integrating factor $\mu = e^{\frac{t}{2}}$ results in

$$y = 3 e^{-\frac{t}{2}}(t^2 - 4t + 8) e^{\frac{t}{2}} + c_1e^{-\frac{t}{2}}$$

which simplifies to

$$y = 3t^2 - 12t + 24 + c_1e^{-\frac{t}{2}}$$

Summary

The solution(s) found are the following

$$y = 3t^2 - 12t + 24 + c_1e^{-\frac{t}{2}} \tag{1}$$

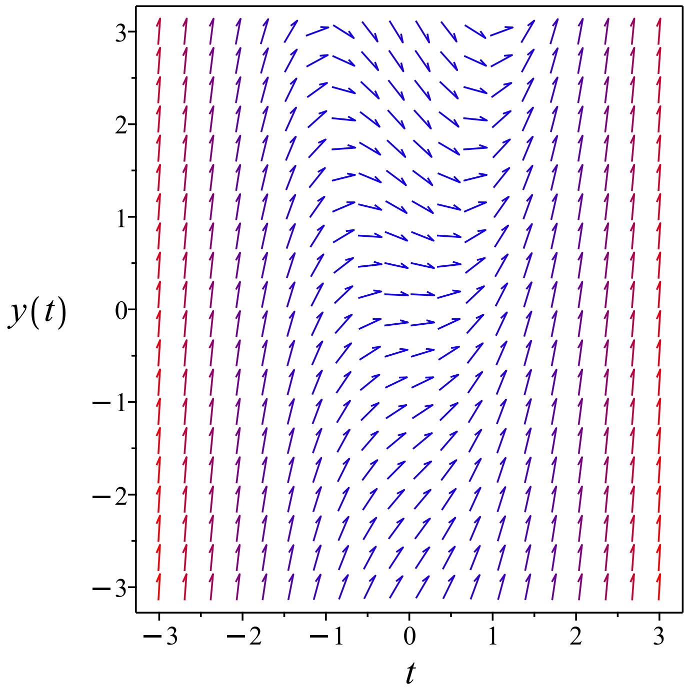

Figure 35: Slope field plot

Verification of solutions

$$y = 3t^2 - 12t + 24 + c_1 e^{-\frac{t}{2}}$$

Verified OK.

1.12.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{y}{2} + \frac{3t^2}{2}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 34: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \mathrm{e}^{-\frac{t}{2}}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{-\frac{t}{2}}} dy \end{aligned}$$

Which results in

$$S = e^{\frac{t}{2}} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = -\frac{y}{2} + \frac{3t^2}{2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= \frac{e^{\frac{t}{2}} y}{2} \\ S_y &= e^{\frac{t}{2}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{3t^2 e^{\frac{t}{2}}}{2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{3R^2 e^{\frac{R}{2}}}{2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = 3\left(R^2 - 4R + 8\right) e^{\frac{R}{2}} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$e^{\frac{t}{2}} y = 3\left(t^2 - 4t + 8\right) e^{\frac{t}{2}} + c_1$$

Which simplifies to

$$\left(-3t^2 + 12t + y - 24\right) e^{\frac{t}{2}} - c_1 = 0$$

Which gives

$$y = \left(3t^2 e^{\frac{t}{2}} - 12t\, e^{\frac{t}{2}} + 24\, e^{\frac{t}{2}} + c_1\right) e^{-\frac{t}{2}}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{y}{2} + \frac{3t^2}{2}$ 	$R = t$ $S = e^{\frac{t}{2}} y$	$\frac{dS}{dR} = \frac{3R^2 e^{\frac{R}{2}}}{2}$ 
Summary

The solution(s) found are the following

$$y = \left(3t^2 e^{\frac{t}{2}} - 12t\, e^{\frac{t}{2}} + 24\, e^{\frac{t}{2}} + c_1\right) e^{-\frac{t}{2}} \tag{1}$$

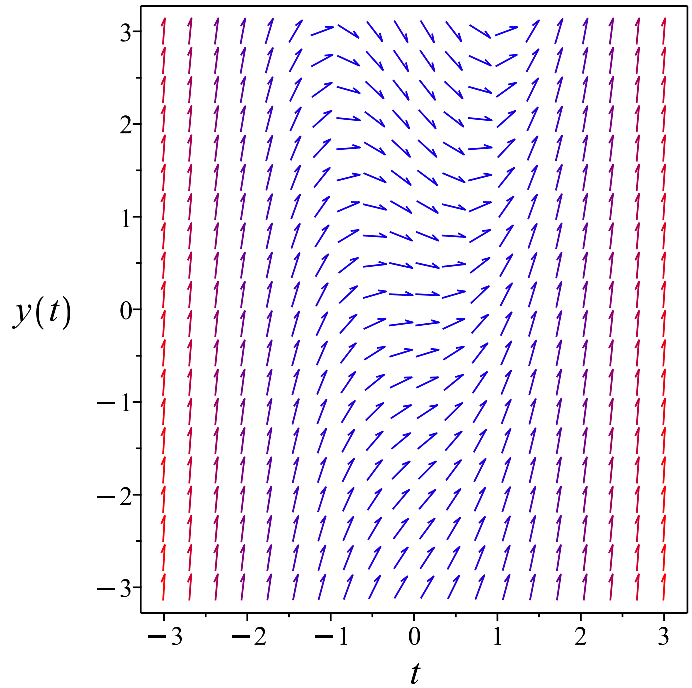

Figure 36: Slope field plot

Verification of solutions

$$y = \left(3t^2 e^{\frac{t}{2}} - 12t\, e^{\frac{t}{2}} + 24\, e^{\frac{t}{2}} + c_1\right) e^{-\frac{t}{2}}$$

Verified OK.

1.12.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\,\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(t, y) \,\mathrm{d}t + N(t, y) \,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
(2) \,\mathrm{d}y &= \left(3t^2 - y\right) \mathrm{d}t \\
\left(-3t^2 + y\right) \mathrm{d}t + (2) \,\mathrm{d}y &= 0
\end{aligned} \tag{2A}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(t, y) &= -3t^2 + y \\
N(t, y) &= 2
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-3t^2 + y\right) \\
&= 1
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(2) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\ &= \frac{1}{2}((1) - (0)) \\ &= \frac{1}{2} \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}t} \\ &= e^{\int \frac{1}{2} \, \mathrm{d}t} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{\frac{t}{2}} \\ &= \mathrm{e}^{\frac{t}{2}} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{\frac{t}{2}}\left(-3t^2 + y\right) \\ &= \left(-3t^2 + y\right)\mathrm{e}^{\frac{t}{2}} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{\frac{t}{2}}(2) \\ &= 2\,\mathrm{e}^{\frac{t}{2}} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\ \left(\left(-3t^2 + y\right)\mathrm{e}^{\frac{t}{2}}\right) + \left(2\,\mathrm{e}^{\frac{t}{2}}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(t,y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \mathrm{d}t = \int \overline{M} \mathrm{d}t$$

$$\int \frac{\partial \phi}{\partial t} \mathrm{d}t = \int \left(-3t^2 + y\right) \mathrm{e}^{\frac{t}{2}} \mathrm{d}t$$

$$\phi = -6\left(t^2 - 4t - \frac{1}{3}y + 8\right) \mathrm{e}^{\frac{t}{2}} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2\,\mathrm{e}^{\frac{t}{2}} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2\,\mathrm{e}^{\frac{t}{2}}$. Therefore equation (4) becomes

$$2\,\mathrm{e}^{\frac{t}{2}} = 2\,\mathrm{e}^{\frac{t}{2}} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -6\left(t^2 - 4t - \frac{1}{3}y + 8\right) \mathrm{e}^{\frac{t}{2}} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -6\left(t^2 - 4t - \frac{1}{3}y + 8\right) \mathrm{e}^{\frac{t}{2}}$$

The solution becomes

$$y = \frac{\left(6t^2 e^{\frac{t}{2}} - 24t\, e^{\frac{t}{2}} + 48\, e^{\frac{t}{2}} + c_1\right) e^{-\frac{t}{2}}}{2}$$

Summary
The solution(s) found are the following

$$y = \frac{\left(6t^2 e^{\frac{t}{2}} - 24t\, e^{\frac{t}{2}} + 48\, e^{\frac{t}{2}} + c_1\right) e^{-\frac{t}{2}}}{2} \tag{1}$$

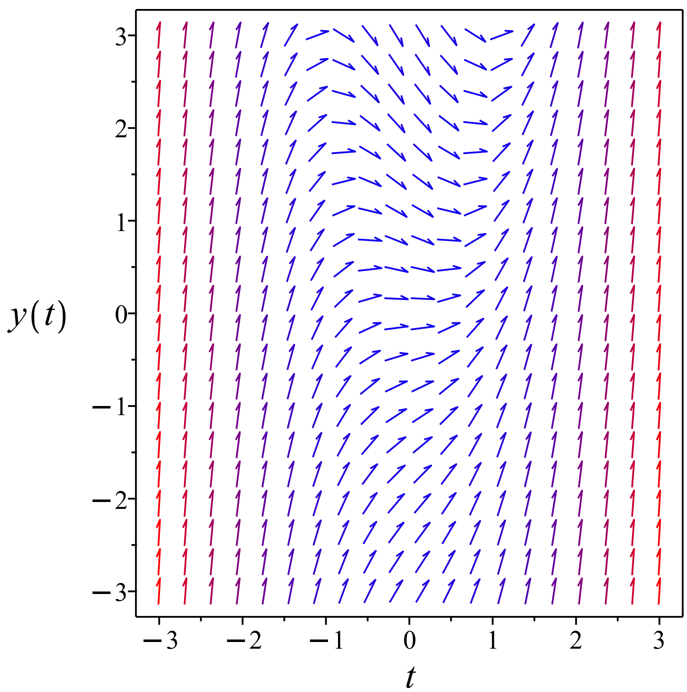

Figure 37: Slope field plot

Verification of solutions

$$y = \frac{\left(6t^2 e^{\frac{t}{2}} - 24t\, e^{\frac{t}{2}} + 48\, e^{\frac{t}{2}} + c_1\right) e^{-\frac{t}{2}}}{2}$$

Verified OK.

1.12.4 Maple step by step solution

Let's solve

$y + 2y' = 3t^2$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{y}{2} + \frac{3t^2}{2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{y}{2} = \frac{3t^2}{2}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(y' + \frac{y}{2}\right) = \frac{3\mu(t)t^2}{2}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

  $\mu(t)\left(y' + \frac{y}{2}\right) = \mu'(t)\,y + \mu(t)\,y'$

- Isolate $\mu'(t)$

  $\mu'(t) = \frac{\mu(t)}{2}$

- Solve to find the integrating factor

  $\mu(t) = e^{\frac{t}{2}}$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\,y)\right) dt = \int \frac{3\mu(t)t^2}{2} dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\,y = \int \frac{3\mu(t)t^2}{2} dt + c_1$

- Solve for y

  $y = \frac{\int \frac{3\mu(t)t^2}{2} dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = e^{\frac{t}{2}}$

  $y = \frac{\int \frac{3t^2 e^{\frac{t}{2}}}{2} dt + c_1}{e^{\frac{t}{2}}}$

- Evaluate the integrals on the rhs

  $y = \frac{3(t^2-4t+8)e^{\frac{t}{2}} + c_1}{e^{\frac{t}{2}}}$

- Simplify

  $y = 3t^2 - 12t + 24 + c_1 e^{-\frac{t}{2}}$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{-y + y' = 2\,\mathrm{e}^{2t}t}$$

With initial conditions

$$[y(0) = 1]$$

1.13.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = -1$$
$$q(t) = 2\,\mathrm{e}^{2t}t$$

Hence the ode is

$$-y + y' = 2\,\mathrm{e}^{2t} t$$

The domain of $p(t) = -1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = 2\,\mathrm{e}^{2t} t$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

1.13.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int (-1) dt} \\ &= \mathrm{e}^{-t}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}(\mu y) &= (\mu)\left(2\,\mathrm{e}^{2t} t\right) \\ \frac{\mathrm{d}}{\mathrm{d}t}\left(\mathrm{e}^{-t} y\right) &= \left(\mathrm{e}^{-t}\right)\left(2\,\mathrm{e}^{2t} t\right) \\ \mathrm{d}\left(\mathrm{e}^{-t} y\right) &= \left(2t\,\mathrm{e}^{t}\right)\,\mathrm{d}t\end{aligned}$$

Integrating gives

$$\begin{aligned}\mathrm{e}^{-t} y &= \int 2t\,\mathrm{e}^{t}\,\mathrm{d}t \\ \mathrm{e}^{-t} y &= 2\,\mathrm{e}^{t}(-1 + t) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-t}$ results in

$$y = 2\,\mathrm{e}^{2t}(-1 + t) + c_1 \mathrm{e}^{t}$$

Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_1 - 2$$

$$c_1 = 3$$

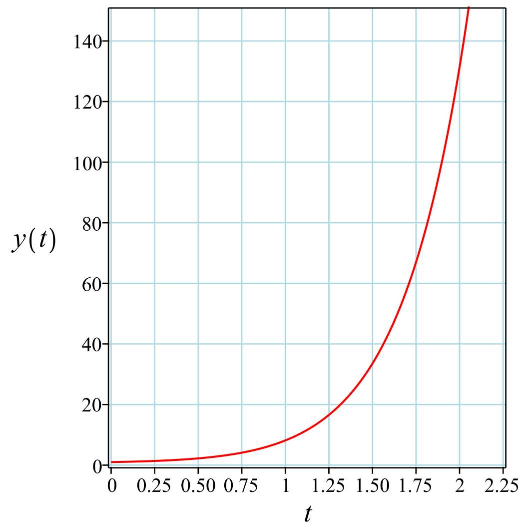
Substituting c_1 found above in the general solution gives

$$y = 2\,\mathrm{e}^{2t}t - 2\,\mathrm{e}^{2t} + 3\,\mathrm{e}^{t}$$

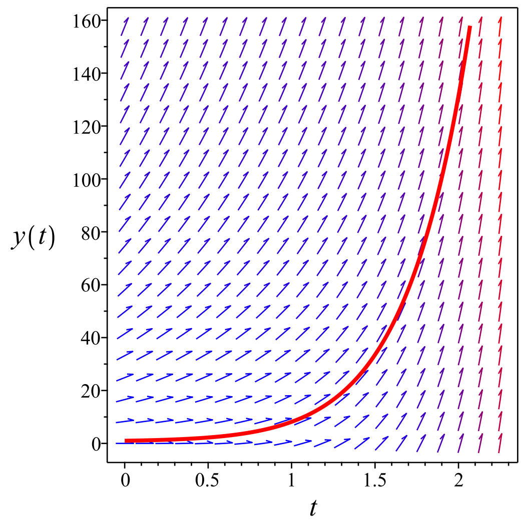
Summary

The solution(s) found are the following

$$y = 2\,\mathrm{e}^{2t}t - 2\,\mathrm{e}^{2t} + 3\,\mathrm{e}^{t} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 2\,\mathrm{e}^{2t}t - 2\,\mathrm{e}^{2t} + 3\,\mathrm{e}^{t}$$

Verified OK.

1.13.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = y + 2\,\mathrm{e}^{2t}t$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 37: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= e^t
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{t}} dy \end{aligned}$$

Which results in

$$S = e^{-t} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y) S_y}{R_t + \omega(t,y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = y + 2\,e^{2t} t$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= -e^{-t} y \\ S_y &= e^{-t} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 2t\,e^{t} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 2R\,e^{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = 2(R-1)\,\mathrm{e}^{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\mathrm{e}^{-t}y = 2\,\mathrm{e}^{t}(-1+t) + c_1$$

Which simplifies to

$$\mathrm{e}^{-t}y = 2\,\mathrm{e}^{t}(-1+t) + c_1$$

Which gives

$$y = \mathrm{e}^{t}\left(2t\,\mathrm{e}^{t} - 2\,\mathrm{e}^{t} + c_1\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = y + 2\,\mathrm{e}^{2t}t$ 	$R = t$ $S = \mathrm{e}^{-t}y$	$\frac{dS}{dR} = 2R\,\mathrm{e}^{R}$ 
Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_1 - 2$$

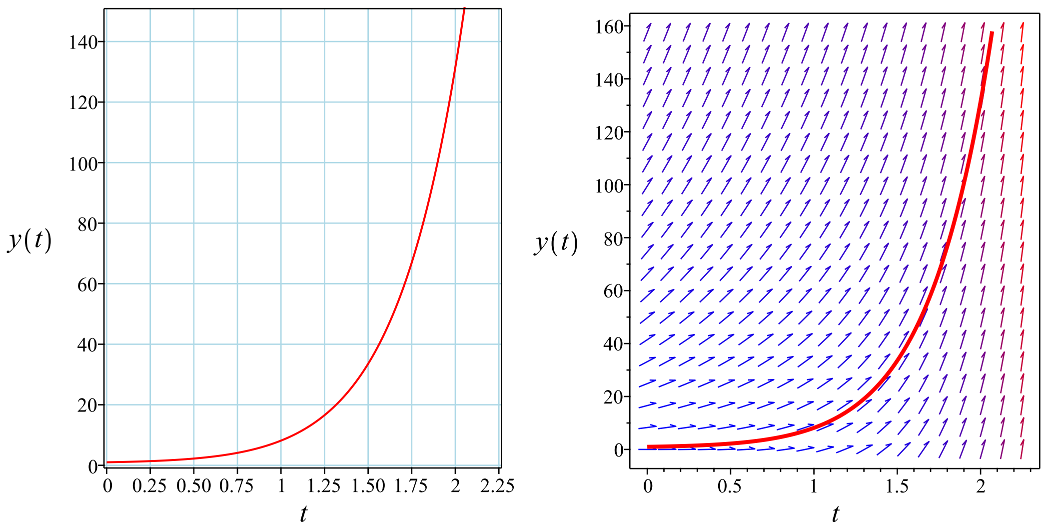
$$c_1 = 3$$

Substituting c_1 found above in the general solution gives

$$y = 2\,\mathrm{e}^{2t}t - 2\,\mathrm{e}^{2t} + 3\,\mathrm{e}^{t}$$

Summary
The solution(s) found are the following

$$y = 2\,\mathrm{e}^{2t}t - 2\,\mathrm{e}^{2t} + 3\,\mathrm{e}^{t} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = 2\,\mathrm{e}^{2t}t - 2\,\mathrm{e}^{2t} + 3\,\mathrm{e}^{t}$$

Verified OK.

1.13.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\,\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x}&=M\\ \frac{\partial \phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t+N(t,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\mathrm{d}y&=\left(y+2\,\mathrm{e}^{2t}t\right)\mathrm{d}t\\ \left(-y-2\,\mathrm{e}^{2t}t\right)\mathrm{d}t+\mathrm{d}y&=0\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t,y)&=-y-2\,\mathrm{e}^{2t}t\\ N(t,y)&=1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}\left(-y-2\,\mathrm{e}^{2t}t\right)\\ &=-1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(1) \\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\ &= 1((-1) - (0)) \\ &= -1\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \, \mathrm{d}t} \\ &= e^{\int -1 \, \mathrm{d}t}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-t} \\ &= \mathrm{e}^{-t}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \mathrm{e}^{-t}\left(-y - 2\,\mathrm{e}^{2t} t\right) \\ &= -\mathrm{e}^{-t} y - 2t\,\mathrm{e}^{t}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N \\ &= \mathrm{e}^{-t}(1) \\ &= \mathrm{e}^{-t}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\ \left(-\mathrm{e}^{-t} y - 2t\,\mathrm{e}^{t}\right) + \left(\mathrm{e}^{-t}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int \overline{M} \, \mathrm{d}t$$
$$\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int -\mathrm{e}^{-t} y - 2t \, \mathrm{e}^{t} \, \mathrm{d}t$$
$$\phi = \mathrm{e}^{-t} y - 2 \, \mathrm{e}^{t}(-1 + t) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{-t} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-t}$. Therefore equation (4) becomes

$$\mathrm{e}^{-t} = \mathrm{e}^{-t} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \mathrm{e}^{-t} y - 2 \, \mathrm{e}^{t}(-1 + t) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \mathrm{e}^{-t} y - 2 \, \mathrm{e}^{t}(-1 + t)$$

The solution becomes

$$y = e^t \left(2t\,e^t - 2\,e^t + c_1\right)$$

Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_1 - 2$$

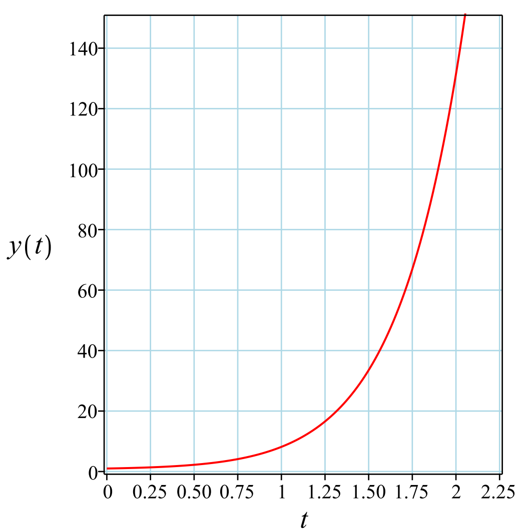
$$c_1 = 3$$

Substituting c_1 found above in the general solution gives

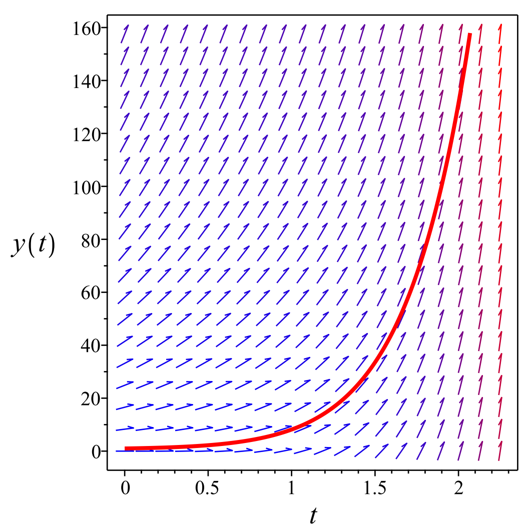
$$y = 2\,e^{2t}t - 2\,e^{2t} + 3\,e^t$$

Summary
The solution(s) found are the following

$$y = 2\,e^{2t}t - 2\,e^{2t} + 3\,e^t \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 2\,e^{2t}t - 2\,e^{2t} + 3\,e^t$$

Verified OK.

1.13.5 Maple step by step solution

Let's solve

$[-y + y' = 2\,\mathrm{e}^{2t} t, y(0) = 1]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = y + 2\,\mathrm{e}^{2t} t$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $-y + y' = 2\,\mathrm{e}^{2t} t$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\,(-y + y') = 2\mu(t)\,\mathrm{e}^{2t} t$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

  $\mu(t)\,(-y + y') = \mu'(t)\,y + \mu(t)\,y'$

- Isolate $\mu'(t)$

  $\mu'(t) = -\mu(t)$

- Solve to find the integrating factor

  $\mu(t) = \mathrm{e}^{-t}$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\,y)\right) dt = \int 2\mu(t)\,\mathrm{e}^{2t} t dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\,y = \int 2\mu(t)\,\mathrm{e}^{2t} t dt + c_1$

- Solve for y

  $y = \frac{\int 2\mu(t)\mathrm{e}^{2t} t dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = \mathrm{e}^{-t}$

  $y = \frac{\int 2\,\mathrm{e}^{2t} t\,\mathrm{e}^{-t} dt + c_1}{\mathrm{e}^{-t}}$

- Evaluate the integrals on the rhs

  $y = \frac{2\,\mathrm{e}^{t}(-1+t) + c_1}{\mathrm{e}^{-t}}$

- Simplify

  $y = (2t - 2)\,(\mathrm{e}^{t})^2 + c_1 \mathrm{e}^{t}$

- Use initial condition $y(0) = 1$

  $1 = c_1 - 2$
- Solve for c_1

  $c_1 = 3$
- Substitute $c_1 = 3$ into general solution and simplify

  $y = (2t - 2)\,e^{2t} + 3\,e^{t}$
- Solution to the IVP

  $y = (2t - 2)\,e^{2t} + 3\,e^{t}$

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{2y + y' = t\,\mathrm{e}^{-2t}}$$

With initial conditions

$$[y(1) = 0]$$

1.14.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$\begin{aligned} p(t) &= 2 \\ q(t) &= t\,\mathrm{e}^{-2t} \end{aligned}$$

Hence the ode is

$$2y + y' = t\,\mathrm{e}^{-2t}$$

The domain of $p(t) = 2$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 1$ is inside this domain. The domain of $q(t) = t\,\mathrm{e}^{-2t}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 1$ is also inside this domain. Hence solution exists and is unique.

1.14.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int 2dt} \\ &= \mathrm{e}^{2t}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}(\mu y) &= (\mu)\left(t\,\mathrm{e}^{-2t}\right) \\ \frac{\mathrm{d}}{\mathrm{d}t}\left(y\,\mathrm{e}^{2t}\right) &= \left(\mathrm{e}^{2t}\right)\left(t\,\mathrm{e}^{-2t}\right) \\ \mathrm{d}\left(y\,\mathrm{e}^{2t}\right) &= t\,\mathrm{d}t\end{aligned}$$

Integrating gives

$$\begin{aligned}y\,\mathrm{e}^{2t} &= \int t\,\mathrm{d}t \\ y\,\mathrm{e}^{2t} &= \frac{t^2}{2} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{2t}$ results in

$$y = \frac{\mathrm{e}^{-2t}t^2}{2} + c_1\mathrm{e}^{-2t}$$

which simplifies to

$$y = \mathrm{e}^{-2t}\left(\frac{t^2}{2} + c_1\right)$$

Initial conditions are used to solve for c_1. Substituting $t = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{e^{-2}(2c_1 + 1)}{2}$$

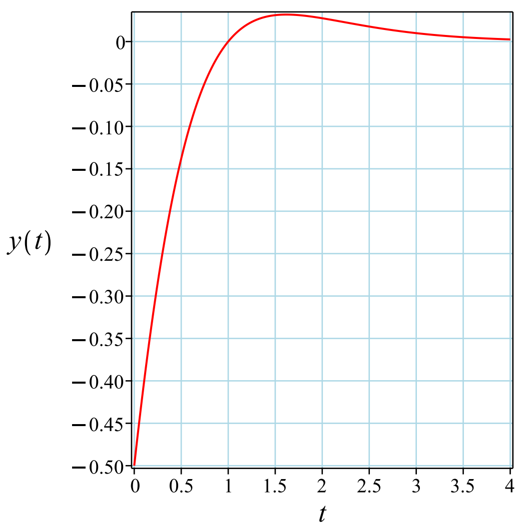
$$c_1 = -\frac{1}{2}$$

Substituting c_1 found above in the general solution gives

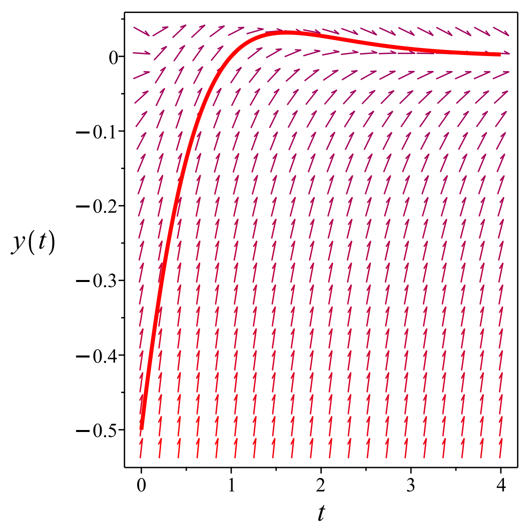
$$y = \frac{e^{-2t}(t^2 - 1)}{2}$$

Summary
The solution(s) found are the following

$$y = \frac{e^{-2t}(t^2 - 1)}{2} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{e^{-2t}(t^2 - 1)}{2}$$

Verified OK.

1.14.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\left(2y\,\mathrm{e}^{2t} - t\right)\mathrm{e}^{-2t} \\
y' &= \omega(t, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 40: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= e^{-2t}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = t
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{e^{-2t}} dy
\end{aligned}
$$

Which results in

$$
S = y\, e^{2t}
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}
$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$
\omega(t, y) = -\left(2y\, e^{2t} - t\right) e^{-2t}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_t &= 1 \\
R_y &= 0 \\
S_t &= 2y\, e^{2t} \\
S_y &= e^{2t}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = t \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$y\,\mathrm{e}^{2t} = \frac{t^2}{2} + c_1$$

Which simplifies to

$$y\,\mathrm{e}^{2t} = \frac{t^2}{2} + c_1$$

Which gives

$$y = \frac{\mathrm{e}^{-2t}(t^2 + 2c_1)}{2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -(2y\,\mathrm{e}^{2t} - t)\,\mathrm{e}^{-2t}$  	$R = t$ $S = y\,\mathrm{e}^{2t}$	$\frac{dS}{dR} = R$ 
Initial conditions are used to solve for c_1. Substituting $t = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \mathrm{e}^{-2}c_1 + \frac{\mathrm{e}^{-2}}{2}$$

$$c_1 = -\frac{1}{2}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{\mathrm{e}^{-2t}t^2}{2} - \frac{\mathrm{e}^{-2t}}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{\mathrm{e}^{-2t}t^2}{2} - \frac{\mathrm{e}^{-2t}}{2} \tag{1}$$

$$y = \frac{e^{-2t}t^2}{2} - \frac{e^{-2t}}{2}$$

Verified OK.

1.14.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(\mathrm{e}^{2t})\,\mathrm{d}y &= (-2y\,\mathrm{e}^{2t} + t)\,\mathrm{d}t\\ (2y\,\mathrm{e}^{2t} - t)\,\mathrm{d}t + (\mathrm{e}^{2t})\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t, y) &= 2y\,\mathrm{e}^{2t} - t\\ N(t, y) &= \mathrm{e}^{2t}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(2y\,\mathrm{e}^{2t} - t)\\ &= 2\,\mathrm{e}^{2t}\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(\mathrm{e}^{2t})\\ &= 2\,\mathrm{e}^{2t}\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t}\, \mathrm{d}t = \int M \, \mathrm{d}t$$
$$\int \frac{\partial \phi}{\partial t}\, \mathrm{d}t = \int 2y\, \mathrm{e}^{2t} - t \, \mathrm{d}t$$
$$\phi = -\frac{t^2}{2} + y\, \mathrm{e}^{2t} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{2t} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{2t}$. Therefore equation (4) becomes

$$\mathrm{e}^{2t} = \mathrm{e}^{2t} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{t^2}{2} + y\, \mathrm{e}^{2t} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{t^2}{2} + y\, \mathrm{e}^{2t}$$

The solution becomes

$$y = \frac{\mathrm{e}^{-2t}(t^2 + 2c_1)}{2}$$

Initial conditions are used to solve for c_1. Substituting $t = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = e^{-2}c_1 + \frac{e^{-2}}{2}$$

$$c_1 = -\frac{1}{2}$$

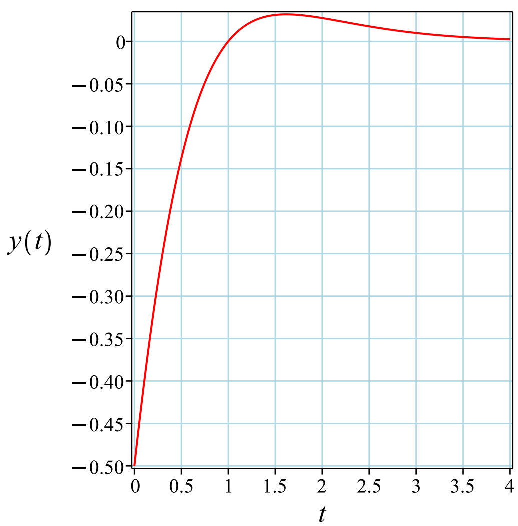
Substituting c_1 found above in the general solution gives

$$y = \frac{e^{-2t}t^2}{2} - \frac{e^{-2t}}{2}$$

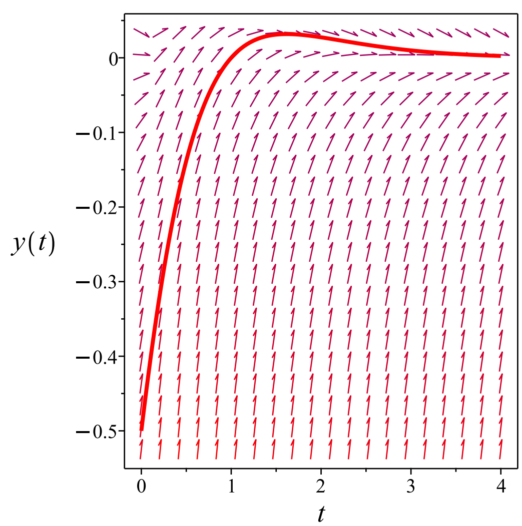
Summary

The solution(s) found are the following

$$y = \frac{e^{-2t}t^2}{2} - \frac{e^{-2t}}{2} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{e^{-2t}t^2}{2} - \frac{e^{-2t}}{2}$$

Verified OK.

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

  $\mu(t)\left(2y+y'\right)=\mu'(t)\,y+\mu(t)\,y'$

- Isolate $\mu'(t)$

  $\mu'(t)=2\mu(t)$

- Solve to find the integrating factor

  $\mu(t)=\left(e^{2t}\right)^2 e^{-2t}$

- Integrate both sides with respect to t

  $\int\left(\frac{d}{dt}(\mu(t)\,y)\right)dt=\int\frac{\mu(t)t}{e^{2t}}dt+c_1$

- Evaluate the integral on the lhs

  $\mu(t)\,y=\int\frac{\mu(t)t}{e^{2t}}dt+c_1$

- Solve for y

  $y=\frac{\int\frac{\mu(t)t}{e^{2t}}dt+c_1}{\mu(t)}$

- Substitute $\mu(t)=\left(e^{2t}\right)^2 e^{-2t}$

  $y=\frac{\int t\,e^{-2t}e^{2t}dt+c_1}{\left(e^{2t}\right)^2 e^{-2t}}$

- Evaluate the integrals on the rhs

  $y=\frac{\frac{t^2}{2}+c_1}{\left(e^{2t}\right)^2 e^{-2t}}$

- Simplify

$$y = \frac{e^{-2t}(t^2+2c_1)}{2}$$

- Use initial condition $y(1) = 0$

$$0 = \frac{e^{-2}(2c_1+1)}{2}$$

- Solve for c_1

$$c_1 = -\frac{1}{2}$$

- Substitute $c_1 = -\frac{1}{2}$ into general solution and simplify

$$y = \frac{e^{-2t}(t^2-1)}{2}$$

- Solution to the IVP

$$y = \frac{e^{-2t}(t^2-1)}{2}$$

1.15 problem 15

Internal problem ID [462]
Internal file name [`OUTPUT/462_Sunday_June_05_2022_01_41_51_AM_24139145/index.tex`]

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.1. Page 40
Problem number: 15.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{2y + ty' = t^2 - t + 1}$$

With initial conditions

$$\left[y(1) = \frac{1}{2}\right]$$

1.15.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \frac{2}{t}$$
$$q(t) = \frac{t^2 - t + 1}{t}$$

Hence the ode is

$$y' + \frac{2y}{t} = \frac{t^2 - t + 1}{t}$$

The domain of $p(t) = \frac{2}{t}$ is

$$\{t < 0 \lor 0 < t\}$$

And the point $t_0 = 1$ is inside this domain. The domain of $q(t) = \frac{t^2-t+1}{t}$ is

$$\{t < 0 \lor 0 < t\}$$

And the point $t_0 = 1$ is also inside this domain. Hence solution exists and is unique.

1.15.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{2}{t} dt} \\ &= t^2\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}(\mu y) &= (\mu)\left(\frac{t^2 - t + 1}{t}\right) \\ \frac{\mathrm{d}}{\mathrm{d}t}(t^2 y) &= (t^2)\left(\frac{t^2 - t + 1}{t}\right) \\ \mathrm{d}(t^2 y) &= \left((t^2 - t + 1)\, t\right)\, \mathrm{d}t\end{aligned}$$

Integrating gives

$$\begin{aligned}t^2 y &= \int (t^2 - t + 1)\, t \,\mathrm{d}t \\ t^2 y &= \frac{1}{4}t^4 - \frac{1}{3}t^3 + \frac{1}{2}t^2 + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = t^2$ results in

$$y = \frac{\frac{1}{4}t^4 - \frac{1}{3}t^3 + \frac{1}{2}t^2}{t^2} + \frac{c_1}{t^2}$$

which simplifies to

$$y = \frac{3t^4 - 4t^3 + 6t^2 + 12c_1}{12t^2}$$

Initial conditions are used to solve for c_1. Substituting $t = 1$ and $y = \frac{1}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{1}{2} = c_1 + \frac{5}{12}$$

$$c_1 = \frac{1}{12}$$

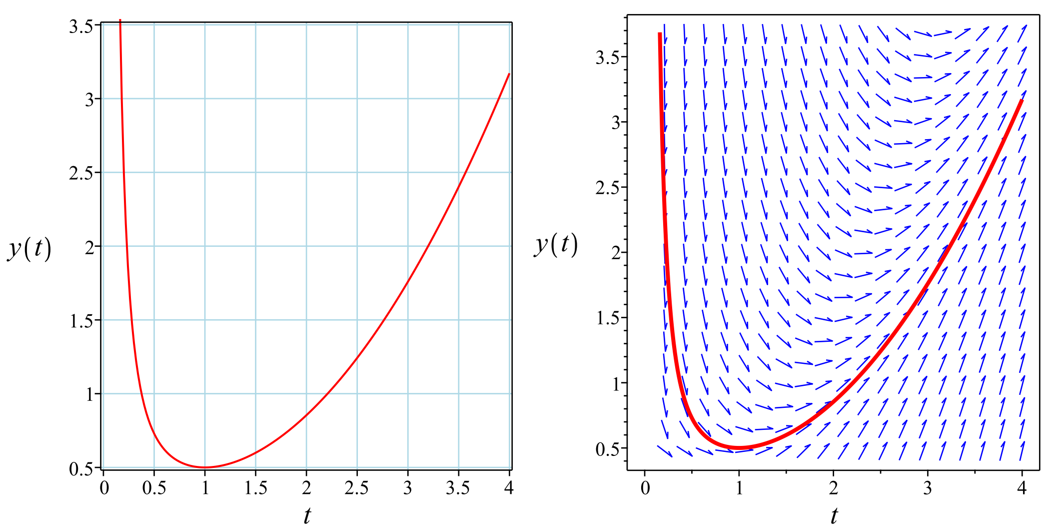
Substituting c_1 found above in the general solution gives

$$y = \frac{3t^4 - 4t^3 + 6t^2 + 1}{12t^2}$$

Summary

The solution(s) found are the following

$$y = \frac{3t^4 - 4t^3 + 6t^2 + 1}{12t^2} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \frac{3t^4 - 4t^3 + 6t^2 + 1}{12t^2}$$

Verified OK.

1.15.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{-t^2+t+2y-1}{t} \\
y' &= \omega(t,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_t+\omega(\eta_y-\xi_t)-\omega^2\xi_y-\omega_t\xi-\omega_y\eta=0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ,η

Table 43: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y'=f(x)y(x)+g(x)$	0	$e^{\int f dx}$
separable ode	$y'=f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y'=f(x)$	0	1
quadrature ode	$y'=g(y)$	1	0
homogeneous ODEs of Class A	$y'=f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y'=(a+bx+cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y'=\frac{y}{x}+g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y'=g(x)\,e^{h(x)+by}+f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y'=\frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y'=f(x)\,y+g(x)\,y^n$	0	$e^{-\int(n-1)f(x)dx}y^n$
Reduced Riccati	$y'=f_1(x)\,y+f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(t,y) &= 0\\ \eta(t,y) &= \frac{1}{t^2}\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial t} + \eta\frac{\partial}{\partial y}\right) S(t,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy\\ &= \int \frac{1}{\frac{1}{t^2}} dy\end{aligned}$$

Which results in

$$S = t^2 y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y)S_y}{R_t + \omega(t,y)R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = -\frac{-t^2 + t + 2y - 1}{t}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_t &= 1 \\
R_y &= 0 \\
S_t &= 2ty \\
S_y &= t^2
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = t^3 - t^2 + t \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R^3 - R^2 + R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{1}{4}R^4 - \frac{1}{3}R^3 + \frac{1}{2}R^2 + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$yt^2 = \frac{1}{4}t^4 - \frac{1}{3}t^3 + \frac{1}{2}t^2 + c_1$$

Which simplifies to

$$yt^2 = \frac{1}{4}t^4 - \frac{1}{3}t^3 + \frac{1}{2}t^2 + c_1$$

Which gives

$$y = \frac{3t^4 - 4t^3 + 6t^2 + 12c_1}{12t^2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{-t^2+t+2y-1}{t}$ 	$R = t$ $S = t^2 y$	$\frac{dS}{dR} = R^3 - R^2 + R$ 
Initial conditions are used to solve for c_1. Substituting $t = 1$ and $y = \frac{1}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{1}{2} = c_1 + \frac{5}{12}$$

$$c_1 = \frac{1}{12}$$

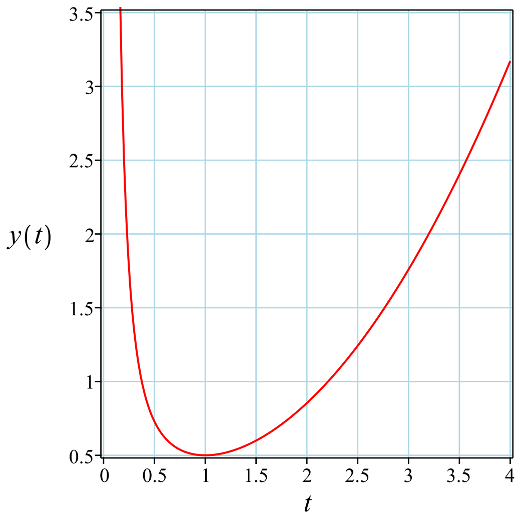
Substituting c_1 found above in the general solution gives

$$y = \frac{3t^4 - 4t^3 + 6t^2 + 1}{12t^2}$$

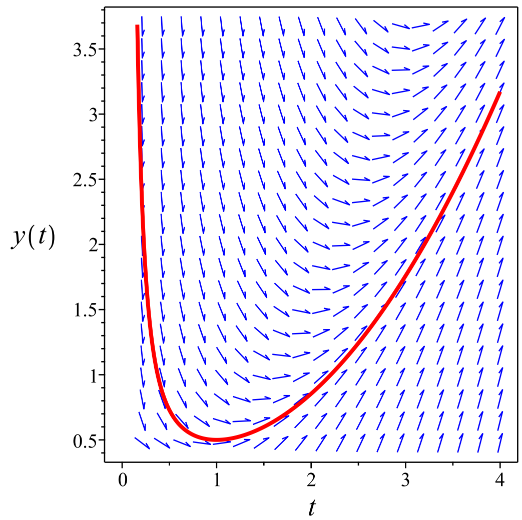
Summary

The solution(s) found are the following

$$y = \frac{3t^4 - 4t^3 + 6t^2 + 1}{12t^2} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{3t^4 - 4t^3 + 6t^2 + 1}{12t^2}$$

Verified OK.

1.15.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\, \mathrm{d}t + N(t, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned} (t)\, \mathrm{d}y &= \left(t^2 - t - 2y + 1\right) \mathrm{d}t \\ \left(-t^2 + t + 2y - 1\right) \mathrm{d}t + (t)\, \mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(t, y) &= -t^2 + t + 2y - 1 \\ N(t, y) &= t \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-t^2 + t + 2y - 1\right) \\ &= 2 \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(t) \\ &= 1 \end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\ &= \frac{1}{t}((2) - (1)) \\ &= \frac{1}{t} \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \,\mathrm{d}t} \\ &= e^{\int \frac{1}{t} \,\mathrm{d}t}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{\ln(t)} \\ &= t\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= t\left(-t^2 + t + 2y - 1\right) \\ &= -t\left(t^2 - t - 2y + 1\right)\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N \\ &= t(t) \\ &= t^2\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\ \left(-t\left(t^2 - t - 2y + 1\right)\right) + \left(t^2\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial t} \,\mathrm{d}t &= \int \overline{M} \,\mathrm{d}t \\ \int \frac{\partial \phi}{\partial t} \,\mathrm{d}t &= \int -t\left(t^2 - t - 2y + 1\right) \mathrm{d}t\end{aligned}$$

$$\phi = -\frac{t^2\left(t^2 - \frac{4}{3}t - 4y + 2\right)}{4} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = t^2 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = t^2$. Therefore equation (4) becomes

$$t^2 = t^2 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{t^2\left(t^2 - \frac{4}{3}t - 4y + 2\right)}{4} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{t^2\left(t^2 - \frac{4}{3}t - 4y + 2\right)}{4}$$

The solution becomes

$$y = \frac{3t^4 - 4t^3 + 6t^2 + 12c_1}{12t^2}$$

Initial conditions are used to solve for c_1. Substituting $t = 1$ and $y = \frac{1}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{1}{2} = c_1 + \frac{5}{12}$$

$$c_1 = \frac{1}{12}$$

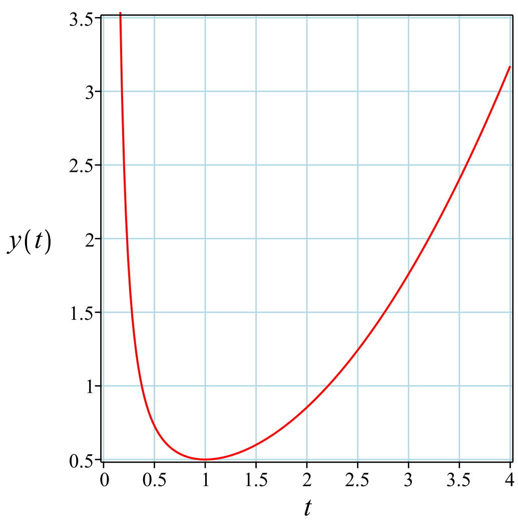
Substituting c_1 found above in the general solution gives

$$y = \frac{3t^4 - 4t^3 + 6t^2 + 1}{12t^2}$$

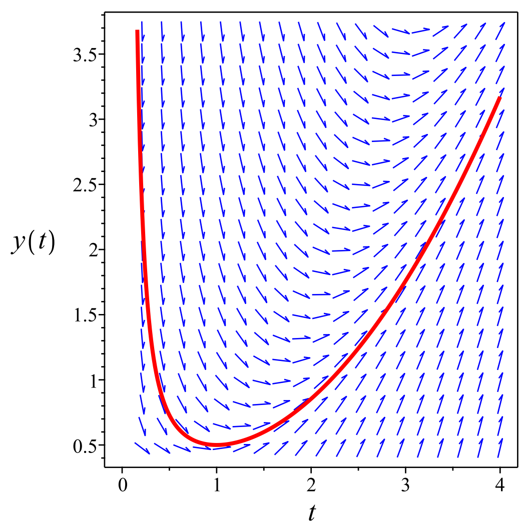
Summary

The solution(s) found are the following

$$y = \frac{3t^4 - 4t^3 + 6t^2 + 1}{12t^2} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{3t^4 - 4t^3 + 6t^2 + 1}{12t^2}$$

Verified OK.

1.15.5 Maple step by step solution

Let's solve

$\left[2y + ty' = t^2 - t + 1, y(1) = \frac{1}{2}\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

$y' = -\frac{2y}{t} + \frac{t^2-t+1}{t}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{2y}{t} = \frac{t^2-t+1}{t}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t) \left(y' + \frac{2y}{t}\right) = \frac{\mu(t)(t^2-t+1)}{t}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, y)$

  $\mu(t) \left(y' + \frac{2y}{t}\right) = \mu'(t)\, y + \mu(t)\, y'$

- Isolate $\mu'(t)$

  $\mu'(t) = \frac{2\mu(t)}{t}$

- Solve to find the integrating factor

  $\mu(t) = t^2$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\, y)\right) dt = \int \frac{\mu(t)(t^2-t+1)}{t} dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\, y = \int \frac{\mu(t)(t^2-t+1)}{t} dt + c_1$

- Solve for y

  $y = \frac{\int \frac{\mu(t)\left(t^2-t+1\right)}{t} dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = t^2$

  $y = \frac{\int (t^2-t+1) t dt + c_1}{t^2}$

- Evaluate the integrals on the rhs

  $y = \frac{\frac{1}{4}t^4 - \frac{1}{3}t^3 + \frac{1}{2}t^2 + c_1}{t^2}$

- Simplify

  $y = \frac{3t^4 - 4t^3 + 6t^2 + 12c_1}{12t^2}$

- Use initial condition $y(1) = \frac{1}{2}$

  $\frac{1}{2} = c_1 + \frac{5}{12}$

- Solve for c_1

  $c_1 = \frac{1}{12}$

- Substitute $c_1 = \frac{1}{12}$ into general solution and simplify

$y = \frac{3t^4 - 4t^3 + 6t^2 + 1}{12t^2}$

- Solution to the IVP

  $y = \frac{3t^4 - 4t^3 + 6t^2 + 1}{12t^2}$

Problem number: 16.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y' + \frac{2y}{t} = \frac{\cos(t)}{t^2}}$$

With initial conditions

$$[y(\pi) = 0]$$

1.16.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \frac{2}{t}$$
$$q(t) = \frac{\cos(t)}{t^2}$$

Hence the ode is

$$y' + \frac{2y}{t} = \frac{\cos(t)}{t^2}$$

The domain of $p(t) = \frac{2}{t}$ is

$$\{t < 0 \lor 0 < t\}$$

And the point $t_0 = \pi$ is inside this domain. The domain of $q(t) = \frac{\cos(t)}{t^2}$ is

$$\{t < 0 \lor 0 < t\}$$

And the point $t_0 = \pi$ is also inside this domain. Hence solution exists and is unique.

1.16.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{2}{t} dt} \\ &= t^2\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dt}(\mu y) &= (\mu)\left(\frac{\cos(t)}{t^2}\right) \\ \frac{d}{dt}(t^2 y) &= (t^2)\left(\frac{\cos(t)}{t^2}\right) \\ d(t^2 y) &= \cos(t)\, dt\end{aligned}$$

Integrating gives

$$\begin{aligned}t^2 y &= \int \cos(t)\, dt \\ t^2 y &= \sin(t) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = t^2$ results in

$$y = \frac{\sin(t)}{t^2} + \frac{c_1}{t^2}$$

which simplifies to

$$y = \frac{\sin(t) + c_1}{t^2}$$

Initial conditions are used to solve for c_1. Substituting $t = \pi$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{c_1}{\pi^2}$$

$$c_1 = 0$$

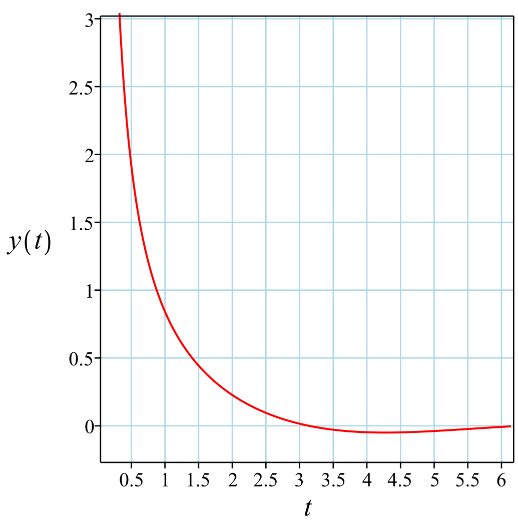
Substituting c_1 found above in the general solution gives

$$y = \frac{\sin(t)}{t^2}$$

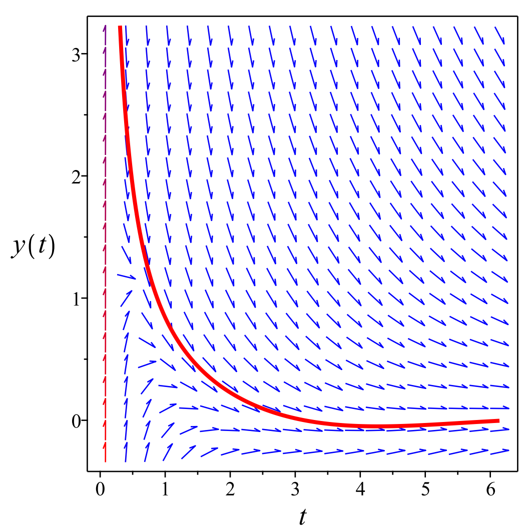
Summary

The solution(s) found are the following

$$y = \frac{\sin(t)}{t^2} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{\sin(t)}{t^2}$$

Verified OK.

1.16.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{-2ty + \cos(t)}{t^2} \\
y' &= \omega(t, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 46: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\xi(t,y) = 0$$
$$\eta(t,y) = \frac{1}{t^2} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial t} + \eta\frac{\partial}{\partial y}\right) S(t,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{t^2}} dy \end{aligned}$$

Which results in

$$S = t^2 y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y)S_y}{R_t + \omega(t,y)R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = \frac{-2ty + \cos(t)}{t^2}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_t &= 1 \\
R_y &= 0 \\
S_t &= 2ty \\
S_y &= t^2
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \cos(t) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \cos(R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \sin(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$yt^2 = \sin(t) + c_1$$

Which simplifies to

$$yt^2 = \sin(t) + c_1$$

Which gives

$$y = \frac{\sin(t) + c_1}{t^2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = \frac{-2ty+\cos(t)}{t^2}$  	$R = t$ $S = t^2 y$	$\frac{dS}{dR} = \cos(R)$ 
Initial conditions are used to solve for c_1. Substituting $t = \pi$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{c_1}{\pi^2}$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$y = \frac{\sin(t)}{t^2}$$

Summary

1.16.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t + N(t,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(t^2)\,\mathrm{d}y &= (-2ty + \cos(t))\,\mathrm{d}t\\ (2ty - \cos(t))\,\mathrm{d}t + (t^2)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t,y) &= 2ty - \cos(t)\\ N(t,y) &= t^2\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(2ty - \cos(t))\\ &= 2t\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(t^2)\\ &= 2t\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(t,y)$

$$\frac{\partial \phi}{\partial t} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. t gives

$$\begin{aligned}
\int \frac{\partial \phi}{\partial t} \,\mathrm{d}t &= \int M \,\mathrm{d}t \\
\int \frac{\partial \phi}{\partial t} \,\mathrm{d}t &= \int 2ty - \cos(t) \,\mathrm{d}t \\
\phi &= t^2 y - \sin(t) + f(y) \qquad (3)
\end{aligned}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = t^2 + f'(y) \qquad (4)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = t^2$. Therefore equation (4) becomes

$$t^2 = t^2 + f'(y) \qquad (5)$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = t^2 y - \sin(t) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = t^2 y - \sin(t)$$

The solution becomes

$$y = \frac{\sin(t) + c_1}{t^2}$$

Initial conditions are used to solve for c_1. Substituting $t = \pi$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{c_1}{\pi^2}$$

$$c_1 = 0$$

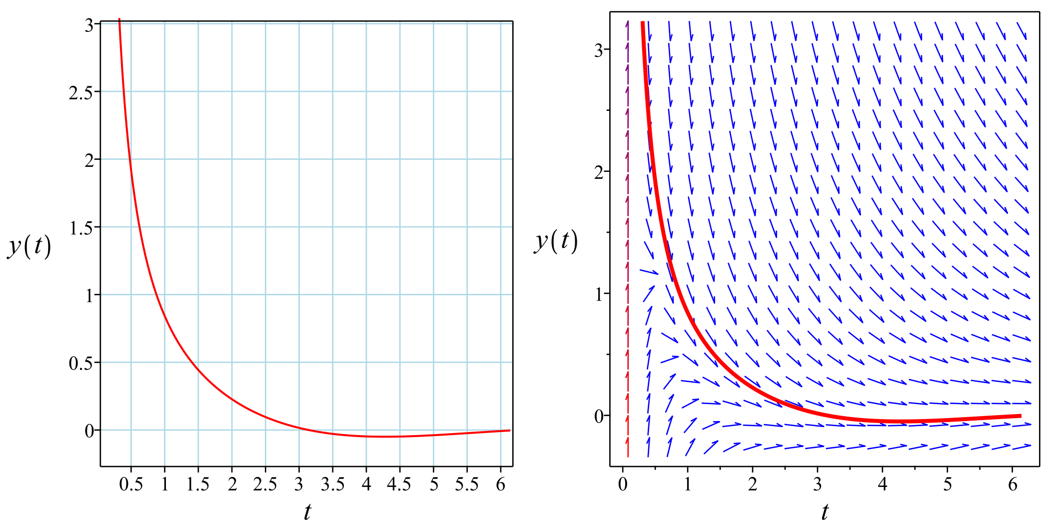
Substituting c_1 found above in the general solution gives

$$y = \frac{\sin(t)}{t^2}$$

Summary

The solution(s) found are the following

$$y = \frac{\sin(t)}{t^2} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \frac{\sin(t)}{t^2}$$

1.16.5 Maple step by step solution

Let's solve

$\left[y' + \frac{2y}{t} = \frac{\cos(t)}{t^2}, y(\pi) = 0\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{2y}{t} + \frac{\cos(t)}{t^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{2y}{t} = \frac{\cos(t)}{t^2}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(y' + \frac{2y}{t}\right) = \frac{\mu(t)\cos(t)}{t^2}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, y)$

  $\mu(t)\left(y' + \frac{2y}{t}\right) = \mu'(t)\, y + \mu(t)\, y'$

- Isolate $\mu'(t)$

  $\mu'(t) = \frac{2\mu(t)}{t}$

- Solve to find the integrating factor

  $\mu(t) = t^2$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\, y)\right) dt = \int \frac{\mu(t)\cos(t)}{t^2} dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\, y = \int \frac{\mu(t)\cos(t)}{t^2} dt + c_1$

- Solve for y

  $y = \frac{\int \frac{\mu(t)\cos(t)}{t^2} dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = t^2$

  $y = \frac{\int \cos(t) dt + c_1}{t^2}$

- Evaluate the integrals on the rhs

  $y = \frac{\sin(t) + c_1}{t^2}$

- Use initial condition $y(\pi) = 0$

$0 = \frac{c_1}{\pi^2}$

- Solve for c_1

  $c_1 = 0$

- Substitute $c_1 = 0$ into general solution and simplify

  $y = \frac{\sin(t)}{t^2}$

- Solution to the IVP

  $y = \frac{\sin(t)}{t^2}$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{-2y + y' = e^{2t}}$$

With initial conditions

$$[y(0) = 2]$$

1.17.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = -2$$
$$q(t) = e^{2t}$$

Hence the ode is

$$-2y + y' = e^{2t}$$

The domain of $p(t) = -2$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = e^{2t}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

1.17.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int (-2)dt} \\ &= e^{-2t}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dt}(\mu y) &= (\mu)\left(e^{2t}\right) \\ \frac{d}{dt}\left(e^{-2t}y\right) &= \left(e^{-2t}\right)\left(e^{2t}\right) \\ d\left(e^{-2t}y\right) &= dt\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{-2t}y &= \int dt \\ e^{-2t}y &= t + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-2t}$ results in

$$y = e^{2t}t + c_1 e^{2t}$$

which simplifies to

$$y = e^{2t}(t + c_1)$$

Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = c_1$$

$$c_1 = 2$$

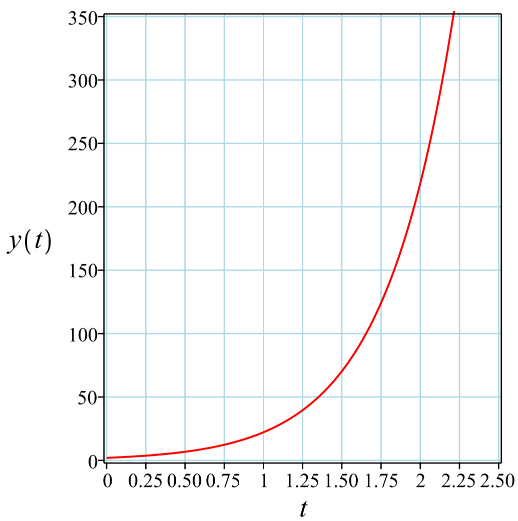
Substituting c_1 found above in the general solution gives

$$y = e^{2t}(2 + t)$$

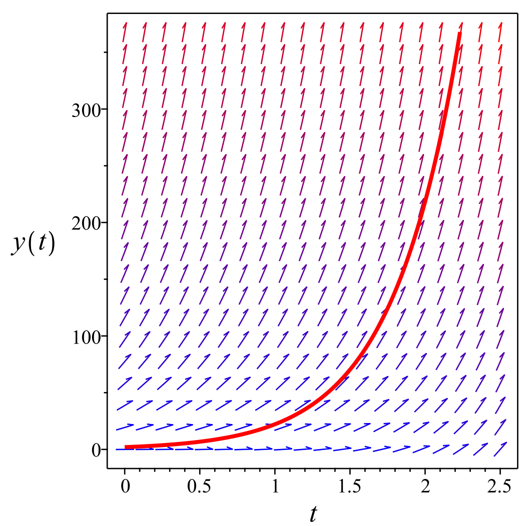
Summary

The solution(s) found are the following

$$y = e^{2t}(2 + t) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^{2t}(2 + t)$$

1.17.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= 2y + e^{2t} \\
y' &= \omega(t, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 49: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(t,y) &= 0 \\ \eta(t,y) &= e^{2t} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial t} + \eta\frac{\partial}{\partial y}\right) S(t,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{2t}} dy \end{aligned}$$

Which results in

$$S = e^{-2t} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y)S_y}{R_t + \omega(t,y)R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = 2y + e^{2t}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= -2\,e^{-2t} y \\ S_y &= e^{-2t} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 1 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$e^{-2t}y = t + c_1$$

Which simplifies to

$$e^{-2t}y = t + c_1$$

Which gives

$$y = e^{2t}(t + c_1)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = 2y + e^{2t}$ 	$R = t$ $S = e^{-2t}y$	$\frac{dS}{dR} = 1$ 
Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = c_1$$

$$c_1 = 2$$

Substituting c_1 found above in the general solution gives

$$y = e^{2t}t + 2e^{2t}$$

<u>Summary</u>
The solution(s) found are the following

$$y = e^{2t}t + 2e^{2t} \tag{1}$$

1.17.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned} \mathrm{d}y &= \left(2y + \mathrm{e}^{2t}\right)\mathrm{d}t \\ \left(-2y - \mathrm{e}^{2t}\right)\mathrm{d}t + \mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(t, y) &= -2y - \mathrm{e}^{2t} \\ N(t, y) &= 1 \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-2y - \mathrm{e}^{2t}\right) \\ &= -2 \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(1) \\ &= 0 \end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\ &= 1((-2) - (0)) \\ &= -2 \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \,\mathrm{d}t} \\ &= e^{\int -2 \,\mathrm{d}t}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-2t} \\ &= \mathrm{e}^{-2t}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \mathrm{e}^{-2t}\left(-2y - \mathrm{e}^{2t}\right) \\ &= -2\,\mathrm{e}^{-2t} y - 1\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N \\ &= \mathrm{e}^{-2t}(1) \\ &= \mathrm{e}^{-2t}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\ \left(-2\,\mathrm{e}^{-2t} y - 1\right) + \left(\mathrm{e}^{-2t}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial t} \,\mathrm{d}t &= \int \overline{M} \,\mathrm{d}t \\ \int \frac{\partial \phi}{\partial t} \,\mathrm{d}t &= \int -2\,\mathrm{e}^{-2t} y - 1 \,\mathrm{d}t\end{aligned}$$

$$\phi = -t + \mathrm{e}^{-2t} y + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = e^{-2t} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = e^{-2t}$. Therefore equation (4) becomes

$$e^{-2t} = e^{-2t} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -t + e^{-2t}y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -t + e^{-2t}y$$

The solution becomes

$$y = e^{2t}(t + c_1)$$

Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = c_1$$

$$c_1 = 2$$

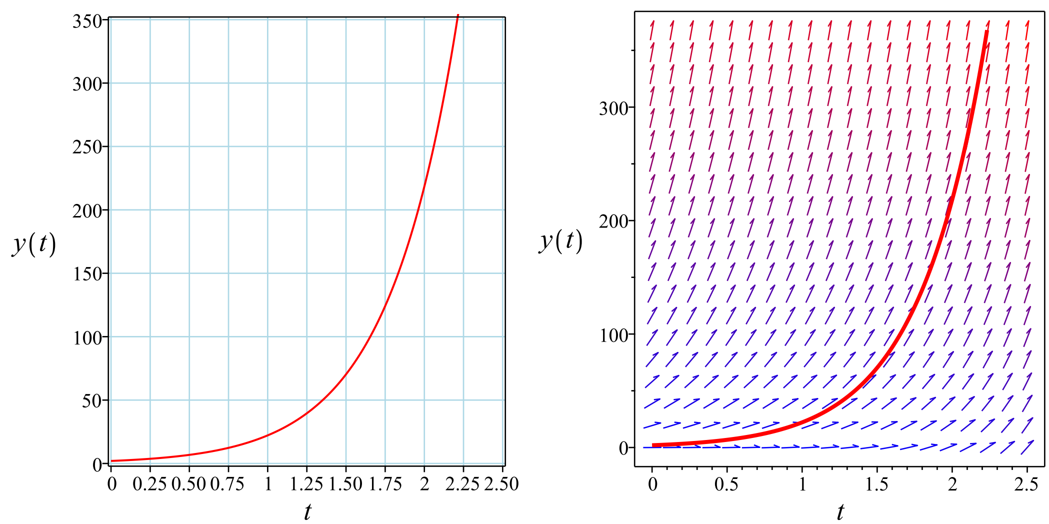
Substituting c_1 found above in the general solution gives

$$y = e^{2t}t + 2\,e^{2t}$$

Summary

The solution(s) found are the following

$$y = e^{2t}t + 2\,e^{2t} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = e^{2t}t + 2\,e^{2t}$$

Verified OK.

1.17.5 Maple step by step solution

Let's solve

$[-2y + y' = e^{2t}, y(0) = 2]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = 2y + e^{2t}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $-2y + y' = e^{2t}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

$\mu(t)\left(-2y+y'\right)=\mu(t)\,\mathrm{e}^{2t}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}\left(\mu(t)\,y\right)$

$\mu(t)\left(-2y+y'\right)=\mu'(t)\,y+\mu(t)\,y'$

- Isolate $\mu'(t)$

$\mu'(t)=-2\mu(t)$

- Solve to find the integrating factor

$\mu(t)=\mathrm{e}^{-2t}$

- Integrate both sides with respect to t

$\int\left(\frac{d}{dt}\left(\mu(t)\,y\right)\right)dt=\int\mu(t)\,\mathrm{e}^{2t}dt+c_1$

- Evaluate the integral on the lhs

$\mu(t)\,y=\int\mu(t)\,\mathrm{e}^{2t}dt+c_1$

- Solve for y

$y=\frac{\int\mu(t)\mathrm{e}^{2t}dt+c_1}{\mu(t)}$

- Substitute $\mu(t)=\mathrm{e}^{-2t}$

$y=\frac{\int\mathrm{e}^{-2t}\mathrm{e}^{2t}dt+c_1}{\mathrm{e}^{-2t}}$

- Evaluate the integrals on the rhs

$y=\frac{t+c_1}{\mathrm{e}^{-2t}}$

- Simplify

$y=\mathrm{e}^{2t}(t+c_1)$

- Use initial condition $y(0)=2$

$2=c_1$

- Solve for c_1

$c_1=2$

- Substitute $c_1=2$ into general solution and simplify

$y=\mathrm{e}^{2t}(2+t)$

- Solution to the IVP

$y=\mathrm{e}^{2t}(2+t)$

ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{2y + ty' = \sin(t)}$$

With initial conditions

$$\left[y\left(\frac{\pi}{2}\right) = 1\right]$$

1.18.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \frac{2}{t}$$
$$q(t) = \frac{\sin(t)}{t}$$

Hence the ode is

$$y' + \frac{2y}{t} = \frac{\sin(t)}{t}$$

The domain of $p(t) = \frac{2}{t}$ is

$$\{t < 0 \lor 0 < t\}$$

And the point $t_0 = \frac{\pi}{2}$ is inside this domain. The domain of $q(t) = \frac{\sin(t)}{t}$ is

$$\{t < 0 \lor 0 < t\}$$

And the point $t_0 = \frac{\pi}{2}$ is also inside this domain. Hence solution exists and is unique.

1.18.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{2}{t} dt} \\ &= t^2\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dt}(\mu y) &= (\mu)\left(\frac{\sin(t)}{t}\right) \\ \frac{d}{dt}(t^2 y) &= (t^2)\left(\frac{\sin(t)}{t}\right) \\ d(t^2 y) &= (t\sin(t))\ dt\end{aligned}$$

Integrating gives

$$\begin{aligned}t^2 y &= \int t\sin(t)\ dt \\ t^2 y &= -t\cos(t) + \sin(t) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = t^2$ results in

$$y = \frac{-t\cos(t) + \sin(t)}{t^2} + \frac{c_1}{t^2}$$

which simplifies to

$$y = \frac{-t\cos(t) + \sin(t) + c_1}{t^2}$$

Initial conditions are used to solve for c_1. Substituting $t = \frac{\pi}{2}$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{4 + 4c_1}{\pi^2}$$

$$c_1 = \frac{\pi^2}{4} - 1$$

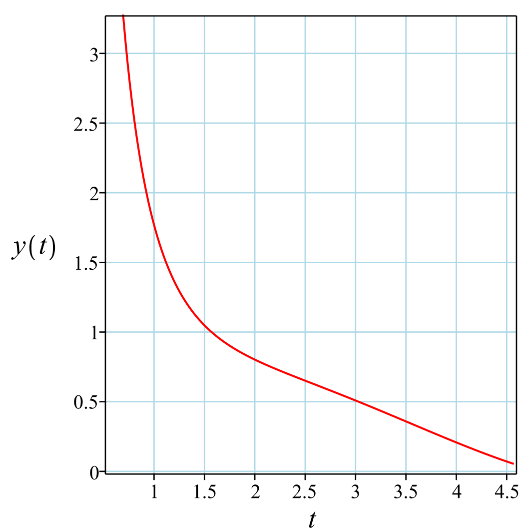
Substituting c_1 found above in the general solution gives

$$y = \frac{-4t\cos(t) + \pi^2 + 4\sin(t) - 4}{4t^2}$$

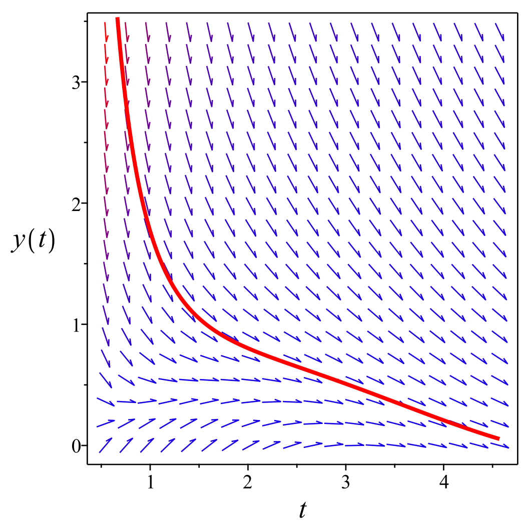
Summary

The solution(s) found are the following

$$y = \frac{-4t\cos(t) + \pi^2 + 4\sin(t) - 4}{4t^2} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{-4t\cos(t) + \pi^2 + 4\sin(t) - 4}{4t^2}$$

Verified OK.

1.18.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{2y - \sin(t)}{t}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 52: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(t,y) &= 0\\ \eta(t,y) &= \frac{1}{t^2}\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial t} + \eta\frac{\partial}{\partial y}\right) S(t,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy\\ &= \int \frac{1}{\frac{1}{t^2}} dy\end{aligned}$$

Which results in

$$S = t^2 y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y)S_y}{R_t + \omega(t,y)R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = -\frac{2y - \sin(t)}{t}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_t &= 1 \\
R_y &= 0 \\
S_t &= 2ty \\
S_y &= t^2
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = t \sin(t) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R \sin(R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -R \cos(R) + \sin(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$yt^2 = -t \cos(t) + \sin(t) + c_1$$

Which simplifies to

$$yt^2 = -t \cos(t) + \sin(t) + c_1$$

Which gives

$$y = -\frac{t \cos(t) - \sin(t) - c_1}{t^2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{2y-\sin(t)}{t}$ 	$R = t$ $S = t^2 y$	$\frac{dS}{dR} = R\sin(R)$ 
Initial conditions are used to solve for c_1. Substituting $t = \frac{\pi}{2}$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{4 + 4c_1}{\pi^2}$$

$$c_1 = \frac{\pi^2}{4} - 1$$

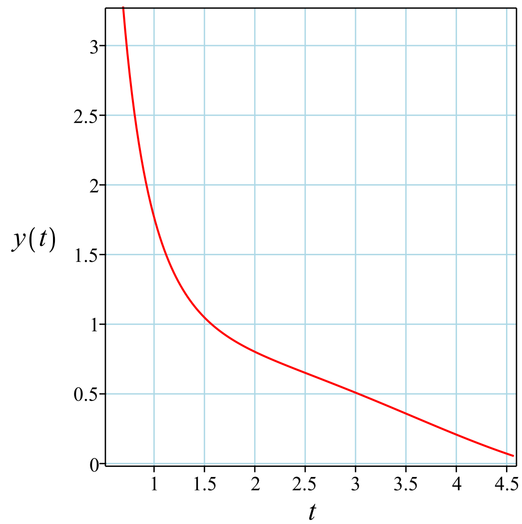
Substituting c_1 found above in the general solution gives

$$y = \frac{-4t\cos(t) + \pi^2 + 4\sin(t) - 4}{4t^2}$$

Summary

The solution(s) found are the following

$$y = \frac{-4t\cos(t) + \pi^2 + 4\sin(t) - 4}{4t^2} \tag{1}$$



(a) Solution plot

Verified OK.

1.18.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t + N(t,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(t)\,\mathrm{d}y &= (-2y + \sin(t))\,\mathrm{d}t\\ (2y - \sin(t))\,\mathrm{d}t + (t)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t,y) &= 2y - \sin(t)\\ N(t,y) &= t\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(2y - \sin(t))\\ &= 2\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(t)\\ &= 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right)\\ &= \frac{1}{t}((2) - (1))\\ &= \frac{1}{t}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}t} \\ &= e^{\int \frac{1}{t}\,\mathrm{d}t}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{\ln(t)} \\ &= t\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= t(2y - \sin(t)) \\ &= (2y - \sin(t))\, t\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N \\ &= t(t) \\ &= t^2\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\ ((2y - \sin(t))\, t) + \left(t^2\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial t}\,\mathrm{d}t &= \int \overline{M}\,\mathrm{d}t \\ \int \frac{\partial \phi}{\partial t}\,\mathrm{d}t &= \int (2y - \sin(t))\, t\,\mathrm{d}t\end{aligned}$$

$$\phi = t^2 y + t\cos(t) - \sin(t) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = t^2 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = t^2$. Therefore equation (4) becomes

$$t^2 = t^2 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = t^2 y + t\cos(t) - \sin(t) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = t^2 y + t\cos(t) - \sin(t)$$

The solution becomes

$$y = -\frac{t\cos(t) - \sin(t) - c_1}{t^2}$$

Initial conditions are used to solve for c_1. Substituting $t = \frac{\pi}{2}$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{4 + 4c_1}{\pi^2}$$

$$c_1 = \frac{\pi^2}{4} - 1$$

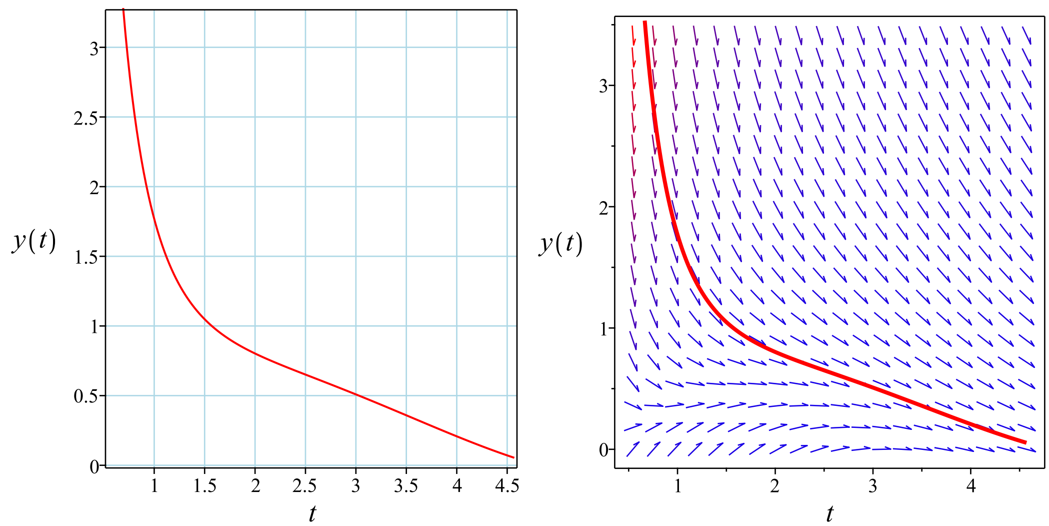
Substituting c_1 found above in the general solution gives

$$y = \frac{-4t\cos(t) + \pi^2 + 4\sin(t) - 4}{4t^2}$$

Summary

The solution(s) found are the following

$$y = \frac{-4t\cos(t) + \pi^2 + 4\sin(t) - 4}{4t^2} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Problem number: 19.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{4yt^2 + y't^3 = e^{-t}}$$

With initial conditions

$$[y(-1) = 0]$$

1.19.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \frac{4}{t}$$
$$q(t) = \frac{e^{-t}}{t^3}$$

Hence the ode is

$$y' + \frac{4y}{t} = \frac{e^{-t}}{t^3}$$

The domain of $p(t) = \frac{4}{t}$ is

$$\{t < 0 \lor 0 < t\}$$

And the point $t_0 = -1$ is inside this domain. The domain of $q(t) = \frac{e^{-t}}{t^3}$ is

$$\{t < 0 \lor 0 < t\}$$

And the point $t_0 = -1$ is also inside this domain. Hence solution exists and is unique.

1.19.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{4}{t} dt} \\ &= t^4\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dt}(\mu y) &= (\mu)\left(\frac{e^{-t}}{t^3}\right) \\ \frac{d}{dt}(t^4 y) &= (t^4)\left(\frac{e^{-t}}{t^3}\right) \\ d(t^4 y) &= (t\,e^{-t})\,dt\end{aligned}$$

Integrating gives

$$\begin{aligned}t^4 y &= \int t\,e^{-t}\,dt \\ t^4 y &= -e^{-t}(t+1) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = t^4$ results in

$$y = -\frac{e^{-t}(t+1)}{t^4} + \frac{c_1}{t^4}$$

which simplifies to

$$y = \frac{(-t-1)\,e^{-t} + c_1}{t^4}$$

Initial conditions are used to solve for c_1. Substituting $t = -1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1$$

$$c_1 = 0$$

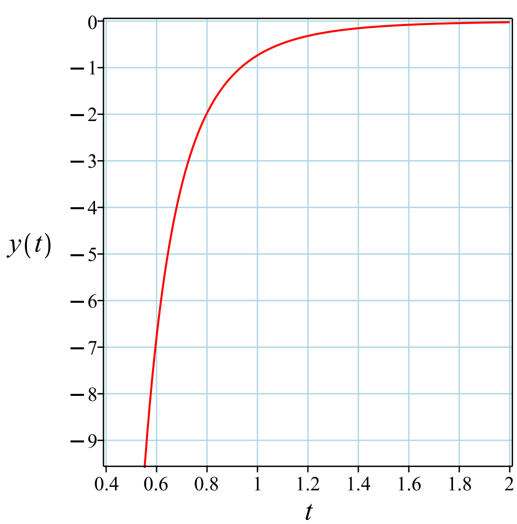
Substituting c_1 found above in the general solution gives

$$y = -\frac{e^{-t}(t+1)}{t^4}$$

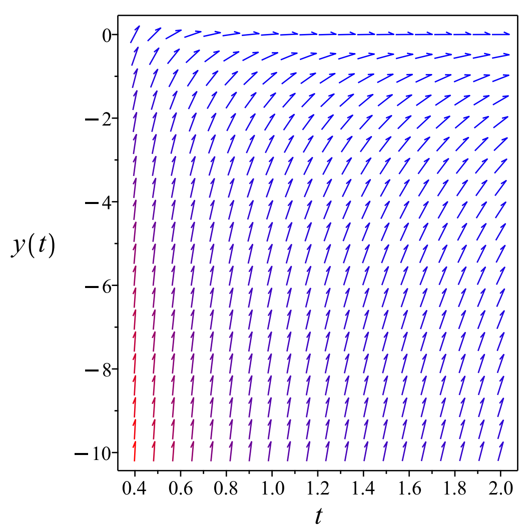
Summary

The solution(s) found are the following

$$y = -\frac{e^{-t}(t+1)}{t^4} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -\frac{e^{-t}(t+1)}{t^4}$$

Verified OK.

1.19.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{-4t^2 y + e^{-t}}{t^3}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 55: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0

homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t,y) &= 0 \\
\eta(t,y) &= \frac{1}{t^4}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial t} + \eta\frac{\partial}{\partial y}\right) S(t,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = t
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{1}{t^4}} dy
\end{aligned}
$$

Which results in

$$
S = t^4 y
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_t + \omega(t,y) S_y}{R_t + \omega(t,y) R_y} \tag{2}
$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$
\omega(t,y) = \frac{-4t^2 y + e^{-t}}{t^3}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_t &= 1 \\
R_y &= 0 \\
S_t &= 4t^3 y \\
S_y &= t^4
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = t\,\mathrm{e}^{-t} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = R\,\mathrm{e}^{-R}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = -(R+1)\,\mathrm{e}^{-R} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$
y t^4 = -\mathrm{e}^{-t}(t+1) + c_1
$$

Which simplifies to

$$
y t^4 = -\mathrm{e}^{-t}(t+1) + c_1
$$

Which gives

$$
y = -\frac{t\,\mathrm{e}^{-t} + \mathrm{e}^{-t} - c_1}{t^4}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>

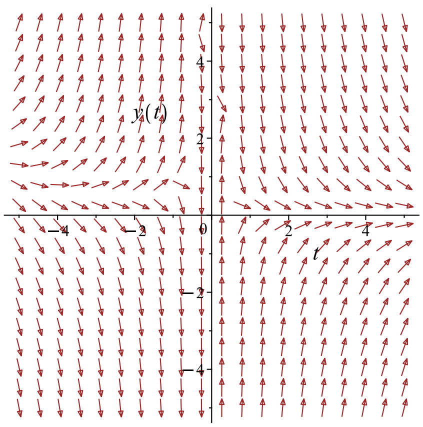
$\frac{dy}{dt} = \frac{-4t^2y+e^{-t}}{t^3}$



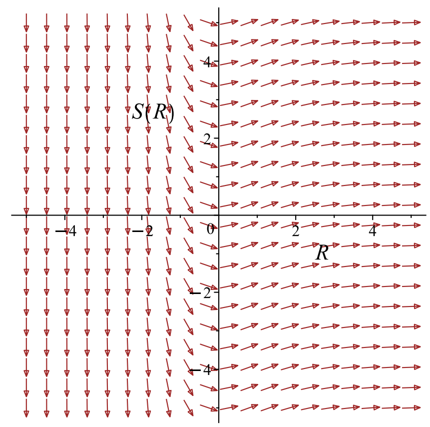
</td><td>

$R = t$

$S = t^4y$

</td><td>

$\frac{dS}{dR} = R\,e^{-R}$



</td></tr>
</table>

Initial conditions are used to solve for c_1. Substituting $t = -1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$y = -\frac{e^{-t}(t+1)}{t^4}$$

Summary

The solution(s) found are the following

$$y = -\frac{e^{-t}(t+1)}{t^4} \tag{1}$$

1.19.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(t^3)\,\mathrm{d}y &= (-4t^2y + \mathrm{e}^{-t})\,\mathrm{d}t\\ (4t^2y - \mathrm{e}^{-t})\,\mathrm{d}t + (t^3)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t, y) &= 4t^2y - \mathrm{e}^{-t}\\ N(t, y) &= t^3\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(4t^2y - \mathrm{e}^{-t})\\ &= 4t^2\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(t^3)\\ &= 3t^2\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right)\\ &= \frac{1}{t^3}\left((4t^2) - (3t^2)\right)\\ &= \frac{1}{t}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}t}\\ &= e^{\int \frac{1}{t}\,\mathrm{d}t}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{\ln(t)}\\ &= t\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= t\left(4t^2y - \mathrm{e}^{-t}\right)\\ &= 4t^3y - t\,\mathrm{e}^{-t}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= t\left(t^3\right)\\ &= t^4\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0\\ \left(4t^3y - t\,\mathrm{e}^{-t}\right) + \left(t^4\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial\phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\begin{aligned}\int \frac{\partial\phi}{\partial t}\,\mathrm{d}t &= \int \overline{M}\,\mathrm{d}t\\ \int \frac{\partial\phi}{\partial t}\,\mathrm{d}t &= \int 4t^3y - t\,\mathrm{e}^{-t}\,\mathrm{d}t\end{aligned}$$

$$\phi = t\,\mathrm{e}^{-t} + \mathrm{e}^{-t} + t^4y + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = t^4 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = t^4$. Therefore equation (4) becomes

$$t^4 = t^4 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = t\,\mathrm{e}^{-t} + \mathrm{e}^{-t} + t^4 y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = t\,\mathrm{e}^{-t} + \mathrm{e}^{-t} + t^4 y$$

The solution becomes

$$y = -\frac{t\,\mathrm{e}^{-t} + \mathrm{e}^{-t} - c_1}{t^4}$$

Initial conditions are used to solve for c_1. Substituting $t = -1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1$$

$$c_1 = 0$$

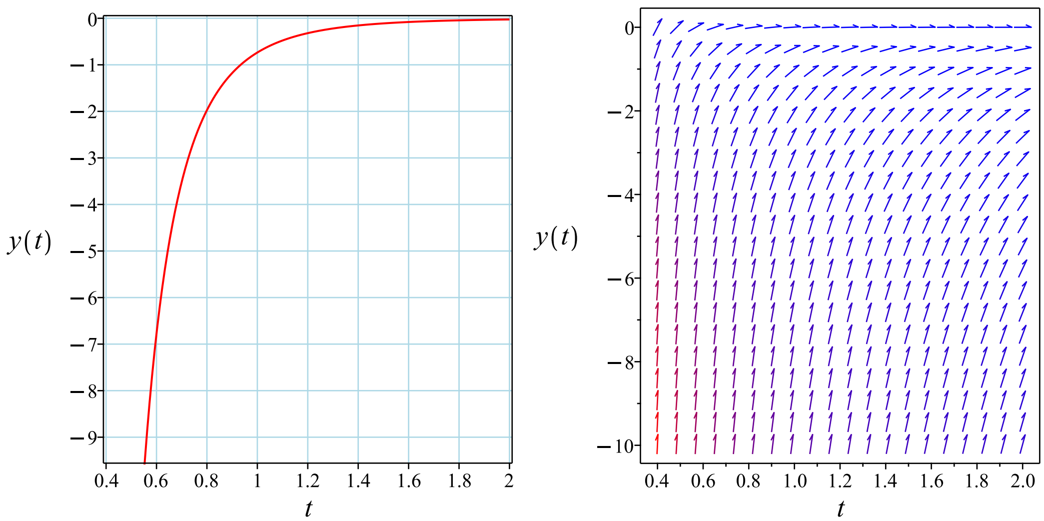
Substituting c_1 found above in the general solution gives

$$y = -\frac{\mathrm{e}^{-t}(t+1)}{t^4}$$

Summary

The solution(s) found are the following

$$y = -\frac{e^{-t}(t+1)}{t^4} \tag{1}$$



(a) Solution plot (b) Slope field plot

1.19.5 Maple step by step solution

Let's solve

$[4yt^2 + y't^3 = e^{-t}, y(-1) = 0]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{4y}{t} + \frac{e^{-t}}{t^3}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{4y}{t} = \frac{e^{-t}}{t^3}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(y'+\frac{4y}{t}\right)=\frac{\mu(t)\mathrm{e}^{-t}}{t^3}$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

  $\mu(t)\left(y'+\frac{4y}{t}\right)=\mu'(t)\,y+\mu(t)\,y'$
- Isolate $\mu'(t)$

  $\mu'(t)=\frac{4\mu(t)}{t}$
- Solve to find the integrating factor

  $\mu(t)=t^4$
- Integrate both sides with respect to t

  $\int\left(\frac{d}{dt}(\mu(t)\,y)\right)dt=\int\frac{\mu(t)\mathrm{e}^{-t}}{t^3}dt+c_1$
- Evaluate the integral on the lhs

  $\mu(t)\,y=\int\frac{\mu(t)\mathrm{e}^{-t}}{t^3}dt+c_1$
- Solve for y

  $y=\frac{\int\frac{\mu(t)\mathrm{e}^{-t}}{t^3}dt+c_1}{\mu(t)}$
- Substitute $\mu(t)=t^4$

  $y=\frac{\int t\,\mathrm{e}^{-t}dt+c_1}{t^4}$
- Evaluate the integrals on the rhs

  $y=\frac{-\mathrm{e}^{-t}(t+1)+c_1}{t^4}$
- Simplify

  $y=\frac{(-t-1)\mathrm{e}^{-t}+c_1}{t^4}$
- Use initial condition $y(-1)=0$

  $0=c_1$
- Solve for c_1

  $c_1=0$
- Substitute $c_1=0$ into general solution and simplify

  $y=-\frac{\mathrm{e}^{-t}(t+1)}{t^4}$
- Solution to the IVP

  $y=-\frac{\mathrm{e}^{-t}(t+1)}{t^4}$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{(t+1)\,y+ty'=t}$$

With initial conditions

$$[y(\ln(2))=1]$$

1.20.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'+p(t)y=q(t)$$

Where here

$$\begin{aligned}p(t)&=-\frac{-t-1}{t}\\ q(t)&=1\end{aligned}$$

Hence the ode is

$$y' - \frac{(-t-1)\, y}{t} = 1$$

The domain of $p(t) = -\frac{-t-1}{t}$ is

$$\{t < 0 \lor 0 < t\}$$

And the point $t_0 = \ln(2)$ is inside this domain. The domain of $q(t) = 1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = \ln(2)$ is also inside this domain. Hence solution exists and is unique.

1.20.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{-t-1}{t}dt} \\ &= \mathrm{e}^{t+\ln(t)}\end{aligned}$$

Which simplifies to

$$\mu = t\,\mathrm{e}^{t}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}(\mu y) &= \mu \\ \frac{\mathrm{d}}{\mathrm{d}t}\left(t\,\mathrm{e}^{t} y\right) &= t\,\mathrm{e}^{t} \\ \mathrm{d}\left(t\,\mathrm{e}^{t} y\right) &= t\,\mathrm{e}^{t} \mathrm{d}t\end{aligned}$$

Integrating gives

$$\begin{aligned}t\,\mathrm{e}^{t} y &= \int t\,\mathrm{e}^{t}\,\mathrm{d}t \\ t\,\mathrm{e}^{t} y &= \mathrm{e}^{t}(-1+t) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = t\,\mathrm{e}^{t}$ results in

$$y = \frac{\mathrm{e}^{-t}\mathrm{e}^{t}(-1+t)}{t} + \frac{c_1 \mathrm{e}^{-t}}{t}$$

which simplifies to

$$y = \frac{c_1 e^{-t} + t - 1}{t}$$

Initial conditions are used to solve for c_1. Substituting $t = \ln(2)$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{c_1 + 2\ln(2) - 2}{2\ln(2)}$$

$$c_1 = 2$$

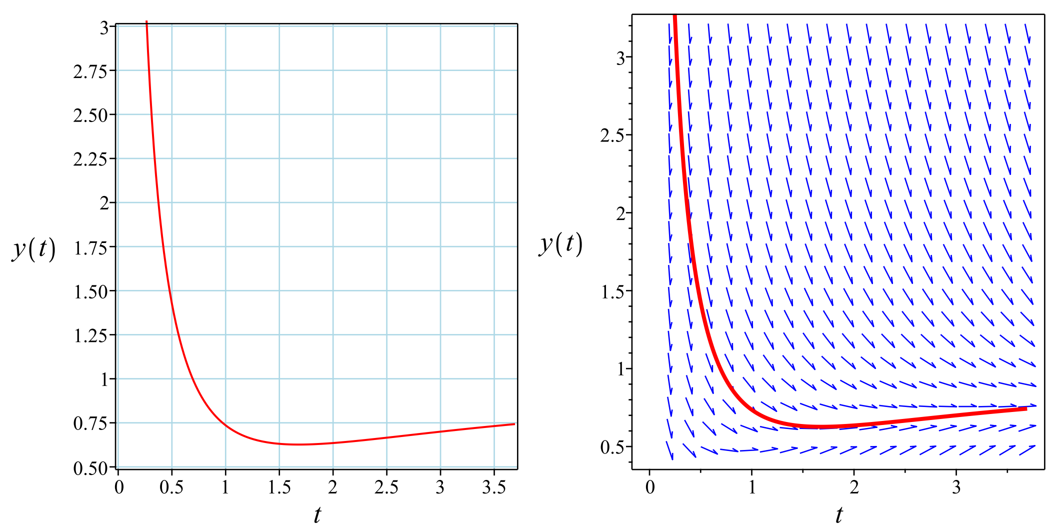
Substituting c_1 found above in the general solution gives

$$y = \frac{-1 + 2\,e^{-t} + t}{t}$$

Summary

The solution(s) found are the following

$$y = \frac{-1 + 2\,e^{-t} + t}{t} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \frac{-1 + 2\,e^{-t} + t}{t}$$

1.20.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{ty-t+y}{t} \\
y' &= \omega(t,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 58: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t,y) &= 0 \\
\eta(t,y) &= \mathrm{e}^{-t-\ln(t)}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = t
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\mathrm{e}^{-t-\ln(t)}} dy
\end{aligned}
$$

Which results in

$$
S = t\,\mathrm{e}^{t} y
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_t + \omega(t,y) S_y}{R_t + \omega(t,y) R_y} \tag{2}
$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$
\omega(t,y) = -\frac{ty - t + y}{t}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_t &= 1 \\
R_y &= 0 \\
S_t &= y\,\mathrm{e}^{t}(t+1) \\
S_y &= t\,\mathrm{e}^{t}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = t\,\mathrm{e}^{t} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R\,\mathrm{e}^{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = (R-1)\,\mathrm{e}^{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$t\,\mathrm{e}^{t} y = \mathrm{e}^{t}(-1+t) + c_1$$

Which simplifies to

$$t\,\mathrm{e}^{t} y = \mathrm{e}^{t}(-1+t) + c_1$$

Which gives

$$y = \frac{(t\,\mathrm{e}^{t} - \mathrm{e}^{t} + c_1)\,\mathrm{e}^{-t}}{t}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{ty-t+y}{t}$ 	$R = t$ $S = t\,\mathrm{e}^{t} y$	$\frac{dS}{dR} = R\,\mathrm{e}^{R}$ 
Initial conditions are used to solve for c_1. Substituting $t = \ln(2)$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{c_1 + 2\ln(2) - 2}{2\ln(2)}$$

$$c_1 = 2$$

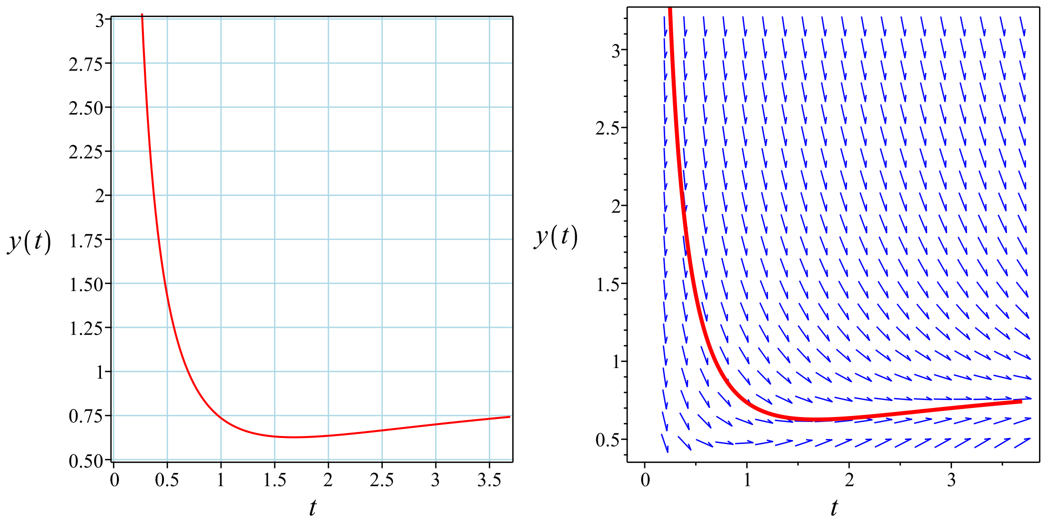
Substituting c_1 found above in the general solution gives

$$y = \frac{\mathrm{e}^{-t}\mathrm{e}^{t}t - \mathrm{e}^{-t}\mathrm{e}^{t} + 2\,\mathrm{e}^{-t}}{t}$$

Summary

The solution(s) found are the following

$$y = \frac{\mathrm{e}^{-t}\mathrm{e}^{t}t - \mathrm{e}^{-t}\mathrm{e}^{t} + 2\,\mathrm{e}^{-t}}{t} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \frac{e^{-t}e^{t}t - e^{-t}e^{t} + 2\,e^{-t}}{t}$$

Verified OK.

1.20.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t + N(t,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(t)\,\mathrm{d}y &= (-(t+1)\,y + t)\,\mathrm{d}t\\ ((t+1)\,y - t)\,\mathrm{d}t + (t)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t,y) &= (t+1)\,y - t\\ N(t,y) &= t\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}((t+1)\,y - t)\\ &= t+1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(t)\\ &= 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right)\\ &= \frac{1}{t}((t+1) - (1))\\ &= 1\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \, \mathrm{d}t} \\ &= e^{\int 1 \, \mathrm{d}t}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{t} \\ &= \mathrm{e}^{t}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \mathrm{e}^{t}((t+1)\,y - t) \\ &= ((y-1)\,t + y)\,\mathrm{e}^{t}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N \\ &= \mathrm{e}^{t}(t) \\ &= t\,\mathrm{e}^{t}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\ \left(((y-1)\,t + y)\,\mathrm{e}^{t}\right) + \left(t\,\mathrm{e}^{t}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int \overline{M} \, \mathrm{d}t \\ \int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int ((y-1)\,t + y)\,\mathrm{e}^{t} \, \mathrm{d}t\end{aligned}$$

$$\phi = (1 + (y-1)\,t)\,\mathrm{e}^{t} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = t\,\mathrm{e}^{t} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = t\,\mathrm{e}^{t}$. Therefore equation (4) becomes

$$t\,\mathrm{e}^{t} = t\,\mathrm{e}^{t} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = (1 + (y-1)\,t)\,\mathrm{e}^{t} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = (1 + (y-1)\,t)\,\mathrm{e}^{t}$$

The solution becomes

$$y = \frac{(t\,\mathrm{e}^{t} - \mathrm{e}^{t} + c_1)\,\mathrm{e}^{-t}}{t}$$

Initial conditions are used to solve for c_1. Substituting $t = \ln(2)$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{c_1 + 2\ln(2) - 2}{2\ln(2)}$$

$$c_1 = 2$$

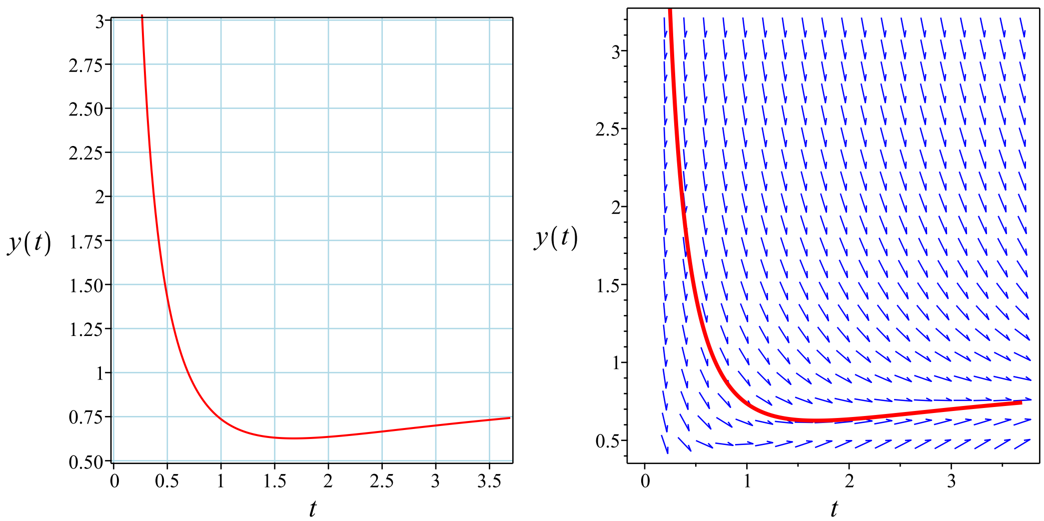
Substituting c_1 found above in the general solution gives

$$y = \frac{\mathrm{e}^{-t}\mathrm{e}^{t}t - \mathrm{e}^{-t}\mathrm{e}^{t} + 2\,\mathrm{e}^{-t}}{t}$$

Summary

The solution(s) found are the following

$$y = \frac{e^{-t}e^{t}t - e^{-t}e^{t} + 2\,e^{-t}}{t} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \frac{e^{-t}e^{t}t - e^{-t}e^{t} + 2\,e^{-t}}{t}$$

Verified OK.

1.20.5 Maple step by step solution

Let's solve

$[(t+1)\,y + ty' = t, y(\ln(2)) = 1]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = 1 - \frac{(t+1)y}{t}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{(t+1)y}{t} = 1$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(y' + \frac{(t+1)y}{t}\right) = \mu(t)$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, y)$

  $\mu(t)\left(y' + \frac{(t+1)y}{t}\right) = \mu'(t)\, y + \mu(t)\, y'$
- Isolate $\mu'(t)$

  $\mu'(t) = \frac{\mu(t)(t+1)}{t}$
- Solve to find the integrating factor

  $\mu(t) = t\, \mathrm{e}^{t}$
- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\, y)\right) dt = \int \mu(t)\, dt + c_1$
- Evaluate the integral on the lhs

  $\mu(t)\, y = \int \mu(t)\, dt + c_1$
- Solve for y

  $y = \frac{\int \mu(t) dt + c_1}{\mu(t)}$
- Substitute $\mu(t) = t\mathrm{e}^{t}$

  $y = \frac{\int t\, \mathrm{e}^{t} dt + c_1}{t\, \mathrm{e}^{t}}$
- Evaluate the integrals on the rhs

  $y = \frac{\mathrm{e}^{t}(-1+t) + c_1}{t\, \mathrm{e}^{t}}$
- Simplify

  $y = \frac{c_1 \mathrm{e}^{-t} + t - 1}{t}$
- Use initial condition $y(\ln(2)) = 1$

  $1 = \frac{\frac{c_1}{2} + \ln(2) - 1}{\ln(2)}$
- Solve for c_1

  $c_1 = 2$
- Substitute $c_1 = 2$ into general solution and simplify

  $y = \frac{-1 + 2\, \mathrm{e}^{-t} + t}{t}$
- Solution to the IVP

  $y = \frac{-1 + 2\, \mathrm{e}^{-t} + t}{t}$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{-\frac{y}{2}+y'=2\cos\left(t\right)}$$

With initial conditions

$$[y(0)=a]$$

1.21.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'+p(t)y=q(t)$$

Where here

$$p(t)=-\frac{1}{2}$$
$$q(t)=2\cos\left(t\right)$$

Hence the ode is

$$-\frac{y}{2}+y'=2\cos\left(t\right)$$

The domain of $p(t)=-\frac{1}{2}$ is

$$\{-\infty<t<\infty\}$$

And the point $t_0=0$ is inside this domain. The domain of $q(t)=2\cos\left(t\right)$ is

$$\{-\infty<t<\infty\}$$

And the point $t_0=0$ is also inside this domain. Hence solution exists and is unique.

1.21.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{1}{2}dt}\\ &= \mathrm{e}^{-\frac{t}{2}}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}(\mu y) &= (\mu)\left(2\cos\left(t\right)\right)\\ \frac{\mathrm{d}}{\mathrm{d}t}\left(\mathrm{e}^{-\frac{t}{2}}y\right) &= \left(\mathrm{e}^{-\frac{t}{2}}\right)\left(2\cos\left(t\right)\right)\\ \mathrm{d}\left(\mathrm{e}^{-\frac{t}{2}}y\right) &= \left(2\cos\left(t\right)\mathrm{e}^{-\frac{t}{2}}\right)\,\mathrm{d}t\end{aligned}$$

Integrating gives

$$\begin{aligned}\mathrm{e}^{-\frac{t}{2}}y &= \int 2\cos\left(t\right)\mathrm{e}^{-\frac{t}{2}}\,\mathrm{d}t\\ \mathrm{e}^{-\frac{t}{2}}y &= -\frac{4\cos\left(t\right)\mathrm{e}^{-\frac{t}{2}}}{5}+\frac{8\sin\left(t\right)\mathrm{e}^{-\frac{t}{2}}}{5}+c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu=\mathrm{e}^{-\frac{t}{2}}$ results in

$$y=\mathrm{e}^{\frac{t}{2}}\left(-\frac{4\cos\left(t\right)\mathrm{e}^{-\frac{t}{2}}}{5}+\frac{8\sin\left(t\right)\mathrm{e}^{-\frac{t}{2}}}{5}\right)+c_1\mathrm{e}^{\frac{t}{2}}$$

which simplifies to

$$y = c_1 e^{\frac{t}{2}} + \frac{8 \sin(t)}{5} - \frac{4 \cos(t)}{5}$$

Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = c_1 - \frac{4}{5}$$

$$c_1 = \frac{4}{5} + a$$

Substituting c_1 found above in the general solution gives

$$y = \left(\frac{4}{5} + a\right) e^{\frac{t}{2}} + \frac{8 \sin(t)}{5} - \frac{4 \cos(t)}{5}$$

Summary
The solution(s) found are the following

$$y = \left(\frac{4}{5} + a\right) e^{\frac{t}{2}} + \frac{8 \sin(t)}{5} - \frac{4 \cos(t)}{5} \tag{1}$$

Verification of solutions

$$y = \left(\frac{4}{5} + a\right) e^{\frac{t}{2}} + \frac{8 \sin(t)}{5} - \frac{4 \cos(t)}{5}$$

Verified OK.

1.21.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y}{2} + 2 \cos(t)$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 61: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \mathrm{e}^{\frac{t}{2}}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{\frac{t}{2}}} dy \end{aligned}$$

Which results in

$$S = e^{-\frac{t}{2}} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = \frac{y}{2} + 2\cos(t)$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= -\frac{e^{-\frac{t}{2}} y}{2} \\ S_y &= e^{-\frac{t}{2}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 2\cos(t)\, e^{-\frac{t}{2}} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 2\cos(R)\, e^{-\frac{R}{2}}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = c_1 - \frac{4\,\mathrm{e}^{-\frac{R}{2}}(\cos(R) - 2\sin(R))}{5} \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\mathrm{e}^{-\frac{t}{2}} y = c_1 - \frac{4\,\mathrm{e}^{-\frac{t}{2}}(\cos(t) - 2\sin(t))}{5}$$

Which simplifies to

$$\mathrm{e}^{-\frac{t}{2}} y = c_1 - \frac{4\,\mathrm{e}^{-\frac{t}{2}}(\cos(t) - 2\sin(t))}{5}$$

Which gives

$$y = -\frac{\mathrm{e}^{\frac{t}{2}}\left(4\cos(t)\,\mathrm{e}^{-\frac{t}{2}} - 8\sin(t)\,\mathrm{e}^{-\frac{t}{2}} - 5c_1\right)}{5}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = \frac{y}{2} + 2\cos(t)$ 	$R = t$ $S = \mathrm{e}^{-\frac{t}{2}} y$	$\frac{dS}{dR} = 2\cos(R)\,\mathrm{e}^{-\frac{R}{2}}$ 
Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = c_1 - \frac{4}{5}$$

$$c_1 = \frac{4}{5} + a$$

Substituting c_1 found above in the general solution gives

$$y = -\frac{\left(4\cos(t)\,\mathrm{e}^{-\frac{t}{2}} - 8\sin(t)\,\mathrm{e}^{-\frac{t}{2}} - 4 - 5a\right)\mathrm{e}^{\frac{t}{2}}}{5}$$

Summary

The solution(s) found are the following

$$y = -\frac{\left(4\cos(t)\,\mathrm{e}^{-\frac{t}{2}} - 8\sin(t)\,\mathrm{e}^{-\frac{t}{2}} - 4 - 5a\right)\mathrm{e}^{\frac{t}{2}}}{5} \tag{1}$$

Verification of solutions

$$y = -\frac{\left(4\cos(t)\,\mathrm{e}^{-\frac{t}{2}} - 8\sin(t)\,\mathrm{e}^{-\frac{t}{2}} - 4 - 5a\right)\mathrm{e}^{\frac{t}{2}}}{5}$$

Verified OK.

1.21.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t + N(t,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\mathrm{d}y &= \left(\frac{y}{2} + 2\cos(t)\right)\mathrm{d}t\\ \left(-\frac{y}{2} - 2\cos(t)\right)\mathrm{d}t + \mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t,y) &= -\frac{y}{2} - 2\cos(t)\\ N(t,y) &= 1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{y}{2} - 2\cos(t)\right)\\ &= -\frac{1}{2}\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(1) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\
&= 1\left(\left(-\frac{1}{2}\right) - (0)\right) \\
&= -\frac{1}{2}
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}t} \\
&= e^{\int -\frac{1}{2} \, \mathrm{d}t}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-\frac{t}{2}} \\
&= \mathrm{e}^{-\frac{t}{2}}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{-\frac{t}{2}}\left(-\frac{y}{2} - 2\cos(t)\right) \\
&= -\frac{(y + 4\cos(t))\,\mathrm{e}^{-\frac{t}{2}}}{2}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-\frac{t}{2}}(1) \\
&= \mathrm{e}^{-\frac{t}{2}}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} = 0$$
$$\left(-\frac{(y + 4\cos(t))\,\mathrm{e}^{-\frac{t}{2}}}{2}\right) + \left(\mathrm{e}^{-\frac{t}{2}}\right)\frac{\mathrm{d}y}{\mathrm{d}t} = 0$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial\phi}{\partial t} = \overline{M} \tag{1}$$
$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial\phi}{\partial t}\,\mathrm{d}t = \int \overline{M}\,\mathrm{d}t$$
$$\int \frac{\partial\phi}{\partial t}\,\mathrm{d}t = \int -\frac{(y + 4\cos(t))\,\mathrm{e}^{-\frac{t}{2}}}{2}\,\mathrm{d}t$$
$$\phi = \frac{(5y + 4\cos(t) - 8\sin(t))\,\mathrm{e}^{-\frac{t}{2}}}{5} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial\phi}{\partial y} = \mathrm{e}^{-\frac{t}{2}} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = \mathrm{e}^{-\frac{t}{2}}$. Therefore equation (4) becomes

$$\mathrm{e}^{-\frac{t}{2}} = \mathrm{e}^{-\frac{t}{2}} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{\left(5y + 4\cos\left(t\right) - 8\sin\left(t\right)\right) e^{-\frac{t}{2}}}{5} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{\left(5y + 4\cos\left(t\right) - 8\sin\left(t\right)\right) e^{-\frac{t}{2}}}{5}$$

The solution becomes

$$y = -\frac{e^{\frac{t}{2}} \left(4\cos\left(t\right) e^{-\frac{t}{2}} - 8\sin\left(t\right) e^{-\frac{t}{2}} - 5c_1\right)}{5}$$

Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = c_1 - \frac{4}{5}$$

$$c_1 = \frac{4}{5} + a$$

Substituting c_1 found above in the general solution gives

$$y = -\frac{\left(4\cos\left(t\right) e^{-\frac{t}{2}} - 8\sin\left(t\right) e^{-\frac{t}{2}} - 4 - 5a\right) e^{\frac{t}{2}}}{5}$$

Summary

The solution(s) found are the following

$$y = -\frac{\left(4\cos\left(t\right) e^{-\frac{t}{2}} - 8\sin\left(t\right) e^{-\frac{t}{2}} - 4 - 5a\right) e^{\frac{t}{2}}}{5} \tag{1}$$

Verification of solutions

$$y = -\frac{\left(4\cos\left(t\right) e^{-\frac{t}{2}} - 8\sin\left(t\right) e^{-\frac{t}{2}} - 4 - 5a\right) e^{\frac{t}{2}}}{5}$$

Verified OK.

1.21.5 Maple step by step solution

Let's solve

$\left[-\frac{y}{2}+y'=2\cos\left(t\right), y(0)=a\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y'=\frac{y}{2}+2\cos\left(t\right)$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $-\frac{y}{2}+y'=2\cos\left(t\right)$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(-\frac{y}{2}+y'\right)=2\mu(t)\cos\left(t\right)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

  $\mu(t)\left(-\frac{y}{2}+y'\right)=\mu'(t)\,y+\mu(t)\,y'$

- Isolate $\mu'(t)$

  $\mu'(t)=-\frac{\mu(t)}{2}$

- Solve to find the integrating factor

  $\mu(t)=\mathrm{e}^{-\frac{t}{2}}$

- Integrate both sides with respect to t

  $\int\left(\frac{d}{dt}(\mu(t)\,y)\right)dt=\int 2\mu(t)\cos\left(t\right)dt+c_1$

- Evaluate the integral on the lhs

  $\mu(t)\,y=\int 2\mu(t)\cos\left(t\right)dt+c_1$

- Solve for y

  $y=\frac{\int 2\mu(t)\cos(t)dt+c_1}{\mu(t)}$

- Substitute $\mu(t)=\mathrm{e}^{-\frac{t}{2}}$

  $y=\frac{\int 2\cos(t)\mathrm{e}^{-\frac{t}{2}}dt+c_1}{\mathrm{e}^{-\frac{t}{2}}}$

- Evaluate the integrals on the rhs

  $y=\frac{-\frac{4\cos(t)\mathrm{e}^{-\frac{t}{2}}}{5}+\frac{8\sin(t)\mathrm{e}^{-\frac{t}{2}}}{5}+c_1}{\mathrm{e}^{-\frac{t}{2}}}$

- Simplify

$$y = c_1 e^{\frac{t}{2}} + \frac{8\sin(t)}{5} - \frac{4\cos(t)}{5}$$

- Use initial condition $y(0) = a$

$$a = c_1 - \frac{4}{5}$$

- Solve for c_1

$$c_1 = \frac{4}{5} + a$$

- Substitute $c_1 = \frac{4}{5} + a$ into general solution and simplify

$$y = e^{\frac{t}{2}} a - \frac{4\cos(t)}{5} + \frac{8\sin(t)}{5} + \frac{4 e^{\frac{t}{2}}}{5}$$

- Solution to the IVP

$$y = e^{\frac{t}{2}} a - \frac{4\cos(t)}{5} + \frac{8\sin(t)}{5} + \frac{4 e^{\frac{t}{2}}}{5}$$

Problem number: 22.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{-y + 2y' = \mathrm{e}^{\frac{t}{3}}}$$

With initial conditions

$$[y(0) = a]$$

1.22.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = -\frac{1}{2}$$
$$q(t) = \frac{\mathrm{e}^{\frac{t}{3}}}{2}$$

Hence the ode is

$$-\frac{y}{2}+y'=\frac{\mathrm{e}^{\frac{t}{3}}}{2}$$

The domain of $p(t)=-\frac{1}{2}$ is

$$\{-\infty<t<\infty\}$$

And the point $t_0=0$ is inside this domain. The domain of $q(t)=\frac{\mathrm{e}^{\frac{t}{3}}}{2}$ is

$$\{-\infty<t<\infty\}$$

And the point $t_0=0$ is also inside this domain. Hence solution exists and is unique.

1.22.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{1}{2}dt}\\ &= \mathrm{e}^{-\frac{t}{2}}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}(\mu y) &= (\mu)\left(\frac{\mathrm{e}^{\frac{t}{3}}}{2}\right)\\ \frac{\mathrm{d}}{\mathrm{d}t}\left(\mathrm{e}^{-\frac{t}{2}}y\right) &= \left(\mathrm{e}^{-\frac{t}{2}}\right)\left(\frac{\mathrm{e}^{\frac{t}{3}}}{2}\right)\\ \mathrm{d}\left(\mathrm{e}^{-\frac{t}{2}}y\right) &= \left(\frac{\mathrm{e}^{-\frac{t}{6}}}{2}\right)\mathrm{d}t\end{aligned}$$

Integrating gives

$$\begin{aligned}\mathrm{e}^{-\frac{t}{2}}y &= \int \frac{\mathrm{e}^{-\frac{t}{6}}}{2}\,\mathrm{d}t\\ \mathrm{e}^{-\frac{t}{2}}y &= -3\,\mathrm{e}^{-\frac{t}{6}}+c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu=\mathrm{e}^{-\frac{t}{2}}$ results in

$$y=-3\,\mathrm{e}^{\frac{t}{2}}\mathrm{e}^{-\frac{t}{6}}+c_1\mathrm{e}^{\frac{t}{2}}$$

which simplifies to

$$y = -3\,\mathrm{e}^{\frac{t}{3}} + c_1 \mathrm{e}^{\frac{t}{2}}$$

Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = -3 + c_1$$

$$c_1 = 3 + a$$

Substituting c_1 found above in the general solution gives

$$y = -3\,\mathrm{e}^{\frac{t}{3}} + (3 + a)\,\mathrm{e}^{\frac{t}{2}}$$

Summary
The solution(s) found are the following

$$y = -3\,\mathrm{e}^{\frac{t}{3}} + (3 + a)\,\mathrm{e}^{\frac{t}{2}} \tag{1}$$

Verification of solutions

$$y = -3\,\mathrm{e}^{\frac{t}{3}} + (3 + a)\,\mathrm{e}^{\frac{t}{2}}$$

Verified OK.

1.22.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y}{2} + \frac{\mathrm{e}^{\frac{t}{3}}}{2}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 64: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int(n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(t, y) &= 0 \\ \eta(t, y) &= e^{\frac{t}{2}} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{\frac{t}{2}}} dy \end{aligned}$$

Which results in

$$S = e^{-\frac{t}{2}} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = \frac{y}{2} + \frac{e^{\frac{t}{3}}}{2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= -\frac{e^{-\frac{t}{2}} y}{2} \\ S_y &= e^{-\frac{t}{2}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{e^{-\frac{t}{6}}}{2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{e^{-\frac{R}{6}}}{2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -3\,\mathrm{e}^{-\frac{R}{6}} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\mathrm{e}^{-\frac{t}{2}} y = -3\,\mathrm{e}^{-\frac{t}{6}} + c_1$$

Which simplifies to

$$\mathrm{e}^{-\frac{t}{2}} y = -3\,\mathrm{e}^{-\frac{t}{6}} + c_1$$

Which gives

$$y = -\left(3\,\mathrm{e}^{-\frac{t}{6}} - c_1\right) \mathrm{e}^{\frac{t}{2}}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = \frac{y}{2} + \frac{\mathrm{e}^{\frac{t}{3}}}{2}$  	$R = t$ $S = \mathrm{e}^{-\frac{t}{2}} y$	$\frac{dS}{dR} = \frac{\mathrm{e}^{-\frac{R}{6}}}{2}$ 
Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = -3 + c_1$$

$$c_1 = 3 + a$$

Substituting c_1 found above in the general solution gives

$$y = -\left(3\,\mathrm{e}^{-\frac{t}{6}} - 3 - a\right)\mathrm{e}^{\frac{t}{2}}$$

Summary

The solution(s) found are the following

$$y = -\left(3\,\mathrm{e}^{-\frac{t}{6}} - 3 - a\right)\mathrm{e}^{\frac{t}{2}} \tag{1}$$

Verification of solutions

$$y = -\left(3\,\mathrm{e}^{-\frac{t}{6}} - 3 - a\right)\mathrm{e}^{\frac{t}{2}}$$

Verified OK.

1.22.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t + N(t,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(2)\,\mathrm{d}y &= \left(y + \mathrm{e}^{\frac{t}{3}}\right)\mathrm{d}t\\ \left(-y - \mathrm{e}^{\frac{t}{3}}\right)\mathrm{d}t + (2)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t,y) &= -y - \mathrm{e}^{\frac{t}{3}}\\ N(t,y) &= 2\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-y - \mathrm{e}^{\frac{t}{3}}\right)\\ &= -1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(2)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right)\\ &= \frac{1}{2}((-1) - (0))\\ &= -\frac{1}{2}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}t} \\
&= e^{\int -\frac{1}{2} \, \mathrm{d}t}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-\frac{t}{2}} \\
&= \mathrm{e}^{-\frac{t}{2}}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{-\frac{t}{2}} \left(-y - \mathrm{e}^{\frac{t}{3}}\right) \\
&= -\left(y + \mathrm{e}^{\frac{t}{3}}\right) \mathrm{e}^{-\frac{t}{2}}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-\frac{t}{2}} (2) \\
&= 2\,\mathrm{e}^{-\frac{t}{2}}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N} \frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\
\left(-\left(y + \mathrm{e}^{\frac{t}{3}}\right) \mathrm{e}^{-\frac{t}{2}}\right) + \left(2\,\mathrm{e}^{-\frac{t}{2}}\right) \frac{\mathrm{d}y}{\mathrm{d}t} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$
\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. t gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int \overline{M} \, \mathrm{d}t \\
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int -\left(y + \mathrm{e}^{\frac{t}{3}}\right) \mathrm{e}^{-\frac{t}{2}} \, \mathrm{d}t
\end{aligned}
$$

$$
\phi = 2\,\mathrm{e}^{-\frac{t}{2}} y + 6\,\mathrm{e}^{-\frac{t}{6}} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2\,\mathrm{e}^{-\frac{t}{2}} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2\,\mathrm{e}^{-\frac{t}{2}}$. Therefore equation (4) becomes

$$2\,\mathrm{e}^{-\frac{t}{2}} = 2\,\mathrm{e}^{-\frac{t}{2}} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = 2\,\mathrm{e}^{-\frac{t}{2}} y + 6\,\mathrm{e}^{-\frac{t}{6}} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = 2\,\mathrm{e}^{-\frac{t}{2}} y + 6\,\mathrm{e}^{-\frac{t}{6}}$$

The solution becomes

$$y = -\frac{\left(6\,\mathrm{e}^{-\frac{t}{6}} - c_1\right) \mathrm{e}^{\frac{t}{2}}}{2}$$

Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = -3 + \frac{c_1}{2}$$

$$c_1 = 6 + 2a$$

Substituting c_1 found above in the general solution gives

$$y = -\frac{\left(6\,\mathrm{e}^{-\frac{t}{6}}-6-2a\right)\mathrm{e}^{\frac{t}{2}}}{2}$$

Summary

The solution(s) found are the following

$$y = -\frac{\left(6\,\mathrm{e}^{-\frac{t}{6}}-6-2a\right)\mathrm{e}^{\frac{t}{2}}}{2} \tag{1}$$

Verification of solutions

$$y = -\frac{\left(6\,\mathrm{e}^{-\frac{t}{6}}-6-2a\right)\mathrm{e}^{\frac{t}{2}}}{2}$$

Verified OK.

1.22.5 Maple step by step solution

Let's solve

$\left[-y+2y'=\mathrm{e}^{\frac{t}{3}}, y(0)=a\right]$

- Highest derivative means the order of the ODE is 1

  y'
- Isolate the derivative

  $y'=\frac{y}{2}+\frac{\mathrm{e}^{\frac{t}{3}}}{2}$
- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $-\frac{y}{2}+y'=\frac{\mathrm{e}^{\frac{t}{3}}}{2}$
- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(-\frac{y}{2}+y'\right)=\frac{\mu(t)\mathrm{e}^{\frac{t}{3}}}{2}$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

  $\mu(t)\left(-\frac{y}{2}+y'\right)=\mu'(t)\,y+\mu(t)\,y'$
- Isolate $\mu'(t)$

  $\mu'(t)=-\frac{\mu(t)}{2}$
- Solve to find the integrating factor

$\mu(t) = \mathrm{e}^{-\frac{t}{2}}$

- Integrate both sides with respect to t

$$\int \left(\frac{d}{dt}(\mu(t)\,y)\right) dt = \int \frac{\mu(t)\mathrm{e}^{\frac{t}{3}}}{2} dt + c_1$$

- Evaluate the integral on the lhs

$$\mu(t)\,y = \int \frac{\mu(t)\mathrm{e}^{\frac{t}{3}}}{2} dt + c_1$$

- Solve for y

$$y = \frac{\int \frac{\mu(t)\mathrm{e}^{\frac{t}{3}}}{2} dt + c_1}{\mu(t)}$$

- Substitute $\mu(t) = \mathrm{e}^{-\frac{t}{2}}$

$$y = \frac{\int \frac{\mathrm{e}^{\frac{t}{3}}\mathrm{e}^{-\frac{t}{2}}}{2} dt + c_1}{\mathrm{e}^{-\frac{t}{2}}}$$

- Evaluate the integrals on the rhs

$$y = \frac{-3\,\mathrm{e}^{-\frac{t}{6}} + c_1}{\mathrm{e}^{-\frac{t}{2}}}$$

- Simplify

$$y = \mathrm{e}^{\frac{t}{3}}\left(\mathrm{e}^{\frac{t}{6}} c_1 - 3\right)$$

- Use initial condition $y(0) = a$

$$a = -3 + c_1$$

- Solve for c_1

$$c_1 = 3 + a$$

- Substitute $c_1 = 3 + a$ into general solution and simplify

$$y = \mathrm{e}^{\frac{t}{3}}\left(\mathrm{e}^{\frac{t}{6}}(3 + a) - 3\right)$$

- Solution to the IVP

$$y = \mathrm{e}^{\frac{t}{3}}\left(\mathrm{e}^{\frac{t}{6}}(3 + a) - 3\right)$$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{-2y + 3y' = e^{-\frac{\pi t}{2}}}$$

With initial conditions

$$[y(0) = a]$$

1.23.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = -\frac{2}{3}$$
$$q(t) = \frac{e^{-\frac{\pi t}{2}}}{3}$$

Hence the ode is

$$y' - \frac{2y}{3} = \frac{e^{-\frac{\pi t}{2}}}{3}$$

The domain of $p(t) = -\frac{2}{3}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = \frac{e^{-\frac{\pi t}{2}}}{3}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

1.23.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int -\frac{2}{3}dt} \\
&= e^{-\frac{2t}{3}}
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dt}(\mu y) &= (\mu)\left(\frac{e^{-\frac{\pi t}{2}}}{3}\right) \\
\frac{d}{dt}\left(e^{-\frac{2t}{3}} y\right) &= \left(e^{-\frac{2t}{3}}\right)\left(\frac{e^{-\frac{\pi t}{2}}}{3}\right) \\
d\left(e^{-\frac{2t}{3}} y\right) &= \left(\frac{e^{t\left(-\frac{\pi}{2}-\frac{2}{3}\right)}}{3}\right) dt
\end{aligned}$$

Integrating gives

$$\begin{aligned}
e^{-\frac{2t}{3}} y &= \int \frac{e^{t\left(-\frac{\pi}{2}-\frac{2}{3}\right)}}{3} dt \\
e^{-\frac{2t}{3}} y &= -\frac{2\,e^{-\frac{t(3\pi+4)}{6}}}{3\pi+4} + c_1
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-\frac{2t}{3}}$ results in

$$y = -\frac{2\,e^{\frac{2t}{3}}\,e^{-\frac{t(3\pi+4)}{6}}}{3\pi+4} + c_1 e^{\frac{2t}{3}}$$

which simplifies to

$$y = \frac{-2\,e^{-\frac{\pi t}{2}} + (3\pi + 4)\,c_1 e^{\frac{2t}{3}}}{3\pi + 4}$$

Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = \frac{3\pi c_1 + 4c_1 - 2}{3\pi + 4}$$

$$c_1 = \frac{3\pi a + 4a + 2}{3\pi + 4}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{-2\,e^{-\frac{\pi t}{2}} + (3\pi a + 4a + 2)\,e^{\frac{2t}{3}}}{3\pi + 4}$$

Summary

The solution(s) found are the following

$$y = \frac{-2\,e^{-\frac{\pi t}{2}} + (3\pi a + 4a + 2)\,e^{\frac{2t}{3}}}{3\pi + 4} \tag{1}$$

Verification of solutions

$$y = \frac{-2\,e^{-\frac{\pi t}{2}} + (3\pi a + 4a + 2)\,e^{\frac{2t}{3}}}{3\pi + 4}$$

Verified OK.

1.23.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{2y}{3} + \frac{e^{-\frac{\pi t}{2}}}{3}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 67: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \mathrm{e}^{\frac{2t}{3}} \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \qquad (1)
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{\frac{2t}{3}}} dy \end{aligned}$$

Which results in

$$S = e^{-\frac{2t}{3}} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = \frac{2y}{3} + \frac{e^{-\frac{\pi t}{2}}}{3}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= -\frac{2 e^{-\frac{2t}{3}} y}{3} \\ S_y &= e^{-\frac{2t}{3}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{e^{t\left(-\frac{\pi}{2} - \frac{2}{3}\right)}}{3} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{e^{R\left(-\frac{\pi}{2} - \frac{2}{3}\right)}}{3}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\frac{2\,\mathrm{e}^{-\frac{R(3\pi+4)}{6}}}{3\pi+4} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\mathrm{e}^{-\frac{2t}{3}} y = -\frac{2\,\mathrm{e}^{-\frac{t(3\pi+4)}{6}}}{3\pi+4} + c_1$$

Which simplifies to

$$\mathrm{e}^{-\frac{2t}{3}} y = -\frac{2\,\mathrm{e}^{-\frac{t(3\pi+4)}{6}}}{3\pi+4} + c_1$$

Which gives

$$y = \frac{\left(3\pi c_1 - 2\,\mathrm{e}^{-\frac{t(3\pi+4)}{6}} + 4c_1\right)\mathrm{e}^{\frac{2t}{3}}}{3\pi+4}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = \frac{2y}{3} + \frac{\mathrm{e}^{-\frac{\pi t}{2}}}{3}$ 	$R = t$ $S = \mathrm{e}^{-\frac{2t}{3}} y$	$\frac{dS}{dR} = \frac{\mathrm{e}^{R\left(-\frac{\pi}{2}-\frac{2}{3}\right)}}{3}$ 
Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = \frac{3\pi c_1 + 4c_1 - 2}{3\pi + 4}$$

$$c_1 = \frac{3\pi a + 4a + 2}{3\pi + 4}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{\left(\frac{3\pi(3\pi a+4a+2)}{3\pi+4} - 2\,\mathrm{e}^{-\frac{t(3\pi+4)}{6}} + \frac{12\pi a+16a+8}{3\pi+4}\right)\mathrm{e}^{\frac{2t}{3}}}{3\pi + 4}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(\frac{3\pi(3\pi a+4a+2)}{3\pi+4} - 2\,\mathrm{e}^{-\frac{t(3\pi+4)}{6}} + \frac{12\pi a+16a+8}{3\pi+4}\right)\mathrm{e}^{\frac{2t}{3}}}{3\pi + 4} \tag{1}$$

Verification of solutions

$$y = \frac{\left(\frac{3\pi(3\pi a+4a+2)}{3\pi+4} - 2\,\mathrm{e}^{-\frac{t(3\pi+4)}{6}} + \frac{12\pi a+16a+8}{3\pi+4}\right)\mathrm{e}^{\frac{2t}{3}}}{3\pi + 4}$$

Verified OK.

1.23.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\, \mathrm{d}t + N(t, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(3)\, \mathrm{d}y = \left(2y + \mathrm{e}^{-\frac{\pi t}{2}}\right) \mathrm{d}t$$
$$\left(-2y - \mathrm{e}^{-\frac{\pi t}{2}}\right) \mathrm{d}t + (3)\, \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(t, y) = -2y - \mathrm{e}^{-\frac{\pi t}{2}}$$
$$N(t, y) = 3$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-2y - \mathrm{e}^{-\frac{\pi t}{2}}\right)$$
$$= -2$$

And

$$\frac{\partial N}{\partial t} = \frac{\partial}{\partial t}(3)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\
&= \frac{1}{3}((-2) - (0)) \\
&= -\frac{2}{3}
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}t} \\
&= e^{\int -\frac{2}{3} \, \mathrm{d}t}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-\frac{2t}{3}} \\
&= \mathrm{e}^{-\frac{2t}{3}}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{-\frac{2t}{3}}\left(-2y - \mathrm{e}^{-\frac{\pi t}{2}}\right) \\
&= -\left(2y + \mathrm{e}^{-\frac{\pi t}{2}}\right)\mathrm{e}^{-\frac{2t}{3}}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-\frac{2t}{3}}(3) \\
&= 3\,\mathrm{e}^{-\frac{2t}{3}}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\
\left(-\left(2y + \mathrm{e}^{-\frac{\pi t}{2}}\right)\mathrm{e}^{-\frac{2t}{3}}\right) + \left(3\,\mathrm{e}^{-\frac{2t}{3}}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t}\,\mathrm{d}t = \int \overline{M}\,\mathrm{d}t$$

$$\int \frac{\partial \phi}{\partial t}\,\mathrm{d}t = \int -\left(2y + \mathrm{e}^{-\frac{\pi t}{2}}\right)\mathrm{e}^{-\frac{2t}{3}}\,\mathrm{d}t$$

$$\phi = \frac{6\,\mathrm{e}^{t\left(-\frac{\pi}{2}-\frac{2}{3}\right)} + 3y(3\pi+4)\,\mathrm{e}^{-\frac{2t}{3}}}{3\pi+4} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 3\,\mathrm{e}^{-\frac{2t}{3}} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 3\,\mathrm{e}^{-\frac{2t}{3}}$. Therefore equation (4) becomes

$$3\,\mathrm{e}^{-\frac{2t}{3}} = 3\,\mathrm{e}^{-\frac{2t}{3}} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{6\,\mathrm{e}^{t\left(-\frac{\pi}{2}-\frac{2}{3}\right)} + 3y(3\pi+4)\,\mathrm{e}^{-\frac{2t}{3}}}{3\pi+4} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{6\,\mathrm{e}^{t\left(-\frac{\pi}{2}-\frac{2}{3}\right)} + 3y(3\pi+4)\,\mathrm{e}^{-\frac{2t}{3}}}{3\pi+4}$$

The solution becomes

$$y = \frac{\left(3\pi c_1 - 6\,\mathrm{e}^{-\frac{t(3\pi+4)}{6}} + 4c_1\right)\mathrm{e}^{\frac{2t}{3}}}{9\pi + 12}$$

Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = \frac{3\pi c_1 + 4c_1 - 6}{9\pi + 12}$$

$$c_1 = \frac{9\pi a + 12a + 6}{3\pi + 4}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{\left(\frac{9\pi(3\pi a+4a+2)}{3\pi+4} - 6\,\mathrm{e}^{-\frac{t(3\pi+4)}{6}} + \frac{36\pi a+48a+24}{3\pi+4}\right)\mathrm{e}^{\frac{2t}{3}}}{9\pi + 12}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(\frac{9\pi(3\pi a+4a+2)}{3\pi+4} - 6\,\mathrm{e}^{-\frac{t(3\pi+4)}{6}} + \frac{36\pi a+48a+24}{3\pi+4}\right)\mathrm{e}^{\frac{2t}{3}}}{9\pi + 12} \tag{1}$$

Verification of solutions

$$y = \frac{\left(\frac{9\pi(3\pi a+4a+2)}{3\pi+4} - 6\,\mathrm{e}^{-\frac{t(3\pi+4)}{6}} + \frac{36\pi a+48a+24}{3\pi+4}\right)\mathrm{e}^{\frac{2t}{3}}}{9\pi + 12}$$

Verified OK.

1.23.5 Maple step by step solution

Let's solve

$\left[-2y + 3y' = \mathrm{e}^{-\frac{\pi t}{2}}, y(0) = a\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \frac{2y}{3} + \frac{\mathrm{e}^{-\frac{\pi t}{2}}}{3}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - \frac{2y}{3} = \frac{e^{-\frac{\pi t}{2}}}{3}$
- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t) \left(y' - \frac{2y}{3}\right) = \frac{\mu(t) e^{-\frac{\pi t}{2}}}{3}$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t) \, y)$

  $\mu(t) \left(y' - \frac{2y}{3}\right) = \mu'(t) \, y + \mu(t) \, y'$
- Isolate $\mu'(t)$

  $\mu'(t) = -\frac{2\mu(t)}{3}$
- Solve to find the integrating factor

  $\mu(t) = e^{-\frac{2t}{3}}$
- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t) \, y)\right) dt = \int \frac{\mu(t) e^{-\frac{\pi t}{2}}}{3} dt + c_1$
- Evaluate the integral on the lhs

  $\mu(t) \, y = \int \frac{\mu(t) e^{-\frac{\pi t}{2}}}{3} dt + c_1$
- Solve for y

  $y = \frac{\int \frac{\mu(t) e^{-\frac{\pi t}{2}}}{3} dt + c_1}{\mu(t)}$
- Substitute $\mu(t) = e^{-\frac{2t}{3}}$

  $y = \frac{\int \frac{e^{-\frac{\pi t}{2}} e^{-\frac{2t}{3}}}{3} dt + c_1}{e^{-\frac{2t}{3}}}$
- Evaluate the integrals on the rhs

  $y = \frac{-\frac{2 e^{-\frac{1}{2}\pi t - \frac{2}{3}t}}{3\pi + 4} + c_1}{e^{-\frac{2t}{3}}}$
- Simplify

  $y = \frac{\left(3\pi c_1 - 2 e^{t\left(-\frac{\pi}{2} - \frac{2}{3}\right)} + 4c_1\right) e^{\frac{2t}{3}}}{3\pi + 4}$
- Use initial condition $y(0) = a$

  $a = \frac{3\pi c_1 + 4c_1 - 2}{3\pi + 4}$
- Solve for c_1

  $c_1 = \frac{3\pi a + 4a + 2}{3\pi + 4}$

- Substitute $c_1 = \frac{3\pi a+4a+2}{3\pi+4}$ into general solution and simplify

$$y = \frac{\left(3\pi a-2\,\mathrm{e}^{t\left(-\frac{\pi}{2}-\frac{2}{3}\right)}+4a+2\right)\mathrm{e}^{\frac{2t}{3}}}{3\pi+4}$$

- Solution to the IVP

$$y = \frac{\left(3\pi a-2\,\mathrm{e}^{t\left(-\frac{\pi}{2}-\frac{2}{3}\right)}+4a+2\right)\mathrm{e}^{\frac{2t}{3}}}{3\pi+4}$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{(t+1)\,y+ty'=2t\,\mathrm{e}^{-t}}$$

With initial conditions

$$[y(1)=a]$$

1.24.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'+p(t)y=q(t)$$

Where here

$$p(t)=-\frac{-t-1}{t}$$
$$q(t)=2\,\mathrm{e}^{-t}$$

Hence the ode is

$$y' - \frac{(-t-1)\,y}{t} = 2\,\mathrm{e}^{-t}$$

The domain of $p(t) = -\frac{-t-1}{t}$ is

$$\{t < 0 \lor 0 < t\}$$

And the point $t_0 = 1$ is inside this domain. The domain of $q(t) = 2\,\mathrm{e}^{-t}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 1$ is also inside this domain. Hence solution exists and is unique.

1.24.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{-t-1}{t}dt} \\ &= \mathrm{e}^{t+\ln(t)}\end{aligned}$$

Which simplifies to

$$\mu = t\,\mathrm{e}^{t}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}(\mu y) &= (\mu)\left(2\,\mathrm{e}^{-t}\right) \\ \frac{\mathrm{d}}{\mathrm{d}t}\left(t\,\mathrm{e}^{t} y\right) &= \left(t\,\mathrm{e}^{t}\right)\left(2\,\mathrm{e}^{-t}\right) \\ \mathrm{d}\left(t\,\mathrm{e}^{t} y\right) &= (2t)\;\mathrm{d}t\end{aligned}$$

Integrating gives

$$\begin{aligned}t\,\mathrm{e}^{t} y &= \int 2t\,\mathrm{d}t \\ t\,\mathrm{e}^{t} y &= t^{2} + c_{1}\end{aligned}$$

Dividing both sides by the integrating factor $\mu = t\,\mathrm{e}^{t}$ results in

$$y = t\,\mathrm{e}^{-t} + \frac{c_{1}\mathrm{e}^{-t}}{t}$$

which simplifies to

$$y = \frac{e^{-t}(t^2 + c_1)}{t}$$

Initial conditions are used to solve for c_1. Substituting $t = 1$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = e^{-1}(1 + c_1)$$

$$c_1 = -(e^{-1} - a)\, e$$

Substituting c_1 found above in the general solution gives

$$y = \frac{e^{-t}(t^2 - (e^{-1} - a)\, e)}{t}$$

Summary

The solution(s) found are the following

$$y = \frac{e^{-t}(t^2 - (e^{-1} - a)\, e)}{t} \tag{1}$$

Verification of solutions

$$y = \frac{e^{-t}(t^2 - (e^{-1} - a)\, e)}{t}$$

Verified OK.

1.24.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{(t\, e^t y + y\, e^t - 2t)\, e^{-t}}{t}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 70: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$

homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \mathrm{e}^{-t-\ln(t)}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{-t-\ln(t)}} dy \end{aligned}$$

Which results in

$$S = t\,\mathrm{e}^{t} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = -\frac{(t\,\mathrm{e}^{t} y + y\,\mathrm{e}^{t} - 2t)\,\mathrm{e}^{-t}}{t}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= y\,\mathrm{e}^{t}(t + 1) \\ S_y &= t\,\mathrm{e}^{t} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 2t \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 2R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = R^2 + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$t\,\mathrm{e}^t y = t^2 + c_1$$

Which simplifies to

$$t\,\mathrm{e}^t y = t^2 + c_1$$

Which gives

$$y = \frac{\mathrm{e}^{-t}(t^2 + c_1)}{t}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{(t\,\mathrm{e}^t y + y\,\mathrm{e}^t - 2t)\,\mathrm{e}^{-t}}{t}$ 	$R = t$ $S = t\,\mathrm{e}^t y$	$\frac{dS}{dR} = 2R$ 
Initial conditions are used to solve for c_1. Substituting $t = 1$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = \mathrm{e}^{-1}c_1 + \mathrm{e}^{-1}$$

$$c_1 = -\left(e^{-1} - a\right) e$$

Substituting c_1 found above in the general solution gives

$$y = \frac{e^{-t}(t^2 - (e^{-1} - a) e)}{t}$$

Summary

The solution(s) found are the following

$$y = \frac{e^{-t}(t^2 - (e^{-1} - a) e)}{t} \tag{1}$$

Verification of solutions

$$y = \frac{e^{-t}(t^2 - (e^{-1} - a) e)}{t}$$

Verified OK.

1.24.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x \partial y} = \frac{\partial^2\phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}
\left(t\,\mathrm{e}^{t}\right)\mathrm{d}y &= \left(-t\,\mathrm{e}^{t}y - y\,\mathrm{e}^{t} + 2t\right)\mathrm{d}t\\
\left(t\,\mathrm{e}^{t}y + y\,\mathrm{e}^{t} - 2t\right)\mathrm{d}t + \left(t\,\mathrm{e}^{t}\right)\mathrm{d}y &= 0
\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(t, y) &= t\,\mathrm{e}^{t}y + y\,\mathrm{e}^{t} - 2t\\
N(t, y) &= t\,\mathrm{e}^{t}
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(t\,\mathrm{e}^{t}y + y\,\mathrm{e}^{t} - 2t\right)\\
&= \mathrm{e}^{t}(t + 1)
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}\left(t\,\mathrm{e}^{t}\right)\\
&= \mathrm{e}^{t}(t + 1)
\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \,\mathrm{d}t = \int M \,\mathrm{d}t$$
$$\int \frac{\partial \phi}{\partial t} \,\mathrm{d}t = \int t\,\mathrm{e}^t y + y\,\mathrm{e}^t - 2t \,\mathrm{d}t$$
$$\phi = -t\left(-y\,\mathrm{e}^t + t\right) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = t\,\mathrm{e}^t + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = t\,\mathrm{e}^t$. Therefore equation (4) becomes

$$t\,\mathrm{e}^t = t\,\mathrm{e}^t + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -t\left(-y\,\mathrm{e}^t + t\right) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -t\left(-y\,\mathrm{e}^t + t\right)$$

The solution becomes

$$y = \frac{\mathrm{e}^{-t}(t^2 + c_1)}{t}$$

Initial conditions are used to solve for c_1. Substituting $t = 1$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = e^{-1}c_1 + e^{-1}$$

$$c_1 = -\left(e^{-1} - a\right) e$$

Substituting c_1 found above in the general solution gives

$$y = \frac{e^{-t}(t^2 - (e^{-1} - a) e)}{t}$$

Summary

The solution(s) found are the following

$$y = \frac{e^{-t}(t^2 - (e^{-1} - a) e)}{t} \tag{1}$$

Verification of solutions

$$y = \frac{e^{-t}(t^2 - (e^{-1} - a) e)}{t}$$

Verified OK.

1.24.5 Maple step by step solution

Let's solve

$\left[(t+1)\, y + ty' = \frac{2t}{e^t}, y(1) = a\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{(t+1)y}{t} + \frac{2}{e^t}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{(t+1)y}{t} = \frac{2}{e^t}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t) \left(y' + \frac{(t+1)y}{t}\right) = \frac{2\mu(t)}{e^t}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, y)$

$\mu(t)\left(y'+\frac{(t+1)y}{t}\right)=\mu'(t)\,y+\mu(t)\,y'$

- Isolate $\mu'(t)$

  $\mu'(t)=\frac{\mu(t)(t+1)}{t}$

- Solve to find the integrating factor

  $\mu(t)=t(\mathrm{e}^{t})^{2}\,\mathrm{e}^{-t}$

- Integrate both sides with respect to t

  $\int\left(\frac{d}{dt}(\mu(t)\,y)\right)dt=\int\frac{2\mu(t)}{\mathrm{e}^{t}}dt+c_1$

- Evaluate the integral on the lhs

  $\mu(t)\,y=\int\frac{2\mu(t)}{\mathrm{e}^{t}}dt+c_1$

- Solve for y

  $y=\frac{\int\frac{2\mu(t)}{\mathrm{e}^{t}}dt+c_1}{\mu(t)}$

- Substitute $\mu(t)=t(\mathrm{e}^{t})^{2}\,\mathrm{e}^{-t}$

  $y=\frac{\int 2\,\mathrm{e}^{-t}\mathrm{e}^{t}t dt+c_1}{t(\mathrm{e}^{t})^{2}\mathrm{e}^{-t}}$

- Evaluate the integrals on the rhs

  $y=\frac{t^{2}+c_1}{t(\mathrm{e}^{t})^{2}\mathrm{e}^{-t}}$

- Simplify

  $y=\frac{\mathrm{e}^{-t}(t^{2}+c_1)}{t}$

- Use initial condition $y(1)=a$

  $a=\mathrm{e}^{-1}(1+c_1)$

- Solve for c_1

  $c_1=-\frac{\mathrm{e}^{-1}-a}{\mathrm{e}^{-1}}$

- Substitute $c_1=-\frac{\mathrm{e}^{-1}-a}{\mathrm{e}^{-1}}$ into general solution and simplify

  $y=\frac{\mathrm{e}^{-t}(-1+\mathrm{e}a+t^{2})}{t}$

- Solution to the IVP

  $y=\frac{\mathrm{e}^{-t}(-1+\mathrm{e}a+t^{2})}{t}$

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{2y + ty' = \frac{\sin(t)}{t}}$$

With initial conditions

$$\left[y\left(-\frac{\pi}{2}\right) = a\right]$$

1.25.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \frac{2}{t}$$
$$q(t) = \frac{\sin(t)}{t^2}$$

Hence the ode is

$$y' + \frac{2y}{t} = \frac{\sin(t)}{t^2}$$

The domain of $p(t) = \frac{2}{t}$ is

$$\{t < 0 \lor 0 < t\}$$

And the point $t_0 = -\frac{\pi}{2}$ is inside this domain. The domain of $q(t) = \frac{\sin(t)}{t^2}$ is

$$\{t < 0 \lor 0 < t\}$$

And the point $t_0 = -\frac{\pi}{2}$ is also inside this domain. Hence solution exists and is unique.

1.25.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{2}{t} dt} \\ &= t^2\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dt}(\mu y) &= (\mu)\left(\frac{\sin(t)}{t^2}\right) \\ \frac{d}{dt}(t^2 y) &= (t^2)\left(\frac{\sin(t)}{t^2}\right) \\ d(t^2 y) &= \sin(t)\ dt\end{aligned}$$

Integrating gives

$$\begin{aligned}t^2 y &= \int \sin(t)\ dt \\ t^2 y &= -\cos(t) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = t^2$ results in

$$y = -\frac{\cos(t)}{t^2} + \frac{c_1}{t^2}$$

which simplifies to

$$y = \frac{-\cos(t) + c_1}{t^2}$$

Initial conditions are used to solve for c_1. Substituting $t = -\frac{\pi}{2}$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = \frac{4c_1}{\pi^2}$$

$$c_1 = \frac{\pi^2 a}{4}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{-\cos(t) + \frac{\pi^2 a}{4}}{t^2}$$

Summary

The solution(s) found are the following

$$y = \frac{-\cos(t) + \frac{\pi^2 a}{4}}{t^2} \tag{1}$$

Verification of solutions

$$y = \frac{-\cos(t) + \frac{\pi^2 a}{4}}{t^2}$$

Verified OK.

1.25.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{-2ty + \sin(t)}{t^2}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 73: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \frac{1}{t^2}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{t^2}} dy \end{aligned}$$

Which results in

$$S = t^2 y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = \frac{-2ty + \sin(t)}{t^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= 2ty \\ S_y &= t^2 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \sin(t) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \sin(R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\cos(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$yt^2 = -\cos(t) + c_1$$

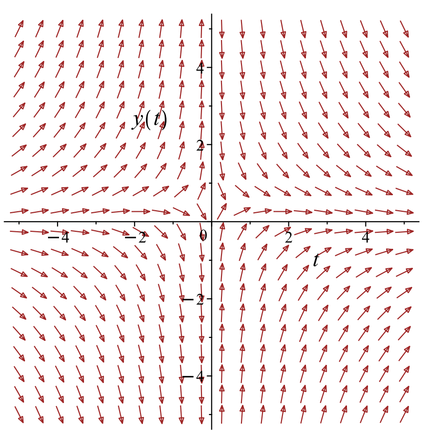
Which simplifies to

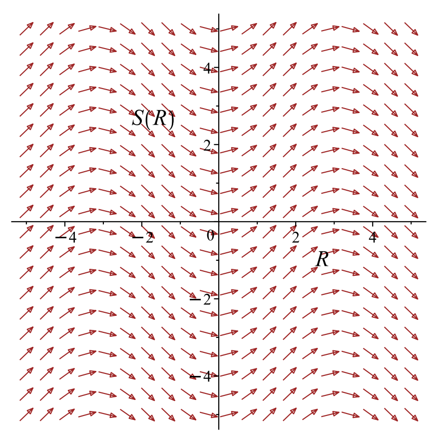
$$yt^2 = -\cos(t) + c_1$$

Which gives

$$y = -\frac{\cos(t) - c_1}{t^2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in t, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>
<tr><td>$\frac{dy}{dt} = \frac{-2ty+\sin(t)}{t^2}$


</td><td>$R = t$
$S = t^2 y$</td><td>$\frac{dS}{dR} = \sin(R)$


</td></tr>
</table>

Initial conditions are used to solve for c_1. Substituting $t = -\frac{\pi}{2}$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = \frac{4c_1}{\pi^2}$$

$$c_1 = \frac{\pi^2 a}{4}$$

Substituting c_1 found above in the general solution gives

$$y = -\frac{\cos(t) - \frac{\pi^2 a}{4}}{t^2}$$

Summary

The solution(s) found are the following

$$y = -\frac{\cos(t) - \frac{\pi^2 a}{4}}{t^2} \tag{1}$$

Verification of solutions

$$y = -\frac{\cos(t) - \frac{\pi^2 a}{4}}{t^2}$$

Verified OK.

1.25.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t + N(t,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(t^2)\,\mathrm{d}y &= (-2ty + \sin(t))\,\mathrm{d}t\\ (2ty - \sin(t))\,\mathrm{d}t + (t^2)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(t,y) &= 2ty - \sin(t)\\ N(t,y) &= t^2 \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(2ty - \sin(t))\\ &= 2t \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(t^2)\\ &= 2t \end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(t,y)$

$$\frac{\partial \phi}{\partial t} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int M \, \mathrm{d}t$$
$$\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int 2ty - \sin(t) \, \mathrm{d}t$$
$$\phi = t^2 y + \cos(t) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = t^2 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = t^2$. Therefore equation (4) becomes

$$t^2 = t^2 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = t^2 y + \cos(t) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = t^2 y + \cos(t)$$

The solution becomes

$$y = -\frac{\cos(t) - c_1}{t^2}$$

Initial conditions are used to solve for c_1. Substituting $t = -\frac{\pi}{2}$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = \frac{4c_1}{\pi^2}$$

$$c_1 = \frac{\pi^2 a}{4}$$

Substituting c_1 found above in the general solution gives

$$y = -\frac{\cos(t) - \frac{\pi^2 a}{4}}{t^2}$$

Summary
The solution(s) found are the following

$$y = -\frac{\cos(t) - \frac{\pi^2 a}{4}}{t^2} \tag{1}$$

Verification of solutions

$$y = -\frac{\cos(t) - \frac{\pi^2 a}{4}}{t^2}$$

Verified OK.

1.25.5 Maple step by step solution

Let's solve

$\left[2y + ty' = \frac{\sin(t)}{t}, y\left(-\frac{\pi}{2}\right) = a\right]$

- Highest derivative means the order of the ODE is 1

  y'
- Isolate the derivative

  $y' = -\frac{2y}{t} + \frac{\sin(t)}{t^2}$
- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{2y}{t} = \frac{\sin(t)}{t^2}$
- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(y' + \frac{2y}{t}\right) = \frac{\mu(t)\sin(t)}{t^2}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, y)$

  $\mu(t)\left(y'+\frac{2y}{t}\right)=\mu'(t)\, y+\mu(t)\, y'$
- Isolate $\mu'(t)$

  $\mu'(t)=\frac{2\mu(t)}{t}$
- Solve to find the integrating factor

  $\mu(t)=t^2$
- Integrate both sides with respect to t

  $\int\left(\frac{d}{dt}(\mu(t)\, y)\right)dt=\int\frac{\mu(t)\sin(t)}{t^2}dt+c_1$
- Evaluate the integral on the lhs

  $\mu(t)\, y=\int\frac{\mu(t)\sin(t)}{t^2}dt+c_1$
- Solve for y

  $y=\frac{\int\frac{\mu(t)\sin(t)}{t^2}dt+c_1}{\mu(t)}$
- Substitute $\mu(t)=t^2$

  $y=\frac{\int\sin(t)dt+c_1}{t^2}$
- Evaluate the integrals on the rhs

  $y=\frac{-\cos(t)+c_1}{t^2}$
- Use initial condition $y\left(-\frac{\pi}{2}\right)=a$

  $a=\frac{4c_1}{\pi^2}$
- Solve for c_1

  $c_1=\frac{\pi^2 a}{4}$
- Substitute $c_1=\frac{\pi^2 a}{4}$ into general solution and simplify

  $y=\frac{-\cos(t)+\frac{\pi^2 a}{4}}{t^2}$
- Solution to the IVP

  $y=\frac{-\cos(t)+\frac{\pi^2 a}{4}}{t^2}$

Internal problem ID [473]
Internal file name [`OUTPUT/473_Sunday_June_05_2022_01_42_02_AM_28951275/index.tex`]

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.1. Page 40
Problem number: 26.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{\cos(t) y + \sin(t) y' = e^t}$$

With initial conditions

$$[y(1) = a]$$

1.26.1 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int \cot(t)dt} \\ &= \sin(t) \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dt}(\mu y) &= (\mu)\left(\csc(t) e^t\right) \\ \frac{d}{dt}(\sin(t) y) &= (\sin(t))\left(\csc(t) e^t\right) \\ d(\sin(t) y) &= e^t \, dt \end{aligned}$$

Integrating gives

$$\sin(t)\, y = \int \mathrm{e}^{t}\, \mathrm{d}t$$
$$\sin(t)\, y = \mathrm{e}^{t} + c_1$$

Dividing both sides by the integrating factor $\mu = \sin(t)$ results in

$$y = \csc(t)\, \mathrm{e}^{t} + c_1 \csc(t)$$

which simplifies to

$$y = \csc(t) \left(\mathrm{e}^{t} + c_1\right)$$

Initial conditions are used to solve for c_1. Substituting $t = 1$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = \frac{\mathrm{e} + c_1}{\sin(1)}$$

$$c_1 = -\frac{\csc(1)\, \mathrm{e} - a}{\csc(1)}$$

Substituting c_1 found above in the general solution gives

$$y = \csc(t) \left(\mathrm{e}^{t} - \frac{\csc(1)\, \mathrm{e} - a}{\csc(1)}\right)$$

Summary

The solution(s) found are the following

$$y = \csc(t) \left(\mathrm{e}^{t} - \frac{\csc(1)\, \mathrm{e} - a}{\csc(1)}\right) \tag{1}$$

Verification of solutions

$$y = \csc(t) \left(\mathrm{e}^{t} - \frac{\csc(1)\, \mathrm{e} - a}{\csc(1)}\right)$$

Verified OK.

1.26.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{\cos(t)\, y - e^t}{\sin(t)}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 76: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \frac{1}{\sin(t)}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = t
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{1}{\sin(t)}} dy
\end{aligned}
$$

Which results in

$$
S = \sin(t) y
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}
$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$
\omega(t, y) = -\frac{\cos(t) y - e^t}{\sin(t)}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_t &= 1 \\
R_y &= 0 \\
S_t &= \cos(t)\, y \\
S_y &= \sin(t)
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = e^t \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = e^R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = e^R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\sin(t)\, y = e^t + c_1$$

Which simplifies to

$$\sin(t)\, y = e^t + c_1$$

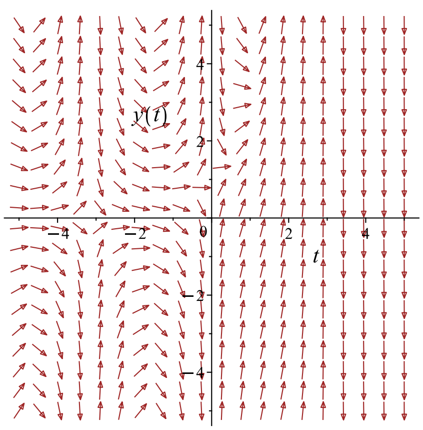
Which gives

$$y = \frac{e^t + c_1}{\sin(t)}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in t, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>
<tr>
<td>

$\frac{dy}{dt} = -\frac{\cos(t) y - e^{t}}{\sin(t)}$



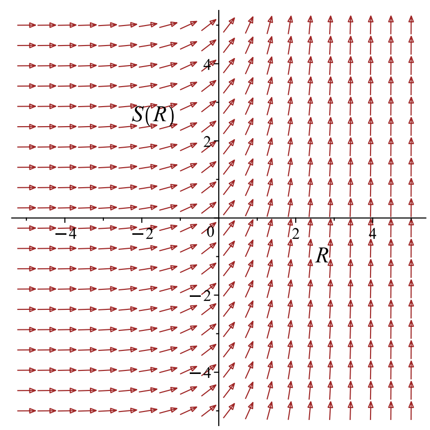
</td>
<td>

$R = t$

$S = \sin(t) y$

</td>
<td>

$\frac{dS}{dR} = e^{R}$



</td>
</tr>
</table>

Initial conditions are used to solve for c_1. Substituting $t = 1$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = \frac{e + c_1}{\sin(1)}$$

$$c_1 = -\frac{\csc(1) e - a}{\csc(1)}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{e^{t} - \frac{\csc(1) e - a}{\csc(1)}}{\sin(t)}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \frac{e^{t} - \frac{\csc(1) e - a}{\csc(1)}}{\sin(t)} \tag{1}$$

Verification of solutions

$$y = \frac{\mathrm{e}^{t} - \frac{\csc(1)\mathrm{e}-a}{\csc(1)}}{\sin(t)}$$

Verified OK.

1.26.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t + N(t,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$
\begin{aligned}
(\sin (t)) \mathrm{d}y &= \left(-\cos (t) y + \mathrm{e}^{t}\right) \mathrm{d}t \\
\left(\cos (t) y - \mathrm{e}^{t}\right) \mathrm{d}t + (\sin (t)) \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(t, y) &= \cos (t) y - \mathrm{e}^{t} \\
N(t, y) &= \sin (t)
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\cos (t) y - \mathrm{e}^{t}\right) \\
&= \cos (t)
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(\sin (t)) \\
&= \cos (t)
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(t, y)$

$$
\frac{\partial \phi}{\partial t} = M \qquad (1)
$$

$$
\frac{\partial \phi}{\partial y} = N \qquad (2)
$$

Integrating (1) w.r.t. t gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial t} \mathrm{d}t &= \int M \mathrm{d}t \\
\int \frac{\partial \phi}{\partial t} \mathrm{d}t &= \int \cos (t) y - \mathrm{e}^{t} \mathrm{d}t \\
\phi &= \sin (t) y - \mathrm{e}^{t} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \sin(t) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \sin(t)$. Therefore equation (4) becomes

$$\sin(t) = \sin(t) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \sin(t)\, y - \mathrm{e}^t + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \sin(t)\, y - \mathrm{e}^t$$

The solution becomes

$$y = \frac{\mathrm{e}^t + c_1}{\sin(t)}$$

Initial conditions are used to solve for c_1. Substituting $t = 1$ and $y = a$ in the above solution gives an equation to solve for the constant of integration.

$$a = \frac{\mathrm{e} + c_1}{\sin(1)}$$

$$c_1 = -\frac{\csc(1)\,\mathrm{e} - a}{\csc(1)}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{e^{t} - \frac{\csc(1)e - a}{\csc(1)}}{\sin(t)}$$

Summary
The solution(s) found are the following

$$y = \frac{e^{t} - \frac{\csc(1)e - a}{\csc(1)}}{\sin(t)} \tag{1}$$

Verification of solutions

$$y = \frac{e^{t} - \frac{\csc(1)e - a}{\csc(1)}}{\sin(t)}$$

Verified OK.

1.26.4 Maple step by step solution

Let's solve

$[\cos(t)\, y + \sin(t)\, y' = e^{t}, y(1) = a]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{\cos(t)y}{\sin(t)} + \frac{e^{t}}{\sin(t)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{\cos(t)y}{\sin(t)} = \frac{e^{t}}{\sin(t)}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(y' + \frac{\cos(t)y}{\sin(t)}\right) = \frac{\mu(t)e^{t}}{\sin(t)}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, y)$

  $\mu(t)\left(y' + \frac{\cos(t)y}{\sin(t)}\right) = \mu'(t)\, y + \mu(t)\, y'$

- Isolate $\mu'(t)$

  $\mu'(t) = \frac{\mu(t)\cos(t)}{\sin(t)}$

- Solve to find the integrating factor

$\mu(t) = \sin(t)$

- Integrate both sides with respect to t

$\int \left(\frac{d}{dt}(\mu(t)\, y)\right) dt = \int \frac{\mu(t)\mathrm{e}^t}{\sin(t)} dt + c_1$

- Evaluate the integral on the lhs

$\mu(t)\, y = \int \frac{\mu(t)\mathrm{e}^t}{\sin(t)} dt + c_1$

- Solve for y

$y = \frac{\int \frac{\mu(t)\mathrm{e}^t}{\sin(t)} dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = \sin(t)$

$y = \frac{\int \mathrm{e}^t dt + c_1}{\sin(t)}$

- Evaluate the integrals on the rhs

$y = \frac{\mathrm{e}^t + c_1}{\sin(t)}$

- Simplify

$y = \csc(t)\,(\mathrm{e}^t + c_1)$

- Use initial condition $y(1) = a$

$a = \csc(1)\,(\mathrm{e} + c_1)$

- Solve for c_1

$c_1 = -\frac{\csc(1)\mathrm{e} - a}{\csc(1)}$

- Substitute $c_1 = -\frac{\csc(1)\mathrm{e} - a}{\csc(1)}$ into general solution and simplify

$y = \csc(t)\,(a \sin(1) + \mathrm{e}^t - \mathrm{e})$

- Solution to the IVP

$y = \csc(t)\,(a \sin(1) + \mathrm{e}^t - \mathrm{e})$

Problem number: 27.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' + \frac{y}{2} = 2\cos(t)}$$

With initial conditions

$$[y(0) = -1]$$

1.27.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \frac{1}{2}$$
$$q(t) = 2\cos(t)$$

Hence the ode is

$$y' + \frac{y}{2} = 2\cos(t)$$

The domain of $p(t) = \frac{1}{2}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = 2\cos(t)$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

1.27.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int \frac{1}{2} dt} \\
&= e^{\frac{t}{2}}
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dt}(\mu y) &= (\mu)(2\cos(t)) \\
\frac{d}{dt}\left(e^{\frac{t}{2}} y\right) &= \left(e^{\frac{t}{2}}\right)(2\cos(t)) \\
d\left(e^{\frac{t}{2}} y\right) &= \left(2\cos(t)\, e^{\frac{t}{2}}\right) dt
\end{aligned}$$

Integrating gives

$$\begin{aligned}
e^{\frac{t}{2}} y &= \int 2\cos(t)\, e^{\frac{t}{2}}\, dt \\
e^{\frac{t}{2}} y &= \frac{4\cos(t)\, e^{\frac{t}{2}}}{5} + \frac{8\sin(t)\, e^{\frac{t}{2}}}{5} + c_1
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{\frac{t}{2}}$ results in

$$y = e^{-\frac{t}{2}} \left(\frac{4\cos(t)\, e^{\frac{t}{2}}}{5} + \frac{8\sin(t)\, e^{\frac{t}{2}}}{5} \right) + c_1 e^{-\frac{t}{2}}$$

which simplifies to

$$y = \frac{8\sin(t)}{5} + \frac{4\cos(t)}{5} + c_1 e^{-\frac{t}{2}}$$

Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = \frac{4}{5} + c_1$$

$$c_1 = -\frac{9}{5}$$

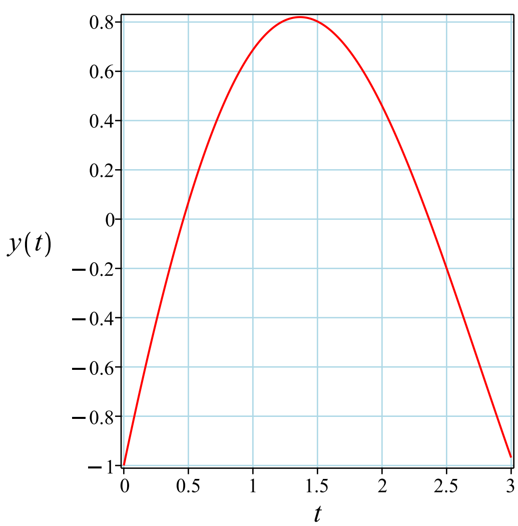
Substituting c_1 found above in the general solution gives

$$y = \frac{8\sin(t)}{5} + \frac{4\cos(t)}{5} - \frac{9\,e^{-\frac{t}{2}}}{5}$$

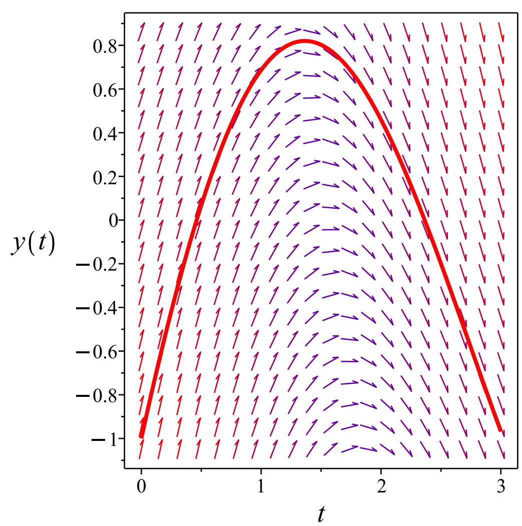
Summary

The solution(s) found are the following

$$y = \frac{8\sin(t)}{5} + \frac{4\cos(t)}{5} - \frac{9\,e^{-\frac{t}{2}}}{5} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{8\sin(t)}{5} + \frac{4\cos(t)}{5} - \frac{9\,e^{-\frac{t}{2}}}{5}$$

Verified OK.

1.27.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{y}{2} + 2\cos(t) \\
y' &= \omega(t, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 79: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$

homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\xi(t,y) = 0$$
$$\eta(t,y) = \mathrm{e}^{-\frac{t}{2}} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial t} + \eta\frac{\partial}{\partial y}\right) S(t,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{-\frac{t}{2}}} dy \end{aligned}$$

Which results in

$$S = \mathrm{e}^{\frac{t}{2}} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y)S_y}{R_t + \omega(t,y)R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = -\frac{y}{2} + 2\cos(t)$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= \frac{\mathrm{e}^{\frac{t}{2}} y}{2} \\ S_y &= \mathrm{e}^{\frac{t}{2}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 2\cos(t)\,\mathrm{e}^{\frac{t}{2}} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 2\cos(R)\,\mathrm{e}^{\frac{R}{2}}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 + \frac{4\,\mathrm{e}^{\frac{R}{2}}(\cos(R) + 2\sin(R))}{5} \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\mathrm{e}^{\frac{t}{2}} y = \frac{4\,\mathrm{e}^{\frac{t}{2}}(\cos(t) + 2\sin(t))}{5} + c_1$$

Which simplifies to

$$\mathrm{e}^{\frac{t}{2}} y = \frac{4\,\mathrm{e}^{\frac{t}{2}}(\cos(t) + 2\sin(t))}{5} + c_1$$

Which gives

$$y = \frac{\mathrm{e}^{-\frac{t}{2}}\left(4\cos(t)\,\mathrm{e}^{\frac{t}{2}} + 8\sin(t)\,\mathrm{e}^{\frac{t}{2}} + 5c_1\right)}{5}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{y}{2} + 2\cos(t)$ 	$R = t$ $S = e^{\frac{t}{2}} y$	$\frac{dS}{dR} = 2\cos(R)\,e^{\frac{R}{2}}$ 
Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = \frac{4}{5} + c_1$$

$$c_1 = -\frac{9}{5}$$

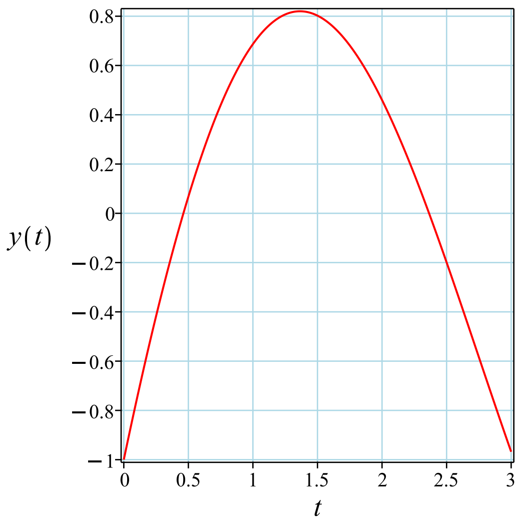
Substituting c_1 found above in the general solution gives

$$y = \frac{8\sin(t)}{5} + \frac{4\cos(t)}{5} - \frac{9\,e^{-\frac{t}{2}}}{5}$$

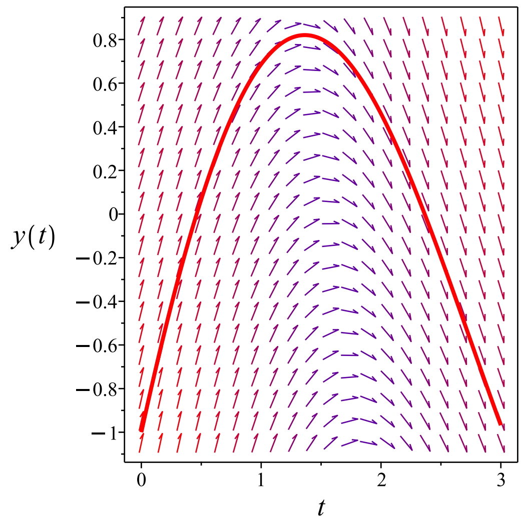
Summary

The solution(s) found are the following

$$y = \frac{8\sin(t)}{5} + \frac{4\cos(t)}{5} - \frac{9\,e^{-\frac{t}{2}}}{5} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = \frac{8\sin(t)}{5} + \frac{4\cos(t)}{5} - \frac{9\,\mathrm{e}^{-\frac{t}{2}}}{5}$$

Verified OK.

1.27.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = \left(-\frac{y}{2} + 2\cos(t)\right)\mathrm{d}t$$

$$\left(\frac{y}{2} - 2\cos(t)\right)\mathrm{d}t + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(t, y) &= \frac{y}{2} - 2\cos(t) \\ N(t, y) &= 1 \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{y}{2} - 2\cos(t)\right) \\ &= \frac{1}{2} \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(1) \\ &= 0 \end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\ &= 1\left(\left(\frac{1}{2}\right) - (0)\right) \\ &= \frac{1}{2} \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}t} \\ &= e^{\int \frac{1}{2} \, \mathrm{d}t} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{\frac{t}{2}} \\ &= \mathrm{e}^{\frac{t}{2}} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{\frac{t}{2}}\left(\frac{y}{2} - 2\cos(t)\right) \\ &= \frac{(y - 4\cos(t))\,\mathrm{e}^{\frac{t}{2}}}{2} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{\frac{t}{2}}(1) \\ &= \mathrm{e}^{\frac{t}{2}} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\ \left(\frac{(y - 4\cos(t))\,\mathrm{e}^{\frac{t}{2}}}{2}\right) + \left(\mathrm{e}^{\frac{t}{2}}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(t,y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \,\mathrm{d}t = \int \overline{M} \,\mathrm{d}t$$

$$\int \frac{\partial \phi}{\partial t} \,\mathrm{d}t = \int \frac{(y - 4\cos(t))\,\mathrm{e}^{\frac{t}{2}}}{2} \,\mathrm{d}t$$

$$\phi = -\frac{\mathrm{e}^{\frac{t}{2}}(-5y + 4\cos(t) + 8\sin(t))}{5} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{\frac{t}{2}} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{\frac{t}{2}}$. Therefore equation (4) becomes

$$\mathrm{e}^{\frac{t}{2}} = \mathrm{e}^{\frac{t}{2}} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\mathrm{e}^{\frac{t}{2}}(-5y + 4\cos(t) + 8\sin(t))}{5} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\mathrm{e}^{\frac{t}{2}}(-5y + 4\cos(t) + 8\sin(t))}{5}$$

The solution becomes

$$y = \frac{\mathrm{e}^{-\frac{t}{2}} \left(4 \cos \left(t\right) \mathrm{e}^{\frac{t}{2}} + 8 \sin \left(t\right) \mathrm{e}^{\frac{t}{2}} + 5 c_1\right)}{5}$$

Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = \frac{4}{5} + c_1$$

$$c_1 = -\frac{9}{5}$$

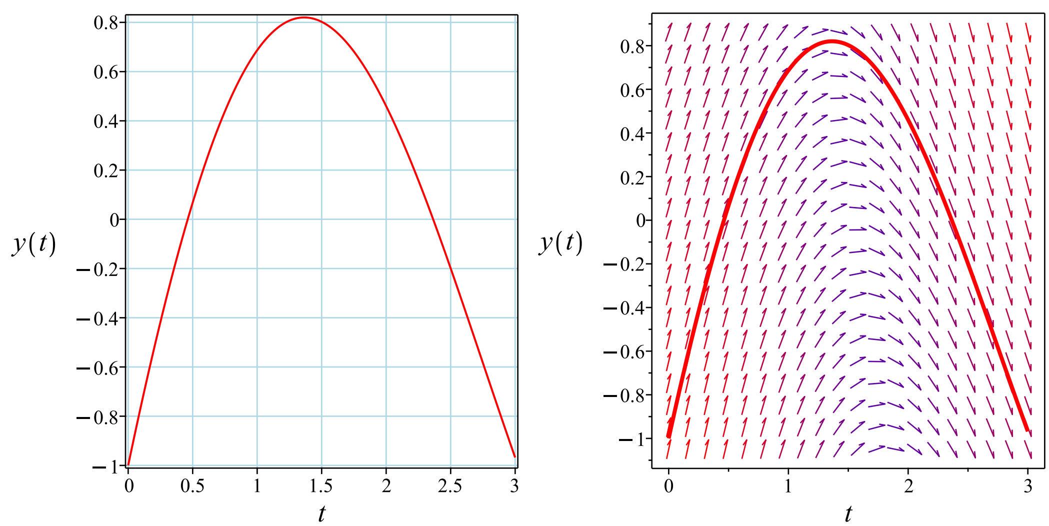
Substituting c_1 found above in the general solution gives

$$y = \frac{8 \sin \left(t\right)}{5} + \frac{4 \cos \left(t\right)}{5} - \frac{9 \,\mathrm{e}^{-\frac{t}{2}}}{5}$$

Summary

The solution(s) found are the following

$$y = \frac{8 \sin \left(t\right)}{5} + \frac{4 \cos \left(t\right)}{5} - \frac{9 \,\mathrm{e}^{-\frac{t}{2}}}{5} \tag{1}$$



(a) Solution plot (b) Slope field plot

1.27.5 Maple step by step solution

Let's solve

$\left[y' + \frac{y}{2} = 2\cos(t), y(0) = -1\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{y}{2} + 2\cos(t)$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{y}{2} = 2\cos(t)$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(y' + \frac{y}{2}\right) = 2\mu(t)\cos(t)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, y)$

  $\mu(t)\left(y' + \frac{y}{2}\right) = \mu'(t)\, y + \mu(t)\, y'$

- Isolate $\mu'(t)$

  $\mu'(t) = \frac{\mu(t)}{2}$

- Solve to find the integrating factor

  $\mu(t) = e^{\frac{t}{2}}$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\, y)\right) dt = \int 2\mu(t)\cos(t)\, dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\, y = \int 2\mu(t)\cos(t)\, dt + c_1$

- Solve for y

  $y = \frac{\int 2\mu(t)\cos(t)dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = e^{\frac{t}{2}}$

  $y = \frac{\int 2\cos(t)e^{\frac{t}{2}}dt + c_1}{e^{\frac{t}{2}}}$

- Evaluate the integrals on the rhs

  $y = \frac{\frac{4\cos(t)e^{\frac{t}{2}}}{5} + \frac{8\sin(t)e^{\frac{t}{2}}}{5} + c_1}{e^{\frac{t}{2}}}$

- Simplify

$$y = \frac{8\sin(t)}{5} + \frac{4\cos(t)}{5} + c_1 e^{-\frac{t}{2}}$$

- Use initial condition $y(0) = -1$

  $$-1 = \frac{4}{5} + c_1$$

- Solve for c_1

  $$c_1 = -\frac{9}{5}$$

- Substitute $c_1 = -\frac{9}{5}$ into general solution and simplify

  $$y = \frac{8\sin(t)}{5} + \frac{4\cos(t)}{5} - \frac{9\,e^{-\frac{t}{2}}}{5}$$

- Solution to the IVP

  $$y = \frac{8\sin(t)}{5} + \frac{4\cos(t)}{5} - \frac{9\,e^{-\frac{t}{2}}}{5}$$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{\frac{2y}{3}+y'=-\frac{t}{2}+1}$$

1.28.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(t)y=q(t)$$

Where here

$$p(t)=\frac{2}{3}$$
$$q(t)=-\frac{t}{2}+1$$

Hence the ode is

$$\frac{2y}{3}+y'=-\frac{t}{2}+1$$

The integrating factor μ is

$$\mu = e^{\int \frac{2}{3}dt}$$
$$= e^{\frac{2t}{3}}$$

The ode becomes

$$\frac{d}{dt}(\mu y) = (\mu)\left(-\frac{t}{2}+1\right)$$
$$\frac{d}{dt}\left(e^{\frac{2t}{3}} y\right) = \left(e^{\frac{2t}{3}}\right)\left(-\frac{t}{2}+1\right)$$
$$d\left(e^{\frac{2t}{3}} y\right) = \left(-\frac{(t-2)\,e^{\frac{2t}{3}}}{2}\right) dt$$

Integrating gives

$$e^{\frac{2t}{3}} y = \int -\frac{(t-2)\,e^{\frac{2t}{3}}}{2}\, dt$$
$$e^{\frac{2t}{3}} y = -\frac{3(2t-7)\,e^{\frac{2t}{3}}}{8} + c_1$$

Dividing both sides by the integrating factor $\mu = e^{\frac{2t}{3}}$ results in

$$y = -\frac{3\,e^{-\frac{2t}{3}}(2t-7)\,e^{\frac{2t}{3}}}{8} + c_1 e^{-\frac{2t}{3}}$$

which simplifies to

$$y = -\frac{3t}{4} + \frac{21}{8} + c_1 e^{-\frac{2t}{3}}$$

Summary
The solution(s) found are the following

$$y = -\frac{3t}{4} + \frac{21}{8} + c_1 e^{-\frac{2t}{3}} \tag{1}$$

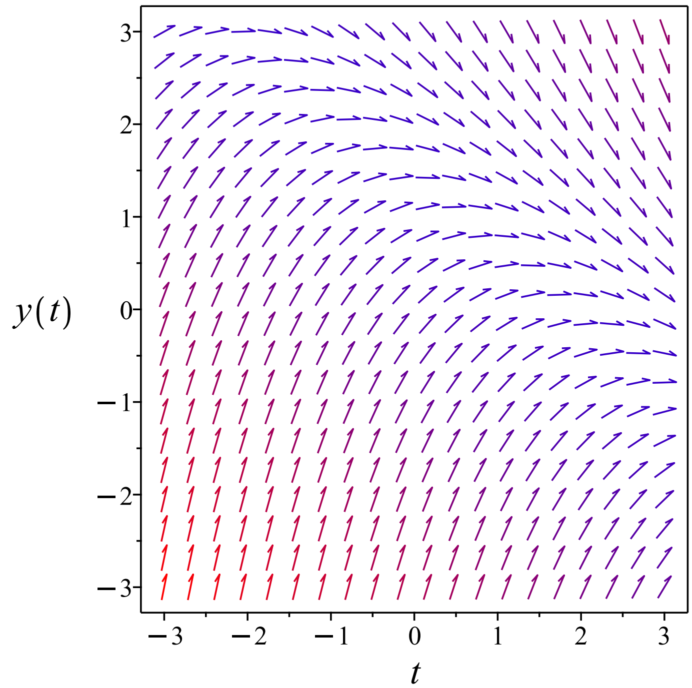

Figure 65: Slope field plot

Verification of solutions

$$y = -\frac{3t}{4} + \frac{21}{8} + c_1 e^{-\frac{2t}{3}}$$

Verified OK.

1.28.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{2y}{3} - \frac{t}{2} + 1$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 82: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \mathrm{e}^{-\frac{2t}{3}}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{-\frac{2t}{3}}} dy \end{aligned}$$

Which results in

$$S = e^{\frac{2t}{3}} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = -\frac{2y}{3} - \frac{t}{2} + 1$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= \frac{2 e^{\frac{2t}{3}} y}{3} \\ S_y &= e^{\frac{2t}{3}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \left(-\frac{t}{2} + 1\right) e^{\frac{2t}{3}} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \left(-\frac{R}{2} + 1\right) e^{\frac{2R}{3}}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\frac{3(2R-7)\,\mathrm{e}^{\frac{2R}{3}}}{8} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\mathrm{e}^{\frac{2t}{3}} y = -\frac{3(2t-7)\,\mathrm{e}^{\frac{2t}{3}}}{8} + c_1$$

Which simplifies to

$$\mathrm{e}^{\frac{2t}{3}} y = -\frac{3(2t-7)\,\mathrm{e}^{\frac{2t}{3}}}{8} + c_1$$

Which gives

$$y = -\frac{\left(6\,\mathrm{e}^{\frac{2t}{3}} t - 21\,\mathrm{e}^{\frac{2t}{3}} - 8c_1\right) \mathrm{e}^{-\frac{2t}{3}}}{8}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{2y}{3} - \frac{t}{2} + 1$ 	$R = t$ $S = \mathrm{e}^{\frac{2t}{3}} y$	$\frac{dS}{dR} = \left(-\frac{R}{2} + 1\right) \mathrm{e}^{\frac{2R}{3}}$ 
Summary
The solution(s) found are the following

$$y = -\frac{\left(6\,\mathrm{e}^{\frac{2t}{3}} t - 21\,\mathrm{e}^{\frac{2t}{3}} - 8c_1\right)\mathrm{e}^{-\frac{2t}{3}}}{8} \tag{1}$$

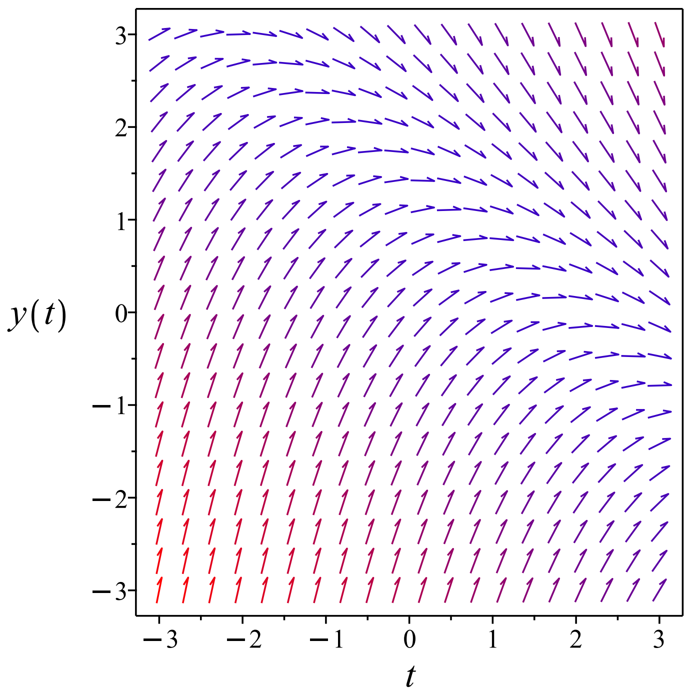

Figure 66: Slope field plot

Verification of solutions

$$y = -\frac{\left(6\,\mathrm{e}^{\frac{2t}{3}} t - 21\,\mathrm{e}^{\frac{2t}{3}} - 8c_1\right)\mathrm{e}^{-\frac{2t}{3}}}{8}$$

Verified OK.

1.28.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\,\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the

ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t + N(t,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = \left(-\frac{2y}{3} - \frac{t}{2} + 1\right)\mathrm{d}t$$

$$\left(\frac{2y}{3} + \frac{t}{2} - 1\right)\mathrm{d}t + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t,y) &= \frac{2y}{3} + \frac{t}{2} - 1\\ N(t,y) &= 1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{2y}{3}+\frac{t}{2}-1\right)\\ &= \frac{2}{3}\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(1)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y}-\frac{\partial N}{\partial t}\right)\\ &= 1\left(\left(\frac{2}{3}\right)-(0)\right)\\ &= \frac{2}{3}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}t}\\ &= e^{\int \frac{2}{3}\,\mathrm{d}t}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{\frac{2t}{3}}\\ &= \mathrm{e}^{\frac{2t}{3}}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \mathrm{e}^{\frac{2t}{3}}\left(\frac{2y}{3}+\frac{t}{2}-1\right)\\ &= \frac{(4y+3t-6)\,\mathrm{e}^{\frac{2t}{3}}}{6}\end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{\frac{2t}{3}}(1) \\
&= \mathrm{e}^{\frac{2t}{3}}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\
\left(\frac{(4y + 3t - 6)\,\mathrm{e}^{\frac{2t}{3}}}{6}\right) + \left(\mathrm{e}^{\frac{2t}{3}}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$
\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. t gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial t}\,\mathrm{d}t &= \int \overline{M}\,\mathrm{d}t \\
\int \frac{\partial \phi}{\partial t}\,\mathrm{d}t &= \int \frac{(4y + 3t - 6)\,\mathrm{e}^{\frac{2t}{3}}}{6}\,\mathrm{d}t
\end{aligned}
$$

$$
\phi = \frac{(6t + 8y - 21)\,\mathrm{e}^{\frac{2t}{3}}}{8} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = \mathrm{e}^{\frac{2t}{3}} + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{\frac{2t}{3}}$. Therefore equation (4) becomes

$$
\mathrm{e}^{\frac{2t}{3}} = \mathrm{e}^{\frac{2t}{3}} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{(6t + 8y - 21)\,\mathrm{e}^{\frac{2t}{3}}}{8} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{(6t + 8y - 21)\,\mathrm{e}^{\frac{2t}{3}}}{8}$$

The solution becomes

$$y = -\frac{\left(6\,\mathrm{e}^{\frac{2t}{3}} t - 21\,\mathrm{e}^{\frac{2t}{3}} - 8c_1\right)\mathrm{e}^{-\frac{2t}{3}}}{8}$$

Summary

The solution(s) found are the following

$$y = -\frac{\left(6\,\mathrm{e}^{\frac{2t}{3}} t - 21\,\mathrm{e}^{\frac{2t}{3}} - 8c_1\right)\mathrm{e}^{-\frac{2t}{3}}}{8} \tag{1}$$

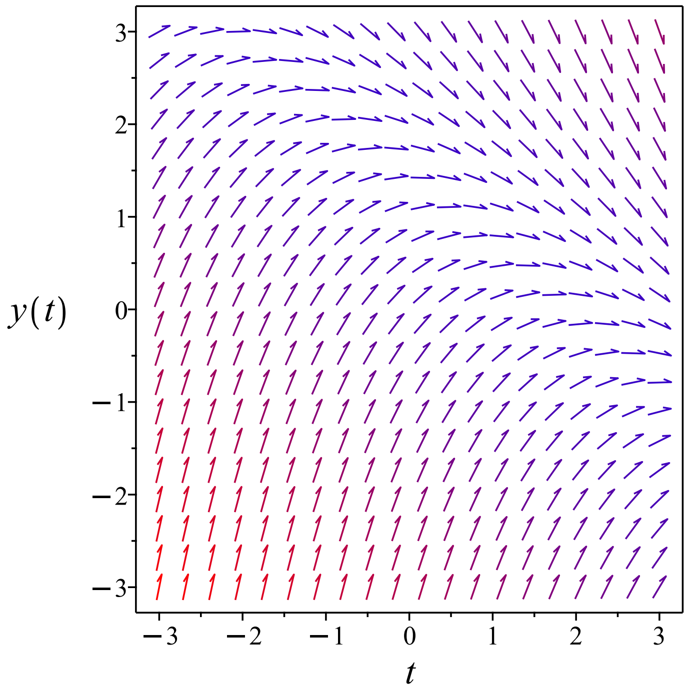

Figure 67: Slope field plot

Verification of solutions

$$y = -\frac{\left(6\,\mathrm{e}^{\frac{2t}{3}} t - 21\,\mathrm{e}^{\frac{2t}{3}} - 8c_1\right)\mathrm{e}^{-\frac{2t}{3}}}{8}$$

Verified OK.

1.28.4 Maple step by step solution

Let's solve

$\frac{2y}{3} + y' = -\frac{t}{2} + 1$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{2y}{3} - \frac{t}{2} + 1$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $\frac{2y}{3} + y' = -\frac{t}{2} + 1$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

$$\mu(t)\left(\frac{2y}{3}+y'\right)=\mu(t)\left(-\frac{t}{2}+1\right)$$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

$$\mu(t)\left(\frac{2y}{3}+y'\right)=\mu'(t)\,y+\mu(t)\,y'$$

- Isolate $\mu'(t)$

$$\mu'(t)=\frac{2\mu(t)}{3}$$

- Solve to find the integrating factor

$$\mu(t)=\mathrm{e}^{\frac{2t}{3}}$$

- Integrate both sides with respect to t

$$\int\left(\frac{d}{dt}(\mu(t)\,y)\right)dt=\int\mu(t)\left(-\frac{t}{2}+1\right)dt+c_1$$

- Evaluate the integral on the lhs

$$\mu(t)\,y=\int\mu(t)\left(-\frac{t}{2}+1\right)dt+c_1$$

- Solve for y

$$y=\frac{\int\mu(t)\left(-\frac{t}{2}+1\right)dt+c_1}{\mu(t)}$$

- Substitute $\mu(t)=\mathrm{e}^{\frac{2t}{3}}$

$$y=\frac{\int\left(-\frac{t}{2}+1\right)\mathrm{e}^{\frac{2t}{3}}dt+c_1}{\mathrm{e}^{\frac{2t}{3}}}$$

- Evaluate the integrals on the rhs

$$y=\frac{-\frac{3(2t-7)\,\mathrm{e}^{\frac{2t}{3}}}{8}+c_1}{\mathrm{e}^{\frac{2t}{3}}}$$

- Simplify

$$y=-\frac{3t}{4}+\frac{21}{8}+c_1\mathrm{e}^{-\frac{2t}{3}}$$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{\frac{y}{4} + y' = 3 + 2\cos(2t)}$$

With initial conditions

$$[y(0) = 0]$$

1.29.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \frac{1}{4}$$
$$q(t) = 3 + 2\cos(2t)$$

Hence the ode is

$$\frac{y}{4}+y' = 3+2\cos(2t)$$

The domain of $p(t)=\frac{1}{4}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0=0$ is inside this domain. The domain of $q(t)=3+2\cos(2t)$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0=0$ is also inside this domain. Hence solution exists and is unique.

1.29.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int \frac{1}{4}dt}\\ &= \mathrm{e}^{\frac{t}{4}}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}(\mu y) &= (\mu)(3+2\cos(2t))\\ \frac{\mathrm{d}}{\mathrm{d}t}\left(\mathrm{e}^{\frac{t}{4}}y\right) &= \left(\mathrm{e}^{\frac{t}{4}}\right)(3+2\cos(2t))\\ \mathrm{d}\left(\mathrm{e}^{\frac{t}{4}}y\right) &= \left((3+2\cos(2t))\,\mathrm{e}^{\frac{t}{4}}\right)\,\mathrm{d}t\end{aligned}$$

Integrating gives

$$\begin{aligned}\mathrm{e}^{\frac{t}{4}}y &= \int (3+2\cos(2t))\,\mathrm{e}^{\frac{t}{4}}\,\mathrm{d}t\\ \mathrm{e}^{\frac{t}{4}}y &= 12\,\mathrm{e}^{\frac{t}{4}}+\frac{8\cos(2t)\,\mathrm{e}^{\frac{t}{4}}}{65}+\frac{64\sin(2t)\,\mathrm{e}^{\frac{t}{4}}}{65}+c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu=\mathrm{e}^{\frac{t}{4}}$ results in

$$y = \mathrm{e}^{-\frac{t}{4}}\left(12\,\mathrm{e}^{\frac{t}{4}}+\frac{8\cos(2t)\,\mathrm{e}^{\frac{t}{4}}}{65}+\frac{64\sin(2t)\,\mathrm{e}^{\frac{t}{4}}}{65}\right)+c_1\mathrm{e}^{-\frac{t}{4}}$$

which simplifies to

$$y = \frac{64\sin(2t)}{65} + \frac{8\cos(2t)}{65} + 12 + c_1 e^{-\frac{t}{4}}$$

Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{788}{65} + c_1$$

$$c_1 = -\frac{788}{65}$$

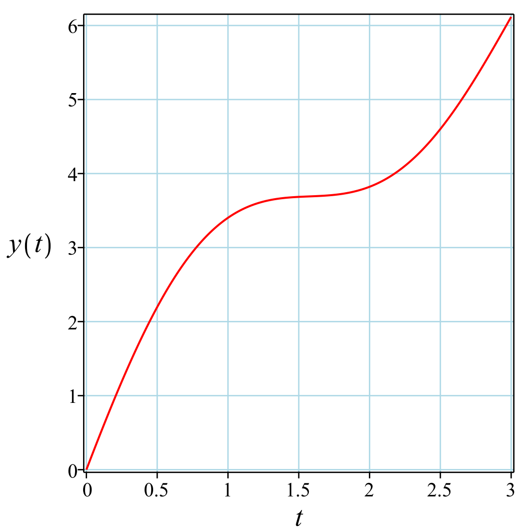
Substituting c_1 found above in the general solution gives

$$y = \frac{64\sin(2t)}{65} + \frac{8\cos(2t)}{65} + 12 - \frac{788\,e^{-\frac{t}{4}}}{65}$$

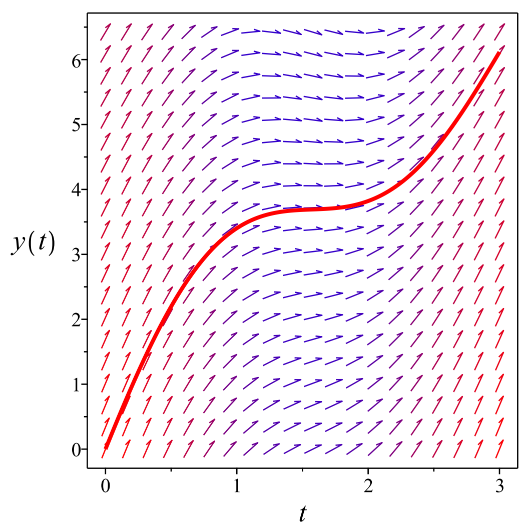
Summary

The solution(s) found are the following

$$y = \frac{64\sin(2t)}{65} + \frac{8\cos(2t)}{65} + 12 - \frac{788\,e^{-\frac{t}{4}}}{65} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{64\sin(2t)}{65} + \frac{8\cos(2t)}{65} + 12 - \frac{788\,e^{-\frac{t}{4}}}{65}$$

Verified OK.

1.29.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{y}{4} + 3 + 2\cos(2t) \\
y' &= \omega(t, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 85: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t,y) &= 0 \\
\eta(t,y) &= \mathrm{e}^{-\frac{t}{4}}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = t
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\mathrm{e}^{-\frac{t}{4}}} dy
\end{aligned}
$$

Which results in

$$
S = \mathrm{e}^{\frac{t}{4}} y
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_t + \omega(t,y) S_y}{R_t + \omega(t,y) R_y} \tag{2}
$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$
\omega(t,y) = -\frac{y}{4} + 3 + 2\cos(2t)
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_t &= 1 \\
R_y &= 0 \\
S_t &= \frac{\mathrm{e}^{\frac{t}{4}} y}{4} \\
S_y &= \mathrm{e}^{\frac{t}{4}}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = (3 + 2\cos(2t))\,\mathrm{e}^{\frac{t}{4}} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = (3 + 2\cos(2R))\,\mathrm{e}^{\frac{R}{4}}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = 12\,\mathrm{e}^{\frac{R}{4}} + c_1 + \frac{8\,\mathrm{e}^{\frac{R}{4}}(\cos(2R) + 8\sin(2R))}{65} \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\mathrm{e}^{\frac{t}{4}} y = 12\,\mathrm{e}^{\frac{t}{4}} + c_1 + \frac{8\,\mathrm{e}^{\frac{t}{4}}(\cos(2t) + 8\sin(2t))}{65}$$

Which simplifies to

$$\frac{(65y - 8\cos(2t) - 64\sin(2t) - 780)\,\mathrm{e}^{\frac{t}{4}}}{65} - c_1 = 0$$

Which gives

$$y = \frac{\mathrm{e}^{-\frac{t}{4}}\left(8\cos(2t)\,\mathrm{e}^{\frac{t}{4}} + 64\sin(2t)\,\mathrm{e}^{\frac{t}{4}} + 780\,\mathrm{e}^{\frac{t}{4}} + 65c_1\right)}{65}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{y}{4} + 3 + 2\cos(2t)$ 	$R = t$ $S = \mathrm{e}^{\frac{t}{4}} y$	$\frac{dS}{dR} = (3 + 2\cos(2R))\,\mathrm{e}^{\frac{R}{4}}$ 
Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{788}{65} + c_1$$

$$c_1 = -\frac{788}{65}$$

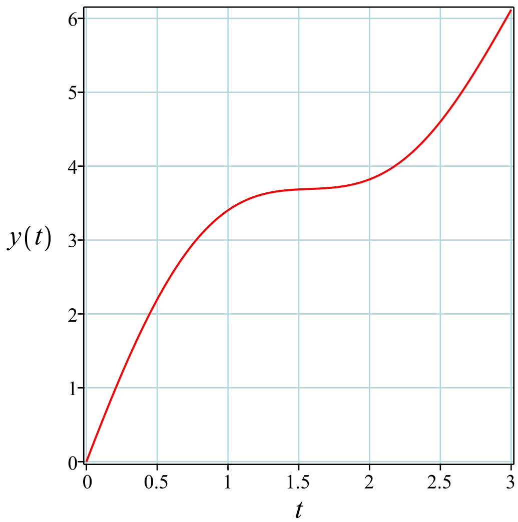
Substituting c_1 found above in the general solution gives

$$y = \frac{64\sin(2t)}{65} + \frac{8\cos(2t)}{65} + 12 - \frac{788\,\mathrm{e}^{-\frac{t}{4}}}{65}$$

Summary

The solution(s) found are the following

$$y = \frac{64\sin(2t)}{65} + \frac{8\cos(2t)}{65} + 12 - \frac{788\,\mathrm{e}^{-\frac{t}{4}}}{65} \tag{1}$$



(a) Solution plot

<u>Verification of solutions</u>

$$y = \frac{64 \sin(2t)}{65} + \frac{8 \cos(2t)}{65} + 12 - \frac{788 \, e^{-\frac{t}{4}}}{65}$$

Verified OK.

1.29.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}
\mathrm{d}y &= \left(-\frac{y}{4} + 3 + 2\cos(2t)\right)\mathrm{d}t \\
\left(\frac{y}{4} - 3 - 2\cos(2t)\right)\mathrm{d}t + \mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(t, y) &= \frac{y}{4} - 3 - 2\cos(2t) \\
N(t, y) &= 1
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{y}{4} - 3 - 2\cos(2t)\right) \\
&= \frac{1}{4}
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(1) \\
&= 0
\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\ &= 1\left(\left(\frac{1}{4}\right) - (0)\right) \\ &= \frac{1}{4} \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}t} \\ &= e^{\int \frac{1}{4} \, \mathrm{d}t} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{\frac{t}{4}} \\ &= \mathrm{e}^{\frac{t}{4}} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{\frac{t}{4}}\left(\frac{y}{4} - 3 - 2\cos(2t)\right) \\ &= \frac{(y - 12 - 8\cos(2t))\,\mathrm{e}^{\frac{t}{4}}}{4} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{\frac{t}{4}}(1) \\ &= \mathrm{e}^{\frac{t}{4}} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\ \left(\frac{(y - 12 - 8\cos(2t))\,\mathrm{e}^{\frac{t}{4}}}{4}\right) + \left(\mathrm{e}^{\frac{t}{4}}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int \overline{M} \, \mathrm{d}t$$

$$\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int \frac{(y - 12 - 8\cos(2t))\, \mathrm{e}^{\frac{t}{4}}}{4} \, \mathrm{d}t$$

$$\phi = -\frac{\mathrm{e}^{\frac{t}{4}} (780 - 65y + 8\cos(2t) + 64\sin(2t))}{65} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{\frac{t}{4}} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{\frac{t}{4}}$. Therefore equation (4) becomes

$$\mathrm{e}^{\frac{t}{4}} = \mathrm{e}^{\frac{t}{4}} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\mathrm{e}^{\frac{t}{4}} (780 - 65y + 8\cos(2t) + 64\sin(2t))}{65} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\mathrm{e}^{\frac{t}{4}} (780 - 65y + 8\cos(2t) + 64\sin(2t))}{65}$$

The solution becomes

$$y = \frac{e^{-\frac{t}{4}} \left(8 \cos \left(2t\right) e^{\frac{t}{4}} + 64 \sin \left(2t\right) e^{\frac{t}{4}} + 780 e^{\frac{t}{4}} + 65 c_1\right)}{65}$$

Initial conditions are used to solve for c_1. Substituting $t = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{788}{65} + c_1$$

$$c_1 = -\frac{788}{65}$$

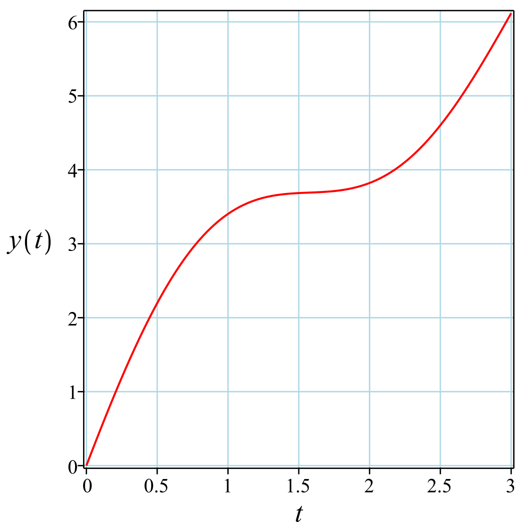
Substituting c_1 found above in the general solution gives

$$y = \frac{64 \sin \left(2t\right)}{65} + \frac{8 \cos \left(2t\right)}{65} + 12 - \frac{788 e^{-\frac{t}{4}}}{65}$$

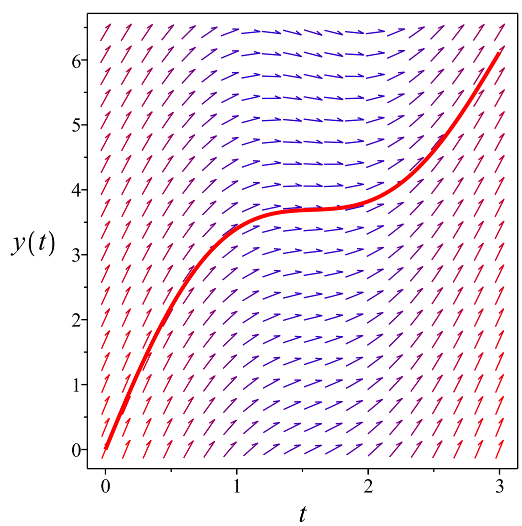
Summary

The solution(s) found are the following

$$y = \frac{64 \sin \left(2t\right)}{65} + \frac{8 \cos \left(2t\right)}{65} + 12 - \frac{788 e^{-\frac{t}{4}}}{65} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{64 \sin \left(2t\right)}{65} + \frac{8 \cos \left(2t\right)}{65} + 12 - \frac{788 e^{-\frac{t}{4}}}{65}$$

Verified OK.

1.29.5 Maple step by step solution

Let's solve

$\left[\frac{y}{4}+y'=3+2\cos(2t), y(0)=0\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y'=-\frac{y}{4}+3+2\cos(2t)$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $\frac{y}{4}+y'=3+2\cos(2t)$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(\frac{y}{4}+y'\right)=\mu(t)\left(3+2\cos(2t)\right)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, y)$

  $\mu(t)\left(\frac{y}{4}+y'\right)=\mu'(t)\, y+\mu(t)\, y'$

- Isolate $\mu'(t)$

  $\mu'(t)=\frac{\mu(t)}{4}$

- Solve to find the integrating factor

  $\mu(t)=\mathrm{e}^{\frac{t}{4}}$

- Integrate both sides with respect to t

  $\int\left(\frac{d}{dt}(\mu(t)\, y)\right)dt=\int\mu(t)\left(3+2\cos(2t)\right)dt+c_1$

- Evaluate the integral on the lhs

  $\mu(t)\, y=\int\mu(t)\left(3+2\cos(2t)\right)dt+c_1$

- Solve for y

  $y=\frac{\int\mu(t)(3+2\cos(2t))dt+c_1}{\mu(t)}$

- Substitute $\mu(t)=\mathrm{e}^{\frac{t}{4}}$

  $y=\frac{\int(3+2\cos(2t))\mathrm{e}^{\frac{t}{4}}dt+c_1}{\mathrm{e}^{\frac{t}{4}}}$

- Evaluate the integrals on the rhs

  $y=\frac{\frac{8\cos(2t)\mathrm{e}^{\frac{t}{4}}}{65}+\frac{64\sin(2t)\mathrm{e}^{\frac{t}{4}}}{65}+12\,\mathrm{e}^{\frac{t}{4}}+c_1}{\mathrm{e}^{\frac{t}{4}}}$

- Simplify

$$y = \frac{64\sin(2t)}{65} + \frac{8\cos(2t)}{65} + 12 + c_1 e^{-\frac{t}{4}}$$

- Use initial condition $y(0) = 0$

$$0 = \frac{788}{65} + c_1$$

- Solve for c_1

$$c_1 = -\frac{788}{65}$$

- Substitute $c_1 = -\frac{788}{65}$ into general solution and simplify

$$y = \frac{64\sin(2t)}{65} + \frac{8\cos(2t)}{65} + 12 - \frac{788\, e^{-\frac{t}{4}}}{65}$$

- Solution to the IVP

$$y = \frac{64\sin(2t)}{65} + \frac{8\cos(2t)}{65} + 12 - \frac{788\, e^{-\frac{t}{4}}}{65}$$

1.30 problem 30

Internal problem ID [477]
Internal file name [`OUTPUT/477_Sunday_June_05_2022_01_42_06_AM_27968450/index.tex`]

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.1. Page 40
Problem number: 30.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{-y + y' = 1 + 3\sin(t)}$$

1.30.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = -1$$
$$q(t) = 1 + 3\sin(t)$$

Hence the ode is

$$-y + y' = 1 + 3\sin(t)$$

The integrating factor μ is

$$\mu = e^{\int (-1)dt}$$
$$= e^{-t}$$

The ode becomes

$$\frac{d}{dt}(\mu y) = (\mu)(1 + 3\sin(t))$$
$$\frac{d}{dt}(e^{-t}y) = (e^{-t})(1 + 3\sin(t))$$
$$d(e^{-t}y) = ((1 + 3\sin(t))e^{-t})\ dt$$

Integrating gives

$$e^{-t}y = \int (1 + 3\sin(t))e^{-t}\,dt$$
$$e^{-t}y = -e^{-t} - \frac{3e^{-t}\cos(t)}{2} - \frac{3e^{-t}\sin(t)}{2} + c_1$$

Dividing both sides by the integrating factor $\mu = e^{-t}$ results in

$$y = e^{t}\left(-e^{-t} - \frac{3e^{-t}\cos(t)}{2} - \frac{3e^{-t}\sin(t)}{2}\right) + c_1 e^{t}$$

which simplifies to

$$y = -1 + c_1 e^{t} - \frac{3\cos(t)}{2} - \frac{3\sin(t)}{2}$$

Summary

The solution(s) found are the following

$$y = -1 + c_1 e^{t} - \frac{3\cos(t)}{2} - \frac{3\sin(t)}{2} \tag{1}$$

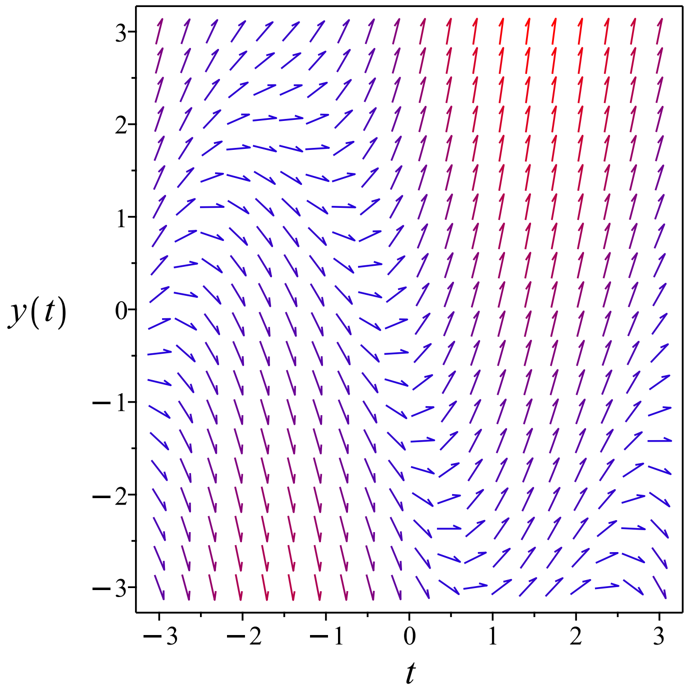

Figure 71: Slope field plot

Verification of solutions

$$y = -1 + c_1 e^t - \frac{3\cos(t)}{2} - \frac{3\sin(t)}{2}$$

Verified OK.

1.30.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = y + 1 + 3\sin(t)$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2\xi_y - \omega_t\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 88: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \mathrm{e}^t
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^t} dy \end{aligned}$$

Which results in

$$S = e^{-t} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y) S_y}{R_t + \omega(t,y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = y + 1 + 3\sin(t)$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= -e^{-t} y \\ S_y &= e^{-t} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = (1 + 3\sin(t)) e^{-t} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = (1 + 3\sin(R)) e^{-R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\mathrm{e}^{-R} + c_1 - \frac{3\,\mathrm{e}^{-R}(\cos(R) + \sin(R))}{2} \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\mathrm{e}^{-t} y = -\mathrm{e}^{-t} + c_1 - \frac{3\,\mathrm{e}^{-t}(\cos(t) + \sin(t))}{2}$$

Which simplifies to

$$\frac{(2y + 3\cos(t) + 3\sin(t) + 2)\,\mathrm{e}^{-t}}{2} - c_1 = 0$$

Which gives

$$y = -\frac{(3\,\mathrm{e}^{-t}\sin(t) + 3\,\mathrm{e}^{-t}\cos(t) + 2\,\mathrm{e}^{-t} - 2c_1)\,\mathrm{e}^{t}}{2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = y + 1 + 3\sin(t)$ 	$R = t$ $S = \mathrm{e}^{-t} y$	$\frac{dS}{dR} = (1 + 3\sin(R))\,\mathrm{e}^{-R}$ 
Summary

The solution(s) found are the following

$$y = -\frac{(3\,\mathrm{e}^{-t}\sin(t) + 3\,\mathrm{e}^{-t}\cos(t) + 2\,\mathrm{e}^{-t} - 2c_1)\,\mathrm{e}^{t}}{2} \tag{1}$$

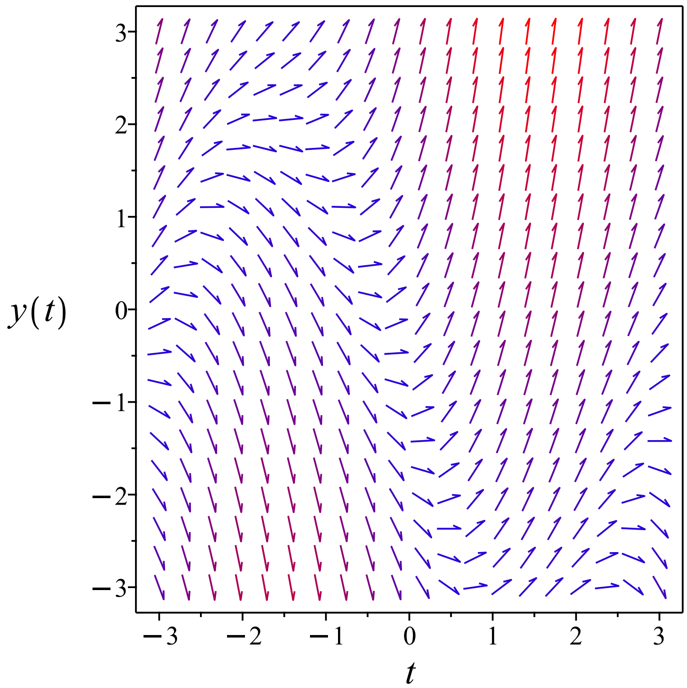

Figure 72: Slope field plot

Verification of solutions

$$y = -\frac{\left(3\,\mathrm{e}^{-t} \sin\left(t\right)+3\,\mathrm{e}^{-t} \cos\left(t\right)+2\,\mathrm{e}^{-t}-2 c_{1}\right) \mathrm{e}^{t}}{2}$$

Verified OK.

1.30.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\mathrm{d}y &= (y + 1 + 3\sin(t))\,\mathrm{d}t\\ (-y - 1 - 3\sin(t))\,\mathrm{d}t + \mathrm{d}y &= 0\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t, y) &= -y - 1 - 3\sin(t)\\ N(t, y) &= 1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-y - 1 - 3\sin(t))\\ &= -1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(1)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\
&= 1((-1) - (0)) \\
&= -1
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}t} \\
&= e^{\int -1 \, \mathrm{d}t}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-t} \\
&= \mathrm{e}^{-t}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{-t}(-y - 1 - 3\sin(t)) \\
&= -\mathrm{e}^{-t}(y + 1 + 3\sin(t))
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-t}(1) \\
&= \mathrm{e}^{-t}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\
\left(-\mathrm{e}^{-t}(y + 1 + 3\sin(t))\right) + \left(\mathrm{e}^{-t}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$
\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \mathrm{d}t = \int \overline{M} \mathrm{d}t$$

$$\int \frac{\partial \phi}{\partial t} \mathrm{d}t = \int -\mathrm{e}^{-t}(y + 1 + 3\sin(t)) \mathrm{d}t$$

$$\phi = \frac{(2y + 3\cos(t) + 3\sin(t) + 2)\,\mathrm{e}^{-t}}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{-t} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-t}$. Therefore equation (4) becomes

$$\mathrm{e}^{-t} = \mathrm{e}^{-t} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{(2y + 3\cos(t) + 3\sin(t) + 2)\,\mathrm{e}^{-t}}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{(2y + 3\cos(t) + 3\sin(t) + 2)\,\mathrm{e}^{-t}}{2}$$

The solution becomes

$$y = -\frac{(3\,\mathrm{e}^{-t}\sin(t) + 3\,\mathrm{e}^{-t}\cos(t) + 2\,\mathrm{e}^{-t} - 2c_1)\,\mathrm{e}^{t}}{2}$$

Summary

The solution(s) found are the following

$$y = -\frac{\left(3\,\mathrm{e}^{-t}\sin\left(t\right)+3\,\mathrm{e}^{-t}\cos\left(t\right)+2\,\mathrm{e}^{-t}-2c_1\right)\mathrm{e}^{t}}{2} \tag{1}$$

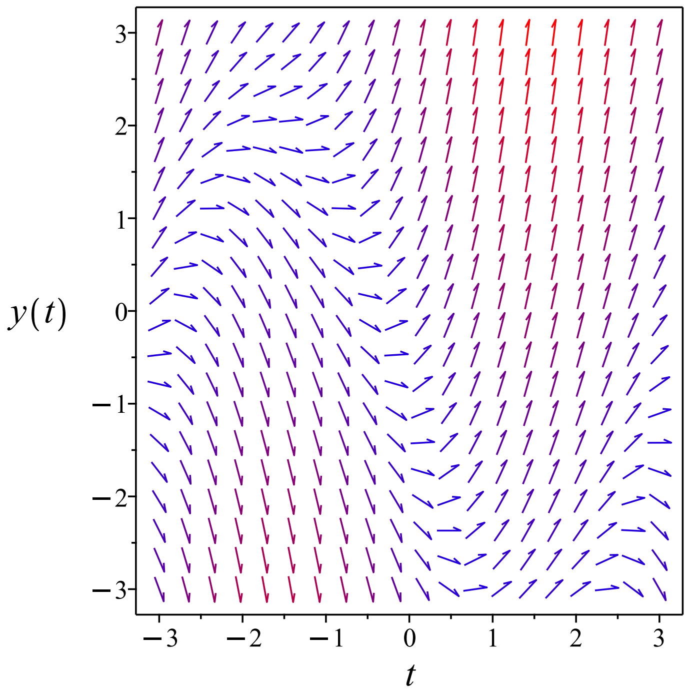

Figure 73: Slope field plot

Verification of solutions

$$y = -\frac{\left(3\,\mathrm{e}^{-t}\sin\left(t\right)+3\,\mathrm{e}^{-t}\cos\left(t\right)+2\,\mathrm{e}^{-t}-2c_1\right)\mathrm{e}^{t}}{2}$$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{-\frac{3y}{2}+y'=2\,\mathrm{e}^{t}+3t}$$

1.31.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(t)y=q(t)$$

Where here

$$p(t)=-\frac{3}{2}$$
$$q(t)=2\,\mathrm{e}^{t}+3t$$

Hence the ode is

$$-\frac{3y}{2}+y'=2\,\mathrm{e}^{t}+3t$$

The integrating factor μ is

$$\mu = e^{\int -\frac{3}{2}dt}$$
$$= e^{-\frac{3t}{2}}$$

The ode becomes

$$\frac{d}{dt}(\mu y) = (\mu)\left(2\,e^{t} + 3t\right)$$
$$\frac{d}{dt}\left(e^{-\frac{3t}{2}} y\right) = \left(e^{-\frac{3t}{2}}\right)\left(2\,e^{t} + 3t\right)$$
$$d\left(e^{-\frac{3t}{2}} y\right) = \left(\left(2\,e^{t} + 3t\right) e^{-\frac{3t}{2}}\right) dt$$

Integrating gives

$$e^{-\frac{3t}{2}} y = \int \left(2\,e^{t} + 3t\right) e^{-\frac{3t}{2}}\,dt$$
$$e^{-\frac{3t}{2}} y = -2\,e^{-\frac{3t}{2}} t - \frac{4\,e^{-\frac{3t}{2}}}{3} - 4\,e^{-\frac{t}{2}} + c_1$$

Dividing both sides by the integrating factor $\mu = e^{-\frac{3t}{2}}$ results in

$$y = e^{\frac{3t}{2}}\left(-2\,e^{-\frac{3t}{2}} t - \frac{4\,e^{-\frac{3t}{2}}}{3} - 4\,e^{-\frac{t}{2}}\right) + c_1 e^{\frac{3t}{2}}$$

which simplifies to

$$y = -2t - \frac{4}{3} - 4\,e^{t} + c_1 e^{\frac{3t}{2}}$$

Summary
The solution(s) found are the following

$$y = -2t - \frac{4}{3} - 4\,e^{t} + c_1 e^{\frac{3t}{2}} \tag{1}$$

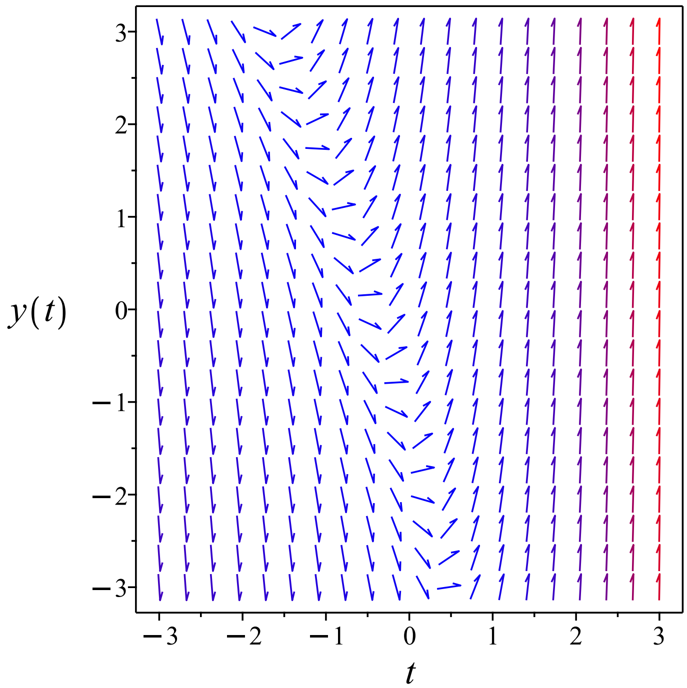

Figure 74: Slope field plot

Verification of solutions

$$
y = -2t - \frac{4}{3} - 4\,\mathrm{e}^{t} + c_1 \mathrm{e}^{\frac{3t}{2}}
$$

Verified OK.

1.31.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{3y}{2} + 2\,\mathrm{e}^{t} + 3t \\
y' &= \omega(t, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 91: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \mathrm{e}^{\frac{3t}{2}} \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \qquad (1)
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{\frac{3t}{2}}} dy \end{aligned}$$

Which results in

$$S = e^{-\frac{3t}{2}} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = \frac{3y}{2} + 2\,e^{t} + 3t$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= -\frac{3\,e^{-\frac{3t}{2}} y}{2} \\ S_y &= e^{-\frac{3t}{2}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 2\,e^{-\frac{t}{2}} + 3\,e^{-\frac{3t}{2}} t \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 2\,e^{-\frac{R}{2}} + 3\,e^{-\frac{3R}{2}} R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -2\,\mathrm{e}^{-\frac{3R}{2}} R - \frac{4\,\mathrm{e}^{-\frac{3R}{2}}}{3} - 4\,\mathrm{e}^{-\frac{R}{2}} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\mathrm{e}^{-\frac{3t}{2}} y = -2\,\mathrm{e}^{-\frac{3t}{2}} t - \frac{4\,\mathrm{e}^{-\frac{3t}{2}}}{3} - 4\,\mathrm{e}^{-\frac{t}{2}} + c_1$$

Which simplifies to

$$\frac{(6t + 3y + 4)\,\mathrm{e}^{-\frac{3t}{2}}}{3} - c_1 + 4\,\mathrm{e}^{-\frac{t}{2}} = 0$$

Which gives

$$y = -\frac{\left(6\,\mathrm{e}^{-\frac{3t}{2}} t + 4\,\mathrm{e}^{-\frac{3t}{2}} + 12\,\mathrm{e}^{-\frac{t}{2}} - 3c_1\right) \mathrm{e}^{\frac{3t}{2}}}{3}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = \frac{3y}{2} + 2\,\mathrm{e}^{t} + 3t$ 	$R = t$ $S = \mathrm{e}^{-\frac{3t}{2}} y$	$\frac{dS}{dR} = 2\,\mathrm{e}^{-\frac{R}{2}} + 3\,\mathrm{e}^{-\frac{3R}{2}} R$ 
Summary
The solution(s) found are the following

$$y = -\frac{\left(6\,\mathrm{e}^{-\frac{3t}{2}} t + 4\,\mathrm{e}^{-\frac{3t}{2}} + 12\,\mathrm{e}^{-\frac{t}{2}} - 3c_1\right) \mathrm{e}^{\frac{3t}{2}}}{3} \tag{1}$$

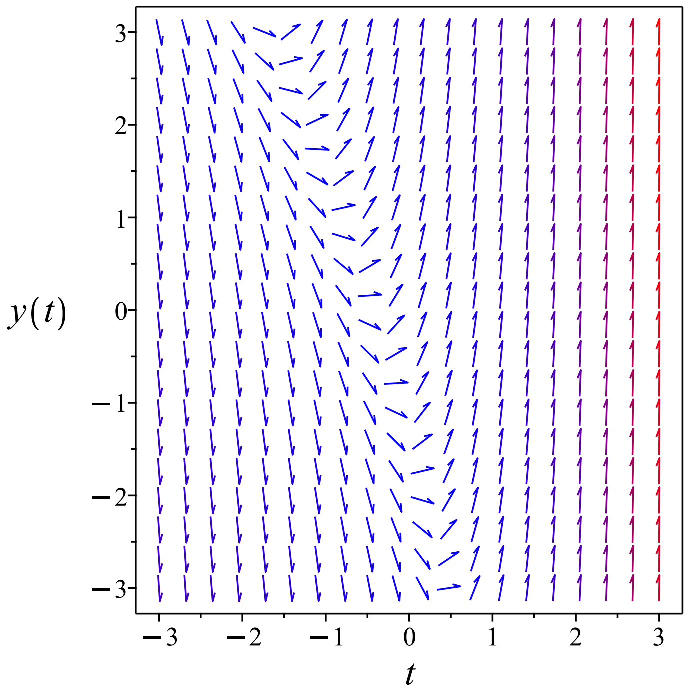

Figure 75: Slope field plot

Verification of solutions

$$y = -\frac{\left(6\,\mathrm{e}^{-\frac{3t}{2}} t + 4\,\mathrm{e}^{-\frac{3t}{2}} + 12\,\mathrm{e}^{-\frac{t}{2}} - 3c_1\right) \mathrm{e}^{\frac{3t}{2}}}{3}$$

Verified OK.

1.31.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the

ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t+N(t,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\mathrm{d}y=\left(\frac{3y}{2}+2\,\mathrm{e}^{t}+3t\right)\mathrm{d}t$$

$$\left(-\frac{3y}{2}-2\,\mathrm{e}^{t}-3t\right)\mathrm{d}t+\mathrm{d}y=0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t,y)&=-\frac{3y}{2}-2\,\mathrm{e}^{t}-3t\\ N(t,y)&=1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial t}$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{3y}{2} - 2\,\mathrm{e}^{t} - 3t\right) \\
&= -\frac{3}{2}
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(1) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\
&= 1\left(\left(-\frac{3}{2}\right) - (0)\right) \\
&= -\frac{3}{2}
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \,\mathrm{d}t} \\
&= e^{\int -\frac{3}{2} \,\mathrm{d}t}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-\frac{3t}{2}} \\
&= \mathrm{e}^{-\frac{3t}{2}}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{-\frac{3t}{2}}\left(-\frac{3y}{2} - 2\,\mathrm{e}^{t} - 3t\right) \\
&= -\frac{(3y + 4\,\mathrm{e}^{t} + 6t)\,\mathrm{e}^{-\frac{3t}{2}}}{2}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-\frac{3t}{2}}(1) \\
&= \mathrm{e}^{-\frac{3t}{2}}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\
\left(-\frac{(3y + 4\,\mathrm{e}^{t} + 6t)\,\mathrm{e}^{-\frac{3t}{2}}}{2}\right) + \left(\mathrm{e}^{-\frac{3t}{2}}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$
\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. t gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial t}\,\mathrm{d}t &= \int \overline{M}\,\mathrm{d}t \\
\int \frac{\partial \phi}{\partial t}\,\mathrm{d}t &= \int -\frac{(3y + 4\,\mathrm{e}^{t} + 6t)\,\mathrm{e}^{-\frac{3t}{2}}}{2}\,\mathrm{d}t
\end{aligned}
$$

$$
\phi = \frac{(6t + 3y + 4)\,\mathrm{e}^{-\frac{3t}{2}}}{3} + 4\,\mathrm{e}^{-\frac{t}{2}} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = \mathrm{e}^{-\frac{3t}{2}} + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-\frac{3t}{2}}$. Therefore equation (4) becomes

$$
\mathrm{e}^{-\frac{3t}{2}} = \mathrm{e}^{-\frac{3t}{2}} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{(6t + 3y + 4)\, e^{-\frac{3t}{2}}}{3} + 4\, e^{-\frac{t}{2}} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{(6t + 3y + 4)\, e^{-\frac{3t}{2}}}{3} + 4\, e^{-\frac{t}{2}}$$

The solution becomes

$$y = -\frac{\left(6\, e^{-\frac{3t}{2}} t + 4\, e^{-\frac{3t}{2}} + 12\, e^{-\frac{t}{2}} - 3c_1\right) e^{\frac{3t}{2}}}{3}$$

Summary

The solution(s) found are the following

$$y = -\frac{\left(6\, e^{-\frac{3t}{2}} t + 4\, e^{-\frac{3t}{2}} + 12\, e^{-\frac{t}{2}} - 3c_1\right) e^{\frac{3t}{2}}}{3} \tag{1}$$

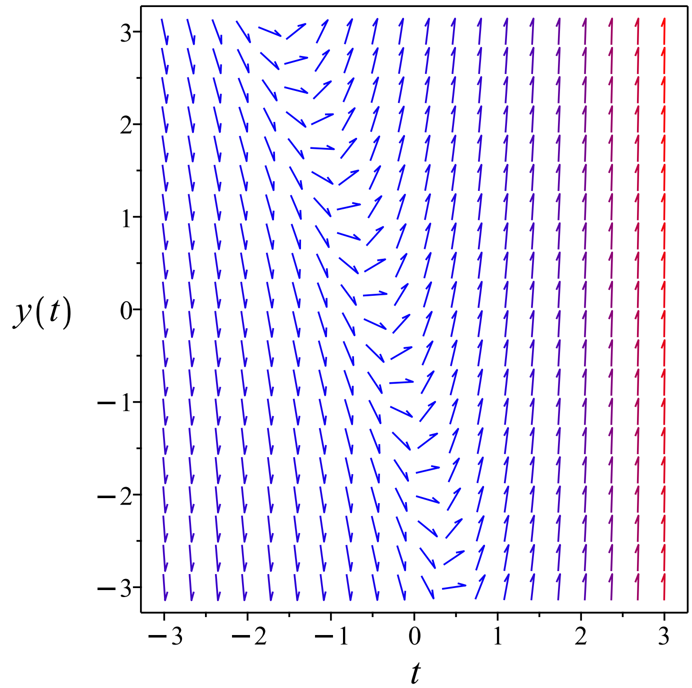

Figure 76: Slope field plot

Verification of solutions

$$y = -\frac{\left(6\,\mathrm{e}^{-\frac{3t}{2}} t + 4\,\mathrm{e}^{-\frac{3t}{2}} + 12\,\mathrm{e}^{-\frac{t}{2}} - 3c_1\right)\mathrm{e}^{\frac{3t}{2}}}{3}$$

Verified OK.

1.31.4 Maple step by step solution

Let's solve

$-\frac{3y}{2} + y' = 2\,\mathrm{e}^{t} + 3t$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \frac{3y}{2} + 2\,\mathrm{e}^{t} + 3t$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $-\frac{3y}{2} + y' = 2\,\mathrm{e}^{t} + 3t$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

$$\mu(t)\left(-\frac{3y}{2}+y'\right)=\mu(t)\left(2\,e^{t}+3t\right)$$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

$$\mu(t)\left(-\frac{3y}{2}+y'\right)=\mu'(t)\,y+\mu(t)\,y'$$

- Isolate $\mu'(t)$

$$\mu'(t)=-\frac{3\mu(t)}{2}$$

- Solve to find the integrating factor

$$\mu(t)=e^{-\frac{3t}{2}}$$

- Integrate both sides with respect to t

$$\int\left(\frac{d}{dt}(\mu(t)\,y)\right)dt=\int\mu(t)\left(2\,e^{t}+3t\right)dt+c_1$$

- Evaluate the integral on the lhs

$$\mu(t)\,y=\int\mu(t)\left(2\,e^{t}+3t\right)dt+c_1$$

- Solve for y

$$y=\frac{\int\mu(t)\left(2\,e^{t}+3t\right)dt+c_1}{\mu(t)}$$

- Substitute $\mu(t)=e^{-\frac{3t}{2}}$

$$y=\frac{\int\left(2\,e^{t}+3t\right)e^{-\frac{3t}{2}}dt+c_1}{e^{-\frac{3t}{2}}}$$

- Evaluate the integrals on the rhs

$$y=\frac{-2\,e^{-\frac{3t}{2}}t-\frac{4\,e^{-\frac{3t}{2}}}{3}-4\,e^{-\frac{t}{2}}+c_1}{e^{-\frac{3t}{2}}}$$

- Simplify

$$y=-2t-\frac{4}{3}-4\,e^{t}+c_1e^{\frac{3t}{2}}$$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "differentialType", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{x^2}{y} = 0}$$

2.1.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{x^2}{y} \end{aligned}$$

Where $f(x) = x^2$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y}}\, dy = x^2\, dx$$

$$\int \frac{1}{\frac{1}{y}}\, dy = \int x^2\, dx$$

$$\frac{y^2}{2} = \frac{x^3}{3} + c_1$$

Which results in

$$y = \frac{\sqrt{6x^3 + 18c_1}}{3}$$

$$y = -\frac{\sqrt{6x^3 + 18c_1}}{3}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \frac{\sqrt{6x^3 + 18c_1}}{3} \tag{1}$$

$$y = -\frac{\sqrt{6x^3 + 18c_1}}{3} \tag{2}$$

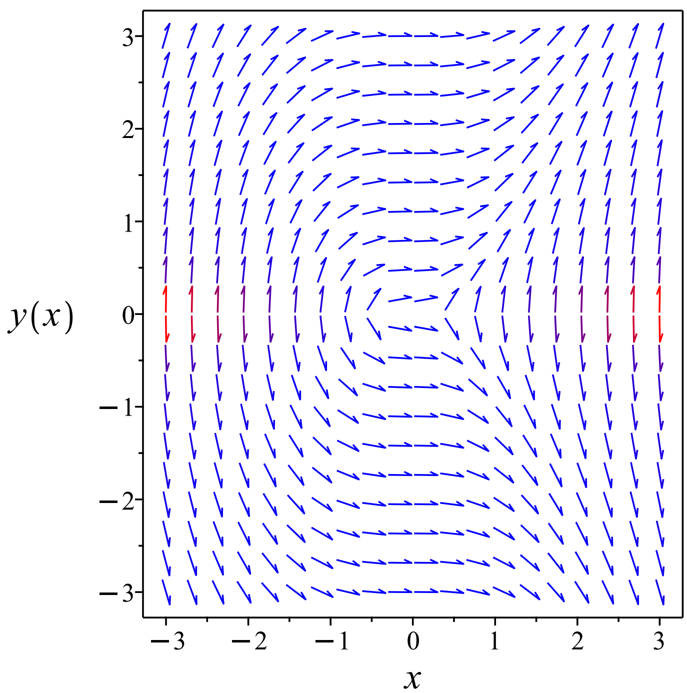

Figure 77: Slope field plot

Verification of solutions

$$y = \frac{\sqrt{6x^3 + 18c_1}}{3}$$

Verified OK.

$$y = -\frac{\sqrt{6x^3 + 18c_1}}{3}$$

Verified OK.

2.1.2 Solving as differentialType ode

Writing the ode as

$$y' = \frac{x^2}{y} \tag{1}$$

Which becomes

$$(y)\, dy = \left(x^2\right) dx \tag{2}$$

But the RHS is complete differential because

$$\left(x^2\right) dx = d\left(\frac{x^3}{3}\right)$$

Hence (2) becomes

$$(y)\, dy = d\left(\frac{x^3}{3}\right)$$

Integrating both sides gives gives these solutions

$$y = \frac{\sqrt{6x^3 + 18c_1}}{3} + c_1$$
$$y = -\frac{\sqrt{6x^3 + 18c_1}}{3} + c_1$$

Summary
The solution(s) found are the following

$$y = \frac{\sqrt{6x^3 + 18c_1}}{3} + c_1 \tag{1}$$
$$y = -\frac{\sqrt{6x^3 + 18c_1}}{3} + c_1 \tag{2}$$

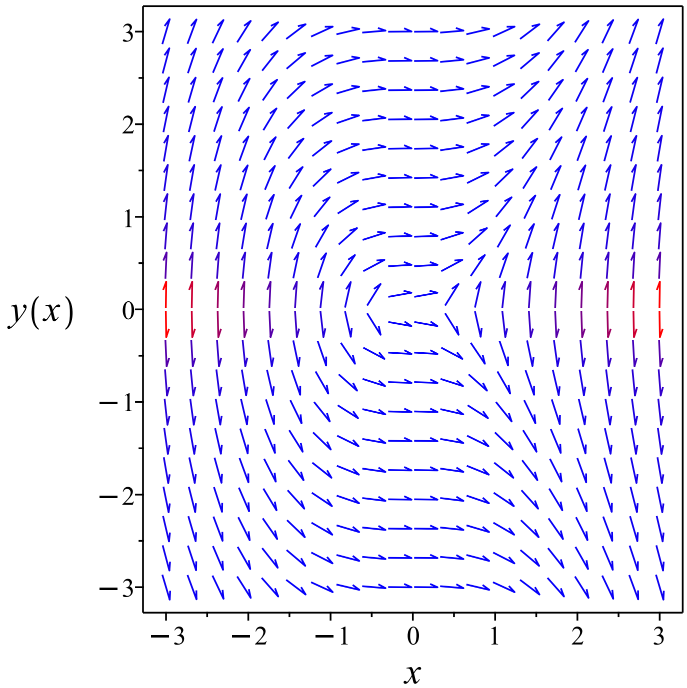

Figure 78: Slope field plot

Verification of solutions

$$y = \frac{\sqrt{6x^3 + 18c_1}}{3} + c_1$$

Verified OK.

$$y = -\frac{\sqrt{6x^3 + 18c_1}}{3} + c_1$$

Verified OK.

2.1.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{x^2}{y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 94: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= \frac{1}{x^2} \\
\eta(x, y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{x^2}} dx \end{aligned}$$

Which results in

$$S = \frac{x^3}{3}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{x^2}{y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= x^2 \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = y \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{R^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{x^3}{3} = \frac{y^2}{2} + c_1$$

Which simplifies to

$$\frac{x^3}{3} = \frac{y^2}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^2}{y}$ 	$R = y$ $S = \frac{x^3}{3}$	$\frac{dS}{dR} = R$ 
Summary

The solution(s) found are the following

$$\frac{x^3}{3} = \frac{y^2}{2} + c_1 \tag{1}$$

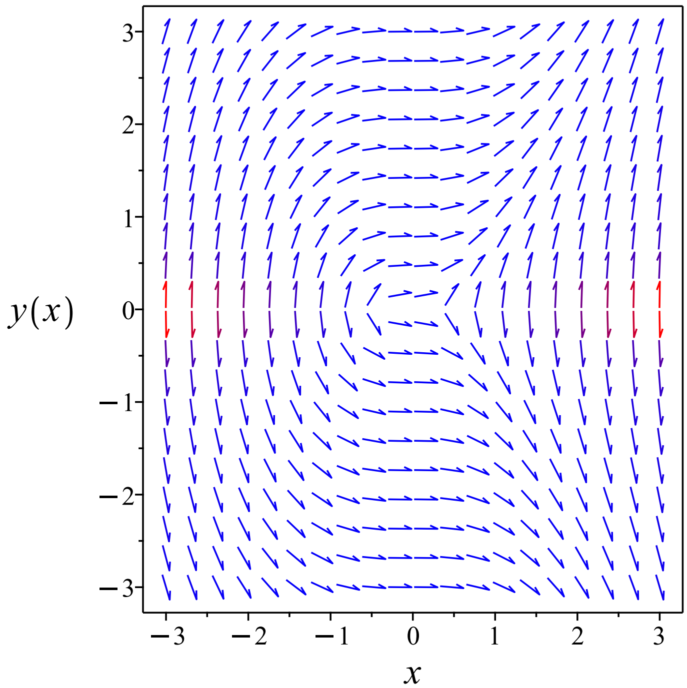

Figure 79: Slope field plot

Verification of solutions

$$\frac{x^3}{3} = \frac{y^2}{2} + c_1$$

Verified OK.

2.1.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(y)\,\mathrm{d}y = (x^2)\,\mathrm{d}x$$
$$(-x^2)\,\mathrm{d}x + (y)\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -x^2$$
$$N(x, y) = y$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-x^2)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(y)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x = \int M\, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x = \int -x^2\, \mathrm{d}x$$
$$\phi = -\frac{x^3}{3} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y$. Therefore equation (4) becomes

$$y = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = y$$

Integrating the above w.r.t y gives

$$\int f'(y)\, \mathrm{d}y = \int (y)\, \mathrm{d}y$$
$$f(y) = \frac{y^2}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x^3}{3} + \frac{y^2}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x^3}{3} + \frac{y^2}{2}$$

Summary

The solution(s) found are the following

$$-\frac{x^3}{3} + \frac{y^2}{2} = c_1 \tag{1}$$

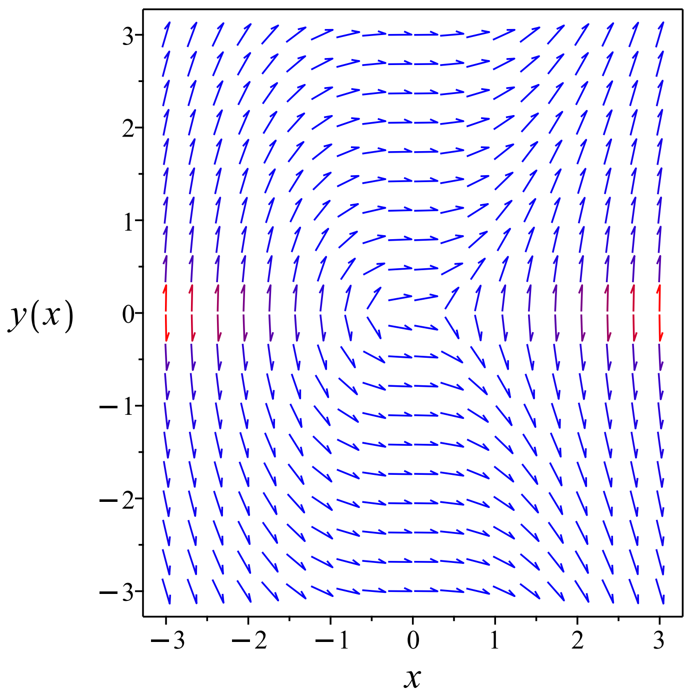

Figure 80: Slope field plot

Verification of solutions

$$-\frac{x^3}{3} + \frac{y^2}{2} = c_1$$

Verified OK.

2.1.5 Maple step by step solution

Let's solve

$y' - \frac{x^2}{y} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $yy' = x^2$

- Integrate both sides with respect to x

  $\int yy'dx = \int x^2 dx + c_1$

- Evaluate integral

  $\frac{y^2}{2} = \frac{x^3}{3} + c_1$

- Solve for y

  $\left\{y = -\frac{\sqrt{6x^3+18c_1}}{3}, y = \frac{\sqrt{6x^3+18c_1}}{3}\right\}$

Problem number: 2.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{y' - \frac{x^2}{(x^3+1)\,y} = 0}$$

2.2.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{x^2}{(x^3+1)\,y} \end{aligned}$$

Where $f(x) = \frac{x^2}{x^3+1}$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y}}\,dy = \frac{x^2}{x^3+1}\,dx$$

$$\int \frac{1}{\frac{1}{y}}dy = \int \frac{x^2}{x^3+1}dx$$
$$\frac{y^2}{2} = \frac{\ln(x^3+1)}{3} + c_1$$

Which results in

$$y = \frac{\sqrt{6\ln(x^3+1)+18c_1}}{3}$$
$$y = -\frac{\sqrt{6\ln(x^3+1)+18c_1}}{3}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{6\ln(x^3+1)+18c_1}}{3} \tag{1}$$
$$y = -\frac{\sqrt{6\ln(x^3+1)+18c_1}}{3} \tag{2}$$

Verified OK.

$$y = -\frac{\sqrt{6 \ln (x^3 + 1) + 18c_1}}{3}$$

Verified OK.

2.2.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{x^2}{(x^3 + 1) y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 97: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= \frac{x^3 + 1}{x^2} \\
\eta(x, y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{x^3+1}{x^2}} dx \end{aligned}$$

Which results in

$$S = \frac{\ln(x^3 + 1)}{3}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{x^2}{(x^3 + 1)\, y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= \frac{x^2}{(x^2 - x + 1)(x + 1)} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = y \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{R^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(x+1)}{3} + \frac{\ln(x^2-x+1)}{3} = \frac{y^2}{2} + c_1$$

Which simplifies to

$$\frac{\ln(x+1)}{3} + \frac{\ln(x^2-x+1)}{3} = \frac{y^2}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^2}{(x^3+1)y}$ 	$R = y$ $S = \frac{\ln(x+1)}{3} + \frac{\ln(x^2 -}{3}$	$\frac{dS}{dR} = R$ 
Summary

The solution(s) found are the following

$$\frac{\ln(x+1)}{3} + \frac{\ln(x^2-x+1)}{3} = \frac{y^2}{2} + c_1 \tag{1}$$

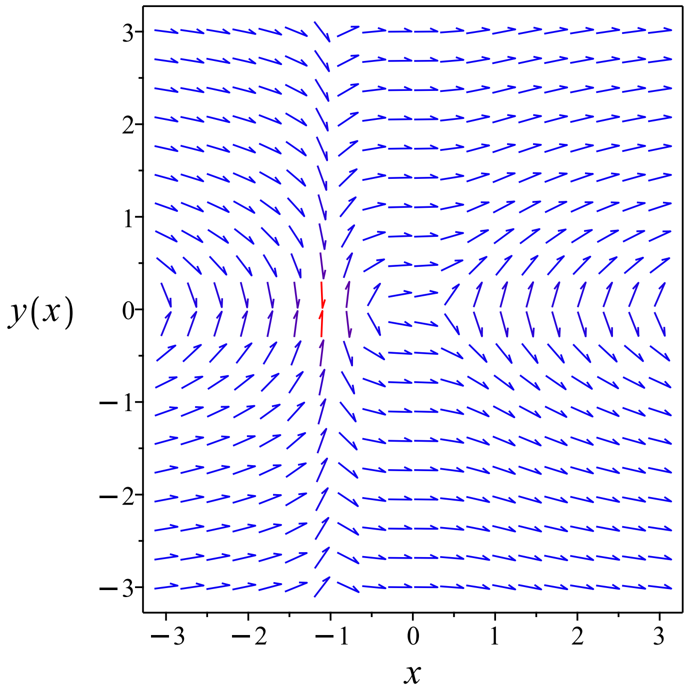

Figure 82: Slope field plot

Verification of solutions

$$\frac{\ln(x+1)}{3}+\frac{\ln(x^2-x+1)}{3}=\frac{y^2}{2}+c_1$$

Verified OK.

2.2.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(y)\,\mathrm{d}y = \left(\frac{x^2}{x^3+1}\right)\mathrm{d}x$$
$$\left(-\frac{x^2}{x^3+1}\right)\mathrm{d}x + (y)\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = -\frac{x^2}{x^3+1}$$
$$N(x,y) = y$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{x^2}{x^3+1}\right)\\ &= 0\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(y) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int M \, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int -\frac{x^2}{x^3+1} \, \mathrm{d}x
\end{aligned}
$$

$$
\phi = -\frac{\ln(x^3+1)}{3} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y$. Therefore equation (4) becomes

$$
y = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = y
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \, \mathrm{d}y &= \int (y) \, \mathrm{d}y \\
f(y) &= \frac{y^2}{2} + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\ln(x^3+1)}{3} + \frac{y^2}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\ln(x^3+1)}{3} + \frac{y^2}{2}$$

Summary

The solution(s) found are the following

$$-\frac{\ln(x^3+1)}{3} + \frac{y^2}{2} = c_1 \tag{1}$$

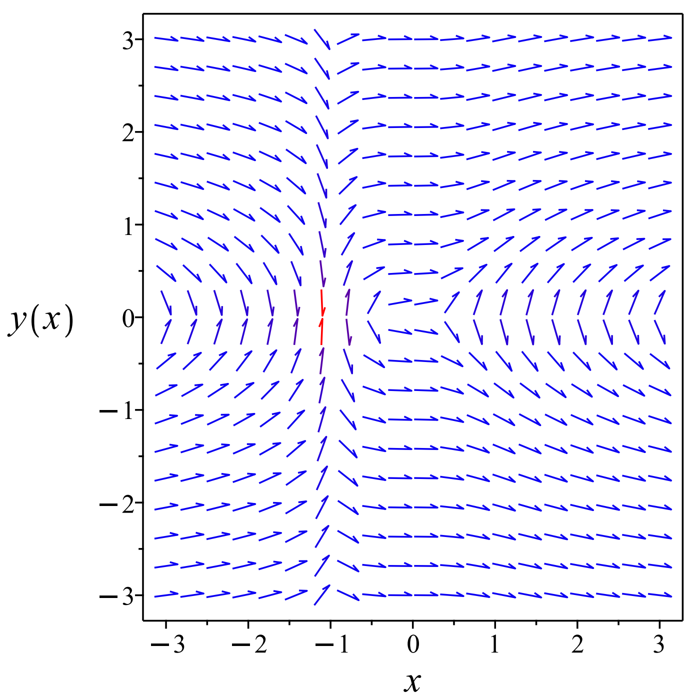

Figure 83: Slope field plot

Verification of solutions

$$-\frac{\ln(x^3+1)}{3} + \frac{y^2}{2} = c_1$$

Verified OK.

Problem number: 3.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "riccati", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{\sin(x)\, y^2 + y' = 0}$$

2.3.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= -\sin(x)\, y^2 \end{aligned}$$

Where $f(x) = -\sin(x)$ and $g(y) = y^2$. Integrating both sides gives

$$\frac{1}{y^2}\, dy = -\sin(x)\, dx$$

$$\int \frac{1}{y^2}\, dy = \int -\sin(x)\, dx$$

$$-\frac{1}{y} = \cos(x) + c_1$$

Which results in

$$y = -\frac{1}{\cos(x) + c_1}$$

Summary

The solution(s) found are the following

$$y = -\frac{1}{\cos(x) + c_1} \tag{1}$$

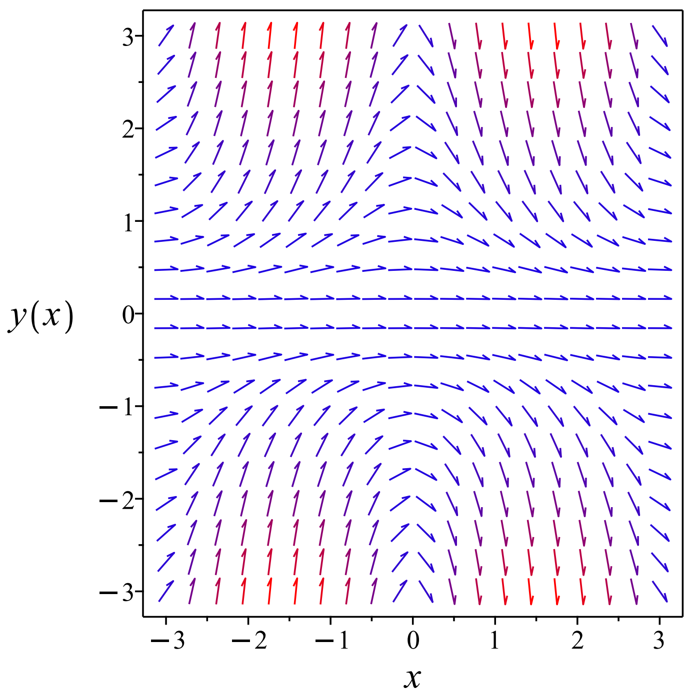

Figure 84: Slope field plot

Verification of solutions

$$y = -\frac{1}{\cos(x) + c_1}$$

Verified OK.

2.3.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\sin(x)\, y^2 \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 100: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= -\frac{1}{\sin(x)} \\
\eta(x,y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{-\frac{1}{\sin(x)}} dx
\end{aligned}
$$

Which results in

$$
S = \cos(x)
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = -\sin(x)\, y^2
$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= -\sin(x) \\
S_y &= 0
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{y^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{1}{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\cos(x) = -\frac{1}{y} + c_1$$

Which simplifies to

$$\cos(x) = -\frac{1}{y} + c_1$$

Which gives

$$y = -\frac{1}{\cos(x) - c_1}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\sin(x)\, y^2$ 	$R = y$ $S = \cos(x)$	$\frac{dS}{dR} = \frac{1}{R^2}$ 
Summary

The solution(s) found are the following

$$y = -\frac{1}{\cos(x) - c_1} \tag{1}$$

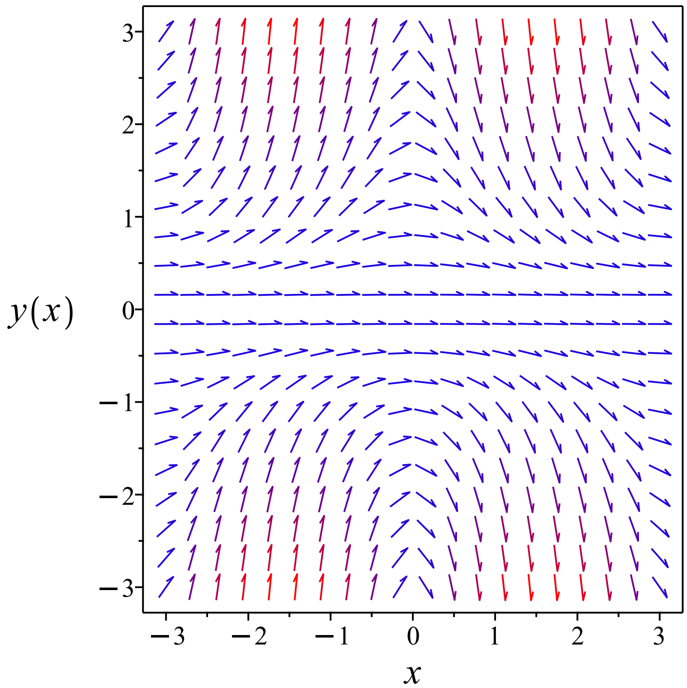

Figure 85: Slope field plot

Verification of solutions

$$y = -\frac{1}{\cos(x) - c_1}$$

2.3.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(-\frac{1}{y^2}\right) \mathrm{d}y &= (\sin(x))\, \mathrm{d}x \\
(-\sin(x))\, \mathrm{d}x + \left(-\frac{1}{y^2}\right) \mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -\sin(x) \\
N(x, y) &= -\frac{1}{y^2}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-\sin(x)) \\
&= 0
\end{aligned}
$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}\left(-\frac{1}{y^2}\right)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int M\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int -\sin(x)\,\mathrm{d}x$$
$$\phi = \cos(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{1}{y^2}$. Therefore equation (4) becomes

$$-\frac{1}{y^2} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{1}{y^2}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(-\frac{1}{y^2}\right)\mathrm{d}y$$
$$f(y) = \frac{1}{y} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \cos(x) + \frac{1}{y} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \cos(x) + \frac{1}{y}$$

The solution becomes

$$y = -\frac{1}{\cos(x) - c_1}$$

Summary

The solution(s) found are the following

$$y = -\frac{1}{\cos(x) - c_1} \tag{1}$$

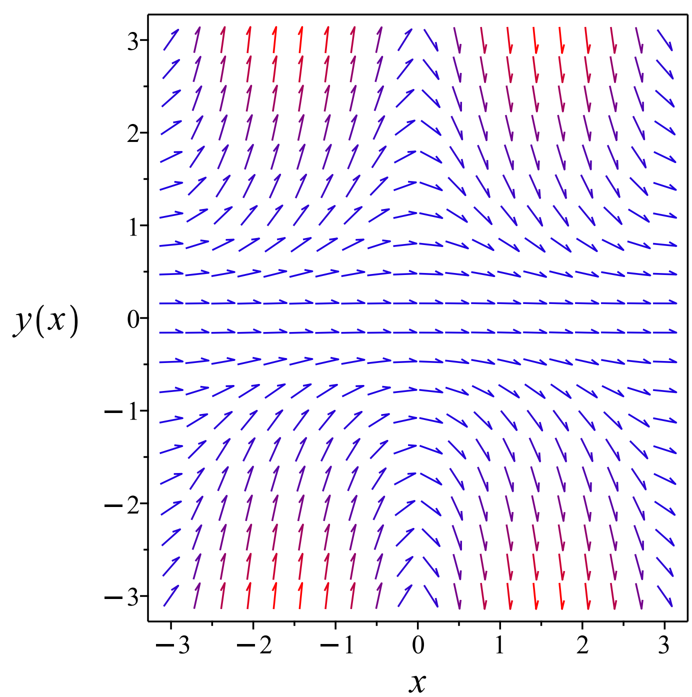

Figure 86: Slope field plot

Verification of solutions

$$y = -\frac{1}{\cos(x) - c_1}$$

Verified OK.

2.3.4 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= -\sin(x)\, y^2 \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -\sin(x)\, y^2$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 0$, $f_1(x) = 0$ and $f_2(x) = -\sin(x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{-\sin(x)\, u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= -\cos(x) \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= 0 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-\sin(x)\, u''(x) + \cos(x)\, u'(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = c_1 + \cos(x) c_2$$

The above shows that

$$u'(x) = -c_2 \sin(x)$$

Using the above in (1) gives the solution

$$y = -\frac{c_2}{c_1 + \cos(x) c_2}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{1}{c_3 + \cos(x)}$$

Summary

The solution(s) found are the following

$$y = -\frac{1}{c_3 + \cos(x)} \tag{1}$$

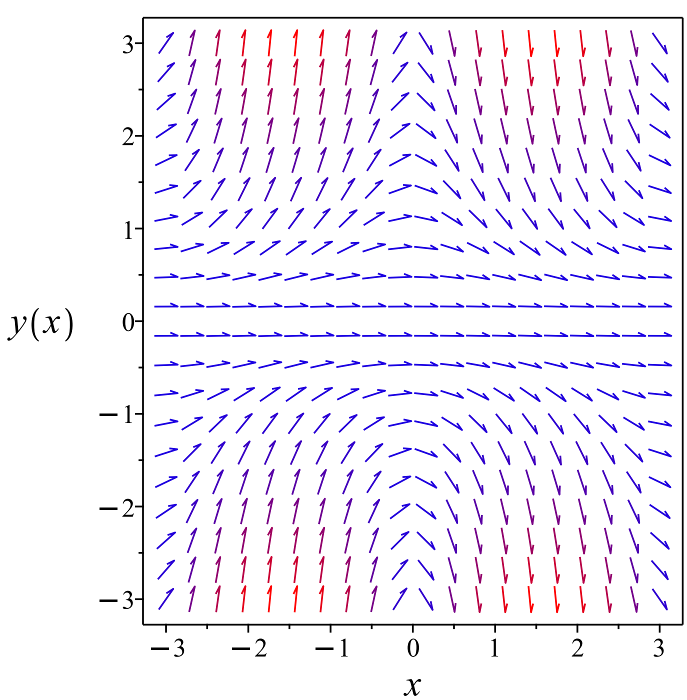

Figure 87: Slope field plot

Verification of solutions

$$y = -\frac{1}{c_3 + \cos(x)}$$

Verified OK.

2.3.5 Maple step by step solution

Let's solve

$\sin(x)\, y^2 + y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y^2} = -\sin(x)$

- Integrate both sides with respect to x

  $\int \frac{y'}{y^2} dx = \int -\sin(x)\, dx + c_1$

- Evaluate integral

  $-\frac{1}{y} = \cos(x) + c_1$

- Solve for y

  $y = -\frac{1}{\cos(x) + c_1}$

Problem number: 4.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "differentialType", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{3x^2 - 1}{3 + 2y} = 0}$$

2.4.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{3x^2 - 1}{3 + 2y} \end{aligned}$$

Where $f(x) = 3x^2 - 1$ and $g(y) = \frac{1}{3+2y}$. Integrating both sides gives

$$\frac{1}{\frac{1}{3+2y}}\, dy = 3x^2 - 1\, dx$$

$$\int \frac{1}{\frac{1}{3+2y}} dy = \int 3x^2 - 1 \, dx$$
$$y^2 + 3y = x^3 + c_1 - x$$

Which results in

$$y = -\frac{3}{2} + \frac{\sqrt{4x^3 + 4c_1 - 4x + 9}}{2}$$
$$y = -\frac{3}{2} - \frac{\sqrt{4x^3 + 4c_1 - 4x + 9}}{2}$$

Summary

The solution(s) found are the following

$$y = -\frac{3}{2} + \frac{\sqrt{4x^3 + 4c_1 - 4x + 9}}{2} \tag{1}$$
$$y = -\frac{3}{2} - \frac{\sqrt{4x^3 + 4c_1 - 4x + 9}}{2} \tag{2}$$

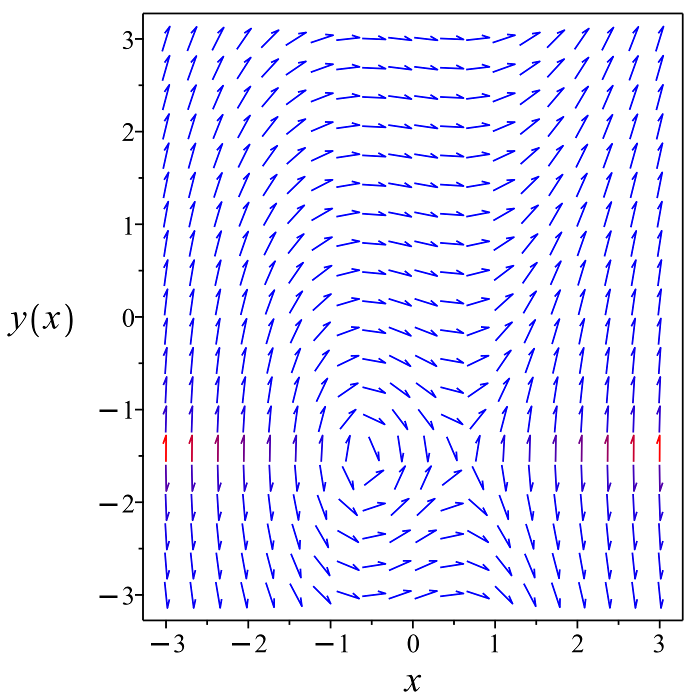

Figure 88: Slope field plot

Verification of solutions

$$y = -\frac{3}{2} + \frac{\sqrt{4x^3 + 4c_1 - 4x + 9}}{2}$$

Verified OK.

$$y = -\frac{3}{2} - \frac{\sqrt{4x^3 + 4c_1 - 4x + 9}}{2}$$

Verified OK.

2.4.2 Solving as differentialType ode

Writing the ode as

$$y' = \frac{3x^2 - 1}{3 + 2y} \tag{1}$$

Which becomes

$$(3 + 2y)\, dy = (3x^2 - 1)\, dx \tag{2}$$

But the RHS is complete differential because

$$(3x^2 - 1)\, dx = d(x^3 - x)$$

Hence (2) becomes

$$(3 + 2y)\, dy = d(x^3 - x)$$

Integrating both sides gives gives these solutions

$$y = -\frac{3}{2} + \frac{\sqrt{4x^3 + 4c_1 - 4x + 9}}{2} + c_1$$
$$y = -\frac{3}{2} - \frac{\sqrt{4x^3 + 4c_1 - 4x + 9}}{2} + c_1$$

Summary
The solution(s) found are the following

$$y = -\frac{3}{2} + \frac{\sqrt{4x^3 + 4c_1 - 4x + 9}}{2} + c_1 \tag{1}$$
$$y = -\frac{3}{2} - \frac{\sqrt{4x^3 + 4c_1 - 4x + 9}}{2} + c_1 \tag{2}$$

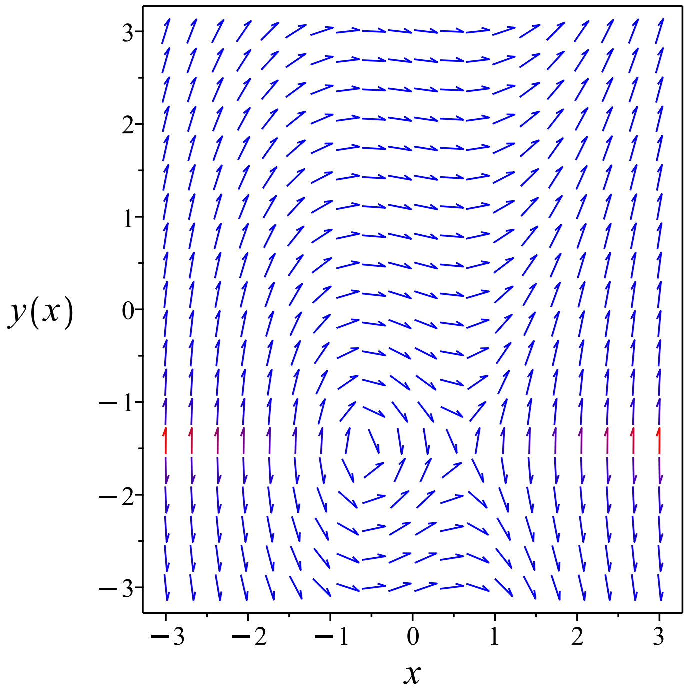

Figure 89: Slope field plot

Verification of solutions

$$y = -\frac{3}{2} + \frac{\sqrt{4x^3 + 4c_1 - 4x + 9}}{2} + c_1$$

Verified OK.

$$y = -\frac{3}{2} - \frac{\sqrt{4x^3 + 4c_1 - 4x + 9}}{2} + c_1$$

Verified OK.

2.4.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{3x^2 - 1}{3 + 2y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 103: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= \frac{1}{3x^2 - 1} \\
\eta(x, y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x}+\eta\frac{\partial}{\partial y}\right)S(x,y)=1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta=0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\xi}dx \\ &= \int \frac{1}{\frac{1}{3x^2-1}}dx\end{aligned}$$

Which results in

$$S = x^3 - x$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{3x^2-1}{3+2y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= 0 \\ R_y &= 1 \\ S_x &= 3x^2-1 \\ S_y &= 0\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 3 + 2y \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 3 + 2R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = R^2 + 3R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$x^3 - x = y^2 + c_1 + 3y$$

Which simplifies to

$$x^3 - x = y^2 + c_1 + 3y$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{3x^2-1}{3+2y}$ 	$R = y$ $S = x^3 - x$	$\frac{dS}{dR} = 3 + 2R$ 
Summary

The solution(s) found are the following

$$x^3 - x = y^2 + c_1 + 3y \tag{1}$$

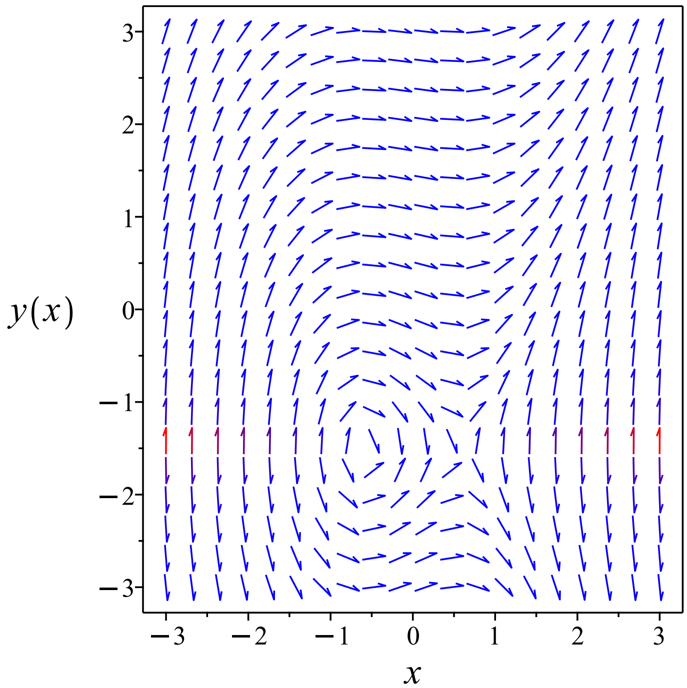

Figure 90: Slope field plot

Verification of solutions

$$x^3 - x = y^2 + c_1 + 3y$$

Verified OK.

2.4.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(3+2y)\,\mathrm{d}y = \left(3x^2-1\right)\mathrm{d}x$$
$$\left(-3x^2+1\right)\mathrm{d}x + (3+2y)\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = -3x^2+1$$
$$N(x,y) = 3+2y$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-3x^2+1\right)$$
$$= 0$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}(3+2y)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -3x^2 + 1 \, \mathrm{d}x$$
$$\phi = -x^3 + x + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 3 + 2y$. Therefore equation (4) becomes

$$3 + 2y = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 3 + 2y$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (3 + 2y) \, \mathrm{d}y$$
$$f(y) = y^2 + 3y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -x^3 + y^2 + x + 3y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x^3 + y^2 + x + 3y$$

Summary
The solution(s) found are the following

$$-x^3 + y^2 + 3y + x = c_1 \tag{1}$$

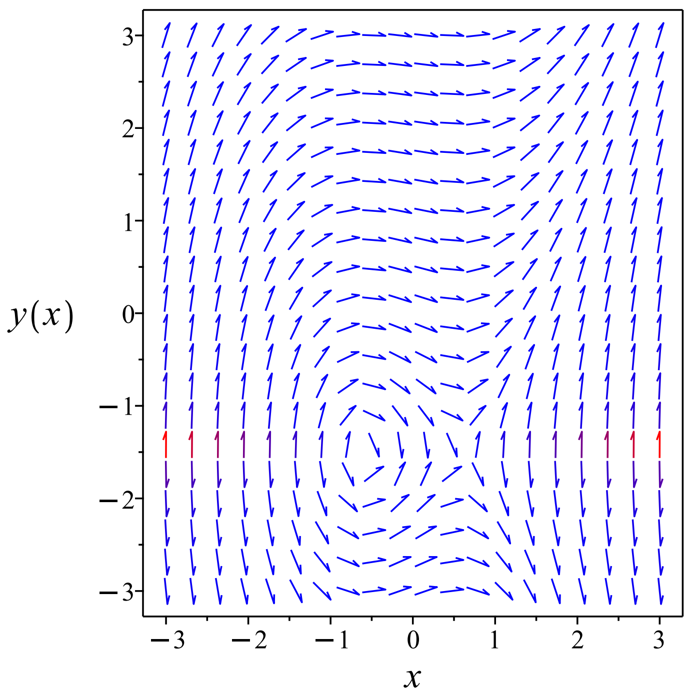

Figure 91: Slope field plot

Verification of solutions

$$-x^3 + y^2 + 3y + x = c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \cos(x)^2 \cos(2y)^2 = 0}$$

2.5.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \cos(x)^2 \cos(2y)^2 \end{aligned}$$

Where $f(x) = \cos(x)^2$ and $g(y) = \cos(2y)^2$. Integrating both sides gives

$$\frac{1}{\cos(2y)^2}\,dy = \cos(x)^2\,dx$$

$$\int \frac{1}{\cos(2y)^2}\,dy = \int \cos(x)^2\,dx$$

$$\frac{\tan(2y)}{2} = \frac{\cos(x)\sin(x)}{2} + \frac{x}{2} + c_1$$

Which results in

$$y = \frac{\arctan(\cos(x)\sin(x) + 2c_1 + x)}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{\arctan(\cos(x)\sin(x) + 2c_1 + x)}{2} \tag{1}$$

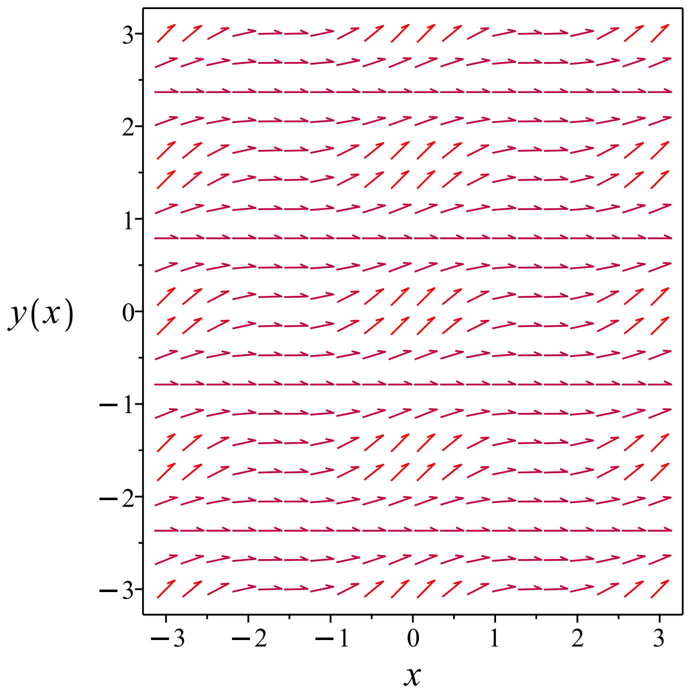

Figure 92: Slope field plot

Verification of solutions

$$y = \frac{\arctan(\cos(x)\sin(x) + 2c_1 + x)}{2}$$

Verified OK.

2.5.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \cos(x)^2 \cos(2y)^2 \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 106: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η

homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\xi(x, y) = \frac{1}{\cos(x)^2}$$
$$\eta(x, y) = 0 \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{\cos(x)^2}} dx \end{aligned}$$

Which results in

$$S = \frac{\cos(x)\sin(x)}{2} + \frac{x}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \cos(x)^2 \cos(2y)^2$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= \frac{\cos(2x)}{2} + \frac{1}{2} \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \sec(2y)^2 \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \sec(2R)^2
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \frac{\tan(2R)}{2} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{\sin(2x)}{4} + \frac{x}{2} = \frac{\tan(2y)}{2} + c_1
$$

Which simplifies to

$$
\frac{\sin(2x)}{4} + \frac{x}{2} = \frac{\tan(2y)}{2} + c_1
$$

Which gives

$$
y = -\frac{\arctan\left(-\frac{\sin(2x)}{2} - x + 2c_1\right)}{2}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \cos(x)^2 \cos(2y)^2$ 	$R = y$ $S = \frac{\sin(2x)}{4} + \frac{x}{2}$	$\frac{dS}{dR} = \sec(2R)^2$ 
Summary

The solution(s) found are the following

$$y = -\frac{\arctan\left(-\frac{\sin(2x)}{2} - x + 2c_1\right)}{2} \tag{1}$$

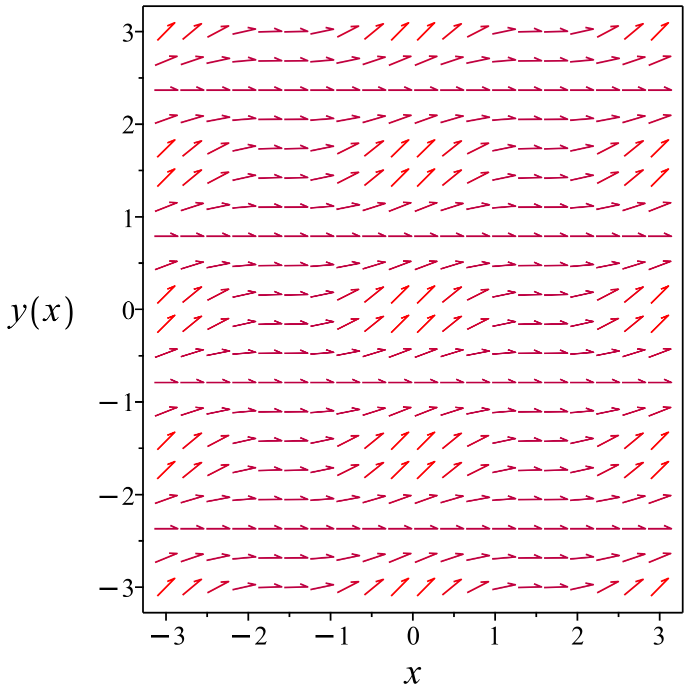

Figure 93: Slope field plot

Verification of solutions

$$y = -\frac{\arctan\left(-\frac{\sin(2x)}{2} - x + 2c_1\right)}{2}$$

Verified OK.

2.5.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{\cos(2y)^2}\right)\mathrm{d}y = \left(\cos(x)^2\right)\mathrm{d}x$$
$$\left(-\cos(x)^2\right)\mathrm{d}x + \left(\frac{1}{\cos(2y)^2}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\cos(x)^2$$
$$N(x, y) = \frac{1}{\cos(2y)^2}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-\cos(x)^2\right)$$
$$= 0$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{\cos(2y)^2}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \qquad (1) \\
\frac{\partial \phi}{\partial y} &= N \qquad (2)
\end{aligned}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\cos(x)^2\,\mathrm{d}x \\
\phi &= -\frac{\sin(2x)}{4} - \frac{x}{2} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \qquad (4)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{\cos(2y)^2}$. Therefore equation (4) becomes

$$
\frac{1}{\cos(2y)^2} = 0 + f'(y) \qquad (5)
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{\cos(2y)^2}
$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\sec(2y)^2\right) \mathrm{d}y$$

$$f(y) = \frac{\tan(2y)}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\sin(2x)}{4} - \frac{x}{2} + \frac{\tan(2y)}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\sin(2x)}{4} - \frac{x}{2} + \frac{\tan(2y)}{2}$$

Summary

The solution(s) found are the following

$$-\frac{x}{2} - \frac{\sin(2x)}{4} + \frac{\tan(2y)}{2} = c_1 \tag{1}$$

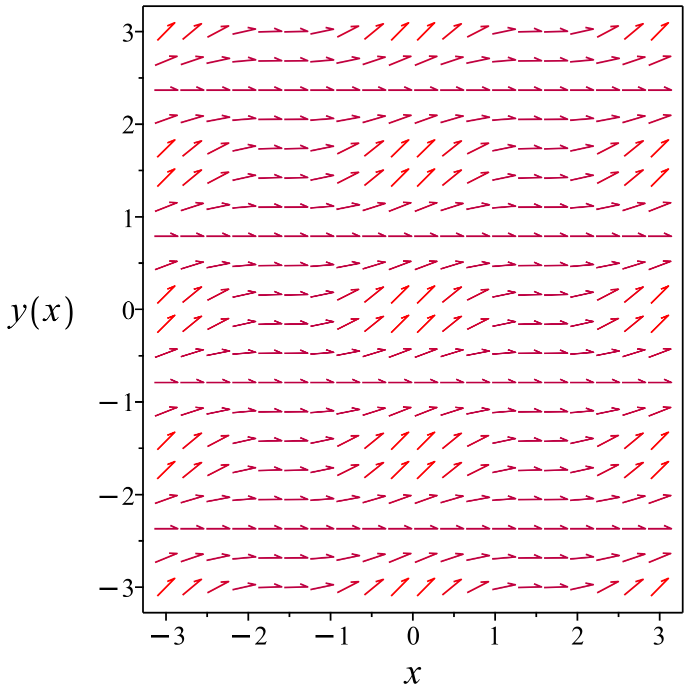

Figure 94: Slope field plot

Verification of solutions

$$-\frac{x}{2} - \frac{\sin(2x)}{4} + \frac{\tan(2y)}{2} = c_1$$

Verified OK.

2.5.4 Maple step by step solution

Let's solve

$y' - \cos(x)^2 \cos(2y)^2 = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{\cos(2y)^2} = \cos(x)^2$

- Integrate both sides with respect to x

  $\int \frac{y'}{\cos(2y)^2} dx = \int \cos(x)^2 dx + c_1$

- Evaluate integral

$$\frac{\tan(2y)}{2} = \frac{\cos(x)\sin(x)}{2} + \frac{x}{2} + c_1$$

- Solve for y

$$y = \frac{\arctan(\cos(x)\sin(x) + 2c_1 + x)}{2}$$

Problem number: 6.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y'x - \sqrt{1 - y^2} = 0}$$

2.6.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= f(x)g(y) \\ &= \frac{\sqrt{-y^2 + 1}}{x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(y) = \sqrt{-y^2 + 1}$. Integrating both sides gives

$$\frac{1}{\sqrt{-y^2 + 1}}\, dy = \frac{1}{x}\, dx$$

$$\int \frac{1}{\sqrt{-y^2 + 1}}\, dy = \int \frac{1}{x}\, dx$$

$$\arcsin(y) = \ln(x) + c_1$$

Which results in

$$y = \sin(\ln(x) + c_1)$$

Summary

The solution(s) found are the following

$$y = \sin(\ln(x) + c_1) \tag{1}$$

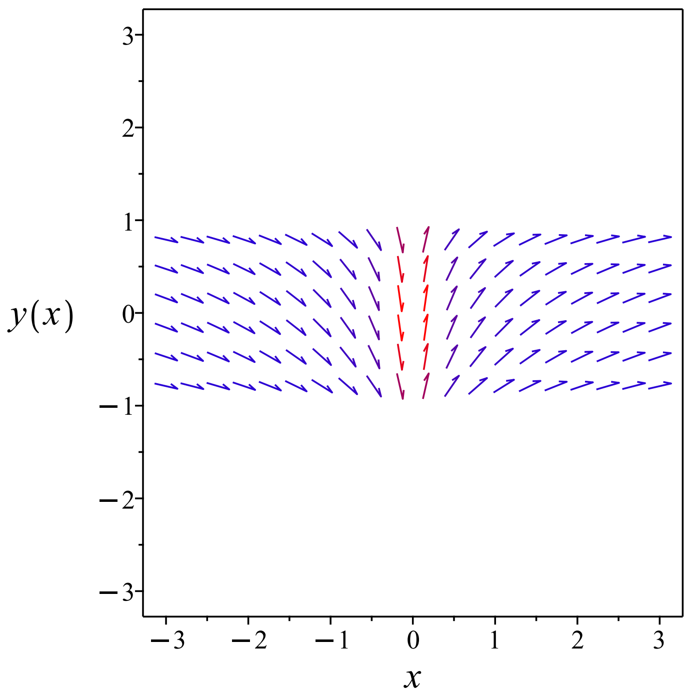

Figure 95: Slope field plot

Verification of solutions

$$y = \sin(\ln(x) + c_1)$$

Verified OK.

2.6.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{\sqrt{-y^2+1}}{x} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 109: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= x \\
\eta(x, y) &= 0
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{x} dx
\end{aligned}
$$

Which results in

$$
S = \ln(x)
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$
\omega(x, y) = \frac{\sqrt{-y^2 + 1}}{x}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= \frac{1}{x} \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{1}{\sqrt{-y^2 + 1}} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{1}{\sqrt{-R^2 + 1}}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \arcsin(R) + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\ln(x) = \arcsin(y) + c_1
$$

Which simplifies to

$$
\ln(x) = \arcsin(y) + c_1
$$

Which gives

$$
y = -\sin(-\ln(x) + c_1)
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{\sqrt{-y^2+1}}{x}$ 	$R = y$ $S = \ln(x)$	$\frac{dS}{dR} = \frac{1}{\sqrt{-R^2+1}}$ 
Summary

The solution(s) found are the following

$$y = -\sin(-\ln(x) + c_1) \tag{1}$$

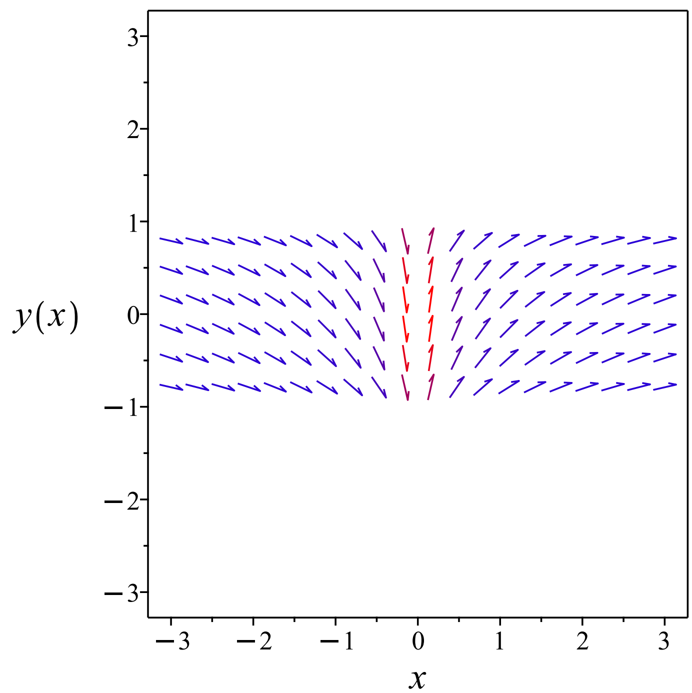

Figure 96: Slope field plot

Verification of solutions

$$y = -\sin(-\ln(x) + c_1)$$

Verified OK.

2.6.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{\sqrt{-y^2 + 1}}\right) \mathrm{d}y = \left(\frac{1}{x}\right) \mathrm{d}x$$
$$\left(-\frac{1}{x}\right) \mathrm{d}x + \left(\frac{1}{\sqrt{-y^2 + 1}}\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\frac{1}{x}$$
$$N(x, y) = \frac{1}{\sqrt{-y^2 + 1}}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-\frac{1}{x}\right)$$
$$= 0$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{\sqrt{-y^2+1}}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int M\, \mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int -\frac{1}{x}\, \mathrm{d}x\end{aligned}$$

$$\phi = -\ln(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{\sqrt{-y^2+1}}$. Therefore equation (4) becomes

$$\frac{1}{\sqrt{-y^2+1}} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{1}{\sqrt{-y^2+1}}$$

Integrating the above w.r.t y gives

$$\begin{aligned}\int f'(y)\, \mathrm{d}y &= \int \left(\frac{1}{\sqrt{-y^2+1}}\right) \mathrm{d}y\\ f(y) &= \arcsin(y) + c_1\end{aligned}$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(x) + \arcsin(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(x) + \arcsin(y)$$

The solution becomes

$$y = \sin(\ln(x) + c_1)$$

Summary

The solution(s) found are the following

$$y = \sin(\ln(x) + c_1) \tag{1}$$

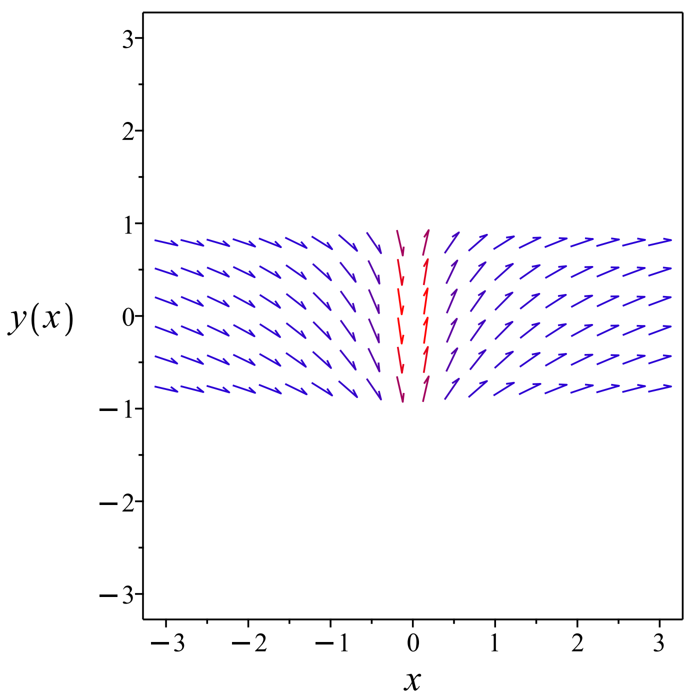

Figure 97: Slope field plot

Verification of solutions

$$y = \sin(\ln(x) + c_1)$$

Verified OK.

Section: Section 2.2. Page 48
Problem number: 8.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "differentialType", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{x^2}{1 + y^2} = 0}$$

2.8.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{x^2}{y^2+1} \end{aligned}$$

Where $f(x) = x^2$ and $g(y) = \frac{1}{y^2+1}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y^2+1}}\, dy = x^2\, dx$$

$$\int \frac{1}{\frac{1}{y^2+1}}\,dy = \int x^2\,dx$$

$$\frac{1}{3}y^3 + y = \frac{x^3}{3} + c_1$$

Which results in

$$y = \frac{\left(4x^3 + 12c_1 + 4\sqrt{x^6 + 6c_1x^3 + 9c_1^2 + 4}\right)^{\frac{1}{3}}}{2} - \frac{2}{\left(4x^3 + 12c_1 + 4\sqrt{x^6 + 6c_1x^3 + 9c_1^2 + 4}\right)^{\frac{1}{3}}}$$

$$y = -\frac{\left(4x^3 + 12c_1 + 4\sqrt{x^6 + 6c_1x^3 + 9c_1^2 + 4}\right)^{\frac{1}{3}}}{4} + \frac{1}{\left(4x^3 + 12c_1 + 4\sqrt{x^6 + 6c_1x^3 + 9c_1^2 + 4}\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(\frac{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}{2} + \frac{2}{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}\right)}{2}$$

$$y = -\frac{\left(4x^3 + 12c_1 + 4\sqrt{x^6 + 6c_1x^3 + 9c_1^2 + 4}\right)^{\frac{1}{3}}}{4} + \frac{1}{\left(4x^3 + 12c_1 + 4\sqrt{x^6 + 6c_1x^3 + 9c_1^2 + 4}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(\frac{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}{2} + \frac{2}{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}\right)}{2}$$

Summary
The solution(s) found are the following

$$y = \frac{\left(4x^3 + 12c_1 + 4\sqrt{x^6 + 6c_1x^3 + 9c_1^2 + 4}\right)^{\frac{1}{3}}}{2} - \frac{2}{\left(4x^3 + 12c_1 + 4\sqrt{x^6 + 6c_1x^3 + 9c_1^2 + 4}\right)^{\frac{1}{3}}} \tag{1}$$

$$y = -\frac{\left(4x^3 + 12c_1 + 4\sqrt{x^6 + 6c_1x^3 + 9c_1^2 + 4}\right)^{\frac{1}{3}}}{4} + \frac{1}{\left(4x^3 + 12c_1 + 4\sqrt{x^6 + 6c_1x^3 + 9c_1^2 + 4}\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(\frac{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}{2} + \frac{2}{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}\right)}{2} \tag{2}$$

$$y = -\frac{\left(4x^3 + 12c_1 + 4\sqrt{x^6 + 6c_1x^3 + 9c_1^2 + 4}\right)^{\frac{1}{3}}}{4} + \frac{1}{\left(4x^3 + 12c_1 + 4\sqrt{x^6 + 6c_1x^3 + 9c_1^2 + 4}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(\frac{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}{2} + \frac{2}{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}\right)}{2} \tag{3}$$

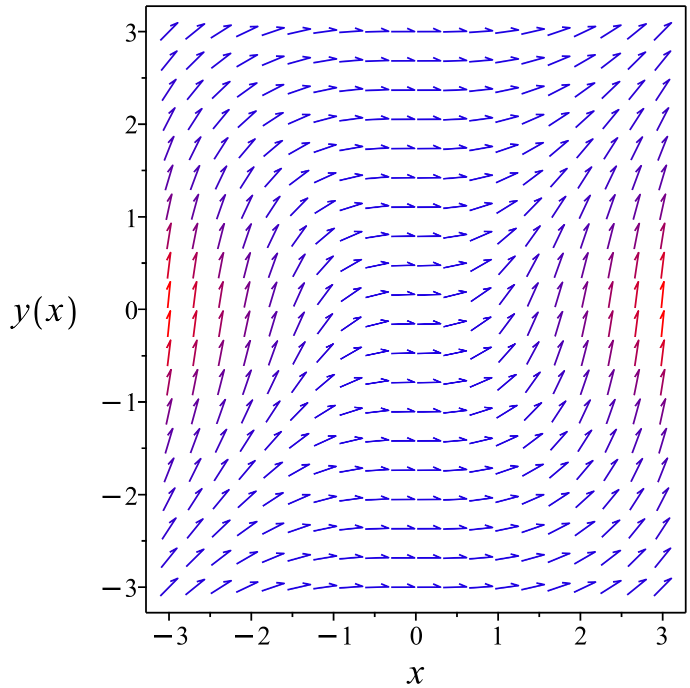

Figure 98: Slope field plot

Verification of solutions

$$y = \frac{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}{2} - \frac{2}{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}$$

Verified OK.

$$y = -\frac{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}{4} + \frac{1}{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(\frac{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}{2} + \frac{2}{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}\right)}{2}$$

Verified OK.

$$y = -\frac{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}{4} + \frac{1}{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(\frac{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}{2} + \frac{2}{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}\right)}{2}$$

Verified OK.

2.8.2 Solving as differentialType ode

Writing the ode as

$$y' = \frac{x^2}{1+y^2} \tag{1}$$

Which becomes

$$\left(y^2+1\right) dy = \left(x^2\right) dx \tag{2}$$

But the RHS is complete differential because

$$\left(x^{2}\right) dx = d\left(\frac{x^{3}}{3}\right)$$

Hence (2) becomes

$$\left(y^{2}+1\right) dy = d\left(\frac{x^{3}}{3}\right)$$

Integrating both sides gives gives these solutions

$$y = \frac{\left(4x^{3}+12c_{1}+4\sqrt{x^{6}+6c_{1}x^{3}+9c_{1}^{2}+4}\right)^{\frac{1}{3}}}{2} - \frac{2}{\left(4x^{3}+12c_{1}+4\sqrt{x^{6}+6c_{1}x^{3}+9c_{1}^{2}+4}\right)^{\frac{1}{3}}} + c_{1}$$

$$y = -\frac{\left(4x^{3}+12c_{1}+4\sqrt{x^{6}+6c_{1}x^{3}+9c_{1}^{2}+4}\right)^{\frac{1}{3}}}{4} + \frac{1}{\left(4x^{3}+12c_{1}+4\sqrt{x^{6}+6c_{1}x^{3}+9c_{1}^{2}+4}\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\,\Bigg(\Big(}{}$$

$$y = -\frac{\left(4x^{3}+12c_{1}+4\sqrt{x^{6}+6c_{1}x^{3}+9c_{1}^{2}+4}\right)^{\frac{1}{3}}}{4} + \frac{1}{\left(4x^{3}+12c_{1}+4\sqrt{x^{6}+6c_{1}x^{3}+9c_{1}^{2}+4}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\,\Bigg(\Big(}{}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}{2} - \frac{2}{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}} + c_1 \tag{1}$$

$$y = -\frac{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}{4} + \frac{1}{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(\frac{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}{2} + \frac{2}{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}\right)}{2} + c_1 \tag{2}$$

$$y = -\frac{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}{4} + \frac{1}{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(\frac{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}{2} + \frac{2}{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}\right)}{2} + c_1 \tag{3}$$

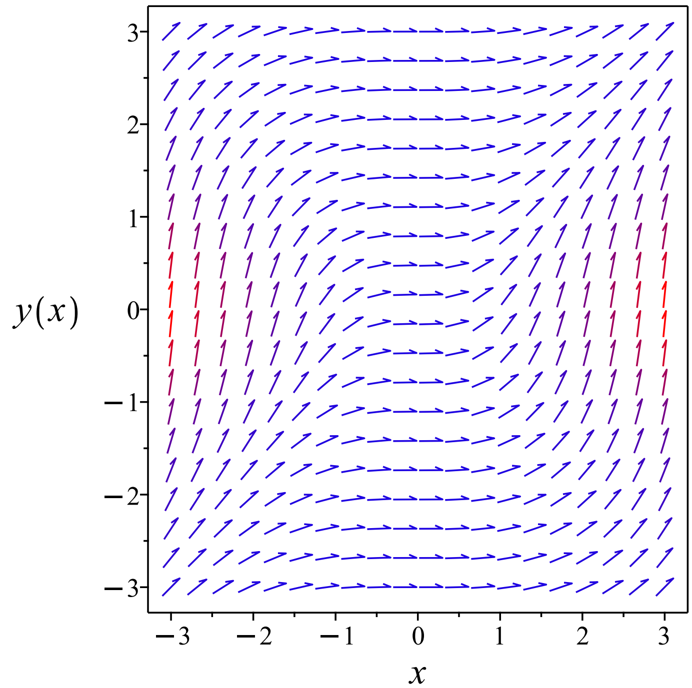

Figure 99: Slope field plot

Verification of solutions

$$y=\frac{\left(4x^{3}+12c_{1}+4\sqrt{x^{6}+6c_{1}x^{3}+9c_{1}^{2}+4}\right)^{\frac{1}{3}}}{2}-\frac{2}{\left(4x^{3}+12c_{1}+4\sqrt{x^{6}+6c_{1}x^{3}+9c_{1}^{2}+4}\right)^{\frac{1}{3}}}+c_{1}$$

Verified OK.

Verified OK.

$$y=-\frac{\left(4x^{3}+12c_{1}+4\sqrt{x^{6}+6c_{1}x^{3}+9c_{1}^{2}+4}\right)^{\frac{1}{3}}}{4}+\frac{1}{\left(4x^{3}+12c_{1}+4\sqrt{x^{6}+6c_{1}x^{3}+9c_{1}^{2}+4}\right)^{\frac{1}{3}}}-\frac{i\sqrt{3}\left(\frac{\left(4x^{3}+12c_{1}+4\sqrt{x^{6}+6c_{1}x^{3}+9c_{1}^{2}+4}\right)^{\frac{1}{3}}}{2}+\frac{2}{\left(4x^{3}+12c_{1}+4\sqrt{x^{6}+6c_{1}x^{3}+9c_{1}^{2}+4}\right)^{\frac{1}{3}}}\right)}{2}+c_{1}$$

Verified OK.

2.8.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y'=\frac{x^{2}}{y^{2}+1}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 112: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= \frac{1}{x^2} \\ \eta(x,y) &= 0 \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{x^2}} dx \end{aligned}$$

Which results in

$$S = \frac{x^3}{3}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{x^2}{y^2 + 1}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= x^2 \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = y^2 + 1 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R^2 + 1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{1}{3}R^3 + R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{x^3}{3} = \frac{y^3}{3} + y + c_1$$

Which simplifies to

$$\frac{x^3}{3} = \frac{y^3}{3} + y + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^2}{y^2+1}$ 	$R = y$ $S = \frac{x^3}{3}$	$\frac{dS}{dR} = R^2 + 1$ 
Summary
The solution(s) found are the following

$$\frac{x^3}{3} = \frac{y^3}{3} + y + c_1 \tag{1}$$

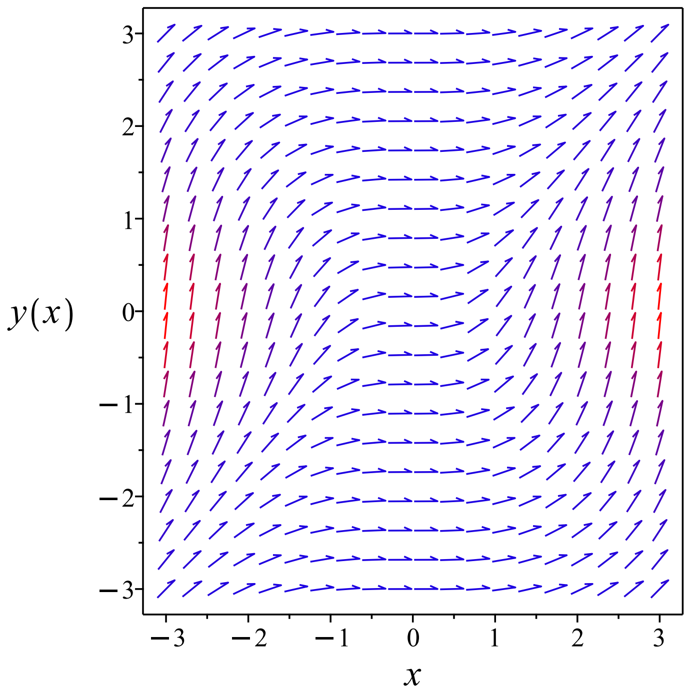

Figure 100: Slope field plot

Verification of solutions

$$\frac{x^3}{3} = \frac{y^3}{3} + y + c_1$$

Verified OK.

2.8.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(y^2 + 1)\,\mathrm{d}y &= (x^2)\,\mathrm{d}x\\ (-x^2)\,\mathrm{d}x + (y^2 + 1)\,\mathrm{d}y &= 0 \qquad \text{(2A)}\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -x^2\\ N(x, y) &= y^2 + 1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-x^2)\\ &= 0\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(y^2+1) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int M \,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int -x^2 \,\mathrm{d}x
\end{aligned}
$$

$$
\phi = -\frac{x^3}{3} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y^2 + 1$. Therefore equation (4) becomes

$$
y^2 + 1 = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = y^2 + 1
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \,\mathrm{d}y &= \int (y^2+1) \,\mathrm{d}y \\
f(y) &= \frac{1}{3}y^3 + y + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{1}{3}x^3 + \frac{1}{3}y^3 + y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{1}{3}x^3 + \frac{1}{3}y^3 + y$$

Summary

The solution(s) found are the following

$$-\frac{x^3}{3} + \frac{y^3}{3} + y = c_1 \tag{1}$$

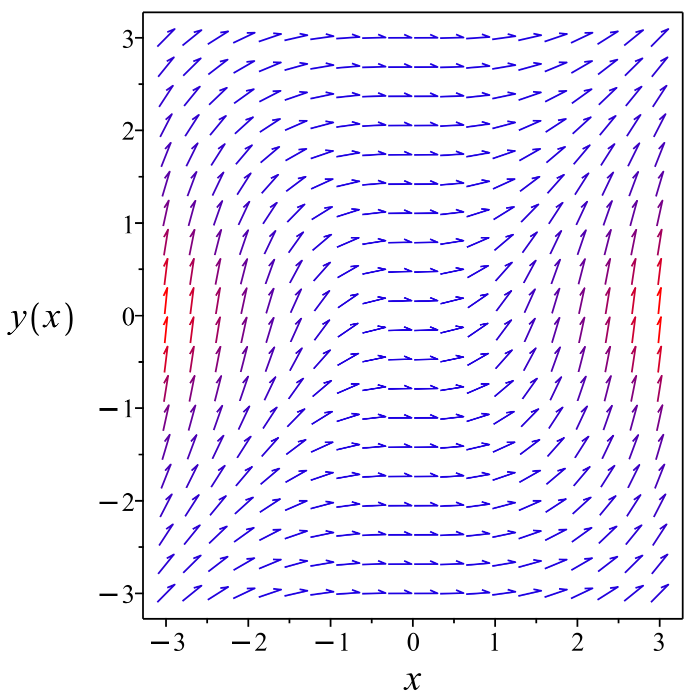

Figure 101: Slope field plot

Verification of solutions

$$-\frac{x^3}{3} + \frac{y^3}{3} + y = c_1$$

Verified OK.

2.8.5 Maple step by step solution

Let's solve

$y' - \frac{x^2}{1+y^2} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $(1+y^2)\, y' = x^2$

- Integrate both sides with respect to x

  $\int (1+y^2)\, y' dx = \int x^2 dx + c_1$

- Evaluate integral

  $\frac{y^3}{3} + y = \frac{x^3}{3} + c_1$

- Solve for y

  $y = \frac{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}{2} - \frac{2}{\left(4x^3+12c_1+4\sqrt{x^6+6c_1x^3+9c_1^2+4}\right)^{\frac{1}{3}}}$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "riccati", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - (1 - 2x)\, y^2 = 0}$$

With initial conditions

$$\left[y(0) = -\frac{1}{6}\right]$$

2.9.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= -y^2(2x - 1) \end{aligned}$$

The x domain of $f(x, y)$ when $y = -\frac{1}{6}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x, y)$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = -\frac{1}{6}$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}
\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(-y^2(2x - 1)\right) \\
&= -2(2x - 1)\, y
\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = -\frac{1}{6}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = -\frac{1}{6}$ is inside this domain. Therefore solution exists and is unique.

2.9.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}
y' &= F(x, y) \\
&= f(x)g(y) \\
&= (1 - 2x)\, y^2
\end{aligned}$$

Where $f(x) = 1 - 2x$ and $g(y) = y^2$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{y^2}\, dy &= 1 - 2x\, dx \\
\int \frac{1}{y^2}\, dy &= \int 1 - 2x\, dx \\
-\frac{1}{y} &= -x^2 + c_1 + x
\end{aligned}$$

Which results in

$$y = -\frac{1}{-x^2 + c_1 + x}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -\frac{1}{6}$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{1}{6} = -\frac{1}{c_1}$$

$$c_1 = 6$$

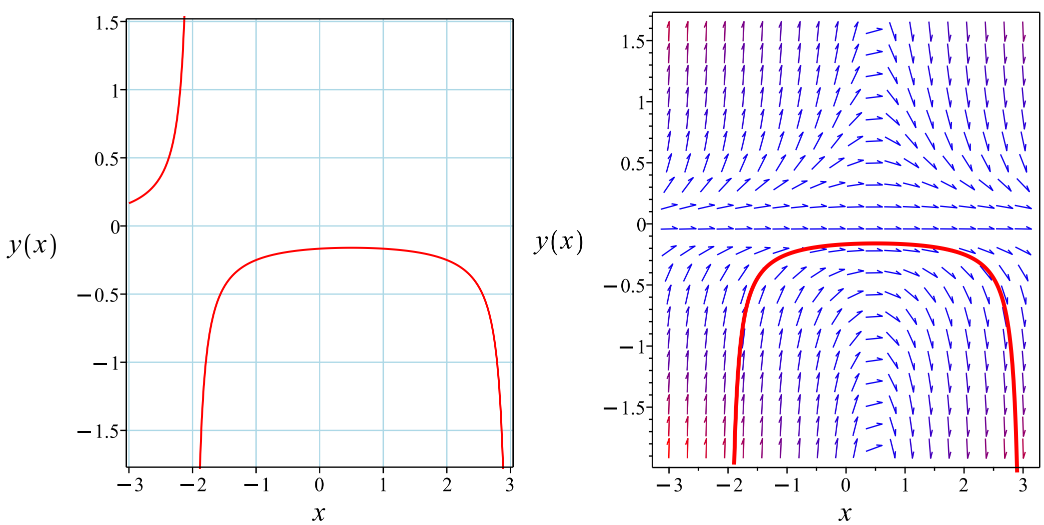
Substituting c_1 found above in the general solution gives

$$y = \frac{1}{x^2 - x - 6}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{x^2 - x - 6} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \frac{1}{x^2 - x - 6}$$

Verified OK.

2.9.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -y^2(2x-1) \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 115: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\xi(x,y) = \frac{1}{1-2x}$$
$$\eta(x,y) = 0 \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{1-2x}} dx \end{aligned}$$

Which results in

$$S = -x^2 + x$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -y^2(2x-1)$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= 1-2x \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{y^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{1}{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-x^2 + x = -\frac{1}{y} + c_1$$

Which simplifies to

$$-x^2 + x = -\frac{1}{y} + c_1$$

Which gives

$$y = \frac{1}{x^2 + c_1 - x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -y^2(2x-1)$ 	$R = y$ $S = -x^2 + x$	$\frac{dS}{dR} = \frac{1}{R^2}$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -\frac{1}{6}$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{1}{6} = \frac{1}{c_1}$$

$$c_1 = -6$$

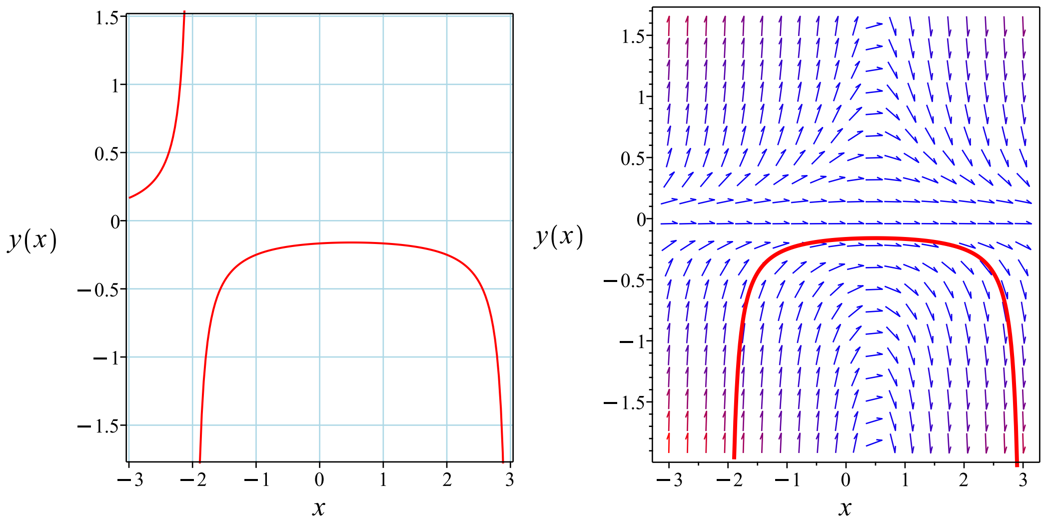
Substituting c_1 found above in the general solution gives

$$y = \frac{1}{x^2 - x - 6}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{x^2 - x - 6} \tag{1}$$



(a) Solution plot (b) Slope field plot

<u>Verification of solutions</u>

$$y = \frac{1}{x^2 - x - 6}$$

Verified OK.

2.9.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(-\frac{1}{y^2}\right)\mathrm{d}y &= (2x-1)\,\mathrm{d}x\\ (1-2x)\,\mathrm{d}x + \left(-\frac{1}{y^2}\right)\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= 1-2x\\ N(x, y) &= -\frac{1}{y^2}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(1-2x)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{1}{y^2}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int 1 - 2x \, \mathrm{d}x$$

$$\phi = -x^2 + x + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{1}{y^2}$. Therefore equation (4) becomes

$$-\frac{1}{y^2} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{1}{y^2}$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int \left(-\frac{1}{y^2}\right) \mathrm{d}y$$

$$f(y) = \frac{1}{y} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -x^2 + x + \frac{1}{y} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x^2 + x + \frac{1}{y}$$

The solution becomes

$$y = \frac{1}{x^2 + c_1 - x}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -\frac{1}{6}$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{1}{6} = \frac{1}{c_1}$$

$$c_1 = -6$$

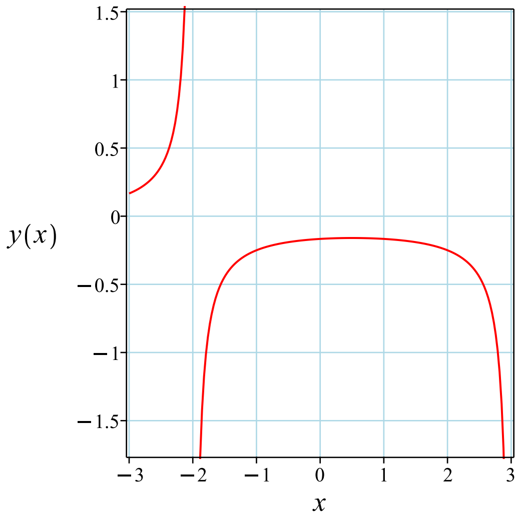
Substituting c_1 found above in the general solution gives

$$y = \frac{1}{x^2 - x - 6}$$

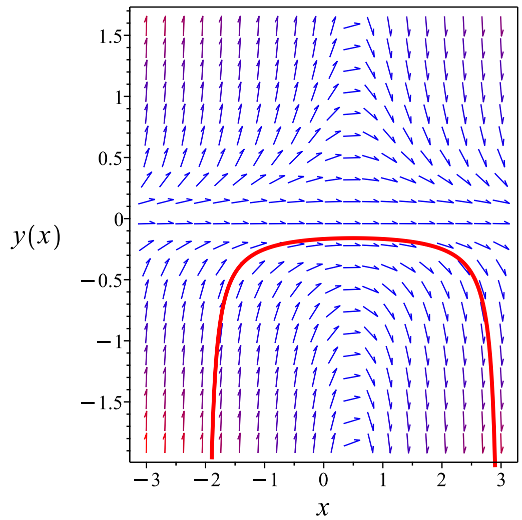
Summary

The solution(s) found are the following

$$y = \frac{1}{x^2 - x - 6} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{1}{x^2 - x - 6}$$

Verified OK.

2.9.5 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= -y^2(2x - 1) \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -2x\, y^2 + y^2$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 0$, $f_1(x) = 0$ and $f_2(x) = 1 - 2x$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{(1 - 2x)\, u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\,u'(x) + f_2^2f_0u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= -2 \\ f_1f_2 &= 0 \\ f_2^2f_0 &= 0 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$(1-2x)\,u''(x) + 2u'(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = c_1 + c_2\left(x - \frac{1}{2}\right)^2$$

The above shows that

$$u'(x) = c_2(2x-1)$$

Using the above in (1) gives the solution

$$y = -\frac{c_2(2x-1)}{(1-2x)\left(c_1 + c_2\left(x-\frac{1}{2}\right)^2\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{4}{4x^2 + 4c_3 - 4x + 1}$$

Initial conditions are used to solve for c_3. Substituting $x = 0$ and $y = -\frac{1}{6}$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{1}{6} = \frac{4}{4c_3 + 1}$$

$$c_3 = -\frac{25}{4}$$

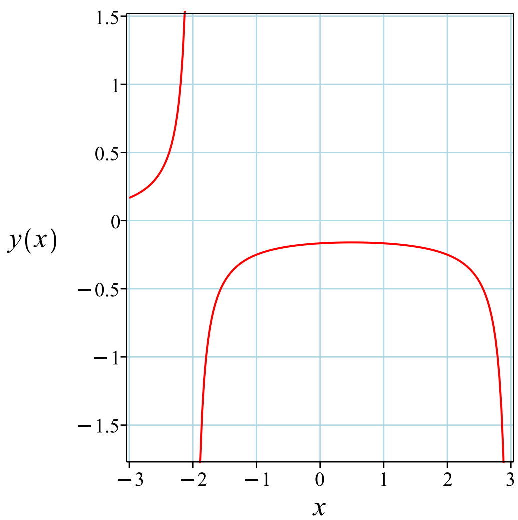
Substituting c_3 found above in the general solution gives

$$y = \frac{1}{x^2 - x - 6}$$

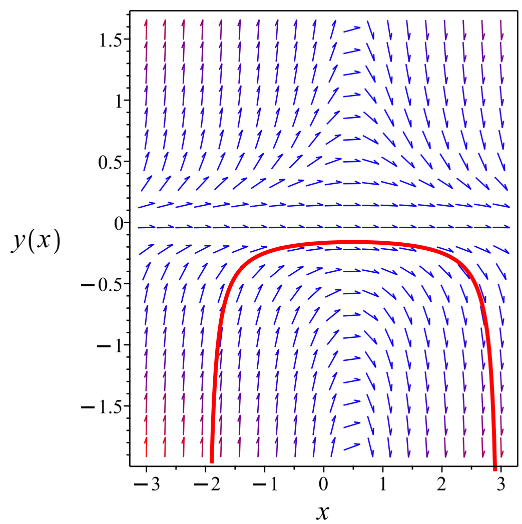
Summary

The solution(s) found are the following

$$y = \frac{1}{x^2 - x - 6} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{1}{x^2 - x - 6}$$

Verified OK.

2.9.6 Maple step by step solution

Let's solve

$\left[y' - (1 - 2x)\,y^2 = 0, y(0) = -\frac{1}{6}\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y^2} = 1 - 2x$

- Integrate both sides with respect to x

  $\int \frac{y'}{y^2}dx = \int (1 - 2x)\,dx + c_1$

- Evaluate integral

  $-\frac{1}{y} = -x^2 + c_1 + x$

- Solve for y

  $y = -\frac{1}{-x^2+c_1+x}$

- Use initial condition $y(0) = -\frac{1}{6}$

  $-\frac{1}{6} = -\frac{1}{c_1}$

- Solve for c_1

  $c_1 = 6$

- Substitute $c_1 = 6$ into general solution and simplify

  $y = \frac{1}{x^2-x-6}$

- Solution to the IVP

  $y = \frac{1}{x^2-x-6}$

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{y' - \frac{1-2x}{y} = 0}$$

With initial conditions

$$[y(1) = -2]$$

2.10.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$
\begin{aligned}
y' &= f(x,y) \\
&= -\frac{2x-1}{y}
\end{aligned}
$$

The x domain of $f(x,y)$ when $y=-2$ is

$$
\{-\infty < x < \infty\}
$$

And the point $x_0 = 1$ is inside this domain. The y domain of $f(x,y)$ when $x = 1$ is

$$
\{y < 0 \lor 0 < y\}
$$

And the point $y_0 = -2$ is inside this domain. Now we will look at the continuity of

$$
\begin{aligned}
\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{2x-1}{y}\right) \\
&= \frac{2x-1}{y^2}
\end{aligned}
$$

The x domain of $\frac{\partial f}{\partial y}$ when $y=-2$ is

$$
\{-\infty < x < \infty\}
$$

And the point $x_0 = 1$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 1$ is

$$
\{y < 0 \lor 0 < y\}
$$

And the point $y_0 = -2$ is inside this domain. Therefore solution exists and is unique.

2.10.2 Solving as separable ode

In canonical form the ODE is

$$
\begin{aligned}
y' &= F(x,y) \\
&= f(x)g(y) \\
&= \frac{1-2x}{y}
\end{aligned}
$$

Where $f(x) = 1 - 2x$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y}}\,dy = 1 - 2x\,dx$$

$$\int \frac{1}{\frac{1}{y}}\,dy = \int 1 - 2x\,dx$$

$$\frac{y^2}{2} = -x^2 + c_1 + x$$

Which results in

$$y = \sqrt{-2x^2 + 2c_1 + 2x}$$

$$y = -\sqrt{-2x^2 + 2c_1 + 2x}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

$$-2 = -\sqrt{c_1}\,\sqrt{2}$$

$$c_1 = 2$$

Substituting c_1 found above in the general solution gives

$$y = -\sqrt{-2x^2 + 2x + 4}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

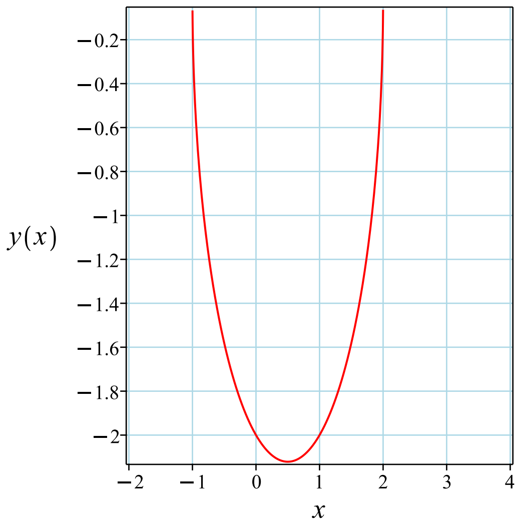
$$-2 = \sqrt{c_1}\,\sqrt{2}$$

Warning: Unable to solve for constant of integration.

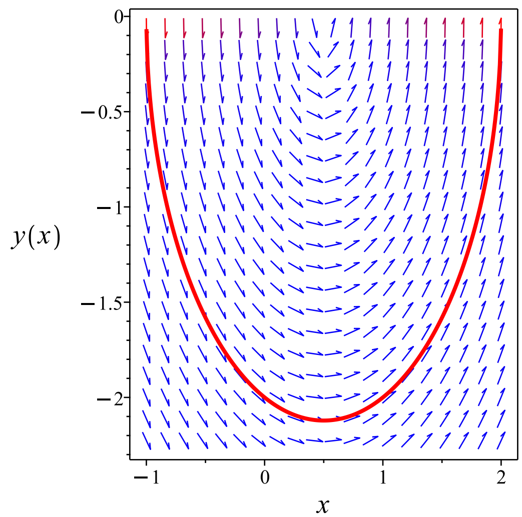
Summary

The solution(s) found are the following

$$y = -\sqrt{-2x^2 + 2x +$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -\sqrt{-2x^2 + 2x + 4}$$

Verified OK.

2.10.3 Solving as differentialType ode

Writing the ode as

$$y' = \frac{1 - 2x}{y} \tag{1}$$

Which becomes

$$(y)\, dy = (1 - 2x)\, dx \tag{2}$$

But the RHS is complete differential because

$$(1 - 2x)\, dx = d\left(-x^2 + x\right)$$

Hence (2) becomes

$$(y)\, dy = d\left(-x^2 + x\right)$$

Integrating both sides gives gives these solutions

$$y = \sqrt{-2x^2 + 2c_1 + 2x} + c_1$$
$$y = -\sqrt{-2x^2 + 2c_1 + 2x} + c_1$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

$$-2 = -\sqrt{c_1}\,\sqrt{2} + c_1$$

$$c_1 = \sqrt{2}\left(\frac{\sqrt{2}}{2} + \frac{i\sqrt{6}}{2}\right) - 2$$

Substituting c_1 found above in the general solution gives

$$y = -\sqrt{-2x^2 - 2 + 2i\sqrt{3} + 2x} - 1 + i\sqrt{3}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

$$-2 = \sqrt{c_1}\,\sqrt{2} + c_1$$

Warning: Unable to solve for constant of integration.

Summary

The solution(s) found are the following

$$y = -\sqrt{-2x^2 - 2 + 2i\sqrt{3} + 2$$

Verification of solutions

$$y = -\sqrt{-2x^2 - 2 + 2i\sqrt{3} + 2x} - 1 + i\sqrt{3}$$

Verified OK.

2.10.4 Solving as homogeneousTypeMapleC ode

Let $Y = y + y_0$ and $X = x + x_0$ then the above is transformed to new ode in $Y(X)$

$$\frac{d}{dX}Y(X) = -\frac{2X + 2x_0 - 1}{Y(X) + y_0}$$

Solving for possible values of x_0 and y_0 which makes the above ode a homogeneous ode results in

$$x_0 = \frac{1}{2}$$
$$y_0 = 0$$

Using these values now it is possible to easily solve for $Y(X)$. The above ode now becomes

$$\frac{d}{dX}Y(X) = -\frac{2X}{Y(X)}$$

In canonical form, the ODE is

$$
\begin{aligned}
Y' &= F(X, Y) \\
&= -\frac{2X}{Y}
\end{aligned} \tag{1}
$$

An ode of the form $Y' = \frac{M(X,Y)}{N(X,Y)}$ is called homogeneous if the functions $M(X, Y)$ and $N(X, Y)$ are both homogeneous functions and of the same order. Recall that a function $f(X, Y)$ is homogeneous of order n if

$$
f(t^n X, t^n Y) = t^n f(X, Y)
$$

In this case, it can be seen that both $M = -2X$ and $N = Y$ are both homogeneous and of the same order $n = 1$. Therefore this is a homogeneous ode. Since this ode is homogeneous, it is converted to separable ODE using the substitution $u = \frac{Y}{X}$, or $Y = uX$. Hence

$$
\frac{\mathrm{d}Y}{\mathrm{d}X} = \frac{\mathrm{d}u}{\mathrm{d}X} X + u
$$

Applying the transformation $Y = uX$ to the above ODE in (1) gives

$$
\begin{aligned}
\frac{\mathrm{d}u}{\mathrm{d}X} X + u &= -\frac{2}{u} \\
\frac{\mathrm{d}u}{\mathrm{d}X} &= \frac{-\frac{2}{u(X)} - u(X)}{X}
\end{aligned}
$$

Or

$$
\frac{d}{dX} u(X) - \frac{-\frac{2}{u(X)} - u(X)}{X} = 0
$$

Or

$$
\left(\frac{d}{dX} u(X)\right) u(X) X + u(X)^2 + 2 = 0
$$

Which is now solved as separable in $u(X)$. Which is now solved in $u(X)$. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(X, u) \\
&= f(X) g(u) \\
&= -\frac{u^2 + 2}{uX}
\end{aligned}
$$

Where $f(X) = -\frac{1}{X}$ and $g(u) = \frac{u^2+2}{u}$. Integrating both sides gives

$$\frac{1}{\frac{u^2+2}{u}}\,du = -\frac{1}{X}\,dX$$

$$\int \frac{1}{\frac{u^2+2}{u}}\,du = \int -\frac{1}{X}\,dX$$

$$\frac{\ln(u^2+2)}{2} = -\ln(X) + c_2$$

Raising both side to exponential gives

$$\sqrt{u^2+2} = e^{-\ln(X)+c_2}$$

Which simplifies to

$$\sqrt{u^2+2} = \frac{c_3}{X}$$

Which simplifies to

$$\sqrt{u(X)^2+2} = \frac{c_3 e^{c_2}}{X}$$

The solution is

$$\sqrt{u(X)^2+2} = \frac{c_3 e^{c_2}}{X}$$

Now u in the above solution is replaced back by Y using $u = \frac{Y}{X}$ which results in the solution

$$\sqrt{\frac{Y(X)^2}{X^2}+2} = \frac{c_3 e^{c_2}}{X}$$

Using the solution for $Y(X)$

$$\sqrt{\frac{Y(X)^2+2X^2}{X^2}} = \frac{c_3 e^{c_2}}{X}$$

And replacing back terms in the above solution using

$$Y = y + y_0$$
$$X = x + x_0$$

Or

$$Y = y$$
$$X = x + \frac{1}{2}$$

Then the solution in y becomes

$$\sqrt{\frac{y^2 + 2\left(x - \frac{1}{2}\right)^2}{\left(x - \frac{1}{2}\right)^2}} = \frac{c_3 e^{c_2}}{x - \frac{1}{2}}$$

Initial conditions are used to solve for c_2. Substituting $x = 1$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

$$3\sqrt{2} = 2c_3 e^{c_2}$$

$$c_2 = \frac{\ln\left(\frac{9}{2c_3^2}\right)}{2}$$

Substituting c_2 found above in the general solution gives

$$\sqrt{\frac{y^2 + 2\left(x - \frac{1}{2}\right)^2}{\left(x - \frac{1}{2}\right)^2}} = \frac{3c_3\sqrt{2}\,\sqrt{\frac{1}{c_3^2}}}{2x - 1}$$

The above simplifies to

$$\sqrt{2}\left(2\sqrt{\frac{4x^2 + 2y^2 - 4x + 1}{(2x - 1)^2}}\, x - 3c_3\sqrt{\frac{1}{c_3^2}} - \sqrt{\frac{4x^2 + 2y^2 - 4x + 1}{(2x - 1)^2}}\right) = 0$$

Summary

The solution(s) found are the following

$$\sqrt{2}\left(2\sqrt{\frac{4x^2 + 2y^2 - 4x + 1}{(2x - 1)^2}}\, x - 3\,\mathrm{csgn}\left(\frac{1}{c_3}\right) - \sqrt{\frac{4x^2 + 2y^2 - 4x + 1}{(2x - 1)^2}}\right) = 0 \quad (1)$$

Verification of solutions

$$\sqrt{2}\left(2\sqrt{\frac{4x^2 + 2y^2 - 4x + 1}{(2x - 1)^2}}\, x - 3\,\mathrm{csgn}\left(\frac{1}{c_3}\right) - \sqrt{\frac{4x^2 + 2y^2 - 4x + 1}{(2x - 1)^2}}\right) = 0$$

Verified OK.

2.10.5 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{2x-1}{y}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 118: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= \frac{1}{1-2x} \\
\eta(x,y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R,S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{\frac{1}{1-2x}} dx
\end{aligned}
$$

Which results in

$$
S = -x^2 + x
$$

Now that R,S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = -\frac{2x-1}{y}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= 1 - 2x \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = y \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = R
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \frac{R^2}{2} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
-x^2 + x = \frac{y^2}{2} + c_1
$$

Which simplifies to

$$
-x^2 + x = \frac{y^2}{2} + c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{2x-1}{y}$ 	$R = y$ $S = -x^2 + x$	$\frac{dS}{dR} = R$ 
Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1 + 2$$

$$c_1 = -2$$

Substituting c_1 found above in the general solution gives

$$-x^2 + x = \frac{y^2}{2} - 2$$

Solving for y from the above gives

$$y = -\sqrt{-2x^2 + 2x + 4}$$

Summary

The solution(s) found are the following

$$y = -\sqrt{-2x^2 + 2x + 4} \tag{1}$$

2.10.6 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(-y)\,\mathrm{d}y &= (2x - 1)\,\mathrm{d}x\\ (1 - 2x)\,\mathrm{d}x + (-y)\,\mathrm{d}y &= 0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= 1 - 2x\\ N(x, y) &= -y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(1 - 2x)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-y)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int 1 - 2x \, \mathrm{d}x$$
$$\phi = -x^2 + x + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -y$. Therefore equation (4) becomes

$$-y = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -y$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (-y) \, \mathrm{d}y$$
$$f(y) = -\frac{y^2}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -x^2 - \frac{1}{2}y^2 + x + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x^2 - \frac{1}{2}y^2 + x$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

$$-2 = c_1$$

$$c_1 = -2$$

Substituting c_1 found above in the general solution gives

$$-x^2 - \frac{1}{2}y^2 + x = -2$$

Solving for y from the above gives

$$y = -\sqrt{-2x^2 + 2x + 4}$$

<u>Summary</u>

2.10.7 Maple step by step solution

Let's solve

$\left[y' - \frac{1-2x}{y} = 0, y(1) = -2\right]$

- Highest derivative means the order of the ODE is 1

  y'
- Separate variables

  $yy' = 1 - 2x$
- Integrate both sides with respect to x

  $\int yy'dx = \int (1 - 2x)\,dx + c_1$
- Evaluate integral

  $\frac{y^2}{2} = -x^2 + c_1 + x$
- Solve for y

  $\{y = \sqrt{-2x^2 + 2c_1 + 2x}, y = -\sqrt{-2x^2 + 2c_1 + 2x}\}$
- Use initial condition $y(1) = -2$

  $-2 = \sqrt{c_1}\,\sqrt{2}$
- Solution does not satisfy initial condition
- Use initial condition $y(1) = -2$

  $-2 = -\sqrt{c_1}\,\sqrt{2}$
- Solve for c_1

  $c_1 = 2$
- Substitute $c_1 = 2$ into general solution and simplify

  $y = -\sqrt{-2x^2 + 2x + 4}$
- Solution to the IVP

  $y = -\sqrt{-2x^2 + 2x + 4}$

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' e^{-x} y = -x}$$

With initial conditions

$$[y(0) = 1]$$

2.11.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= -\frac{x\,e^{x}}{y} \end{aligned}$$

The x domain of $f(x, y)$ when $y = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x, y)$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 1$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{x\,\mathrm{e}^{x}}{y}\right)\\&= \frac{x\,\mathrm{e}^{x}}{y^2}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 1$ is inside this domain. Therefore solution exists and is unique.

2.11.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x, y)\\&= f(x)g(y)\\&= -\frac{x\,\mathrm{e}^{x}}{y}\end{aligned}$$

Where $f(x) = -x\,\mathrm{e}^{x}$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y}}\,dy = -x\,\mathrm{e}^{x}\,dx$$

$$\int \frac{1}{\frac{1}{y}}\,dy = \int -x\,\mathrm{e}^{x}\,dx$$

$$\frac{y^2}{2} = -(x-1)\,\mathrm{e}^{x} + c_1$$

Which results in

$$y = \sqrt{-2x\,e^{x} + 2\,e^{x} + 2c_1}$$
$$y = -\sqrt{-2x\,e^{x} + 2\,e^{x} + 2c_1}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\sqrt{2 + 2c_1}$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \sqrt{2 + 2c_1}$$

$$c_1 = -\frac{1}{2}$$

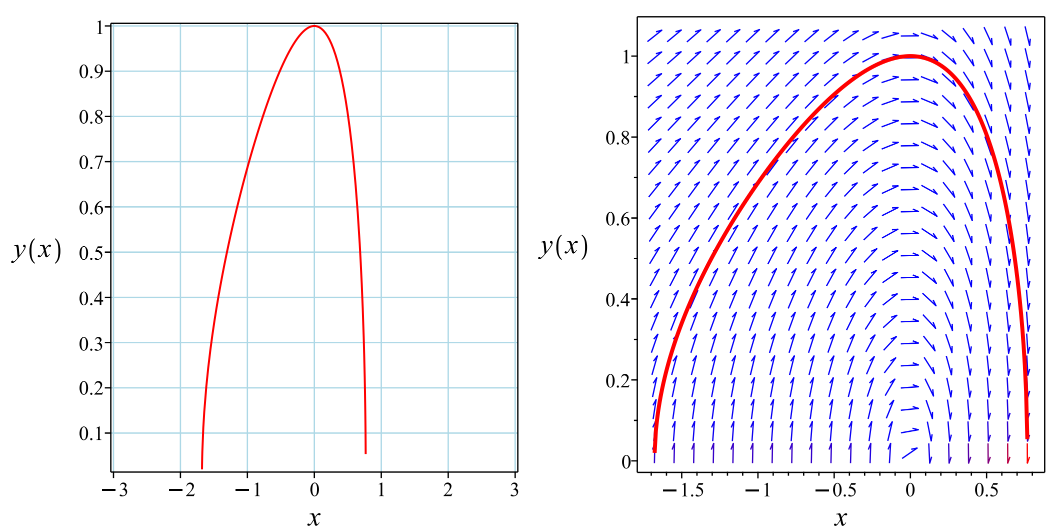
Substituting c_1 found above in the general solution gives

$$y = \sqrt{-2x\,e^{x} + 2\,e^{x} - 1}$$

Summary

The solution(s) found are the following

$$y = \sqrt{-2x\,e^{x} + 2\,e^{x} - 1} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \sqrt{-2x\,\mathrm{e}^{x} + 2\,\mathrm{e}^{x} - 1}$$

Verified OK.

2.11.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{x\,\mathrm{e}^{x}}{y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 121: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= -\frac{e^{-x}}{x} \\
\eta(x, y) &= 0
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{-\frac{e^{-x}}{x}} dx \end{aligned}$$

Which results in

$$S = -(x - 1)\, e^{x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{x\, e^{x}}{y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= -x\, e^{x} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = y \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-(x-1)\,\mathrm{e}^x = \frac{y^2}{2} + c_1$$

Which simplifies to

$$-(x-1)\,\mathrm{e}^x = \frac{y^2}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{x\,\mathrm{e}^x}{y}$ 	$R = y$ $S = -(x-1)\,\mathrm{e}^x$	$\frac{dS}{dR} = R$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{1}{2} + c_1$$

$$c_1 = \frac{1}{2}$$

Substituting c_1 found above in the general solution gives

$$-(x-1)\,\mathrm{e}^{x} = \frac{y^2}{2} + \frac{1}{2}$$

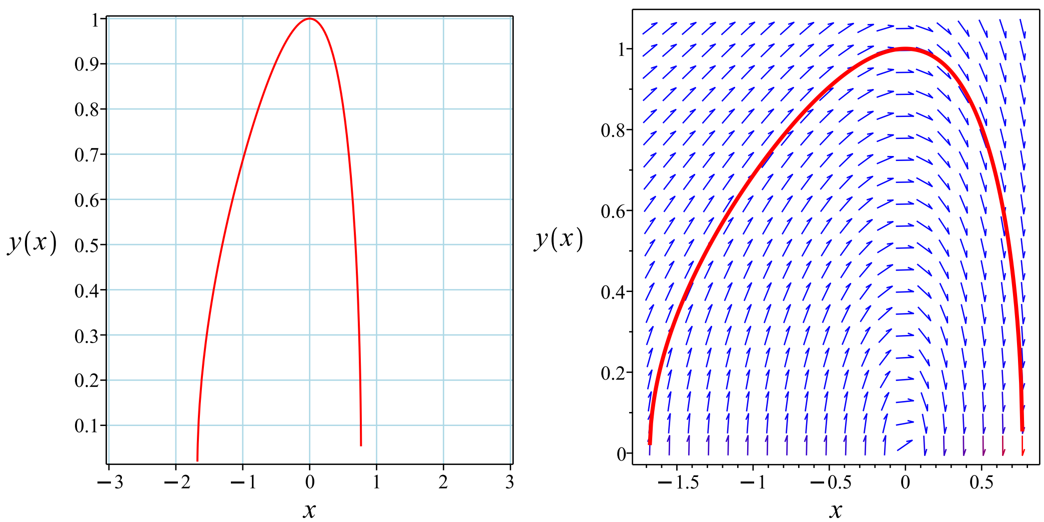
Solving for y from the above gives

$$y = \sqrt{-2x\,\mathrm{e}^{x} + 2\,\mathrm{e}^{x} - 1}$$

Summary

The solution(s) found are the following

$$y = \sqrt{-2x\,\mathrm{e}^{x} + 2\,\mathrm{e}^{x} - 1} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \sqrt{-2x\,\mathrm{e}^{x} + 2\,\mathrm{e}^{x} - 1}$$

Verified OK.

2.11.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(-y)\,\mathrm{d}y &= (x\,\mathrm{e}^{x})\,\mathrm{d}x\\ (-x\,\mathrm{e}^{x})\,\mathrm{d}x + (-y)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -x\,\mathrm{e}^{x}\\ N(x,y) &= -y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-x\,\mathrm{e}^{x}) \\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-y) \\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x \\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -x\,\mathrm{e}^{x}\,\mathrm{d}x \\ \phi &= -(x-1)\,\mathrm{e}^{x} + f(y)\end{aligned} \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -y$. Therefore equation (4) becomes

$$-y = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -y$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (-y) \, \mathrm{d}y$$
$$f(y) = -\frac{y^2}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -(x-1)\,\mathrm{e}^x - \frac{y^2}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -(x-1)\,\mathrm{e}^x - \frac{y^2}{2}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{1}{2} = c_1$$

$$c_1 = \frac{1}{2}$$

Substituting c_1 found above in the general solution gives

$$-(x-1)\,\mathrm{e}^x - \frac{y^2}{2} = \frac{1}{2}$$

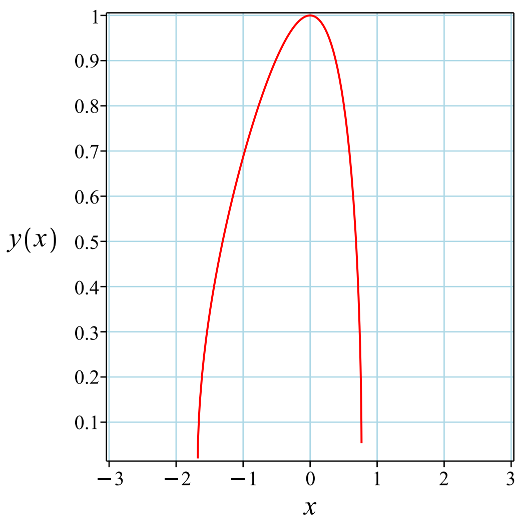
Solving for y from the above gives

$$y = \sqrt{-2x\,\mathrm{e}^x + 2\,\mathrm{e}^x - 1}$$

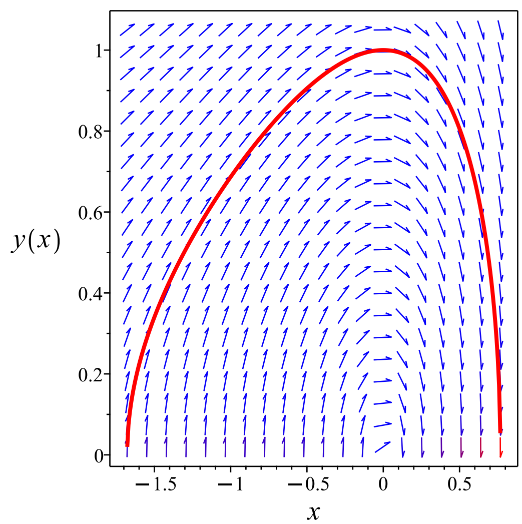
Summary

The solution(s) found are the following

$$y = \sqrt{-2x\,\mathrm{e}^{x} + 2\,\mathrm{e}^{x} - 1} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \sqrt{-2x\,\mathrm{e}^{x} + 2\,\mathrm{e}^{x} - 1}$$

Verified OK.

2.11.5 Maple step by step solution

Let's solve

$\left[\frac{yy'}{\mathrm{e}^{x}} = -x, y(0) = 1\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $yy' = -x\,\mathrm{e}^{x}$

- Integrate both sides with respect to x

  $\int yy'dx = \int -x\,\mathrm{e}^{x}dx + c_1$

- Evaluate integral

$$\frac{y^2}{2} = -(x-1)\,e^x + c_1$$

- Solve for y

$$\left\{y = \sqrt{-2x\,e^x + 2\,e^x + 2c_1}, y = -\sqrt{-2x\,e^x + 2\,e^x + 2c_1}\right\}$$

- Use initial condition $y(0) = 1$

$$1 = \sqrt{2 + 2c_1}$$

- Solve for c_1

$$c_1 = -\frac{1}{2}$$

- Substitute $c_1 = -\frac{1}{2}$ into general solution and simplify

$$y = \sqrt{-2x\,e^x + 2\,e^x - 1}$$

- Use initial condition $y(0) = 1$

$$1 = -\sqrt{2 + 2c_1}$$

- Solution does not satisfy initial condition
- Solution to the IVP

$$y = \sqrt{-2x\,e^x + 2\,e^x - 1}$$

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.2. Page 48
Problem number: 12.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "riccati", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{r' - \frac{r^2}{x} = 0}$$

With initial conditions

$$[r(1) = 2]$$

2.12.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} r' &= f(x, r) \\ &= \frac{r^2}{x} \end{aligned}$$

The x domain of $f(x,r)$ when $r=2$ is

$$\{x<0 \lor 0<x\}$$

And the point $x_0=1$ is inside this domain. The r domain of $f(x,r)$ when $x=1$ is

$$\{-\infty<r<\infty\}$$

And the point $r_0=2$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial r}&=\frac{\partial}{\partial r}\left(\frac{r^2}{x}\right)\\&=\frac{2r}{x}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial r}$ when $r=2$ is

$$\{x<0 \lor 0<x\}$$

And the point $x_0=1$ is inside this domain. The r domain of $\frac{\partial f}{\partial r}$ when $x=1$ is

$$\{-\infty<r<\infty\}$$

And the point $r_0=2$ is inside this domain. Therefore solution exists and is unique.

2.12.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}r'&=F(x,r)\\&=f(x)g(r)\\&=\frac{r^2}{x}\end{aligned}$$

Where $f(x)=\frac{1}{x}$ and $g(r)=r^2$. Integrating both sides gives

$$\begin{aligned}\frac{1}{r^2}\,dr&=\frac{1}{x}\,dx\\\int\frac{1}{r^2}\,dr&=\int\frac{1}{x}\,dx\\-\frac{1}{r}&=\ln(x)+c_1\end{aligned}$$

Which results in

$$r = -\frac{1}{\ln(x) + c_1}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $r = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = -\frac{1}{c_1}$$

$$c_1 = -\frac{1}{2}$$

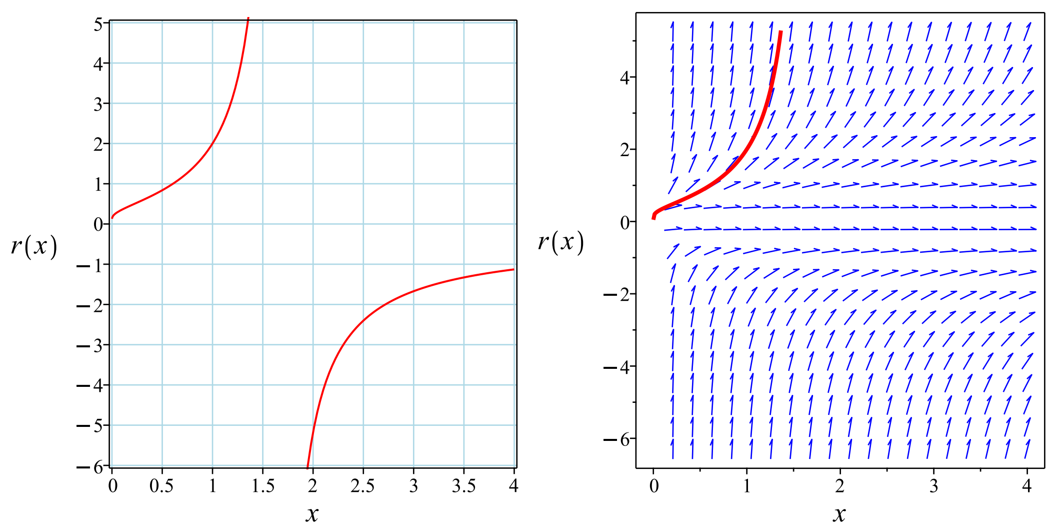
Substituting c_1 found above in the general solution gives

$$r = -\frac{2}{2\ln(x) - 1}$$

Summary

The solution(s) found are the following

$$r = -\frac{2}{2\ln(x) - 1} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$r = -\frac{2}{2\ln(x) - 1}$$

Verified OK.

2.12.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
r' &= \frac{r^2}{x} \\
r' &= \omega(x, r)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_r - \xi_x) - \omega^2 \xi_r - \omega_x \xi - \omega_r \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 124: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x + b_1y + c_1}{a_2x + b_2y + c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x, r) &= x \\ \eta(x, r) &= 0\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, r) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dr}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial r}\right) S(x, r) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = r$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{x} dx\end{aligned}$$

Which results in

$$S = \ln(x)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, r) S_r}{R_x + \omega(x, r) R_r} \tag{2}$$

Where in the above R_x, R_r, S_x, S_r are all partial derivatives and $\omega(x, r)$ is the right hand side of the original ode given by

$$\omega(x, r) = \frac{r^2}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= 0 \\ R_r &= 1 \\ S_x &= \frac{1}{x} \\ S_r &= 0\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{r^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, r in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{1}{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, r coordinates. This results in

$$\ln(x) = -\frac{1}{r} + c_1$$

Which simplifies to

$$\ln(x) = -\frac{1}{r} + c_1$$

Which gives

$$r = -\frac{1}{\ln(x) - c_1}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, r coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dr}{dx} = \frac{r^2}{x}$ 	$R = r$ $S = \ln(x)$	$\frac{dS}{dR} = \frac{1}{R^2}$ 
Initial conditions are used to solve for c_1. Substituting $x = 1$ and $r = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = \frac{1}{c_1}$$

$$c_1 = \frac{1}{2}$$

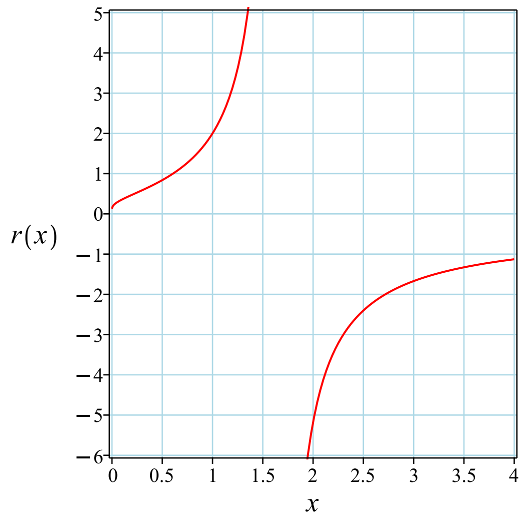
Substituting c_1 found above in the general solution gives

$$r = -\frac{2}{2\ln(x) - 1}$$

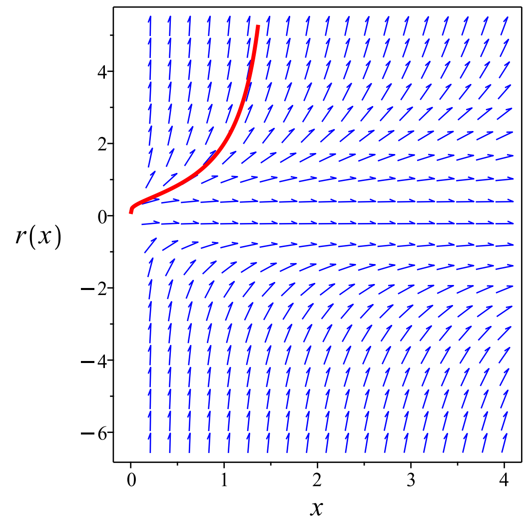
Summary

The solution(s) found are the following

$$r = -\frac{2}{2\ln(x) - 1} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$r = -\frac{2}{2\ln(x) - 1}$$

Verified OK.

2.12.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,r)\,\mathrm{d}x + N(x,r)\,\mathrm{d}r = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{r^2}\right)\mathrm{d}r = \left(\frac{1}{x}\right)\mathrm{d}x$$
$$\left(-\frac{1}{x}\right)\mathrm{d}x + \left(\frac{1}{r^2}\right)\mathrm{d}r = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,r) = -\frac{1}{x}$$
$$N(x,r) = \frac{1}{r^2}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial r} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial r} &= \frac{\partial}{\partial r}\left(-\frac{1}{x}\right)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{r^2}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial r} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, r)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial r} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int -\frac{1}{x} \mathrm{d}x$$

$$\phi = -\ln(x) + f(r) \tag{3}$$

Where $f(r)$ is used for the constant of integration since ϕ is a function of both x and r. Taking derivative of equation (3) w.r.t r gives

$$\frac{\partial \phi}{\partial r} = 0 + f'(r) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial r} = \frac{1}{r^2}$. Therefore equation (4) becomes

$$\frac{1}{r^2} = 0 + f'(r) \tag{5}$$

Solving equation (5) for $f'(r)$ gives

$$f'(r) = \frac{1}{r^2}$$

Integrating the above w.r.t r gives

$$\int f'(r) \mathrm{d}r = \int \left(\frac{1}{r^2}\right) \mathrm{d}r$$

$$f(r) = -\frac{1}{r} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(r)$ into equation (3) gives ϕ

$$\phi = -\ln(x) - \frac{1}{r} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(x) - \frac{1}{r}$$

The solution becomes

$$r = -\frac{1}{\ln(x) + c_1}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $r = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = -\frac{1}{c_1}$$

$$c_1 = -\frac{1}{2}$$

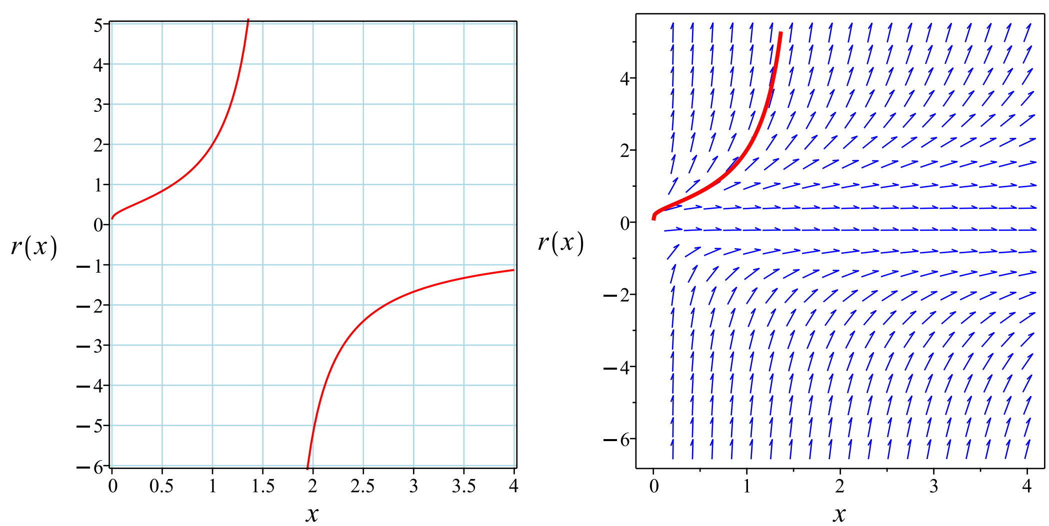
Substituting c_1 found above in the general solution gives

$$r = -\frac{2}{2\ln(x) - 1}$$

Summary

The solution(s) found are the following

$$r = -\frac{2}{2\ln(x) - 1} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$r = -\frac{2}{2\ln(x) - 1}$$

Verified OK.

2.12.5 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} r' &= F(x, r) \\ &= \frac{r^2}{x} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$r' = \frac{r^2}{x}$$

With Riccati ODE standard form

$$r' = f_0(x) + f_1(x)r + f_2(x)r^2$$

Shows that $f_0(x) = 0$, $f_1(x) = 0$ and $f_2(x) = \frac{1}{x}$. Let

$$\begin{aligned} r &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{\frac{u}{x}} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= -\frac{1}{x^2} \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= 0 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$\frac{u''(x)}{x} + \frac{u'(x)}{x^2} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = c_2 \ln(x) + c_1$$

The above shows that

$$u'(x) = \frac{c_2}{x}$$

Using the above in (1) gives the solution

$$r = -\frac{c_2}{c_2 \ln(x) + c_1}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$r = -\frac{1}{\ln(x) + c_3}$$

Initial conditions are used to solve for c_3. Substituting $x = 1$ and $r = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = -\frac{1}{c_3}$$

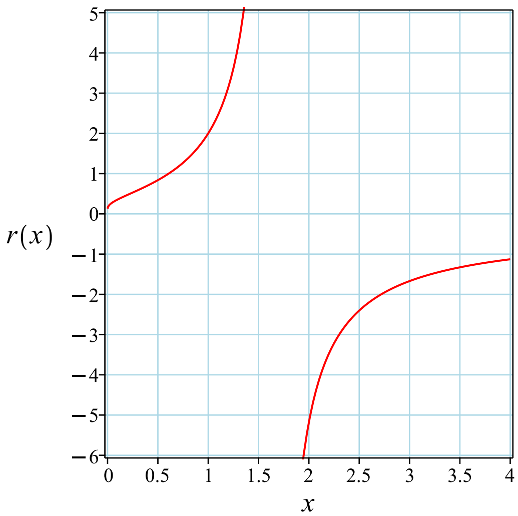
$$c_3 = -\frac{1}{2}$$

Substituting c_3 found above in the general solution gives

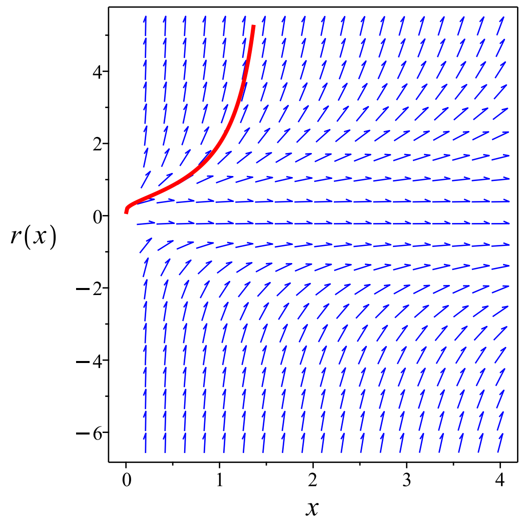
$$r = -\frac{2}{2 \ln(x) - 1}$$

Summary
The solution(s) found are the following

$$r = -\frac{2}{2 \ln(x) - 1} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$r = -\frac{2}{2\ln(x) - 1}$$

Verified OK.

2.12.6 Maple step by step solution

Let's solve

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.2. Page 48
Problem number: 13.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{2x}{y + x^2 y} = 0}$$

With initial conditions

$$[y(0) = -2]$$

2.13.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= \frac{2x}{y\,(x^2+1)} \end{aligned}$$

The x domain of $f(x,y)$ when $y=-2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x,y)$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = -2$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{2x}{y\,(x^2+1)}\right)\\ &= -\frac{2x}{y^2\,(x^2+1)}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = -2$ is inside this domain. Therefore solution exists and is unique.

2.13.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x,y)\\ &= f(x)g(y)\\ &= \frac{2x}{y\,(x^2+1)}\end{aligned}$$

Where $f(x) = \frac{2x}{x^2+1}$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\begin{aligned}\frac{1}{\frac{1}{y}}\,dy &= \frac{2x}{x^2+1}\,dx\\ \int \frac{1}{\frac{1}{y}}\,dy &= \int \frac{2x}{x^2+1}\,dx\\ \frac{y^2}{2} &= \ln\left(x^2+1\right) + c_1\end{aligned}$$

Which results in

$$y = \sqrt{2\ln(x^2+1) + 2c_1}$$
$$y = -\sqrt{2\ln(x^2+1) + 2c_1}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

$$-2 = -\sqrt{c_1}\,\sqrt{2}$$

$$c_1 = 2$$

Substituting c_1 found above in the general solution gives

$$y = -\sqrt{2\ln(x^2+1) + 4}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

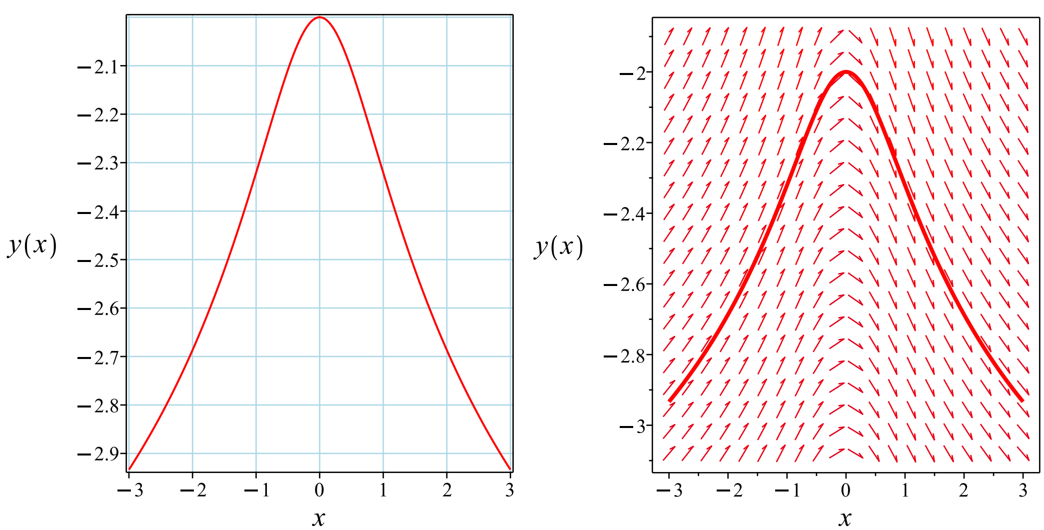
$$-2 = \sqrt{c_1}\,\sqrt{2}$$

Warning: Unable to solve for constant of integration.

Summary

The solution(s) found are the following

$$y = -\sqrt{2\ln(x^2+1)$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = -\sqrt{2\ln\left(x^2+1\right)+4}$$

Verified OK.

2.13.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned}y' &= \frac{2x}{y\left(x^2+1\right)}\\ y' &= \omega(x,y)\end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 127: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= \frac{x^2 + 1}{2x} \\
\eta(x,y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{x^2+1}{2x}} dx \end{aligned}$$

Which results in

$$S = \ln\left(x^2 + 1\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{2x}{y\left(x^2 + 1\right)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= \frac{2x}{x^2 + 1} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = y \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{R^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\ln\left(x^2+1\right) = \frac{y^2}{2} + c_1$$

Which simplifies to

$$\ln\left(x^2+1\right) = \frac{y^2}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{2x}{y(x^2+1)}$  	$R = y$ $S = \ln\left(x^2+1\right)$	$\frac{dS}{dR} = R$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1 + 2$$

$$c_1 = -2$$

Substituting c_1 found above in the general solution gives

$$\ln\left(x^2+1\right) = \frac{y^2}{2} - 2$$

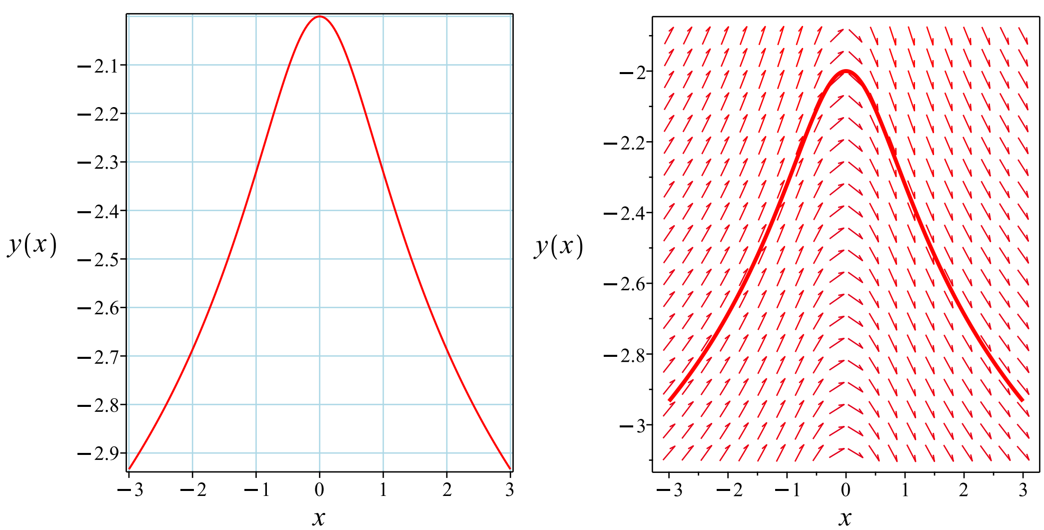
Solving for y from the above gives

$$y = -\sqrt{2\ln\left(x^2+1\right)+4}$$

Summary

The solution(s) found are the following

$$y = -\sqrt{2\ln\left(x^2+1\right)+4} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = -\sqrt{2\ln\left(x^2+1\right)+4}$$

Verified OK.

2.13.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\frac{y}{2}\right)\mathrm{d}y&=\left(\frac{x}{x^2+1}\right)\mathrm{d}x\\ \left(-\frac{x}{x^2+1}\right)\mathrm{d}x+\left(\frac{y}{2}\right)\mathrm{d}y&=0 \qquad\text{(2A)}\end{aligned}$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x,y) &= -\frac{x}{x^2+1} \\
N(x,y) &= \frac{y}{2}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{x}{x^2+1}\right) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{y}{2}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\frac{x}{x^2+1}\,\mathrm{d}x \\
\phi &= -\frac{\ln(x^2+1)}{2} + f(y)
\end{aligned} \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{y}{2}$. Therefore equation (4) becomes

$$\frac{y}{2} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{y}{2}$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int \left(\frac{y}{2}\right) \mathrm{d}y$$

$$f(y) = \frac{y^2}{4} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\ln(x^2+1)}{2} + \frac{y^2}{4} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\ln(x^2+1)}{2} + \frac{y^2}{4}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_1$$

$$c_1 = 1$$

Substituting c_1 found above in the general solution gives

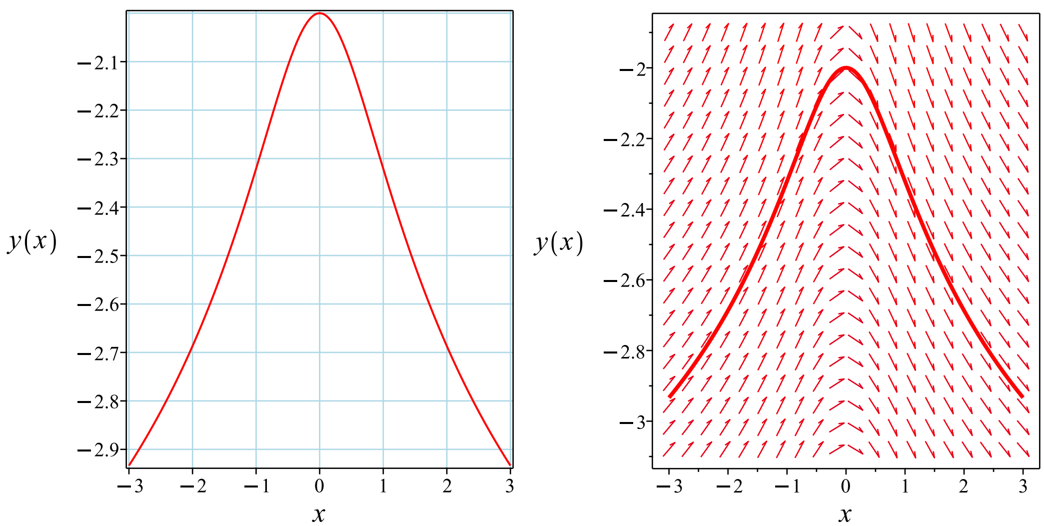
$$-\frac{\ln(x^2+1)}{2} + \frac{y^2}{4} = 1$$

Solving for y from the above gives

$$y = -\sqrt{2\ln(x^2+1)+4}$$

Summary
The solution(s) found are the following

$$y = -\sqrt{2\ln(x^2+1)+4} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = -\sqrt{2\ln(x^2+1)+4}$$

Verified OK.

2.13.5 Maple step by step solution

Let's solve

$\left[y' - \frac{2x}{y+x^2y} = 0, y(0) = -2\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $yy' = \frac{2x}{x^2+1}$

- Integrate both sides with respect to x

  $\int yy'dx = \int \frac{2x}{x^2+1}dx + c_1$

- Evaluate integral

  $\frac{y^2}{2} = \ln(x^2+1) + c_1$

- Solve for y

  $\left\{y = \sqrt{2\ln(x^2+1)+2c_1}, y = -\sqrt{2\ln(x^2+1)+2c_1}\right\}$

- Use initial condition $y(0) = -2$

  $-2 = \sqrt{c_1}\sqrt{2}$

- Solution does not satisfy initial condition
- Use initial condition $y(0) = -2$

  $-2 = -\sqrt{c_1}\sqrt{2}$

- Solve for c_1

  $c_1 = 2$

- Substitute $c_1 = 2$ into general solution and simplify

  $y = -\sqrt{2\ln(x^2+1)+4}$

- Solution to the IVP

  $y = -\sqrt{2\ln(x^2+1)+4}$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "riccati", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{x y^2}{\sqrt{x^2+1}} = 0}$$

With initial conditions

$$[y(0) = 1]$$

2.14.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned}
y' &= f(x,y)\\
&= \frac{x\,y^2}{\sqrt{x^2+1}}
\end{aligned}$$

The x domain of $f(x,y)$ when $y=1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x,y)$ when $x=0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 1$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}
\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{x\,y^2}{\sqrt{x^2+1}}\right)\\
&= \frac{2xy}{\sqrt{x^2+1}}
\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y=1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x=0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 1$ is inside this domain. Therefore solution exists and is unique.

2.14.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}
y' &= F(x,y)\\
&= f(x)g(y)\\
&= \frac{x\,y^2}{\sqrt{x^2+1}}
\end{aligned}$$

Where $f(x) = \frac{x}{\sqrt{x^2+1}}$ and $g(y) = y^2$. Integrating both sides gives

$$\frac{1}{y^2}\,dy = \frac{x}{\sqrt{x^2+1}}\,dx$$

$$\int \frac{1}{y^2}\,dy = \int \frac{x}{\sqrt{x^2+1}}\,dx$$

$$-\frac{1}{y} = \sqrt{x^2+1} + c_1$$

Which results in

$$y = -\frac{1}{\sqrt{x^2+1} + c_1}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{1}{1 + c_1}$$

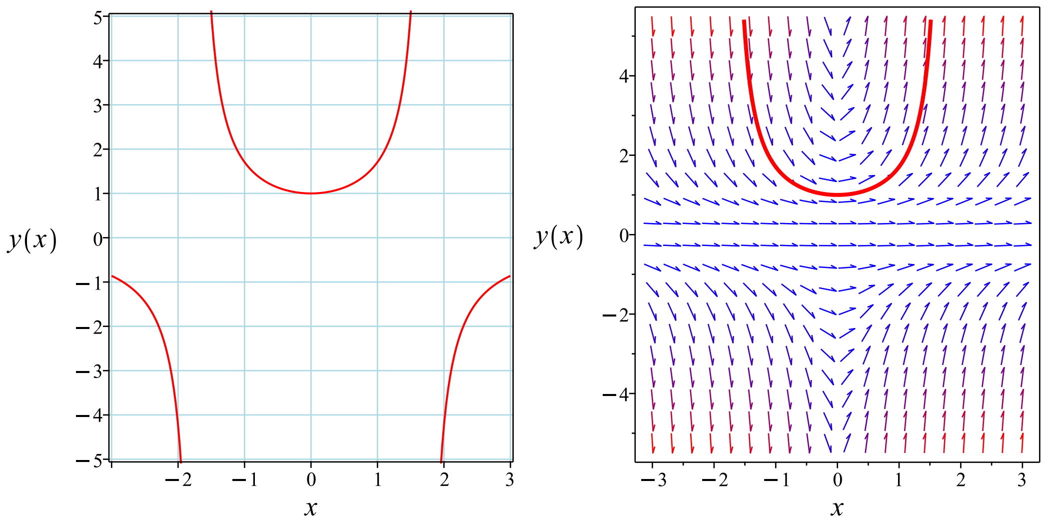
$$c_1 = -2$$

Substituting c_1 found above in the general solution gives

$$y = -\frac{1}{\sqrt{x^2+1} - 2}$$

Summary
The solution(s) found are the following

$$y = -\frac{1}{\sqrt{x^2+1} - 2} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = -\frac{1}{\sqrt{x^2+1}-2}$$

Verified OK.

2.14.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{x\,y^2}{\sqrt{x^2+1}}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 130: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x) dx - h(x)}}{g(x)}$	$\frac{f(x) e^{-\int b f(x) dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= \frac{\sqrt{x^2 + 1}}{x} \\
\eta(x, y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{\sqrt{x^2+1}}{x}} dx \end{aligned}$$

Which results in

$$S = \sqrt{x^2+1}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{x\, y^2}{\sqrt{x^2+1}}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= \frac{x}{\sqrt{x^2+1}} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{y^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{1}{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\sqrt{x^2+1} = -\frac{1}{y} + c_1$$

Which simplifies to

$$\sqrt{x^2+1} = -\frac{1}{y} + c_1$$

Which gives

$$y = -\frac{1}{\sqrt{x^2+1} - c_1}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x\,y^2}{\sqrt{x^2+1}}$  	$R = y$ $S = \sqrt{x^2+1}$	$\frac{dS}{dR} = \frac{1}{R^2}$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{1}{c_1 - 1}$$

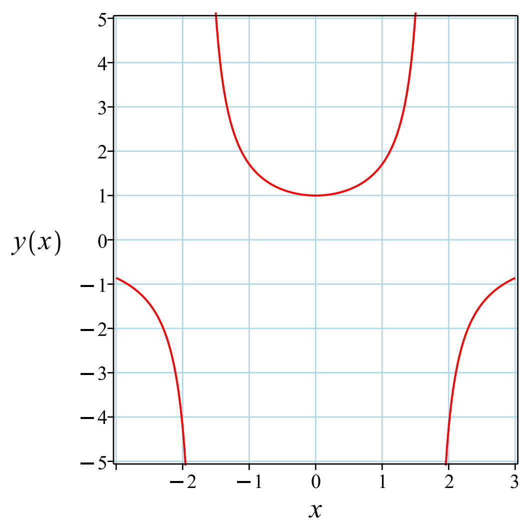
$$c_1 = 2$$

Substituting c_1 found above in the general solution gives

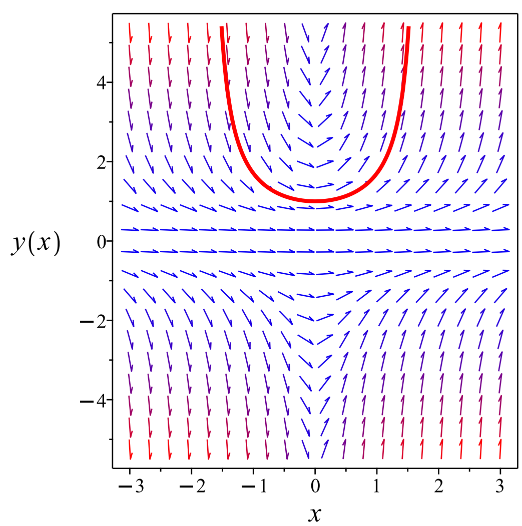
$$y = -\frac{1}{\sqrt{x^2+1} - 2}$$

Summary
The solution(s) found are the following

$$y = -\frac{1}{\sqrt{x^2+1} - 2} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -\frac{1}{\sqrt{x^2+1} - 2}$$

Verified OK.

2.14.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\frac{1}{y^2}\right)\mathrm{d}y &= \left(\frac{x}{\sqrt{x^2+1}}\right)\mathrm{d}x\\ \left(-\frac{x}{\sqrt{x^2+1}}\right)\mathrm{d}x + \left(\frac{1}{y^2}\right)\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x,y) &= -\frac{x}{\sqrt{x^2+1}} \\
N(x,y) &= \frac{1}{y^2}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{x}{\sqrt{x^2+1}}\right) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{y^2}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int M \, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int -\frac{x}{\sqrt{x^2+1}} \, \mathrm{d}x
\end{aligned}
$$

$$
\phi = -\sqrt{x^2+1} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y^2}$. Therefore equation (4) becomes

$$\frac{1}{y^2} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{1}{y^2}$$

Integrating the above w.r.t y gives

$$\int f'(y)\, \mathrm{d}y = \int \left(\frac{1}{y^2}\right) \mathrm{d}y$$

$$f(y) = -\frac{1}{y} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\sqrt{x^2+1} - \frac{1}{y} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\sqrt{x^2+1} - \frac{1}{y}$$

The solution becomes

$$y = -\frac{1}{\sqrt{x^2+1} + c_1}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{1}{1 + c_1}$$

$$c_1 = -2$$

Substituting c_1 found above in the general solution gives

$$y = -\frac{1}{\sqrt{x^2+1}-2}$$

<u>Summary</u>
The solution(s) found are the following

$$y = -\frac{1}{\sqrt{x^2+1}-2} \tag{1}$$

2.14.5 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{x\,y^2}{\sqrt{x^2+1}} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = \frac{x\,y^2}{\sqrt{x^2+1}}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 0$, $f_1(x) = 0$ and $f_2(x) = \frac{x}{\sqrt{x^2+1}}$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{\frac{xu}{\sqrt{x^2+1}}} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= \frac{1}{\sqrt{x^2+1}} - \frac{x^2}{(x^2+1)^{\frac{3}{2}}} \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= 0 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$\frac{x u''(x)}{\sqrt{x^2+1}} - \left(\frac{1}{\sqrt{x^2+1}} - \frac{x^2}{(x^2+1)^{\frac{3}{2}}}\right) u'(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = c_1 + \sqrt{x^2+1}\, c_2$$

The above shows that

$$u'(x) = \frac{c_2 x}{\sqrt{x^2+1}}$$

Using the above in (1) gives the solution

$$y = -\frac{c_2}{c_1 + \sqrt{x^2+1}\, c_2}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{1}{c_3 + \sqrt{x^2 + 1}}$$

Initial conditions are used to solve for c_3. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{1}{c_3 + 1}$$

$$c_3 = -2$$

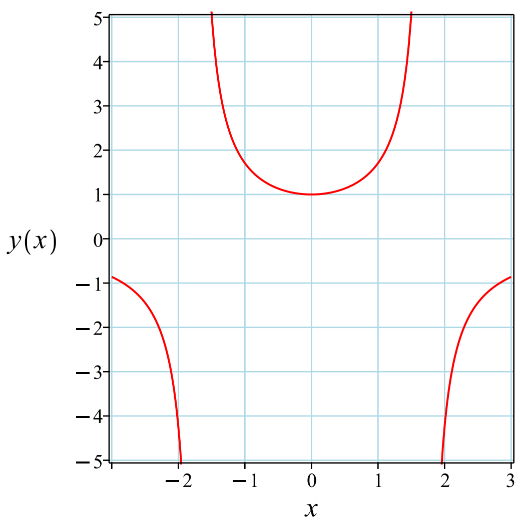
Substituting c_3 found above in the general solution gives

$$y = -\frac{1}{\sqrt{x^2 + 1} - 2}$$

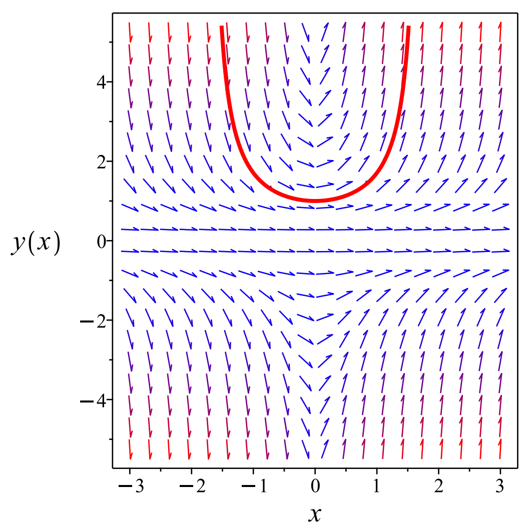
Summary

The solution(s) found are the following

$$y = -\frac{1}{\sqrt{x^2 + 1} - 2} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -\frac{1}{\sqrt{x^2 + 1} - 2}$$

Verified OK.

2.14.6 Maple step by step solution

Let's solve

$\left[y' - \frac{x y^2}{\sqrt{x^2+1}} = 0, y(0) = 1\right]$

- Highest derivative means the order of the ODE is 1

  y'
- Separate variables

  $\frac{y'}{y^2} = \frac{x}{\sqrt{x^2+1}}$
- Integrate both sides with respect to x

  $\int \frac{y'}{y^2} dx = \int \frac{x}{\sqrt{x^2+1}} dx + c_1$
- Evaluate integral

  $-\frac{1}{y} = \sqrt{x^2+1} + c_1$
- Solve for y

  $y = -\frac{1}{\sqrt{x^2+1}+c_1}$
- Use initial condition $y(0) = 1$

  $1 = -\frac{1}{1+c_1}$
- Solve for c_1

  $c_1 = -2$
- Substitute $c_1 = -2$ into general solution and simplify

  $y = -\frac{1}{\sqrt{x^2+1}-2}$
- Solution to the IVP

  $y = -\frac{1}{\sqrt{x^2+1}-2}$

The type(s) of ODE detected by this program : **"exact", "separable", "differentialType", "homogeneousTypeMapleC", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{2x}{1+2y} = 0}$$

With initial conditions

$$[y(2) = 0]$$

2.15.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= \frac{2x}{1+2y} \end{aligned}$$

The x domain of $f(x,y)$ when $y=0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 2$ is inside this domain. The y domain of $f(x,y)$ when $x=2$ is

$$\left\{y < -\frac{1}{2} \lor -\frac{1}{2} < y\right\}$$

And the point $y_0 = 0$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned} \frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{2x}{1+2y}\right) \\ &= -\frac{4x}{(1+2y)^2} \end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y=0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 2$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x=2$ is

$$\left\{y < -\frac{1}{2} \lor -\frac{1}{2} < y\right\}$$

And the point $y_0 = 0$ is inside this domain. Therefore solution exists and is unique.

2.15.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{2x}{1+2y} \end{aligned}$$

Where $f(x) = 2x$ and $g(y) = \frac{1}{1+2y}$. Integrating both sides gives

$$\begin{aligned} \frac{1}{\frac{1}{1+2y}}\,dy &= 2x\,dx \\ \int \frac{1}{\frac{1}{1+2y}}\,dy &= \int 2x\,dx \\ y^2 + y &= x^2 + c_1 \end{aligned}$$

Which results in

$$\begin{aligned} y &= -\frac{1}{2} + \frac{\sqrt{4x^2+4c_1+1}}{2} \\ y &= -\frac{1}{2} - \frac{\sqrt{4x^2+4c_1+1}}{2} \end{aligned}$$

Initial conditions are used to solve for c_1. Substituting $x = 2$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -\frac{1}{2} - \frac{\sqrt{17+4c_1}}{2}$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = 2$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -\frac{1}{2} + \frac{\sqrt{17+4c_1}}{2}$$

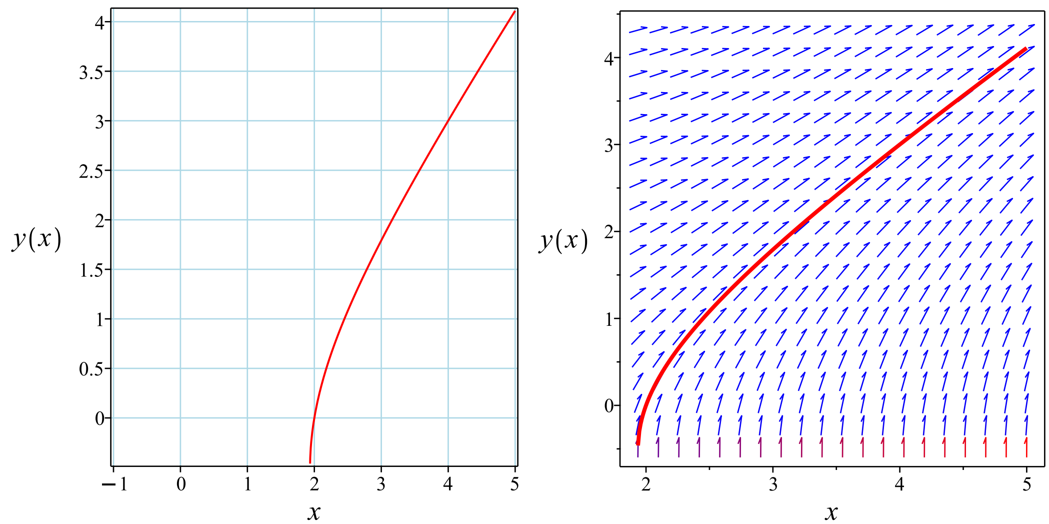
$$c_1 = -4$$

Substituting c_1 found above in the general solution gives

$$y = -\frac{1}{2} + \frac{\sqrt{4x^2-15}}{2}$$

Summary
The solution(s) found are the following

$$y = -\frac{1}{2} + \frac{\sqrt{4x^2 - 15}}{2} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = -\frac{1}{2} + \frac{\sqrt{4x^2 - 15}}{2}$$

Verified OK.

2.15.3 Solving as differentialType ode

Writing the ode as

$$y' = \frac{2x}{1 + 2y} \tag{1}$$

Which becomes

$$(1 + 2y)\, dy = (2x)\, dx \tag{2}$$

But the RHS is complete differential because

$$(2x)\, dx = d(x^2)$$

Hence (2) becomes

$$(1+2y)\,dy = d(x^2)$$

Integrating both sides gives gives these solutions

$$y = -\frac{1}{2} + \frac{\sqrt{4x^2+4c_1+1}}{2} + c_1$$
$$y = -\frac{1}{2} - \frac{\sqrt{4x^2+4c_1+1}}{2} + c_1$$

Initial conditions are used to solve for c_1. Substituting $x = 2$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -\frac{1}{2} - \frac{\sqrt{17+4c_1}}{2} + c_1$$

$$c_1 = \sqrt{5}+1$$

Substituting c_1 found above in the general solution gives

$$y = \frac{1}{2} - \frac{\sqrt{4x^2+4\sqrt{5}+5}}{2} + \sqrt{5}$$

Initial conditions are used to solve for c_1. Substituting $x = 2$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -\frac{1}{2} + \frac{\sqrt{17+4c_1}}{2} + c_1$$

$$c_1 = -\sqrt{5}+1$$

Substituting c_1 found above in the general solution gives

$$y = \frac{1}{2} + \frac{\sqrt{4x^2-4\sqrt{5}+5}}{2} - \sqrt{5}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{2} + \frac{\sqrt{4x^2-4\sqrt{5}+5}}{2} - \sqrt{5} \tag{1}$$
$$y = \frac{1}{2} - \frac{\sqrt{4x^2+4\sqrt{5}+5}}{2} + \sqrt{5} \tag{2}$$

2.15.4 Solving as homogeneousTypeMapleC ode

Let $Y = y + y_0$ and $X = x + x_0$ then the above is transformed to new ode in $Y(X)$

$$\frac{d}{dX}Y(X) = \frac{2X + 2x_0}{1 + 2Y(X) + 2y_0}$$

Solving for possible values of x_0 and y_0 which makes the above ode a homogeneous ode results in

$$x_0 = 0$$
$$y_0 = -\frac{1}{2}$$

Using these values now it is possible to easily solve for $Y(X)$. The above ode now becomes

$$\frac{d}{dX}Y(X) = \frac{X}{Y(X)}$$

In canonical form, the ODE is

$$\begin{aligned} Y' &= F(X, Y) \\ &= \frac{X}{Y} \end{aligned} \tag{1}$$

An ode of the form $Y' = \frac{M(X,Y)}{N(X,Y)}$ is called homogeneous if the functions $M(X, Y)$ and $N(X, Y)$ are both homogeneous functions and of the same order. Recall that a function $f(X, Y)$ is homogeneous of order n if

$$f(t^n X, t^n Y) = t^n f(X, Y)$$

In this case, it can be seen that both $M = X$ and $N = Y$ are both homogeneous and of the same order $n = 1$. Therefore this is a homogeneous ode. Since this ode is homogeneous, it is converted to separable ODE using the substitution $u = \frac{Y}{X}$, or $Y = uX$. Hence

$$\frac{\mathrm{d}Y}{\mathrm{d}X} = \frac{\mathrm{d}u}{\mathrm{d}X}X + u$$

Applying the transformation $Y = uX$ to the above ODE in (1) gives

$$\begin{aligned} \frac{\mathrm{d}u}{\mathrm{d}X}X + u &= \frac{1}{u} \\ \frac{\mathrm{d}u}{\mathrm{d}X} &= \frac{\frac{1}{u(X)} - u(X)}{X} \end{aligned}$$

Or

$$\frac{d}{dX}u(X) - \frac{\frac{1}{u(X)} - u(X)}{X} = 0$$

Or

$$\left(\frac{d}{dX}u(X)\right) u(X) X + u(X)^2 - 1 = 0$$

Which is now solved as separable in $u(X)$. Which is now solved in $u(X)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(X, u) \\ &= f(X)g(u) \\ &= -\frac{u^2 - 1}{uX} \end{aligned}$$

Where $f(X) = -\frac{1}{X}$ and $g(u) = \frac{u^2-1}{u}$. Integrating both sides gives

$$\frac{1}{\frac{u^2-1}{u}}\,du = -\frac{1}{X}\,dX$$

$$\int \frac{1}{\frac{u^2-1}{u}}\,du = \int -\frac{1}{X}\,dX$$

$$\frac{\ln(u-1)}{2} + \frac{\ln(u+1)}{2} = -\ln(X) + c_2$$

The above can be written as

$$\left(\frac{1}{2}\right)(\ln(u-1) + \ln(u+1)) = -\ln(X) + 2c_2$$

$$\begin{aligned}\ln(u-1) + \ln(u+1) &= (2)(-\ln(X) + 2c_2)\\ &= -2\ln(X) + 4c_2\end{aligned}$$

Raising both side to exponential gives

$$e^{\ln(u-1)+\ln(u+1)} = e^{-2\ln(X)+2c_2}$$

Which simplifies to

$$\begin{aligned}u^2 - 1 &= \frac{2c_2}{X^2}\\ &= \frac{c_3}{X^2}\end{aligned}$$

The solution is

$$u(X)^2 - 1 = \frac{c_3}{X^2}$$

Now u in the above solution is replaced back by Y using $u = \frac{Y}{X}$ which results in the solution

$$\frac{Y(X)^2}{X^2} - 1 = \frac{c_3}{X^2}$$

Which simplifies to

$$-(X - Y(X))(X + Y(X)) = c_3$$

Using the solution for $Y(X)$

$$-(X - Y(X))(X + Y(X)) = c_3$$

And replacing back terms in the above solution using

$$
\begin{aligned}
Y &= y + y_0 \\
X &= x + x_0
\end{aligned}
$$

Or

$$
\begin{aligned}
Y &= y - \frac{1}{2} \\
X &= x
\end{aligned}
$$

Then the solution in y becomes

$$
-\left(x - y - \frac{1}{2}\right)\left(x + y + \frac{1}{2}\right) = c_3
$$

Initial conditions are used to solve for c_3. Substituting $x = 2$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$
-\frac{15}{4} = c_3
$$

$$
c_3 = -\frac{15}{4}
$$

Substituting c_3 found above in the general solution gives

$$
-\left(x - y - \frac{1}{2}\right)\left(x + y + \frac{1}{2}\right) = -\frac{15}{4}
$$

Solving for y from the above gives

$$
y = -\frac{1}{2} + \frac{\sqrt{4x^2 - 15}}{2}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = -\frac{1}{2} + \frac{\sqrt{4x^2 - 15}}{2} \tag{1}
$$

2.15.5 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{2x}{1 + 2y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 133: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= \frac{1}{2x} \\
\eta(x,y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{2x}} dx \end{aligned}$$

Which results in

$$S = x^2$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{2x}{1 + 2y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= 2x \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 1 + 2y \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 1 + 2R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = R^2 + R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$x^2 = y^2 + c_1 + y$$

Which simplifies to

$$x^2 = y^2 + c_1 + y$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{2x}{1+2y}$ 	$R = y$ $S = x^2$	$\frac{dS}{dR} = 1 + 2R$ 
Initial conditions are used to solve for c_1. Substituting $x = 2$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$4 = c_1$$

$$c_1 = 4$$

Substituting c_1 found above in the general solution gives

$$x^2 = y^2 + y + 4$$

<u>Summary</u>
The solution(s) found are the following

$$x^2 = y^2 + y + 4 \tag{1}$$

<u>Verification of solutions</u>

$$x^2 = y^2 + y + 4$$

Verified OK.

2.15.6 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work

and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(y+\frac{1}{2}\right)\mathrm{d}y &= (x)\,\mathrm{d}x\\ (-x)\,\mathrm{d}x + \left(y+\frac{1}{2}\right)\mathrm{d}y &= 0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -x\\ N(x,y) &= y+\frac{1}{2}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-x)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(y+\frac{1}{2}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, dx = \int M \, dx$$
$$\int \frac{\partial \phi}{\partial x} \, dx = \int -x \, dx$$
$$\phi = -\frac{x^2}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y + \frac{1}{2}$. Therefore equation (4) becomes

$$y + \frac{1}{2} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = y + \frac{1}{2}$$

Integrating the above w.r.t y gives

$$\int f'(y) \, dy = \int \left(y + \frac{1}{2}\right) dy$$
$$f(y) = \frac{1}{2}y^2 + \frac{1}{2}y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{1}{2}x^2 + \frac{1}{2}y^2 + \frac{1}{2}y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{1}{2}x^2 + \frac{1}{2}y^2 + \frac{1}{2}y$$

Initial conditions are used to solve for c_1. Substituting $x = 2$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$-2 = c_1$$

$$c_1 = -2$$

Substituting c_1 found above in the general solution gives

$$-\frac{1}{2}x^2 + \frac{1}{2}y^2 + \frac{1}{2}y = -2$$

Summary

The solution(s) found are the following

$$-\frac{x^2}{2} + \frac{y^2}{2} + \frac{y}{2} = -2 \tag{1}$$

Verification of solutions

$$-\frac{x^2}{2} + \frac{y^2}{2} + \frac{y}{2} = -2$$

Verified OK.

2.15.7 Maple step by step solution

Let's solve

$\left[y' - \frac{2x}{1+2y} = 0, y(2) = 0\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $y'(1 + 2y) = 2x$

- Integrate both sides with respect to x

  $\int y'(1 + 2y)\, dx = \int 2x dx + c_1$

- Evaluate integral

  $y^2 + y = x^2 + c_1$

- Solve for y

$$\left\{y=-\frac{1}{2}-\frac{\sqrt{4x^2+4c_1+1}}{2}, y=-\frac{1}{2}+\frac{\sqrt{4x^2+4c_1+1}}{2}\right\}$$

- Use initial condition $y(2)=0$

  $0=-\frac{1}{2}-\frac{\sqrt{17+4c_1}}{2}$
- Solution does not satisfy initial condition
- Use initial condition $y(2)=0$

  $0=-\frac{1}{2}+\frac{\sqrt{17+4c_1}}{2}$
- Solve for c_1

  $c_1=-4$
- Substitute $c_1=-4$ into general solution and simplify

  $y=-\frac{1}{2}+\frac{\sqrt{4x^2-15}}{2}$
- Solution to the IVP

  $y=-\frac{1}{2}+\frac{\sqrt{4x^2-15}}{2}$

Problem number: 16.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "differentialType", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{x(x^2+1)}{4y^3} = 0}$$

With initial conditions

$$\left[y(0) = -\frac{\sqrt{2}}{2}\right]$$

2.16.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= \frac{x(x^2+1)}{4y^3} \end{aligned}$$

The x domain of $f(x,y)$ when $y = -\frac{\sqrt{2}}{2}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x,y)$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = -\frac{\sqrt{2}}{2}$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned} \frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{x(x^2+1)}{4y^3}\right) \\ &= -\frac{3x(x^2+1)}{4y^4} \end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = -\frac{\sqrt{2}}{2}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = -\frac{\sqrt{2}}{2}$ is inside this domain. Therefore solution exists and is unique.

2.16.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{x(x^2+1)}{4y^3} \end{aligned}$$

Where $f(x) = \frac{x(x^2+1)}{4}$ and $g(y) = \frac{1}{y^3}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y^3}}\,dy = \frac{x(x^2+1)}{4}\,dx$$

$$\int \frac{1}{\frac{1}{y^3}}\,dy = \int \frac{x(x^2+1)}{4}\,dx$$

$$\frac{y^4}{4} = \frac{(x^2+1)^2}{16} + c_1$$

The solution is

$$\frac{y^4}{4} - \frac{(x^2+1)^2}{16} - c_1 = 0$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -\frac{\sqrt{2}}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$-c_1 = 0$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$\frac{1}{4}y^4 - \frac{1}{16}x^4 - \frac{1}{8}x^2 - \frac{1}{16} = 0$$

<u>Summary</u>
The solution(s) found are the following

$$\frac{y^4}{4} - \frac{x^4}{16} - \frac{x^2}{8} - \frac{1}{16} = 0 \tag{1}$$

<u>Verification of solutions</u>

$$\frac{y^4}{4} - \frac{x^4}{16} - \frac{x^2}{8} - \frac{1}{16} = 0$$

Verified OK.

2.16.3 Solving as differentialType ode

Writing the ode as

$$y' = \frac{x(x^2+1)}{4y^3} \tag{1}$$

Which becomes

$$(4y^3)\, dy = (x(x^2+1))\, dx \tag{2}$$

But the RHS is complete differential because

$$(x(x^2+1))\, dx = d\left(\frac{1}{2}x^2 + \frac{1}{4}x^4\right)$$

Hence (2) becomes

$$(4y^3)\, dy = d\left(\frac{1}{2}x^2 + \frac{1}{4}x^4\right)$$

Integrating both sides gives gives these solutions

$$\begin{aligned}
y &= \left(\frac{1}{2}x^2 + \frac{1}{4}x^4 + c_1\right)^{\frac{1}{4}} + c_1 \\
y &= i\left(\frac{1}{2}x^2 + \frac{1}{4}x^4 + c_1\right)^{\frac{1}{4}} + c_1 \\
y &= -\left(\frac{1}{2}x^2 + \frac{1}{4}x^4 + c_1\right)^{\frac{1}{4}} + c_1 \\
y &= -i\left(\frac{1}{2}x^2 + \frac{1}{4}x^4 + c_1\right)^{\frac{1}{4}} + c_1
\end{aligned}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -\frac{\sqrt{2}}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{\sqrt{2}}{2} = -ic_1^{\frac{1}{4}} + c_1$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -\frac{\sqrt{2}}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{\sqrt{2}}{2} = -c_1^{\frac{1}{4}} + c_1$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -\frac{\sqrt{2}}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{\sqrt{2}}{2} = i c_1^{\frac{1}{4}} + c_1$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -\frac{\sqrt{2}}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{\sqrt{2}}{2} = c_1^{\frac{1}{4}} + c_1$$

Warning: Unable to solve for constant of integration.

Verification of solutions N/A

2.16.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= \frac{x(x^2+1)}{4y^3} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 136: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x) dx - h(x)}}{g(x)}$	$\frac{f(x) e^{-\int b f(x) dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= \frac{4}{(x^2 + 1)\, x} \\
\eta(x, y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{4}{(x^2+1)x}} dx \end{aligned}$$

Which results in

$$S = \frac{(x^2+1)^2}{16}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{x(x^2+1)}{4y^3}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= \frac{x(x^2+1)}{4} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = y^3 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R^3$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{R^4}{4} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{(x^2+1)^2}{16} = \frac{y^4}{4} + c_1$$

Which simplifies to

$$\frac{(x^2+1)^2}{16} = \frac{y^4}{4} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x(x^2+1)}{4y^3}$ 	$R = y$ $S = \frac{(x^2+1)^2}{16}$	$\frac{dS}{dR} = R^3$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -\frac{\sqrt{2}}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{1}{16} = \frac{1}{16} + c_1$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$\frac{(x^2+1)^2}{16} = \frac{y^4}{4}$$

Summary

The solution(s) found are the following

$$\frac{(x^2+1)^2}{16} = \frac{y^4}{4} \tag{1}$$

Verification of solutions

$$\frac{(x^2+1)^2}{16} = \frac{y^4}{4}$$

Verified OK.

2.16.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(4y^3)\,\mathrm{d}y &= \left(x\left(x^2+1\right)\right)\mathrm{d}x\\ \left(-x\left(x^2+1\right)\right)\mathrm{d}x + \left(4y^3\right)\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -x\left(x^2+1\right)\\ N(x,y) &= 4y^3\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-x\left(x^2+1\right)\right)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(4y^3\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = M \tag{1}$$

$$\frac{\partial\phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int M\,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int -x(x^2+1)\,\mathrm{d}x$$

$$\phi = -\frac{(x^2+1)^2}{4} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 4y^3$. Therefore equation (4) becomes

$$4y^3 = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 4y^3$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (4y^3)\,\mathrm{d}y$$

$$f(y) = y^4 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{(x^2+1)^2}{4} + y^4 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{(x^2+1)^2}{4} + y^4$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -\frac{\sqrt{2}}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$-\frac{(x^2+1)^2}{4} + y^4 = 0$$

Summary
The solution(s) found are the following

$$-\frac{(x^2+1)^2}{4} + y^4 = 0 \tag{1}$$

Verification of solutions

$$-\frac{(x^2+1)^2}{4} + y^4 = 0$$

Verified OK.

2.16.6 Maple step by step solution

Let's solve
$\left[y' - \frac{x(x^2+1)}{4y^3} = 0, y(0) = -\frac{\sqrt{2}}{2}\right]$

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.2. Page 48
Problem number: 17.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{-e^{x} + 3x^{2}}{-5 + 2y} = 0}$$

With initial conditions

$$[y(0) = 1]$$

2.17.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= -\frac{-3x^{2} + e^{x}}{-5 + 2y} \end{aligned}$$

The x domain of $f(x, y)$ when $y = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x, y)$ when $x = 0$ is

$$\left\{y < \frac{5}{2} \lor \frac{5}{2} < y\right\}$$

And the point $y_0 = 1$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{-3x^2 + e^x}{-5 + 2y}\right) \\ &= \frac{-6x^2 + 2e^x}{(-5 + 2y)^2}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 0$ is

$$\left\{y < \frac{5}{2} \lor \frac{5}{2} < y\right\}$$

And the point $y_0 = 1$ is inside this domain. Therefore solution exists and is unique.

2.17.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x, y) \\ &= f(x)g(y) \\ &= \frac{-e^x + 3x^2}{-5 + 2y}\end{aligned}$$

Where $f(x) = -e^x + 3x^2$ and $g(y) = \frac{1}{-5+2y}$. Integrating both sides gives

$$\begin{aligned}\frac{1}{\frac{1}{-5+2y}}\,dy &= -e^x + 3x^2\,dx \\ \int \frac{1}{\frac{1}{-5+2y}}\,dy &= \int -e^x + 3x^2\,dx \\ y^2 - 5y &= x^3 - e^x + c_1\end{aligned}$$

Which results in

$$y = \frac{5}{2} + \frac{\sqrt{25 + 4x^3 - 4\,\mathrm{e}^x + 4c_1}}{2}$$
$$y = \frac{5}{2} - \frac{\sqrt{25 + 4x^3 - 4\,\mathrm{e}^x + 4c_1}}{2}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{5}{2} - \frac{\sqrt{21 + 4c_1}}{2}$$

$$c_1 = -3$$

Substituting c_1 found above in the general solution gives

$$y = \frac{5}{2} - \frac{\sqrt{13 + 4x^3 - 4\,\mathrm{e}^x}}{2}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

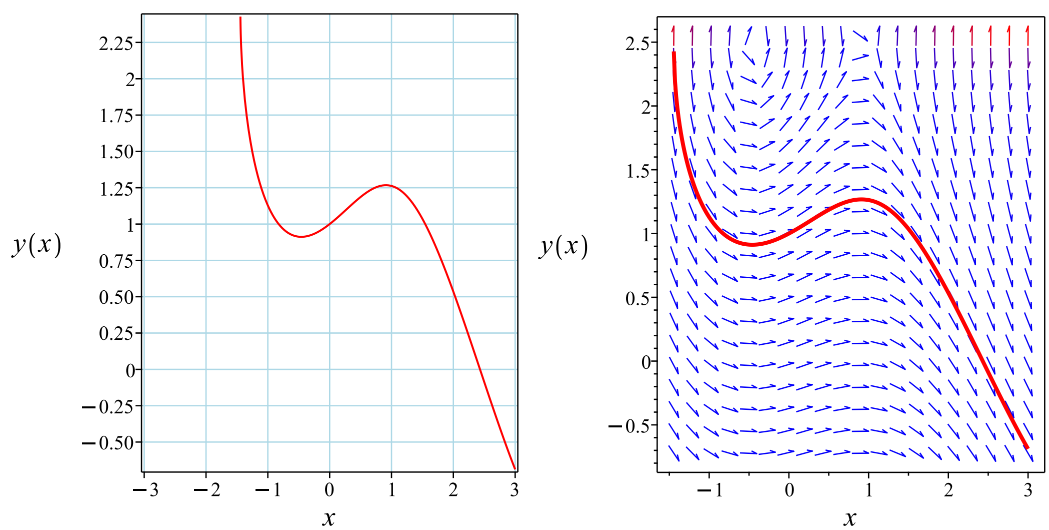
$$1 = \frac{5}{2} + \frac{\sqrt{21 + 4c_1}}{2}$$

Summary

The solution(s) found are the following

Warning: Unable to solve for constant of integration.

$$y = \frac{5}{2} - \frac{\sqrt{13 + 4x^3 -}}{2}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \frac{5}{2} - \frac{\sqrt{13 + 4x^3 - 4\,\mathrm{e}^x}}{2}$$

Verified OK.

2.17.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{-3x^2 + \mathrm{e}^x}{-5 + 2y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 139: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= \frac{1}{-e^{x} + 3x^2} \\
\eta(x,y) &= 0 \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \qquad (1)
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{-e^x + 3x^2}} dx \end{aligned}$$

Which results in

$$S = x^3 - e^x$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{-3x^2 + e^x}{-5 + 2y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= -e^x + 3x^2 \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -5 + 2y \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -5 + 2R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = R^2 - 5R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$x^3 - e^x = y^2 + c_1 - 5y$$

Which simplifies to

$$x^3 - e^x = y^2 + c_1 - 5y$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{-3x^2+e^x}{-5+2y}$ 	$R = y$ $S = x^3 - e^x$	$\frac{dS}{dR} = -5 + 2R$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = -4 + c_1$$

$$c_1 = 3$$

Substituting c_1 found above in the general solution gives

$$x^3 - e^x = y^2 - 5y + 3$$

Summary
The solution(s) found are the following

$$x^3 - e^x = y^2 - 5y + 3 \tag{1}$$

Verification of solutions

$$x^3 - e^x = y^2 - 5y + 3$$

Verified OK.

2.17.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work

and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(5-2y)\,\mathrm{d}y &= \left(-3x^2+\mathrm{e}^x\right)\mathrm{d}x\\ \left(-\mathrm{e}^x+3x^2\right)\mathrm{d}x + (5-2y)\,\mathrm{d}y &= 0 \qquad (2\mathrm{A})\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -\mathrm{e}^x+3x^2\\ N(x,y) &= 5-2y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\mathrm{e}^x+3x^2\right)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(5-2y)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\mathrm{e}^x+3x^2\,\mathrm{d}x\\ \phi &= x^3-\mathrm{e}^x+f(y) \qquad (3)\end{aligned}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 5 - 2y$. Therefore equation (4) becomes

$$5 - 2y = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 5 - 2y$$

Integrating the above w.r.t y gives

$$\int f'(y)\, \mathrm{d}y = \int (5 - 2y)\, \mathrm{d}y$$
$$f(y) = -y^2 + 5y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = x^3 - y^2 - \mathrm{e}^x + 5y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x^3 - y^2 - \mathrm{e}^x + 5y$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$3 = c_1$$

$$c_1 = 3$$

Substituting c_1 found above in the general solution gives

$$x^3 - y^2 - \mathrm{e}^x + 5y = 3$$

Summary
The solution(s) found are the following

$$x^3 - y^2 - e^x + 5y = 3 \tag{1}$$

Verification of solutions

$$x^3 - y^2 - e^x + 5y = 3$$

Verified OK.

2.17.5 Maple step by step solution

Let's solve

$\left[y' - \frac{-e^x+3x^2}{-5+2y} = 0, y(0) = 1\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $y'(-5+2y) = -e^x + 3x^2$

- Integrate both sides with respect to x

  $\int y'(-5+2y)\,dx = \int (-e^x + 3x^2)\,dx + c_1$

- Evaluate integral

  $y^2 - 5y = x^3 - e^x + c_1$

- Solve for y

  $\left\{y = \frac{5}{2} - \frac{\sqrt{25+4x^3-4\,e^x+4c_1}}{2}, y = \frac{5}{2} + \frac{\sqrt{25+4x^3-4\,e^x+4c_1}}{2}\right\}$

- Use initial condition $y(0) = 1$

  $1 = \frac{5}{2} - \frac{\sqrt{21+4c_1}}{2}$

- Solve for c_1

  $c_1 = -3$

- Substitute $c_1 = -3$ into general solution and simplify

  $y = \frac{5}{2} - \frac{\sqrt{13+4x^3-4\,e^x}}{2}$

- Use initial condition $y(0) = 1$

  $1 = \frac{5}{2} + \frac{\sqrt{21+4c_1}}{2}$

- Solution does not satisfy initial condition

- Solution to the IVP

  $y = \frac{5}{2} - \frac{\sqrt{13+4x^3-4\,\mathrm{e}^x}}{2}$

Problem number: 18.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{-\mathrm{e}^{x} + \mathrm{e}^{-x}}{3 + 4y} = 0}$$

With initial conditions

$$[y(0) = 1]$$

2.18.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= -\frac{\mathrm{e}^{x} - \mathrm{e}^{-x}}{3 + 4y} \end{aligned}$$

The x domain of $f(x, y)$ when $y = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x,y)$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 1$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{e^{x} - e^{-x}}{3+4y}\right) \\ &= \frac{4\,e^{x} - 4\,e^{-x}}{(3+4y)^2}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 1$ is inside this domain. Therefore solution exists and is unique.

2.18.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{-e^{x} + e^{-x}}{3+4y}\end{aligned}$$

Where $f(x) = -e^{x} + e^{-x}$ and $g(y) = \frac{1}{3+4y}$. Integrating both sides gives

$$\begin{aligned}\frac{1}{\frac{1}{3+4y}}\,dy &= -e^{x} + e^{-x}\,dx \\ \int \frac{1}{\frac{1}{3+4y}}\,dy &= \int -e^{x} + e^{-x}\,dx \\ 2y^2 + 3y &= -e^{x} - e^{-x} + c_1\end{aligned}$$

Which results in

$$y = -\frac{\left(3\,\mathrm{e}^{x}-\sqrt{-8\,\mathrm{e}^{3x}+8c_1\mathrm{e}^{2x}+9\,\mathrm{e}^{2x}-8\,\mathrm{e}^{x}}\right)\mathrm{e}^{-x}}{4}$$

$$y = -\frac{\left(3\,\mathrm{e}^{x}+\sqrt{-8\,\mathrm{e}^{3x}+8c_1\mathrm{e}^{2x}+9\,\mathrm{e}^{2x}-8\,\mathrm{e}^{x}}\right)\mathrm{e}^{-x}}{4}$$

Initial conditions are used to solve for c_1. Substituting $x=0$ and $y=1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{3}{4}-\frac{\sqrt{-7+8c_1}}{4}$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x=0$ and $y=1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{3}{4}+\frac{\sqrt{-7+8c_1}}{4}$$

$$c_1 = 7$$

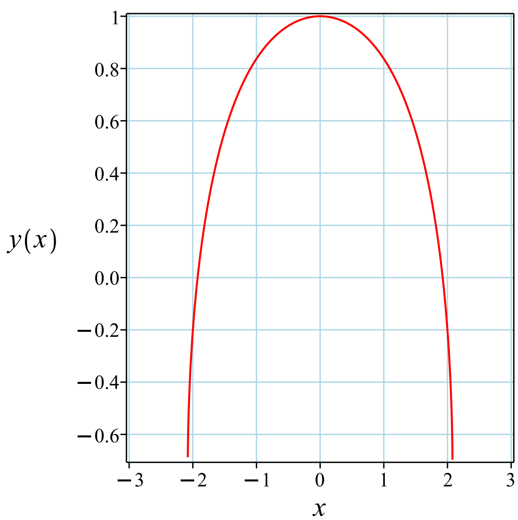
Substituting c_1 found above in the general solution gives

$$y = -\frac{3}{4}+\frac{\mathrm{e}^{-x}\sqrt{65\,\mathrm{e}^{2x}-8\,\mathrm{e}^{x}\mathrm{e}^{2x}-8\,\mathrm{e}^{x}}}{4}$$

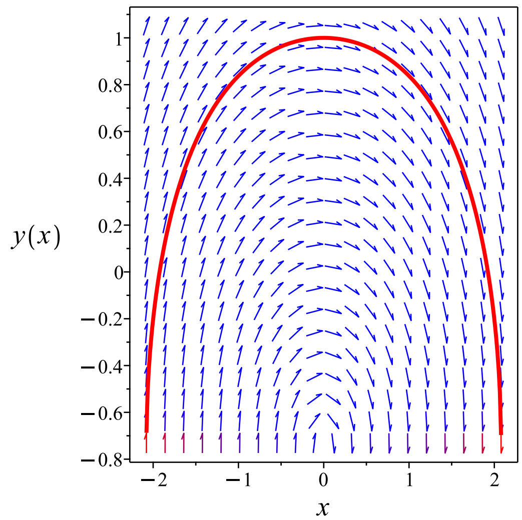
Summary

The solution(s) found are the following

$$y = -\frac{3}{4}+\frac{\mathrm{e}^{-x}\sqrt{65\,\mathrm{e}^{2x}-8\,\mathrm{e}^{x}\mathrm{e}^{2x}-8\,\mathrm{e}^{x}}}{4} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -\frac{3}{4} + \frac{e^{-x}\sqrt{65\,e^{2x} - 8\,e^{x}e^{2x} - 8\,e^{x}}}{4}$$

Verified OK.

2.18.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{e^{x} - e^{-x}}{3 + 4y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 142: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= \frac{1}{-\mathrm{e}^{x} + \mathrm{e}^{-x}} \\
\eta(x, y) &= 0 \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \qquad (1)
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{-e^x + e^{-x}}} dx \end{aligned}$$

Which results in

$$S = -e^x - e^{-x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{e^x - e^{-x}}{3 + 4y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= -e^x + e^{-x} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 3 + 4y \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 3 + 4R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = 2R^2 + 3R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-e^x - e^{-x} = 2y^2 + c_1 + 3y$$

Which simplifies to

$$-e^x - e^{-x} = 2y^2 + c_1 + 3y$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{e^x - e^{-x}}{3+4y}$ 	$R = y$ $S = -e^x - e^{-x}$	$\frac{dS}{dR} = 3 + 4R$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$-2 = 5 + c_1$$

$$c_1 = -7$$

Substituting c_1 found above in the general solution gives

$$-e^{x}-e^{-x}=2y^{2}+3y-7$$

Summary
The solution(s) found are the following

$$-e^{x}-e^{-x}=2y^{2}+3y-7 \tag{1}$$

Verification of solutions

$$-e^{x}-e^{-x}=2y^{2}+3y-7$$

Verified OK.

2.18.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x}=M$$
$$\frac{\partial\phi}{\partial y}=N$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work

and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(-3-4y)\,\mathrm{d}y &= \left(\mathrm{e}^{x}-\mathrm{e}^{-x}\right)\mathrm{d}x\\ \left(-\mathrm{e}^{x}+\mathrm{e}^{-x}\right)\mathrm{d}x + (-3-4y)\,\mathrm{d}y &= 0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x,y) &= -\mathrm{e}^{x}+\mathrm{e}^{-x}\\ N(x,y) &= -3-4y \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\mathrm{e}^{x}+\mathrm{e}^{-x}\right)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-3-4y)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\mathrm{e}^{x}+\mathrm{e}^{-x}\,\mathrm{d}x\\ \phi &= -\mathrm{e}^{x}-\mathrm{e}^{-x}+f(y)\end{aligned}\tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -3 - 4y$. Therefore equation (4) becomes

$$-3 - 4y = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -3 - 4y$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (-3 - 4y)\,\mathrm{d}y$$
$$f(y) = -2y^2 - 3y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -2y^2 - \mathrm{e}^x - 3y - \mathrm{e}^{-x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -2y^2 - \mathrm{e}^x - 3y - \mathrm{e}^{-x}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$-7 = c_1$$

$$c_1 = -7$$

Substituting c_1 found above in the general solution gives

$$-2y^2 - \mathrm{e}^x - 3y - \mathrm{e}^{-x} = -7$$

Summary

The solution(s) found are the following

$$-2y^2 - e^x - 3y - e^{-x} = -7 \tag{1}$$

Verification of solutions

$$-2y^2 - e^x - 3y - e^{-x} = -7$$

Verified OK.

2.18.5 Maple step by step solution

Let's solve

$\left[y' - \frac{-e^x + e^{-x}}{3+4y} = 0, y(0) = 1\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $y'(3+4y) = -e^x + e^{-x}$

- Integrate both sides with respect to x

  $\int y'(3+4y)\, dx = \int (-e^x + e^{-x})\, dx + c_1$

- Evaluate integral

  $2y^2 + 3y = -e^x - e^{-x} + c_1$

- Solve for y

  $\left\{y = -\frac{3\,e^x - \sqrt{-8(e^x)^3 + 8c_1(e^x)^2 + 9(e^x)^2 - 8\,e^x}}{4\,e^x}, y = -\frac{3\,e^x + \sqrt{-8(e^x)^3 + 8c_1(e^x)^2 + 9(e^x)^2 - 8\,e^x}}{4\,e^x}\right\}$

- Use initial condition $y(0) = 1$

  $1 = -\frac{3}{4} + \frac{\sqrt{-7+8c_1}}{4}$

- Solve for c_1

  $c_1 = 7$

- Substitute $c_1 = 7$ into general solution and simplify

  $y = -\frac{3}{4} + \frac{e^{-x}\sqrt{(-8\,e^{2x} + 65\,e^x - 8)e^x}}{4}$

- Use initial condition $y(0) = 1$

  $1 = -\frac{3}{4} - \frac{\sqrt{-7+8c_1}}{4}$

- Solution does not satisfy initial condition
- Solution to the IVP

  $y = -\frac{3}{4} + \frac{e^{-x}\sqrt{(-8\,e^{2x}+65\,e^{x}-8)e^{x}}}{4}$

Section: Section 2.2. Page 48
Problem number: 19.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{\cos (3y)\, y' = -\sin (2x)}$$

With initial conditions

$$\left[y\left(\frac{\pi}{2}\right) = 0\right]$$

2.19.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= -\frac{\sin (2x)}{\cos (3y)} \end{aligned}$$

The x domain of $f(x,y)$ when $y=0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = \frac{\pi}{2}$ is inside this domain. The y domain of $f(x, y)$ when $x = \frac{\pi}{2}$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 0$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{\sin(2x)}{\cos(3y)}\right) \\ &= -\frac{3\sin(2x)\sin(3y)}{\cos(3y)^2}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = \frac{\pi}{2}$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = \frac{\pi}{2}$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 0$ is inside this domain. Therefore solution exists and is unique.

2.19.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x, y) \\ &= f(x)g(y) \\ &= -\sin(2x)\sec(3y)\end{aligned}$$

Where $f(x) = -\sin(2x)$ and $g(y) = \sec(3y)$. Integrating both sides gives

$$\begin{aligned}\frac{1}{\sec(3y)}\, dy &= -\sin(2x)\, dx \\ \int \frac{1}{\sec(3y)}\, dy &= \int -\sin(2x)\, dx \\ \frac{\sin(3y)}{3} &= \frac{\cos(2x)}{2} + c_1\end{aligned}$$

Which results in

$$y = \frac{\arcsin\left(\frac{3\cos(2x)}{2} + 3c_1\right)}{3}$$

Initial conditions are used to solve for c_1. Substituting $x = \frac{\pi}{2}$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{\arcsin\left(-\frac{3}{2} + 3c_1\right)}{3}$$

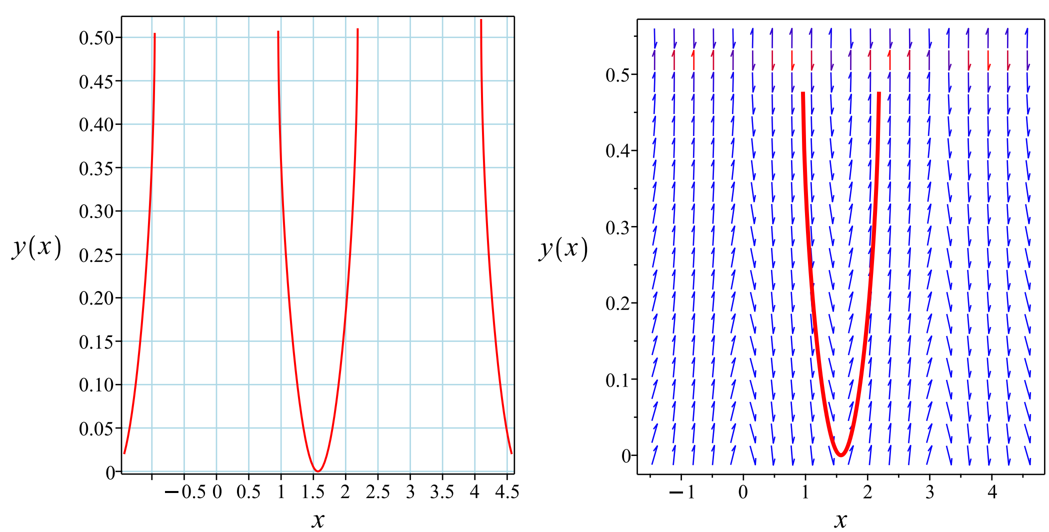
$$c_1 = \frac{1}{2}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{\arcsin\left(\frac{3\cos(2x)}{2} + \frac{3}{2}\right)}{3}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \frac{\arcsin\left(\frac{3\cos(2x)}{2} + \frac{3}{2}\right)}{3} \tag{1}$$



(a) Solution plot (b) Slope field plot

<u>Verification of solutions</u>

$$y = \frac{\arcsin\left(\frac{3\cos(2x)}{2} + \frac{3}{2}\right)}{3}$$

Verified OK.

2.19.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{\sin(2x)}{\cos(3y)}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 145: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= -\frac{1}{\sin(2x)} \\ \eta(x,y) &= 0 \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{-\frac{1}{\sin(2x)}} dx \end{aligned}$$

Which results in

$$S = \frac{\cos(2x)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{\sin(2x)}{\cos(3y)}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= -\sin(2x) \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \cos(3y) \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \cos(3R)
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \frac{\sin(3R)}{3} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{\cos(2x)}{2} = \frac{\sin(3y)}{3} + c_1
$$

Which simplifies to

$$
\frac{\cos(2x)}{2} = \frac{\sin(3y)}{3} + c_1
$$

Which gives

$$
y = -\frac{\arcsin\left(-\frac{3\cos(2x)}{2} + 3c_1\right)}{3}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{\sin(2x)}{\cos(3y)}$ 	$R = y$ $S = \frac{\cos(2x)}{2}$	$\frac{dS}{dR} = \cos(3R)$ 
Initial conditions are used to solve for c_1. Substituting $x = \frac{\pi}{2}$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -\frac{\arcsin\left(\frac{3}{2} + 3c_1\right)}{3}$$

$$c_1 = -\frac{1}{2}$$

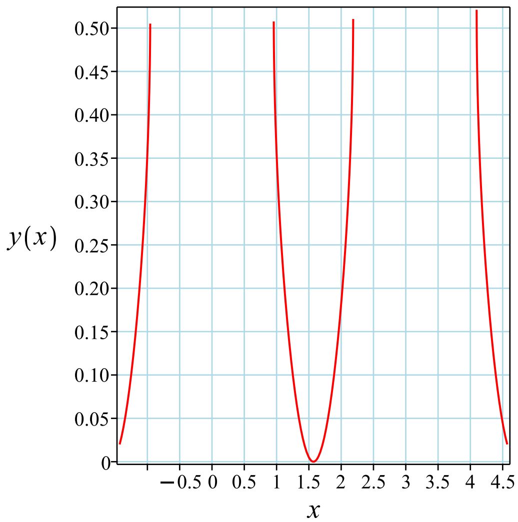
Substituting c_1 found above in the general solution gives

$$y = \frac{\arcsin\left(\frac{3\cos(2x)}{2} + \frac{3}{2}\right)}{3}$$

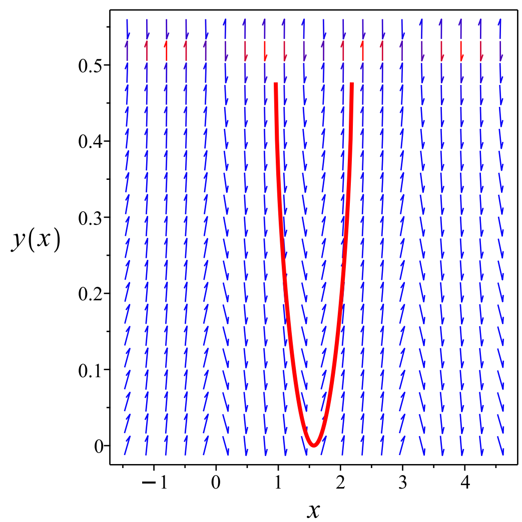
Summary

The solution(s) found are the following

$$y = \frac{\arcsin\left(\frac{3\cos(2x)}{2} + \frac{3}{2}\right)}{3} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = \frac{\arcsin\left(\frac{3\cos(2x)}{2} + \frac{3}{2}\right)}{3}$$

Verified OK.

2.19.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(-\cos(3y))\,\mathrm{d}y &= (\sin(2x))\,\mathrm{d}x \\ (-\sin(2x))\,\mathrm{d}x + (-\cos(3y))\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x, y) &= -\sin(2x) \\ N(x, y) &= -\cos(3y) \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-\sin(2x)) \\ &= 0 \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-\cos(3y)) \\ &= 0 \end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial\phi}{\partial x} = M \tag{1}$$

$$\frac{\partial\phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int -\sin(2x) \mathrm{d}x$$
$$\phi = \frac{\cos(2x)}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\cos(3y)$. Therefore equation (4) becomes

$$-\cos(3y) = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\cos(3y)$$

Integrating the above w.r.t y gives

$$\int f'(y) \mathrm{d}y = \int (-\cos(3y)) \mathrm{d}y$$
$$f(y) = -\frac{\sin(3y)}{3} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{\cos(2x)}{2} - \frac{\sin(3y)}{3} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{\cos(2x)}{2} - \frac{\sin(3y)}{3}$$

Initial conditions are used to solve for c_1. Substituting $x = \frac{\pi}{2}$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{1}{2} = c_1$$

$$c_1 = -\frac{1}{2}$$

Substituting c_1 found above in the general solution gives

$$\frac{\cos(2x)}{2} - \frac{\sin(3y)}{3} = -\frac{1}{2}$$

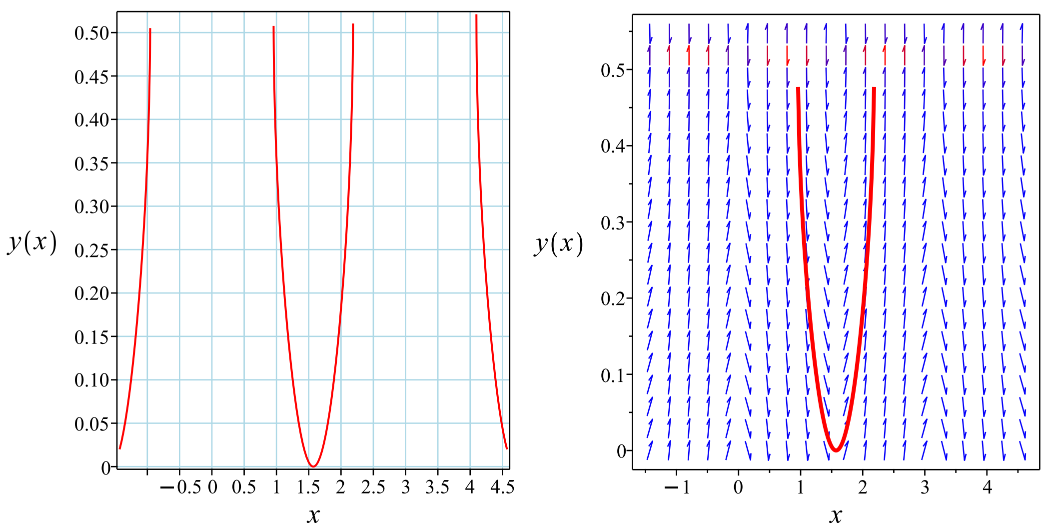
Solving for y from the above gives

$$y = \frac{\arcsin\left(\frac{3\cos(2x)}{2} + \frac{3}{2}\right)}{3}$$

Summary

The solution(s) found are the following

$$y = \frac{\arcsin\left(\frac{3\cos(2x)}{2} + \frac{3}{2}\right)}{3} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \frac{\arcsin\left(\frac{3\cos(2x)}{2} + \frac{3}{2}\right)}{3}$$

Verified OK.

$$[y(0) = 1]$$

2.20.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= \frac{\arcsin\left(x\right)}{\sqrt{-x^{2}+1}\, y^{2}} \end{aligned}$$

The x domain of $f(x,y)$ when $y=1$ is

$$\{-1<x<1\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x,y)$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 1$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{\arcsin(x)}{\sqrt{-x^2+1}\,y^2}\right)\\&= -\frac{2\arcsin(x)}{\sqrt{-x^2+1}\,y^3}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 1$ is

$$\{-1 < x < 1\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 1$ is inside this domain. Therefore solution exists and is unique.

2.20.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x,y)\\&= f(x)g(y)\\&= \frac{\arcsin(x)}{\sqrt{-x^2+1}\,y^2}\end{aligned}$$

Where $f(x) = \frac{\arcsin(x)}{\sqrt{-x^2+1}}$ and $g(y) = \frac{1}{y^2}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y^2}}\,dy = \frac{\arcsin(x)}{\sqrt{-x^2+1}}\,dx$$

$$\int \frac{1}{\frac{1}{y^2}}\,dy = \int \frac{\arcsin(x)}{\sqrt{-x^2+1}}\,dx$$

$$\frac{y^3}{3} = \frac{\arcsin(x)^2}{2} + c_1$$

Which results in

$$y = \frac{\left(12 \arcsin \left(x\right)^{2}+24 c_{1}\right)^{\frac{1}{3}}}{2}$$

$$y = -\frac{\left(12 \arcsin \left(x\right)^{2}+24 c_{1}\right)^{\frac{1}{3}}}{4}+\frac{i \sqrt{3}\, \left(12 \arcsin \left(x\right)^{2}+24 c_{1}\right)^{\frac{1}{3}}}{4}$$

$$y = -\frac{\left(12 \arcsin \left(x\right)^{2}+24 c_{1}\right)^{\frac{1}{3}}}{4}-\frac{i \sqrt{3}\, \left(12 \arcsin \left(x\right)^{2}+24 c_{1}\right)^{\frac{1}{3}}}{4}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{i c_{1}^{\frac{1}{3}} 24^{\frac{1}{3}} \sqrt{3}}{4}-\frac{c_{1}^{\frac{1}{3}} 24^{\frac{1}{3}}}{4}$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{i c_{1}^{\frac{1}{3}} 24^{\frac{1}{3}} \sqrt{3}}{4}-\frac{c_{1}^{\frac{1}{3}} 24^{\frac{1}{3}}}{4}$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{c_{1}^{\frac{1}{3}} 24^{\frac{1}{3}}}{2}$$

$$c_1 = \frac{1}{3}$$

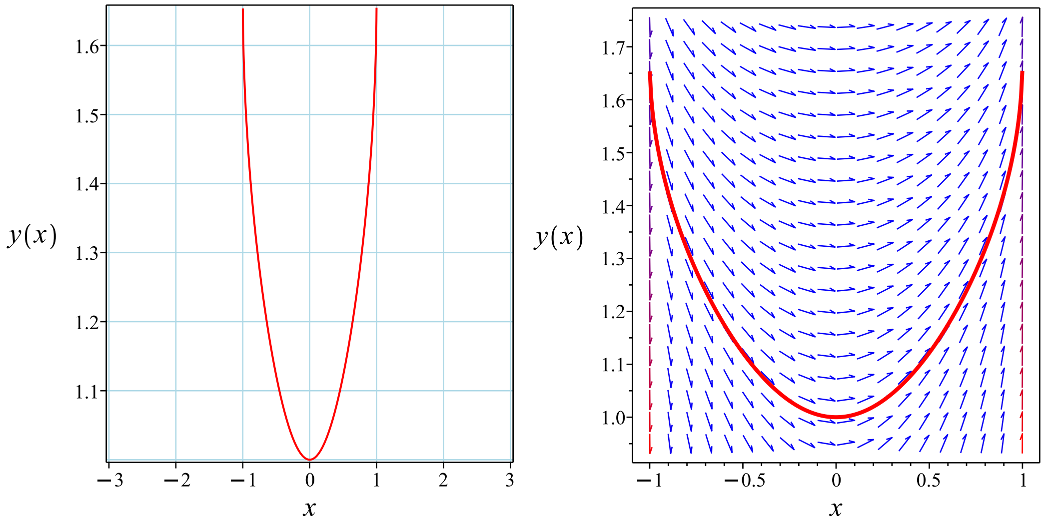
Substituting c_1 found above in the general solution gives

$$y = \frac{\left(12 \arcsin \left(x\right)^{2}+8\right)^{\frac{1}{3}}}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(12 \arcsin \left(x\right)^{2}+8\right)^{\frac{1}{3}}}{2} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \frac{\left(12 \arcsin\left(x\right)^{2}+8\right)^{\frac{1}{3}}}{2}$$

Verified OK.

2.20.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{\arcsin\left(x\right)}{\sqrt{-x^{2}+1}\, y^{2}}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 148: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= \frac{\sqrt{-x^2 + 1}}{\arcsin(x)} \\
\eta(x, y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{\sqrt{-x^2+1}}{\arcsin(x)}} dx \end{aligned}$$

Which results in

$$S = \frac{\arcsin(x)^2}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{\arcsin(x)}{\sqrt{-x^2+1}\, y^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= \frac{\arcsin(x)}{\sqrt{-x^2+1}} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = y^2 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R^2$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{R^3}{3} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\arcsin(x)^2}{2} = \frac{y^3}{3} + c_1$$

Which simplifies to

$$\frac{\arcsin(x)^2}{2} = \frac{y^3}{3} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{\arcsin(x)}{\sqrt{-x^2+1}\, y^2}$ 	$R = y$ $S = \frac{\arcsin(x)^2}{2}$	$\frac{dS}{dR} = R^2$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{1}{3} + c_1$$

$$
c_1 = -\frac{1}{3}
$$

Substituting c_1 found above in the general solution gives

$$
\frac{\arcsin(x)^2}{2} = \frac{y^3}{3} - \frac{1}{3}
$$

Summary

The solution(s) found are the following

$$
\frac{\arcsin(x)^2}{2} = \frac{y^3}{3} - \frac{1}{3} \tag{1}
$$

Verification of solutions

$$
\frac{\arcsin(x)^2}{2} = \frac{y^3}{3} - \frac{1}{3}
$$

Verified OK.

2.20.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$
M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}
$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$
\frac{d}{dx}\phi(x,y) = 0
$$

Hence

$$
\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}
$$

Comparing (A,B) shows that

$$
\frac{\partial \phi}{\partial x} = M
$$
$$
\frac{\partial \phi}{\partial y} = N
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(y^2)\,\mathrm{d}y = \left(\frac{\arcsin(x)}{\sqrt{-x^2+1}}\right)\mathrm{d}x$$

$$\left(-\frac{\arcsin(x)}{\sqrt{-x^2+1}}\right)\mathrm{d}x + (y^2)\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = -\frac{\arcsin(x)}{\sqrt{-x^2+1}}$$
$$N(x,y) = y^2$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-\frac{\arcsin(x)}{\sqrt{-x^2+1}}\right)$$
$$= 0$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}(y^2)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -\frac{\arcsin(x)}{\sqrt{-x^2+1}} \, \mathrm{d}x$$

$$\phi = -\frac{\arcsin(x)^2}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y^2$. Therefore equation (4) becomes

$$y^2 = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = y^2$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (y^2) \, \mathrm{d}y$$

$$f(y) = \frac{y^3}{3} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\arcsin(x)^2}{2} + \frac{y^3}{3} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\arcsin(x)^2}{2} + \frac{y^3}{3}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{1}{3} = c_1$$

$$c_1 = \frac{1}{3}$$

Substituting c_1 found above in the general solution gives

$$-\frac{\arcsin(x)^2}{2} + \frac{y^3}{3} = \frac{1}{3}$$

Summary

The solution(s) found are the following

$$-\frac{\arcsin(x)^2}{2} + \frac{y^3}{3} = \frac{1}{3} \tag{1}$$

Verification of solutions

$$-\frac{\arcsin(x)^2}{2} + \frac{y^3}{3} = \frac{1}{3}$$

Verified OK.

2.20.5 Maple step by step solution

Let's solve

$\left[\sqrt{-x^2+1}\, y^2 y' = \arcsin(x), y(0) = 1\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $y' y^2 = \frac{\arcsin(x)}{\sqrt{-x^2+1}}$

- Integrate both sides with respect to x

  $\int y' y^2 dx = \int \frac{\arcsin(x)}{\sqrt{-x^2+1}} dx + c_1$

- Evaluate integral

  $\frac{y^3}{3} = \frac{\arcsin(x)^2}{2} + c_1$

- Solve for y

$$y = \frac{\left(12 \arcsin(x)^2+24c_1\right)^{\frac{1}{3}}}{2}$$

- Use initial condition $y(0) = 1$

$$1 = \frac{c_1^{\frac{1}{3}} 24^{\frac{1}{3}}}{2}$$

- Solve for c_1

$$c_1 = \frac{1}{3}$$

- Substitute $c_1 = \frac{1}{3}$ into general solution and simplify

$$y = \frac{\left(12 \arcsin(x)^2+8\right)^{\frac{1}{3}}}{2}$$

- Solution to the IVP

$$y = \frac{\left(12 \arcsin(x)^2+8\right)^{\frac{1}{3}}}{2}$$

The type(s) of ODE detected by this program : **"exact", "separable", "differentialType", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{3x^2 + 1}{-6y + 3y^2} = 0}$$

With initial conditions

$$[y(0) = 1]$$

2.21.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= \frac{3x^2+1}{3y\,(y-2)} \end{aligned}$$

The x domain of $f(x, y)$ when $y = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x, y)$ when $x = 0$ is

$$\{-\infty \leq y < 0, 0 < y < 2, 2 < y \leq \infty\}$$

And the point $y_0 = 1$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned} \frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{3x^2+1}{3y\,(y-2)}\right) \\ &= -\frac{3x^2+1}{3y^2\,(y-2)} - \frac{3x^2+1}{3y\,(y-2)^2} \end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 0$ is

$$\{-\infty \leq y < 0, 0 < y < 2, 2 < y \leq \infty\}$$

And the point $y_0 = 1$ is inside this domain. Therefore solution exists and is unique.

2.21.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= f(x)g(y) \\ &= \frac{x^2+\frac{1}{3}}{y\,(y-2)} \end{aligned}$$

Where $f(x) = x^2 + \frac{1}{3}$ and $g(y) = \frac{1}{y(y-2)}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y(y-2)}}\,dy = x^2 + \frac{1}{3}\,dx$$

$$\int \frac{1}{\frac{1}{y(y-2)}}\,dy = \int x^2 + \frac{1}{3}\,dx$$

$$\frac{1}{3}y^3 - y^2 = \frac{1}{3}x^3 + \frac{1}{3}x + c_1$$

Which results in

$$y = \frac{\left(8 + 4x^3 + 12c_1 + 4x + 4\sqrt{x^6 + 6c_1x^3 + 2x^4 + 4x^3 + 9c_1^2 + 6c_1x + x^2 + 12c_1 + 4x}\right)^{\frac{1}{3}}}{2} + \frac{2}{\left(8 + 4x^3 + 12c_1 + 4x + 4\sqrt{x^6 + 6c_1x^3 + 2x^4 + 4x^3 + 9c_1^2 + 6c_1x + x^2 + 12c_1 + 4x}\right)^{\frac{1}{3}}} + 1$$

$$y = -\frac{\left(8 + 4x^3 + 12c_1 + 4x + 4\sqrt{x^6 + 6c_1x^3 + 2x^4 + 4x^3 + 9c_1^2 + 6c_1x + x^2 + 12c_1 + 4x}\right)^{\frac{1}{3}}}{4} - \frac{1}{\left(8 + 4x^3 + 12c_1 + 4x + 4\sqrt{x^6 + 6c_1x^3 + 2x^4 + 4x^3 + 9c_1^2 + 6c_1x + x^2 + 12c_1 + 4x}\right)^{\frac{1}{3}}} + 1 + \frac{i\sqrt{3}\left(\frac{\left(8+4x^3+12c_1+4x+4\sqrt{x^6+6c_1x^3+2x^4+4x^3+9c_1^2+6c_1x+x^2+12c_1+4x}\right)^{\frac{1}{3}}}{2} - \frac{2}{\left(8+4x^3+12c_1+4x+4\sqrt{x^6+6c_1x^3+2x^4+4x^3+9c_1^2 \ldots\right.}}\right.}{2}$$

$$y = -\frac{\left(8+4x^3+12c_1+4x+4\sqrt{x^6+6c_1x^3+2x^4+4x^3+9c_1^2+6c_1x+x^2+12c_1+4x}\right)^{\frac{1}{3}}}{4} - \frac{1}{\left(8+4x^3+12c_1+4x+4\sqrt{x^6+6c_1x^3+2x^4+4x^3+9c_1^2+6c_1x+x^2+12c_1+4x}\right)^{\frac{1}{3}}} + 1 - \frac{i\sqrt{3}\left(\frac{\left(8+4x^3+12c_1+4x+4\sqrt{x^6+6c_1x^3+2x^4+4x^3+9c_1^2+6c_1x+x^2+12c_1+4x}\right)^{\frac{1}{3}}}{2} - \frac{2}{\left(8+4x^3+12c_1+4x+4\sqrt{x^6+6c_1x^3+2x^4+4x^3+9c\right.}}\right.}{2}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{-i\sqrt{3}\left(8+12c_1+4\sqrt{3}\,\sqrt{3c_1^2+4c_1}\right)^{\frac{2}{3}} + 4i\sqrt{3} - \left(8+12c_1+4\sqrt{3}\,\sqrt{3c_1^2+4c_1}\right)^{\frac{2}{3}} + 4\left(8+12c_1+4\sqrt{\right.}}{4\left(8+12c_1+4\sqrt{3}\,\sqrt{3c_1^2+4c_1}\right)^{\frac{1}{3}}}$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{i\sqrt{3}\left(8+12c_1+4\sqrt{3}\,\sqrt{3c_1^2+4c_1}\right)^{\frac{2}{3}} - 4i\sqrt{3} - \left(8+12c_1+4\sqrt{3}\,\sqrt{3c_1^2+4c_1}\right)^{\frac{2}{3}} + 4\left(8+12c_1+4\sqrt{3}\right.}{4\left(8+12c_1+4\sqrt{3}\,\sqrt{3c_1^2+4c_1}\right)^{\frac{1}{3}}}$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{\left(8+12c_1+4\sqrt{3}\,\sqrt{3c_1^2+4c_1}\right)^{\frac{2}{3}} + 2\left(8+12c_1+4\sqrt{3}\,\sqrt{3c_1^2+4c_1}\right)^{\frac{1}{3}} + 4}{2\left(8+12c_1+4\sqrt{3}\,\sqrt{3c_1^2+4c_1}\right)^{\frac{1}{3}}}$$

Warning: Unable to solve for constant of integration.

Verification of solutions N/A

2.21.3 Solving as differentialType ode

Writing the ode as

$$y' = \frac{3x^2+1}{-6y+3y^2} \tag{1}$$

Which becomes

$$\left(3y^2-6y\right)dy = \left(3x^2+1\right)dx \tag{2}$$

But the RHS is complete differential because

$$\left(3x^2+1\right)dx = d\left(x^3+x\right)$$

Hence (2) becomes

$$\left(3y^2-6y\right)dy = d\left(x^3+x\right)$$

Integrating both sides gives gives these solutions

$$y = \frac{\left(8+4x^3+4c_1+4x+4\sqrt{x^6+2c_1x^3+2x^4+4x^3+c_1^2+2c_1x+x^2+4c_1+4x}\right)^{\frac{1}{3}}}{2} + \frac{}{\left(8+4x^3+4c_1\right.}$$

$$y = -\frac{\left(8+4x^3+4c_1+4x+4\sqrt{x^6+2c_1x^3+2x^4+4x^3+c_1^2+2c_1x+x^2+4c_1+4x}\right)^{\frac{1}{3}}}{4} - \frac{}{\left(8+4x^3+4c\right.}$$

$$y = -\frac{\left(8+4x^3+4c_1+4x+4\sqrt{x^6+2c_1x^3+2x^4+4x^3+c_1^2+2c_1x+x^2+4c_1+4x}\right)^{\frac{1}{3}}}{4} - \frac{}{\left(8+4x^3+4c\right.}$$

Initial conditions are used to solve for c_1. Substituting $x=0$ and $y=1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{-i\sqrt{3}\left(8+4c_1+4\sqrt{c_1^2+4c_1}\right)^{\frac{2}{3}}+4i\sqrt{3}-\left(8+4c_1+4\sqrt{c_1^2+4c_1}\right)^{\frac{2}{3}}+4c_1\left(8+4c_1+4\sqrt{c_1^2+4c_1}\right)^{\frac{1}{3}}}{4\left(8+4c_1+4\sqrt{c_1^2+4c_1}\right)^{\frac{1}{3}}}$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x=0$ and $y=1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{i\sqrt{3}\left(8+4c_1+4\sqrt{c_1^2+4c_1}\right)^{\frac{2}{3}} - 4i\sqrt{3} - \left(8+4c_1+4\sqrt{c_1^2+4c_1}\right)^{\frac{2}{3}} + 4c_1\left(8+4c_1+4\sqrt{c_1^2+4c_1}\right)^{\frac{1}{3}} +}{4\left(8+4c_1+4\sqrt{c_1^2+4c_1}\right)^{\frac{1}{3}}}$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x=0$ and $y=1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{\left(8+4c_1+4\sqrt{c_1^2+4c_1}\right)^{\frac{2}{3}} + 2c_1\left(8+4c_1+4\sqrt{c_1^2+4c_1}\right)^{\frac{1}{3}} + 2\left(8+4c_1+4\sqrt{c_1^2+4c_1}\right)^{\frac{1}{3}} + 4}{2\left(8+4c_1+4\sqrt{c_1^2+4c_1}\right)^{\frac{1}{3}}}$$

Warning: Unable to solve for constant of integration.

Verification of solutions N/A

2.21.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= \frac{3x^2+1}{3y(y-2)} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 151: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= \frac{1}{x^2 + \frac{1}{3}} \\
\eta(x, y) &= 0
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{x^2+\frac{1}{3}}} dx \end{aligned}$$

Which results in

$$S = \frac{1}{3}x^3 + \frac{1}{3}x$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{3x^2+1}{3y(y-2)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= x^2 + \frac{1}{3} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = y(y-2) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R(R-2)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{1}{3}R^3 - R^2 + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{1}{3}x^3 + \frac{1}{3}x = \frac{y^3}{3} - y^2 + c_1$$

Which simplifies to

$$\frac{1}{3}x^3 + \frac{1}{3}x = \frac{y^3}{3} - y^2 + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{3x^2+1}{3y(y-2)}$ 	$R = y$ $S = \frac{1}{3}x^3 + \frac{1}{3}x$	$\frac{dS}{dR} = R(R-2)$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -\frac{2}{3} + c_1$$

$$c_1 = \frac{2}{3}$$

Substituting c_1 found above in the general solution gives

$$\frac{1}{3}x^3 + \frac{1}{3}x = \frac{1}{3}y^3 - y^2 + \frac{2}{3}$$

Summary

The solution(s) found are the following

$$\frac{1}{3}x^3 + \frac{1}{3}x = \frac{y^3}{3} - y^2 + \frac{2}{3} \tag{1}$$

Verification of solutions

$$\frac{1}{3}x^3 + \frac{1}{3}x = \frac{y^3}{3} - y^2 + \frac{2}{3}$$

Verified OK.

2.21.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(3y(y-2))\,\mathrm{d}y&=\left(3x^2+1\right)\mathrm{d}x\\ \left(-3x^2-1\right)\mathrm{d}x+(3y(y-2))\,\mathrm{d}y&=0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=-3x^2-1\\ N(x,y)&=3y(y-2)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}\left(-3x^2-1\right)\\ &=0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x}&=\frac{\partial}{\partial x}(3y(y-2))\\ &=0\end{aligned}$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x}=M \tag{1}$$

$$\frac{\partial\phi}{\partial y}=N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int M\,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int -3x^2 - 1\,\mathrm{d}x$$

$$\phi = -x^3 - x + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 3y(y-2)$. Therefore equation (4) becomes

$$3y(y-2) = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 3y(y-2)$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (3y(y-2))\,\mathrm{d}y$$

$$f(y) = y^3 - 3y^2 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -x^3 + y^3 - 3y^2 - x + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x^3 + y^3 - 3y^2 - x$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$-2 = c_1$$

$$c_1 = -2$$

Substituting c_1 found above in the general solution gives

$$-x^3 + y^3 - 3y^2 - x = -2$$

Summary

The solution(s) found are the following

$$-x^3 + y^3 - 3y^2 - x = -2 \tag{1}$$

Verification of solutions

$$-x^3 + y^3 - 3y^2 - x = -2$$

Verified OK.

2.21.6 Maple step by step solution

Let's solve

$\left[y' - \frac{3x^2+1}{-6y+3y^2} = 0, y(0) = 1\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $y'(-6y + 3y^2) = 3x^2 + 1$

- Integrate both sides with respect to x

  $\int y'(-6y + 3y^2)\, dx = \int (3x^2 + 1)\, dx + c_1$

- Evaluate integral

  $y^3 - 3y^2 = x^3 + c_1 + x$

- Solve for y

  $y = \frac{\left(8+4x^3+4c_1+4x+4\sqrt{x^6+2c_1x^3+2x^4+4x^3+c_1^2+2c_1x+x^2+4c_1+4x}\right)^{\frac{1}{3}}}{2} + \frac{2}{\left(8+4x^3+4c_1+4x+4\sqrt{x^6+2c_1x^3+2x^4+4x^3+c_1^2+2c}\right.}$

- Use initial condition $y(0) = 1$

$$1 = \frac{\left(8+4c_1+4\sqrt{c_1^2+4c_1}\right)^{\frac{1}{3}}}{2} + \frac{2}{\left(8+4c_1+4\sqrt{c_1^2+4c_1}\right)^{\frac{1}{3}}} + 1$$

- Solve for c_1

$$c_1 = RootOf\left(\left(8+4\_Z+4\sqrt{\_Z^2+4\_Z}\right)^{\frac{2}{3}}+4\right)$$

- Substitute $c_1 = RootOf\left(\left(8+4\_Z+4\sqrt{\_Z^2+4\_Z}\right)^{\frac{2}{3}}+4\right)$ into general solution and simplify

$$y = \frac{\left(8+4x^3+4RootOf\left(\left(8+4\_Z+4\sqrt{\_Z(\_Z+4)}\right)^{\frac{2}{3}}+4\right)+4x+4\sqrt{\left(x^3+x+RootOf\left(\left(8+4\_Z+4\sqrt{\_Z(\_Z+4)}\right)^{\frac{2}{3}}+4\right)+\cdots\right.}\right.}{2\left(8+4x^3+4RootOf\left(\left(8+4\cdots\right.\right.\right.}$$

- Solution to the IVP

$$y = \frac{\left(8+4x^3+4RootOf\left(\left(8+4\_Z+4\sqrt{\_Z(\_Z+4)}\right)^{\frac{2}{3}}+4\right)+4x+4\sqrt{\left(x^3+x+RootOf\left(\left(8+4\_Z+4\sqrt{\_Z(\_Z+4)}\right)^{\frac{2}{3}}+4\right)+\cdots\right.}\right.}{2\left(8+4x^3+4RootOf\left(\left(8+4\cdots\right.\right.\right.}$$

The type(s) of ODE detected by this program : **"exact", "separable", "differential-Type", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{3x^2}{-4 + 3y^2} = 0}$$

With initial conditions

$$[y(1) = 0]$$

2.22.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= f(x)g(y) \\ &= \frac{3x^2}{3y^2 - 4} \end{aligned}$$

Where $f(x) = 3x^2$ and $g(y) = \frac{1}{3y^2-4}$. Integrating both sides gives

$$\frac{1}{\frac{1}{3y^2-4}}\,dy = 3x^2\,dx$$

$$\int \frac{1}{\frac{1}{3y^2-4}}\,dy = \int 3x^2\,dx$$

$$y^3 - 4y = x^3 + c_1$$

Which results in

$$y = \frac{\left(108x^3 + 108c_1 + 12\sqrt{81x^6 + 162c_1x^3 + 81c_1^2 - 768}\right)^{\frac{1}{3}}}{6} + \frac{8}{\left(108x^3 + 108c_1 + 12\sqrt{81x^6 + 162c_1x^3 + 81c_1^2 - 768}\right)^{\frac{1}{3}}}$$

$$y = -\frac{\left(108x^3 + 108c_1 + 12\sqrt{81x^6 + 162c_1x^3 + 81c_1^2 - 768}\right)^{\frac{1}{3}}}{12} - \frac{4}{\left(108x^3 + 108c_1 + 12\sqrt{81x^6 + 162c_1x^3 + 81c_1^2 - 768}\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(\frac{\left(108x^3+108c_1+12\sqrt{81x^6+162c_1x^3+81c_1^2-768}\right)^{\frac{1}{3}}}{6} - \frac{8}{\left(108x^3+108c_1+12\sqrt{81x^6+162c_1x^3+81c_1^2-768}\right)^{\frac{1}{3}}}\right)}{2}$$

$$y = -\frac{\left(108x^3 + 108c_1 + 12\sqrt{81x^6 + 162c_1x^3 + 81c_1^2 - 768}\right)^{\frac{1}{3}}}{12} - \frac{4}{\left(108x^3 + 108c_1 + 12\sqrt{81x^6 + 162c_1x^3 + 81c_1^2 - 768}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(\frac{\left(108x^3+108c_1+12\sqrt{81x^6+162c_1x^3+81c_1^2-768}\right)^{\frac{1}{3}}}{6} - \frac{8}{\left(108x^3+108c_1+12\sqrt{81x^6+162c_1x^3+81c_1^2-768}\right)^{\frac{1}{3}}}\right)}{2}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{-i\sqrt{3}\left(108+108c_1+12\sqrt{81c_1^2+162c_1-687}\right)^{\frac{2}{3}}+48i\sqrt{3}-\left(108+108c_1+12\sqrt{81c_1^2+162c_1-687\right.}}{12\left(108+108c_1+12\sqrt{81c_1^2+162c_1-687}\right)^{\frac{1}{3}}}$$

$$c_1 = -1$$

Substituting c_1 found above in the general solution gives

$$y = \frac{-i\sqrt{3}\left(108x^3-108+12\sqrt{81x^6-162x^3-687}\right)^{\frac{2}{3}}-\left(108x^3-108+12\sqrt{81x^6-162x^3-687}\right)^{\frac{2}{3}}+48i}{12\left(108x^3-108+12\sqrt{81x^6-162x^3-687}\right)^{\frac{1}{3}}}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{i\sqrt{3}\left(108+108c_1+12\sqrt{81c_1^2+162c_1-687}\right)^{\frac{2}{3}}-48i\sqrt{3}-\left(108+108c_1+12\sqrt{81c_1^2+162c_1-687}\right)}{12\left(108+108c_1+12\sqrt{81c_1^2+162c_1-687}\right)^{\frac{1}{3}}}$$

Unable to solve for constant of integration. Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{48+\left(108+108c_1+12\sqrt{81c_1^2+162c_1-687}\right)^{\frac{2}{3}}}{6\left(108+108c_1+12\sqrt{81c_1^2+162c_1-687}\right)^{\frac{1}{3}}}$$

Summary

The solution(s) found are the following

Warning: Unable to solve for constant of integration.

$$y = \frac{-i\sqrt{3}\left(108x^3-108+12\sqrt{81x^6-162x^3-687}\right)^{\frac{2}{3}} -}{12\left(108x^3-108+\right.}$$

Verification of solutions

$$y = \frac{-i\sqrt{3}\left(108x^3-108+12\sqrt{81x^6-162x^3-687}\right)^{\frac{2}{3}}-\left(108x^3-108+12\sqrt{81x^6-162x^3-687}\right)^{\frac{2}{3}}+48i\sqrt{}}{12\left(108x^3-108+12\sqrt{81x^6-162x^3-687}\right)^{\frac{1}{3}}}$$

Verified OK.

2.22.2 Solving as differentialType ode

Writing the ode as

$$y' = \frac{3x^2}{-4 + 3y^2} \tag{1}$$

Which becomes

$$(3y^2 - 4)\, dy = (3x^2)\, dx \tag{2}$$

But the RHS is complete differential because

$$(3x^2)\, dx = d(x^3)$$

Hence (2) becomes

$$(3y^2 - 4)\, dy = d(x^3)$$

Integrating both sides gives gives these solutions

$$y = \frac{\left(108x^3 + 108c_1 + 12\sqrt{81x^6 + 162c_1x^3 + 81c_1^2 - 768}\right)^{\frac{1}{3}}}{6} + \frac{8}{\left(108x^3 + 108c_1 + 12\sqrt{81x^6 + 162c_1x^3 + 8\cdots}\right.}$$

$$y = -\frac{\left(108x^3 + 108c_1 + 12\sqrt{81x^6 + 162c_1x^3 + 81c_1^2 - 768}\right)^{\frac{1}{3}}}{12} - \frac{4}{\left(108x^3 + 108c_1 + 12\sqrt{81x^6 + 162c_1x^3 + \cdots}\right.}$$

$$y = -\frac{\left(108x^3 + 108c_1 + 12\sqrt{81x^6 + 162c_1x^3 + 81c_1^2 - 768}\right)^{\frac{1}{3}}}{12} - \frac{4}{\left(108x^3 + 108c_1 + 12\sqrt{81x^6 + 162c_1x^3 + \cdots}\right.}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{-i\sqrt{3}\left(108 + 108c_1 + 12\sqrt{81c_1^2 + 162c_1 - 687}\right)^{\frac{2}{3}} + 48i\sqrt{3} - \left(108 + 108c_1 + 12\sqrt{81c_1^2 + 162c_1 - 687\cdots}\right.}{12\left(108 + 108c_1 + 12\sqrt{81c_1^2 + 162c_1 - 687}\right)\cdots}$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$
0 = \frac{i\sqrt{3}\left(108 + 108c_1 + 12\sqrt{81c_1^2 + 162c_1 - 687}\right)^{\frac{2}{3}} - 48i\sqrt{3} - \left(108 + 108c_1 + 12\sqrt{81c_1^2 + 162c_1 - 687}\right)}{12\left(108 + 108c_1 + 12\sqrt{81c_1^2 + 162c_1 - 687}\right)^{\frac{1}{3}}}
$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$
0 = \frac{\left(108 + 108c_1 + 12\sqrt{81c_1^2 + 162c_1 - 687}\right)^{\frac{2}{3}} + 6c_1\left(108 + 108c_1 + 12\sqrt{81c_1^2 + 162c_1 - 687}\right)^{\frac{1}{3}} + 48}{6\left(108 + 108c_1 + 12\sqrt{81c_1^2 + 162c_1 - 687}\right)^{\frac{1}{3}}}
$$

Warning: Unable to solve for constant of integration.

Verification of solutions N/A

2.22.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{3x^2}{3y^2 - 4} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 154: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= \frac{1}{3x^2} \\
\eta(x,y) &= 0 \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \qquad (1)
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{3x^2}} dx \end{aligned}$$

Which results in

$$S = x^3$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{3x^2}{3y^2 - 4}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= 3x^2 \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 3y^2 - 4 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 3R^2 - 4$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = R^3 - 4R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$x^3 = y^3 + c_1 - 4y$$

Which simplifies to

$$x^3 = y^3 + c_1 - 4y$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{3x^2}{3y^2-4}$ 	$R = y$ $S = x^3$	$\frac{dS}{dR} = 3R^2 - 4$ 
Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_1$$

$$c_1 = 1$$

Substituting c_1 found above in the general solution gives

$$x^3 = y^3 - 4y + 1$$

Summary

The solution(s) found are the following

$$x^3 = y^3 - 4y + 1 \tag{1}$$

Verification of solutions

$$x^3 = y^3 - 4y + 1$$

Verified OK.

2.22.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work

and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(y^2 - \frac{4}{3}\right)\mathrm{d}y &= \left(x^2\right)\mathrm{d}x\\ \left(-x^2\right)\mathrm{d}x + \left(y^2 - \frac{4}{3}\right)\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x,y) &= -x^2\\ N(x,y) &= y^2 - \frac{4}{3} \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-x^2\right)\\ &= 0 \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(y^2 - \frac{4}{3}\right)\\ &= 0 \end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int M \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int -x^2 \mathrm{d}x \\
\phi &= -\frac{x^3}{3} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \qquad (4)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y^2 - \frac{4}{3}$. Therefore equation (4) becomes

$$
y^2 - \frac{4}{3} = 0 + f'(y) \qquad (5)
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = y^2 - \frac{4}{3}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \mathrm{d}y &= \int \left(y^2 - \frac{4}{3}\right) \mathrm{d}y \\
f(y) &= \frac{1}{3}y^3 - \frac{4}{3}y + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$
\phi = -\frac{1}{3}x^3 + \frac{1}{3}y^3 - \frac{4}{3}y + c_1
$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$
c_1 = -\frac{1}{3}x^3 + \frac{1}{3}y^3 - \frac{4}{3}y
$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{1}{3} = c_1$$

$$c_1 = -\frac{1}{3}$$

Substituting c_1 found above in the general solution gives

$$-\frac{1}{3}x^3 + \frac{1}{3}y^3 - \frac{4}{3}y = -\frac{1}{3}$$

Summary

The solution(s) found are the following

$$-\frac{x^3}{3} + \frac{y^3}{3} - \frac{4y}{3} = -\frac{1}{3} \tag{1}$$

Verification of solutions

$$-\frac{x^3}{3} + \frac{y^3}{3} - \frac{4y}{3} = -\frac{1}{3}$$

Verified OK.

2.22.5 Maple step by step solution

Let's solve

$\left[y' - \frac{3x^2}{-4+3y^2} = 0, y(1) = 0\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $y'(-4 + 3y^2) = 3x^2$

- Integrate both sides with respect to x

  $\int y'(-4 + 3y^2)\, dx = \int 3x^2 dx + c_1$

- Evaluate integral

  $y^3 - 4y = x^3 + c_1$

- Solve for y

$$y=\frac{\left(108x^3+108c_1+12\sqrt{81x^6+162c_1x^3+81c_1^2-768}\right)^{\frac{1}{3}}}{6}+\frac{8}{\left(108x^3+108c_1+12\sqrt{81x^6+162c_1x^3+81c_1^2-768}\right)^{\frac{1}{3}}}$$

- Use initial condition $y(1)=0$

$$0=\frac{\left(108+108c_1+12\sqrt{81c_1^2+162c_1-687}\right)^{\frac{1}{3}}}{6}+\frac{8}{\left(108+108c_1+12\sqrt{81c_1^2+162c_1-687}\right)^{\frac{1}{3}}}$$

- Solution does not satisfy initial condition

The type(s) of ODE detected by this program : **"exact", "riccati", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - 2y^2 - xy^2 = 0}$$

With initial conditions

$$[y(0) = 1]$$

2.23.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= x\,y^2 + 2y^2 \end{aligned}$$

The x domain of $f(x, y)$ when $y = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x, y)$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 1$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(x\, y^2 + 2y^2\right) \\ &= 2yx + 4y\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 1$ is inside this domain. Therefore solution exists and is unique.

2.23.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x, y) \\ &= f(x)g(y) \\ &= y^2(2 + x)\end{aligned}$$

Where $f(x) = 2 + x$ and $g(y) = y^2$. Integrating both sides gives

$$\begin{aligned}\frac{1}{y^2}\, dy &= 2 + x\, dx \\ \int \frac{1}{y^2}\, dy &= \int 2 + x\, dx \\ -\frac{1}{y} &= 2x + \frac{1}{2}x^2 + c_1\end{aligned}$$

Which results in

$$y = -\frac{2}{x^2 + 2c_1 + 4x}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{1}{c_1}$$

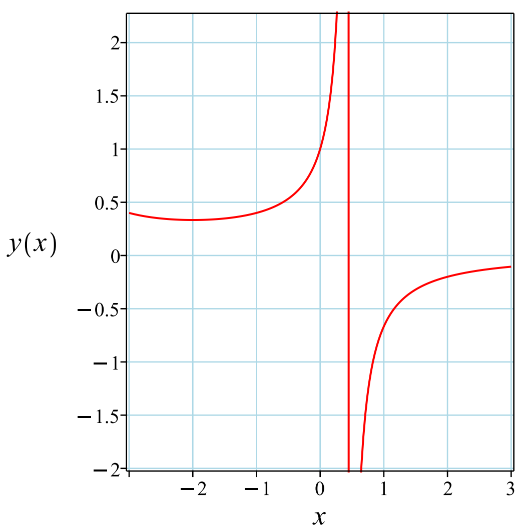
$$c_1 = -1$$

Substituting c_1 found above in the general solution gives

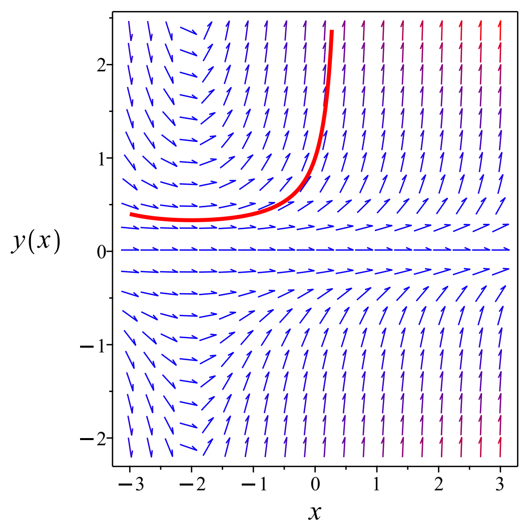
$$y = -\frac{2}{x^2 + 4x - 2}$$

Summary
The solution(s) found are the following

$$y = -\frac{2}{x^2 + 4x - 2} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -\frac{2}{x^2 + 4x - 2}$$

Verified OK.

2.23.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = x\,y^2 + 2y^2$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 157: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int(n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,y) &= \frac{1}{2+x} \\ \eta(x,y) &= 0\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{2+x}} dx\end{aligned}$$

Which results in

$$S = 2x + \frac{1}{2}x^2$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = x\,y^2 + 2y^2$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= 0 \\ R_y &= 1 \\ S_x &= 2+x \\ S_y &= 0\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{y^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{1}{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$2x + \frac{1}{2}x^2 = -\frac{1}{y} + c_1$$

Which simplifies to

$$2x + \frac{1}{2}x^2 = -\frac{1}{y} + c_1$$

Which gives

$$y = \frac{2}{-x^2 + 2c_1 - 4x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = x\,y^2 + 2y^2$ 	$R = y$ $S = 2x + \frac{1}{2}x^2$	$\frac{dS}{dR} = \frac{1}{R^2}$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{1}{c_1}$$

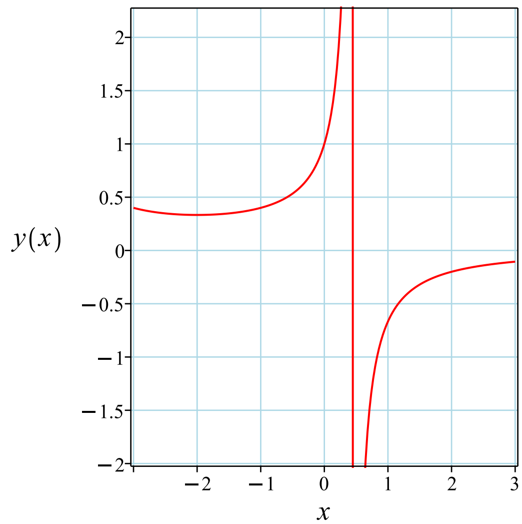
$$c_1 = 1$$

Substituting c_1 found above in the general solution gives

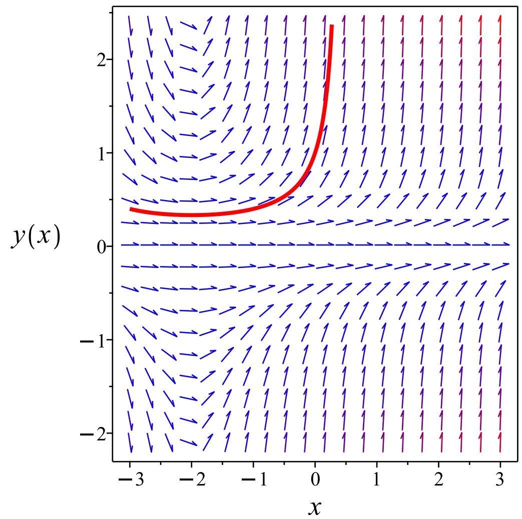
$$y = -\frac{2}{x^2 + 4x - 2}$$

<u>Summary</u>
The solution(s) found are the following

$$y = -\frac{2}{x^2 + 4x - 2} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -\frac{2}{x^2 + 4x - 2}$$

Verified OK.

2.23.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{y^2}\right) \mathrm{d}y = (2 + x)\, \mathrm{d}x$$
$$(-x - 2)\, \mathrm{d}x + \left(\frac{1}{y^2}\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -x - 2$$
$$N(x, y) = \frac{1}{y^2}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}(-x - 2)$$
$$= 0$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}\left(\frac{1}{y^2}\right)$$
$$= 0$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \qquad (1)\\
\frac{\partial \phi}{\partial y} &= N \qquad (2)
\end{aligned}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int M \,\mathrm{d}x\\
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int -x-2 \,\mathrm{d}x\\
\phi &= -\frac{1}{2}x^2-2x+f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0+f'(y) \qquad (4)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y}=\frac{1}{y^2}$. Therefore equation (4) becomes

$$
\frac{1}{y^2} = 0+f'(y) \qquad (5)
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{y^2}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \,\mathrm{d}y &= \int \left(\frac{1}{y^2}\right) \mathrm{d}y\\
f(y) &= -\frac{1}{y}+c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x^2}{2} - 2x - \frac{1}{y} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x^2}{2} - 2x - \frac{1}{y}$$

The solution becomes

$$y = -\frac{2}{x^2 + 2c_1 + 4x}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{1}{c_1}$$

$$c_1 = -1$$

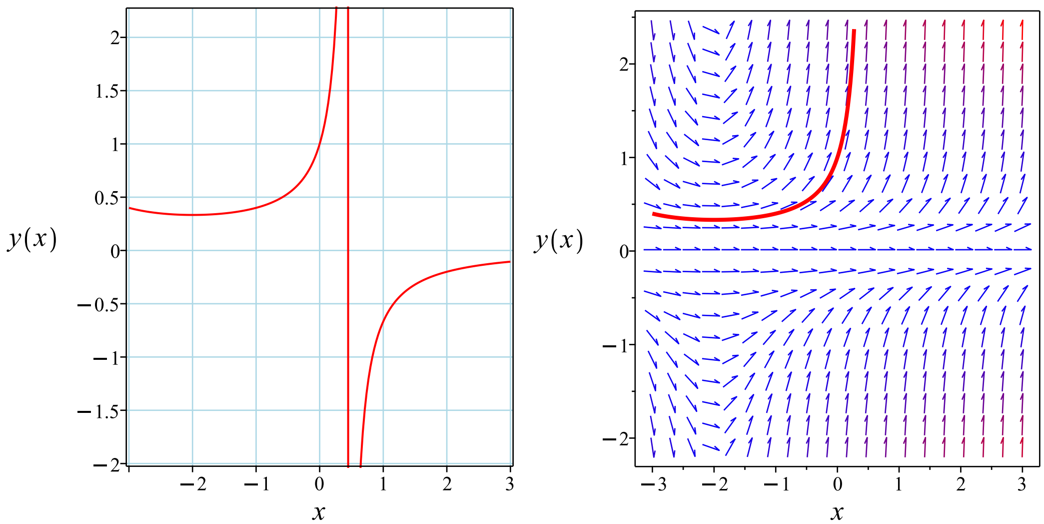
Substituting c_1 found above in the general solution gives

$$y = -\frac{2}{x^2 + 4x - 2}$$

Summary

The solution(s) found are the following

$$y = -\frac{2}{x^2 + 4x - 2} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = -\frac{2}{x^2 + 4x - 2}$$

Verified OK.

2.23.5 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= x\,y^2 + 2y^2 \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = x\,y^2 + 2y^2$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 0$, $f_1(x) = 0$ and $f_2(x) = 2 + x$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{(2 + x)\,u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 1 \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= 0 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$(2 + x)\, u''(x) - u'(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = c_1 + c_2(2 + x)^2$$

The above shows that

$$u'(x) = 2(2 + x)\, c_2$$

Using the above in (1) gives the solution

$$y = -\frac{2c_2}{c_1 + c_2\,(2 + x)^2}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{2}{x^2 + c_3 + 4x + 4}$$

Initial conditions are used to solve for c_3. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{2}{c_3 + 4}$$

$$c_3 = -6$$

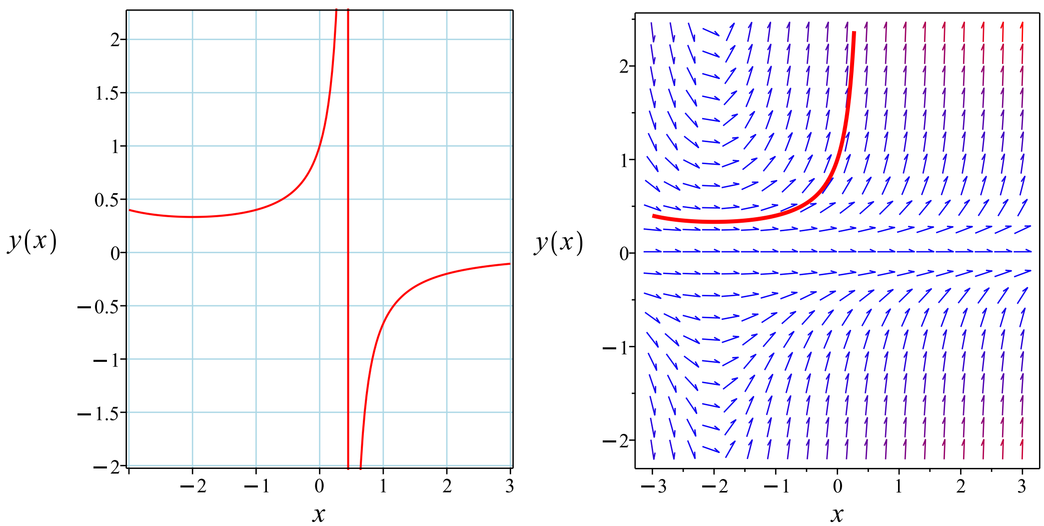
Substituting c_3 found above in the general solution gives

$$y = -\frac{2}{x^2 + 4x - 2}$$

Summary

The solution(s) found are the following

$$y = -\frac{2}{x^2 + 4x - 2} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = -\frac{2}{x^2 + 4x - 2}$$

Verified OK.

2.23.6 Maple step by step solution

Let's solve

$[y' - 2y^2 - xy^2 = 0, y(0) = 1]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

$\frac{y'}{y^2} = 2 + x$

- Integrate both sides with respect to x

  $\int \frac{y'}{y^2} dx = \int (2 + x)\, dx + c_1$

- Evaluate integral

  $-\frac{1}{y} = 2x + \frac{1}{2}x^2 + c_1$

- Solve for y

  $y = -\frac{2}{x^2 + 2c_1 + 4x}$

- Use initial condition $y(0) = 1$

  $1 = -\frac{1}{c_1}$

- Solve for c_1

  $c_1 = -1$

- Substitute $c_1 = -1$ into general solution and simplify

  $y = -\frac{2}{x^2 + 4x - 2}$

- Solution to the IVP

  $y = -\frac{2}{x^2 + 4x - 2}$

ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{2 - e^{x}}{3 + 2y} = 0}$$

With initial conditions

$$[y(0) = 0]$$

2.24.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= -\frac{-2 + e^{x}}{3 + 2y} \end{aligned}$$

The x domain of $f(x, y)$ when $y = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x,y)$ when $x = 0$ is

$$\left\{y < -\frac{3}{2} \vee -\frac{3}{2} < y\right\}$$

And the point $y_0 = 0$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{-2 + e^{x}}{3 + 2y}\right) \\ &= \frac{-4 + 2\,e^{x}}{(3 + 2y)^{2}}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 0$ is

$$\left\{y < -\frac{3}{2} \vee -\frac{3}{2} < y\right\}$$

And the point $y_0 = 0$ is inside this domain. Therefore solution exists and is unique.

2.24.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{2 - e^{x}}{3 + 2y}\end{aligned}$$

Where $f(x) = 2 - e^{x}$ and $g(y) = \frac{1}{3+2y}$. Integrating both sides gives

$$\begin{aligned}\frac{1}{\frac{1}{3+2y}}\,dy &= 2 - e^{x}\,dx \\ \int \frac{1}{\frac{1}{3+2y}}\,dy &= \int 2 - e^{x}\,dx \\ y^{2} + 3y &= 2x - e^{x} + c_1\end{aligned}$$

Which results in

$$y = -\frac{3}{2}+\frac{\sqrt{9-4\,\mathrm{e}^{x}+4c_1+8x}}{2}$$
$$y = -\frac{3}{2}-\frac{\sqrt{9-4\,\mathrm{e}^{x}+4c_1+8x}}{2}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -\frac{3}{2}-\frac{\sqrt{5+4c_1}}{2}$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -\frac{3}{2}+\frac{\sqrt{5+4c_1}}{2}$$

$$c_1 = 1$$

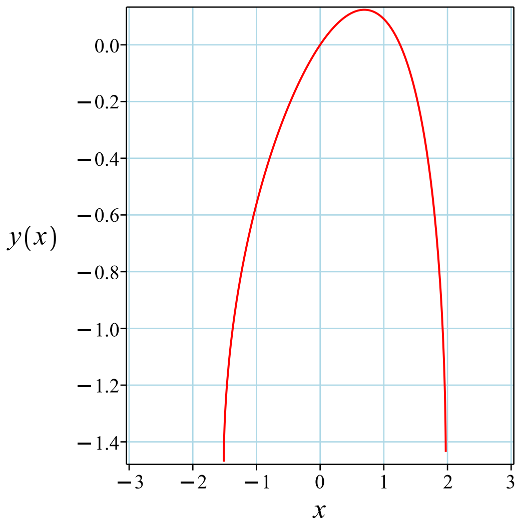
Substituting c_1 found above in the general solution gives

$$y = -\frac{3}{2}+\frac{\sqrt{13-4\,\mathrm{e}^{x}+8x}}{2}$$

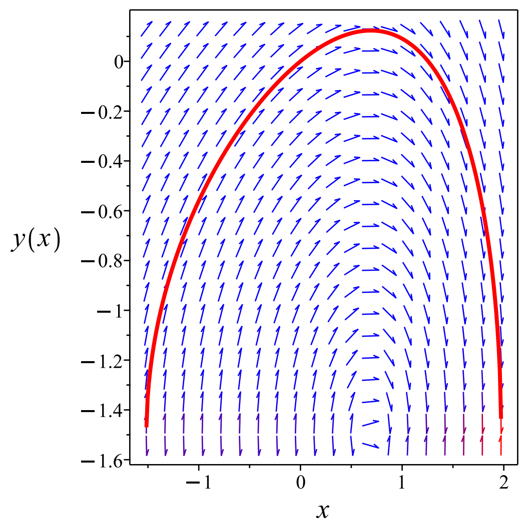
Summary

The solution(s) found are the following

$$y = -\frac{3}{2}+\frac{\sqrt{13-4\,\mathrm{e}^{x}+8x}}{2} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -\frac{3}{2} + \frac{\sqrt{13 - 4\,e^{x} + 8x}}{2}$$

Verified OK.

2.24.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{-2 + e^{x}}{3 + 2y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 160: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= \frac{1}{2 - \mathrm{e}^x} \\
\eta(x, y) &= 0
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{2-e^x}} dx \end{aligned}$$

Which results in

$$S = 2x - e^x$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{-2 + e^x}{3 + 2y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= 2 - e^x \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 3 + 2y \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 3 + 2R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = R^2 + 3R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$2x - e^x = y^2 + c_1 + 3y$$

Which simplifies to

$$2x - e^x = y^2 + c_1 + 3y$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{-2+e^x}{3+2y}$ 	$R = y$ $S = 2x - e^x$	$\frac{dS}{dR} = 3 + 2R$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = c_1$$

$$c_1 = -1$$

Substituting c_1 found above in the general solution gives

$$2x - e^x = y^2 + 3y - 1$$

Summary

The solution(s) found are the following

$$2x - e^x = y^2 + 3y - 1 \tag{1}$$

Verification of solutions

$$2x - e^x = y^2 + 3y - 1$$

Verified OK.

2.24.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work

and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(-3-2y)\,\mathrm{d}y &= (-2+\mathrm{e}^{x})\,\mathrm{d}x\\ (2-\mathrm{e}^{x})\,\mathrm{d}x + (-3-2y)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= 2-\mathrm{e}^{x}\\ N(x,y) &= -3-2y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(2-\mathrm{e}^{x})\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-3-2y)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int 2-\mathrm{e}^{x}\,\mathrm{d}x\\ \phi &= 2x-\mathrm{e}^{x}+f(y)\end{aligned} \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -3 - 2y$. Therefore equation (4) becomes

$$-3 - 2y = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -3 - 2y$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (-3 - 2y)\,\mathrm{d}y$$

$$f(y) = -y^2 - 3y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -y^2 - \mathrm{e}^x + 2x - 3y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -y^2 - \mathrm{e}^x + 2x - 3y$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = c_1$$

$$c_1 = -1$$

Substituting c_1 found above in the general solution gives

$$-y^2 - \mathrm{e}^x + 2x - 3y = -1$$

Summary

The solution(s) found are the following

$$-y^2 - e^x + 2x - 3y = -1 \tag{1}$$

Verification of solutions

$$-y^2 - e^x + 2x - 3y = -1$$

Verified OK.

2.24.5 Maple step by step solution

Let's solve

ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{2\cos(2x)}{3+2y} = 0}$$

With initial conditions

$$[y(0) = -1]$$

2.25.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= \frac{2\cos(2x)}{3+2y} \end{aligned}$$

The x domain of $f(x,y)$ when $y=-1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x, y)$ when $x = 0$ is

$$\left\{y < -\frac{3}{2} \vee -\frac{3}{2} < y\right\}$$

And the point $y_0 = -1$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{2\cos(2x)}{3+2y}\right)\\ &= -\frac{4\cos(2x)}{(3+2y)^2}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = -1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 0$ is

$$\left\{y < -\frac{3}{2} \vee -\frac{3}{2} < y\right\}$$

And the point $y_0 = -1$ is inside this domain. Therefore solution exists and is unique.

2.25.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x, y)\\ &= f(x)g(y)\\ &= \frac{2\cos(2x)}{3+2y}\end{aligned}$$

Where $f(x) = 2\cos(2x)$ and $g(y) = \frac{1}{3+2y}$. Integrating both sides gives

$$\begin{aligned}\frac{1}{\frac{1}{3+2y}}\,dy &= 2\cos(2x)\,dx\\ \int \frac{1}{\frac{1}{3+2y}}\,dy &= \int 2\cos(2x)\,dx\\ y^2 + 3y &= \sin(2x) + c_1\end{aligned}$$

Which results in

$$y = -\frac{3}{2}+\frac{\sqrt{9+4\sin\left(2x\right)+4c_1}}{2}$$
$$y = -\frac{3}{2}-\frac{\sqrt{9+4\sin\left(2x\right)+4c_1}}{2}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = -\frac{3}{2}-\frac{\sqrt{9+4c_1}}{2}$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = -\frac{3}{2}+\frac{\sqrt{9+4c_1}}{2}$$

$$c_1 = -2$$

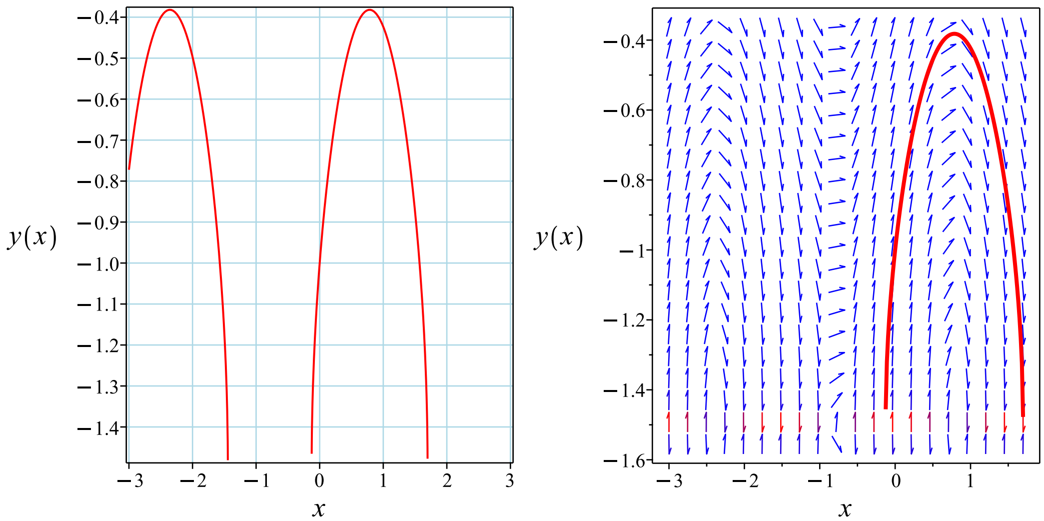
Substituting c_1 found above in the general solution gives

$$y = -\frac{3}{2}+\frac{\sqrt{1+4\sin\left(2x\right)}}{2}$$

Summary

The solution(s) found are the following

$$y = -\frac{3}{2}+\frac{\sqrt{1+4\sin\left(2x\right)}}{2} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = -\frac{3}{2} + \frac{\sqrt{1 + 4\sin(2x)}}{2}$$

Verified OK.

2.25.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{2\cos(2x)}{3 + 2y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 163: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= \frac{1}{2\cos(2x)} \\
\eta(x, y) &= 0
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{2\cos(2x)}} dx \end{aligned}$$

Which results in

$$S = \sin(2x)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{2\cos(2x)}{3+2y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= 2\cos(2x) \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 3 + 2y \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 3 + 2R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = R^2 + 3R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\sin(2x) = y^2 + c_1 + 3y$$

Which simplifies to

$$\sin(2x) = y^2 + c_1 + 3y$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{2\cos(2x)}{3+2y}$ 	$R = y$ $S = \sin(2x)$	$\frac{dS}{dR} = 3 + 2R$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1 - 2$$

$$c_1 = 2$$

Substituting c_1 found above in the general solution gives

$$\sin(2x) = y^2 + 3y + 2$$

Summary
The solution(s) found are the following

$$\sin(2x) = y^2 + 3y + 2 \tag{1}$$

Verification of solutions

$$\sin(2x) = y^2 + 3y + 2$$

Verified OK.

2.25.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work

and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\frac{3}{2}+y\right)\mathrm{d}y &= (\cos(2x))\,\mathrm{d}x\\(-\cos(2x))\,\mathrm{d}x + \left(\frac{3}{2}+y\right)\mathrm{d}y &= 0\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -\cos(2x)\\N(x,y) &= \frac{3}{2}+y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-\cos(2x))\\&= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{3}{2}+y\right)\\&= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int M \,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int -\cos(2x) \,\mathrm{d}x$$

$$\phi = -\frac{\sin(2x)}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{3}{2} + y$. Therefore equation (4) becomes

$$\frac{3}{2} + y = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{3}{2} + y$$

Integrating the above w.r.t y gives

$$\int f'(y) \,\mathrm{d}y = \int \left(\frac{3}{2} + y\right) \mathrm{d}y$$

$$f(y) = \frac{3}{2}y + \frac{1}{2}y^2 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\sin(2x)}{2} + \frac{3y}{2} + \frac{y^2}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\sin(2x)}{2} + \frac{3y}{2} + \frac{y^2}{2}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = c_1$$

$$c_1 = -1$$

Substituting c_1 found above in the general solution gives

$$-\frac{\sin(2x)}{2} + \frac{3y}{2} + \frac{y^2}{2} = -1$$

Summary

The solution(s) found are the following

$$-\frac{\sin(2x)}{2} + \frac{3y}{2} + \frac{y^2}{2} = -1 \tag{1}$$

Verification of solutions

$$-\frac{\sin(2x)}{2} + \frac{3y}{2} + \frac{y^2}{2} = -1$$

Verified OK.

2.25.5 Maple step by step solution

Let's solve

$\left[y' - \frac{2\cos(2x)}{3+2y} = 0, y(0) = -1\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $(3 + 2y)\, y' = 2\cos(2x)$

- Integrate both sides with respect to x

  $\int (3 + 2y)\, y' dx = \int 2\cos(2x)\, dx + c_1$

- Evaluate integral

  $y^2 + 3y = \sin(2x) + c_1$

- Solve for y

$$\left\{y = -\frac{3}{2} - \frac{\sqrt{9+4\sin(2x)+4c_1}}{2}, y = -\frac{3}{2} + \frac{\sqrt{9+4\sin(2x)+4c_1}}{2}\right\}$$

- Use initial condition $y(0) = -1$

  $-1 = -\frac{3}{2} - \frac{\sqrt{9+4c_1}}{2}$

- Solution does not satisfy initial condition
- Use initial condition $y(0) = -1$

  $-1 = -\frac{3}{2} + \frac{\sqrt{9+4c_1}}{2}$

- Solve for c_1

  $c_1 = -2$

- Substitute $c_1 = -2$ into general solution and simplify

  $y = -\frac{3}{2} + \frac{\sqrt{1+4\sin(2x)}}{2}$

- Solution to the IVP

  $y = -\frac{3}{2} + \frac{\sqrt{1+4\sin(2x)}}{2}$

The type(s) of ODE detected by this program : **"exact", "riccati", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - 2(x+1)\left(1+y^2\right) = 0}$$

With initial conditions

$$[y(0) = 0]$$

2.26.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= 2(x+1)\left(y^2+1\right) \end{aligned}$$

The x domain of $f(x,y)$ when $y=0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x, y)$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 0$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(2(x+1)\left(y^2+1\right)\right)\\ &= 4(x+1)\,y\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 0$ is inside this domain. Therefore solution exists and is unique.

2.26.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x, y)\\ &= f(x)g(y)\\ &= (x+1)\left(2y^2+2\right)\end{aligned}$$

Where $f(x) = x + 1$ and $g(y) = 2y^2 + 2$. Integrating both sides gives

$$\begin{aligned}\frac{1}{2y^2+2}\,dy &= x+1\,dx\\ \int \frac{1}{2y^2+2}\,dy &= \int x+1\,dx\\ \frac{\arctan(y)}{2} &= \frac{1}{2}x^2 + x + c_1\end{aligned}$$

Which results in

$$y = \tan\left(x^2 + 2c_1 + 2x\right)$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \tan(2c_1)$$

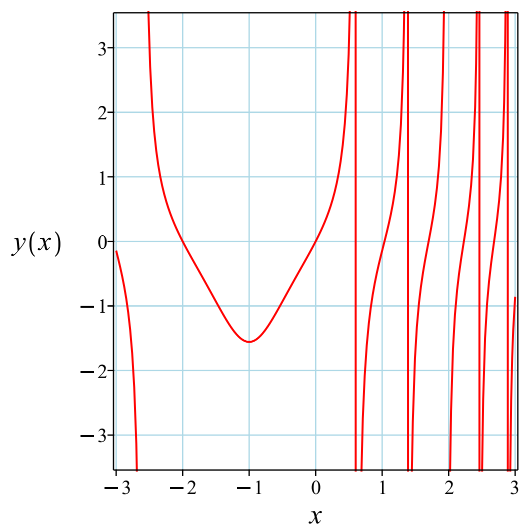
$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

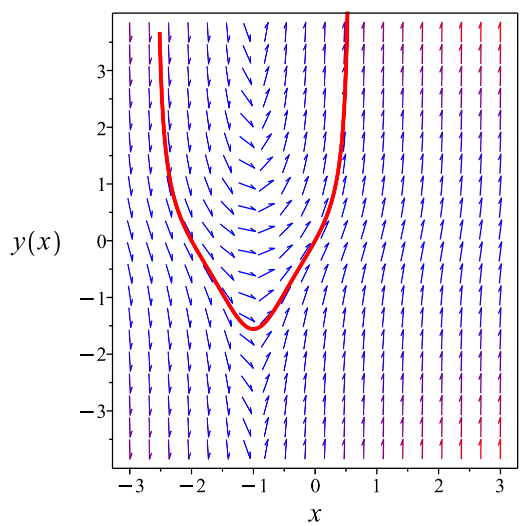
$$y = \tan(x^2 + 2x)$$

<u>Summary</u>
The solution(s) found are the following

$$y = \tan(x^2 + 2x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = \tan(x^2 + 2x)$$

Verified OK.

2.26.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= 2(x+1)\left(y^2+1\right) \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 166: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x) dx - h(x)}}{g(x)}$	$\frac{f(x) e^{-\int b f(x) dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\xi(x, y) = \frac{1}{x+1}$$
$$\eta(x, y) = 0 \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$S = \int \frac{1}{\xi} dx$$
$$= \int \frac{1}{\frac{1}{x+1}} dx$$

Which results in

$$S = \frac{1}{2}x^2 + x$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = 2(x + 1)\left(y^2 + 1\right)$$

Evaluating all the partial derivatives gives

$$R_x = 0$$
$$R_y = 1$$
$$S_x = x + 1$$
$$S_y = 0$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{2y^2 + 2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{2R^2 + 2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{\arctan(R)}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{1}{2}x^2 + x = \frac{\arctan(y)}{2} + c_1$$

Which simplifies to

$$\frac{1}{2}x^2 + x = \frac{\arctan(y)}{2} + c_1$$

Which gives

$$y = -\tan\left(-x^2 + 2c_1 - 2x\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = 2(x+1)(y^2+1)$ 	$R = y$ $S = \frac{1}{2}x^2 + x$	$\frac{dS}{dR} = \frac{1}{2R^2+2}$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -\tan(2c_1)$$

$$c_1 = 0$$

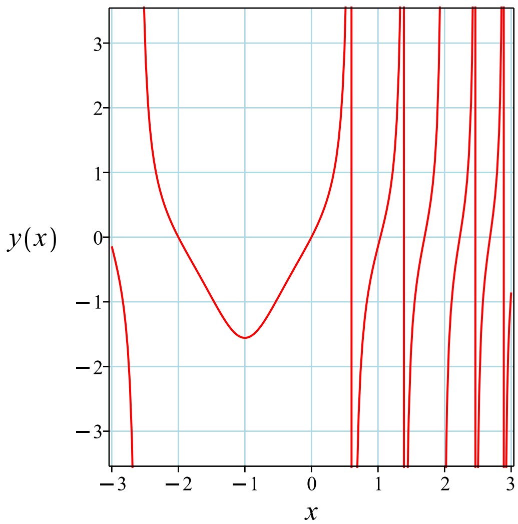
Substituting c_1 found above in the general solution gives

$$y = \tan(x^2 + 2x)$$

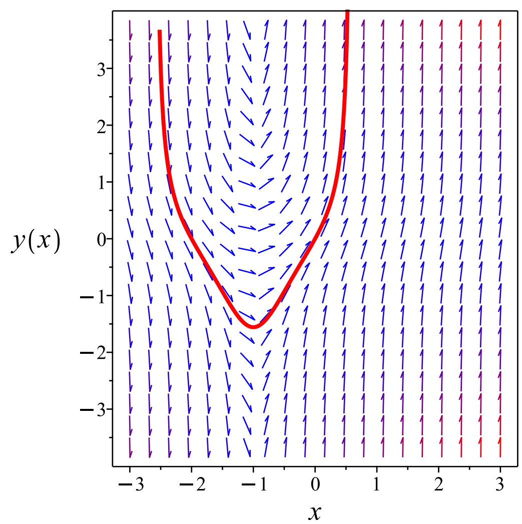
Summary

The solution(s) found are the following

$$y = \tan(x^2 + 2x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \tan\left(x^2 + 2x\right)$$

Verified OK.

2.26.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\frac{1}{2y^2+2}\right)\mathrm{d}y &= (x+1)\,\mathrm{d}x\\ (-x-1)\,\mathrm{d}x + \left(\frac{1}{2y^2+2}\right)\mathrm{d}y &= 0 \qquad (2\mathrm{A})\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -x - 1\\ N(x, y) &= \frac{1}{2y^2+2}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-x-1)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{2y^2+2}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x}=M \tag{1}$$
$$\frac{\partial \phi}{\partial y}=N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x=\int M\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x=\int -x-1\,\mathrm{d}x$$
$$\phi=-\frac{1}{2}x^2-x+f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y}=0+f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y}=\frac{1}{2y^2+2}$. Therefore equation (4) becomes

$$\frac{1}{2y^2+2}=0+f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y)=\frac{1}{2y^2+2}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y=\int \left(\frac{1}{2y^2+2}\right)\mathrm{d}y$$
$$f(y)=\frac{\arctan(y)}{2}+c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x^2}{2} - x + \frac{\arctan(y)}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x^2}{2} - x + \frac{\arctan(y)}{2}$$

The solution becomes

$$y = \tan\left(x^2 + 2c_1 + 2x\right)$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \tan(2c_1)$$

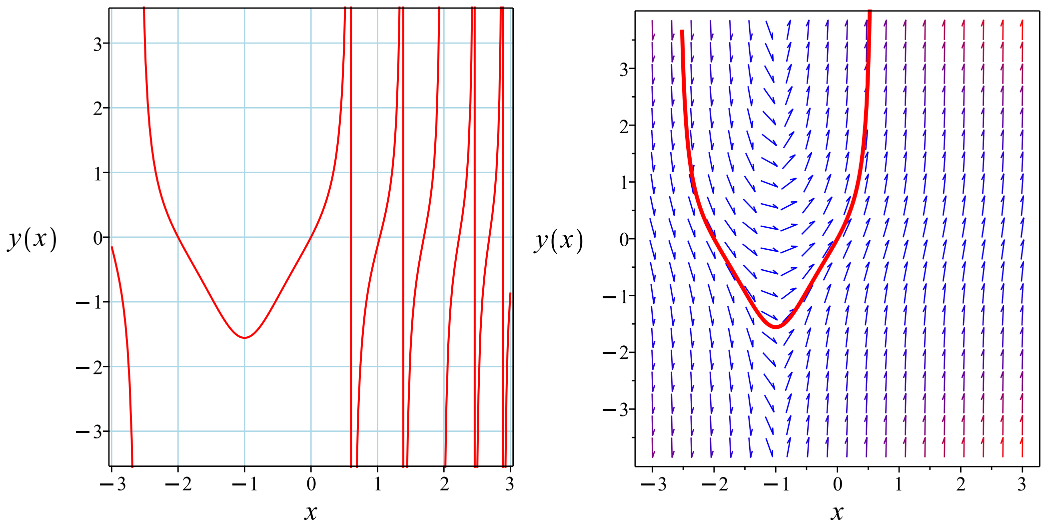
$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$y = \tan\left(x^2 + 2x\right)$$

Summary
The solution(s) found are the following

$$y = \tan\left(x^2 + 2x\right) \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \tan\left(x^2 + 2x\right)$$

Verified OK.

2.26.5 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= 2(x+1)\left(y^2+1\right) \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = 2x\,y^2 + 2y^2 + 2x + 2$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 2 + 2x$, $f_1(x) = 0$ and $f_2(x) = 2 + 2x$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{(2+2x)\,u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\,u'(x) + f_2^2f_0u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 2 \\ f_1f_2 &= 0 \\ f_2^2f_0 &= (2+2x)^3 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$(2+2x)\,u''(x) - 2u'(x) + (2+2x)^3\,u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = c_1\sin\left(x^2+2x\right) + c_2\cos\left(x^2+2x\right)$$

The above shows that

$$u'(x) = -2(x+1)\left(c_2\sin\left(x^2+2x\right) - c_1\cos\left(x^2+2x\right)\right)$$

Using the above in (1) gives the solution

$$y = \frac{2(x+1)\,(c_2\sin(x^2+2x) - c_1\cos(x^2+2x))}{(2+2x)\,(c_1\sin(x^2+2x) + c_2\cos(x^2+2x))}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{\sin(x^2+2x) - c_3\cos(x^2+2x)}{c_3\sin(x^2+2x) + \cos(x^2+2x)}$$

Initial conditions are used to solve for c_3. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -c_3$$

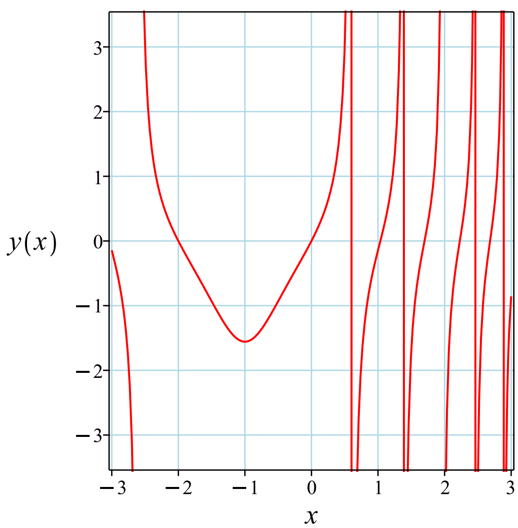
$$c_3 = 0$$

Substituting c_3 found above in the general solution gives

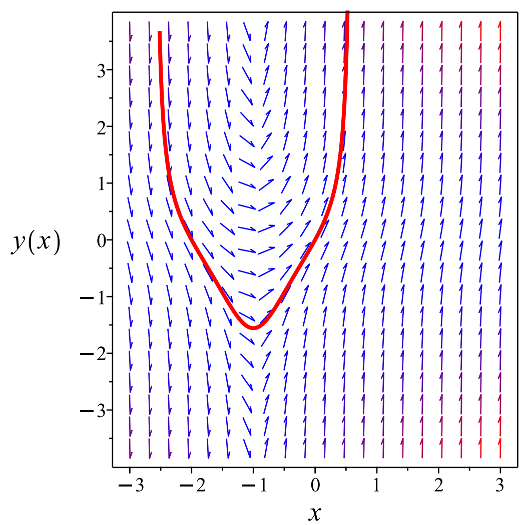
$$y = \frac{\sin(x(2+x))}{\cos(x(2+x))}$$

Summary
The solution(s) found are the following

$$y = \frac{\sin(x(2+x))}{\cos(x(2+x))} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{\sin(x(2+x))}{\cos(x(2+x))}$$

Verified OK.

2.26.6 Maple step by step solution

Let's solve

$[y' - 2(x+1)(1+y^2) = 0, y(0) = 0]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{1+y^2} = 2 + 2x$
- Integrate both sides with respect to x

  $\int \frac{y'}{1+y^2} dx = \int (2 + 2x) \, dx + c_1$
- Evaluate integral

  $\arctan(y) = x^2 + c_1 + 2x$
- Solve for y

  $y = \tan(x^2 + c_1 + 2x)$
- Use initial condition $y(0) = 0$

  $0 = \tan(c_1)$
- Solve for c_1

  $c_1 = 0$
- Substitute $c_1 = 0$ into general solution and simplify

  $y = \tan(x^2 + 2x)$
- Solution to the IVP

  $y = \tan(x^2 + 2x)$

The type(s) of ODE detected by this program : **"exact", "riccati", "bernoulli", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{t(4-y)\,y}{3} = 0}$$

2.27.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(t,y)\\ &= f(t)g(y)\\ &= -\frac{ty(y-4)}{3} \end{aligned}$$

Where $f(t) = -\frac{t}{3}$ and $g(y) = y(y-4)$. Integrating both sides gives

$$\frac{1}{y\,(y-4)}\,dy = -\frac{t}{3}\,dt$$
$$\int \frac{1}{y\,(y-4)}\,dy = \int -\frac{t}{3}\,dt$$
$$\frac{\ln\,(y-4)}{4} - \frac{\ln\,(y)}{4} = -\frac{t^2}{6} + c_1$$

The above can be written as

$$\left(\frac{1}{4}\right)(\ln\,(y-4) - \ln\,(y)) = -\frac{t^2}{6} + 2c_1$$
$$\ln\,(y-4) - \ln\,(y) = (4)\left(-\frac{t^2}{6} + 2c_1\right)$$
$$= -\frac{2t^2}{3} + 8c_1$$

Raising both side to exponential gives

$$e^{\ln(y-4)-\ln(y)} = e^{-\frac{2t^2}{3}+4c_1}$$

Which simplifies to

$$\frac{y-4}{y} = 4c_1 e^{-\frac{2t^2}{3}}$$
$$= c_2 e^{-\frac{2t^2}{3}}$$

Summary

The solution(s) found are the following

$$y = -\frac{4}{-1 + c_2 e^{-\frac{2t^2}{3}}} \tag{1}$$

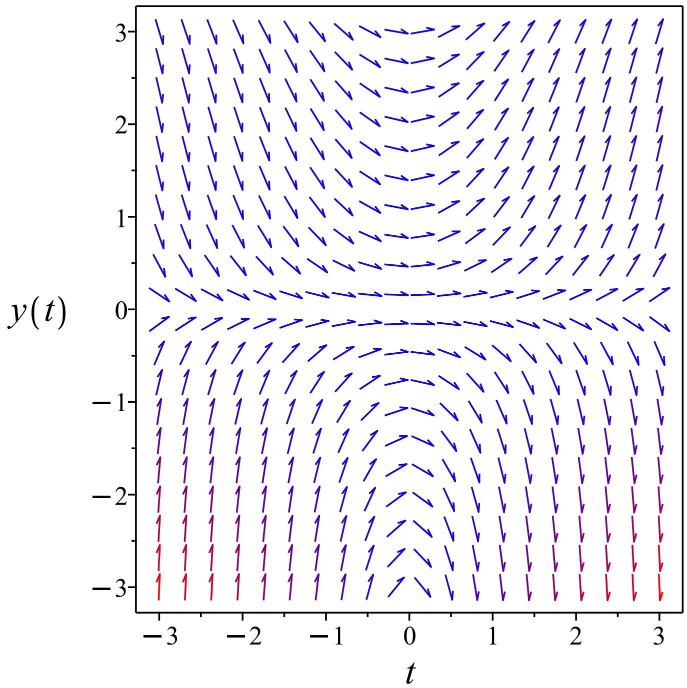

Figure 142: Slope field plot

Verification of solutions

$$y = -\frac{4}{-1 + c_2 e^{-\frac{2t^2}{3}}}$$

Verified OK.

2.27.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{ty(y-4)}{3}$$
$$y' = \omega(t,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 169: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int(n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= -\frac{3}{t} \\
\eta(t, y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dt \\ &= \int \frac{1}{-\frac{3}{t}} dt \end{aligned}$$

Which results in

$$S = -\frac{t^2}{6}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = -\frac{ty(y - 4)}{3}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 0 \\ R_y &= 1 \\ S_t &= -\frac{t}{3} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{y\,(y - 4)} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R\,(R - 4)}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{\ln(R-4)}{4} - \frac{\ln(R)}{4} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$-\frac{t^2}{6} = \frac{\ln(y-4)}{4} - \frac{\ln(y)}{4} + c_1$$

Which simplifies to

$$-\frac{t^2}{6} = \frac{\ln(y-4)}{4} - \frac{\ln(y)}{4} + c_1$$

Which gives

$$y = \frac{4\,\mathrm{e}^{\frac{2t^2}{3}+4c_1}}{-1+\mathrm{e}^{\frac{2t^2}{3}+4c_1}}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{ty(y-4)}{3}$ 	$R = y$ $S = -\frac{t^2}{6}$	$\frac{dS}{dR} = \frac{1}{R(R-4)}$ 
Summary

The solution(s) found are the following

$$y = \frac{4\,\mathrm{e}^{\frac{2t^2}{3}+4c_1}}{-1+\mathrm{e}^{\frac{2t^2}{3}+4c_1}} \tag{1}$$

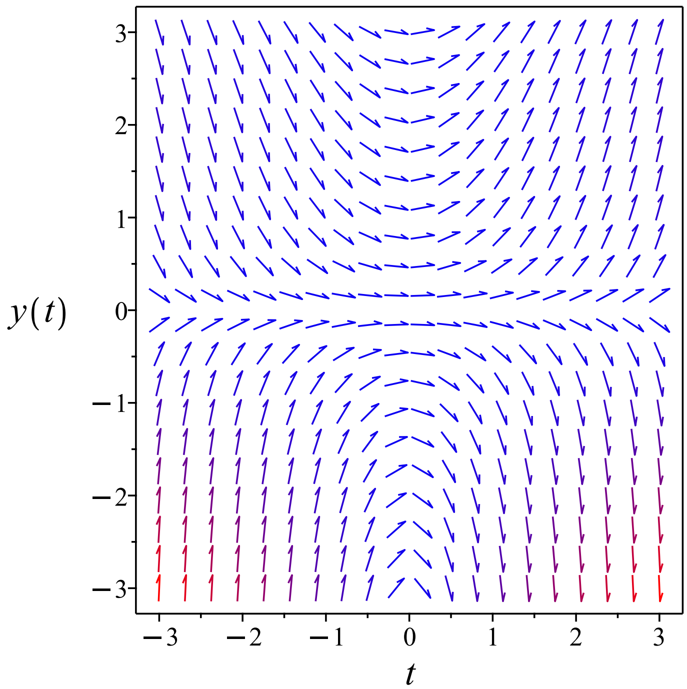

Figure 143: Slope field plot

Verification of solutions

$$y = \frac{4\,\mathrm{e}^{\frac{2t^2}{3}+4c_1}}{-1+\mathrm{e}^{\frac{2t^2}{3}+4c_1}}$$

Verified OK.

2.27.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(t,y) \\ &= -\frac{ty(y-4)}{3} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = \frac{4t}{3}y - \frac{t}{3}y^2 \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(t)y + f_1(t)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(t)y^{1-n} + f_1(t) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(t)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(t)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(t) &= \frac{4t}{3} \\ f_1(t) &= -\frac{t}{3} \\ n &= 2 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = y^2$ gives

$$y'\frac{1}{y^2} = \frac{4t}{3y} - \frac{t}{3} \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= \frac{1}{y} \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t t gives

$$w' = -\frac{1}{y^2}y' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} -w'(t) &= \frac{4w(t)\,t}{3} - \frac{t}{3} \\ w' &= -\frac{4}{3}tw + \frac{1}{3}t \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(t)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(t) + p(t)w(t) = q(t)$$

Where here

$$p(t) = \frac{4t}{3}$$
$$q(t) = \frac{t}{3}$$

Hence the ode is

$$w'(t) + \frac{4w(t)\,t}{3} = \frac{t}{3}$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int \frac{4t}{3}dt}$$
$$= \mathrm{e}^{\frac{2t^2}{3}}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}t}(\mu w) = (\mu)\left(\frac{t}{3}\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\mathrm{e}^{\frac{2t^2}{3}} w\right) = \left(\mathrm{e}^{\frac{2t^2}{3}}\right)\left(\frac{t}{3}\right)$$
$$\mathrm{d}\left(\mathrm{e}^{\frac{2t^2}{3}} w\right) = \left(\frac{t\,\mathrm{e}^{\frac{2t^2}{3}}}{3}\right)\,\mathrm{d}t$$

Integrating gives

$$\mathrm{e}^{\frac{2t^2}{3}} w = \int \frac{t\,\mathrm{e}^{\frac{2t^2}{3}}}{3}\,\mathrm{d}t$$
$$\mathrm{e}^{\frac{2t^2}{3}} w = \frac{\mathrm{e}^{\frac{2t^2}{3}}}{4} + c_1$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\frac{2t^2}{3}}$ results in

$$w(t) = \frac{\mathrm{e}^{-\frac{2t^2}{3}}\,\mathrm{e}^{\frac{2t^2}{3}}}{4} + c_1 \mathrm{e}^{-\frac{2t^2}{3}}$$

which simplifies to

$$w(t) = \frac{1}{4} + c_1 \mathrm{e}^{-\frac{2t^2}{3}}$$

Replacing w in the above by $\frac{1}{y}$ using equation (5) gives the final solution.

$$\frac{1}{y} = \frac{1}{4} + c_1 \mathrm{e}^{-\frac{2t^2}{3}}$$

Or

$$y = \frac{1}{\frac{1}{4} + c_1 \mathrm{e}^{-\frac{2t^2}{3}}}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{\frac{1}{4} + c_1 \mathrm{e}^{-\frac{2t^2}{3}}} \tag{1}$$

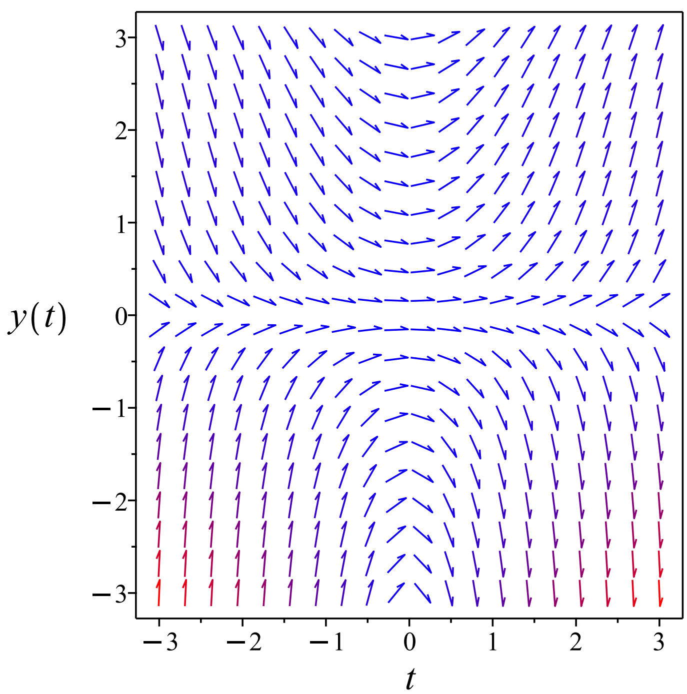

Figure 144: Slope field plot

Verification of solutions

$$y = \frac{1}{\frac{1}{4} + c_1 \mathrm{e}^{-\frac{2t^2}{3}}}$$

Verified OK.

2.27.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t+N(t,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(-\frac{3}{y\,(y-4)}\right)\mathrm{d}y&=(t)\,\mathrm{d}t\\ (-t)\,\mathrm{d}t+\left(-\frac{3}{y\,(y-4)}\right)\mathrm{d}y&=0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(t, y) &= -t \\
N(t, y) &= -\frac{3}{y(y-4)}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-t) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}\left(-\frac{3}{y(y-4)}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(t, y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial t} &= M \qquad (1) \\
\frac{\partial \phi}{\partial y} &= N \qquad (2)
\end{aligned}
$$

Integrating (1) w.r.t. t gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int M \, \mathrm{d}t \\
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int -t \, \mathrm{d}t \\
\phi &= -\frac{t^2}{2} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \qquad (4)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{3}{y(y-4)}$. Therefore equation (4) becomes

$$-\frac{3}{y\left(y-4\right)} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{3}{y\left(y-4\right)}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(-\frac{3}{y\left(y-4\right)}\right)\mathrm{d}y$$

$$f(y) = -\frac{3\ln\left(y-4\right)}{4} + \frac{3\ln\left(y\right)}{4} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{t^2}{2} - \frac{3\ln\left(y-4\right)}{4} + \frac{3\ln\left(y\right)}{4} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{t^2}{2} - \frac{3\ln\left(y-4\right)}{4} + \frac{3\ln\left(y\right)}{4}$$

The solution becomes

$$y = \frac{4\,\mathrm{e}^{\frac{2t^2}{3}+\frac{4c_1}{3}}}{-1+\mathrm{e}^{\frac{2t^2}{3}+\frac{4c_1}{3}}}$$

Summary

The solution(s) found are the following

$$y = \frac{4\,\mathrm{e}^{\frac{2t^2}{3}+\frac{4c_1}{3}}}{-1+\mathrm{e}^{\frac{2t^2}{3}+\frac{4c_1}{3}}} \tag{1}$$

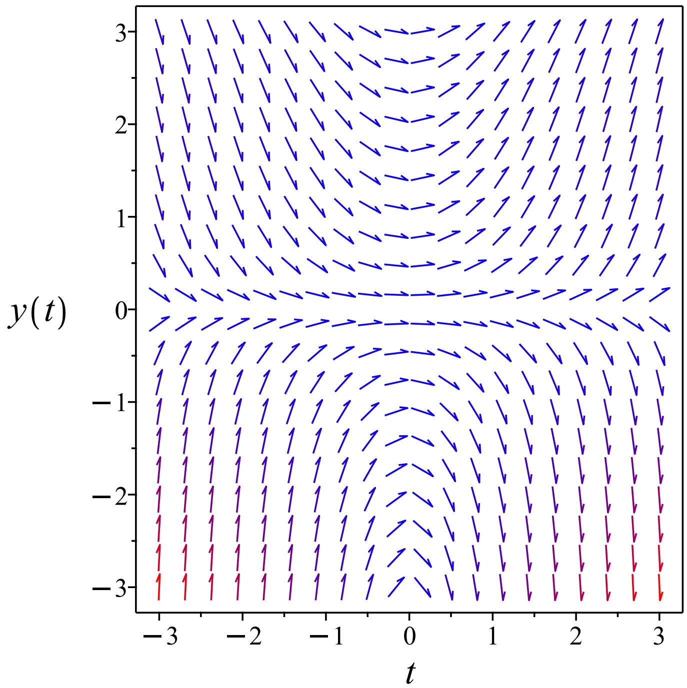

Figure 145: Slope field plot

Verification of solutions

$$y = \frac{4\,\mathrm{e}^{\frac{2t^2}{3}+\frac{4c_1}{3}}}{-1+\mathrm{e}^{\frac{2t^2}{3}+\frac{4c_1}{3}}}$$

Verified OK.

2.27.5 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(t,y) \\ &= -\frac{ty(y-4)}{3} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -\frac{1}{3}t\,y^2 + \frac{4}{3}ty$$

With Riccati ODE standard form

$$y' = f_0(t) + f_1(t)y + f_2(t)y^2$$

Shows that $f_0(t) = 0$, $f_1(t) = \frac{4t}{3}$ and $f_2(t) = -\frac{t}{3}$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{-\frac{tu}{3}} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(t) - (f_2' + f_1 f_2) u'(t) + f_2^2 f_0 u(t) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= -\frac{1}{3} \\ f_1 f_2 &= -\frac{4t^2}{9} \\ f_2^2 f_0 &= 0 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-\frac{t u''(t)}{3} - \left(-\frac{1}{3} - \frac{4t^2}{9}\right) u'(t) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(t) = c_1 + \mathrm{e}^{\frac{2t^2}{3}} c_2$$

The above shows that

$$u'(t) = \frac{4t\,\mathrm{e}^{\frac{2t^2}{3}} c_2}{3}$$

Using the above in (1) gives the solution

$$y = \frac{4\,\mathrm{e}^{\frac{2t^2}{3}} c_2}{c_1 + \mathrm{e}^{\frac{2t^2}{3}} c_2}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{4\,\mathrm{e}^{\frac{2t^2}{3}}}{c_3 + \mathrm{e}^{\frac{2t^2}{3}}}$$

Summary

The solution(s) found are the following

$$y = \frac{4\,\mathrm{e}^{\frac{2t^2}{3}}}{c_3 + \mathrm{e}^{\frac{2t^2}{3}}} \tag{1}$$

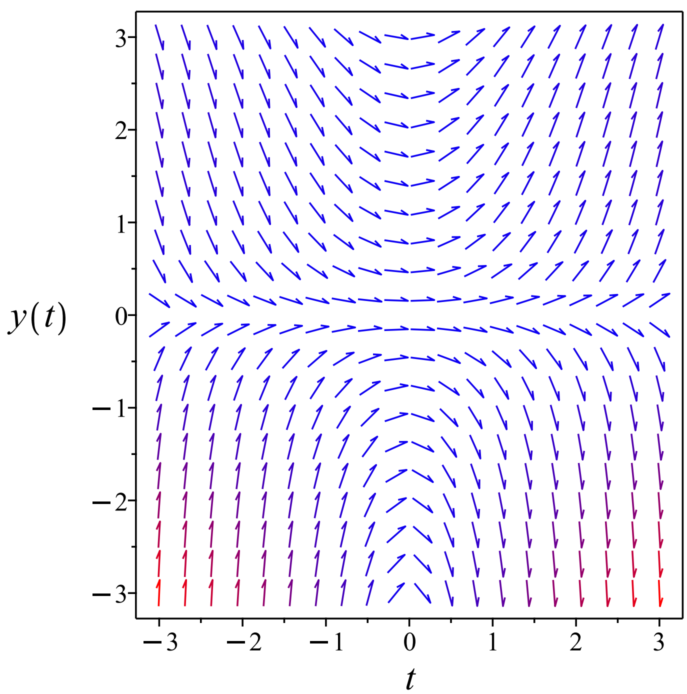

Figure 146: Slope field plot

Verification of solutions

$$y = \frac{4\,\mathrm{e}^{\frac{2t^2}{3}}}{c_3 + \mathrm{e}^{\frac{2t^2}{3}}}$$

Verified OK.

2.27.6 Maple step by step solution

Let's solve

$y' - \frac{t(4-y)y}{3} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{(4-y)y} = \frac{t}{3}$

- Integrate both sides with respect to t

  $\int \frac{y'}{(4-y)y} dt = \int \frac{t}{3} dt + c_1$

- Evaluate integral

  $-\frac{\ln(y-4)}{4} + \frac{\ln(y)}{4} = \frac{t^2}{6} + c_1$

- Solve for y

  $y = \frac{4\,\mathrm{e}^{\frac{2t^2}{3}+4c_1}}{-1+\mathrm{e}^{\frac{2t^2}{3}+4c_1}}$

The type(s) of ODE detected by this program : **"exact", "riccati", "bernoulli", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{ty(4-y)}{t+1} = 0}$$

2.28.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(t, y) \\ &= f(t)g(y) \\ &= -\frac{ty(y-4)}{t+1} \end{aligned}$$

Where $f(t) = -\frac{t}{t+1}$ and $g(y) = y(y-4)$. Integrating both sides gives

$$\frac{1}{y(y-4)}\,dy = -\frac{t}{t+1}\,dt$$
$$\int \frac{1}{y(y-4)}\,dy = \int -\frac{t}{t+1}\,dt$$
$$\frac{\ln(y-4)}{4} - \frac{\ln(y)}{4} = -t + \ln(t+1) + c_1$$

The above can be written as

$$\left(\frac{1}{4}\right)(\ln(y-4) - \ln(y)) = -t + \ln(t+1) + 2c_1$$
$$\ln(y-4) - \ln(y) = (4)(-t + \ln(t+1) + 2c_1)$$
$$= -4t + 4\ln(t+1) + 8c_1$$

Raising both side to exponential gives

$$e^{\ln(y-4)-\ln(y)} = e^{-4t+4\ln(t+1)+4c_1}$$

Which simplifies to

$$\frac{y-4}{y} = 4c_1 e^{-4t+4\ln(t+1)}$$
$$= c_2 e^{-4t+4\ln(t+1)}$$

Summary

The solution(s) found are the following

$$y = -\frac{4}{-1 + c_2 e^{-4t+4\ln(t+1)}} \tag{1}$$

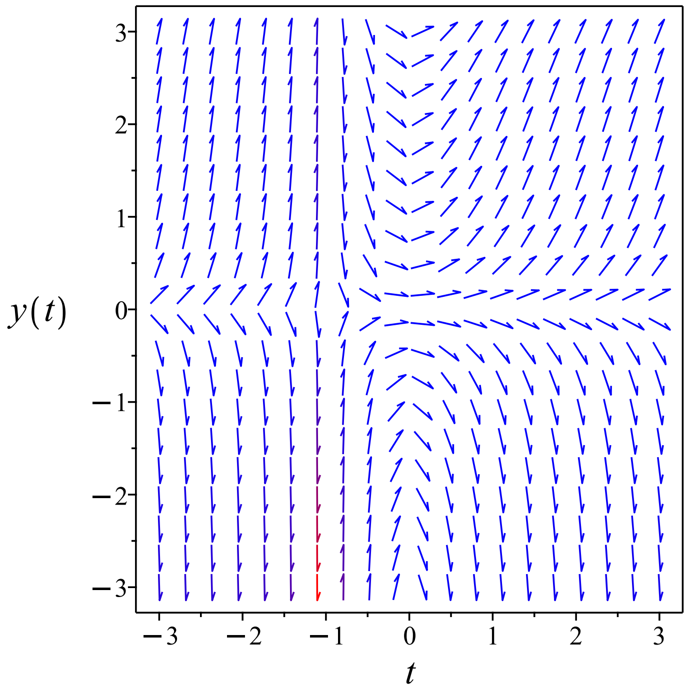

Figure 147: Slope field plot

Verification of solutions

$$y = -\frac{4}{-1 + c_2 \mathrm{e}^{-4t+4\ln(t+1)}}$$

Verified OK.

2.28.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= -\frac{ty(y-4)}{t+1} \\ y' &= \omega(t,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 172: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= -\frac{t+1}{t} \\
\eta(t, y) &= 0
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dt \\ &= \int \frac{1}{-\frac{t+1}{t}} dt \end{aligned}$$

Which results in

$$S = -t + \ln(t + 1)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y)S_y}{R_t + \omega(t, y)R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = -\frac{ty(y - 4)}{t + 1}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 0 \\ R_y &= 1 \\ S_t &= -\frac{t}{t + 1} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{y(y - 4)} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R(R - 4)}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{\ln (R-4)}{4} - \frac{\ln (R)}{4} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$-t + \ln (t+1) = \frac{\ln (y-4)}{4} - \frac{\ln (y)}{4} + c_1$$

Which simplifies to

$$-t + \ln (t+1) = \frac{\ln (y-4)}{4} - \frac{\ln (y)}{4} + c_1$$

Which gives

$$y = \frac{4\,\mathrm{e}^{4t+4c_1}}{-1 - t^4 - 4t^3 - 6t^2 + \mathrm{e}^{4t+4c_1} - 4t}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{ty(y-4)}{t+1}$ 	$R = y$ $S = -t + \ln (t+1)$	$\frac{dS}{dR} = \frac{1}{R(R-4)}$ 
Summary
The solution(s) found are the following

$$y = \frac{4\,\mathrm{e}^{4t+4c_1}}{-1-t^4-4t^3-6t^2+\mathrm{e}^{4t+4c_1}-4t} \tag{1}$$

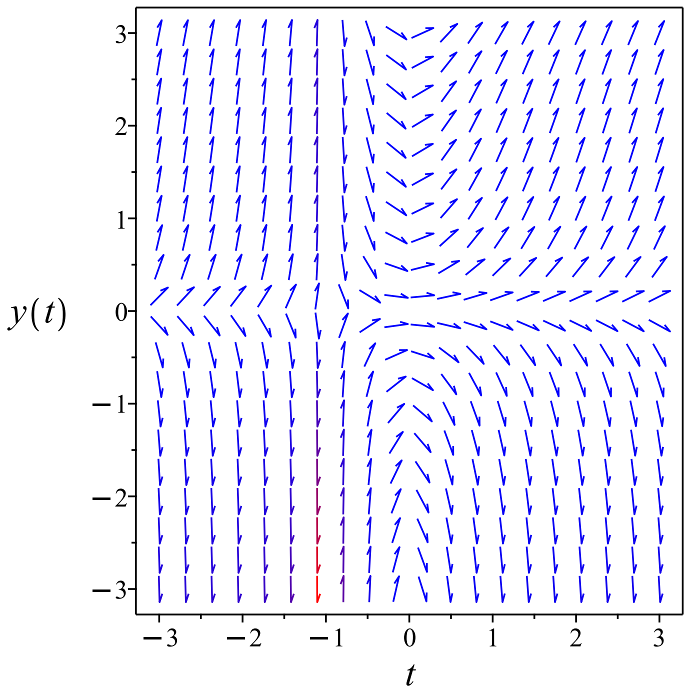

Figure 148: Slope field plot

Verification of solutions

$$y = \frac{4\,\mathrm{e}^{4t+4c_1}}{-1-t^4-4t^3-6t^2+\mathrm{e}^{4t+4c_1}-4t}$$

Verified OK.

2.28.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(t,y) \\ &= -\frac{ty(y-4)}{t+1} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = \frac{4t}{t+1}y - \frac{t}{t+1}y^2 \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(t)y + f_1(t)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(t)y^{1-n} + f_1(t) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(t)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(t)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned}
f_0(t) &= \frac{4t}{t+1} \\
f_1(t) &= -\frac{t}{t+1} \\
n &= 2
\end{aligned}$$

Dividing both sides of ODE (1) by $y^n = y^2$ gives

$$y'\frac{1}{y^2} = \frac{4t}{(t+1)\,y} - \frac{t}{t+1} \tag{4}$$

Let

$$\begin{aligned}
w &= y^{1-n} \\
&= \frac{1}{y}
\end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t t gives

$$w' = -\frac{1}{y^2}y' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned}
-w'(t) &= \frac{4tw(t)}{t+1} - \frac{t}{t+1} \\
w' &= -\frac{4tw}{t+1} + \frac{t}{t+1}
\end{aligned} \tag{7}$$

The above now is a linear ODE in $w(t)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(t) + p(t)w(t) = q(t)$$

Where here

$$\begin{aligned}
p(t) &= \frac{4t}{t+1} \\
q(t) &= \frac{t}{t+1}
\end{aligned}$$

Hence the ode is

$$w'(t) + \frac{4tw(t)}{t+1} = \frac{t}{t+1}$$

The integrating factor μ is

$$\begin{aligned}
\mu &= \mathrm{e}^{\int \frac{4t}{t+1}dt} \\
&= \mathrm{e}^{4t-4\ln(t+1)}
\end{aligned}$$

Which simplifies to

$$\mu = \frac{\mathrm{e}^{4t}}{(t+1)^4}$$

The ode becomes

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}t}(\mu w) &= (\mu)\left(\frac{t}{t+1}\right) \\
\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\mathrm{e}^{4t}w}{(t+1)^4}\right) &= \left(\frac{\mathrm{e}^{4t}}{(t+1)^4}\right)\left(\frac{t}{t+1}\right) \\
\mathrm{d}\left(\frac{\mathrm{e}^{4t}w}{(t+1)^4}\right) &= \left(\frac{t\,\mathrm{e}^{4t}}{(t+1)^5}\right)\mathrm{d}t
\end{aligned}$$

Integrating gives

$$\begin{aligned}
\frac{\mathrm{e}^{4t}w}{(t+1)^4} &= \int \frac{t\,\mathrm{e}^{4t}}{(t+1)^5}\,\mathrm{d}t \\
\frac{\mathrm{e}^{4t}w}{(t+1)^4} &= \frac{\mathrm{e}^{4t}}{4\,(t+1)^4} + c_1
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{\mathrm{e}^{4t}}{(t+1)^4}$ results in

$$w(t) = \frac{\mathrm{e}^{-4t}\mathrm{e}^{4t}}{4} + c_1\mathrm{e}^{-4t}(t+1)^4$$

which simplifies to

$$w(t) = \frac{1}{4} + c_1 e^{-4t} (t+1)^4$$

Replacing w in the above by $\frac{1}{y}$ using equation (5) gives the final solution.

$$\frac{1}{y} = \frac{1}{4} + c_1 e^{-4t} (t+1)^4$$

Or

$$y = \frac{1}{\frac{1}{4} + c_1 e^{-4t} (t+1)^4}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{\frac{1}{4} + c_1 e^{-4t} (t+1)^4} \tag{1}$$

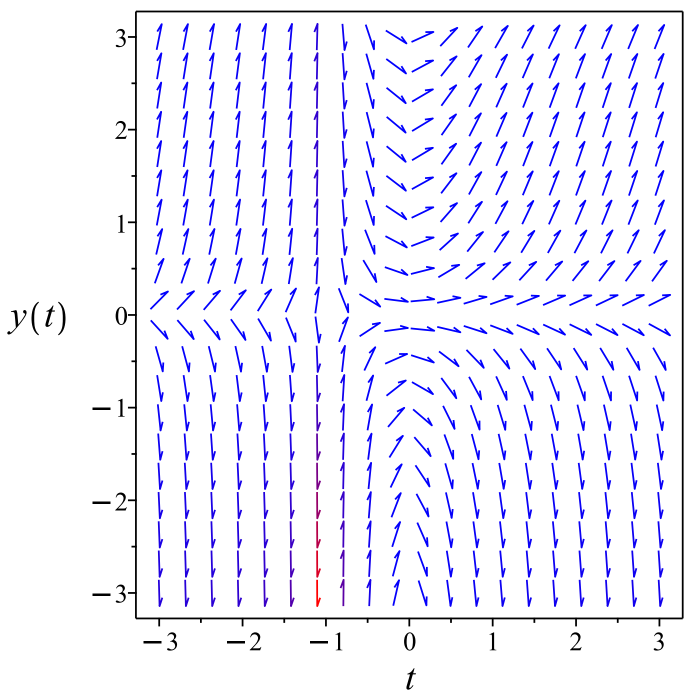

Figure 149: Slope field plot

Verification of solutions

$$y = \frac{1}{\frac{1}{4} + c_1 e^{-4t} (t+1)^4}$$

Verified OK.

2.28.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t+N(t,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(-\frac{1}{y\,(y-4)}\right)\mathrm{d}y&=\left(\frac{t}{t+1}\right)\mathrm{d}t\\ \left(-\frac{t}{t+1}\right)\mathrm{d}t+\left(-\frac{1}{y\,(y-4)}\right)\mathrm{d}y&=0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(t, y) &= -\frac{t}{t+1} \\
N(t, y) &= -\frac{1}{y\,(y-4)}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{t}{t+1}\right) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}\left(-\frac{1}{y\,(y-4)}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(t, y)$

$$
\frac{\partial \phi}{\partial t} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. t gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int M \, \mathrm{d}t \\
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int -\frac{t}{t+1} \, \mathrm{d}t
\end{aligned}
$$

$$
\phi = -t + \ln(t+1) + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{1}{y(y-4)}$. Therefore equation (4) becomes

$$-\frac{1}{y\left(y-4\right)} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{1}{y\left(y-4\right)}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(-\frac{1}{y\left(y-4\right)}\right)\mathrm{d}y$$

$$f(y) = -\frac{\ln\left(y-4\right)}{4} + \frac{\ln\left(y\right)}{4} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -t + \ln\left(t+1\right) - \frac{\ln\left(y-4\right)}{4} + \frac{\ln\left(y\right)}{4} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -t + \ln\left(t+1\right) - \frac{\ln\left(y-4\right)}{4} + \frac{\ln\left(y\right)}{4}$$

The solution becomes

$$y = \frac{4\,\mathrm{e}^{4t+4c_1}}{-1 - t^4 - 4t^3 - 6t^2 + \mathrm{e}^{4t+4c_1} - 4t}$$

Summary

The solution(s) found are the following

$$y = \frac{4\,\mathrm{e}^{4t+4c_1}}{-1 - t^4 - 4t^3 - 6t^2 + \mathrm{e}^{4t+4c_1} - 4t} \tag{1}$$

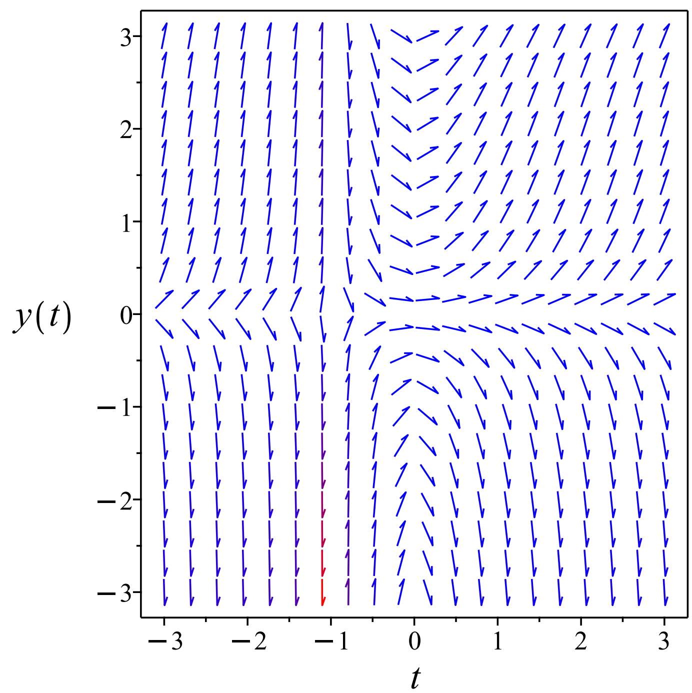

Figure 150: Slope field plot

<u>Verification of solutions</u>

$$y = \frac{4\,\mathrm{e}^{4t+4c_1}}{-1 - t^4 - 4t^3 - 6t^2 + \mathrm{e}^{4t+4c_1} - 4t}$$

Verified OK.

2.28.5 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(t, y) \\ &= -\frac{ty(y-4)}{t+1} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = \frac{4ty}{t+1} - \frac{t\,y^2}{t+1}$$

With Riccati ODE standard form

$$y' = f_0(t) + f_1(t)y + f_2(t)y^2$$

Shows that $f_0(t) = 0$, $f_1(t) = \frac{4t}{t+1}$ and $f_2(t) = -\frac{t}{t+1}$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{-\frac{tu}{t+1}} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(t) - (f_2' + f_1 f_2)\, u'(t) + f_2^2 f_0 u(t) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= -\frac{1}{t+1} + \frac{t}{(t+1)^2} \\ f_1 f_2 &= -\frac{4t^2}{(t+1)^2} \\ f_2^2 f_0 &= 0 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-\frac{tu''(t)}{t+1} - \left(-\frac{1}{t+1} + \frac{t}{(t+1)^2} - \frac{4t^2}{(t+1)^2}\right) u'(t) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(t) = \frac{c_2 e^{4t} + (t+1)^4 c_1}{(t+1)^4}$$

The above shows that

$$u'(t) = \frac{4\, e^{4t} c_2 t}{(t+1)^5}$$

Using the above in (1) gives the solution

$$y = \frac{4\, e^{4t} c_2}{c_2 e^{4t} + (t+1)^4 c_1}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{4\,e^{4t}}{e^{4t} + c_3 \left(t^4 + 4t^3 + 6t^2 + 4t + 1\right)}$$

Summary

The solution(s) found are the following

$$y = \frac{4\,e^{4t}}{e^{4t} + c_3 \left(t^4 + 4t^3 + 6t^2 + 4t + 1\right)} \tag{1}$$

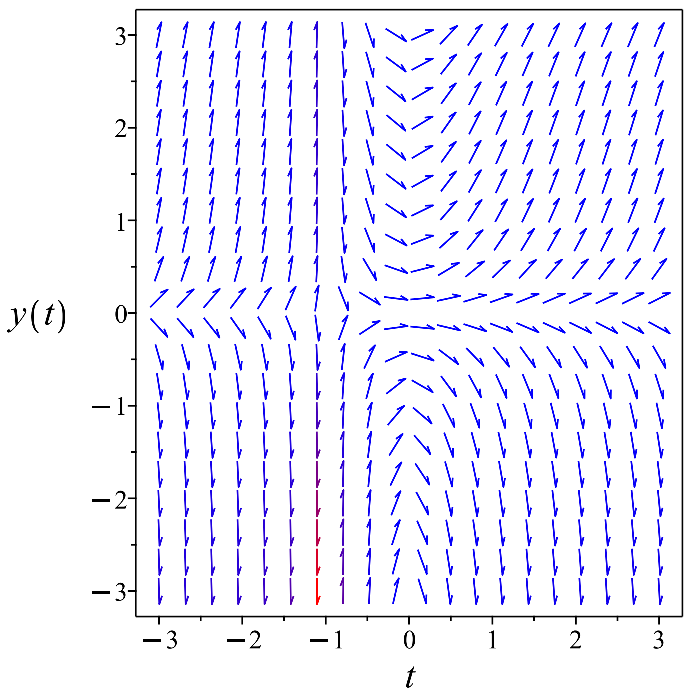

Figure 151: Slope field plot

Verification of solutions

$$y = \frac{4\,e^{4t}}{e^{4t} + c_3 \left(t^4 + 4t^3 + 6t^2 + 4t + 1\right)}$$

Verified OK.

2.28.6 Maple step by step solution

Let's solve

$y' - \frac{ty(4-y)}{t+1} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{(4-y)y} = \frac{t}{t+1}$

- Integrate both sides with respect to t

  $\int \frac{y'}{(4-y)y} dt = \int \frac{t}{t+1} dt + c_1$

- Evaluate integral

  $-\frac{\ln(y-4)}{4} + \frac{\ln(y)}{4} = t - \ln(t+1) + c_1$

- Solve for y

  $y = \frac{4\,\mathrm{e}^{4t+4c_1}}{-1-t^4-4t^3-6t^2+\mathrm{e}^{4t+4c_1}-4t}$

ODE degree: 1.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y' - \frac{b + ay}{d + cy} = 0}$$

2.29.1 Solving as quadrature ode

Integrating both sides gives

$$\int \frac{cy + d}{ay + b} dy = x + c_1$$
$$\frac{cy}{a} + \frac{(ad - bc)\ln(ay + b)}{a^2} = x + c_1$$

Solving for y gives these solutions

Summary
The solution(s) found are the following

$$y = \frac{c_1 a^2 + x\,a^2 - \left(-\operatorname{LambertW}\left(-\frac{c\,\mathrm{e}^{\frac{c_1 a^2 + x\,a^2 + bc}{ad - bc}}}{-ad + bc}\right) + \frac{c_1 a^2 + x\,a^2 + bc}{ad - bc}\right) ad + \left(-\operatorname{LambertW}\left(-\frac{c\,\mathrm{e}^{\frac{c_1 a^2 + x\,a^2 + bc}{ad - bc}}}{-ad + bc}\right)\right.}{ac} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 a^2 + x\,a^2 - \left(-\operatorname{LambertW}\left(-\frac{c\,\mathrm{e}^{\frac{c_1 a^2 + x\,a^2 + bc}{ad-bc}}}{-ad+bc}\right) + \frac{c_1 a^2 + x\,a^2 + bc}{ad-bc}\right) ad + \left(-\operatorname{LambertW}\left(-\frac{c\,\mathrm{e}^{\frac{c_1 a^2 + x\,a^2 + bc}{ad-bc}}}{-ad+bc}\right)\right.}{ac}$$

Verified OK.

2.29.2 Maple step by step solution

Let's solve

$y' - \frac{b+ay}{d+cy} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'(d+cy)}{b+ay} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'(d+cy)}{b+ay}dx = \int 1dx + c_1$

- Evaluate integral

  $\frac{cy}{a} + \frac{(ad-bc)\ln(b+ay)}{a^2} = x + c_1$

- Solve for y

  $$y = \frac{c_1 a^2 + x\,a^2 - \left(-\mathit{LambertW}\left(-\frac{c\,\mathrm{e}^{\frac{c_1 a^2 + x\,a^2 + bc}{ad-bc}}}{-ad+bc}\right) + \frac{c_1 a^2 + x\,a^2 + bc}{ad-bc}\right) ad + \left(-\mathit{LambertW}\left(-\frac{c\,\mathrm{e}^{\frac{c_1 a^2 + x\,a^2 + bc}{ad-bc}}}{-ad+bc}\right) + \frac{c_1 a^2 + x\,a^2 + bc}{ad-bc}\right) bc}{ac}$$

2.30 problem 31

Internal problem ID [508]
Internal file name [`OUTPUT/508_Sunday_June_05_2022_01_42_41_AM_3383851/index.tex`]

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.2. Page 48
Problem number: 31.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _Riccati]
```

$$\boxed{y' - \frac{x^2 + yx + y^2}{x^2} = 0}$$

2.30.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x + u(x) - \frac{x^2 + u(x)\,x^2 + u(x)^2\,x^2}{x^2} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{u^2+1}{x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(u) = u^2 + 1$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u^2+1}\,du &= \frac{1}{x}\,dx \\
\int \frac{1}{u^2+1}\,du &= \int \frac{1}{x}\,dx \\
\arctan(u) &= \ln(x) + c_2
\end{aligned}
$$

The solution is

$$
\arctan(u(x)) - \ln(x) - c_2 = 0
$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$
\begin{aligned}
\arctan\left(\frac{y}{x}\right) - \ln(x) - c_2 &= 0 \\
\arctan\left(\frac{y}{x}\right) - \ln(x) - c_2 &= 0
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\arctan\left(\frac{y}{x}\right) - \ln(x) - c_2 = 0 \tag{1}
$$

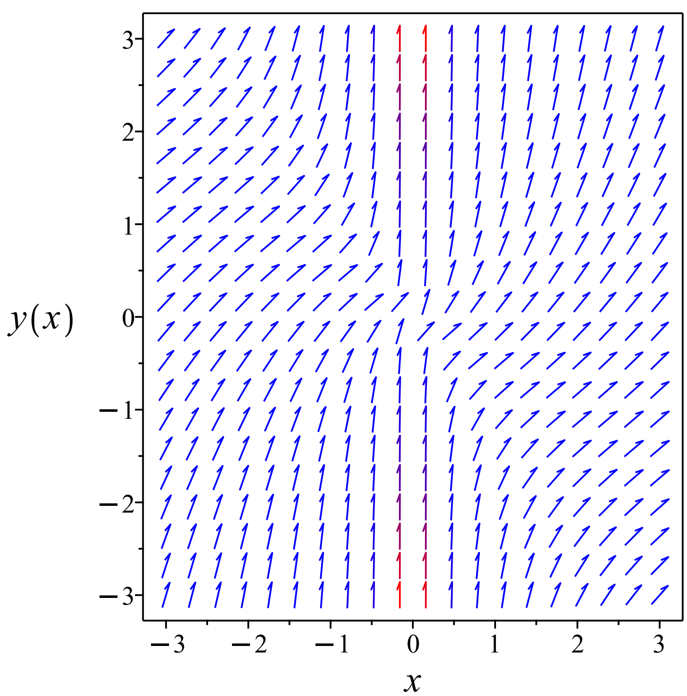

Figure 152: Slope field plot

Verification of solutions

$$\arctan\left(\frac{y}{x}\right) - \ln(x) - c_2 = 0$$

Verified OK.

2.30.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= \frac{x^2 + yx + y^2}{x^2} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} & b_2 + \frac{(x^2 + yx + y^2)(b_3 - a_2)}{x^2} - \frac{(x^2 + yx + y^2)^2 a_3}{x^4} \\ & - \left(\frac{2x + y}{x^2} - \frac{2(x^2 + yx + y^2)}{x^3}\right)(x a_2 + y a_3 + a_1) \\ & - \frac{(x + 2y)(x b_2 + y b_3 + b_1)}{x^2} = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{x^4 a_2 + x^4 a_3 - x^4 b_3 + 2x^3 y a_3 + 2x^3 y b_2 - x^2 y^2 a_2 + 2x^2 y^2 a_3 + x^2 y^2 b_3 + y^4 a_3 + x^3 b_1 - x^2 y a_1 + 2x^2 y b_1 -}{x^4}$$
$$= 0$$

Setting the numerator to zero gives

$$-x^4a_2 - x^4a_3 + x^4b_3 - 2x^3ya_3 - 2x^3yb_2 + x^2y^2a_2 - 2x^2y^2a_3 - x^2y^2b_3 - y^4a_3 - x^3b_1 + x^2ya_1 - 2x^2yb_1 + 2x\,y^2a_1 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$-a_2v_1^4 + a_2v_1^2v_2^2 - a_3v_1^4 - 2a_3v_1^3v_2 - 2a_3v_1^2v_2^2 - a_3v_2^4 - 2b_2v_1^3v_2 + b_3v_1^4 - b_3v_1^2v_2^2 + a_1v_1^2v_2 + 2a_1v_1v_2^2 - b_1v_1^3 - 2b_1v_1^2v_2 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$(-a_2 - a_3 + b_3)\,v_1^4 + (-2a_3 - 2b_2)\,v_1^3v_2 - b_1v_1^3 + (a_2 - 2a_3 - b_3)\,v_1^2v_2^2 + (a_1 - 2b_1)\,v_1^2v_2 + 2a_1v_1v_2^2 - a_3v_2^4 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
2a_1 &= 0 \\
-a_3 &= 0 \\
-b_1 &= 0 \\
a_1 - 2b_1 &= 0 \\
-2a_3 - 2b_2 &= 0 \\
-a_2 - a_3 + b_3 &= 0 \\
a_2 - 2a_3 - b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= b_3 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\, \xi \\
&= y - \left(\frac{x^2 + yx + y^2}{x^2}\right)(x) \\
&= \frac{-x^2 - y^2}{x} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-x^2 - y^2}{x}} dy
\end{aligned}
$$

Which results in

$$S = -\arctan\left(\frac{y}{x}\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{x^2 + yx + y^2}{x^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{y}{x^2 + y^2} \\
S_y &= -\frac{x}{x^2 + y^2}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\ln(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\arctan\left(\frac{y}{x}\right) = -\ln(x) + c_1$$

Which simplifies to

$$-\arctan\left(\frac{y}{x}\right) = -\ln(x) + c_1$$

Which gives

$$y = -\tan(-\ln(x) + c_1)\, x$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>

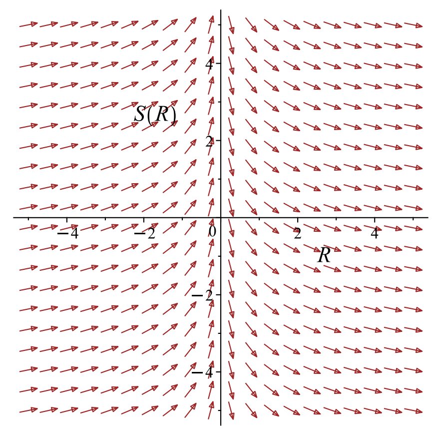
$R = x$

$S = -\arctan\left(\frac{y}{x}\right)$

</td>
<td>

$\frac{dS}{dR} = -\frac{1}{R}$



</td>
</tr>
</table>

Summary

The solution(s) found are the following

$$y = -\tan(-\ln(x) + c_1)\, x \tag{1}$$

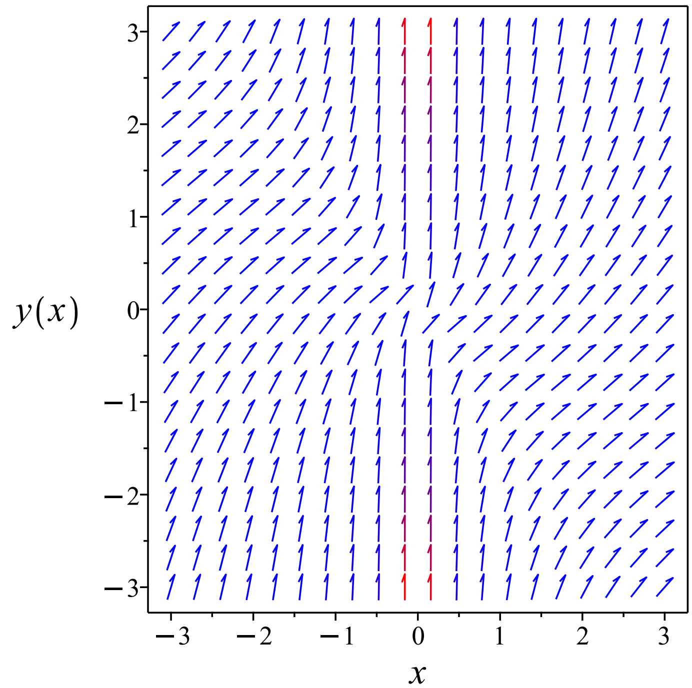


Figure 153: Slope field plot

Verification of solutions

$$y = -\tan(-\ln(x) + c_1)\, x$$

Verified OK.

2.30.3 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{x^2 + yx + y^2}{x^2} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = 1 + \frac{y}{x} + \frac{y^2}{x^2}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 1$, $f_1(x) = \frac{1}{x}$ and $f_2(x) = \frac{1}{x^2}$. Let

$$
\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{\frac{u}{x^2}}
\end{aligned} \tag{1}
$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$
f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}
$$

But

$$
\begin{aligned}
f_2' &= -\frac{2}{x^3} \\
f_1 f_2 &= \frac{1}{x^3} \\
f_2^2 f_0 &= \frac{1}{x^4}
\end{aligned}
$$

Substituting the above terms back in equation (2) gives

$$
\frac{u''(x)}{x^2} + \frac{u'(x)}{x^3} + \frac{u(x)}{x^4} = 0
$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$
u(x) = c_1 \sin(\ln(x)) + c_2 \cos(\ln(x))
$$

The above shows that

$$
u'(x) = \frac{c_1 \cos(\ln(x)) - c_2 \sin(\ln(x))}{x}
$$

Using the above in (1) gives the solution

$$
y = -\frac{x(c_1 \cos(\ln(x)) - c_2 \sin(\ln(x)))}{c_1 \sin(\ln(x)) + c_2 \cos(\ln(x))}
$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{(-c_3 \cos(\ln(x)) + \sin(\ln(x)))\, x}{c_3 \sin(\ln(x)) + \cos(\ln(x))}$$

Summary

The solution(s) found are the following

$$y = \frac{(-c_3 \cos(\ln(x)) + \sin(\ln(x)))\, x}{c_3 \sin(\ln(x)) + \cos(\ln(x))} \tag{1}$$

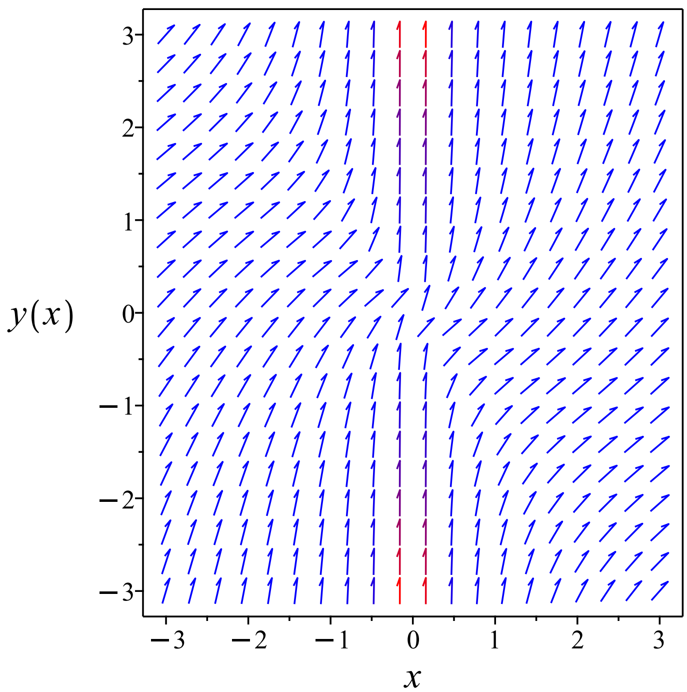

Figure 154: Slope field plot

Verification of solutions

$$y = \frac{(-c_3 \cos(\ln(x)) + \sin(\ln(x)))\, x}{c_3 \sin(\ln(x)) + \cos(\ln(x))}$$

Verified OK.

Section: Section 2.2. Page 48
Problem number: 32.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"bernoulli", "homogeneousTypeD2", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _Bernoulli]
```

$$\boxed{y' - \frac{x^2 + 3y^2}{2xy} = 0}$$

2.31.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x + u(x) - \frac{x^2 + 3u(x)^2\,x^2}{2x^2u\,(x)} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{u^2+1}{2xu} \end{aligned}$$

Where $f(x) = \frac{1}{2x}$ and $g(u) = \frac{u^2+1}{u}$. Integrating both sides gives

$$\frac{1}{\frac{u^2+1}{u}}\, du = \frac{1}{2x}\, dx$$

$$\int \frac{1}{\frac{u^2+1}{u}}\, du = \int \frac{1}{2x}\, dx$$

$$\frac{\ln\left(u^2+1\right)}{2} = \frac{\ln\left(x\right)}{2} + c_2$$

Raising both side to exponential gives

$$\sqrt{u^2+1} = \mathrm{e}^{\frac{\ln(x)}{2}+c_2}$$

Which simplifies to

$$\sqrt{u^2+1} = c_3\sqrt{x}$$

Which simplifies to

$$\sqrt{u\left(x\right)^2+1} = c_3\sqrt{x}\,\mathrm{e}^{c_2}$$

The solution is

$$\sqrt{u\left(x\right)^2+1} = c_3\sqrt{x}\,\mathrm{e}^{c_2}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\sqrt{\frac{y^2}{x^2}+1} = c_3\sqrt{x}\,\mathrm{e}^{c_2}$$

$$\sqrt{\frac{x^2+y^2}{x^2}} = c_3\sqrt{x}\,\mathrm{e}^{c_2}$$

Summary

The solution(s) found are the following

$$\sqrt{\frac{x^2+y^2}{x^2}} = c_3\sqrt{x}\,\mathrm{e}^{c_2} \tag{1}$$

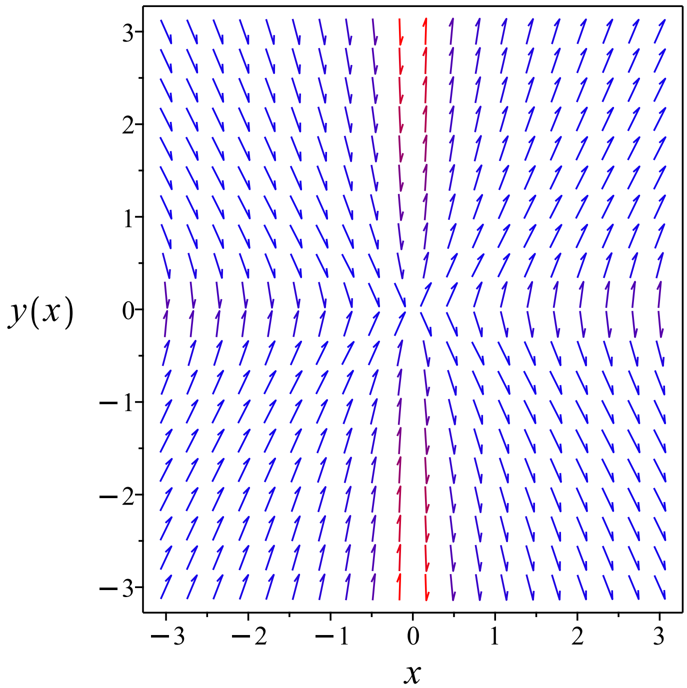

Figure 155: Slope field plot

Verification of solutions

$$\sqrt{\frac{x^2+y^2}{x^2}} = c_3\sqrt{x}\,\mathrm{e}^{c_2}$$

Verified OK.

2.31.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{x^2+3y^2}{2xy}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 176: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{x^3}{y} \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \qquad (1)
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x^3}{y}} dy \end{aligned}$$

Which results in

$$S = \frac{y^2}{2x^3}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{x^2 + 3y^2}{2xy}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{3y^2}{2x^4} \\ S_y &= \frac{y}{x^3} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{2x^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{2R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\frac{1}{2R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y^2}{2x^3} = -\frac{1}{2x} + c_1$$

Which simplifies to

$$\frac{y^2}{2x^3} = -\frac{1}{2x} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^2+3y^2}{2xy}$ 	$R = x$ $S = \frac{y^2}{2x^3}$	$\frac{dS}{dR} = \frac{1}{2R^2}$ 
Summary

The solution(s) found are the following

$$\frac{y^2}{2x^3} = -\frac{1}{2x} + c_1 \tag{1}$$

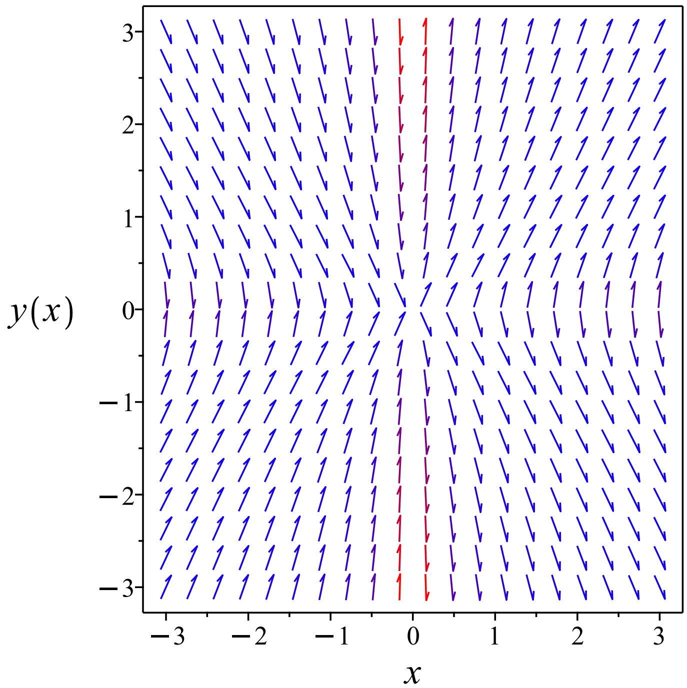

Figure 156: Slope field plot

Verification of solutions

$$\frac{y^2}{2x^3} = -\frac{1}{2x} + c_1$$

Verified OK.

2.31.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{x^2 + 3y^2}{2xy} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = \frac{3}{2x}y + \frac{x}{2}\frac{1}{y} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$
\begin{aligned}
f_0(x) &= \frac{3}{2x} \\
f_1(x) &= \frac{x}{2} \\
n &= -1
\end{aligned}
$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y}$ gives

$$
y'y = \frac{3y^2}{2x} + \frac{x}{2} \tag{4}
$$

Let

$$
\begin{aligned}
w &= y^{1-n} \\
&= y^2
\end{aligned} \tag{5}
$$

Taking derivative of equation (5) w.r.t x gives

$$
w' = 2yy' \tag{6}
$$

Substituting equations (5) and (6) into equation (4) gives

$$
\begin{aligned}
\frac{w'(x)}{2} &= \frac{3w(x)}{2x} + \frac{x}{2} \\
w' &= \frac{3w}{x} + x
\end{aligned} \tag{7}
$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
w'(x) + p(x)w(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{3}{x} \\
q(x) &= x
\end{aligned}
$$

Hence the ode is

$$w'(x) - \frac{3w(x)}{x} = x$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{3}{x}dx} \\ &= \frac{1}{x^3}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu w) &= (\mu)(x) \\ \frac{d}{dx}\left(\frac{w}{x^3}\right) &= \left(\frac{1}{x^3}\right)(x) \\ d\left(\frac{w}{x^3}\right) &= \frac{1}{x^2}\, dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{w}{x^3} &= \int \frac{1}{x^2}\, dx \\ \frac{w}{x^3} &= -\frac{1}{x} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^3}$ results in

$$w(x) = c_1 x^3 - x^2$$

Replacing w in the above by y^2 using equation (5) gives the final solution.

$$y^2 = c_1 x^3 - x^2$$

Solving for y gives

$$\begin{aligned}y(x) &= \sqrt{c_1 x - 1}\, x \\ y(x) &= -\sqrt{c_1 x - 1}\, x\end{aligned}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \sqrt{c_1 x - 1}\, x \tag{1}$$

$$y = -\sqrt{c_1 x - 1}\, x \tag{2}$$

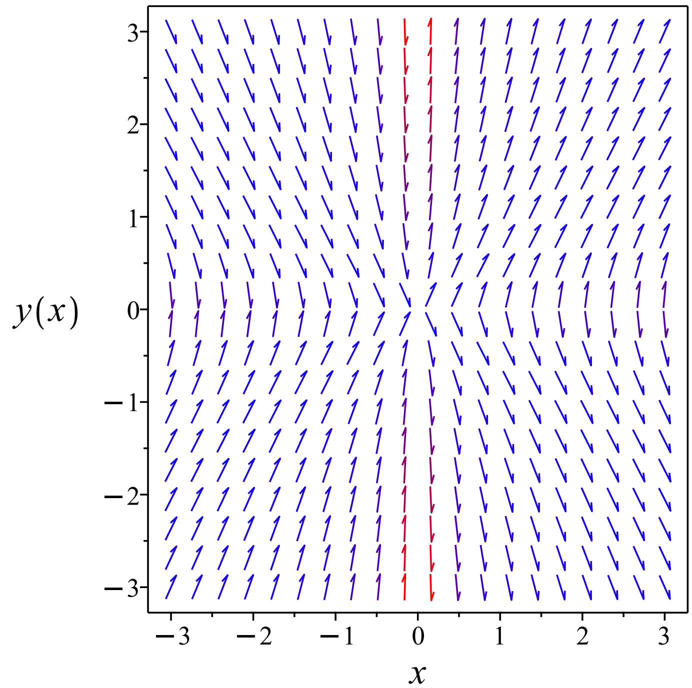

Figure 157: Slope field plot

Verification of solutions

$$y = \sqrt{c_1 x - 1}\, x$$

Verified OK.

$$y = -\sqrt{c_1 x - 1}\, x$$

Verified OK.

2.31.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(2yx)\,\mathrm{d}y &= \left(x^2 + 3y^2\right)\mathrm{d}x \\ \left(-x^2 - 3y^2\right)\mathrm{d}x + (2yx)\,\mathrm{d}y &= 0 \qquad \text{(2A)}\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -x^2 - 3y^2 \\ N(x,y) &= 2yx\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-x^2 - 3y^2\right) \\ &= -6y\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2yx)\\ &= 2y\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{2yx}((-6y) - (2y))\\ &= -\frac{4}{x}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}x}\\ &= e^{\int -\frac{4}{x}\,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-4\ln(x)}\\ &= \frac{1}{x^4}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \frac{1}{x^4}(-x^2 - 3y^2)\\ &= \frac{-x^2 - 3y^2}{x^4}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \frac{1}{x^4}(2yx)\\ &= \frac{2y}{x^3}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$
$$\left(\frac{-x^2 - 3y^2}{x^4}\right) + \left(\frac{2y}{x^3}\right)\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \frac{-x^2 - 3y^2}{x^4}\,\mathrm{d}x$$
$$\phi = \frac{x^2 + y^2}{x^3} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{2y}{x^3} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{2y}{x^3}$. Therefore equation (4) becomes

$$\frac{2y}{x^3} = \frac{2y}{x^3} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{x^2 + y^2}{x^3} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{x^2 + y^2}{x^3}$$

Summary

The solution(s) found are the following

$$\frac{x^2 + y^2}{x^3} = c_1 \tag{1}$$

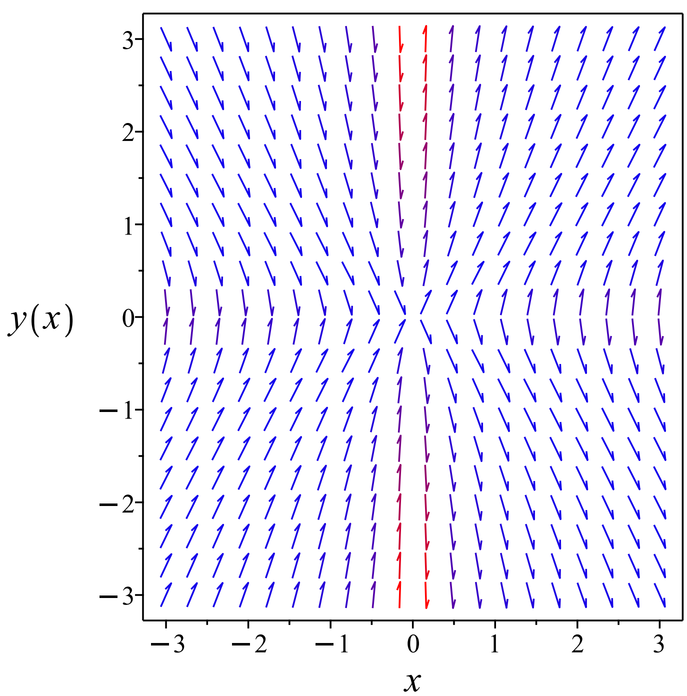

Figure 158: Slope field plot

Verification of solutions

$$\frac{x^2 + y^2}{x^3} = c_1$$

Verified OK.

Section: Section 2.2. Page 48
Problem number: 33.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{y' - \frac{4y - 3x}{2x - y} = 0}$$

2.32.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x + u(x) - \frac{4u(x)\,x - 3x}{2x - u(x)\,x} = 0$$

In canonical form the ODE is

$$\begin{aligned}
u' &= F(x, u) \\
&= f(x)g(u) \\
&= -\frac{u^2 + 2u - 3}{x\,(u - 2)}
\end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{u^2+2u-3}{u-2}$. Integrating both sides gives

$$\frac{1}{\frac{u^2+2u-3}{u-2}}\,du = -\frac{1}{x}\,dx$$
$$\int \frac{1}{\frac{u^2+2u-3}{u-2}}\,du = \int -\frac{1}{x}\,dx$$
$$-\frac{\ln(u-1)}{4} + \frac{5\ln(u+3)}{4} = -\ln(x) + c_2$$

The above can be written as

$$\frac{-\ln(u-1) + 5\ln(u+3)}{4} = -\ln(x) + c_2$$
$$-\ln(u-1) + 5\ln(u+3) = (4)(-\ln(x) + c_2)$$
$$= -4\ln(x) + 4c_2$$

Raising both side to exponential gives

$$e^{-\ln(u-1)+5\ln(u+3)} = e^{-4\ln(x)+4c_2}$$

Which simplifies to

$$\frac{(u+3)^5}{u-1} = \frac{4c_2}{x^4}$$
$$= \frac{c_3}{x^4}$$

Which simplifies to

$$u(x) = \operatorname{RootOf}\left(\_Z^5 + 15\_Z^4 + 90\_Z^3 + 270\_Z^2 + \left(-\frac{c_3 e^{4c_2}}{x^4} + 405\right)\_Z + \frac{c_3 e^{4c_2}}{x^4} + 243\right)$$

Therefore the solution y is

$$y = ux$$
$$= x \operatorname{RootOf}\left(\_Z^5 x^4 + 15x^4\_Z^4 + 90\_Z^3 x^4 + 270x^4\_Z^2 + \left(-c_3 e^{4c_2} + 405x^4\right)\_Z + c_3 e^{4c_2} + 243x^4\right)$$

Summary

The solution(s) found are the following

$$y = x \operatorname{RootOf}\left(\_Z^5 x^4 + 15x^4\_Z^4 + 90\_Z^3 x^4 + 270x^4\_Z^2 + \left(-c_3 e^{4c_2} + 405x^4\right)\_Z + c_3 e^{4c_2} + 243x^4\right) \tag{1}$$

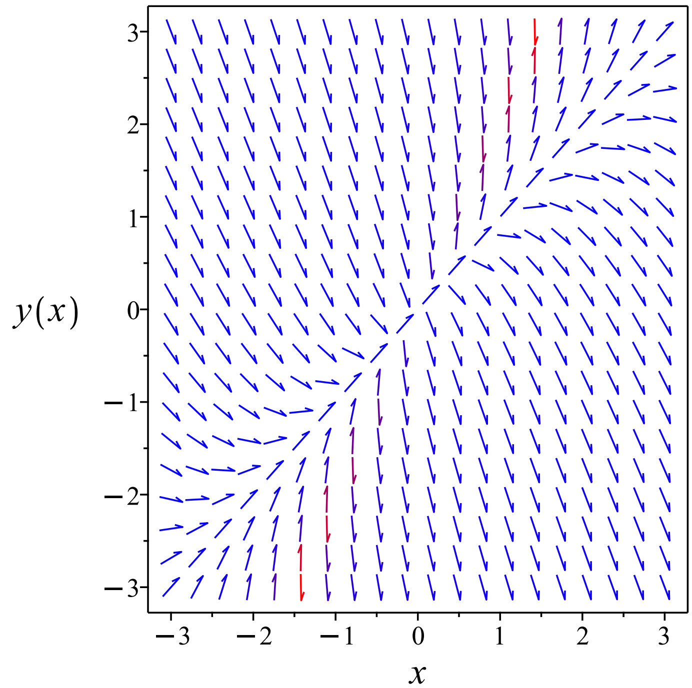

Figure 159: Slope field plot

Verification of solutions

$$y = x \operatorname{RootOf}\left(\_Z^5x^4 + 15x^4\_Z^4 + 90\_Z^3x^4 + 270x^4\_Z^2 + \left(-c_3 e^{4c_2} + 405x^4\right)\_Z + c_3 e^{4c_2} + 243x^4\right)$$

Verified OK.

2.32.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -\frac{4y - 3x}{-2x + y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} & b_2 - \frac{(4y-3x)(b_3-a_2)}{-2x+y} - \frac{(4y-3x)^2 a_3}{(-2x+y)^2} \\ & - \left(\frac{3}{-2x+y} - \frac{2(4y-3x)}{(-2x+y)^2}\right)(xa_2 + ya_3 + a_1) \\ & - \left(-\frac{4}{-2x+y} + \frac{4y-3x}{(-2x+y)^2}\right)(xb_2 + yb_3 + b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{6x^2a_2 - 9x^2a_3 - x^2b_2 - 6x^2b_3 - 6xya_2 + 24xya_3 - 4xyb_2 + 6xyb_3 + 4y^2a_2 - 11y^2a_3 + y^2b_2 - 4y^2b_3 - 5xb}{(2x-y)^2} = 0$$

Setting the numerator to zero gives

$$\begin{aligned} & 6x^2a_2 - 9x^2a_3 - x^2b_2 - 6x^2b_3 - 6xya_2 + 24xya_3 - 4xyb_2 \\ & + 6xyb_3 + 4y^2a_2 - 11y^2a_3 + y^2b_2 - 4y^2b_3 - 5xb_1 + 5ya_1 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned} & 6a_2v_1^2 - 6a_2v_1v_2 + 4a_2v_2^2 - 9a_3v_1^2 + 24a_3v_1v_2 - 11a_3v_2^2 - b_2v_1^2 \\ & - 4b_2v_1v_2 + b_2v_2^2 - 6b_3v_1^2 + 6b_3v_1v_2 - 4b_3v_2^2 + 5a_1v_2 - 5b_1v_1 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$(6a_2 - 9a_3 - b_2 - 6b_3) v_1^2 + (-6a_2 + 24a_3 - 4b_2 + 6b_3) v_1 v_2 \\ - 5b_1 v_1 + (4a_2 - 11a_3 + b_2 - 4b_3) v_2^2 + 5a_1 v_2 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} 5a_1 &= 0 \\ -5b_1 &= 0 \\ -6a_2 + 24a_3 - 4b_2 + 6b_3 &= 0 \\ 4a_2 - 11a_3 + b_2 - 4b_3 &= 0 \\ 6a_2 - 9a_3 - b_2 - 6b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= 2a_3 + b_3 \\ a_3 &= a_3 \\ b_1 &= 0 \\ b_2 &= 3a_3 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= x \\ \eta &= y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned} \eta &= \eta - \omega(x, y) \xi \\ &= y - \left(-\frac{4y - 3x}{-2x + y}\right)(x) \\ &= \frac{3x^2 - 2yx - y^2}{2x - y} \\ \xi &= 0 \end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{3x^2 - 2yx - y^2}{2x - y}} dy \end{aligned}$$

Which results in

$$S = \frac{5 \ln (3x + y)}{4} - \frac{\ln (-x + y)}{4}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{4y - 3x}{-2x + y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{-4y + 3x}{(3x + y)(x - y)} \\ S_y &= \frac{2x - y}{(3x + y)(x - y)} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{5\ln(3x+y)}{4} - \frac{\ln(-x+y)}{4} = c_1$$

Which simplifies to

$$\frac{5\ln(3x+y)}{4} - \frac{\ln(-x+y)}{4} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{4y-3x}{-2x+y}$ 	$R = x$ $S = \frac{5\ln(3x+y)}{4} - \ln(-$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{5 \ln(3x+y)}{4} - \frac{\ln(-x+y)}{4} = c_1 \tag{1}$$

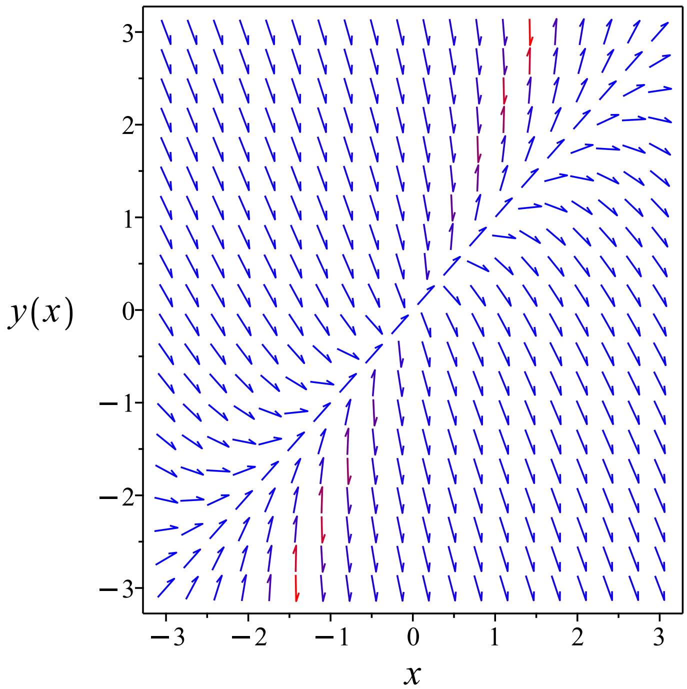

Figure 160: Slope field plot

Verification of solutions

$$\frac{5 \ln(3x+y)}{4} - \frac{\ln(-x+y)}{4} = c_1$$

Verified OK.

Internal file name [`OUTPUT/511_Sunday_June_05_2022_01_42_45_AM_86261302/index.tex`]

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.2. Page 48
Problem number: 34.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{y' + \frac{4x+3y}{2x+y} = 0}$$

2.33.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x + u(x) + \frac{4x+3u(x)\,x}{2x+u(x)\,x} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{u^2+5u+4}{x\,(u+2)} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{u^2+5u+4}{u+2}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{u^2+5u+4}{u+2}}\,du &= -\frac{1}{x}\,dx \\
\int \frac{1}{\frac{u^2+5u+4}{u+2}}\,du &= \int -\frac{1}{x}\,dx \\
\frac{2\ln(u+4)}{3} + \frac{\ln(u+1)}{3} &= -\ln(x) + c_2
\end{aligned}
$$

The above can be written as

$$
\begin{aligned}
\frac{2\ln(u+4) + \ln(u+1)}{3} &= -\ln(x) + c_2 \\
2\ln(u+4) + \ln(u+1) &= (3)(-\ln(x) + c_2) \\
&= -3\ln(x) + 3c_2
\end{aligned}
$$

Raising both side to exponential gives

$$
e^{2\ln(u+4)+\ln(u+1)} = e^{-3\ln(x)+3c_2}
$$

Which simplifies to

$$
\begin{aligned}
(u+4)^2(u+1) &= \frac{3c_2}{x^3} \\
&= \frac{c_3}{x^3}
\end{aligned}
$$

Which simplifies to

$$
(u(x)+4)^2(u(x)+1) = \frac{c_3 e^{3c_2}}{x^3}
$$

The solution is

$$
(u(x)+4)^2(u(x)+1) = \frac{c_3 e^{3c_2}}{x^3}
$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$
\begin{aligned}
\left(\frac{y}{x}+4\right)^2\left(1+\frac{y}{x}\right) &= \frac{c_3 e^{3c_2}}{x^3} \\
\frac{(4x+y)^2(x+y)}{x^3} &= \frac{c_3 e^{3c_2}}{x^3}
\end{aligned}
$$

Which simplifies to

$$(4x+y)^2 (x+y) = c_3 e^{3c_2}$$

Summary

The solution(s) found are the following

$$(4x+y)^2 (x+y) = c_3 e^{3c_2} \tag{1}$$

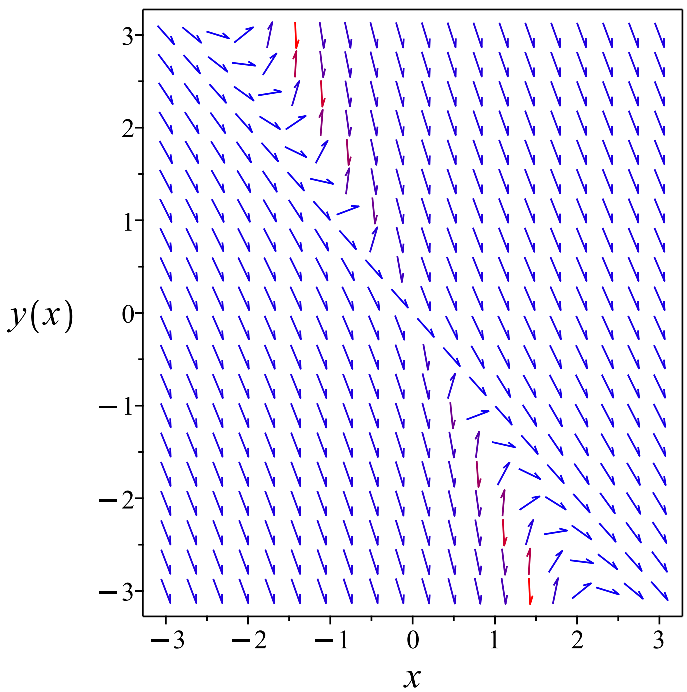

Figure 161: Slope field plot

Verification of solutions

$$(4x+y)^2 (x+y) = c_3 e^{3c_2}$$

Verified OK.

2.33.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{4x+3y}{2x+y} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$
\xi = x a_2 + y a_3 + a_1 \tag{1E}
$$

$$
\eta = x b_2 + y b_3 + b_1 \tag{2E}
$$

Where the unknown coefficients are

$$
\{a_1, a_2, a_3, b_1, b_2, b_3\}
$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
&b_2 - \frac{(4x+3y)(b_3-a_2)}{2x+y} - \frac{(4x+3y)^2 a_3}{(2x+y)^2} \\
&- \left(-\frac{4}{2x+y} + \frac{8x+6y}{(2x+y)^2}\right)(x a_2 + y a_3 + a_1) \\
&- \left(-\frac{3}{2x+y} + \frac{4x+3y}{(2x+y)^2}\right)(x b_2 + y b_3 + b_1) = 0
\end{aligned} \tag{5E}
$$

Putting the above in normal form gives

$$
\frac{8x^2 a_2 - 16x^2 a_3 + 6x^2 b_2 - 8x^2 b_3 + 8xy a_2 - 24xy a_3 + 4xy b_2 - 8xy b_3 + 3y^2 a_2 - 11y^2 a_3 + y^2 b_2 - 3y^2 b_3 + 2}{(2x+y)^2}
$$

$$
= 0
$$

Setting the numerator to zero gives

$$
\begin{aligned}
&8x^2 a_2 - 16x^2 a_3 + 6x^2 b_2 - 8x^2 b_3 + 8xy a_2 - 24xy a_3 + 4xy b_2 \\
&- 8xy b_3 + 3y^2 a_2 - 11y^2 a_3 + y^2 b_2 - 3y^2 b_3 + 2x b_1 - 2y a_1 = 0
\end{aligned} \tag{6E}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned} &8a_2v_1^2 + 8a_2v_1v_2 + 3a_2v_2^2 - 16a_3v_1^2 - 24a_3v_1v_2 - 11a_3v_2^2 + 6b_2v_1^2 \\ &+ 4b_2v_1v_2 + b_2v_2^2 - 8b_3v_1^2 - 8b_3v_1v_2 - 3b_3v_2^2 - 2a_1v_2 + 2b_1v_1 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned} &(8a_2 - 16a_3 + 6b_2 - 8b_3)\, v_1^2 + (8a_2 - 24a_3 + 4b_2 - 8b_3)\, v_1v_2 \\ &+ 2b_1v_1 + (3a_2 - 11a_3 + b_2 - 3b_3)\, v_2^2 - 2a_1v_2 = 0 \end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} -2a_1 &= 0 \\ 2b_1 &= 0 \\ 3a_2 - 11a_3 + b_2 - 3b_3 &= 0 \\ 8a_2 - 24a_3 + 4b_2 - 8b_3 &= 0 \\ 8a_2 - 16a_3 + 6b_2 - 8b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= 5a_3 + b_3 \\ a_3 &= a_3 \\ b_1 &= 0 \\ b_2 &= -4a_3 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\xi = x$$
$$\eta = y$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}\eta &= \eta - \omega(x, y)\,\xi \\ &= y - \left(-\frac{4x + 3y}{2x + y}\right)(x) \\ &= \frac{4x^2 + 5yx + y^2}{2x + y} \\ \xi &= 0\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{4x^2+5yx+y^2}{2x+y}} dy\end{aligned}$$

Which results in

$$S = \frac{2\ln(4x + y)}{3} + \frac{\ln(x + y)}{3}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{4x + 3y}{2x + y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{4x + 3y}{(x + y)(4x + y)} \\ S_y &= \frac{2x + y}{(x + y)(4x + y)} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{2\ln(4x + y)}{3} + \frac{\ln(x + y)}{3} = c_1$$

Which simplifies to

$$\frac{2\ln(4x + y)}{3} + \frac{\ln(x + y)}{3} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{4x+3y}{2x+y}$ 	$R = x$ $S = \frac{2\ln(4x+y)}{3} + \frac{\ln(x}{3}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{2\ln(4x+y)}{3} + \frac{\ln(x+y)}{3} = c_1 \tag{1}$$

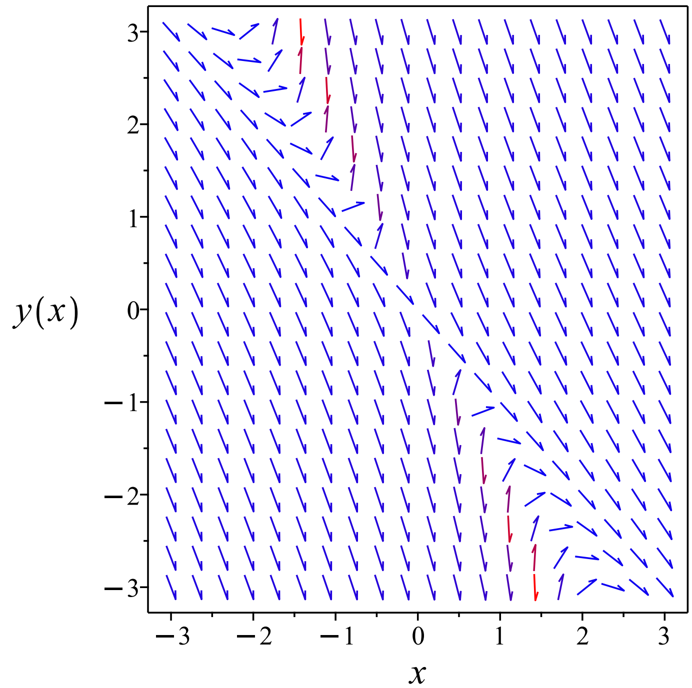

Figure 162: Slope field plot

Verification of solutions

$$\frac{2\ln(4x+y)}{3}+\frac{\ln(x+y)}{3}=c_1$$

Verified OK.

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.2. Page 48
Problem number: 35.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$y' - \frac{x + 3y}{x - y} = 0$$

2.34.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x + u(x) - \frac{x + 3u(x)\,x}{x - u(x)\,x} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{(u+1)^2}{x\,(u-1)} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{(u+1)^2}{u-1}$. Integrating both sides gives

$$\frac{1}{\frac{(u+1)^2}{u-1}}\,du = -\frac{1}{x}\,dx$$

$$\int \frac{1}{\frac{(u+1)^2}{u-1}}\,du = \int -\frac{1}{x}\,dx$$

$$\ln(u+1) + \frac{2}{u+1} = -\ln(x) + c_2$$

The solution is

$$\ln(u(x)+1) + \frac{2}{u(x)+1} + \ln(x) - c_2 = 0$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\ln\left(1+\frac{y}{x}\right) + \frac{2}{1+\frac{y}{x}} + \ln(x) - c_2 = 0$$

$$\ln\left(\frac{x+y}{x}\right) + \frac{2x}{x+y} + \ln(x) - c_2 = 0$$

Summary

The solution(s) found are the following

$$\ln\left(\frac{x+y}{x}\right) + \frac{2x}{x+y} + \ln(x) - c_2 = 0 \tag{1}$$

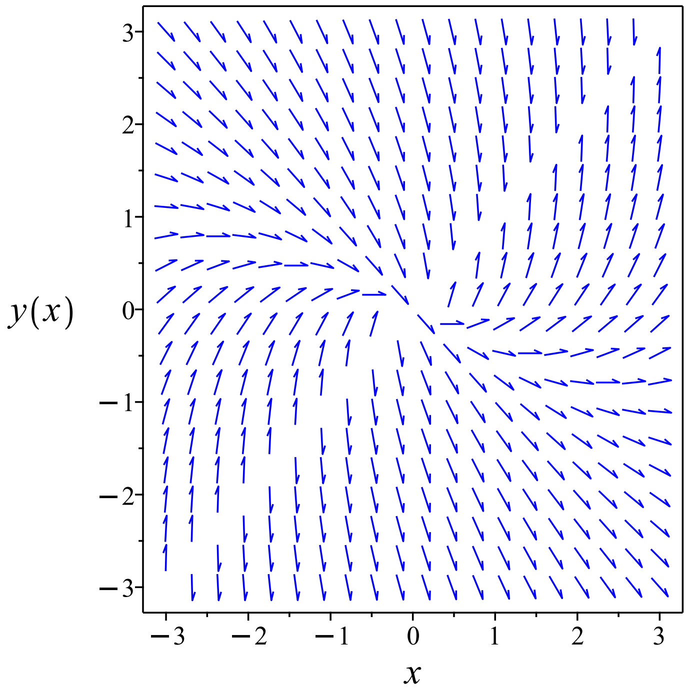

Figure 163: Slope field plot

Verification of solutions

$$\ln\left(\frac{x+y}{x}\right)+\frac{2x}{x+y}+\ln(x)-c_2=0$$

Verified OK.

2.34.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=-\frac{3y+x}{-x+y}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 - \frac{(3y+x)(b_3-a_2)}{-x+y} - \frac{(3y+x)^2 a_3}{(-x+y)^2} - \left(-\frac{1}{-x+y} - \frac{3y+x}{(-x+y)^2}\right)(xa_2+ya_3+a_1) - \left(-\frac{3}{-x+y} + \frac{3y+x}{(-x+y)^2}\right)(xb_2+yb_3+b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{x^2a_2 + x^2a_3 + 3x^2b_2 - x^2b_3 - 2xya_2 + 6xya_3 + 2xyb_2 + 2xyb_3 - 3y^2a_2 + 5y^2a_3 - y^2b_2 + 3y^2b_3 + 4xb_1 -}{(x-y)^2} = 0$$

Setting the numerator to zero gives

$$-x^2a_2 - x^2a_3 - 3x^2b_2 + x^2b_3 + 2xya_2 - 6xya_3 - 2xyb_2 - 2xyb_3 + 3y^2a_2 - 5y^2a_3 + y^2b_2 - 3y^2b_3 - 4xb_1 + 4ya_1 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$-a_2v_1^2 + 2a_2v_1v_2 + 3a_2v_2^2 - a_3v_1^2 - 6a_3v_1v_2 - 5a_3v_2^2 - 3b_2v_1^2 - 2b_2v_1v_2 + b_2v_2^2 + b_3v_1^2 - 2b_3v_1v_2 - 3b_3v_2^2 + 4a_1v_2 - 4b_1v_1 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}(-a_2 - a_3 - 3b_2 + b_3) v_1^2 + (2a_2 - 6a_3 - 2b_2 - 2b_3) v_1 v_2 \\ - 4b_1 v_1 + (3a_2 - 5a_3 + b_2 - 3b_3) v_2^2 + 4a_1 v_2 = 0\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}4a_1 &= 0\\ -4b_1 &= 0\\ -a_2 - a_3 - 3b_2 + b_3 &= 0\\ 2a_2 - 6a_3 - 2b_2 - 2b_3 &= 0\\ 3a_2 - 5a_3 + b_2 - 3b_3 &= 0\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}a_1 &= 0\\ a_2 &= -2b_2 + b_3\\ a_3 &= -b_2\\ b_1 &= 0\\ b_2 &= b_2\\ b_3 &= b_3\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}\xi &= x\\ \eta &= y\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}\eta &= \eta - \omega(x, y)\, \xi\\ &= y - \left(-\frac{3y + x}{-x + y}\right)(x)\\ &= \frac{-x^2 - 2yx - y^2}{x - y}\\ \xi &= 0\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{-x^2-2yx-y^2}{x-y}} dy \end{aligned}$$

Which results in

$$S = \frac{2x}{x+y} + \ln(x+y)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{3y + x}{-x + y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{3y + x}{(x+y)^2} \\ S_y &= \frac{-x + y}{(x+y)^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{(x+y)\ln(x+y)+2x}{x+y} = c_1$$

Which simplifies to

$$\frac{(x+y)\ln(x+y)+2x}{x+y} = c_1$$

Which gives

$$y = e^{\text{LambertW}\left(-2x\,e^{-c_1}\right)+c_1} - x$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{3y+x}{-x+y}$ 	$R = x$ $S = \frac{(x+y)\ln(x+y) + 2}{x+y}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$y = \mathrm{e}^{\mathrm{LambertW}\left(-2x\,\mathrm{e}^{-c_1}\right)+c_1} - x \tag{1}$$

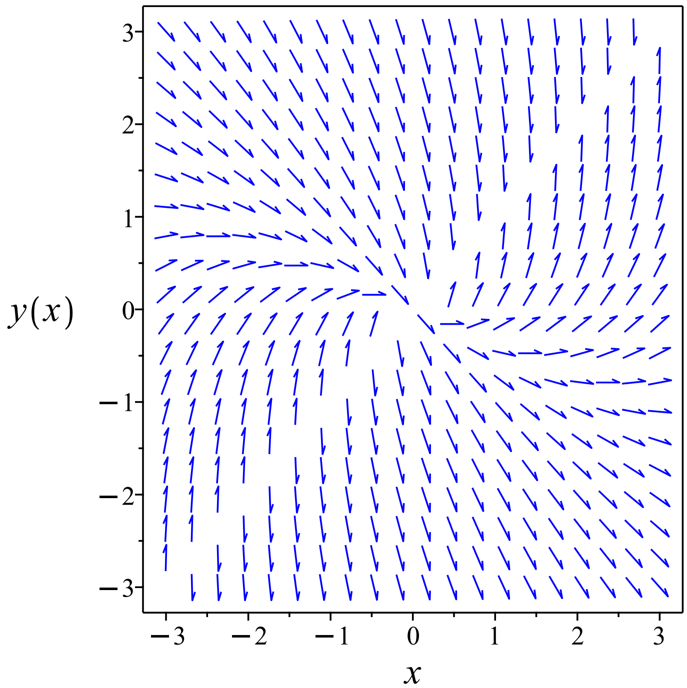

Figure 164: Slope field plot

Verification of solutions

$$y = e^{\text{LambertW}\left(-2x\,e^{-c_1}\right)+c_1} - x$$

Verified OK.

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.2. Page 48
Problem number: 36.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _Riccati]
```

$$\boxed{3yx + y^2 - y'x^2 = -x^2}$$

2.35.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$3u(x)\,x^2 + u(x)^2\,x^2 - (u'(x)\,x + u(x))\,x^2 = -x^2$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{u^2 + 2u + 1}{x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(u) = u^2 + 2u + 1$. Integrating both sides gives

$$\frac{1}{u^2 + 2u + 1}\,du = \frac{1}{x}\,dx$$
$$\int \frac{1}{u^2 + 2u + 1}\,du = \int \frac{1}{x}\,dx$$
$$-\frac{1}{u+1} = \ln(x) + c_2$$

The solution is

$$-\frac{1}{u(x)+1} - \ln(x) - c_2 = 0$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$-\frac{1}{1+\frac{y}{x}} - \ln(x) - c_2 = 0$$
$$\frac{(-c_2 - \ln(x))\,y - x(c_2 + \ln(x) + 1)}{x+y} = 0$$

Which simplifies to

$$-\frac{\ln(x)\,y + c_2 y + x\ln(x) + c_2 x + x}{x+y} = 0$$

Summary

The solution(s) found are the following

$$-\frac{\ln(x)\,y + c_2 y + x\ln(x) + c_2 x + x}{x+y} = 0 \tag{1}$$

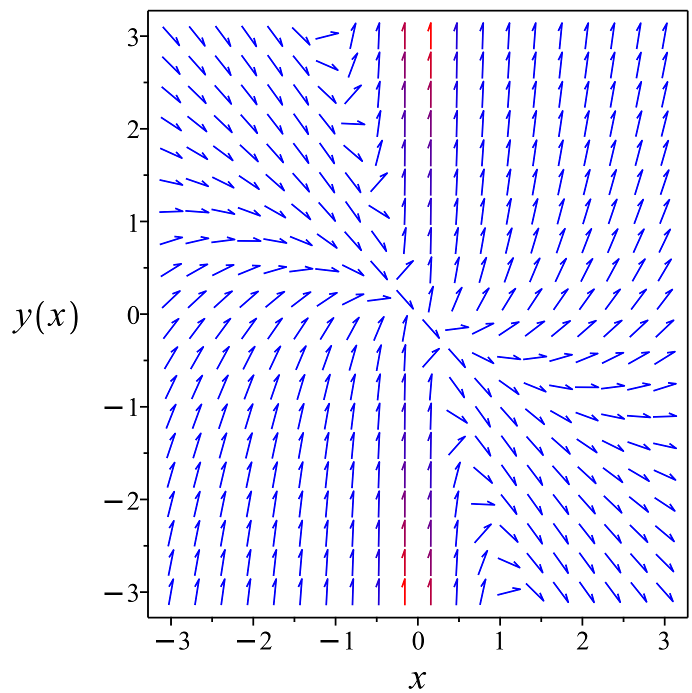

Figure 165: Slope field plot

Verification of solutions

$$-\frac{\ln (x) y+c_2 y+x \ln (x)+c_2 x+x}{x+y}=0$$

Verified OK.

2.35.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= \frac{x^2+3yx+y^2}{x^2} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2+ya_3+a_1 \tag{1E}$$

$$\eta = xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} &b_2 + \frac{(x^2 + 3yx + y^2)(b_3 - a_2)}{x^2} - \frac{(x^2 + 3yx + y^2)^2 a_3}{x^4} \\ &- \left(\frac{2x + 3y}{x^2} - \frac{2(x^2 + 3yx + y^2)}{x^3}\right)(xa_2 + ya_3 + a_1) \\ &- \frac{(3x + 2y)(xb_2 + yb_3 + b_1)}{x^2} = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{x^4 a_2 + x^4 a_3 + 2b_2 x^4 - x^4 b_3 + 6x^3 y a_3 + 2x^3 y b_2 - x^2 y^2 a_2 + 8x^2 y^2 a_3 + x^2 y^2 b_3 + 4x\,y^3 a_3 + y^4 a_3 + 3x^3 b_1 -}{x^4}$$
$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} &-x^4 a_2 - x^4 a_3 - 2b_2 x^4 + x^4 b_3 - 6x^3 y a_3 - 2x^3 y b_2 + x^2 y^2 a_2 - 8x^2 y^2 a_3 \\ &- x^2 y^2 b_3 - 4x\,y^3 a_3 - y^4 a_3 - 3x^3 b_1 + 3x^2 y a_1 - 2x^2 y b_1 + 2x\,y^2 a_1 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned} &-a_2 v_1^4 + a_2 v_1^2 v_2^2 - a_3 v_1^4 - 6a_3 v_1^3 v_2 - 8a_3 v_1^2 v_2^2 - 4a_3 v_1 v_2^3 - a_3 v_2^4 - 2b_2 v_1^4 \\ &- 2b_2 v_1^3 v_2 + b_3 v_1^4 - b_3 v_1^2 v_2^2 + 3a_1 v_1^2 v_2 + 2a_1 v_1 v_2^2 - 3b_1 v_1^3 - 2b_1 v_1^2 v_2 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$(-a_2 - a_3 - 2b_2 + b_3) v_1^4 + (-6a_3 - 2b_2) v_1^3 v_2 - 3b_1 v_1^3 + (a_2 - 8a_3 - b_3) v_1^2 v_2^2 \\ + (3a_1 - 2b_1) v_1^2 v_2 - 4a_3 v_1 v_2^3 + 2a_1 v_1 v_2^2 - a_3 v_2^4 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} 2a_1 &= 0 \\ -4a_3 &= 0 \\ -a_3 &= 0 \\ -3b_1 &= 0 \\ 3a_1 - 2b_1 &= 0 \\ -6a_3 - 2b_2 &= 0 \\ a_2 - 8a_3 - b_3 &= 0 \\ -a_2 - a_3 - 2b_2 + b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= b_3 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= x \\ \eta &= y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= y - \left(\frac{x^2 + 3yx + y^2}{x^2}\right)(x) \\
&= \frac{-x^2 - 2yx - y^2}{x} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-x^2 - 2yx - y^2}{x}} dy
\end{aligned}
$$

Which results in

$$
S = \frac{x}{x + y}
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$
\omega(x, y) = \frac{x^2 + 3yx + y^2}{x^2}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{y}{(x+y)^2} \\
S_y &= -\frac{x}{(x+y)^2}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\ln(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{x}{x+y} = -\ln(x) + c_1$$

Which simplifies to

$$\frac{x}{x+y} = -\ln(x) + c_1$$

Which gives

$$y = -\frac{x(\ln(x) - c_1 + 1)}{\ln(x) - c_1}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^2+3yx+y^2}{x^2}$  	$R = x$ $S = \frac{x}{x+y}$	$\frac{dS}{dR} = -\frac{1}{R}$ 
Summary

The solution(s) found are the following

$$y = -\frac{x(\ln(x) - c_1 + 1)}{\ln(x) - c_1} \tag{1}$$

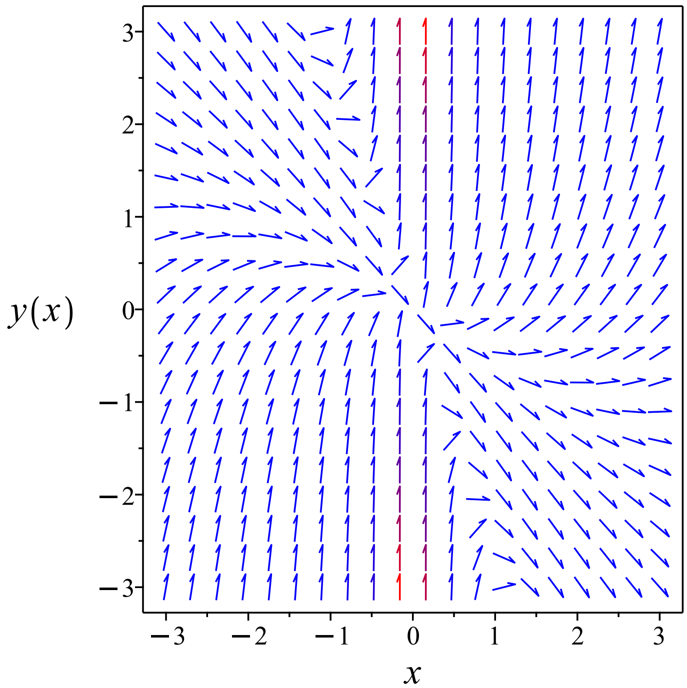

Figure 166: Slope field plot

Verification of solutions

$$y = -\frac{x(\ln(x) - c_1 + 1)}{\ln(x) - c_1}$$

Verified OK.

2.35.3 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{x^2 + 3yx + y^2}{x^2} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = 1 + \frac{3y}{x} + \frac{y^2}{x^2}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 1$, $f_1(x) = \frac{3}{x}$ and $f_2(x) = \frac{1}{x^2}$. Let

$$
\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{\frac{u}{x^2}}
\end{aligned} \tag{1}
$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$
f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}
$$

But

$$
\begin{aligned}
f_2' &= -\frac{2}{x^3} \\
f_1 f_2 &= \frac{3}{x^3} \\
f_2^2 f_0 &= \frac{1}{x^4}
\end{aligned}
$$

Substituting the above terms back in equation (2) gives

$$
\frac{u''(x)}{x^2} - \frac{u'(x)}{x^3} + \frac{u(x)}{x^4} = 0
$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$
u(x) = x(c_2 \ln(x) + c_1)
$$

The above shows that

$$
u'(x) = c_2 \ln(x) + c_1 + c_2
$$

Using the above in (1) gives the solution

$$
y = -\frac{(c_2 \ln(x) + c_1 + c_2)\, x}{c_2 \ln(x) + c_1}
$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$
y = -\frac{(\ln(x) + c_3 + 1)\, x}{\ln(x) + c_3}
$$

Summary

The solution(s) found are the following

$$y = -\frac{(\ln(x) + c_3 + 1)\, x}{\ln(x) + c_3} \tag{1}$$

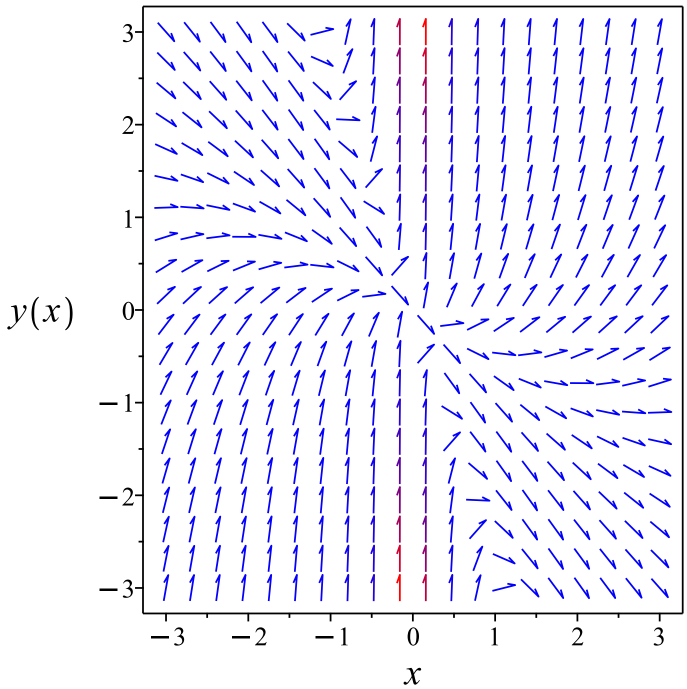

Figure 167: Slope field plot

Verification of solutions

$$y = -\frac{(\ln(x) + c_3 + 1)\, x}{\ln(x) + c_3}$$

Verified OK.

2.36 problem 37

Internal problem ID [514]
Internal file name [`OUTPUT/514_Sunday_June_05_2022_01_42_50_AM_58581911/index.tex`]

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.2. Page 48
Problem number: 37.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"bernoulli", "homogeneousTypeD2", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _Bernoulli]
```

$$\boxed{y' - \frac{x^2 - 3y^2}{2yx} = 0}$$

2.36.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x + u(x) - \frac{x^2 - 3u(x)^2\,x^2}{2u\,(x)\,x^2} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{5u^2 - 1}{2xu} \end{aligned}$$

Where $f(x) = -\frac{1}{2x}$ and $g(u) = \frac{5u^2-1}{u}$. Integrating both sides gives

$$\frac{1}{\frac{5u^2-1}{u}}\, du = -\frac{1}{2x}\, dx$$
$$\int \frac{1}{\frac{5u^2-1}{u}}\, du = \int -\frac{1}{2x}\, dx$$
$$\frac{\ln(5u^2-1)}{10} = -\frac{\ln(x)}{2} + c_2$$

Raising both side to exponential gives

$$\left(5u^2-1\right)^{\frac{1}{10}} = \mathrm{e}^{-\frac{\ln(x)}{2}+c_2}$$

Which simplifies to

$$\left(5u^2-1\right)^{\frac{1}{10}} = \frac{c_3}{\sqrt{x}}$$

Which simplifies to

$$\left(5u(x)^2-1\right)^{\frac{1}{10}} = \frac{c_3\mathrm{e}^{c_2}}{\sqrt{x}}$$

The solution is

$$\left(5u(x)^2-1\right)^{\frac{1}{10}} = \frac{c_3\mathrm{e}^{c_2}}{\sqrt{x}}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\left(\frac{5y^2}{x^2}-1\right)^{\frac{1}{10}} = \frac{c_3\mathrm{e}^{c_2}}{\sqrt{x}}$$
$$\left(\frac{5y^2-x^2}{x^2}\right)^{\frac{1}{10}} = \frac{c_3\mathrm{e}^{c_2}}{\sqrt{x}}$$

Which simplifies to

$$\left(-\frac{-5y^2+x^2}{x^2}\right)^{\frac{1}{10}} = \frac{c_3\mathrm{e}^{c_2}}{\sqrt{x}}$$

Summary

The solution(s) found are the following

$$\left(-\frac{-5y^2+x^2}{x^2}\right)^{\frac{1}{10}} = \frac{c_3\mathrm{e}^{c_2}}{\sqrt{x}} \tag{1}$$

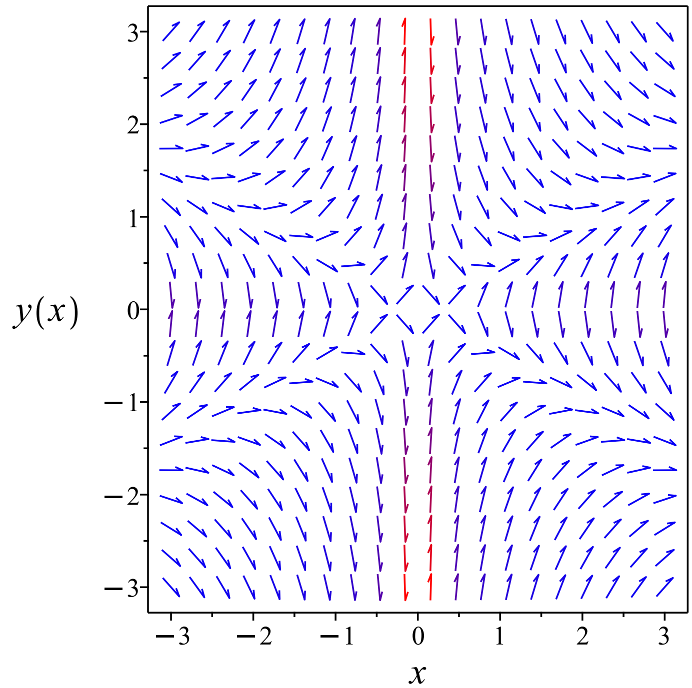

Figure 168: Slope field plot

Verification of solutions

$$
\left(-\frac{-5y^2+x^2}{x^2}\right)^{\frac{1}{10}} = \frac{c_3 e^{c_2}}{\sqrt{x}}
$$

Verified OK.

2.36.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{-x^2+3y^2}{2yx} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 178: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \frac{1}{x^3 y}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{x^3 y}} dy \end{aligned}$$

Which results in

$$S = \frac{x^3 y^2}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{-x^2 + 3y^2}{2yx}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{3x^2 y^2}{2} \\ S_y &= y\, x^3 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{x^4}{2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{R^4}{2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^5}{10} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{x^3y^2}{2} = \frac{x^5}{10} + c_1$$

Which simplifies to

$$\frac{x^3y^2}{2} = \frac{x^5}{10} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{-x^2+3y^2}{2yx}$ 	$R = x$ $S = \frac{x^3y^2}{2}$	$\frac{dS}{dR} = \frac{R^4}{2}$ 
Summary

The solution(s) found are the following

$$\frac{x^3y^2}{2} = \frac{x^5}{10} + c_1 \tag{1}$$

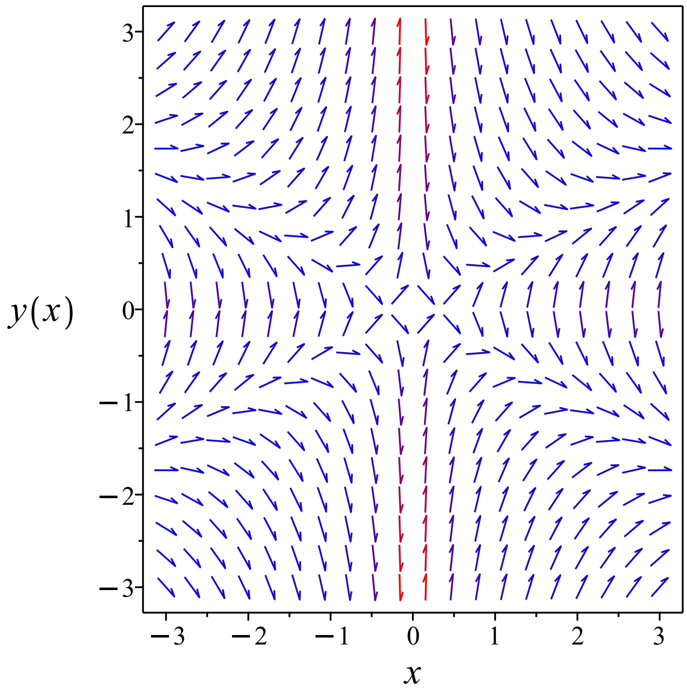

Figure 169: Slope field plot

Verification of solutions

$$\frac{x^3y^2}{2} = \frac{x^5}{10} + c_1$$

Verified OK.

2.36.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= -\frac{-x^2 + 3y^2}{2yx} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = -\frac{3}{2x}y + \frac{x}{2}\frac{1}{y} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= -\frac{3}{2x} \\ f_1(x) &= \frac{x}{2} \\ n &= -1 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y}$ gives

$$y'y = -\frac{3y^2}{2x} + \frac{x}{2} \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= y^2 \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = 2yy' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} \frac{w'(x)}{2} &= -\frac{3w(x)}{2x} + \frac{x}{2} \\ w' &= -\frac{3w}{x} + x \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= \frac{3}{x} \\ q(x) &= x \end{aligned}$$

Hence the ode is

$$w'(x) + \frac{3w(x)}{x} = x$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{3}{x}dx} \\ &= x^3\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu w) &= (\mu)(x) \\ \frac{\mathrm{d}}{\mathrm{d}x}(x^3 w) &= (x^3)(x) \\ \mathrm{d}(x^3 w) &= x^4 \,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}x^3 w &= \int x^4 \,\mathrm{d}x \\ x^3 w &= \frac{x^5}{5} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = x^3$ results in

$$w(x) = \frac{x^2}{5} + \frac{c_1}{x^3}$$

Replacing w in the above by y^2 using equation (5) gives the final solution.

$$y^2 = \frac{x^2}{5} + \frac{c_1}{x^3}$$

Solving for y gives

$$\begin{aligned}y(x) &= \frac{\sqrt{5}\,\sqrt{x\,(x^5 + 5c_1)}}{5x^2} \\ y(x) &= -\frac{\sqrt{5}\,\sqrt{x\,(x^5 + 5c_1)}}{5x^2}\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{5}\,\sqrt{x\,(x^5 + 5c_1)}}{5x^2} \tag{1}$$

$$y = -\frac{\sqrt{5}\,\sqrt{x\,(x^5 + 5c_1)}}{5x^2} \tag{2}$$

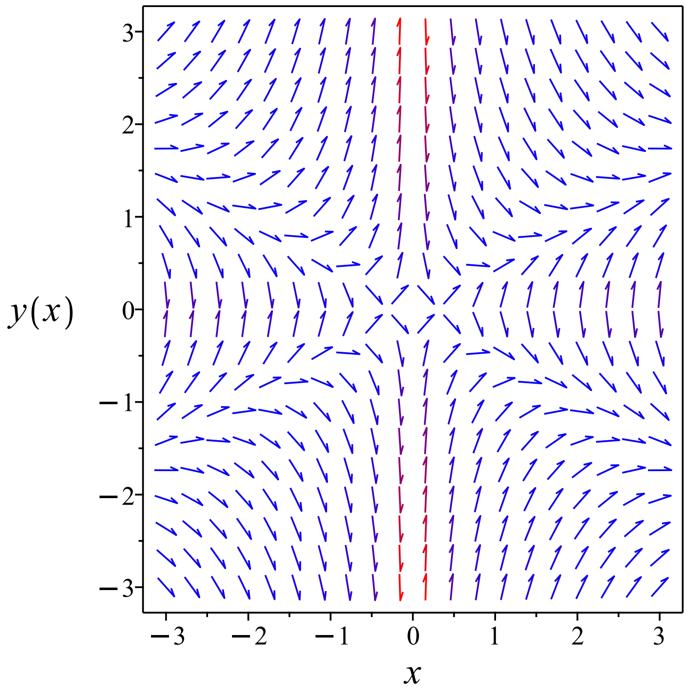

Figure 170: Slope field plot

Verification of solutions

$$y = \frac{\sqrt{5}\,\sqrt{x\,(x^5+5c_1)}}{5x^2}$$

Verified OK.

$$y = -\frac{\sqrt{5}\,\sqrt{x\,(x^5+5c_1)}}{5x^2}$$

Verified OK.

2.36.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\,\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(2yx)\,\mathrm{d}y = (x^2 - 3y^2)\,\mathrm{d}x$$
$$(-x^2 + 3y^2)\,\mathrm{d}x + (2yx)\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -x^2 + 3y^2$$
$$N(x, y) = 2yx$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}(-x^2 + 3y^2)$$
$$= 6y$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2yx) \\
&= 2y
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{2yx}((6y) - (2y)) \\
&= \frac{2}{x}
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int \frac{2}{x} \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{2\ln(x)} \\
&= x^2
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= x^2(-x^2 + 3y^2) \\
&= -x^2(x^2 - 3y^2)
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= x^2(2yx) \\
&= 2y\,x^3
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(-x^2(x^2 - 3y^2)\right) + \left(2y\,x^3\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= \overline{M} && (1)\\
\frac{\partial \phi}{\partial y} &= \overline{N} && (2)
\end{aligned}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int \overline{M} \,\mathrm{d}x\\
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int -x^2(x^2 - 3y^2) \,\mathrm{d}x\\
\phi &= -\frac{1}{5}x^5 + x^3y^2 + f(y) && (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 2y\,x^3 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2y\,x^3$. Therefore equation (4) becomes

$$
2y\,x^3 = 2y\,x^3 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = 0
$$

Therefore

$$
f(y) = c_1
$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$
\phi = -\frac{1}{5}x^5 + x^3y^2 + c_1
$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$
c_1 = -\frac{1}{5}x^5 + x^3y^2
$$

Summary

The solution(s) found are the following

$$-\frac{x^5}{5}+x^3y^2=c_1 \tag{1}$$

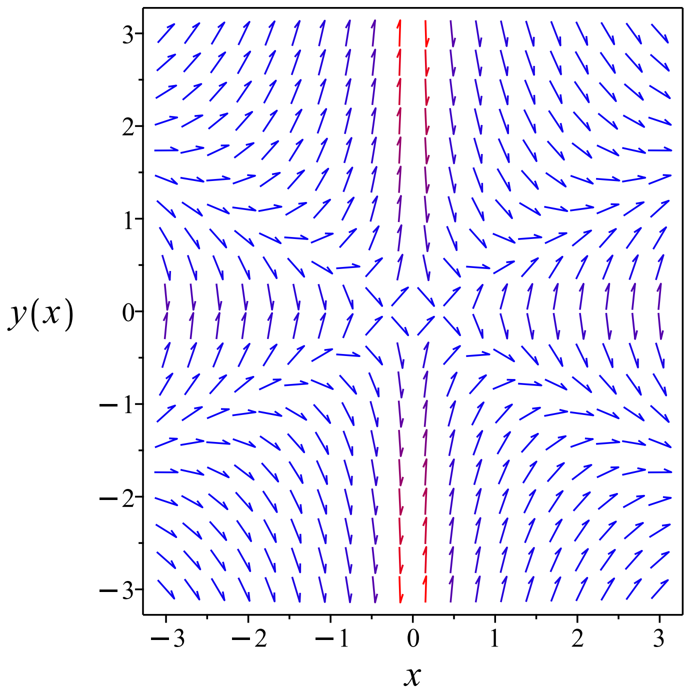

Figure 171: Slope field plot

Verification of solutions

$$-\frac{x^5}{5}+x^3y^2=c_1$$

Verified OK.

Section: Section 2.2. Page 48
Problem number: 38.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"bernoulli", "homogeneousTypeD2", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _Bernoulli]
```

$$\boxed{y' - \frac{3y^2 - x^2}{2yx} = 0}$$

2.37.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x + u(x) - \frac{3u(x)^2\,x^2 - x^2}{2u\,(x)\,x^2} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{u^2-1}{2xu} \end{aligned}$$

Where $f(x) = \frac{1}{2x}$ and $g(u) = \frac{u^2-1}{u}$. Integrating both sides gives

$$\frac{1}{\frac{u^2-1}{u}}\,du = \frac{1}{2x}\,dx$$
$$\int \frac{1}{\frac{u^2-1}{u}}\,du = \int \frac{1}{2x}\,dx$$
$$\frac{\ln(u-1)}{2} + \frac{\ln(u+1)}{2} = \frac{\ln(x)}{2} + c_2$$

The above can be written as

$$\left(\frac{1}{2}\right)(\ln(u-1) + \ln(u+1)) = \frac{\ln(x)}{2} + 2c_2$$
$$\ln(u-1) + \ln(u+1) = (2)\left(\frac{\ln(x)}{2} + 2c_2\right)$$
$$= \ln(x) + 4c_2$$

Raising both side to exponential gives

$$e^{\ln(u-1)+\ln(u+1)} = e^{\ln(x)+2c_2}$$

Which simplifies to

$$u^2 - 1 = 2c_2 x$$
$$= c_3 x$$

The solution is

$$u(x)^2 - 1 = c_3 x$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\frac{y^2}{x^2} - 1 = c_3 x$$
$$\frac{y^2}{x^2} - 1 = c_3 x$$

Summary
The solution(s) found are the following

$$\frac{y^2}{x^2} - 1 = c_3 x \tag{1}$$

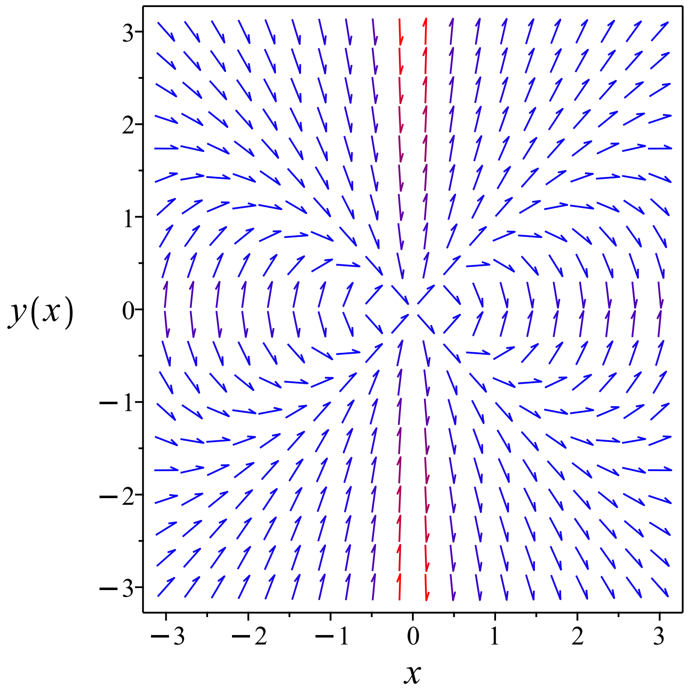

Figure 172: Slope field plot

Verification of solutions

$$\frac{y^2}{x^2} - 1 = c_3 x$$

Verified OK.

2.37.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{-x^2 + 3y^2}{2yx}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 180: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \frac{x^3}{y}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x^3}{y}} dy \end{aligned}$$

Which results in

$$S = \frac{y^2}{2x^3}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{-x^2 + 3y^2}{2yx}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{3y^2}{2x^4} \\ S_y &= \frac{y}{x^3} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{2x^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{2R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{1}{2R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y^2}{2x^3} = \frac{1}{2x} + c_1$$

Which simplifies to

$$\frac{y^2}{2x^3} = \frac{1}{2x} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{-x^2+3y^2}{2yx}$ 	$R = x$ $S = \frac{y^2}{2x^3}$	$\frac{dS}{dR} = -\frac{1}{2R^2}$ 
Summary

The solution(s) found are the following

$$\frac{y^2}{2x^3} = \frac{1}{2x} + c_1 \tag{1}$$

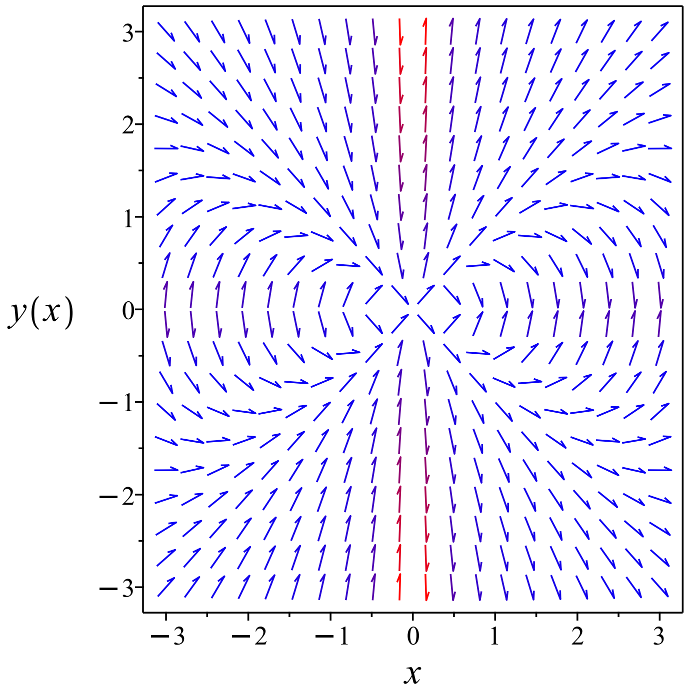

Figure 173: Slope field plot

Verification of solutions

$$\frac{y^2}{2x^3} = \frac{1}{2x} + c_1$$

Verified OK.

2.37.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{-x^2+3y^2}{2yx} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = \frac{3}{2x}y - \frac{x}{2}\frac{1}{y} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$
\begin{aligned}
f_0(x) &= \frac{3}{2x} \\
f_1(x) &= -\frac{x}{2} \\
n &= -1
\end{aligned}
$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y}$ gives

$$
y'y = \frac{3y^2}{2x} - \frac{x}{2} \tag{4}
$$

Let

$$
\begin{aligned}
w &= y^{1-n} \\
&= y^2
\end{aligned} \tag{5}
$$

Taking derivative of equation (5) w.r.t x gives

$$
w' = 2yy' \tag{6}
$$

Substituting equations (5) and (6) into equation (4) gives

$$
\begin{aligned}
\frac{w'(x)}{2} &= \frac{3w(x)}{2x} - \frac{x}{2} \\
w' &= \frac{3w}{x} - x
\end{aligned} \tag{7}
$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
w'(x) + p(x)w(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{3}{x} \\
q(x) &= -x
\end{aligned}
$$

Hence the ode is

$$w'(x) - \frac{3w(x)}{x} = -x$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{3}{x}dx} \\ &= \frac{1}{x^3}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu w) &= (\mu)(-x) \\ \frac{d}{dx}\left(\frac{w}{x^3}\right) &= \left(\frac{1}{x^3}\right)(-x) \\ d\left(\frac{w}{x^3}\right) &= \left(-\frac{1}{x^2}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{w}{x^3} &= \int -\frac{1}{x^2}\, dx \\ \frac{w}{x^3} &= \frac{1}{x} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^3}$ results in

$$w(x) = c_1 x^3 + x^2$$

Replacing w in the above by y^2 using equation (5) gives the final solution.

$$y^2 = c_1 x^3 + x^2$$

Solving for y gives

$$\begin{aligned}y(x) &= \sqrt{c_1 x + 1}\, x \\ y(x) &= -\sqrt{c_1 x + 1}\, x\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \sqrt{c_1 x + 1}\, x \tag{1}$$

$$y = -\sqrt{c_1 x + 1}\, x \tag{2}$$

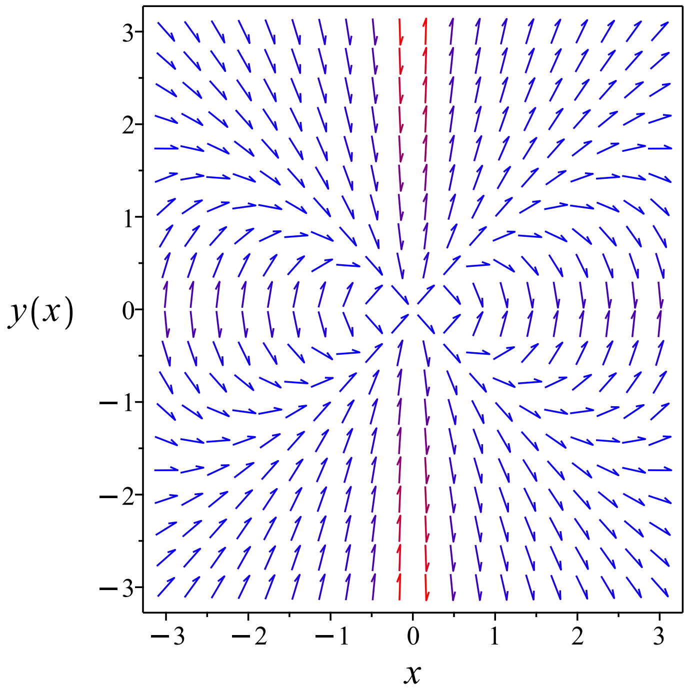

Figure 174: Slope field plot

$$y = \sqrt{c_1 x + 1}\, x$$

Verified OK.

$$y = -\sqrt{c_1 x + 1}\, x$$

Verified OK.

2.37.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx} \phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(2yx)\,\mathrm{d}y &= \left(-x^2 + 3y^2\right)\mathrm{d}x \\ \left(x^2 - 3y^2\right)\mathrm{d}x + (2yx)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= x^2 - 3y^2 \\ N(x, y) &= 2yx\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(x^2 - 3y^2\right) \\ &= -6y\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2yx) \\
&= 2y
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{2yx}((-6y) - (2y)) \\
&= -\frac{4}{x}
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int -\frac{4}{x} \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-4\ln(x)} \\
&= \frac{1}{x^4}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \frac{1}{x^4}(x^2 - 3y^2) \\
&= \frac{x^2 - 3y^2}{x^4}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{x^4}(2yx) \\
&= \frac{2y}{x^3}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$
$$\left(\frac{x^2 - 3y^2}{x^4}\right) + \left(\frac{2y}{x^3}\right)\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \frac{x^2 - 3y^2}{x^4}\,\mathrm{d}x$$
$$\phi = -\frac{1}{x} + \frac{y^2}{x^3} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{2y}{x^3} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{2y}{x^3}$. Therefore equation (4) becomes

$$\frac{2y}{x^3} = \frac{2y}{x^3} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{1}{x} + \frac{y^2}{x^3} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{1}{x} + \frac{y^2}{x^3}$$

Summary

The solution(s) found are the following

$$-\frac{1}{x} + \frac{y^2}{x^3} = c_1 \tag{1}$$

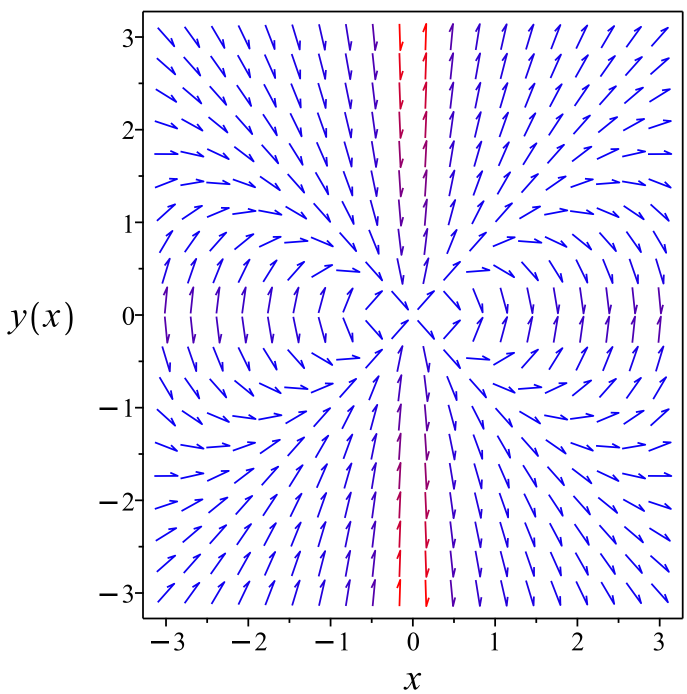

Figure 175: Slope field plot

Verification of solutions

$$-\frac{1}{x} + \frac{y^2}{x^3} = c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{\ln(t)\, y + (t-3)\, y' = 2t}$$

3.1.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \frac{\ln(t)}{t-3}$$
$$q(t) = \frac{2t}{t-3}$$

Hence the ode is

$$y' + \frac{\ln(t)\, y}{t-3} = \frac{2t}{t-3}$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int \frac{\ln(t)}{t-3}dt}$$

The ode becomes

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}t}(\mu y) &= (\mu)\left(\frac{2t}{t-3}\right) \\
\frac{\mathrm{d}}{\mathrm{d}t}\left(\mathrm{e}^{\int \frac{\ln(t)}{t-3}dt} y\right) &= \left(\mathrm{e}^{\int \frac{\ln(t)}{t-3}dt}\right)\left(\frac{2t}{t-3}\right) \\
\mathrm{d}\left(\mathrm{e}^{\int \frac{\ln(t)}{t-3}dt} y\right) &= \left(\frac{2t\,\mathrm{e}^{\int \frac{\ln(t)}{t-3}dt}}{t-3}\right)\mathrm{d}t
\end{aligned}$$

Integrating gives

$$\begin{aligned}
\mathrm{e}^{\int \frac{\ln(t)}{t-3}dt} y &= \int \frac{2t\,\mathrm{e}^{\int \frac{\ln(t)}{t-3}dt}}{t-3}\,\mathrm{d}t \\
\mathrm{e}^{\int \frac{\ln(t)}{t-3}dt} y &= \int \frac{2t\,\mathrm{e}^{\int \frac{\ln(t)}{t-3}dt}}{t-3}dt + c_1
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\int \frac{\ln(t)}{t-3}dt}$ results in

$$y = \mathrm{e}^{-\left(\int \frac{\ln(t)}{t-3}dt\right)}\left(\int \frac{2t\,\mathrm{e}^{\int \frac{\ln(t)}{t-3}dt}}{t-3}dt\right) + c_1 \mathrm{e}^{-\left(\int \frac{\ln(t)}{t-3}dt\right)}$$

which simplifies to

$$y = \mathrm{e}^{-\left(\int \frac{\ln(t)}{t-3}dt\right)}\left(2\left(\int \frac{t\,\mathrm{e}^{\int \frac{\ln(t)}{t-3}dt}}{t-3}dt\right) + c_1\right)$$

Which can be simplified to become

$$y = \mathrm{e}^{\int -\frac{\ln(t)}{t-3}dt}\left(2\left(\int \frac{t\,\mathrm{e}^{\int \frac{\ln(t)}{t-3}dt}}{t-3}dt\right) + c_1\right)$$

<u>Summary</u>

The solution(s) found are the following

$$y = \mathrm{e}^{\int -\frac{\ln(t)}{t-3}dt}\left(2\left(\int \frac{t\,\mathrm{e}^{\int \frac{\ln(t)}{t-3}dt}}{t-3}dt\right) + c_1\right) \tag{1}$$

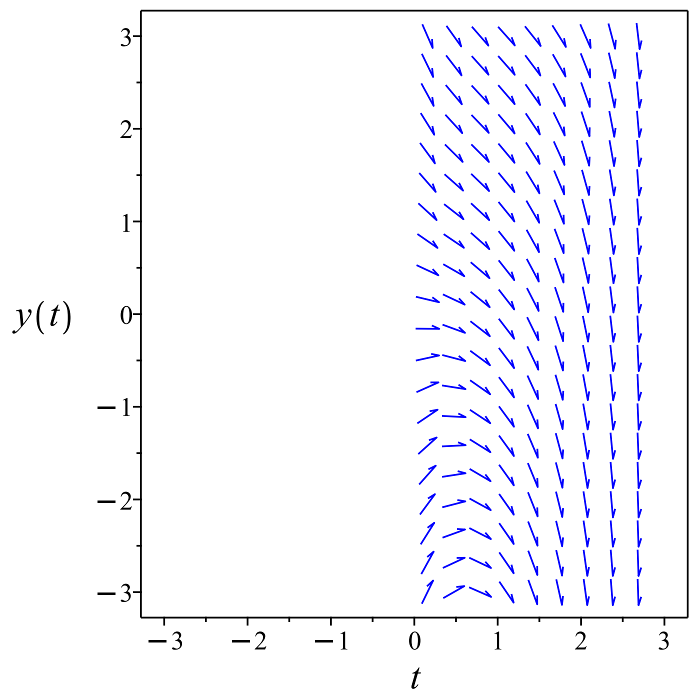

Figure 176: Slope field plot

Verification of solutions

$$y = e^{\int -\frac{\ln(t)}{t-3}dt} \left(2\left(\int \frac{t\, e^{\int \frac{\ln(t)}{t-3}dt}}{t-3}dt\right) + c_1\right)$$

Verified OK.

3.1.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{\ln(t)\, y - 2t}{t-3}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 182: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \mathrm{e}^{-\left(\ln(t) - \ln\left(\frac{t}{3}\right)\right) \ln\left(-\frac{t}{3}+1\right) + \operatorname{dilog}\left(\frac{t}{3}\right)}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{-\left(\ln(t)-\ln\left(\frac{t}{3}\right)\right)\ln\left(-\frac{t}{3}+1\right)+\mathrm{dilog}\left(\frac{t}{3}\right)}} dy \end{aligned}$$

Which results in

$$S = \mathrm{e}^{-\ln\left(\frac{1}{3}\right)\ln\left(-\frac{t}{3}+1\right)-\mathrm{dilog}\left(\frac{t}{3}\right)} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y) S_y}{R_t + \omega(t,y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = -\frac{\ln(t)\, y - 2t}{t-3}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= -(-t+3)^{-1+\ln(3)}\, y \ln(t)\, \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{t}{3}\right)} \\ S_y &= (-t+3)^{\ln(3)}\, \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{t}{3}\right)} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -2\,\mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{t}{3}\right)} (-t+3)^{-1+\ln(3)}\, t \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -2\,\mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{R}{3}\right)} (-R+3)^{-1+\ln(3)}\, R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \int -2\,\mathrm{e}^{-\ln(3)^2 - \mathrm{dilog}\left(\frac{R}{3}\right)} (-R+3)^{-1+\ln(3)} R dR + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$y(-t+3)^{\ln(3)}\,\mathrm{e}^{-\ln(3)^2 - \mathrm{dilog}\left(\frac{t}{3}\right)} = \int -2\,\mathrm{e}^{-\ln(3)^2 - \mathrm{dilog}\left(\frac{t}{3}\right)} (-t+3)^{-1+\ln(3)} t dt + c_1$$

Which simplifies to

$$y(-t+3)^{\ln(3)}\,\mathrm{e}^{-\ln(3)^2 - \mathrm{dilog}\left(\frac{t}{3}\right)} = \int -2\,\mathrm{e}^{-\ln(3)^2 - \mathrm{dilog}\left(\frac{t}{3}\right)} (-t+3)^{-1+\ln(3)} t dt + c_1$$

Which gives

$$y = \left(\int -2\,\mathrm{e}^{-\ln(3)^2 - \mathrm{dilog}\left(\frac{t}{3}\right)} (-t+3)^{-1+\ln(3)} t dt + c_1\right) (-t+3)^{-\ln(3)}\,\mathrm{e}^{\ln(3)^2 + \mathrm{dilog}\left(\frac{t}{3}\right)}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{\ln(t)y-2t}{t-3}$ 	$R = t$ $S = y(-t+3)^{\ln(3)}\,\mathrm{e}^{-\ln(3)^2}$	$\frac{dS}{dR} = -2\,\mathrm{e}^{-\ln(3)^2 - \mathrm{dilog}\left(\frac{R}{3}\right)} (-R+3)^{-1+\ln(3)} R$ 
Summary
The solution(s) found are the following

$$y = \left(\int -2\,\mathrm{e}^{-\ln(3)^2-\operatorname{dilog}\left(\frac{t}{3}\right)}(-t+3)^{-1+\ln(3)}\,t\,dt + c_1\right)(-t+3)^{-\ln(3)}\,\mathrm{e}^{\ln(3)^2+\operatorname{dilog}\left(\frac{t}{3}\right)} \tag{1}$$

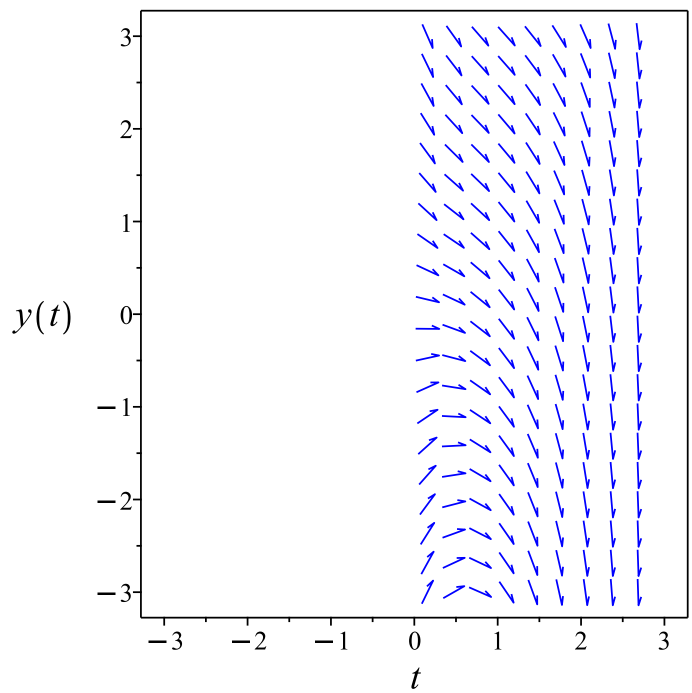

Figure 177: Slope field plot

Verification of solutions

$$y = \left(\int -2\,\mathrm{e}^{-\ln(3)^2-\operatorname{dilog}\left(\frac{t}{3}\right)}(-t+3)^{-1+\ln(3)}\,t\,dt + c_1\right)(-t+3)^{-\ln(3)}\,\mathrm{e}^{\ln(3)^2+\operatorname{dilog}\left(\frac{t}{3}\right)}$$

Verified OK.

3.1.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the

ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x}&=M\\ \frac{\partial \phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t+N(t,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(t-3)\,\mathrm{d}y&=(-\ln(t)\,y+2t)\,\mathrm{d}t\\ (\ln(t)\,y-2t)\,\mathrm{d}t+(t-3)\,\mathrm{d}y&=0 \qquad \text{(2A)}\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t,y)&=\ln(t)\,y-2t\\ N(t,y)&=t-3\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial t}$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(\ln(t)\, y - 2t) \\
&= \ln(t)
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(t - 3) \\
&= 1
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\
&= \frac{1}{t-3}((\ln(t)) - (1)) \\
&= \frac{\ln(t) - 1}{t-3}
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}t} \\
&= e^{\int \frac{\ln(t)-1}{t-3} \, \mathrm{d}t}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{(\ln(t)-\ln(\frac{t}{3}))\ln(-\frac{t}{3}+1)-\mathrm{dilog}(\frac{t}{3})-\ln(t-3)} \\
&= -(-t+3)^{-1+\ln(3)}\, \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}(\frac{t}{3})}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= -(-t+3)^{-1+\ln(3)}\, \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}(\frac{t}{3})}(\ln(t)\, y - 2t) \\
&= (-t+3)^{-1+\ln(3)}\,(-\ln(t)\, y + 2t)\, \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}(\frac{t}{3})}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= -(-t+3)^{-1+\ln(3)}\, \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}(\frac{t}{3})}(t-3) \\
&= (-t+3)^{\ln(3)}\, \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}(\frac{t}{3})}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} = 0$$

$$\left(\left(-t+3\right)^{-1+\ln(3)} \left(-\ln\left(t\right) y + 2t\right) \mathrm{e}^{-\ln(3)^{2}-\mathrm{dilog}\left(\frac{t}{3}\right)}\right) + \left(\left(-t+3\right)^{\ln(3)} \mathrm{e}^{-\ln(3)^{2}-\mathrm{dilog}\left(\frac{t}{3}\right)}\right) \frac{\mathrm{d}y}{\mathrm{d}t} = 0$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial\phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial\phi}{\partial t}\,\mathrm{d}t = \int \overline{M}\,\mathrm{d}t$$

$$\int \frac{\partial\phi}{\partial t}\,\mathrm{d}t = \int \left(-t+3\right)^{-1+\ln(3)} \left(-\ln\left(t\right) y + 2t\right) \mathrm{e}^{-\ln(3)^{2}-\mathrm{dilog}\left(\frac{t}{3}\right)}\,\mathrm{d}t$$

$$\phi = \int^{t} \left(-\_a+3\right)^{-1+\ln(3)} \left(-\ln\left(\_a\right) y + 2\_a\right) \mathrm{e}^{-\ln(3)^{2}-\mathrm{dilog}\left(\frac{\_a}{3}\right)} d\_a + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial\phi}{\partial y} = -\left(\int^{t} \left(-\_a+3\right)^{-1+\ln(3)} \ln\left(\_a\right) \mathrm{e}^{-\ln(3)^{2}-\mathrm{dilog}\left(\frac{\_a}{3}\right)} d\_a\right) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = \left(-t+3\right)^{\ln(3)} \mathrm{e}^{-\ln(3)^{2}-\mathrm{dilog}\left(\frac{t}{3}\right)}$. Therefore equation (4) becomes

$$\left(-t+3\right)^{\ln(3)} \mathrm{e}^{-\ln(3)^{2}-\mathrm{dilog}\left(\frac{t}{3}\right)} = -\left(\int^{t} \left(-\_a+3\right)^{-1+\ln(3)} \ln\left(\_a\right) \mathrm{e}^{-\ln(3)^{2}-\mathrm{dilog}\left(\frac{\_a}{3}\right)} d\_a\right) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \left(-t+3\right)^{\ln(3)} \mathrm{e}^{-\ln(3)^{2}-\mathrm{dilog}\left(\frac{t}{3}\right)} + \int^{t} \left(-\_a+3\right)^{-1+\ln(3)} \ln\left(\_a\right) \mathrm{e}^{-\ln(3)^{2}-\mathrm{dilog}\left(\frac{\_a}{3}\right)} d\_a$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\left(-t+3\right)^{\ln(3)} \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{t}{3}\right)} + \int^{t} \left(-\_a+3\right)^{-1+\ln(3)} \ln\left(\_a\right) \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{\_a}{3}\right)} d\_a\right) \mathrm{d}y$$

$$f(y) = \left(\left(-t+3\right)^{\ln(3)} \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{t}{3}\right)} + \int^{t} \left(-\_a+3\right)^{-1+\ln(3)} \ln\left(\_a\right) \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{\_a}{3}\right)} d\_a\right) y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \int^{t} \left(-\_a+3\right)^{-1+\ln(3)} \left(-\ln\left(\_a\right) y + 2\_a\right) \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{\_a}{3}\right)} d\_a + \left(\left(-t+3\right)^{\ln(3)} \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{t}{3}\right)} + \int^{t} \left(-\_a+3\right)^{-1+\ln(3)} \ln\left(\_a\right) \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{\_a}{3}\right)} d\_a\right) y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \int^{t} \left(-\_a+3\right)^{-1+\ln(3)} \left(-\ln\left(\_a\right) y + 2\_a\right) \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{\_a}{3}\right)} d\_a + \left(\left(-t+3\right)^{\ln(3)} \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{t}{3}\right)} + \int^{t} \left(-\_a+3\right)^{-1+\ln(3)} \ln\left(\_a\right) \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{\_a}{3}\right)} d\_a\right) y$$

Summary

The solution(s) found are the following

$$\int^{t} \left(-\_a+3\right)^{-1+\ln(3)} \left(-\ln\left(\_a\right) y + 2\_a\right) \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{\_a}{3}\right)} d\_a + \left(\left(-t+3\right)^{\ln(3)} \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{t}{3}\right)} + \int^{t} \left(-\_a+3\right)^{-1+\ln(3)} \ln\left(\_a\right) \mathrm{e}^{-\ln(3)^2-\mathrm{dilog}\left(\frac{\_a}{3}\right)} d\_a\right) y = c_1 \tag{1}$$

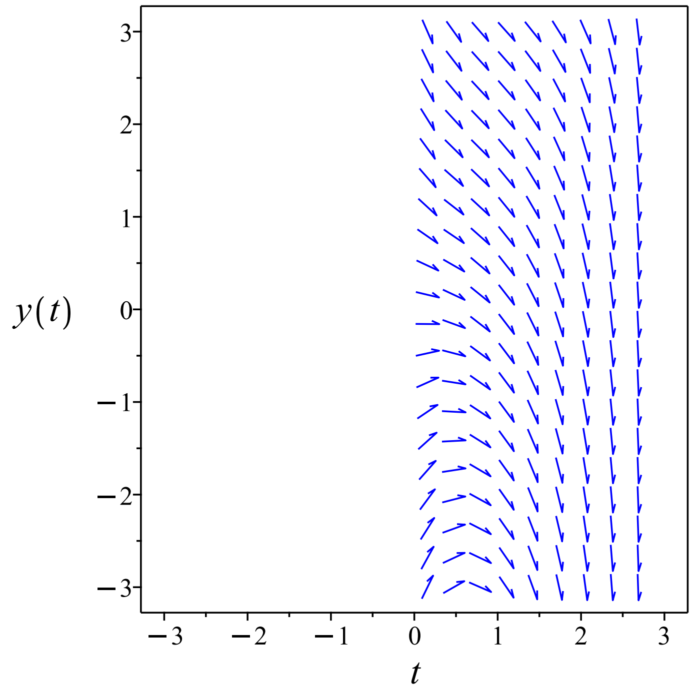

Figure 178: Slope field plot

Verification of solutions

$$\int^{t} (-\_a+3)^{-1+\ln(3)} \left(-\ln(\_a)\, y+2\_a\right) \mathrm{e}^{-\ln(3)^{2}-\operatorname{dilog}\left(\frac{\_a}{3}\right)} d\_a + \left((-t+3)^{\ln(3)} \mathrm{e}^{-\ln(3)^{2}-\operatorname{dilog}\left(\frac{t}{3}\right)} + \int^{t} (-\_a+3)^{-1+\ln(3)} \ln(\_a)\, \mathrm{e}^{-\ln(3)^{2}-\operatorname{dilog}\left(\frac{\_a}{3}\right)} d\_a\right) y = c_1$$

Verified OK.

3.1.4 Maple step by step solution

Let's solve

$\ln(t)\, y+(t-3)\, y' = 2t$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{\ln(t) y}{t-3}+\frac{2t}{t-3}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $$y' + \frac{\ln(t)y}{t-3} = \frac{2t}{t-3}$$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $$\mu(t)\left(y' + \frac{\ln(t)y}{t-3}\right) = \frac{2\mu(t)t}{t-3}$$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

  $$\mu(t)\left(y' + \frac{\ln(t)y}{t-3}\right) = \mu'(t)\,y + \mu(t)\,y'$$

- Isolate $\mu'(t)$

  $$\mu'(t) = \frac{\mu(t)\ln(t)}{t-3}$$

- Solve to find the integrating factor

  $$\mu(t) = 3^{\ln(-t+3)}\mathrm{e}^{-\ln(3)^2 - \mathit{dilog}\left(\frac{t}{3}\right)}$$

- Integrate both sides with respect to t

  $$\int \left(\frac{d}{dt}(\mu(t)\,y)\right) dt = \int \frac{2\mu(t)t}{t-3} dt + c_1$$

- Evaluate the integral on the lhs

  $$\mu(t)\,y = \int \frac{2\mu(t)t}{t-3} dt + c_1$$

- Solve for y

  $$y = \frac{\int \frac{2\mu(t)t}{t-3} dt + c_1}{\mu(t)}$$

- Substitute $\mu(t) = 3^{\ln(-t+3)}\mathrm{e}^{-\ln(3)^2 - \mathit{dilog}\left(\frac{t}{3}\right)}$

  $$y = \frac{\int \frac{2\,3^{\ln(-t+3)}\mathrm{e}^{-\ln(3)^2 - \mathit{dilog}\left(\frac{t}{3}\right)}t}{t-3} dt + c_1}{3^{\ln(-t+3)}\mathrm{e}^{-\ln(3)^2 - \mathit{dilog}\left(\frac{t}{3}\right)}}$$

- Simplify

  $$y = \left(-2\left(\int \mathrm{e}^{-\ln(3)^2 - \mathit{dilog}\left(\frac{t}{3}\right)}(-t+3)^{-1+\ln(3)}\,t dt\right) + c_1\right)(-t+3)^{-\ln(3)}\,\mathrm{e}^{\ln(3)^2 + \mathit{dilog}\left(\frac{t}{3}\right)}$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y + (t-4)\, t y' = 0}$$

With initial conditions

$$[y(2) = 1]$$

3.2.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$\begin{aligned} p(t) &= \frac{1}{(t-4)\,t} \\ q(t) &= 0 \end{aligned}$$

Hence the ode is

$$y' + \frac{y}{(t-4)\,t} = 0$$

The domain of $p(t) = \frac{1}{(t-4)t}$ is

$$\{-\infty \leq t < 0, 0 < t < 4, 4 < t \leq \infty\}$$

And the point $t_0 = 2$ is inside this domain. Hence solution exists and is unique.

3.2.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(t,y) \\ &= f(t)g(y) \\ &= -\frac{y}{(t-4)\,t} \end{aligned}$$

Where $f(t) = -\frac{1}{(t-4)t}$ and $g(y) = y$. Integrating both sides gives

$$\begin{aligned} \frac{1}{y}\,dy &= -\frac{1}{(t-4)\,t}\,dt \\ \int \frac{1}{y}\,dy &= \int -\frac{1}{(t-4)\,t}\,dt \\ \ln(y) &= -\frac{\ln(t-4)}{4} + \frac{\ln(t)}{4} + c_1 \\ y &= \mathrm{e}^{-\frac{\ln(t-4)}{4} + \frac{\ln(t)}{4} + c_1} \\ &= c_1 \mathrm{e}^{-\frac{\ln(t-4)}{4} + \frac{\ln(t)}{4}} \end{aligned}$$

Which can be simplified to become

$$y = \frac{c_1 t^{\frac{1}{4}}}{(t-4)^{\frac{1}{4}}}$$

Initial conditions are used to solve for c_1. Substituting $t = 2$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{\sqrt{2}\, c_1}{2} - \frac{i\sqrt{2}\, c_1}{2}$$

$$c_1 = \left(\frac{1}{2} + \frac{i}{2}\right)\sqrt{2}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{\sqrt{2}\, t^{\frac{1}{4}} + i\sqrt{2}\, t^{\frac{1}{4}}}{2\,(t-4)^{\frac{1}{4}}}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{2}\, t^{\frac{1}{4}} + i\sqrt{2}\, t^{\frac{1}{4}}}{2\,(t-4)^{\frac{1}{4}}} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{2}\, t^{\frac{1}{4}} + i\sqrt{2}\, t^{\frac{1}{4}}}{2\,(t-4)^{\frac{1}{4}}}$$

Verified OK.

3.2.3 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{1}{(t-4)t} dt} \\ &= e^{\frac{\ln(t-4)}{4} - \frac{\ln(t)}{4}}\end{aligned}$$

Which simplifies to

$$\mu = \frac{(t-4)^{\frac{1}{4}}}{t^{\frac{1}{4}}}$$

The ode becomes

$$\frac{d}{dt}\mu y = 0$$

$$\frac{d}{dt}\left(\frac{(t-4)^{\frac{1}{4}} y}{t^{\frac{1}{4}}}\right) = 0$$

Integrating gives

$$\frac{(t-4)^{\frac{1}{4}} y}{t^{\frac{1}{4}}} = c_1$$

Dividing both sides by the integrating factor $\mu = \frac{(t-4)^{\frac{1}{4}}}{t^{\frac{1}{4}}}$ results in

$$y = \frac{c_1 t^{\frac{1}{4}}}{(t-4)^{\frac{1}{4}}}$$

Initial conditions are used to solve for c_1. Substituting $t = 2$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{\sqrt{2}\, c_1}{2} - \frac{i\sqrt{2}\, c_1}{2}$$

$$c_1 = \left(\frac{1}{2} + \frac{i}{2}\right)\sqrt{2}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{\sqrt{2}\, t^{\frac{1}{4}} + i\sqrt{2}\, t^{\frac{1}{4}}}{2\,(t-4)^{\frac{1}{4}}}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{2}\, t^{\frac{1}{4}} + i\sqrt{2}\, t^{\frac{1}{4}}}{2\,(t-4)^{\frac{1}{4}}} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{2}\, t^{\frac{1}{4}} + i\sqrt{2}\, t^{\frac{1}{4}}}{2\,(t-4)^{\frac{1}{4}}}$$

Verified OK.

3.2.4 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(t)\,t$ on the above ode results in new ode in $u(t)$

$$u(t)\,t + (t-4)\,t(u'(t)\,t + u(t)) = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(t,u) \\ &= f(t)g(u) \\ &= -\frac{u(t-3)}{t\,(t-4)} \end{aligned}$$

Where $f(t) = -\frac{t-3}{(t-4)t}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{t-3}{(t-4)\,t}\,dt \\ \int \frac{1}{u}\,du &= \int -\frac{t-3}{(t-4)\,t}\,dt \\ \ln(u) &= -\frac{\ln(t-4)}{4} - \frac{3\ln(t)}{4} + c_2 \\ u &= \mathrm{e}^{-\frac{\ln(t-4)}{4} - \frac{3\ln(t)}{4} + c_2} \\ &= c_2 \mathrm{e}^{-\frac{\ln(t-4)}{4} - \frac{3\ln(t)}{4}} \end{aligned}$$

Which simplifies to

$$u(t) = \frac{c_2}{(t-4)^{\frac{1}{4}}\,t^{\frac{3}{4}}}$$

Therefore the solution y is

$$\begin{aligned} y &= ut \\ &= \frac{t^{\frac{1}{4}} c_2}{(t-4)^{\frac{1}{4}}} \end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $t = 2$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{\sqrt{2}\,c_2}{2} - \frac{i\sqrt{2}\,c_2}{2}$$

$$c_2 = \left(\frac{1}{2} + \frac{i}{2}\right)\sqrt{2}$$

Substituting c_2 found above in the general solution gives

$$y = \frac{\sqrt{2}\, t^{\frac{1}{4}} + i\sqrt{2}\, t^{\frac{1}{4}}}{2\left(t-4\right)^{\frac{1}{4}}}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{2}\, t^{\frac{1}{4}} + i\sqrt{2}\, t^{\frac{1}{4}}}{2\left(t-4\right)^{\frac{1}{4}}} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{2}\, t^{\frac{1}{4}} + i\sqrt{2}\, t^{\frac{1}{4}}}{2\left(t-4\right)^{\frac{1}{4}}}$$

Verified OK.

3.2.5 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= -\frac{y}{\left(t-4\right)t} \\ y' &= \omega(t, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2\xi_y - \omega_t\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 185: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \mathrm{e}^{-\frac{\ln(t-4)}{4} + \frac{\ln(t)}{4}}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{-\frac{\ln(t-4)}{4}+\frac{\ln(t)}{4}}} dy \end{aligned}$$

Which results in

$$S = \mathrm{e}^{\ln\left((t-4)^{\frac{1}{4}}\right)+\ln\left(\frac{1}{t^{\frac{1}{4}}}\right)} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y) S_y}{R_t + \omega(t,y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t,y) = -\frac{y}{(t-4)\,t}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= \frac{y}{(t-4)^{\frac{3}{4}}\, t^{\frac{5}{4}}} \\ S_y &= \frac{(t-4)^{\frac{1}{4}}}{t^{\frac{1}{4}}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\frac{(t-4)^{\frac{1}{4}} y}{t^{\frac{1}{4}}} = c_1$$

Which simplifies to

$$\frac{(t-4)^{\frac{1}{4}} y}{t^{\frac{1}{4}}} = c_1$$

Which gives

$$y = \frac{c_1 t^{\frac{1}{4}}}{(t-4)^{\frac{1}{4}}}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{y}{(t-4)t}$ 	$R = t$ $S = \frac{(t-4)^{\frac{1}{4}} y}{t^{\frac{1}{4}}}$	$\frac{dS}{dR} = 0$ 
Initial conditions are used to solve for c_1. Substituting $t = 2$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{\sqrt{2}\, c_1}{2} - \frac{i\sqrt{2}\, c_1}{2}$$

$$c_1 = \left(\frac{1}{2} + \frac{i}{2}\right)\sqrt{2}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{\sqrt{2}\, t^{\frac{1}{4}} + i\sqrt{2}\, t^{\frac{1}{4}}}{2\,(t-4)^{\frac{1}{4}}}$$

Summary
The solution(s) found are the following

$$y = \frac{\sqrt{2}\, t^{\frac{1}{4}} + i\sqrt{2}\, t^{\frac{1}{4}}}{2\,(t-4)^{\frac{1}{4}}} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{2}\, t^{\frac{1}{4}} + i\sqrt{2}\, t^{\frac{1}{4}}}{2\,(t-4)^{\frac{1}{4}}}$$

Verified OK.

3.2.6 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\,\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(-\frac{1}{y}\right)\mathrm{d}y = \left(\frac{1}{(t-4)\,t}\right)\mathrm{d}t$$
$$\left(-\frac{1}{(t-4)\,t}\right)\mathrm{d}t + \left(-\frac{1}{y}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(t, y) = -\frac{1}{(t-4)\,t}$$
$$N(t, y) = -\frac{1}{y}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{(t-4)\,t}\right)\\ &= 0\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}\left(-\frac{1}{y}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial t}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(t,y)$

$$
\frac{\partial \phi}{\partial t} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. t gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial t}\, \mathrm{d}t &= \int M\, \mathrm{d}t \\
\int \frac{\partial \phi}{\partial t}\, \mathrm{d}t &= \int -\frac{1}{(t-4)\,t}\, \mathrm{d}t
\end{aligned}
$$

$$
\phi = -\frac{\ln(t-4)}{4} + \frac{\ln(t)}{4} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{1}{y}$. Therefore equation (4) becomes

$$
-\frac{1}{y} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = -\frac{1}{y}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y)\, \mathrm{d}y &= \int \left(-\frac{1}{y}\right) \mathrm{d}y \\
f(y) &= -\ln(y) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\ln(t-4)}{4} + \frac{\ln(t)}{4} - \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\ln(t-4)}{4} + \frac{\ln(t)}{4} - \ln(y)$$

The solution becomes

$$y = \mathrm{e}^{-\frac{\ln(t-4)}{4} + \frac{\ln(t)}{4} - c_1}$$

Initial conditions are used to solve for c_1. Substituting $t = 2$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{\sqrt{2}\,\mathrm{e}^{-c_1}}{2} - \frac{i\sqrt{2}\,\mathrm{e}^{-c_1}}{2}$$

$$c_1 = -\frac{i\pi}{4}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{\sqrt{2}\,t^{\frac{1}{4}} + i\sqrt{2}\,t^{\frac{1}{4}}}{2\,(t-4)^{\frac{1}{4}}}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{2}\,t^{\frac{1}{4}} + i\sqrt{2}\,t^{\frac{1}{4}}}{2\,(t-4)^{\frac{1}{4}}} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{2}\,t^{\frac{1}{4}} + i\sqrt{2}\,t^{\frac{1}{4}}}{2\,(t-4)^{\frac{1}{4}}}$$

Verified OK.

3.2.7 Maple step by step solution

Let's solve

$[y+(t-4)\,ty'=0, y(2)=1]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y}=-\frac{1}{(t-4)t}$

- Integrate both sides with respect to t

  $\int \frac{y'}{y}dt=\int -\frac{1}{(t-4)t}dt+c_1$

- Evaluate integral

  $\ln(y)=-\frac{\ln(t-4)}{4}+\frac{\ln(t)}{4}+c_1$

- Use initial condition $y(2)=1$

  $0=-\frac{\mathrm{I}\pi}{4}+c_1$

- Solve for c_1

  $c_1=\frac{\mathrm{I}}{4}\pi$

- Substitute $c_1=\frac{\mathrm{I}}{4}\pi$ into general solution and simplify

  $\ln(y)=-\frac{\ln(t-4)}{4}+\frac{\ln(t)}{4}+\frac{\mathrm{I}\pi}{4}$

- Solution to the IVP

  $\ln(y)=-\frac{\ln(t-4)}{4}+\frac{\ln(t)}{4}+\frac{\mathrm{I}\pi}{4}$

3.3 problem 3

Internal problem ID [518]
Internal file name [`OUTPUT/518_Sunday_June_05_2022_01_42_55_AM_79033667/index.tex`]

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.4. Page 76
Problem number: 3.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{\tan(t)\, y + y' = \sin(t)}$$

With initial conditions

$$[y(\pi) = 0]$$

3.3.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \tan(t)$$
$$q(t) = \sin(t)$$

Hence the ode is

$$\tan(t)\, y + y' = \sin(t)$$

The domain of $p(t) = \tan(t)$ is

$$\left\{t < \frac{1}{2}\pi + \pi\_Z8 \vee \frac{1}{2}\pi + \pi\_Z8 < t\right\}$$

And the point $t_0 = \pi$ is inside this domain. The domain of $q(t) = \sin(t)$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = \pi$ is also inside this domain. Hence solution exists and is unique.

3.3.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int \tan(t)dt} \\ &= \frac{1}{\cos(t)}\end{aligned}$$

Which simplifies to

$$\mu = \sec(t)$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}(\mu y) &= (\mu)(\sin(t)) \\ \frac{\mathrm{d}}{\mathrm{d}t}(\sec(t)\, y) &= (\sec(t))(\sin(t)) \\ \mathrm{d}(\sec(t)\, y) &= \tan(t)\, \mathrm{d}t\end{aligned}$$

Integrating gives

$$\begin{aligned}\sec(t)\, y &= \int \tan(t)\, \mathrm{d}t \\ \sec(t)\, y &= -\ln(\cos(t)) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \sec(t)$ results in

$$y = -\cos(t)\ln(\cos(t)) + c_1\cos(t)$$

which simplifies to

$$y = \cos(t)\left(-\ln(\cos(t)) + c_1\right)$$

Initial conditions are used to solve for c_1. Substituting $t = \pi$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = i\pi - c_1$$

$$c_1 = i\pi$$

Substituting c_1 found above in the general solution gives

$$y = i\cos(t)\,\pi - \cos(t)\ln(\cos(t))$$

Summary
The solution(s) found are the following

$$y = i\cos(t)\,\pi - \cos(t)\ln(\cos(t)) \tag{1}$$

Verification of solutions

$$y = i\cos(t)\,\pi - \cos(t)\ln(\cos(t))$$

Verified OK.

3.3.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= -\tan(t)\,y + \sin(t) \\ y' &= \omega(t, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2\xi_y - \omega_t\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 188: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \cos(t) \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \qquad (1)
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\cos(t)} dy \end{aligned}$$

Which results in

$$S = \frac{y}{\cos(t)}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y) S_y}{R_t + \omega(t,y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = -\tan(t)\, y + \sin(t)$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= \sec(t)\tan(t)\, y \\ S_y &= \sec(t) \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \tan(t) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \tan(R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\ln(\cos(R)) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\sec(t)\, y = -\ln(\cos(t)) + c_1$$

Which simplifies to

$$\sec(t)\, y = -\ln(\cos(t)) + c_1$$

Which gives

$$y = -\frac{\ln(\cos(t)) - c_1}{\sec(t)}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\tan(t)\, y + \sin(t)$ 	$R = t$ $S = \sec(t)\, y$	$\frac{dS}{dR} = \tan(R)$ 
Initial conditions are used to solve for c_1. Substituting $t = \pi$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = i\pi - c_1$$

$$c_1 = i\pi$$

Substituting c_1 found above in the general solution gives

$$y = i\cos(t)\,\pi - \cos(t)\ln(\cos(t))$$

Summary

The solution(s) found are the following

$$y = i\cos(t)\,\pi - \cos(t)\ln(\cos(t)) \tag{1}$$

Verification of solutions

$$y = i\cos(t)\,\pi - \cos(t)\ln(\cos(t))$$

Verified OK.

3.3.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition

$\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = (-\tan(t)\,y + \sin(t))\,\mathrm{d}t$$
$$(\tan(t)\,y - \sin(t))\,\mathrm{d}t + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(t, y) = \tan(t)\,y - \sin(t)$$
$$N(t, y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(\tan(t)\,y - \sin(t)) \\ &= \tan(t)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(1) \\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\ &= 1((\tan(t)) - (0)) \\ &= \tan(t)\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}t} \\ &= e^{\int \tan(t)\,\mathrm{d}t}\end{aligned}$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-\ln(\cos(t))} \\
&= \sec(t)
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \sec(t)(\tan(t)\, y - \sin(t)) \\
&= \tan(t)(\sec(t)\, y - 1)
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \sec(t)\,(1) \\
&= \sec(t)
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\
(\tan(t)(\sec(t)\, y - 1)) + (\sec(t))\frac{\mathrm{d}y}{\mathrm{d}t} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$
\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. t gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial t}\,\mathrm{d}t &= \int \overline{M}\,\mathrm{d}t \\
\int \frac{\partial \phi}{\partial t}\,\mathrm{d}t &= \int \tan(t)(\sec(t)\, y - 1)\,\mathrm{d}t
\end{aligned}
$$

$$
\phi = \sec(t)\, y - \ln(\sec(t)) + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \sec(t) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \sec(t)$. Therefore equation (4) becomes

$$\sec(t) = \sec(t) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \sec(t)\, y - \ln(\sec(t)) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \sec(t)\, y - \ln(\sec(t))$$

The solution becomes

$$y = \frac{\ln(\sec(t)) + c_1}{\sec(t)}$$

Initial conditions are used to solve for c_1. Substituting $t = \pi$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -i\pi - c_1$$

$$c_1 = -i\pi$$

Substituting c_1 found above in the general solution gives

$$y = -i\cos(t)\,\pi + \ln(\sec(t))\cos(t)$$

Summary
The solution(s) found are the following

$$y = -i\cos(t)\,\pi + \ln(\sec(t))\cos(t) \tag{1}$$

Verification of solutions

$$y = -i\cos(t)\,\pi + \ln(\sec(t))\cos(t)$$

Verified OK.

3.3.5 Maple step by step solution

Let's solve

$[\tan(t)\,y + y' = \sin(t)\,, y(\pi) = 0]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\tan(t)\,y + \sin(t)$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $\tan(t)\,y + y' = \sin(t)$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\,(\tan(t)\,y + y') = \mu(t)\sin(t)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

  $\mu(t)\,(\tan(t)\,y + y') = \mu'(t)\,y + \mu(t)\,y'$

- Isolate $\mu'(t)$

  $\mu'(t) = \mu(t)\tan(t)$

- Solve to find the integrating factor

  $\mu(t) = \frac{1}{\cos(t)}$

- Integrate both sides with respect to t

  $\int\left(\frac{d}{dt}(\mu(t)\,y)\right)dt = \int \mu(t)\sin(t)\,dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\,y = \int \mu(t)\sin(t)\,dt + c_1$

- Solve for y

$y = \frac{\int \mu(t) \sin(t) dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = \frac{1}{\cos(t)}$

  $y = \cos(t) \left(\int \frac{\sin(t)}{\cos(t)} dt + c_1\right)$

- Evaluate the integrals on the rhs

  $y = \cos(t) \left(-\ln(\cos(t)) + c_1\right)$

- Use initial condition $y(\pi) = 0$

  $0 = \mathrm{I}\pi - c_1$

- Solve for c_1

  $c_1 = \mathrm{I}\pi$

- Substitute $c_1 = \mathrm{I}\pi$ into general solution and simplify

  $y = (-\ln(\cos(t)) + \mathrm{I}\pi) \cos(t)$

- Solution to the IVP

  $y = (-\ln(\cos(t)) + \mathrm{I}\pi) \cos(t)$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_linear]
```

$$\boxed{2yt + \left(-t^2 + 4\right) y' = 3t^2}$$

With initial conditions

$$[y(-3) = 1]$$

3.4.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = -\frac{2t}{t^2 - 4}$$
$$q(t) = -\frac{3t^2}{t^2 - 4}$$

Hence the ode is

$$y' - \frac{2ty}{t^2-4} = -\frac{3t^2}{t^2-4}$$

The domain of $p(t) = -\frac{2t}{t^2-4}$ is

$$\{-\infty \le t < -2, -2 < t < 2, 2 < t \le \infty\}$$

And the point $t_0 = -3$ is inside this domain. The domain of $q(t) = -\frac{3t^2}{t^2-4}$ is

$$\{-\infty \le t < -2, -2 < t < 2, 2 < t \le \infty\}$$

And the point $t_0 = -3$ is also inside this domain. Hence solution exists and is unique.

3.4.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{2t}{t^2-4}dt} \\ &= \frac{1}{t^2-4}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dt}(\mu y) &= (\mu)\left(-\frac{3t^2}{t^2-4}\right) \\ \frac{d}{dt}\left(\frac{y}{t^2-4}\right) &= \left(\frac{1}{t^2-4}\right)\left(-\frac{3t^2}{t^2-4}\right) \\ d\left(\frac{y}{t^2-4}\right) &= \left(-\frac{3t^2}{(t^2-4)^2}\right) dt\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{y}{t^2-4} &= \int -\frac{3t^2}{(t^2-4)^2} dt \\ \frac{y}{t^2-4} &= \frac{3}{4(t-2)} - \frac{3\ln(t-2)}{8} + \frac{3}{4(2+t)} + \frac{3\ln(2+t)}{8} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{t^2-4}$ results in

$$y = (t^2-4)\left(\frac{3}{4(t-2)} - \frac{3\ln(t-2)}{8} + \frac{3}{4(2+t)} + \frac{3\ln(2+t)}{8}\right) + c_1(t^2-4)$$

which simplifies to

$$y = \frac{3(t^2-4)\ln(2+t)}{8} + c_1 t^2 - \frac{3\ln(t-2)\,t^2}{8} + \frac{3t}{2} - 4c_1 + \frac{3\ln(t-2)}{2}$$

Initial conditions are used to solve for c_1. Substituting $t = -3$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{9}{2} + 5c_1 - \frac{15\ln(5)}{8}$$

$$c_1 = \frac{11}{10} + \frac{3\ln(5)}{8}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{3\ln(2+t)\,t^2}{8} - \frac{3\ln(2+t)}{2} + \frac{11t^2}{10} + \frac{3t^2\ln(5)}{8} - \frac{3\ln(t-2)\,t^2}{8} + \frac{3t}{2} - \frac{22}{5} - \frac{3\ln(5)}{2} + \frac{3\ln(t-2)}{2}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & \frac{3\ln(2+t)\,t^2}{8} - \frac{3\ln(2+t)}{2} + \frac{11t^2}{10} + \frac{3t^2\ln(5)}{8} \\ & - \frac{3\ln(t-2)\,t^2}{8} + \frac{3t}{2} - \frac{22}{5} - \frac{3\ln(5)}{2} + \frac{3\ln(t-2)}{2} \end{aligned} \tag{1}$$

Verification of solutions

$$\begin{aligned} y = {} & \frac{3\ln(2+t)\,t^2}{8} - \frac{3\ln(2+t)}{2} + \frac{11t^2}{10} + \frac{3t^2\ln(5)}{8} \\ & - \frac{3\ln(t-2)\,t^2}{8} + \frac{3t}{2} - \frac{22}{5} - \frac{3\ln(5)}{2} + \frac{3\ln(t-2)}{2} \end{aligned}$$

Verified OK.

3.4.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{t(-3t+2y)}{t^2-4}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2\xi_y - \omega_t\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 191: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= t^2 - 4 \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \qquad (1)
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t}+\eta \frac{\partial}{\partial y}\right) S(t, y)=1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi=0$ then in this special case

$$R=t$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} d y \\
&= \int \frac{1}{t^{2}-4} d y
\end{aligned}$$

Which results in

$$S=\frac{y}{t^{2}-4}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{d S}{d R}=\frac{S_{t}+\omega(t, y) S_{y}}{R_{t}+\omega(t, y) R_{y}} \tag{2}$$

Where in the above $R_{t}, R_{y}, S_{t}, S_{y}$ are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y)=\frac{t(-3 t+2 y)}{t^{2}-4}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_{t} &= 1 \\
R_{y} &= 0 \\
S_{t} &= -\frac{2 y t}{\left(t^{2}-4\right)^{2}} \\
S_{y} &= \frac{1}{t^{2}-4}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{d S}{d R}=-\frac{3 t^{2}}{\left(t^{2}-4\right)^{2}} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{d S}{d R}=-\frac{3 R^{2}}{\left(R^{2}-4\right)^{2}}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{3}{4(R-2)} - \frac{3\ln(R-2)}{8} + \frac{3}{4(R+2)} + \frac{3\ln(R+2)}{8} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\frac{y}{t^2-4} = \frac{3}{4(t-2)} - \frac{3\ln(t-2)}{8} + \frac{3}{4(2+t)} + \frac{3\ln(2+t)}{8} + c_1$$

Which simplifies to

$$\frac{y}{t^2-4} = \frac{3}{4(t-2)} - \frac{3\ln(t-2)}{8} + \frac{3}{4(2+t)} + \frac{3\ln(2+t)}{8} + c_1$$

Which gives

$$y = -\frac{3\ln(t-2)\,t^2}{8} + \frac{3\ln(2+t)\,t^2}{8} + c_1 t^2 + \frac{3\ln(t-2)}{2} - \frac{3\ln(2+t)}{2} - 4c_1 + \frac{3t}{2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = \frac{t(-3t+2y)}{t^2-4}$ 	$R = t$ $S = \frac{y}{t^2-4}$	$\frac{dS}{dR} = -\frac{3R^2}{(R^2-4)^2}$ 
Initial conditions are used to solve for c_1. Substituting $t = -3$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{9}{2} + 5c_1 - \frac{15\ln(5)}{8}$$

$$c_1 = \frac{11}{10} + \frac{3\ln(5)}{8}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{3\ln(2+t)\,t^2}{8} - \frac{3\ln(2+t)}{2} + \frac{11t^2}{10} + \frac{3t^2\ln(5)}{8} - \frac{3\ln(t-2)\,t^2}{8} + \frac{3t}{2} - \frac{22}{5} - \frac{3\ln(5)}{2} + \frac{3\ln(t-2)}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{3\ln(2+t)\,t^2}{8} - \frac{3\ln(2+t)}{2} + \frac{11t^2}{10} + \frac{3t^2\ln(5)}{8} - \frac{3\ln(t-2)\,t^2}{8} + \frac{3t}{2} - \frac{22}{5} - \frac{3\ln(5)}{2} + \frac{3\ln(t-2)}{2} \tag{1}$$

Verification of solutions

$$y = \frac{3\ln(2+t)\,t^2}{8} - \frac{3\ln(2+t)}{2} + \frac{11t^2}{10} + \frac{3t^2\ln(5)}{8} - \frac{3\ln(t-2)\,t^2}{8} + \frac{3t}{2} - \frac{22}{5} - \frac{3\ln(5)}{2} + \frac{3\ln(t-2)}{2}$$

Verified OK.

3.4.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t + N(t,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(-t^2+4)\,\mathrm{d}y &= (3t^2-2ty)\,\mathrm{d}t\\ (-3t^2+2ty)\,\mathrm{d}t + (-t^2+4)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t,y) &= -3t^2+2ty\\ N(t,y) &= -t^2+4\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-3t^2+2ty)\\ &= 2t\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(-t^2+4)\\ &= -2t\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\
&= -\frac{1}{t^2-4}((2t)-(-2t)) \\
&= -\frac{4t}{t^2-4}
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A\,\mathrm{d}t} \\
&= e^{\int -\frac{4t}{t^2-4}\,\mathrm{d}t}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-2\ln(t^2-4)} \\
&= \frac{1}{(t^2-4)^2}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \frac{1}{(t^2-4)^2}(-3t^2+2ty) \\
&= \frac{-3t^2+2ty}{(t^2-4)^2}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{(t^2-4)^2}(-t^2+4) \\
&= -\frac{1}{t^2-4}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\
\left(\frac{-3t^2+2ty}{(t^2-4)^2}\right) + \left(-\frac{1}{t^2-4}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \mathrm{d}t = \int \overline{M} \mathrm{d}t$$
$$\int \frac{\partial \phi}{\partial t} \mathrm{d}t = \int \frac{-3t^2 + 2ty}{(t^2-4)^2} \mathrm{d}t$$
$$\phi = -\frac{3\ln(t-2)}{8} + \frac{3-y}{4t-8} + \frac{3\ln(2+t)}{8} + \frac{3+y}{8+4t} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -\frac{1}{4t-8} + \frac{1}{8+4t} + f'(y) \tag{4}$$
$$= -\frac{1}{t^2-4} + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{1}{t^2-4}$. Therefore equation (4) becomes

$$-\frac{1}{t^2-4} = -\frac{1}{t^2-4} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{3\ln(t-2)}{8} + \frac{3-y}{4t-8} + \frac{3\ln(2+t)}{8} + \frac{3+y}{8+4t} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{3\ln(t-2)}{8} + \frac{3-y}{4t-8} + \frac{3\ln(2+t)}{8} + \frac{3+y}{8+4t}$$

The solution becomes

$$y = -\frac{3\ln(t-2)\,t^2}{8} + \frac{3\ln(2+t)\,t^2}{8} - c_1 t^2 + \frac{3\ln(t-2)}{2} - \frac{3\ln(2+t)}{2} + 4c_1 + \frac{3t}{2}$$

Initial conditions are used to solve for c_1. Substituting $t = -3$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{15\ln(5)}{8} - \frac{9}{2} - 5c_1$$

$$c_1 = -\frac{11}{10} - \frac{3\ln(5)}{8}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{3\ln(2+t)\,t^2}{8} - \frac{3\ln(2+t)}{2} + \frac{11t^2}{10} + \frac{3t^2\ln(5)}{8} - \frac{3\ln(t-2)\,t^2}{8} + \frac{3t}{2} - \frac{22}{5} - \frac{3\ln(5)}{2} + \frac{3\ln(t-2)}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{3\ln(2+t)\,t^2}{8} - \frac{3\ln(2+t)}{2} + \frac{11t^2}{10} + \frac{3t^2\ln(5)}{8} - \frac{3\ln(t-2)\,t^2}{8} + \frac{3t}{2} - \frac{22}{5} - \frac{3\ln(5)}{2} + \frac{3\ln(t-2)}{2} \tag{1}$$

Verification of solutions

$$y = \frac{3\ln(2+t)\,t^2}{8} - \frac{3\ln(2+t)}{2} + \frac{11t^2}{10} + \frac{3t^2\ln(5)}{8} - \frac{3\ln(t-2)\,t^2}{8} + \frac{3t}{2} - \frac{22}{5} - \frac{3\ln(5)}{2} + \frac{3\ln(t-2)}{2}$$

Verified OK.

3.4.5 Maple step by step solution

Let's solve

$\left[2yt+\left(-t^{2}+4\right) y'=3t^{2}, y(-3)=1\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y'=\frac{2ty}{t^{2}-4}-\frac{3t^{2}}{t^{2}-4}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y'-\frac{2ty}{t^{2}-4}=-\frac{3t^{2}}{t^{2}-4}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(y'-\frac{2ty}{t^{2}-4}\right)=-\frac{3\mu(t)t^{2}}{t^{2}-4}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, y)$

  $\mu(t)\left(y'-\frac{2ty}{t^{2}-4}\right)=\mu'(t)\, y+\mu(t)\, y'$

- Isolate $\mu'(t)$

  $\mu'(t)=-\frac{2\mu(t)t}{t^{2}-4}$

- Solve to find the integrating factor

  $\mu(t)=\frac{1}{(t-2)(2+t)}$

- Integrate both sides with respect to t

  $\int\left(\frac{d}{dt}(\mu(t)\, y)\right)dt=\int-\frac{3\mu(t)t^{2}}{t^{2}-4}dt+c_{1}$

- Evaluate the integral on the lhs

  $\mu(t)\, y=\int-\frac{3\mu(t)t^{2}}{t^{2}-4}dt+c_{1}$

- Solve for y

  $y=\frac{\int-\frac{3\mu(t)t^{2}}{t^{2}-4}dt+c_{1}}{\mu(t)}$

- Substitute $\mu(t)=\frac{1}{(t-2)(2+t)}$

  $y=(t-2)\,(2+t)\left(\int-\frac{3t^{2}}{(t-2)(2+t)(t^{2}-4)}dt+c_{1}\right)$

- Evaluate the integrals on the rhs

  $y=(t-2)\,(2+t)\left(\frac{3}{4(t-2)}-\frac{3\ln(t-2)}{8}+\frac{3}{4(2+t)}+\frac{3\ln(2+t)}{8}+c_{1}\right)$

- Simplify

  $y = \frac{3(t^2-4)\ln(2+t)}{8} + c_1t^2 - \frac{3\ln(t-2)t^2}{8} + \frac{3t}{2} - 4c_1 + \frac{3\ln(t-2)}{2}$
- Use initial condition $y(-3) = 1$

  $1 = -\frac{9}{2} + 5c_1 - \frac{15\ln(5)}{8}$
- Solve for c_1

  $c_1 = \frac{11}{10} + \frac{3\ln(5)}{8}$
- Substitute $c_1 = \frac{11}{10} + \frac{3\ln(5)}{8}$ into general solution and simplify

  $y = -\frac{22}{5} + \frac{3(t^2-4)\ln(2+t)}{8} + \frac{(44+15\ln(5))t^2}{40} - \frac{3\ln(t-2)t^2}{8} + \frac{3t}{2} - \frac{3\ln(5)}{2} + \frac{3\ln(t-2)}{2}$
- Solution to the IVP

  $y = -\frac{22}{5} + \frac{3(t^2-4)\ln(2+t)}{8} + \frac{(44+15\ln(5))t^2}{40} - \frac{3\ln(t-2)t^2}{8} + \frac{3t}{2} - \frac{3\ln(5)}{2} + \frac{3\ln(t-2)}{2}$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{2yt + \left(-t^2+4\right) y' = 3t^2}$$

With initial conditions

$$[y(1) = -3]$$

3.5.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = -\frac{2t}{t^2-4}$$
$$q(t) = -\frac{3t^2}{t^2-4}$$

Hence the ode is

$$y' - \frac{2ty}{t^2-4} = -\frac{3t^2}{t^2-4}$$

The domain of $p(t) = -\frac{2t}{t^2-4}$ is

$$\{-\infty \le t < -2, -2 < t < 2, 2 < t \le \infty\}$$

And the point $t_0 = 1$ is inside this domain. The domain of $q(t) = -\frac{3t^2}{t^2-4}$ is

$$\{-\infty \le t < -2, -2 < t < 2, 2 < t \le \infty\}$$

And the point $t_0 = 1$ is also inside this domain. Hence solution exists and is unique.

3.5.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int -\frac{2t}{t^2-4}dt} \\
&= \frac{1}{t^2-4}
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dt}(\mu y) &= (\mu)\left(-\frac{3t^2}{t^2-4}\right) \\
\frac{d}{dt}\left(\frac{y}{t^2-4}\right) &= \left(\frac{1}{t^2-4}\right)\left(-\frac{3t^2}{t^2-4}\right) \\
d\left(\frac{y}{t^2-4}\right) &= \left(-\frac{3t^2}{(t^2-4)^2}\right) dt
\end{aligned}$$

Integrating gives

$$\begin{aligned}
\frac{y}{t^2-4} &= \int -\frac{3t^2}{(t^2-4)^2} dt \\
\frac{y}{t^2-4} &= \frac{3}{4(t-2)} - \frac{3\ln(t-2)}{8} + \frac{3}{4(2+t)} + \frac{3\ln(2+t)}{8} + c_1
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{t^2-4}$ results in

$$y = (t^2-4)\left(\frac{3}{4(t-2)} - \frac{3\ln(t-2)}{8} + \frac{3}{4(2+t)} + \frac{3\ln(2+t)}{8}\right) + c_1(t^2-4)$$

which simplifies to

$$y = \frac{3(t^2-4)\ln(2+t)}{8} + c_1 t^2 - \frac{3\ln(t-2)\,t^2}{8} + \frac{3t}{2} - 4c_1 + \frac{3\ln(t-2)}{2}$$

Initial conditions are used to solve for c_1. Substituting $t = 1$ and $y = -3$ in the above solution gives an equation to solve for the constant of integration.

$$-3 = -\frac{9\ln(3)}{8} - 3c_1 + \frac{9i\pi}{8} + \frac{3}{2}$$

$$c_1 = -\frac{3\ln(3)}{8} + \frac{3i\pi}{8} + \frac{3}{2}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{3\ln(2+t)\,t^2}{8} - \frac{3\ln(2+t)}{2} - \frac{3t^2\ln(3)}{8} + \frac{3it^2\pi}{8} + \frac{3t^2}{2} - \frac{3\ln(t-2)\,t^2}{8} + \frac{3t}{2} + \frac{3\ln(3)}{2} - \frac{3i\pi}{2} - 6 +$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & \frac{3\ln(2+t)\,t^2}{8} - \frac{3\ln(2+t)}{2} - \frac{3t^2\ln(3)}{8} + \frac{3it^2\pi}{8} + \frac{3t^2}{2} \\ & - \frac{3\ln(t-2)\,t^2}{8} + \frac{3t}{2} + \frac{3\ln(3)}{2} - \frac{3i\pi}{2} - 6 + \frac{3\ln(t-2)}{2} \end{aligned} \tag{1}$$

Verification of solutions

$$\begin{aligned} y = {} & \frac{3\ln(2+t)\,t^2}{8} - \frac{3\ln(2+t)}{2} - \frac{3t^2\ln(3)}{8} + \frac{3it^2\pi}{8} + \frac{3t^2}{2} \\ & - \frac{3\ln(t-2)\,t^2}{8} + \frac{3t}{2} + \frac{3\ln(3)}{2} - \frac{3i\pi}{2} - 6 + \frac{3\ln(t-2)}{2} \end{aligned}$$

Verified OK.

3.5.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= \frac{t(-3t+2y)}{t^2-4} \\ y' &= \omega(t,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 194: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= t^2 - 4
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{t^2 - 4} dy \end{aligned}$$

Which results in

$$S = \frac{y}{t^2 - 4}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y) S_y}{R_t + \omega(t,y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = \frac{t(-3t + 2y)}{t^2 - 4}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= -\frac{2yt}{(t^2 - 4)^2} \\ S_y &= \frac{1}{t^2 - 4} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{3t^2}{(t^2 - 4)^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{3R^2}{(R^2 - 4)^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{3}{4(R-2)} - \frac{3\ln(R-2)}{8} + \frac{3}{4(R+2)} + \frac{3\ln(R+2)}{8} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\frac{y}{t^2-4} = \frac{3}{4(t-2)} - \frac{3\ln(t-2)}{8} + \frac{3}{4(2+t)} + \frac{3\ln(2+t)}{8} + c_1$$

Which simplifies to

$$\frac{y}{t^2-4} = \frac{3}{4(t-2)} - \frac{3\ln(t-2)}{8} + \frac{3}{4(2+t)} + \frac{3\ln(2+t)}{8} + c_1$$

Which gives

$$y = -\frac{3\ln(t-2)\,t^2}{8} + \frac{3\ln(2+t)\,t^2}{8} + c_1 t^2 + \frac{3\ln(t-2)}{2} - \frac{3\ln(2+t)}{2} - 4c_1 + \frac{3t}{2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = \frac{t(-3t+2y)}{t^2-4}$ 	$R = t$ $S = \frac{y}{t^2-4}$	$\frac{dS}{dR} = -\frac{3R^2}{(R^2-4)^2}$ 
Initial conditions are used to solve for c_1. Substituting $t = 1$ and $y = -3$ in the above solution gives an equation to solve for the constant of integration.

$$-3 = -\frac{9 \ln (3)}{8} - 3c_1 + \frac{9i\pi}{8} + \frac{3}{2}$$

$$c_1 = -\frac{3 \ln (3)}{8} + \frac{3i\pi}{8} + \frac{3}{2}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{3 \ln (2+t) t^2}{8} - \frac{3 \ln (2+t)}{2} - \frac{3t^2 \ln (3)}{8} + \frac{3it^2\pi}{8} + \frac{3t^2}{2} - \frac{3 \ln (t-2) t^2}{8} + \frac{3t}{2} + \frac{3 \ln (3)}{2} - \frac{3i\pi}{2} - 6 +$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & \frac{3 \ln (2+t) t^2}{8} - \frac{3 \ln (2+t)}{2} - \frac{3t^2 \ln (3)}{8} + \frac{3it^2\pi}{8} + \frac{3t^2}{2} \\ & - \frac{3 \ln (t-2) t^2}{8} + \frac{3t}{2} + \frac{3 \ln (3)}{2} - \frac{3i\pi}{2} - 6 + \frac{3 \ln (t-2)}{2} \end{aligned} \tag{1}$$

Verification of solutions

$$\begin{aligned} y = {} & \frac{3 \ln (2+t) t^2}{8} - \frac{3 \ln (2+t)}{2} - \frac{3t^2 \ln (3)}{8} + \frac{3it^2\pi}{8} + \frac{3t^2}{2} \\ & - \frac{3 \ln (t-2) t^2}{8} + \frac{3t}{2} + \frac{3 \ln (3)}{2} - \frac{3i\pi}{2} - 6 + \frac{3 \ln (t-2)}{2} \end{aligned}$$

Verified OK.

3.5.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx} \phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y} \frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(-t^2 + 4)\,\mathrm{d}y &= (3t^2 - 2ty)\,\mathrm{d}t \\ (-3t^2 + 2ty)\,\mathrm{d}t + (-t^2 + 4)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$M(t, y) = -3t^2 + 2ty$$
$$N(t, y) = -t^2 + 4$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-3t^2 + 2ty) \\ &= 2t\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(-t^2 + 4) \\ &= -2t\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\ &= -\frac{1}{t^2-4}((2t) - (-2t)) \\ &= -\frac{4t}{t^2-4} \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A\, \mathrm{d}t} \\ &= e^{\int -\frac{4t}{t^2-4}\, \mathrm{d}t} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-2\ln(t^2-4)} \\ &= \frac{1}{(t^2-4)^2} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \frac{1}{(t^2-4)^2}(-3t^2+2ty) \\ &= \frac{-3t^2+2ty}{(t^2-4)^2} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \frac{1}{(t^2-4)^2}(-t^2+4) \\ &= -\frac{1}{t^2-4} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\ \left(\frac{-3t^2+2ty}{(t^2-4)^2}\right) + \left(-\frac{1}{t^2-4}\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int \overline{M} \, \mathrm{d}t$$

$$\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int \frac{-3t^2 + 2ty}{(t^2 - 4)^2} \, \mathrm{d}t$$

$$\phi = -\frac{3 \ln (t - 2)}{8} + \frac{3 - y}{4t - 8} + \frac{3 \ln (2 + t)}{8} + \frac{3 + y}{8 + 4t} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -\frac{1}{4t - 8} + \frac{1}{8 + 4t} + f'(y) \tag{4}$$

$$= -\frac{1}{t^2 - 4} + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{1}{t^2 - 4}$. Therefore equation (4) becomes

$$-\frac{1}{t^2 - 4} = -\frac{1}{t^2 - 4} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{3 \ln (t - 2)}{8} + \frac{3 - y}{4t - 8} + \frac{3 \ln (2 + t)}{8} + \frac{3 + y}{8 + 4t} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{3\ln\left(t-2\right)}{8} + \frac{3-y}{4t-8} + \frac{3\ln\left(2+t\right)}{8} + \frac{3+y}{8+4t}$$

The solution becomes

$$y = -\frac{3\ln\left(t-2\right)t^2}{8} + \frac{3\ln\left(2+t\right)t^2}{8} - c_1 t^2 + \frac{3\ln\left(t-2\right)}{2} - \frac{3\ln\left(2+t\right)}{2} + 4c_1 + \frac{3t}{2}$$

Initial conditions are used to solve for c_1. Substituting $t = 1$ and $y = -3$ in the above solution gives an equation to solve for the constant of integration.

$$-3 = \frac{9i\pi}{8} - \frac{9\ln\left(3\right)}{8} + 3c_1 + \frac{3}{2}$$

$$c_1 = \frac{3\ln\left(3\right)}{8} - \frac{3i\pi}{8} - \frac{3}{2}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{3\ln\left(2+t\right)t^2}{8} - \frac{3\ln\left(2+t\right)}{2} - \frac{3t^2\ln\left(3\right)}{8} + \frac{3it^2\pi}{8} + \frac{3t^2}{2} - \frac{3\ln\left(t-2\right)t^2}{8} + \frac{3t}{2} + \frac{3\ln\left(3\right)}{2} - \frac{3i\pi}{2} - 6 +$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & \frac{3\ln\left(2+t\right)t^2}{8} - \frac{3\ln\left(2+t\right)}{2} - \frac{3t^2\ln\left(3\right)}{8} + \frac{3it^2\pi}{8} + \frac{3t^2}{2} \\ & - \frac{3\ln\left(t-2\right)t^2}{8} + \frac{3t}{2} + \frac{3\ln\left(3\right)}{2} - \frac{3i\pi}{2} - 6 + \frac{3\ln\left(t-2\right)}{2} \end{aligned} \tag{1}$$

Verification of solutions

$$\begin{aligned} y = {} & \frac{3\ln\left(2+t\right)t^2}{8} - \frac{3\ln\left(2+t\right)}{2} - \frac{3t^2\ln\left(3\right)}{8} + \frac{3it^2\pi}{8} + \frac{3t^2}{2} \\ & - \frac{3\ln\left(t-2\right)t^2}{8} + \frac{3t}{2} + \frac{3\ln\left(3\right)}{2} - \frac{3i\pi}{2} - 6 + \frac{3\ln\left(t-2\right)}{2} \end{aligned}$$

Verified OK.

3.5.5 Maple step by step solution

Let's solve

$[2yt + (-t^2 + 4) y' = 3t^2, y(1) = -3]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \frac{2ty}{t^2-4} - \frac{3t^2}{t^2-4}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - \frac{2ty}{t^2-4} = -\frac{3t^2}{t^2-4}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t) \left(y' - \frac{2ty}{t^2-4}\right) = -\frac{3\mu(t)t^2}{t^2-4}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t) y)$

  $\mu(t) \left(y' - \frac{2ty}{t^2-4}\right) = \mu'(t) y + \mu(t) y'$

- Isolate $\mu'(t)$

  $\mu'(t) = -\frac{2\mu(t)t}{t^2-4}$

- Solve to find the integrating factor

  $\mu(t) = \frac{1}{(t-2)(2+t)}$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t) y)\right) dt = \int -\frac{3\mu(t)t^2}{t^2-4} dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t) y = \int -\frac{3\mu(t)t^2}{t^2-4} dt + c_1$

- Solve for y

  $y = \frac{\int -\frac{3\mu(t)t^2}{t^2-4} dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = \frac{1}{(t-2)(2+t)}$

  $y = (t-2)(2+t)\left(\int -\frac{3t^2}{(t-2)(2+t)(t^2-4)} dt + c_1\right)$

- Evaluate the integrals on the rhs

  $y = (t-2)(2+t)\left(\frac{3}{4(t-2)} - \frac{3\ln(t-2)}{8} + \frac{3}{4(2+t)} + \frac{3\ln(2+t)}{8} + c_1\right)$

- Simplify

  $y = \frac{3(t^2-4)\ln(2+t)}{8} + c_1 t^2 - \frac{3\ln(t-2)t^2}{8} + \frac{3t}{2} - 4c_1 + \frac{3\ln(t-2)}{2}$
- Use initial condition $y(1) = -3$

  $-3 = -\frac{9\ln(3)}{8} - 3c_1 + \frac{9\,\mathrm{I}\pi}{8} + \frac{3}{2}$
- Solve for c_1

  $c_1 = -\frac{3\ln(3)}{8} + \frac{3\,\mathrm{I}\pi}{8} + \frac{3}{2}$
- Substitute $c_1 = -\frac{3\ln(3)}{8} + \frac{3\,\mathrm{I}\pi}{8} + \frac{3}{2}$ into general solution and simplify

  $y = -6 + \frac{3(t^2-4)\ln(2+t)}{8} + \frac{3\,\mathrm{I}t^2\pi}{8} - \frac{3t^2\ln(3)}{8} - \frac{3\ln(t-2)t^2}{8} - \frac{3\,\mathrm{I}\pi}{2} + \frac{3t^2}{2} + \frac{3t}{2} + \frac{3\ln(3)}{2} + \frac{3\ln(t-2)}{2}$
- Solution to the IVP

  $y = -6 + \frac{3(t^2-4)\ln(2+t)}{8} + \frac{3\,\mathrm{I}t^2\pi}{8} - \frac{3t^2\ln(3)}{8} - \frac{3\ln(t-2)t^2}{8} - \frac{3\,\mathrm{I}\pi}{2} + \frac{3t^2}{2} + \frac{3t}{2} + \frac{3\ln(3)}{2} + \frac{3\ln(t-2)}{2}$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_linear]
```

$$\boxed{y + \ln(t)\, y' = \cot(t)}$$

3.6.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \frac{1}{\ln(t)}$$
$$q(t) = \frac{\cot(t)}{\ln(t)}$$

Hence the ode is

$$y' + \frac{y}{\ln(t)} = \frac{\cot(t)}{\ln(t)}$$

The integrating factor μ is

$$\mu = e^{\int \frac{1}{\ln(t)}dt}$$

The ode becomes

$$\frac{d}{dt}(\mu y) = (\mu)\left(\frac{\cot(t)}{\ln(t)}\right)$$

$$\frac{d}{dt}\left(e^{\int \frac{1}{\ln(t)}dt} y\right) = \left(e^{\int \frac{1}{\ln(t)}dt}\right)\left(\frac{\cot(t)}{\ln(t)}\right)$$

$$d\left(e^{\int \frac{1}{\ln(t)}dt} y\right) = \left(\frac{\cot(t)\, e^{\int \frac{1}{\ln(t)}dt}}{\ln(t)}\right) dt$$

Integrating gives

$$e^{\int \frac{1}{\ln(t)}dt} y = \int \frac{\cot(t)\, e^{\int \frac{1}{\ln(t)}dt}}{\ln(t)}\, dt$$

$$e^{\int \frac{1}{\ln(t)}dt} y = \int \frac{\cot(t)\, e^{\int \frac{1}{\ln(t)}dt}}{\ln(t)} dt + c_1$$

Dividing both sides by the integrating factor $\mu = e^{\int \frac{1}{\ln(t)}dt}$ results in

$$y = e^{-\left(\int \frac{1}{\ln(t)}dt\right)}\left(\int \frac{\cot(t)\, e^{\int \frac{1}{\ln(t)}dt}}{\ln(t)} dt\right) + c_1 e^{-\left(\int \frac{1}{\ln(t)}dt\right)}$$

which simplifies to

$$y = e^{-\left(\int \frac{1}{\ln(t)}dt\right)}\left(\int \frac{\cot(t)\, e^{\int \frac{1}{\ln(t)}dt}}{\ln(t)} dt + c_1\right)$$

Which can be simplified to become

$$y = e^{\int -\frac{1}{\ln(t)}dt}\left(\int \frac{\cot(t)\, e^{\int \frac{1}{\ln(t)}dt}}{\ln(t)} dt + c_1\right)$$

Summary

The solution(s) found are the following

$$y = e^{\int -\frac{1}{\ln(t)}dt}\left(\int \frac{\cot(t)\, e^{\int \frac{1}{\ln(t)}dt}}{\ln(t)} dt + c_1\right) \tag{1}$$

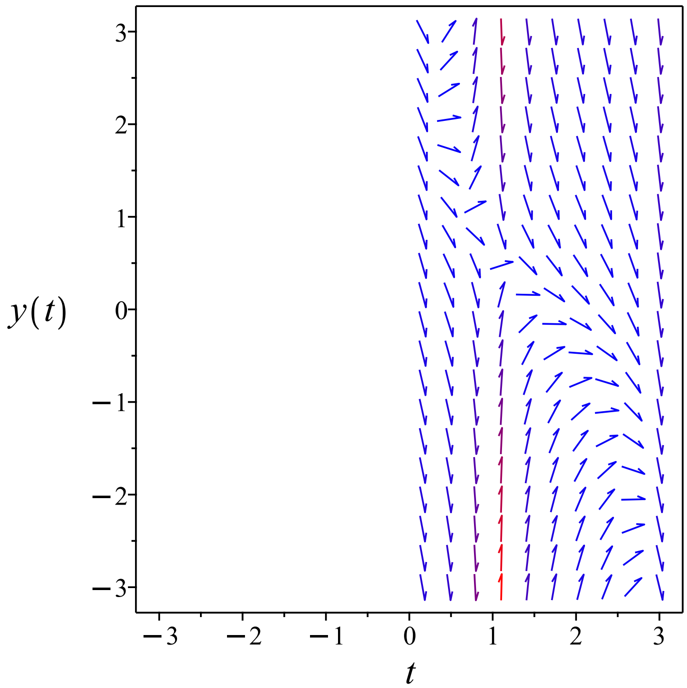

Figure 179: Slope field plot

Verification of solutions

$$y = e^{\int -\frac{1}{\ln(t)}dt} \left(\int \frac{\cot(t)\, e^{\int \frac{1}{\ln(t)}dt}}{\ln(t)} dt + c_1 \right)$$

Verified OK.

3.6.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{-y + \cot(t)}{\ln(t)}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 197: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t,y) &= 0 \\
\eta(t,y) &= \mathrm{e}^{\mathrm{expIntegral}_1(-\ln(t))}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{\text{expIntegral}_1(-\ln(t))}} dy \end{aligned}$$

Which results in

$$S = e^{-\text{expIntegral}_1(-\ln(t))} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = \frac{-y + \cot(t)}{\ln(t)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= \frac{e^{-\text{expIntegral}_1(-\ln(t))} y}{\ln(t)} \\ S_y &= e^{-\text{expIntegral}_1(-\ln(t))} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{e^{-\text{expIntegral}_1(-\ln(t))} \cot(t)}{\ln(t)} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{e^{-\text{expIntegral}_1(-\ln(R))} \cot(R)}{\ln(R)}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \int \frac{\mathrm{e}^{-\mathrm{expIntegral}_1(-\ln(R))} \cot(R)}{\ln(R)} dR + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\mathrm{e}^{-\mathrm{expIntegral}_1(-\ln(t))} y = \int \frac{\mathrm{e}^{-\mathrm{expIntegral}_1(-\ln(t))} \cot(t)}{\ln(t)} dt + c_1$$

Which simplifies to

$$\mathrm{e}^{-\mathrm{expIntegral}_1(-\ln(t))} y = \int \frac{\mathrm{e}^{-\mathrm{expIntegral}_1(-\ln(t))} \cot(t)}{\ln(t)} dt + c_1$$

Which gives

$$y = \left(\int \frac{\mathrm{e}^{-\mathrm{expIntegral}_1(-\ln(t))} \cot(t)}{\ln(t)} dt + c_1\right) \mathrm{e}^{\mathrm{expIntegral}_1(-\ln(t))}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = \frac{-y+\cot(t)}{\ln(t)}$ 	$R = t$ $S = \mathrm{e}^{-\mathrm{expIntegral}_1(-\ln(t))} y$	$\frac{dS}{dR} = \frac{\mathrm{e}^{-\mathrm{expIntegral}_1(-\ln(R))} \cot(R)}{\ln(R)}$ 
Summary

The solution(s) found are the following

$$y = \left(\int \frac{e^{-\operatorname{expIntegral}_1(-\ln(t))} \cot(t)}{\ln(t)} dt + c_1\right) e^{\operatorname{expIntegral}_1(-\ln(t))} \tag{1}$$

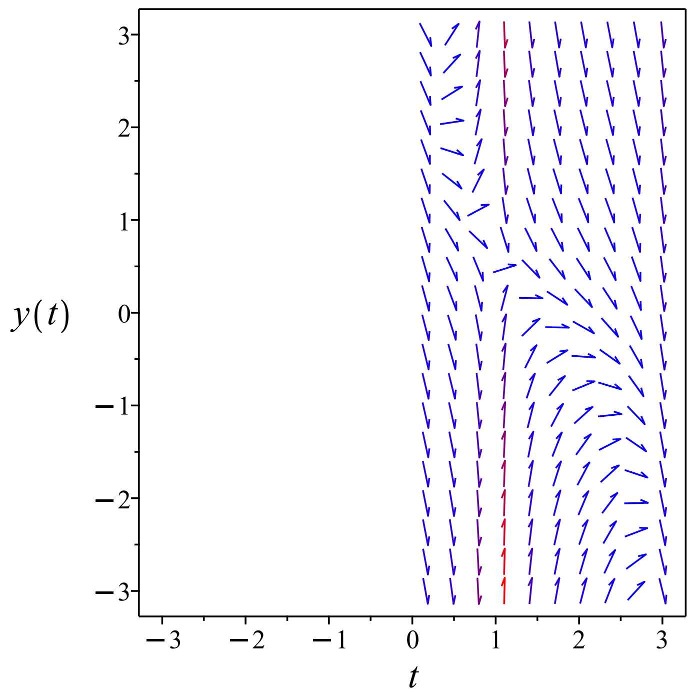

Figure 180: Slope field plot

Verification of solutions

$$y = \left(\int \frac{e^{-\operatorname{expIntegral}_1(-\ln(t))} \cot(t)}{\ln(t)} dt + c_1\right) e^{\operatorname{expIntegral}_1(-\ln(t))}$$

Verified OK.

3.6.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the

ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(\ln(t))\,\mathrm{d}y = (-y + \cot(t))\,\mathrm{d}t$$
$$(y - \cot(t))\,\mathrm{d}t + (\ln(t))\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(t, y) = y - \cot(t)$$
$$N(t, y) = \ln(t)$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(y-\cot(t)) \\ &= 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(\ln(t)) \\ &= \frac{1}{t}\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\ &= \frac{1}{\ln(t)}\left((1) - \left(\frac{1}{t}\right)\right) \\ &= \frac{-1+t}{t\ln(t)}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \, \mathrm{d}t} \\ &= e^{\int \frac{-1+t}{t\ln(t)} \, \mathrm{d}t}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-\operatorname{expIntegral}_1(-\ln(t)) - \ln(\ln(t))} \\ &= \frac{\mathrm{e}^{-\operatorname{expIntegral}_1(-\ln(t))}}{\ln(t)}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \frac{\mathrm{e}^{-\operatorname{expIntegral}_1(-\ln(t))}}{\ln(t)}(y-\cot(t)) \\ &= \frac{(y-\cot(t))\,\mathrm{e}^{-\operatorname{expIntegral}_1(-\ln(t))}}{\ln(t)}\end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{e^{-\operatorname{expIntegral}_1(-\ln(t))}}{\ln(t)}(\ln(t)) \\
&= e^{-\operatorname{expIntegral}_1(-\ln(t))}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{dy}{dt} &= 0 \\
\left(\frac{(y - \cot(t))\, e^{-\operatorname{expIntegral}_1(-\ln(t))}}{\ln(t)}\right) + \left(e^{-\operatorname{expIntegral}_1(-\ln(t))}\right)\frac{dy}{dt} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$
\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. t gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial t}\, dt &= \int \overline{M}\, dt \\
\int \frac{\partial \phi}{\partial t}\, dt &= \int \frac{(y - \cot(t))\, e^{-\operatorname{expIntegral}_1(-\ln(t))}}{\ln(t)}\, dt \\
\phi &= \int^t \frac{(y - \cot(\_a))\, e^{-\operatorname{expIntegral}_1(-\ln(\_a))}}{\ln(\_a)} d\_a + f(y)
\end{aligned} \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = e^{-\operatorname{expIntegral}_1(-\ln(t))} + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = e^{-\operatorname{expIntegral}_1(-\ln(t))}$. Therefore equation (4) becomes

$$
e^{-\operatorname{expIntegral}_1(-\ln(t))} = e^{-\operatorname{expIntegral}_1(-\ln(t))} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \int^t \frac{(y - \cot(\_a))\, e^{-\operatorname{expIntegral}_1(-\ln(\_a))}}{\ln(\_a)} d\_a + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \int^t \frac{(y - \cot(\_a))\, e^{-\operatorname{expIntegral}_1(-\ln(\_a))}}{\ln(\_a)} d\_a$$

Summary

The solution(s) found are the following

$$\int^t \frac{(y - \cot(\_a))\, e^{-\operatorname{expIntegral}_1(-\ln(\_a))}}{\ln(\_a)} d\_a = c_1 \tag{1}$$

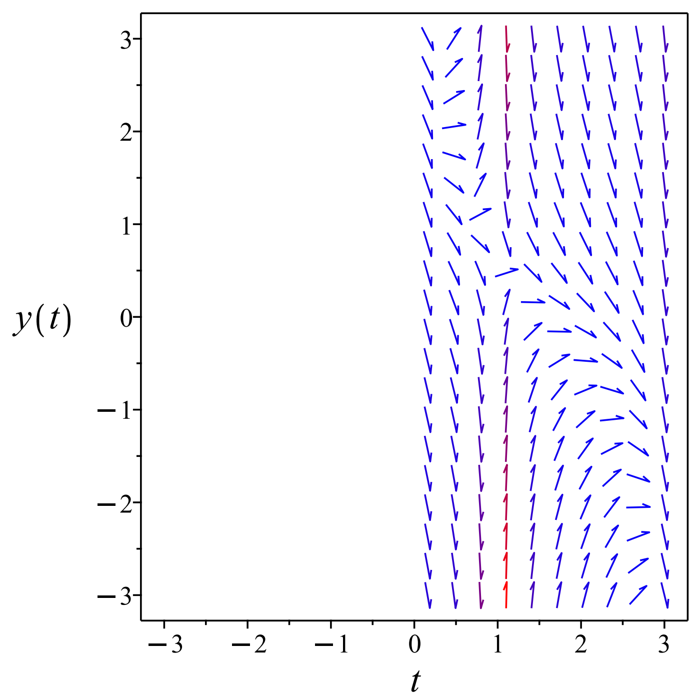

Figure 181: Slope field plot

Verification of solutions

$$\int^{t} \frac{(y-\cot(\_a))\, \mathrm{e}^{-\operatorname{expIntegral}_1(-\ln(\_a))}}{\ln(\_a)} d\_a = c_1$$

Verified OK.

3.6.4 Maple step by step solution

Let's solve

$y + \ln(t)\, y' = \cot(t)$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{y}{\ln(t)} + \frac{\cot(t)}{\ln(t)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{y}{\ln(t)} = \frac{\cot(t)}{\ln(t)}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(y' + \frac{y}{\ln(t)}\right) = \frac{\mu(t)\cot(t)}{\ln(t)}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, y)$

  $\mu(t)\left(y' + \frac{y}{\ln(t)}\right) = \mu'(t)\, y + \mu(t)\, y'$

- Isolate $\mu'(t)$

  $\mu'(t) = \frac{\mu(t)}{\ln(t)}$

- Solve to find the integrating factor

  $\mu(t) = \mathrm{e}^{-\mathrm{Ei}_1(-\ln(t))}$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\, y)\right) dt = \int \frac{\mu(t)\cot(t)}{\ln(t)} dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\, y = \int \frac{\mu(t)\cot(t)}{\ln(t)} dt + c_1$

- Solve for y

  $y = \frac{\int \frac{\mu(t)\cot(t)}{\ln(t)} dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = e^{-\mathrm{Ei}_1(-\ln(t))}$

$$y = \frac{\int \frac{e^{-\mathrm{Ei}_1(-\ln(t))}\cot(t)}{\ln(t)}dt + c_1}{e^{-\mathrm{Ei}_1(-\ln(t))}}$$

- Simplify

$$y = \left(\int \frac{e^{-\mathrm{Ei}_1(-\ln(t))}\cot(t)}{\ln(t)}dt + c_1\right) e^{\mathrm{Ei}_1(-\ln(t))}$$

The type(s) of ODE detected by this program : **"exact", "separable", "differentialType", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{t^2+1}{3y-y^2} = 0}$$

3.7.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(t,y) \\ &= f(t)g(y) \\ &= \frac{-t^2-1}{y\,(-3+y)} \end{aligned}$$

Where $f(t) = -t^2 - 1$ and $g(y) = \frac{1}{y(-3+y)}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y(-3+y)}}\,dy = -t^2 - 1\,dt$$

$$\int \frac{1}{\frac{1}{y(-3+y)}}\, dy = \int -t^2 - 1\, dt$$

$$\frac{1}{3}y^3 - \frac{3}{2}y^2 = -\frac{1}{3}t^3 - t + c_1$$

Which results in

$$y = \frac{\left(27 - 4t^3 + 12c_1 - 12t + 2\sqrt{4t^6 - 24c_1t^3 + 24t^4 - 54t^3 + 36c_1^2 - 72c_1t + 36t^2 + 162c_1 - 162t}\right)^{\frac{1}{3}}}{2} + \frac{9}{2\left(27 - 4t^3 + 12c_1 - 12t + 2\sqrt{4t^6 - 24c_1t^3 + 24t^4 - 54t^3 + 36c_1^2 - 72c_1t + 36t^2 + 162c_1 - 162t}\right)^{\frac{1}{3}}} + \frac{3}{2}$$

$$y = -\frac{\left(27 - 4t^3 + 12c_1 - 12t + 2\sqrt{4t^6 - 24c_1t^3 + 24t^4 - 54t^3 + 36c_1^2 - 72c_1t + 36t^2 + 162c_1 - 162t}\right)^{\frac{1}{3}}}{4} - \frac{9}{4\left(27 - 4t^3 + 12c_1 - 12t + 2\sqrt{4t^6 - 24c_1t^3 + 24t^4 - 54t^3 + 36c_1^2 - 72c_1t + 36t^2 + 162c_1 - 162t}\right)^{\frac{1}{3}}} + \frac{3}{2} + \frac{i\sqrt{3}\left(\frac{\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}}{2} - \frac{}{2\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3}\right.}\right.}{2}$$

$$y = -\frac{\left(27 - 4t^3 + 12c_1 - 12t + 2\sqrt{4t^6 - 24c_1t^3 + 24t^4 - 54t^3 + 36c_1^2 - 72c_1t + 36t^2 + 162c_1 - 162t}\right)^{\frac{1}{3}}}{4} - \frac{9}{4\left(27 - 4t^3 + 12c_1 - 12t + 2\sqrt{4t^6 - 24c_1t^3 + 24t^4 - 54t^3 + 36c_1^2 - 72c_1t + 36t^2 + 162c_1 - 162t}\right)^{\frac{1}{3}}} + \frac{3}{2} - \frac{i\sqrt{3}\left(\frac{\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}}{2} - \frac{}{2\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3}\right.}\right.}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}}{2} + \frac{9}{2\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}} + \frac{3}{2} \tag{1}$$

$$y = -\frac{\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}}{4} - \frac{9}{4\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}} + \frac{3}{2} + \frac{i\sqrt{3}\left(\frac{\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}}{2} - \frac{\cdots}{2\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3\cdots}\right)}\cdots\right)}{2} \tag{2}$$

$$y = -\frac{\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}}{4} - \frac{9}{4\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}} + \frac{3}{2} - \frac{i\sqrt{3}\left(\frac{\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}}{2} - \frac{\cdots}{2\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3\cdots}\right)}\cdots\right)}{2} \tag{3}$$

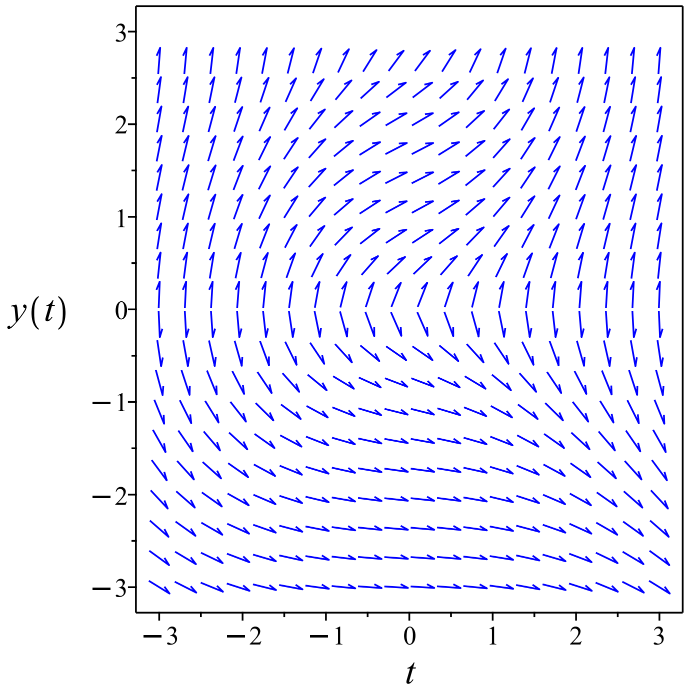

Figure 182: Slope field plot

3.7.2 Solving as differentialType ode

Writing the ode as

$$y' = \frac{t^2+1}{3y-y^2} \tag{1}$$

Which becomes

$$(y^2-3y)\,dy = (-t^2-1)\,dt \tag{2}$$

But the RHS is complete differential because

$$(-t^2-1)\,dt = d\left(-\frac{1}{3}t^3-t\right)$$

Hence (2) becomes

$$(y^2-3y)\,dy = d\left(-\frac{1}{3}t^3-t\right)$$

Integrating both sides gives gives these solutions

$$y = \frac{\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}}{2} + \frac{}{2}$$

$$y = -\frac{\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}}{4} -$$

$$y = -\frac{\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}}{4} -$$

Summary

The solution(s) found are the following

$$y = \frac{\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}}{2} + \frac{9}{2\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}} + \frac{3}{2} + c_1 \tag{1}$$

$$y = -\frac{\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}}{4} - \frac{9}{4\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}} + \frac{3}{2} + \frac{i\sqrt{3}\left(\frac{\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}}{2} - \frac{}{2\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3\cdots}\right.}\right.}{2} + c_1 \tag{2}$$

$$y = -\frac{\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}}{4} - \frac{9}{4\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}} + \frac{3}{2} - \frac{i\sqrt{3}\left(\frac{\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3+24t^4-54t^3+36c_1^2-72c_1t+36t^2+162c_1-162t}\right)^{\frac{1}{3}}}{2} - \frac{}{2\left(27-4t^3+12c_1-12t+2\sqrt{4t^6-24c_1t^3\cdots}\right.}\right.}{2} + c_1 \tag{3}$$

Verified OK.

3.7.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{t^2 + 1}{y(-3 + y)}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 200: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\xi(t, y) = \frac{1}{-t^2 - 1}$$
$$\eta(t, y) = 0 \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dt \\ &= \int \frac{1}{\frac{1}{-t^2-1}} dt \end{aligned}$$

Which results in

$$S = -\frac{1}{3}t^3 - t$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y)S_y}{R_t + \omega(t, y)R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = -\frac{t^2 + 1}{y(-3 + y)}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_t &= 0 \\
R_y &= 1 \\
S_t &= -t^2 - 1 \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = y(-3 + y) \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = R(-3 + R)
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \frac{1}{3}R^3 - \frac{3}{2}R^2 + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$
-\frac{1}{3}t^3 - t = \frac{y^3}{3} - \frac{3y^2}{2} + c_1
$$

Which simplifies to

$$
-\frac{1}{3}t^3 - t = \frac{y^3}{3} - \frac{3y^2}{2} + c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{t^2+1}{y(-3+y)}$ 	$R = y$ $S = -\frac{1}{3}t^3 - t$	$\frac{dS}{dR} = R(-3+R)$ 
Summary

The solution(s) found are the following

$$-\frac{1}{3}t^3 - t = \frac{y^3}{3} - \frac{3y^2}{2} + c_1 \tag{1}$$

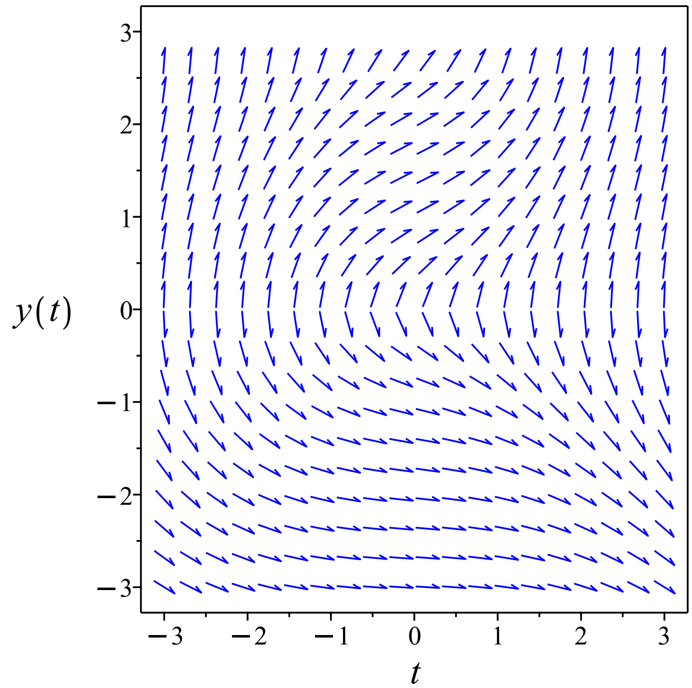

Figure 184: Slope field plot

Verification of solutions

$$-\frac{1}{3}t^3 - t = \frac{y^3}{3} - \frac{3y^2}{2} + c_1$$

Verified OK.

3.7.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t + N(t,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(-y(-3+y))\,\mathrm{d}y &= \left(t^2+1\right)\mathrm{d}t\\ \left(-t^2-1\right)\mathrm{d}t + (-y(-3+y))\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t,y) &= -t^2-1\\ N(t,y) &= -y(-3+y)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-t^2-1\right)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(-y(-3+y))\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \,\mathrm{d}t = \int M \,\mathrm{d}t$$

$$\int \frac{\partial \phi}{\partial t} \,\mathrm{d}t = \int -t^2 - 1 \,\mathrm{d}t$$

$$\phi = -\frac{1}{3}t^3 - t + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -y(-3 + y)$. Therefore equation (4) becomes

$$-y(-3 + y) = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -y(-3 + y)$$

Integrating the above w.r.t y gives

$$\int f'(y) \,\mathrm{d}y = \int (-y(-3 + y)) \,\mathrm{d}y$$

$$f(y) = -\frac{1}{3}y^3 + \frac{3}{2}y^2 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{1}{3}t^3 - t - \frac{1}{3}y^3 + \frac{3}{2}y^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{1}{3}t^3 - t - \frac{1}{3}y^3 + \frac{3}{2}y^2$$

Summary

The solution(s) found are the following

$$-\frac{t^3}{3} - \frac{y^3}{3} + \frac{3y^2}{2} - t = c_1 \tag{1}$$

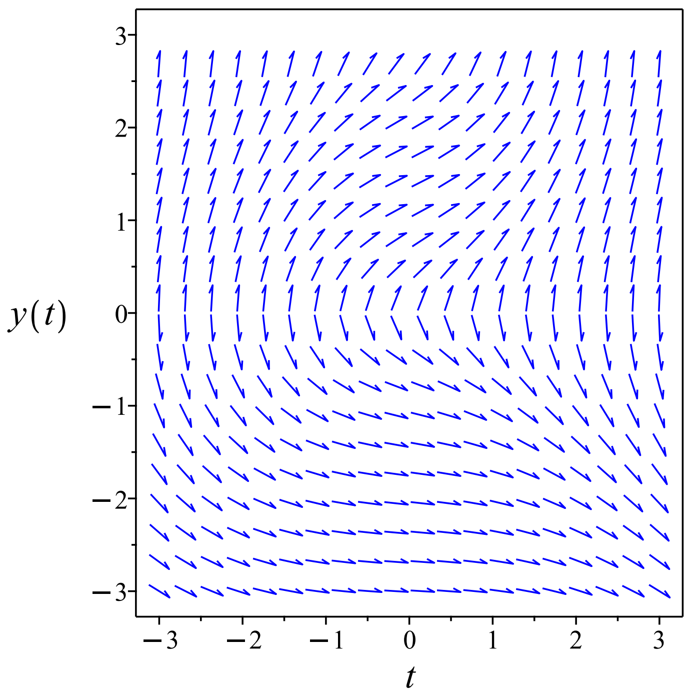

Figure 185: Slope field plot

Verification of solutions

$$-\frac{t^3}{3} - \frac{y^3}{3} + \frac{3y^2}{2} - t = c_1$$

Verified OK.

3.7.5 Maple step by step solution

Let's solve

$y' - \frac{t^2+1}{3y-y^2} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $(3y - y^2)\, y' = t^2 + 1$

- Integrate both sides with respect to t

  $\int (3y - y^2)\, y' dt = \int (t^2 + 1)\, dt + c_1$

- Evaluate integral

  $-\frac{y^3}{3} + \frac{3y^2}{2} = \frac{1}{3}t^3 + c_1 + t$

- Solve for y

  $y = \frac{\left(27-4t^3-12c_1-12t+2\sqrt{4t^6+24c_1t^3+24t^4-54t^3+36c_1^2+72c_1t+36t^2-162c_1-162t}\right)^{\frac{1}{3}}}{2} + \frac{}{2\left(27-4t^3-12c_1-12t+2\sqrt{4t^6+24c_1t^3}\right.}$

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.4. Page 76
Problem number: 12.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{\cot(t)\, y}{1+y} = 0}$$

3.8.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(t,y) \\ &= f(t)g(y) \\ &= \frac{\cot(t)\, y}{y+1} \end{aligned}$$

Where $f(t) = \cot(t)$ and $g(y) = \frac{y}{y+1}$. Integrating both sides gives

$$\frac{1}{\frac{y}{y+1}}\, dy = \cot(t)\, dt$$

$$\int \frac{1}{\frac{y}{y+1}}dy = \int \cot(t)\, dt$$

$$y + \ln(y) = \ln(\sin(t)) + c_1$$

Which results in

$$y = \text{LambertW}\left(e^{c_1} \sin(t)\right)$$

Since c_1 is constant, then exponential powers of this constant are constants also, and these can be simplified to just c_1 in the above solution. Which simplifies to

$$y = \text{LambertW}\left(e^{c_1} \sin(t)\right)$$

gives

$$y = \text{LambertW}(c_1 \sin(t))$$

Summary

The solution(s) found are the following

$$y = \text{LambertW}(c_1 \sin(t)) \tag{1}$$

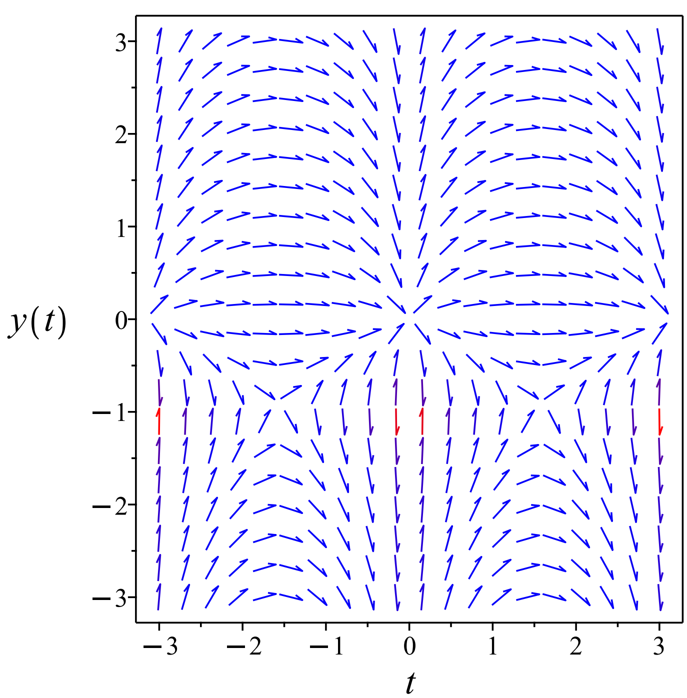

Figure 186: Slope field plot

Verification of solutions

$$
y = \text{LambertW}\left(c_1 \sin\left(t\right)\right)
$$

Verified OK.

3.8.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
y' = \frac{\cot\left(t\right) y}{y+1}
$$
$$
y' = \omega(t, y)
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 203: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= \frac{1}{\cot(t)} \\
\eta(t, y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dt \\ &= \int \frac{1}{\frac{1}{\cot(t)}} dt \end{aligned}$$

Which results in

$$S = \ln (\sin (t))$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = \frac{\cot (t) \, y}{y + 1}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 0 \\ R_y &= 1 \\ S_t &= \cot (t) \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{y + 1}{y} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{R + 1}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = R + \ln(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\ln(\sin(t)) = y + \ln(y) + c_1$$

Which simplifies to

$$\ln(\sin(t)) = y + \ln(y) + c_1$$

Which gives

$$y = \text{LambertW}\left(e^{-c_1} \sin(t)\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in t, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>
<tr><td>$\frac{dy}{dt} = \frac{\cot(t)y}{y+1}$
</td><td>$R = y$
$S = \ln(\sin(t))$</td><td>$\frac{dS}{dR} = \frac{R+1}{R}$
</td></tr>
</table>

Summary

The solution(s) found are the following

$$y = \text{LambertW}\left(e^{-c_1} \sin(t)\right) \tag{1}$$

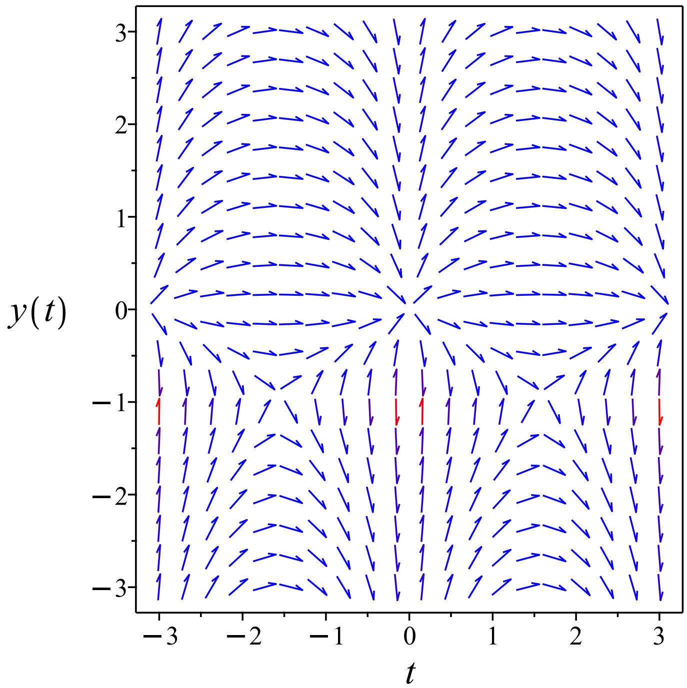

Figure 187: Slope field plot

Verification of solutions

$$y = \text{LambertW}\left(\mathrm{e}^{-c_1} \sin\left(t\right)\right)$$

Verified OK.

3.8.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\, \mathrm{d}t + N(t, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\frac{y+1}{y}\right) \mathrm{d}y &= (\cot(t))\, \mathrm{d}t\\ (-\cot(t))\, \mathrm{d}t + \left(\frac{y+1}{y}\right) \mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(t, y) &= -\cot(t)\\ N(t, y) &= \frac{y+1}{y}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-\cot(t))\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}\left(\frac{y+1}{y}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(t, y)$

$$\frac{\partial \phi}{\partial t} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. t gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial t}\,\mathrm{d}t &= \int M\,\mathrm{d}t\\ \int \frac{\partial \phi}{\partial t}\,\mathrm{d}t &= \int -\cot(t)\,\mathrm{d}t\\ \phi &= -\ln(\sin(t)) + f(y)\end{aligned} \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{y+1}{y}$. Therefore equation (4) becomes

$$\frac{y+1}{y} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{y+1}{y}$$

Integrating the above w.r.t y gives

$$\begin{aligned}\int f'(y)\,\mathrm{d}y &= \int \left(\frac{y+1}{y}\right)\mathrm{d}y\\ f(y) &= y + \ln(y) + c_1\end{aligned}$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(\sin(t)) + y + \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(\sin(t)) + y + \ln(y)$$

The solution becomes

$$y = \text{LambertW}\left(e^{c_1} \sin(t)\right)$$

Summary

The solution(s) found are the following

$$y = \text{LambertW}\left(e^{c_1} \sin(t)\right) \tag{1}$$

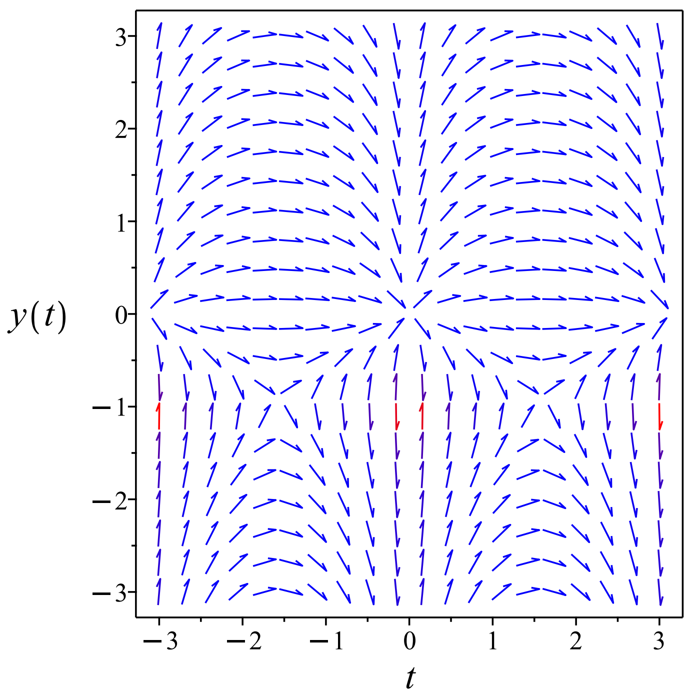

Figure 188: Slope field plot

Verification of solutions

$$y = \text{LambertW}\left(e^{c_1} \sin(t)\right)$$

Verified OK.

3.8.4 Maple step by step solution

Let's solve

$y' - \frac{\cot(t)y}{1+y} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'(1+y)}{y} = \cot(t)$

- Integrate both sides with respect to t

  $\int \frac{y'(1+y)}{y} dt = \int \cot(t)\, dt + c_1$

- Evaluate integral

  $y + \ln(y) = \ln(\sin(t)) + c_1$

- Solve for y

  $y = \mathit{LambertW}(e^{c_1} \sin(t))$

Problem number: 13.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "differentialType", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' + \frac{4t}{y} = 0}$$

3.9.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(t, y) \\ &= f(t)g(y) \\ &= -\frac{4t}{y} \end{aligned}$$

Where $f(t) = -4t$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y}}\,dy = -4t\,dt$$

$$\int \frac{1}{\frac{1}{y}}\,dy = \int -4t\,dt$$

$$\frac{y^2}{2} = -2t^2 + c_1$$

Which results in

$$y = \sqrt{-4t^2 + 2c_1}$$

$$y = -\sqrt{-4t^2 + 2c_1}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \sqrt{-4t^2 + 2c_1} \tag{1}$$

$$y = -\sqrt{-4t^2 + 2c_1} \tag{2}$$

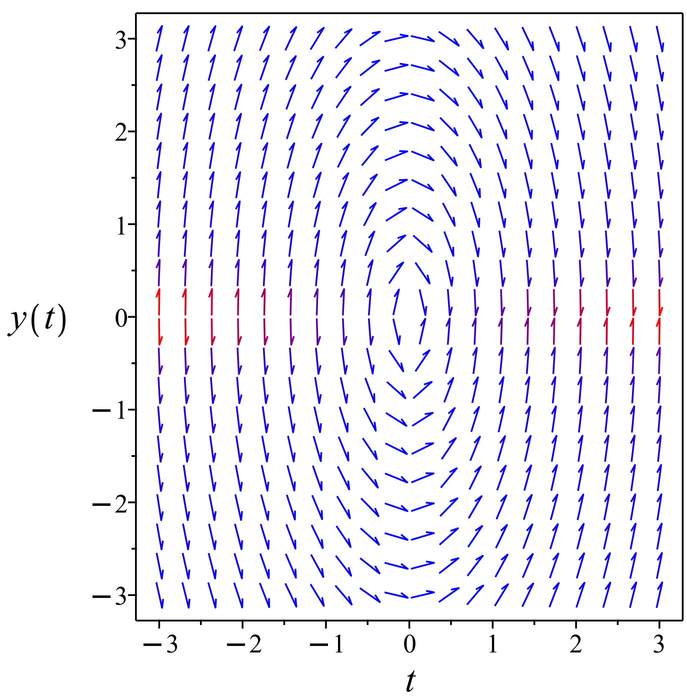

Figure 189: Slope field plot

Verification of solutions

$$y = \sqrt{-4t^2 + 2c_1}$$

Verified OK.

$$y = -\sqrt{-4t^2 + 2c_1}$$

Verified OK.

3.9.2 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(t)\, t$ on the above ode results in new ode in $u(t)$

$$u'(t)\, t + u(t) + \frac{4}{u\,(t)} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(t, u) \\ &= f(t) g(u) \\ &= -\frac{u^2 + 4}{tu} \end{aligned}$$

Where $f(t) = -\frac{1}{t}$ and $g(u) = \frac{u^2+4}{u}$. Integrating both sides gives

$$\begin{aligned} \frac{1}{\frac{u^2+4}{u}}\, du &= -\frac{1}{t}\, dt \\ \int \frac{1}{\frac{u^2+4}{u}}\, du &= \int -\frac{1}{t}\, dt \\ \frac{\ln(u^2 + 4)}{2} &= -\ln(t) + c_2 \end{aligned}$$

Raising both side to exponential gives

$$\sqrt{u^2 + 4} = \mathrm{e}^{-\ln(t) + c_2}$$

Which simplifies to

$$\sqrt{u^2 + 4} = \frac{c_3}{t}$$

Which simplifies to

$$\sqrt{u\,(t)^2 + 4} = \frac{c_3 \mathrm{e}^{c_2}}{t}$$

The solution is

$$\sqrt{u(t)^2 + 4} = \frac{c_3 e^{c_2}}{t}$$

Replacing $u(t)$ in the above solution by $\frac{y}{t}$ results in the solution for y in implicit form

$$\sqrt{\frac{y^2}{t^2} + 4} = \frac{c_3 e^{c_2}}{t}$$
$$\sqrt{\frac{y^2 + 4t^2}{t^2}} = \frac{c_3 e^{c_2}}{t}$$

Summary

The solution(s) found are the following

$$\sqrt{\frac{y^2 + 4t^2}{t^2}} = \frac{c_3 e^{c_2}}{t} \tag{1}$$

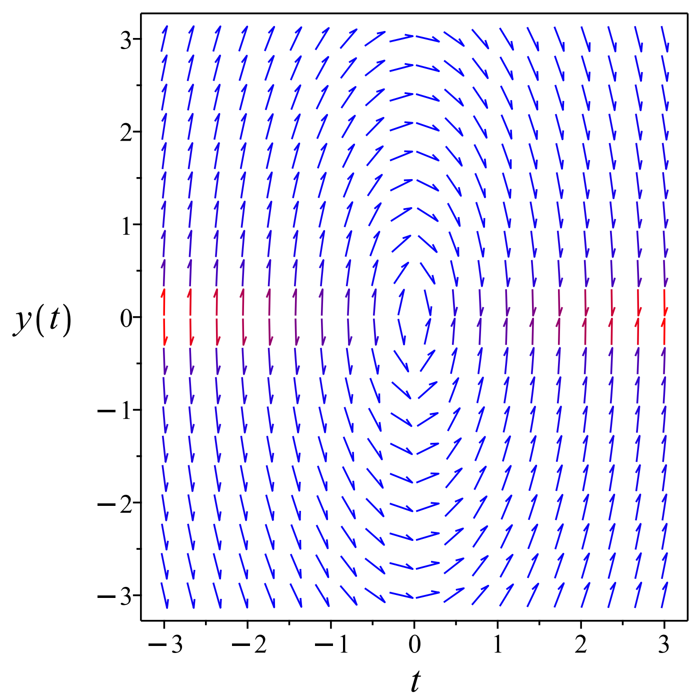

Figure 190: Slope field plot

Verification of solutions

$$\sqrt{\frac{y^2 + 4t^2}{t^2}} = \frac{c_3 e^{c_2}}{t}$$

Verified OK.

3.9.3 Solving as differentialType ode

Writing the ode as

$$y' = -\frac{4t}{y} \tag{1}$$

Which becomes

$$(y)\, dy = (-4t)\, dt \tag{2}$$

But the RHS is complete differential because

$$(-4t)\, dt = d\left(-2t^2\right)$$

Hence (2) becomes

$$(y)\, dy = d\left(-2t^2\right)$$

Integrating both sides gives gives these solutions

$$y = \sqrt{-4t^2 + 2c_1} + c_1$$
$$y = -\sqrt{-4t^2 + 2c_1} + c_1$$

Summary

The solution(s) found are the following

$$y = \sqrt{-4t^2 + 2c_1} + c_1 \tag{1}$$
$$y = -\sqrt{-4t^2 + 2c_1} + c_1 \tag{2}$$

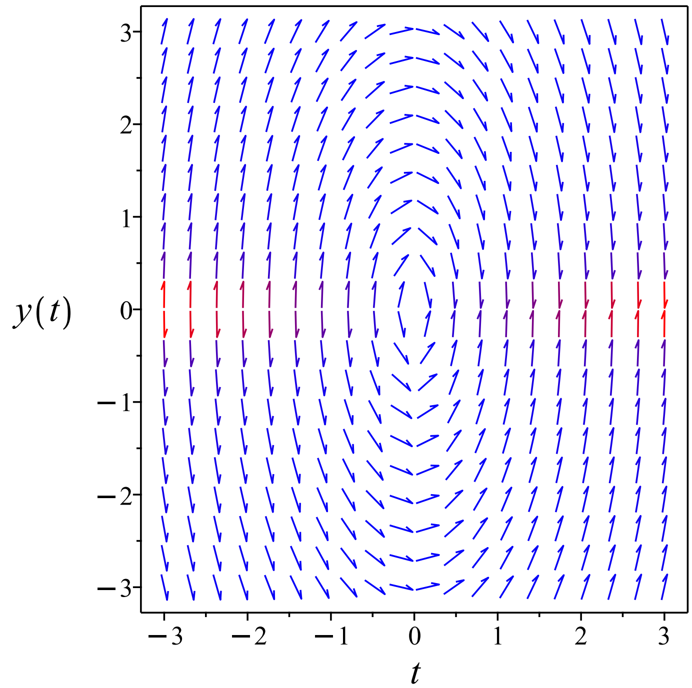

Figure 191: Slope field plot

Verification of solutions

$$y = \sqrt{-4t^2 + 2c_1} + c_1$$

Verified OK.

$$y = -\sqrt{-4t^2 + 2c_1} + c_1$$

Verified OK.

3.9.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{4t}{y}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 206: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= -\frac{1}{4t} \\
\eta(t, y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dt \\ &= \int \frac{1}{-\frac{1}{4t}} dt \end{aligned}$$

Which results in

$$S = -2t^2$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = -\frac{4t}{y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 0 \\ R_y &= 1 \\ S_t &= -4t \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = y \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$-2t^2 = \frac{y^2}{2} + c_1$$

Which simplifies to

$$-2t^2 = \frac{y^2}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{4t}{y}$ 	$R = y$ $S = -2t^2$	$\frac{dS}{dR} = R$ 
Summary

The solution(s) found are the following

$$-2t^2 = \frac{y^2}{2} + c_1 \tag{1}$$

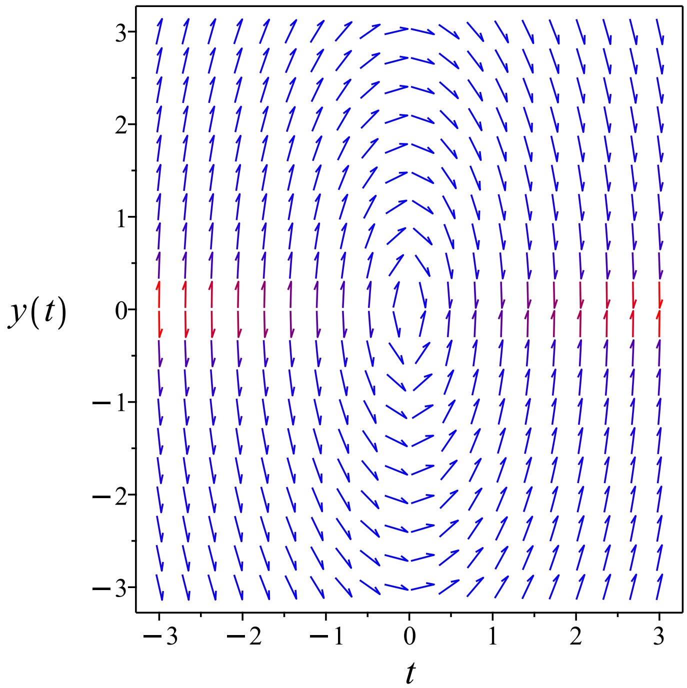

Figure 192: Slope field plot

Verification of solutions

$$-2t^2 = \frac{y^2}{2} + c_1$$

Verified OK.

3.9.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(-\frac{y}{4}\right)\mathrm{d}y = (t)\,\mathrm{d}t$$
$$(-t)\,\mathrm{d}t + \left(-\frac{y}{4}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(t, y) = -t$$
$$N(t, y) = -\frac{y}{4}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-t)\\ &= 0\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}\left(-\frac{y}{4}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(t, y)$

$$
\frac{\partial \phi}{\partial t} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. t gives

$$
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int M \, \mathrm{d}t
$$

$$
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t = \int -t \, \mathrm{d}t
$$

$$
\phi = -\frac{t^2}{2} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{y}{4}$. Therefore equation (4) becomes

$$
-\frac{y}{4} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = -\frac{y}{4}
$$

Integrating the above w.r.t y gives

$$
\int f'(y) \, \mathrm{d}y = \int \left(-\frac{y}{4}\right) \mathrm{d}y
$$

$$
f(y) = -\frac{y^2}{8} + c_1
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{t^2}{2} - \frac{y^2}{8} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{t^2}{2} - \frac{y^2}{8}$$

Summary

The solution(s) found are the following

$$-\frac{t^2}{2} - \frac{y^2}{8} = c_1 \tag{1}$$

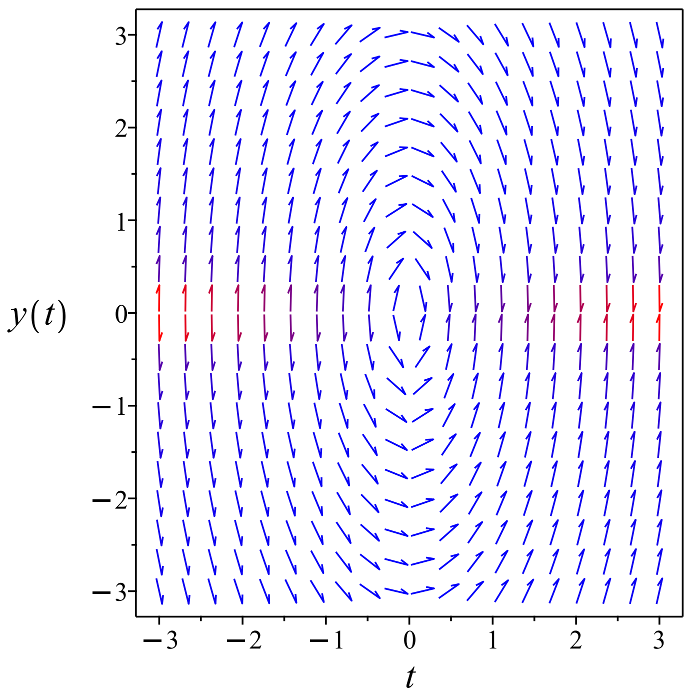

Figure 193: Slope field plot

Verification of solutions

$$-\frac{t^2}{2} - \frac{y^2}{8} = c_1$$

Verified OK.

3.9.6 Maple step by step solution

Let's solve

$y' + \frac{4t}{y} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $y'y = -4t$

- Integrate both sides with respect to t

  $\int y'ydt = \int -4tdt + c_1$

- Evaluate integral

  $\frac{y^2}{2} = -2t^2 + c_1$

- Solve for y

  $\left\{y = \sqrt{-4t^2 + 2c_1}, y = -\sqrt{-4t^2 + 2c_1}\right\}$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "riccati", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - 2ty^2 = 0}$$

3.10.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(t, y) \\ &= f(t)g(y) \\ &= 2t\, y^2 \end{aligned}$$

Where $f(t) = 2t$ and $g(y) = y^2$. Integrating both sides gives

$$\frac{1}{y^2}\, dy = 2t\, dt$$

$$\int \frac{1}{y^2}\, dy = \int 2t\, dt$$

$$-\frac{1}{y} = t^2 + c_1$$

Which results in

$$y = -\frac{1}{t^2 + c_1}$$

Summary
The solution(s) found are the following

$$y = -\frac{1}{t^2 + c_1} \tag{1}$$

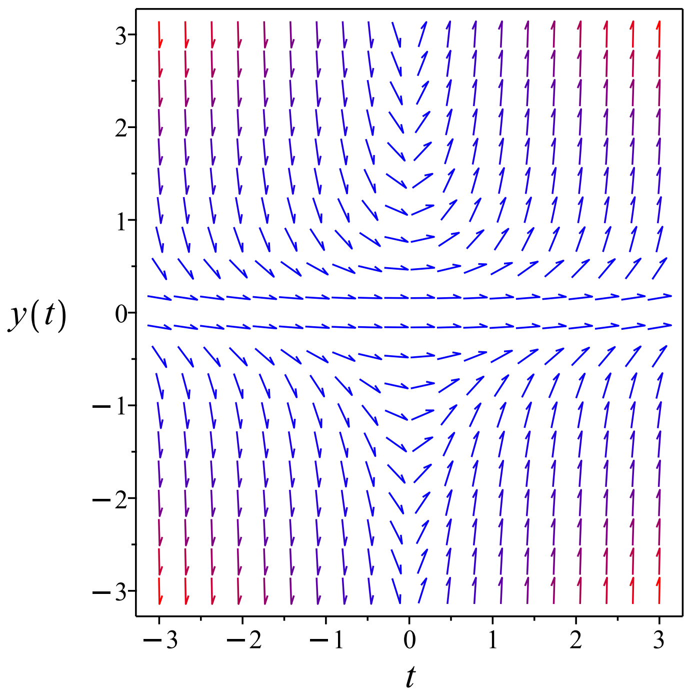

Figure 194: Slope field plot

Verification of solutions

$$y = -\frac{1}{t^2 + c_1}$$

Verified OK.

3.10.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = 2t\,y^2$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 209: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x + b_1y + c_1}{a_2x + b_2y + c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(t,y) &= \frac{1}{2t}\\ \eta(t,y) &= 0\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial t} + \eta\frac{\partial}{\partial y}\right) S(t,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\xi} dt\\ &= \int \frac{1}{\frac{1}{2t}} dt\end{aligned}$$

Which results in

$$S = t^2$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y)S_y}{R_t + \omega(t,y)R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = 2t\, y^2$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_t &= 0\\ R_y &= 1\\ S_t &= 2t\\ S_y &= 0\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{y^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{1}{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$t^2 = -\frac{1}{y} + c_1$$

Which simplifies to

$$t^2 = -\frac{1}{y} + c_1$$

Which gives

$$y = \frac{1}{-t^2 + c_1}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = 2t\,y^2$ 	$R = y$ $S = t^2$	$\frac{dS}{dR} = \frac{1}{R^2}$ 
Summary

The solution(s) found are the following

$$y = \frac{1}{-t^2 + c_1} \tag{1}$$

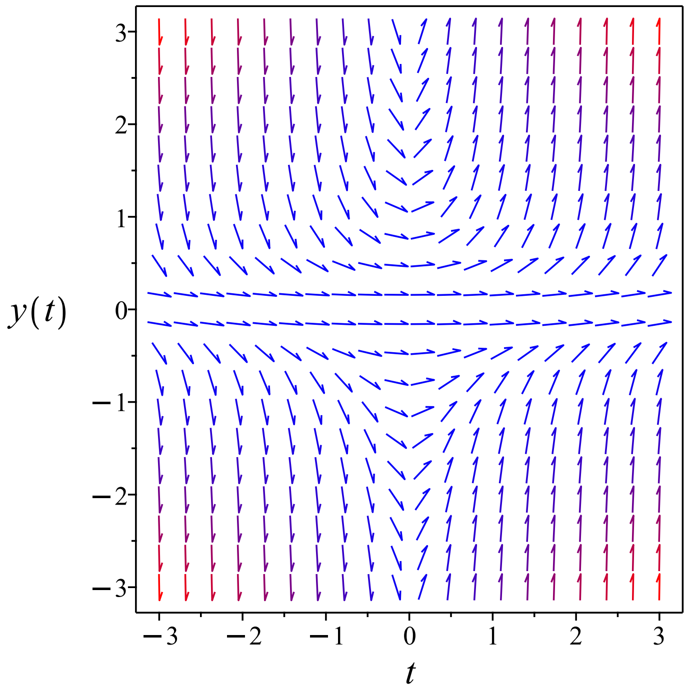

Figure 195: Slope field plot

Verification of solutions

$$y = \frac{1}{-t^2 + c_1}$$

Verified OK.

3.10.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(\frac{1}{2y^2}\right) \mathrm{d}y &= (t)\,\mathrm{d}t \\
(-t)\,\mathrm{d}t + \left(\frac{1}{2y^2}\right) \mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(t, y) &= -t \\
N(t, y) &= \frac{1}{2y^2}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-t) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}\left(\frac{1}{2y^2}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(t, y)$

$$
\frac{\partial \phi}{\partial t} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. t gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int M \, \mathrm{d}t \\
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int -t \, \mathrm{d}t \\
\phi &= -\frac{t^2}{2} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{2y^2}$. Therefore equation (4) becomes

$$
\frac{1}{2y^2} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{2y^2}
$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{1}{2y^2}\right) \mathrm{d}y$$
$$f(y) = -\frac{1}{2y} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{t^2}{2} - \frac{1}{2y} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{t^2}{2} - \frac{1}{2y}$$

The solution becomes

$$y = -\frac{1}{t^2 + 2c_1}$$

Summary

The solution(s) found are the following

$$y = -\frac{1}{t^2 + 2c_1} \tag{1}$$

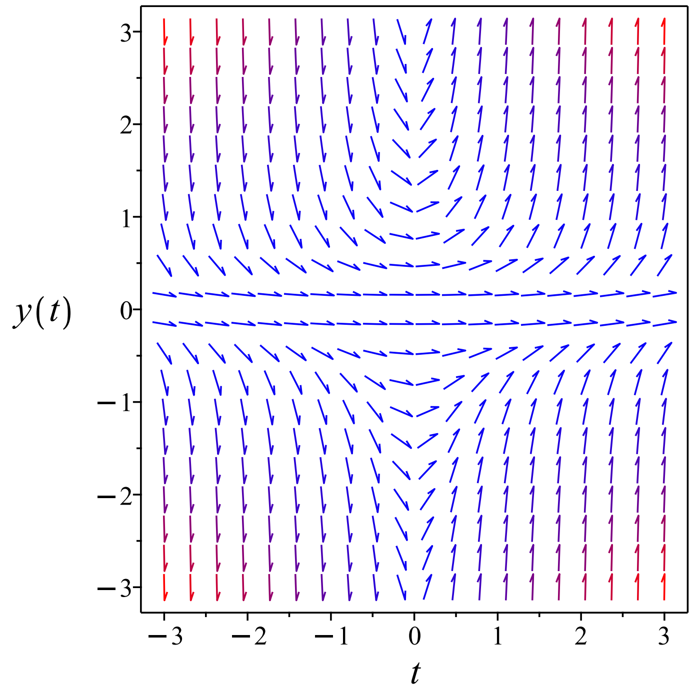

Figure 196: Slope field plot

Verification of solutions

$$y = -\frac{1}{t^2 + 2c_1}$$

Verified OK.

3.10.4 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned}
y' &= F(t, y) \\
&= 2t\,y^2
\end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = 2t\,y^2$$

With Riccati ODE standard form

$$y' = f_0(t) + f_1(t)y + f_2(t)y^2$$

Shows that $f_0(t) = 0$, $f_1(t) = 0$ and $f_2(t) = 2t$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{2tu} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(t) - (f_2' + f_1 f_2) u'(t) + f_2^2 f_0 u(t) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 2 \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= 0 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$2tu''(t) - 2u'(t) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(t) = c_2 t^2 + c_1$$

The above shows that

$$u'(t) = 2c_2 t$$

Using the above in (1) gives the solution

$$y = -\frac{c_2}{c_2 t^2 + c_1}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{1}{t^2 + c_3}$$

Summary

The solution(s) found are the following

$$y = -\frac{1}{t^2 + c_3} \tag{1}$$

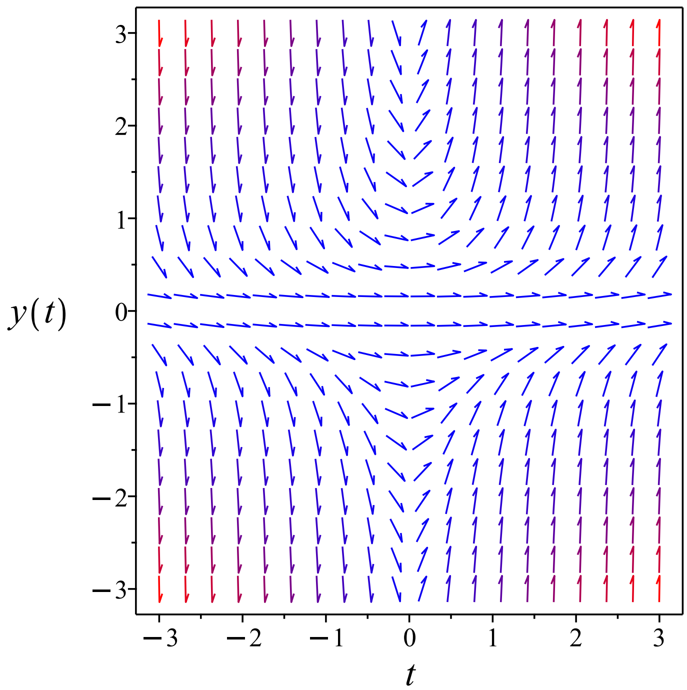

Figure 197: Slope field plot

Verification of solutions

$$y = -\frac{1}{t^2 + c_3}$$

Verified OK.

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{y' - \frac{t^2}{(t^3+1)\,y} = 0}$$

3.12.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(t,y) \\ &= f(t)g(y) \\ &= \frac{t^2}{(t^3+1)\,y} \end{aligned}$$

Where $f(t) = \frac{t^2}{t^3+1}$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y}}\,dy = \frac{t^2}{t^3+1}\,dt$$

$$\int \frac{1}{\frac{1}{y}}\,dy = \int \frac{t^2}{t^3+1}\,dt$$
$$\frac{y^2}{2} = \frac{\ln\left(t^3+1\right)}{3} + c_1$$

Which results in

$$y = \frac{\sqrt{6\ln\left(t^3+1\right)+18c_1}}{3}$$
$$y = -\frac{\sqrt{6\ln\left(t^3+1\right)+18c_1}}{3}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \frac{\sqrt{6\ln\left(t^3+1\right)+18c_1}}{3} \tag{1}$$
$$y = -\frac{\sqrt{6\ln\left(t^3+1\right)+18c_1}}{3} \tag{2}$$

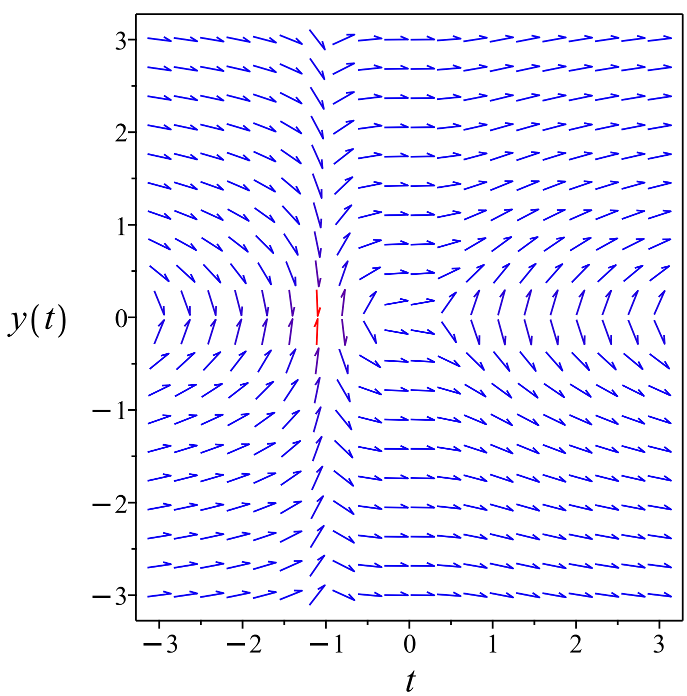

Figure 199: Slope field plot

$$y = \frac{\sqrt{6 \ln \left(t^3+1\right)+18 c_1}}{3}$$

Verified OK.

$$y = -\frac{\sqrt{6 \ln \left(t^3+1\right)+18 c_1}}{3}$$

Verified OK.

3.12.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{t^2}{\left(t^3+1\right) y}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 213: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x) dx - h(x)}}{g(x)}$	$\frac{f(x) e^{-\int b f(x) dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= \frac{t^3 + 1}{t^2} \\
\eta(t, y) &= 0
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dt \\ &= \int \frac{1}{\frac{t^3+1}{t^2}} dt \end{aligned}$$

Which results in

$$S = \frac{\ln(t^3+1)}{3}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y)S_y}{R_t + \omega(t,y)R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = \frac{t^2}{(t^3+1)\,y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 0 \\ R_y &= 1 \\ S_t &= \frac{t^2}{(t^2-t+1)(t+1)} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = y \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{R^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$\frac{\ln(t+1)}{3} + \frac{\ln(t^2 - t + 1)}{3} = \frac{y^2}{2} + c_1$$

Which simplifies to

$$\frac{\ln(t+1)}{3} + \frac{\ln(t^2 - t + 1)}{3} = \frac{y^2}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = \frac{t^2}{(t^3+1)y}$ 	$R = y$ $S = \frac{\ln(t+1)}{3} + \frac{\ln(t^2 -}{3}$	$\frac{dS}{dR} = R$ 
Summary

The solution(s) found are the following

$$\frac{\ln(t+1)}{3} + \frac{\ln(t^2 - t + 1)}{3} = \frac{y^2}{2} + c_1 \tag{1}$$

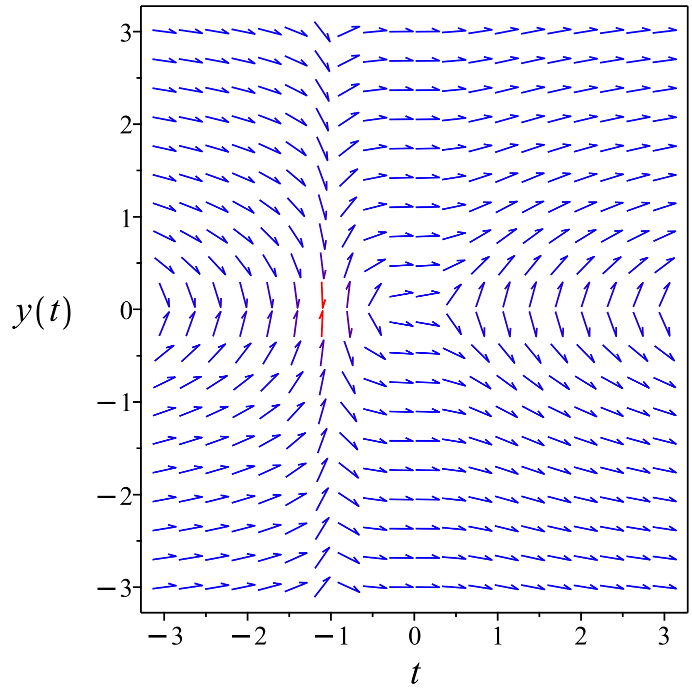

Figure 200: Slope field plot

Verification of solutions

$$\frac{\ln(t+1)}{3}+\frac{\ln(t^2-t+1)}{3}=\frac{y^2}{2}+c_1$$

Verified OK.

3.12.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t + N(t,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(y)\,\mathrm{d}y = \left(\frac{t^2}{t^3+1}\right)\mathrm{d}t$$
$$\left(-\frac{t^2}{t^3+1}\right)\mathrm{d}t + (y)\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(t,y) = -\frac{t^2}{t^3+1}$$
$$N(t,y) = y$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{t^2}{t^3+1}\right) \\ &= 0\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(y) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(t, y)$

$$
\frac{\partial \phi}{\partial t} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. t gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int M \, \mathrm{d}t \\
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int -\frac{t^2}{t^3+1} \, \mathrm{d}t
\end{aligned}
$$

$$
\phi = -\frac{\ln(t^3+1)}{3} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y$. Therefore equation (4) becomes

$$
y = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = y
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \, \mathrm{d}y &= \int (y) \, \mathrm{d}y \\
f(y) &= \frac{y^2}{2} + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\ln(t^3+1)}{3} + \frac{y^2}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\ln(t^3+1)}{3} + \frac{y^2}{2}$$

Summary

The solution(s) found are the following

$$-\frac{\ln(t^3+1)}{3} + \frac{y^2}{2} = c_1 \tag{1}$$

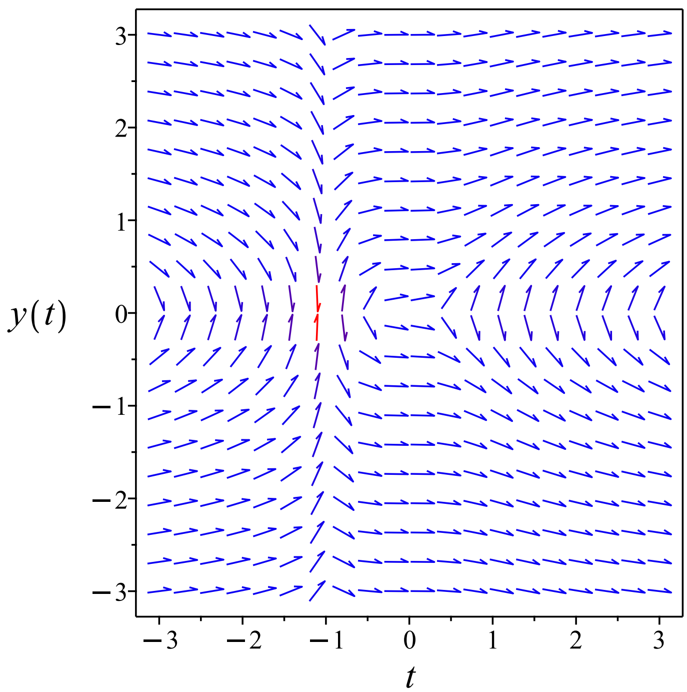

Figure 201: Slope field plot

Verification of solutions

$$-\frac{\ln(t^3+1)}{3} + \frac{y^2}{2} = c_1$$

Verified OK.

3.12.4 Maple step by step solution

Let's solve

$y' - \frac{t^2}{(t^3+1)y} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $y'y = \frac{t^2}{t^3+1}$

- Integrate both sides with respect to t

  $\int y'ydt = \int \frac{t^2}{t^3+1}dt + c_1$

- Evaluate integral

  $\frac{y^2}{2} = \frac{\ln(t^3+1)}{3} + c_1$

- Solve for y

  $\left\{y = -\frac{\sqrt{6\ln(t^3+1)+18c_1}}{3}, y = \frac{\sqrt{6\ln(t^3+1)+18c_1}}{3}\right\}$

The type(s) of ODE detected by this program : **"exact", "riccati", "bernoulli", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - t(3 - y)\, y = 0}$$

3.13.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(t, y) \\ &= f(t)g(y) \\ &= -ty(-3 + y) \end{aligned}$$

Where $f(t) = -t$ and $g(y) = y(-3 + y)$. Integrating both sides gives

$$\frac{1}{y\,(-3 + y)}\, dy = -t\, dt$$

$$\int \frac{1}{y(-3+y)}\,dy = \int -t\,dt$$

$$-\frac{\ln(y)}{3} + \frac{\ln(-3+y)}{3} = -\frac{t^2}{2} + c_1$$

The above can be written as

$$\left(-\frac{1}{3}\right)(\ln(y) - \ln(-3+y)) = -\frac{t^2}{2} + 2c_1$$

$$\begin{aligned}\ln(y) - \ln(-3+y) &= (-3)\left(-\frac{t^2}{2} + 2c_1\right)\\ &= \frac{3t^2}{2} - 6c_1\end{aligned}$$

Raising both side to exponential gives

$$e^{\ln(y)-\ln(-3+y)} = e^{\frac{3t^2}{2}-3c_1}$$

Which simplifies to

$$\begin{aligned}\frac{y}{-3+y} &= -3c_1 e^{\frac{3t^2}{2}}\\ &= c_2 e^{\frac{3t^2}{2}}\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{3c_2 e^{\frac{3t^2}{2}}}{-1 + c_2 e^{\frac{3t^2}{2}}} \tag{1}$$

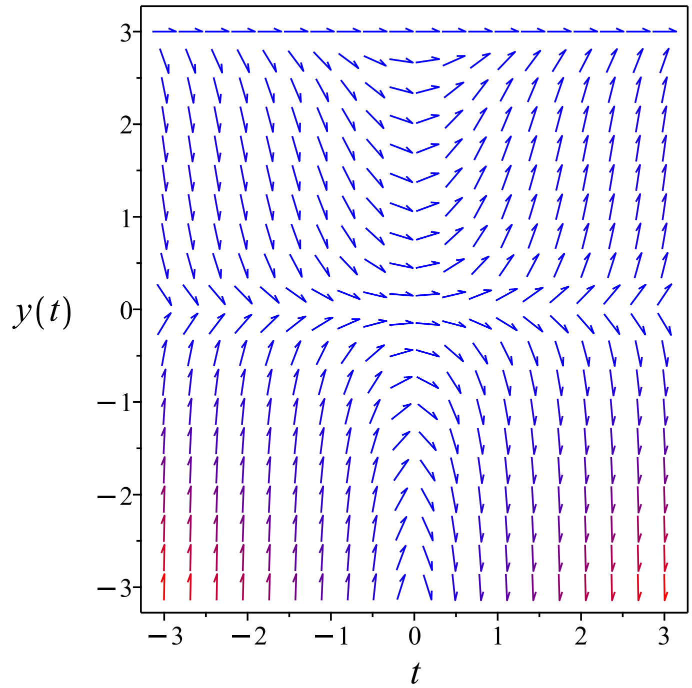

Figure 202: Slope field plot

Verification of solutions

$$y = \frac{3c_2 e^{\frac{3t^2}{2}}}{-1 + c_2 e^{\frac{3t^2}{2}}}$$

Verified OK.

3.13.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -ty(-3 + y)$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 216: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= -\frac{1}{t} \\
\eta(t, y) &= 0
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dt \\ &= \int \frac{1}{-\frac{1}{t}} dt \end{aligned}$$

Which results in

$$S = -\frac{t^2}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y) S_y}{R_t + \omega(t,y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t,y) = -ty(-3+y)$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 0 \\ R_y &= 1 \\ S_t &= -t \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{y(-3+y)} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R(-3+R)}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\frac{\ln(R)}{3} + \frac{\ln(-3+R)}{3} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$-\frac{t^2}{2} = -\frac{\ln(y)}{3} + \frac{\ln(-3+y)}{3} + c_1$$

Which simplifies to

$$-\frac{t^2}{2} = -\frac{\ln(y)}{3} + \frac{\ln(-3+y)}{3} + c_1$$

Which gives

$$y = \frac{3\,e^{\frac{3t^2}{2}+3c_1}}{-1+e^{\frac{3t^2}{2}+3c_1}}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -ty(-3+y)$ 	$R = y$ $S = -\frac{t^2}{2}$	$\frac{dS}{dR} = \frac{1}{R(-3+R)}$ 
Summary
The solution(s) found are the following

$$y = \frac{3\,\mathrm{e}^{\frac{3t^2}{2}+3c_1}}{-1+\mathrm{e}^{\frac{3t^2}{2}+3c_1}} \tag{1}$$

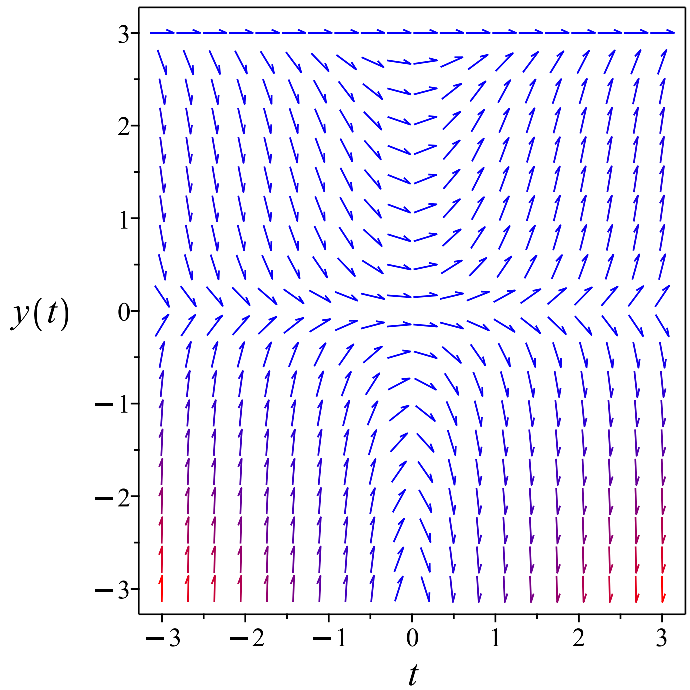

Figure 203: Slope field plot

Verification of solutions

$$y = \frac{3\,\mathrm{e}^{\frac{3t^2}{2}+3c_1}}{-1+\mathrm{e}^{\frac{3t^2}{2}+3c_1}}$$

Verified OK.

3.13.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(t,y) \\ &= -ty(-3+y) \end{aligned}$$

This is a Bernoulli ODE.

$$y' = 3ty - ty^2 \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(t)y + f_1(t)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(t)y^{1-n} + f_1(t) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(t)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(t)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(t) &= 3t \\ f_1(t) &= -t \\ n &= 2 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = y^2$ gives

$$y'\frac{1}{y^2} = \frac{3t}{y} - t \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= \frac{1}{y} \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t t gives

$$w' = -\frac{1}{y^2}y' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} -w'(t) &= 3w(t)\, t - t \\ w' &= -3tw + t \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(t)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(t) + p(t)w(t) = q(t)$$

Where here

$$
\begin{aligned}
p(t) &= 3t \\
q(t) &= t
\end{aligned}
$$

Hence the ode is

$$
w'(t) + 3w(t)\,t = t
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int 3t dt} \\
&= \mathrm{e}^{\frac{3t^2}{2}}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}t}(\mu w) &= (\mu)\,(t) \\
\frac{\mathrm{d}}{\mathrm{d}t}\left(\mathrm{e}^{\frac{3t^2}{2}} w\right) &= \left(\mathrm{e}^{\frac{3t^2}{2}}\right)(t) \\
\mathrm{d}\left(\mathrm{e}^{\frac{3t^2}{2}} w\right) &= \left(t\,\mathrm{e}^{\frac{3t^2}{2}}\right)\,\mathrm{d}t
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{\frac{3t^2}{2}} w &= \int t\,\mathrm{e}^{\frac{3t^2}{2}}\,\mathrm{d}t \\
\mathrm{e}^{\frac{3t^2}{2}} w &= \frac{\mathrm{e}^{\frac{3t^2}{2}}}{3} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\frac{3t^2}{2}}$ results in

$$
w(t) = \frac{\mathrm{e}^{-\frac{3t^2}{2}}\,\mathrm{e}^{\frac{3t^2}{2}}}{3} + c_1 \mathrm{e}^{-\frac{3t^2}{2}}
$$

which simplifies to

$$
w(t) = \frac{1}{3} + c_1 \mathrm{e}^{-\frac{3t^2}{2}}
$$

Replacing w in the above by $\frac{1}{y}$ using equation (5) gives the final solution.

$$
\frac{1}{y} = \frac{1}{3} + c_1 \mathrm{e}^{-\frac{3t^2}{2}}
$$

Or

$$y = \frac{1}{\frac{1}{3} + c_1 \mathrm{e}^{-\frac{3t^2}{2}}}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{\frac{1}{3} + c_1 \mathrm{e}^{-\frac{3t^2}{2}}} \tag{1}$$

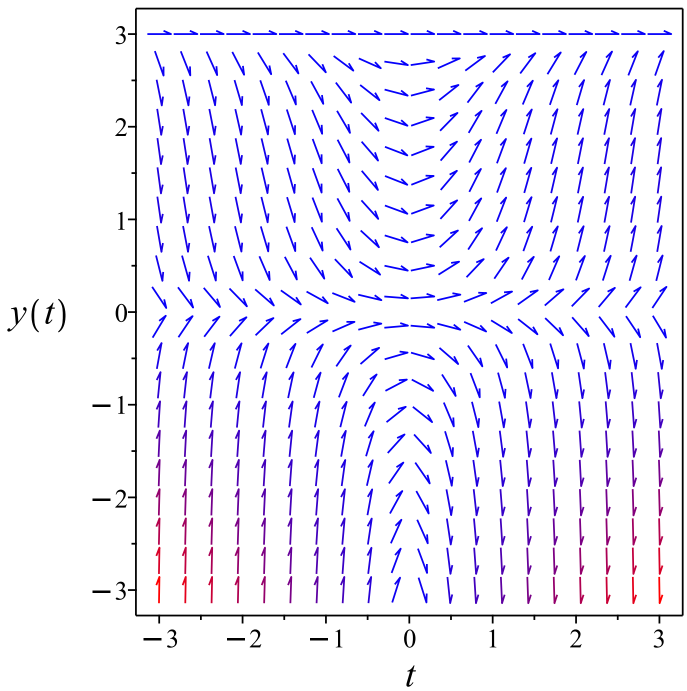

Figure 204: Slope field plot

Verification of solutions

$$y = \frac{1}{\frac{1}{3} + c_1 \mathrm{e}^{-\frac{3t^2}{2}}}$$

Verified OK.

3.13.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t,y)\,\mathrm{d}t+N(t,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(-\frac{1}{y\,(-3+y)}\right)\mathrm{d}y&=(t)\,\mathrm{d}t\\ (-t)\,\mathrm{d}t+\left(-\frac{1}{y\,(-3+y)}\right)\mathrm{d}y&=0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(t, y) &= -t \\
N(t, y) &= -\frac{1}{y(-3+y)}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-t) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}\left(-\frac{1}{y(-3+y)}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(t, y)$

$$
\frac{\partial \phi}{\partial t} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. t gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int M \, \mathrm{d}t \\
\int \frac{\partial \phi}{\partial t} \, \mathrm{d}t &= \int -t \, \mathrm{d}t
\end{aligned}
$$

$$
\phi = -\frac{t^2}{2} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{1}{y(-3+y)}$. Therefore equation (4) becomes

$$-\frac{1}{y\left(-3+y\right)} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{1}{y\left(-3+y\right)}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(-\frac{1}{y\left(-3+y\right)}\right) \mathrm{d}y$$

$$f(y) = \frac{\ln\left(y\right)}{3} - \frac{\ln\left(-3+y\right)}{3} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{t^2}{2} + \frac{\ln\left(y\right)}{3} - \frac{\ln\left(-3+y\right)}{3} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{t^2}{2} + \frac{\ln\left(y\right)}{3} - \frac{\ln\left(-3+y\right)}{3}$$

The solution becomes

$$y = \frac{3\,\mathrm{e}^{\frac{3t^2}{2}+3c_1}}{-1+\mathrm{e}^{\frac{3t^2}{2}+3c_1}}$$

Summary

The solution(s) found are the following

$$y = \frac{3\,\mathrm{e}^{\frac{3t^2}{2}+3c_1}}{-1+\mathrm{e}^{\frac{3t^2}{2}+3c_1}} \tag{1}$$

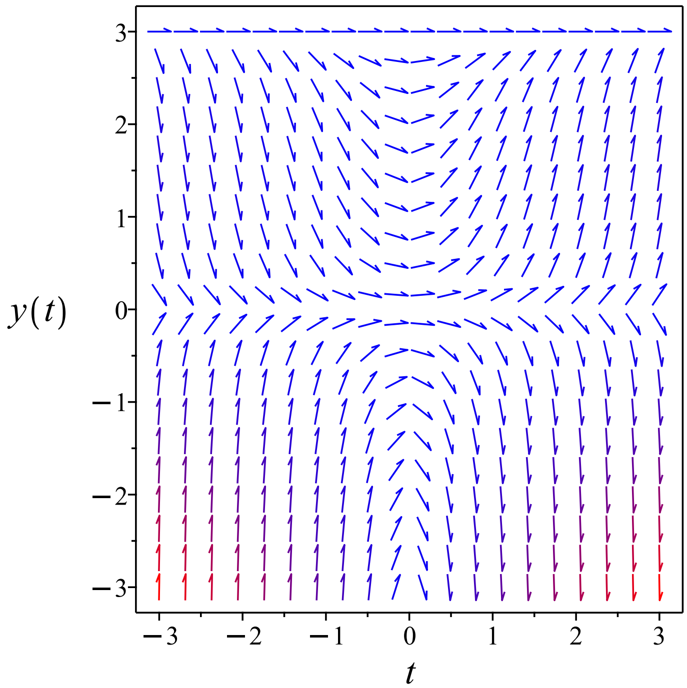

Figure 205: Slope field plot

Verification of solutions

$$y = \frac{3\,\mathrm{e}^{\frac{3t^2}{2}+3c_1}}{-1+\mathrm{e}^{\frac{3t^2}{2}+3c_1}}$$

Verified OK.

3.13.5 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(t,y) \\ &= -ty(-3+y) \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -t\,y^2 + 3ty$$

With Riccati ODE standard form

$$y' = f_0(t) + f_1(t)y + f_2(t)y^2$$

Shows that $f_0(t) = 0$, $f_1(t) = 3t$ and $f_2(t) = -t$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{-tu} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(t) - (f_2' + f_1 f_2) u'(t) + f_2^2 f_0 u(t) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= -1 \\ f_1 f_2 &= -3t^2 \\ f_2^2 f_0 &= 0 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-tu''(t) - (-3t^2 - 1) u'(t) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(t) = c_1 + c_2 e^{\frac{3t^2}{2}}$$

The above shows that

$$u'(t) = 3c_2 t\, e^{\frac{3t^2}{2}}$$

Using the above in (1) gives the solution

$$y = \frac{3c_2 e^{\frac{3t^2}{2}}}{c_1 + c_2 e^{\frac{3t^2}{2}}}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{3\, e^{\frac{3t^2}{2}}}{c_3 + e^{\frac{3t^2}{2}}}$$

Summary
The solution(s) found are the following

$$y = \frac{3\,\mathrm{e}^{\frac{3t^2}{2}}}{c_3 + \mathrm{e}^{\frac{3t^2}{2}}} \tag{1}$$

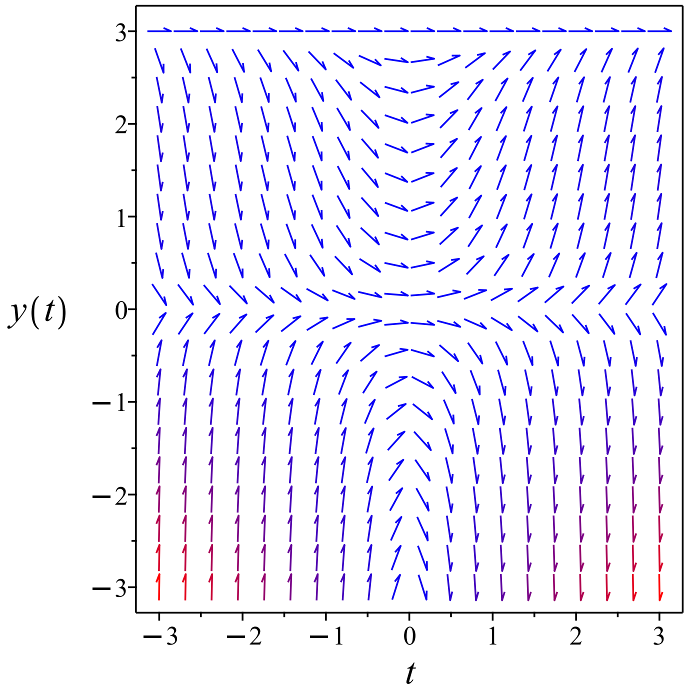

Figure 206: Slope field plot

Verification of solutions

$$y = \frac{3\,\mathrm{e}^{\frac{3t^2}{2}}}{c_3 + \mathrm{e}^{\frac{3t^2}{2}}}$$

Verified OK.

3.13.6 Maple step by step solution

Let's solve

$y' - t(3 - y)\,y = 0$

- Highest derivative means the order of the ODE is 1

y'

- Separate variables

  $\frac{y'}{(3-y)y} = t$

- Integrate both sides with respect to t

  $\int \frac{y'}{(3-y)y} dt = \int t dt + c_1$

- Evaluate integral

  $\frac{\ln(y)}{3} - \frac{\ln(-3+y)}{3} = \frac{t^2}{2} + c_1$

- Solve for y

  $y = \frac{3\,\mathrm{e}^{\frac{3t^2}{2}+3c_1}}{-1+\mathrm{e}^{\frac{3t^2}{2}+3c_1}}$

The type(s) of ODE detected by this program : **"riccati", "bernoulli", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_Bernoulli]`

$$\boxed{y' - y(3 - yt) = 0}$$

3.14.1 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -y(ty - 3)$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 219: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\xi(t, y) = 0$$
$$\eta(t, y) = y^2 \mathrm{e}^{-3t} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{y^2 e^{-3t}} dy
\end{aligned}$$

Which results in

$$S = -\frac{e^{3t}}{y}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t,y) S_y}{R_t + \omega(t,y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t,y)$ is the right hand side of the original ode given by

$$\omega(t,y) = -y(ty - 3)$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_t &= 1 \\
R_y &= 0 \\
S_t &= -\frac{3 e^{3t}}{y} \\
S_y &= \frac{e^{3t}}{y^2}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -e^{3t} t \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -e^{3R} R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\frac{(3R-1)\,\mathrm{e}^{3R}}{9} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$-\frac{\mathrm{e}^{3t}}{y} = -\frac{(-1+3t)\,\mathrm{e}^{3t}}{9} + c_1$$

Which simplifies to

$$-\frac{\mathrm{e}^{3t}}{y} = -\frac{(-1+3t)\,\mathrm{e}^{3t}}{9} + c_1$$

Which gives

$$y = \frac{9\,\mathrm{e}^{3t}}{3\,\mathrm{e}^{3t}t - \mathrm{e}^{3t} - 9c_1}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>

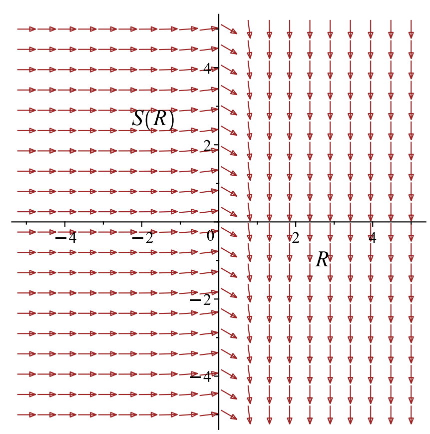
$R = t$

$S = -\frac{\mathrm{e}^{3t}}{y}$

</td><td>

$\frac{dS}{dR} = -\mathrm{e}^{3R}R$



</td></tr>
</table>

Summary
The solution(s) found are the following

$$y = \frac{9\,e^{3t}}{3\,e^{3t}t - e^{3t} - 9c_1} \tag{1}$$

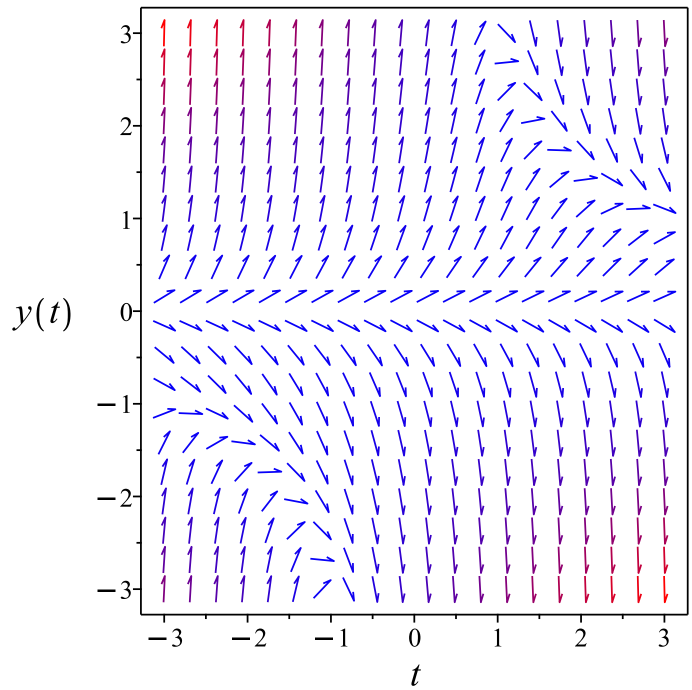


Figure 207: Slope field plot

Verification of solutions

$$y = \frac{9\,e^{3t}}{3\,e^{3t}t - e^{3t} - 9c_1}$$

Verified OK.

3.14.2 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(t, y) \\ &= -y(ty - 3) \end{aligned}$$

This is a Bernoulli ODE.

$$y' = 3y - t y^2 \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(t)y + f_1(t)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(t)y^{1-n} + f_1(t) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(t)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(t)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(t) &= 3 \\ f_1(t) &= -t \\ n &= 2 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = y^2$ gives

$$y'\frac{1}{y^2} = \frac{3}{y} - t \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= \frac{1}{y} \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t t gives

$$w' = -\frac{1}{y^2}y' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} -w'(t) &= 3w(t) - t \\ w' &= -3w + t \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(t)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(t) + p(t)w(t) = q(t)$$

Where here

$$p(t) = 3$$
$$q(t) = t$$

Hence the ode is

$$w'(t) + 3w(t) = t$$

The integrating factor μ is

$$\mu = e^{\int 3dt}$$
$$= e^{3t}$$

The ode becomes

$$\frac{d}{dt}(\mu w) = (\mu)(t)$$
$$\frac{d}{dt}(e^{3t}w) = (e^{3t})(t)$$
$$d(e^{3t}w) = (e^{3t}t)\ dt$$

Integrating gives

$$e^{3t}w = \int e^{3t}t\,dt$$
$$e^{3t}w = \frac{(-1+3t)\,e^{3t}}{9} + c_1$$

Dividing both sides by the integrating factor $\mu = e^{3t}$ results in

$$w(t) = \frac{e^{-3t}(-1+3t)\,e^{3t}}{9} + c_1e^{-3t}$$

which simplifies to

$$w(t) = \frac{t}{3} - \frac{1}{9} + c_1e^{-3t}$$

Replacing w in the above by $\frac{1}{y}$ using equation (5) gives the final solution.

$$\frac{1}{y} = \frac{t}{3} - \frac{1}{9} + c_1e^{-3t}$$

Or

$$y = \frac{1}{\frac{t}{3} - \frac{1}{9} + c_1e^{-3t}}$$

Which is simplified to

$$y = \frac{9}{9c_1 e^{-3t} + 3t - 1}$$

Summary

The solution(s) found are the following

$$y = \frac{9}{9c_1 e^{-3t} + 3t - 1} \tag{1}$$

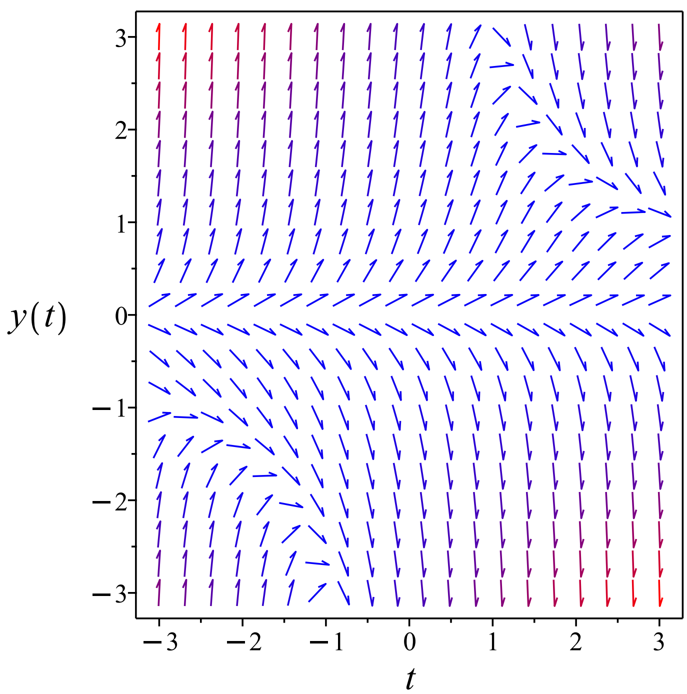

Figure 208: Slope field plot

Verification of solutions

$$y = \frac{9}{9c_1 e^{-3t} + 3t - 1}$$

Verified OK.

3.14.3 Solving as riccati ode

In canonical form the ODE is

$$
\begin{aligned}
y' &= F(t, y) \\
&= -y(ty - 3)
\end{aligned}
$$

This is a Riccati ODE. Comparing the ODE to solve

$$
y' = -t\,y^2 + 3y
$$

With Riccati ODE standard form

$$
y' = f_0(t) + f_1(t)y + f_2(t)y^2
$$

Shows that $f_0(t) = 0$, $f_1(t) = 3$ and $f_2(t) = -t$. Let

$$
\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{-tu}
\end{aligned} \tag{1}
$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$
f_2 u''(t) - (f_2' + f_1 f_2)\,u'(t) + f_2^2 f_0 u(t) = 0 \tag{2}
$$

But

$$
\begin{aligned}
f_2' &= -1 \\
f_1 f_2 &= -3t \\
f_2^2 f_0 &= 0
\end{aligned}
$$

Substituting the above terms back in equation (2) gives

$$
-tu''(t) - (-3t - 1)\,u'(t) = 0
$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$
u(t) = c_1 + (-1 + 3t)\,\mathrm{e}^{3t} c_2
$$

The above shows that

$$
u'(t) = 9c_2 \mathrm{e}^{3t} t
$$

Using the above in (1) gives the solution

$$y = \frac{9c_2 e^{3t}}{c_1 + (-1+3t)\,e^{3t} c_2}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{9\,e^{3t}}{c_3 + (-1+3t)\,e^{3t}}$$

Summary

The solution(s) found are the following

$$y = \frac{9\,e^{3t}}{c_3 + (-1+3t)\,e^{3t}} \tag{1}$$

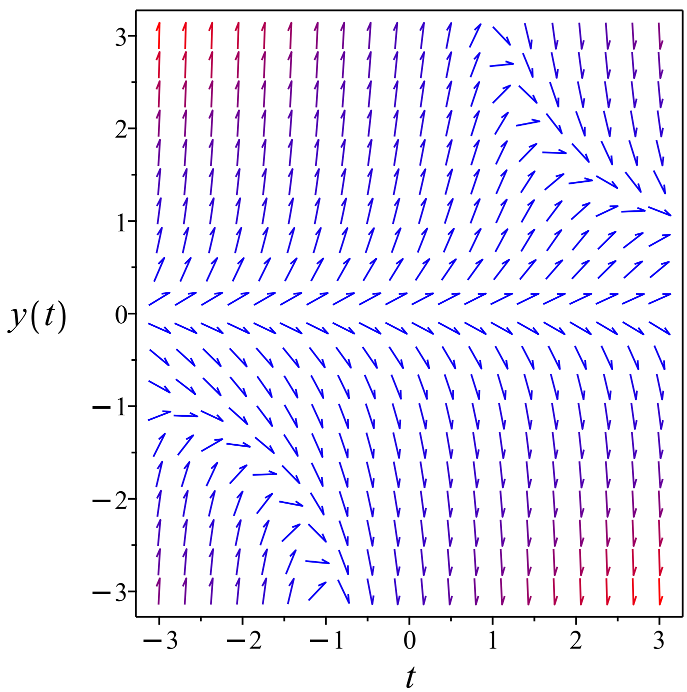

Figure 209: Slope field plot

Verification of solutions

$$y = \frac{9\,e^{3t}}{c_3 + (-1+3t)\,e^{3t}}$$

Verified OK.

Maple gives the following as the ode type

`[_Bernoulli]`

$$\boxed{y' + y(3 - yt) = 0}$$

3.15.1 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= y(ty - 3) \\ y' &= \omega(t, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 221: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= y^2 \mathrm{e}^{3t}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{y^2 e^{3t}} dy \end{aligned}$$

Which results in

$$S = -\frac{e^{-3t}}{y}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = y(ty - 3)$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= \frac{3 e^{-3t}}{y} \\ S_y &= \frac{e^{-3t}}{y^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = t e^{-3t} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R e^{-3R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\frac{(3R+1)\,e^{-3R}}{9} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$-\frac{e^{-3t}}{y} = -\frac{(1+3t)\,e^{-3t}}{9} + c_1$$

Which simplifies to

$$-\frac{e^{-3t}}{y} = -\frac{(1+3t)\,e^{-3t}}{9} + c_1$$

Which gives

$$y = \frac{9\,e^{-3t}}{3t\,e^{-3t} + e^{-3t} - 9c_1}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = y(ty-3)$ 	$R = t$ $S = -\frac{e^{-3t}}{y}$	$\frac{dS}{dR} = R\,e^{-3R}$ 
Summary
The solution(s) found are the following

$$y = \frac{9\,e^{-3t}}{3t\,e^{-3t} + e^{-3t} - 9c_1} \tag{1}$$

$$y = \frac{9\,e^{-3t}}{3t\,e^{-3t} + e^{-3t} - 9c_1}$$

Verified OK.

3.15.2 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(t,y) \\ &= y(ty-3) \end{aligned}$$

This is a Bernoulli ODE.

$$y' = -3y + ty^2 \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(t)y + f_1(t)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(t)y^{1-n} + f_1(t) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(t)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(t)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(t) &= -3 \\ f_1(t) &= t \\ n &= 2 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = y^2$ gives

$$y'\frac{1}{y^2} = -\frac{3}{y} + t \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= \frac{1}{y} \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t t gives

$$w' = -\frac{1}{y^2}y' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} -w'(t) &= -3w(t) + t \\ w' &= 3w - t \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(t)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(t) + p(t)w(t) = q(t)$$

Where here

$$
\begin{aligned}
p(t) &= -3 \\
q(t) &= -t
\end{aligned}
$$

Hence the ode is

$$
w'(t) - 3w(t) = -t
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int (-3)dt} \\
&= \mathrm{e}^{-3t}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}t}(\mu w) &= (\mu)\,(-t) \\
\frac{\mathrm{d}}{\mathrm{d}t}\left(\mathrm{e}^{-3t} w\right) &= \left(\mathrm{e}^{-3t}\right)(-t) \\
\mathrm{d}\left(\mathrm{e}^{-3t} w\right) &= \left(-t\,\mathrm{e}^{-3t}\right)\,\mathrm{d}t
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{-3t} w &= \int -t\,\mathrm{e}^{-3t}\,\mathrm{d}t \\
\mathrm{e}^{-3t} w &= \frac{(1+3t)\,\mathrm{e}^{-3t}}{9} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-3t}$ results in

$$
w(t) = \frac{\mathrm{e}^{3t}(1+3t)\,\mathrm{e}^{-3t}}{9} + c_1 \mathrm{e}^{3t}
$$

which simplifies to

$$
w(t) = \frac{1}{9} + \frac{t}{3} + c_1 \mathrm{e}^{3t}
$$

Replacing w in the above by $\frac{1}{y}$ using equation (5) gives the final solution.

$$
\frac{1}{y} = \frac{1}{9} + \frac{t}{3} + c_1 \mathrm{e}^{3t}
$$

Or

$$
y = \frac{1}{\frac{1}{9} + \frac{t}{3} + c_1 \mathrm{e}^{3t}}
$$

Which is simplified to

$$y = \frac{9}{9c_1 e^{3t} + 3t + 1}$$

Summary
The solution(s) found are the following

$$y = \frac{9}{9c_1 e^{3t} + 3t + 1} \tag{1}$$

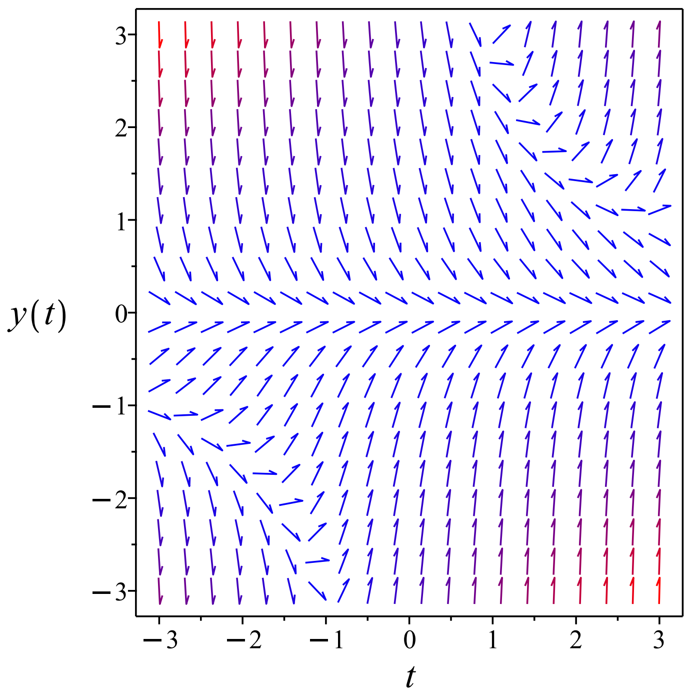

Figure 211: Slope field plot

Verification of solutions

$$y = \frac{9}{9c_1 e^{3t} + 3t + 1}$$

Verified OK.

3.15.3 Solving as riccati ode

In canonical form the ODE is

$$
\begin{aligned}
y' &= F(t, y) \\
&= y(ty - 3)
\end{aligned}
$$

This is a Riccati ODE. Comparing the ODE to solve

$$
y' = t\,y^2 - 3y
$$

With Riccati ODE standard form

$$
y' = f_0(t) + f_1(t)y + f_2(t)y^2
$$

Shows that $f_0(t) = 0$, $f_1(t) = -3$ and $f_2(t) = t$. Let

$$
\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{tu} \qquad (1)
\end{aligned}
$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$
f_2 u''(t) - (f_2' + f_1 f_2)\,u'(t) + f_2^2 f_0 u(t) = 0 \qquad (2)
$$

But

$$
\begin{aligned}
f_2' &= 1 \\
f_1 f_2 &= -3t \\
f_2^2 f_0 &= 0
\end{aligned}
$$

Substituting the above terms back in equation (2) gives

$$
tu''(t) - (1 - 3t)\,u'(t) = 0
$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$
u(t) = c_1 + (1 + 3t)\,e^{-3t} c_2
$$

The above shows that

$$
u'(t) = -9c_2 e^{-3t} t
$$

Using the above in (1) gives the solution

$$y = \frac{9c_2 e^{-3t}}{c_1 + (1+3t)\, e^{-3t} c_2}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{9\, e^{-3t}}{3t\, e^{-3t} + e^{-3t} + c_3}$$

Summary

The solution(s) found are the following

$$y = \frac{9\, e^{-3t}}{3t\, e^{-3t} + e^{-3t} + c_3} \tag{1}$$

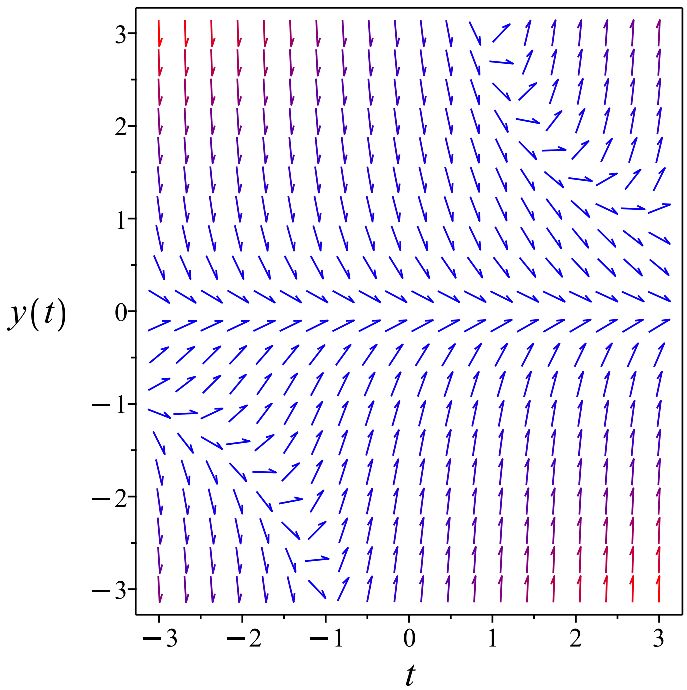

Figure 212: Slope field plot

Verification of solutions

$$y = \frac{9\, e^{-3t}}{3t\, e^{-3t} + e^{-3t} + c_3}$$

Verified OK.

ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' + y^2 = -1 + t}$$

3.16.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(t, y) \\ &= -y^2 + t - 1 \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -y^2 + t - 1$$

With Riccati ODE standard form

$$y' = f_0(t) + f_1(t)y + f_2(t)y^2$$

Shows that $f_0(t) = -1 + t$, $f_1(t) = 0$ and $f_2(t) = -1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{-u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(t) - (f_2' + f_1 f_2)\, u'(t) + f_2^2 f_0 u(t) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= -1 + t \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-u''(t) + (-1 + t)\, u(t) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(t) = c_1 \operatorname{AiryAi}(-1 + t) + c_2 \operatorname{AiryBi}(-1 + t)$$

The above shows that

$$u'(t) = c_1 \operatorname{AiryAi}(1, -1 + t) + c_2 \operatorname{AiryBi}(1, -1 + t)$$

Using the above in (1) gives the solution

$$y = \frac{c_1 \operatorname{AiryAi}(1, -1 + t) + c_2 \operatorname{AiryBi}(1, -1 + t)}{c_1 \operatorname{AiryAi}(-1 + t) + c_2 \operatorname{AiryBi}(-1 + t)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{c_3 \operatorname{AiryAi}(1, -1 + t) + \operatorname{AiryBi}(1, -1 + t)}{c_3 \operatorname{AiryAi}(-1 + t) + \operatorname{AiryBi}(-1 + t)}$$

Summary
The solution(s) found are the following

$$y = \frac{c_3 \operatorname{AiryAi}(1, -1 + t) + \operatorname{AiryBi}(1, -1 + t)}{c_3 \operatorname{AiryAi}(-1 + t) + \operatorname{AiryBi}(-1 + t)} \tag{1}$$

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.5. Page 88
Problem number: 1.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y' - ay - by^2 = 0}$$

4.1.1 Solving as quadrature ode

Integrating both sides gives

$$\int \frac{1}{b\,y^2 + ay} dy = \int dx$$
$$\frac{\ln(y)}{a} - \frac{\ln(by + a)}{a} = x + c_1$$

The above can be written as

$$\left(\frac{1}{a}\right)(\ln(y) - \ln(by + a)) = x + c_1$$
$$\ln(y) - \ln(by + a) = (a)(x + c_1)$$
$$= a(x + c_1)$$

Raising both side to exponential gives

$$e^{\ln(y) - \ln(by + a)} = ac_1 e^{ax}$$

Which simplifies to

$$\frac{y}{by+a} = c_2 e^{ax}$$

Summary

The solution(s) found are the following

$$y = -\frac{e^{ax} c_2 a}{-1 + e^{ax} c_2 b} \tag{1}$$

Verification of solutions

$$y = -\frac{e^{ax} c_2 a}{-1 + e^{ax} c_2 b}$$

Verified OK.

4.1.2 Maple step by step solution

Let's solve

Summary
The solution(s) found are the following

$$y = \frac{c_1 k + tk + 1}{k\left(t+c_1\right)} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 k + tk + 1}{k (t + c_1)}$$

Verified OK.

4.6.2 Maple step by step solution

Let's solve

$y' + k(-1+y)^2 = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{(-1+y)^2} = -k$

- Integrate both sides with respect to t

  $\int \frac{y'}{(-1+y)^2} dt = \int -k dt + c_1$

- Evaluate integral

  $-\frac{1}{-1+y} = -tk + c_1$

- Solve for y

  $y = \frac{-tk + c_1 - 1}{-tk + c_1}$

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

```
[_quadrature]
```

$$\boxed{y' + b\sqrt{y} - ay = 0}$$

4.9.1 Solving as quadrature ode

Integrating both sides gives

$$\int \frac{1}{-b\sqrt{y} + ay} dy = \int dt$$
$$\frac{\ln(a^2y - b^2)}{a} - \frac{\ln(a\sqrt{y} + b)}{a} + \frac{\ln(a\sqrt{y} - b)}{a} = t + c_1$$

The above can be written as

$$\left(\frac{1}{a}\right)\left(\ln(a^2y - b^2) - \ln(a\sqrt{y} + b) + \ln(a\sqrt{y} - b)\right) = t + c_1$$
$$\ln(a^2y - b^2) - \ln(a\sqrt{y} + b) + \ln(a\sqrt{y} - b) = (a)(t + c_1)$$
$$= a(t + c_1)$$

Raising both side to exponential gives

$$e^{\ln(a^2y - b^2) - \ln(a\sqrt{y} + b) + \ln(a\sqrt{y} - b)} = ac_1 e^{at}$$

Which simplifies to

$$\frac{(a^2y - b^2)\left(a\sqrt{y} - b\right)}{a\sqrt{y} + b} = c_2 e^{at}$$

Summary

The solution(s) found are the following

$$y = \frac{2b\left(b - \sqrt{c_2 e^{at}}\right) + c_2 e^{at} - b^2}{a^2} \tag{1}$$

Verification of solutions

5.1 problem 1

Internal problem ID [543]
Internal file name [`OUTPUT/543_Sunday_June_05_2022_01_44_01_AM_47710901/index.tex`]

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.6. Page 100
Problem number: 1.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "differentialType", "homogeneousTypeMapleC", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{(-2+2y)\,y' = -3-2x}$$

5.1.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{-\frac{3}{2}-x}{y-1} \end{aligned}$$

Where $f(x) = -\frac{3}{2}-x$ and $g(y) = \frac{1}{y-1}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y-1}}\,dy = -\frac{3}{2}-x\,dx$$

$$\int \frac{1}{\frac{1}{y-1}} dy = \int -\frac{3}{2} - x \, dx$$

$$\frac{1}{2} y^2 - y = -\frac{3}{2}x - \frac{1}{2}x^2 + c_1$$

Which results in

$$y = 1 + \sqrt{-x^2 + 2c_1 - 3x + 1}$$

$$y = 1 - \sqrt{-x^2 + 2c_1 - 3x + 1}$$

<u>Summary</u>

The solution(s) found are the following

$$y = 1 + \sqrt{-x^2 + 2c_1 - 3x + 1} \tag{1}$$

$$y = 1 - \sqrt{-x^2 + 2c_1 - 3x + 1} \tag{2}$$

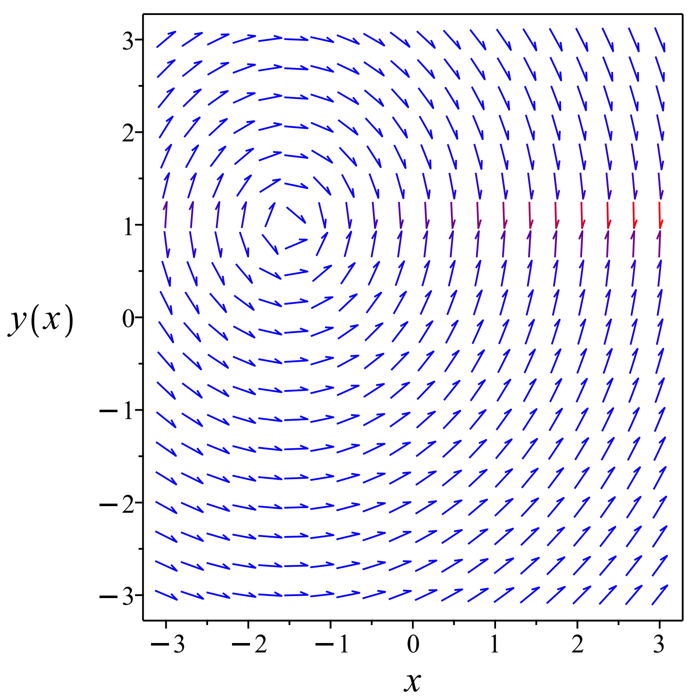

Figure 222: Slope field plot

Verification of solutions

$$y = 1 + \sqrt{-x^2 + 2c_1 - 3x + 1}$$

Verified OK.

$$y = 1 - \sqrt{-x^2 + 2c_1 - 3x + 1}$$

Verified OK.

5.1.2 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-3 - 2x}{-2 + 2y} \tag{1}$$

Which becomes

$$(2y - 2)\, dy = (-3 - 2x)\, dx \tag{2}$$

But the RHS is complete differential because

$$(-3 - 2x)\, dx = d\left(-x^2 - 3x\right)$$

Hence (2) becomes

$$(2y - 2)\, dy = d\left(-x^2 - 3x\right)$$

Integrating both sides gives gives these solutions

$$y = 1 + \sqrt{-x^2 + c_1 - 3x + 1} + c_1$$
$$y = 1 - \sqrt{-x^2 + c_1 - 3x + 1} + c_1$$

Summary
The solution(s) found are the following

$$y = 1 + \sqrt{-x^2 + c_1 - 3x + 1} + c_1 \tag{1}$$
$$y = 1 - \sqrt{-x^2 + c_1 - 3x + 1} + c_1 \tag{2}$$

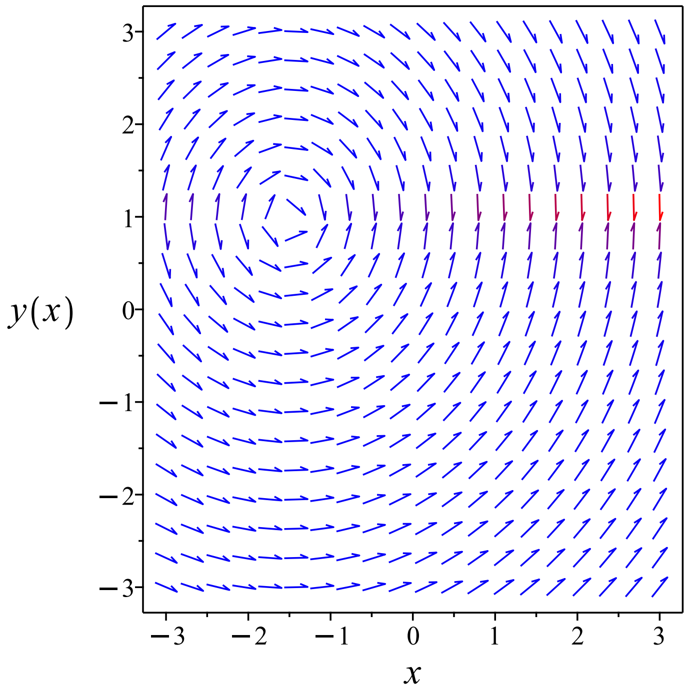

Figure 223: Slope field plot

Verification of solutions

$$y = 1 + \sqrt{-x^2 + c_1 - 3x + 1} + c_1$$

Verified OK.

$$y = 1 - \sqrt{-x^2 + c_1 - 3x + 1} + c_1$$

Verified OK.

5.1.3 Solving as homogeneousTypeMapleC ode

Let $Y = y + y_0$ and $X = x + x_0$ then the above is transformed to new ode in $Y(X)$

$$\frac{d}{dX}Y(X) = -\frac{2X + 2x_0 + 3}{2\left(Y\left(X\right) + y_0 - 1\right)}$$

Solving for possible values of x_0 and y_0 which makes the above ode a homogeneous ode results in

$$x_0 = -\frac{3}{2}$$
$$y_0 = 1$$

Using these values now it is possible to easily solve for $Y(X)$. The above ode now becomes

$$\frac{d}{dX}Y(X) = -\frac{X}{Y(X)}$$

In canonical form, the ODE is

$$\begin{aligned} Y' &= F(X, Y) \\ &= -\frac{X}{Y} \end{aligned} \tag{1}$$

An ode of the form $Y' = \frac{M(X,Y)}{N(X,Y)}$ is called homogeneous if the functions $M(X, Y)$ and $N(X, Y)$ are both homogeneous functions and of the same order. Recall that a function $f(X, Y)$ is homogeneous of order n if

$$f(t^n X, t^n Y) = t^n f(X, Y)$$

In this case, it can be seen that both $M = -X$ and $N = Y$ are both homogeneous and of the same order $n = 1$. Therefore this is a homogeneous ode. Since this ode is homogeneous, it is converted to separable ODE using the substitution $u = \frac{Y}{X}$, or $Y = uX$. Hence

$$\frac{\mathrm{d}Y}{\mathrm{d}X} = \frac{\mathrm{d}u}{\mathrm{d}X}X + u$$

Applying the transformation $Y = uX$ to the above ODE in (1) gives

$$\begin{aligned} \frac{\mathrm{d}u}{\mathrm{d}X}X + u &= -\frac{1}{u} \\ \frac{\mathrm{d}u}{\mathrm{d}X} &= \frac{-\frac{1}{u(X)} - u(X)}{X} \end{aligned}$$

Or

$$\frac{d}{dX}u(X) - \frac{-\frac{1}{u(X)} - u(X)}{X} = 0$$

Or

$$\left(\frac{d}{dX}u(X)\right)u(X)\,X + u(X)^2 + 1 = 0$$

Which is now solved as separable in $u(X)$. Which is now solved in $u(X)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(X, u) \\ &= f(X)g(u) \\ &= -\frac{u^2 + 1}{uX} \end{aligned}$$

Where $f(X) = -\frac{1}{X}$ and $g(u) = \frac{u^2+1}{u}$. Integrating both sides gives

$$\frac{1}{\frac{u^2+1}{u}}\,du = -\frac{1}{X}\,dX$$
$$\int \frac{1}{\frac{u^2+1}{u}}\,du = \int -\frac{1}{X}\,dX$$
$$\frac{\ln(u^2+1)}{2} = -\ln(X) + c_2$$

Raising both side to exponential gives

$$\sqrt{u^2+1} = \mathrm{e}^{-\ln(X)+c_2}$$

Which simplifies to

$$\sqrt{u^2+1} = \frac{c_3}{X}$$

Which simplifies to

$$\sqrt{u(X)^2+1} = \frac{c_3\,\mathrm{e}^{c_2}}{X}$$

The solution is

$$\sqrt{u(X)^2+1} = \frac{c_3\,\mathrm{e}^{c_2}}{X}$$

Now u in the above solution is replaced back by Y using $u = \frac{Y}{X}$ which results in the solution

$$\sqrt{\frac{Y(X)^2}{X^2}+1} = \frac{c_3\,\mathrm{e}^{c_2}}{X}$$

Using the solution for $Y(X)$

$$\sqrt{\frac{Y(X)^2+X^2}{X^2}} = \frac{c_3\,\mathrm{e}^{c_2}}{X}$$

And replacing back terms in the above solution using

$$Y = y + y_0$$
$$X = x + x_0$$

Or

$$Y = y + 1$$
$$X = x - \frac{3}{2}$$

Then the solution in y becomes

$$\sqrt{\frac{(y-1)^2 + \left(x+\frac{3}{2}\right)^2}{\left(x+\frac{3}{2}\right)^2}} = \frac{c_3 \mathrm{e}^{c_2}}{x+\frac{3}{2}}$$

Summary
The solution(s) found are the following

$$\sqrt{\frac{(y-1)^2 + \left(x+\frac{3}{2}\right)^2}{\left(x+\frac{3}{2}\right)^2}} = \frac{c_3 \mathrm{e}^{c_2}}{x+\frac{3}{2}} \tag{1}$$

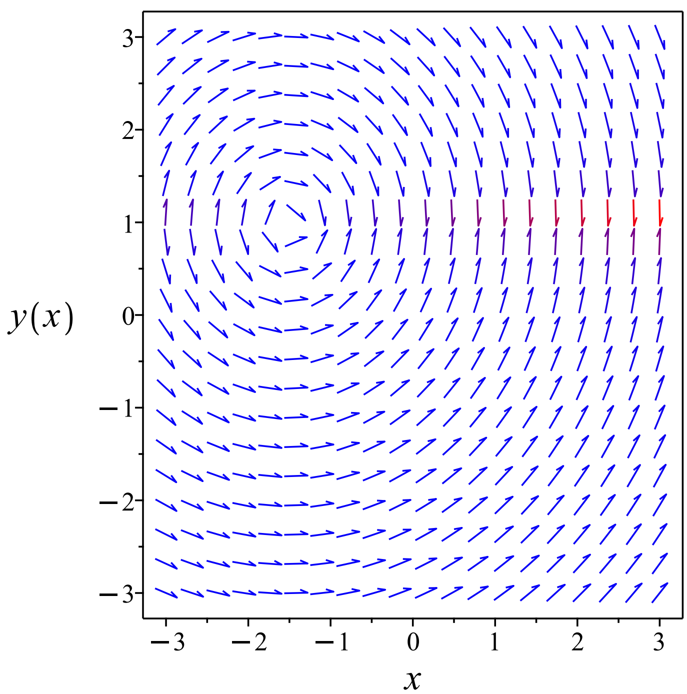

Figure 224: Slope field plot

Verification of solutions

$$
\sqrt{\frac{(y-1)^2+\left(x+\frac{3}{2}\right)^2}{\left(x+\frac{3}{2}\right)^2}}=\frac{c_3\mathrm{e}^{c_2}}{x+\frac{3}{2}}
$$

Verified OK.

5.1.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{2x+3}{2\,(y-1)} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ,η

Table 234: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= \frac{1}{-\frac{3}{2} - x} \\
\eta(x,y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{-\frac{3}{2} - x}} dx \end{aligned}$$

Which results in

$$S = -\frac{3}{2}x - \frac{1}{2}x^2$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{2x+3}{2(y-1)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= -\frac{3}{2} - x \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = y - 1 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R - 1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{1}{2}R^2 - R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{3}{2}x - \frac{1}{2}x^2 = \frac{y^2}{2} - y + c_1$$

Which simplifies to

$$-\frac{3}{2}x - \frac{1}{2}x^2 = \frac{y^2}{2} - y + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{2x+3}{2(y-1)}$ 	$R = y$ $S = -\frac{3}{2}x - \frac{1}{2}x^2$	$\frac{dS}{dR} = R - 1$ 
Summary

The solution(s) found are the following

$$-\frac{3}{2}x - \frac{1}{2}x^2 = \frac{y^2}{2} - y + c_1 \tag{1}$$

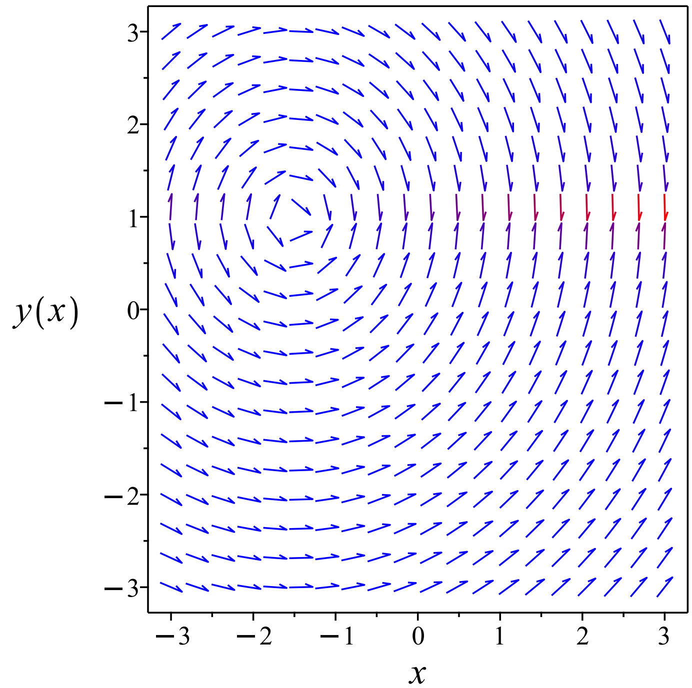

Figure 225: Slope field plot

Verification of solutions

$$-\frac{3}{2}x - \frac{1}{2}x^2 = \frac{y^2}{2} - y + c_1$$

Verified OK.

5.1.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \, \mathrm{d}x + N(x, y) \, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(-2y + 2) \, \mathrm{d}y = (2x + 3) \, \mathrm{d}x$$
$$(-3 - 2x) \, \mathrm{d}x + (-2y + 2) \, \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -3 - 2x$$
$$N(x, y) = -2y + 2$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-3 - 2x) \\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-2y + 2) \\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -3 - 2x \, \mathrm{d}x$$
$$\phi = -x^2 - 3x + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -2y + 2$. Therefore equation (4) becomes

$$-2y + 2 = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -2y + 2$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (-2y + 2) \, \mathrm{d}y$$
$$f(y) = -y^2 + 2y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -x^2 - y^2 - 3x + 2y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x^2 - y^2 - 3x + 2y$$

Summary

The solution(s) found are the following

$$-y^2 - x^2 + 2y - 3x = c_1 \tag{1}$$

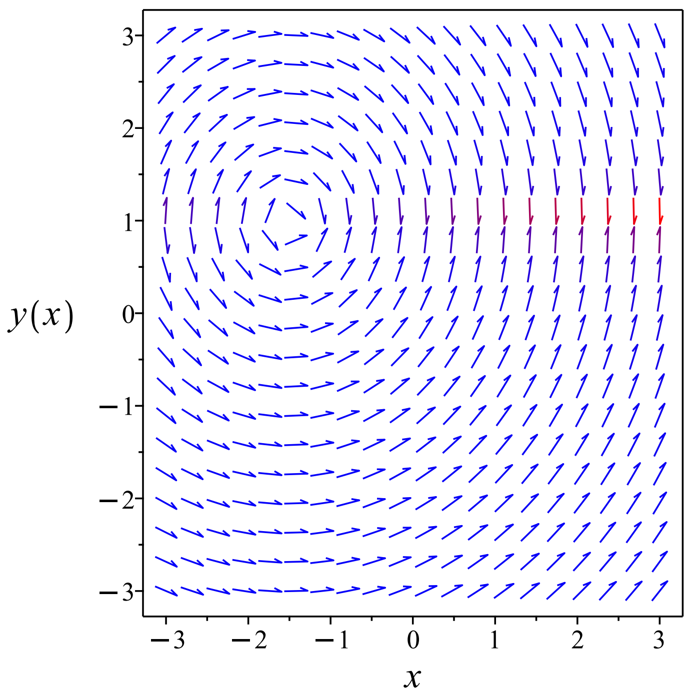

Figure 226: Slope field plot

Verification of solutions

$$-y^2 - x^2 + 2y - 3x = c_1$$

Verified OK.

5.1.6 Maple step by step solution

Let's solve

$(-2+2y)\,y' = -3-2x$

- Highest derivative means the order of the ODE is 1

  y'

- Integrate both sides with respect to x

  $\int (-2+2y)\,y' dx = \int (-3-2x)\,dx + c_1$

- Evaluate integral

  $y^2 - 2y = -x^2 + c_1 - 3x$

- Solve for y

  $\left\{y = 1-\sqrt{-x^2+c_1-3x+1}, y = 1+\sqrt{-x^2+c_1-3x+1}\right\}$

The type(s) of ODE detected by this program : **"homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{4y + (2x - 2y)\, y' = -2x}$$

5.2.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$4u(x)\, x + (2x - 2u(x)\, x)\, (u'(x)\, x + u(x)) = -2x$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{u^2 - 3u - 1}{(u-1)\, x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{u^2-3u-1}{u-1}$. Integrating both sides gives

$$\frac{1}{\frac{u^2-3u-1}{u-1}}\,du = -\frac{1}{x}\,dx$$

$$\int \frac{1}{\frac{u^2-3u-1}{u-1}}\,du = \int -\frac{1}{x}\,dx$$

$$\frac{\ln(u^2-3u-1)}{2} - \frac{\sqrt{13}\,\operatorname{arctanh}\left(\frac{(2u-3)\sqrt{13}}{13}\right)}{13} = -\ln(x) + c_2$$

The solution is

$$\frac{\ln\left(u(x)^2-3u(x)-1\right)}{2} - \frac{\sqrt{13}\,\operatorname{arctanh}\left(\frac{(2u(x)-3)\sqrt{13}}{13}\right)}{13} + \ln(x) - c_2 = 0$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\frac{\ln\left(\frac{y^2}{x^2}-\frac{3y}{x}-1\right)}{2} - \frac{\sqrt{13}\,\operatorname{arctanh}\left(\frac{\left(\frac{2y}{x}-3\right)\sqrt{13}}{13}\right)}{13} + \ln(x) - c_2 = 0$$

$$\frac{\ln\left(\frac{y^2}{x^2}-\frac{3y}{x}-1\right)}{2} - \frac{\sqrt{13}\,\operatorname{arctanh}\left(\frac{(2y-3x)\sqrt{13}}{13x}\right)}{13} + \ln(x) - c_2 = 0$$

Summary

The solution(s) found are the following

$$\frac{\ln\left(\frac{y^2}{x^2}-\frac{3y}{x}-1\right)}{2} - \frac{\sqrt{13}\,\operatorname{arctanh}\left(\frac{(2y-3x)\sqrt{13}}{13x}\right)}{13} + \ln(x) - c_2 = 0 \tag{1}$$

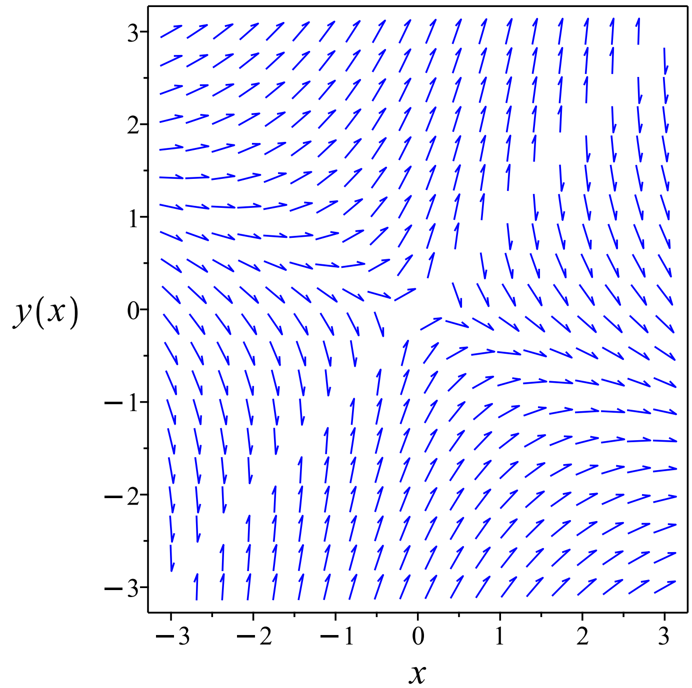

Figure 227: Slope field plot

Verification of solutions

$$\frac{\ln\left(\frac{y^2}{x^2}-\frac{3y}{x}-1\right)}{2}-\frac{\sqrt{13}\,\operatorname{arctanh}\left(\frac{(2y-3x)\sqrt{13}}{13x}\right)}{13}+\ln(x)-c_2=0$$

Verified OK.

5.2.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=\frac{x+2y}{-x+y}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$

$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} & b_2 + \frac{(x+2y)(b_3 - a_2)}{-x+y} - \frac{(x+2y)^2 a_3}{(-x+y)^2} \\ & - \left(\frac{1}{-x+y} + \frac{x+2y}{(-x+y)^2}\right)(xa_2 + ya_3 + a_1) \\ & - \left(\frac{2}{-x+y} - \frac{x+2y}{(-x+y)^2}\right)(xb_2 + yb_3 + b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{x^2a_2 - x^2a_3 + 4x^2b_2 - x^2b_3 - 2xya_2 - 4xya_3 - 2xyb_2 + 2xyb_3 - 2y^2a_2 - 7y^2a_3 + y^2b_2 + 2y^2b_3 + 3xb_1 - 3}{(x-y)^2}$$
$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} & x^2a_2 - x^2a_3 + 4x^2b_2 - x^2b_3 - 2xya_2 - 4xya_3 - 2xyb_2 \\ & + 2xyb_3 - 2y^2a_2 - 7y^2a_3 + y^2b_2 + 2y^2b_3 + 3xb_1 - 3ya_1 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned} & a_2v_1^2 - 2a_2v_1v_2 - 2a_2v_2^2 - a_3v_1^2 - 4a_3v_1v_2 - 7a_3v_2^2 + 4b_2v_1^2 \\ & - 2b_2v_1v_2 + b_2v_2^2 - b_3v_1^2 + 2b_3v_1v_2 + 2b_3v_2^2 - 3a_1v_2 + 3b_1v_1 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$(a_2 - a_3 + 4b_2 - b_3) v_1^2 + (-2a_2 - 4a_3 - 2b_2 + 2b_3) v_1 v_2 + 3b_1 v_1 + (-2a_2 - 7a_3 + b_2 + 2b_3) v_2^2 - 3a_1 v_2 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} -3a_1 &= 0 \\ 3b_1 &= 0 \\ -2a_2 - 7a_3 + b_2 + 2b_3 &= 0 \\ -2a_2 - 4a_3 - 2b_2 + 2b_3 &= 0 \\ a_2 - a_3 + 4b_2 - b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= -3a_3 + b_3 \\ a_3 &= a_3 \\ b_1 &= 0 \\ b_2 &= a_3 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= x \\ \eta &= y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned} \eta &= \eta - \omega(x, y)\, \xi \\ &= y - \left(\frac{x + 2y}{-x + y}\right)(x) \\ &= \frac{x^2 + 3yx - y^2}{x - y} \\ \xi &= 0 \end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x^2+3yx-y^2}{x-y}} dy \end{aligned}$$

Which results in

$$S = \frac{\ln\left(-x^2 - 3yx + y^2\right)}{2} - \frac{\sqrt{13}\, \operatorname{arctanh}\left(\frac{(-3x+2y)\sqrt{13}}{13x}\right)}{13}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{x + 2y}{-x + y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{x + 2y}{x^2 + 3yx - y^2} \\ S_y &= \frac{x - y}{x^2 + 3yx - y^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln (y^2 - 3yx - x^2)}{2} + \frac{\sqrt{13}\, \operatorname{arctanh}\left(\frac{(-2y+3x)\sqrt{13}}{13x}\right)}{13} = c_1$$

Which simplifies to

$$\frac{\ln (y^2 - 3yx - x^2)}{2} + \frac{\sqrt{13}\, \operatorname{arctanh}\left(\frac{(-2y+3x)\sqrt{13}}{13x}\right)}{13} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x+2y}{-x+y}$ 	$R = x$ $S = \frac{\ln(-x^2 - 3yx + y^2)}{2}$	$\frac{dS}{dR} = 0$ 
Summary
The solution(s) found are the following

$$\frac{\ln(y^2 - 3yx - x^2)}{2} + \frac{\sqrt{13}\, \operatorname{arctanh}\left(\frac{(-2y+3x)\sqrt{13}}{13x}\right)}{13} = c_1 \tag{1}$$

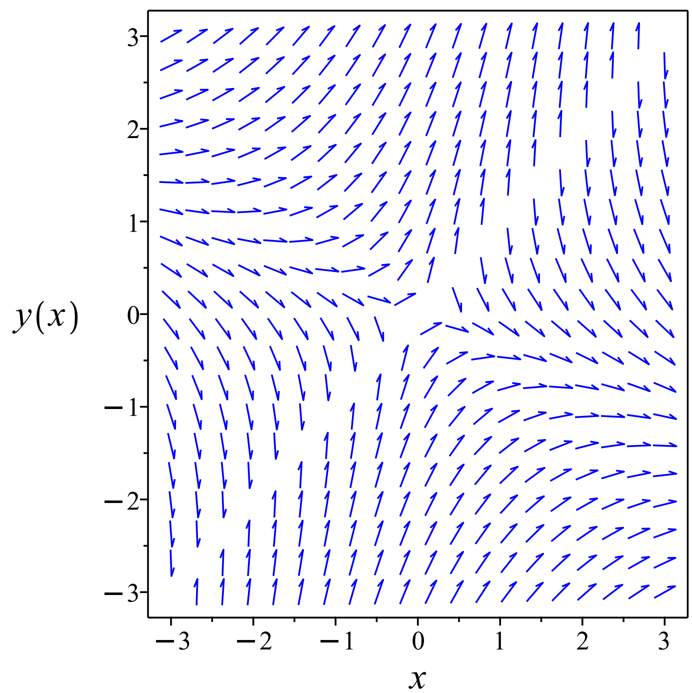

Figure 228: Slope field plot

The type(s) of ODE detected by this program : **"exact", "differentialType"**

Maple gives the following as the ode type

```
[_exact, _rational]
```

$$\boxed{-2yx + (3 - x^2 + 6y^2)\, y' = -3x^2 - 2}$$

5.3.1 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-2 - 3x^2 + 2yx}{3 - x^2 + 6y^2} \tag{1}$$

Which becomes

$$(-6y^2 - 3)\, dy = (-x^2)\, dy + (3x^2 - 2yx + 2)\, dx \tag{2}$$

But the RHS is complete differential because

$$(-x^2)\, dy + (3x^2 - 2yx + 2)\, dx = d(x^3 - y\, x^2 + 2x)$$

Hence (2) becomes

$$(-6y^2 - 3)\, dy = d(x^3 - y\, x^2 + 2x)$$

Integrating both sides gives gives these solutions

$$y = \frac{\left(-54x^3 - 54c_1 - 108x + 6\sqrt{75x^6 + 162c_1x^3 + 378x^4 + 81c_1^2 + 324c_1x + 162x^2 + 162}\right)^{\frac{1}{3}}}{6} - \frac{}{\left(-54x^3 -\right.}$$

$$y = -\frac{\left(-54x^3 - 54c_1 - 108x + 6\sqrt{75x^6 + 162c_1x^3 + 378x^4 + 81c_1^2 + 324c_1x + 162x^2 + 162}\right)^{\frac{1}{3}}}{12} + \frac{}{\left(-54x^3\right.}$$

$$y = -\frac{\left(-54x^3 - 54c_1 - 108x + 6\sqrt{75x^6 + 162c_1x^3 + 378x^4 + 81c_1^2 + 324c_1x + 162x^2 + 162}\right)^{\frac{1}{3}}}{12} + \frac{}{\left(-54x^3\right.}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(-54x^3-54c_1-108x+6\sqrt{75x^6+162c_1x^3+378x^4+81c_1^2+324c_1x+162x^2+162}\right)^{\frac{1}{3}}}{6} - \frac{6\left(-\frac{x^2}{6}+\frac{1}{2}\right)}{\left(-54x^3-54c_1-108x+6\sqrt{75x^6+162c_1x^3+378x^4+81c_1^2+324c_1x+162x^2+162}\right)^{\frac{1}{3}}} + c_1 \tag{1}$$

$$y = -\frac{\left(-54x^3-54c_1-108x+6\sqrt{75x^6+162c_1x^3+378x^4+81c_1^2+324c_1x+162x^2+162}\right)^{\frac{1}{3}}}{12} + \frac{-\frac{x^2}{2}+\frac{3}{2}}{\left(-54x^3-54c_1-108x+6\sqrt{75x^6+162c_1x^3+378x^4+81c_1^2+324c_1x+162x^2+162}\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(\frac{\left(-54x^3-54c_1-108x+6\sqrt{75x^6+162c_1x^3+378x^4+81c_1^2+324c_1x+162x^2+162}\right)^{\frac{1}{3}}}{6} + \frac{-x^2+3\cdots}{\left(-54x^3-54c_1-108x+6\sqrt{75x^6+162c_1x^3+3\cdots}\right.}\right.}{2} + c_1 \tag{2}$$

$$y = -\frac{\left(-54x^3-54c_1-108x+6\sqrt{75x^6+162c_1x^3+378x^4+81c_1^2+324c_1x+162x^2+162}\right)^{\frac{1}{3}}}{12} + \frac{-\frac{x^2}{2}+\frac{3}{2}}{\left(-54x^3-54c_1-108x+6\sqrt{75x^6+162c_1x^3+378x^4+81c_1^2+324c_1x+162x^2+162}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(\frac{\left(-54x^3-54c_1-108x+6\sqrt{75x^6+162c_1x^3+378x^4+81c_1^2+324c_1x+162x^2+162}\right)^{\frac{1}{3}}}{6} + \frac{-x^2+3\cdots}{\left(-54x^3-54c_1-108x+6\sqrt{75x^6+162c_1x^3+3\cdots}\right.}\right.}{2} + c_1 \tag{3}$$

Verification of solutions

$$y = \frac{\left(-54x^3 - 54c_1 - 108x + 6\sqrt{75x^6 + 162c_1x^3 + 378x^4 + 81c_1^2 + 324c_1x + 162x^2 + 162}\right)^{\frac{1}{3}}}{6} - \frac{6\left(-\frac{x^2}{6} + \frac{1}{2}\right)}{\left(-54x^3 - 54c_1 - 108x + 6\sqrt{75x^6 + 162c_1x^3 + 378x^4 + 81c_1^2 + 324c_1x + 162x^2 + 162}\right)^{\frac{1}{3}}} + c_1$$

Verified OK.

$$y = -\frac{\left(-54x^3 - 54c_1 - 108x + 6\sqrt{75x^6 + 162c_1x^3 + 378x^4 + 81c_1^2 + 324c_1x + 162x^2 + 162}\right)^{\frac{1}{3}}}{12} + \frac{-\frac{x^2}{2} + \frac{3}{2}}{\left(-54x^3 - 54c_1 - 108x + 6\sqrt{75x^6 + 162c_1x^3 + 378x^4 + 81c_1^2 + 324c_1x + 162x^2 + 162}\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(\frac{\left(-54x^3 - 54c_1 - 108x + 6\sqrt{75x^6 + 162c_1x^3 + 378x^4 + 81c_1^2 + 324c_1x + 162x^2 + 162}\right)^{\frac{1}{3}}}{6} + \frac{-x^2 + 3}{\left(-54x^3 - 54c_1 - 108x + 6\sqrt{75x^6 + 162c_1x^3 + 3}\right.}\right.}{2} + c_1$$

Verified OK.

$$y = -\frac{\left(-54x^3 - 54c_1 - 108x + 6\sqrt{75x^6 + 162c_1x^3 + 378x^4 + 81c_1^2 + 324c_1x + 162x^2 + 162}\right)^{\frac{1}{3}}}{12} + \frac{-\frac{x^2}{2} + \frac{3}{2}}{\left(-54x^3 - 54c_1 - 108x + 6\sqrt{75x^6 + 162c_1x^3 + 378x^4 + 81c_1^2 + 324c_1x + 162x^2 + 162}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(\frac{\left(-54x^3 - 54c_1 - 108x + 6\sqrt{75x^6 + 162c_1x^3 + 378x^4 + 81c_1^2 + 324c_1x + 162x^2 + 162}\right)^{\frac{1}{3}}}{6} + \frac{-x^2 + 3}{\left(-54x^3 - 54c_1 - 108x + 6\sqrt{75x^6 + 162c_1x^3 + 3}\right.}\right.}{2} + c_1$$

Verified OK.

5.3.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(-x^2+6y^2+3\right)\mathrm{d}y&=\left(-3x^2+2yx-2\right)\mathrm{d}x\\ \left(3x^2-2yx+2\right)\mathrm{d}x+\left(-x^2+6y^2+3\right)\mathrm{d}y&=0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=3x^2-2yx+2\\ N(x,y)&=-x^2+6y^2+3\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(3x^2 - 2yx + 2)\\ &= -2x\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-x^2 + 6y^2 + 3)\\ &= -2x\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int M\, \mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int 3x^2 - 2yx + 2\, \mathrm{d}x\end{aligned}$$

$$\phi = x^3 - y\, x^2 + 2x + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -x^2 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -x^2 + 6y^2 + 3$. Therefore equation (4) becomes

$$-x^2 + 6y^2 + 3 = -x^2 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 6y^2 + 3$$

Integrating the above w.r.t y gives

$$\int f'(y)\, \mathrm{d}y = \int (6y^2 + 3)\, \mathrm{d}y$$
$$f(y) = 2y^3 + 3y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = x^3 - y\,x^2 + 2y^3 + 2x + 3y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x^3 - y\,x^2 + 2y^3 + 2x + 3y$$

Summary
The solution(s) found are the following

$$x^3 - x^2y + 2y^3 + 2x + 3y = c_1 \tag{1}$$

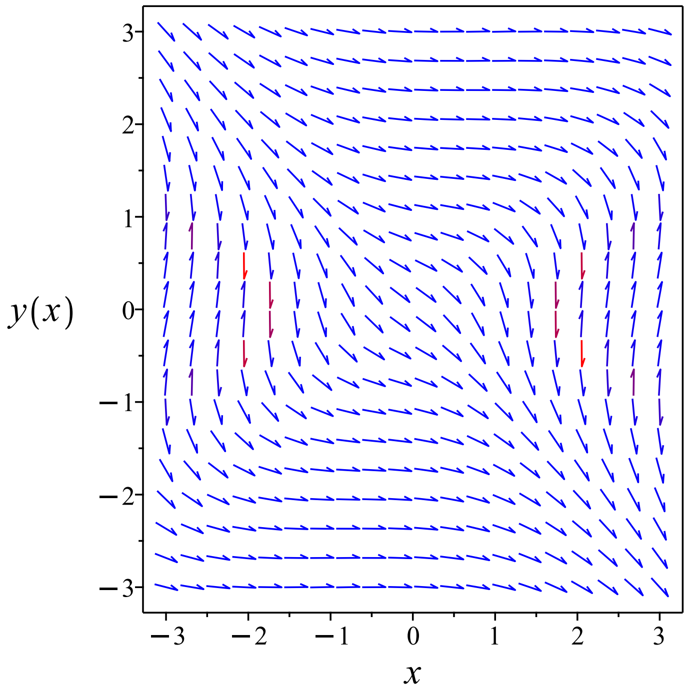

Figure 230: Slope field plot

Verification of solutions

$$x^3 - x^2y + 2y^3 + 2x + 3y = c_1$$

Verified OK.

5.3.3 Maple step by step solution

Let's solve

$-2yx + (3 - x^2 + 6y^2)\, y' = -3x^2 - 2$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

  ◦ ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$

  ◦ Compute derivative of lhs

    $F'(x, y) + \left(\frac{\partial}{\partial y} F(x, y)\right) y' = 0$

- Evaluate derivatives

  $-2x = -2x$
- Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y) = c_1, M(x,y) = F'(x,y), N(x,y) = \frac{\partial}{\partial y}F(x,y)\right]$
- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y) = \int (3x^2 - 2yx + 2)\,dx + f_1(y)$
- Evaluate integral

  $F(x,y) = x^3 - y\,x^2 + 2x + f_1(y)$
- Take derivative of $F(x,y)$ with respect to y

  $N(x,y) = \frac{\partial}{\partial y}F(x,y)$
- Compute derivative

  $-x^2 + 6y^2 + 3 = -x^2 + \frac{d}{dy}f_1(y)$
- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y) = 6y^2 + 3$
- Solve for $f_1(y)$

  $f_1(y) = 2y^3 + 3y$
- Substitute $f_1(y)$ into equation for $F(x,y)$

  $F(x,y) = x^3 - y\,x^2 + 2y^3 + 2x + 3y$
- Substitute $F(x,y)$ into the solution of the ODE

  $x^3 - y\,x^2 + 2y^3 + 2x + 3y = c_1$
- Solve for y

  $$\left\{y = \frac{\left(-54x^3+54c_1-108x+6\sqrt{75x^6-162c_1x^3+378x^4+81c_1^2-324c_1x+162x^2+162}\right)^{\frac{1}{3}}}{6} - \frac{6(-}{\left(-54x^3+54c_1-108x+6\sqrt{75x^6-162c}\right.}\right.$$

Problem number: 4.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "differentialType", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{2y + 2xy^2 + (2x + 2x^2y)\, y' = 0}$$

5.4.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= -\frac{y}{x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(y) = y$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{y}\,dy &= -\frac{1}{x}\,dx \\
\int \frac{1}{y}\,dy &= \int -\frac{1}{x}\,dx \\
\ln(y) &= -\ln(x) + c_1 \\
y &= e^{-\ln(x)+c_1} \\
&= \frac{c_1}{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1}{x} \tag{1}
$$

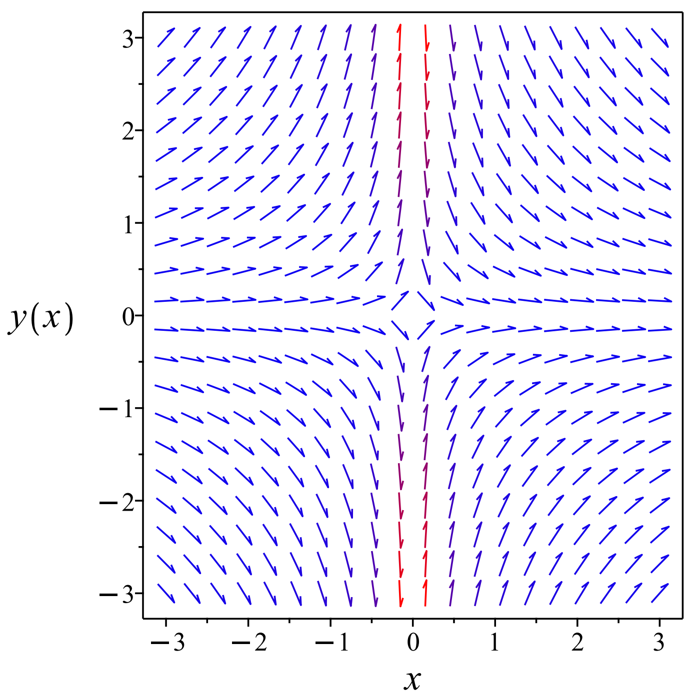

Figure 231: Slope field plot

Verification of solutions

$$
y = \frac{c_1}{x}
$$

Verified OK.

5.4.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= 0 \end{aligned}$$

Hence the ode is

$$y' + \frac{y}{x} = 0$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int \frac{1}{x}dx} \\ &= x \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}\mu y &= 0 \\ \frac{d}{dx}(yx) &= 0 \end{aligned}$$

Integrating gives

$$yx = c_1$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$y = \frac{c_1}{x}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1}{x} \tag{1}$$

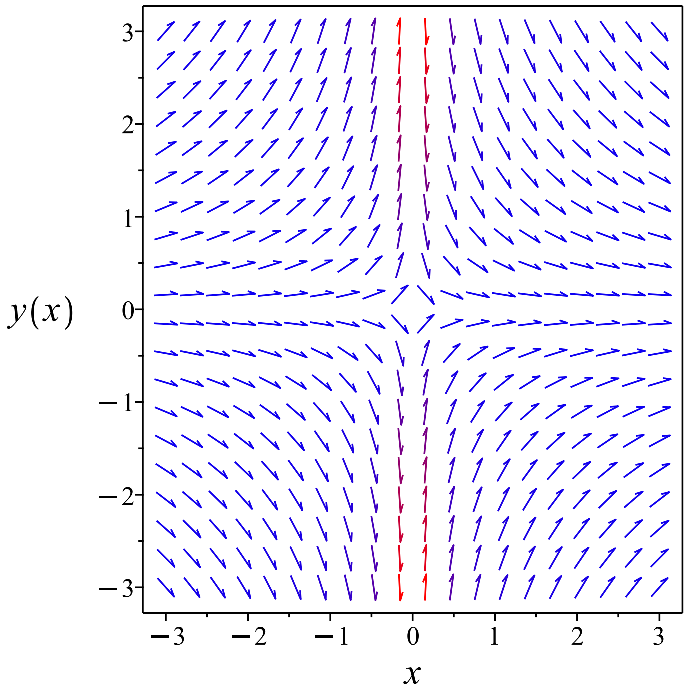

Figure 232: Slope field plot

Verification of solutions

$$y = \frac{c_1}{x}$$

Verified OK.

5.4.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$2u(x)\,x + 2x^3u(x)^2 + \left(2x + 2x^3u(x)\right)\left(u'(x)\,x + u(x)\right) = 0$$

In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= -\frac{2u}{x}
\end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\, du &= -\frac{2}{x}\, dx \\
\int \frac{1}{u}\, du &= \int -\frac{2}{x}\, dx \\
\ln(u) &= -2\ln(x) + c_2 \\
u &= \mathrm{e}^{-2\ln(x)+c_2} \\
&= \frac{c_2}{x^2}
\end{aligned}
$$

Therefore the solution y is

$$
\begin{aligned}
y &= ux \\
&= \frac{c_2}{x}
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = \frac{c_2}{x} \tag{1}
$$

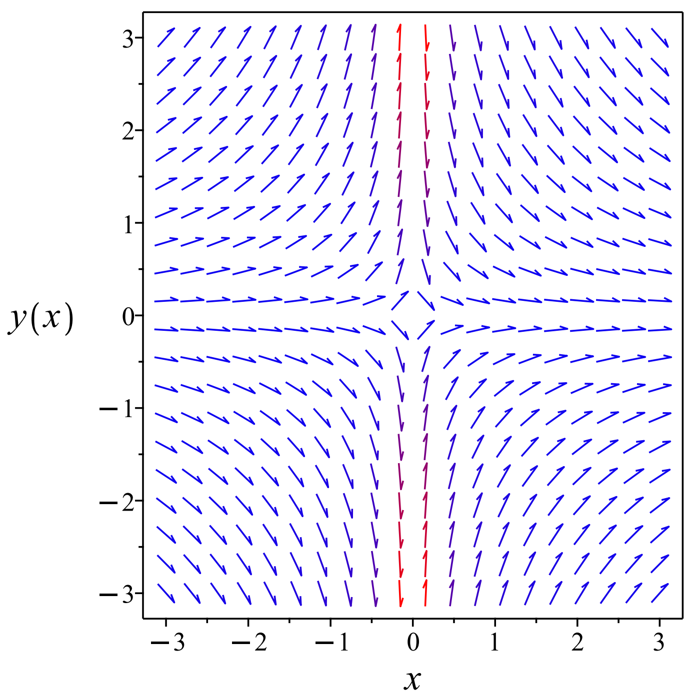

Figure 233: Slope field plot

Verification of solutions

$$y = \frac{c_2}{x}$$

Verified OK.

5.4.4 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-2y - 2xy^2}{2x + 2x^2 y} \tag{1}$$

Which becomes

$$0 = (-x)\,dy + (-y)\,dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\,dy + (-y)\,dx = d(-yx)$$

Hence (2) becomes

$$0 = d(-yx)$$

Integrating both sides gives gives these solutions

$$y = \frac{c_1}{x} + c_1$$

Summary
The solution(s) found are the following

$$y = \frac{c_1}{x} + c_1 \tag{1}$$

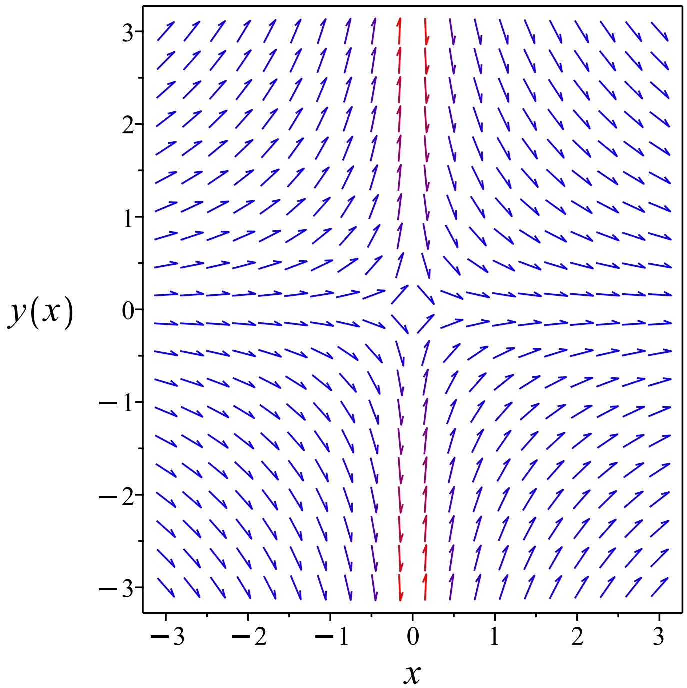

Figure 234: Slope field plot

Verification of solutions

$$y = \frac{c_1}{x} + c_1$$

Verified OK.

5.4.5 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{y}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 238: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= 0 \\ \eta(x,y) &= \frac{1}{x} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{x}} dy \end{aligned}$$

Which results in

$$S = yx$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{y}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= y \\ S_y &= x \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$yx = c_1$$

Which simplifies to

$$yx = c_1$$

Which gives

$$y = \frac{c_1}{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y}{x}$ 	$R = x$ $S = yx$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$y = \frac{c_1}{x} \tag{1}$$

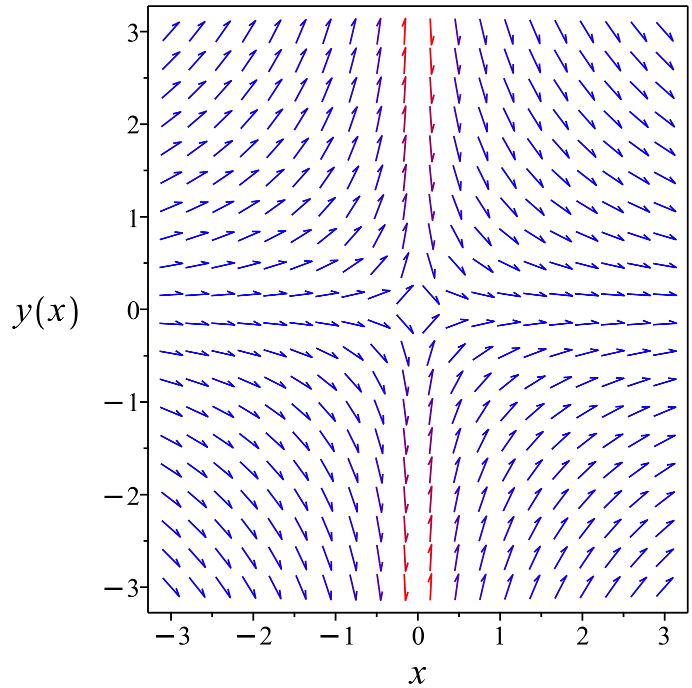

Figure 235: Slope field plot

Verification of solutions

$$y = \frac{c_1}{x}$$

Verified OK.

5.4.6 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y) \, \mathrm{d}x + N(x, y) \, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(-\frac{1}{y}\right) \mathrm{d}y &= \left(\frac{1}{x}\right) \mathrm{d}x \\
\left(-\frac{1}{x}\right) \mathrm{d}x + \left(-\frac{1}{y}\right) \mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -\frac{1}{x} \\
N(x, y) &= -\frac{1}{y}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x}\right) \\
&= 0
\end{aligned}
$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}\left(-\frac{1}{y}\right) \\ = 0$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, dx = \int M \, dx$$

$$\int \frac{\partial \phi}{\partial x} \, dx = \int -\frac{1}{x} \, dx$$

$$\phi = -\ln(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{1}{y}$. Therefore equation (4) becomes

$$-\frac{1}{y} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{1}{y}$$

Integrating the above w.r.t y gives

$$\int f'(y) \, dy = \int \left(-\frac{1}{y}\right) dy$$

$$f(y) = -\ln(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(x) - \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(x) - \ln(y)$$

The solution becomes

$$y = \frac{e^{-c_1}}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{e^{-c_1}}{x} \tag{1}$$

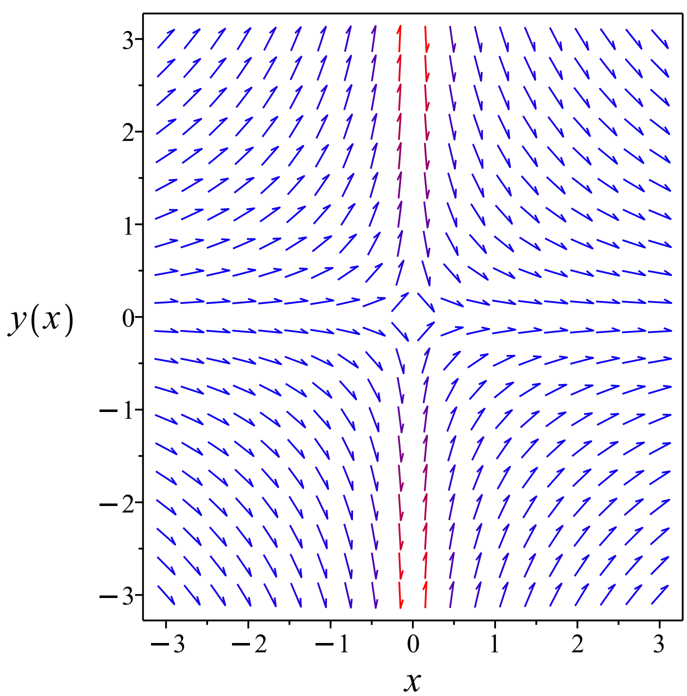

Figure 236: Slope field plot

Verification of solutions

$$y = \frac{e^{-c_1}}{x}$$

Verified OK.

5.4.7 Maple step by step solution

Let's solve

$2y + 2xy^2 + (2x + 2x^2y)\,y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Integrate both sides with respect to x

  $\int (2y + 2xy^2 + (2x + 2x^2y)\,y')\,dx = \int 0dx + c_1$

- Evaluate integral

  $2x\left(\frac{xy^2}{2} + y\right) = c_1$

- Solve for y

  $\left\{y = \frac{-1-\sqrt{1+c_1}}{x}, y = \frac{-1+\sqrt{1+c_1}}{x}\right\}$

Problem number: 5.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{y' - \frac{-ax - by}{bx + cy} = 0}$$

5.5.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x + u(x) - \frac{-ax - bu(x)\,x}{bx + cu\,(x)\,x} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{c\,u^2 + 2bu + a}{x\,(cu + b)} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{c\,u^2+2bu+a}{cu+b}$. Integrating both sides gives

$$\frac{1}{\frac{c\,u^2+2bu+a}{cu+b}}\,du = -\frac{1}{x}\,dx$$

$$\int \frac{1}{\frac{c\,u^2+2bu+a}{cu+b}}\,du = \int -\frac{1}{x}\,dx$$

$$\frac{\ln\left(c\,u^2+2bu+a\right)}{2} = -\ln\left(x\right)+c_2$$

Raising both side to exponential gives

$$\sqrt{c\,u^2+2bu+a} = \mathrm{e}^{-\ln(x)+c_2}$$

Which simplifies to

$$\sqrt{c\,u^2+2bu+a} = \frac{c_3}{x}$$

Which simplifies to

$$\sqrt{u\left(x\right)^2 c+2u\left(x\right) b+a} = \frac{c_3\mathrm{e}^{c_2}}{x}$$

The solution is

$$\sqrt{u\left(x\right)^2 c+2u\left(x\right) b+a} = \frac{c_3\mathrm{e}^{c_2}}{x}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\sqrt{\frac{y^2c}{x^2}+\frac{2yb}{x}+a} = \frac{c_3\mathrm{e}^{c_2}}{x}$$

$$\sqrt{\frac{cy^2+2byx+a\,x^2}{x^2}} = \frac{c_3\mathrm{e}^{c_2}}{x}$$

Summary

The solution(s) found are the following

$$\sqrt{\frac{cy^2+2byx+a\,x^2}{x^2}} = \frac{c_3\mathrm{e}^{c_2}}{x} \tag{1}$$

Verification of solutions

$$\sqrt{\frac{cy^2+2byx+a\,x^2}{x^2}} = \frac{c_3\mathrm{e}^{c_2}}{x}$$

Verified OK.

5.5.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{ax+by}{bx+cy} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$
\xi = x a_2 + y a_3 + a_1 \tag{1E}
$$

$$
\eta = x b_2 + y b_3 + b_1 \tag{2E}
$$

Where the unknown coefficients are

$$
\{a_1, a_2, a_3, b_1, b_2, b_3\}
$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
&b_2 - \frac{(ax+by)(b_3 - a_2)}{bx+cy} - \frac{(ax+by)^2 a_3}{(bx+cy)^2} \\
&- \left(-\frac{a}{bx+cy} + \frac{(ax+by) b}{(bx+cy)^2}\right)(x a_2 + y a_3 + a_1) \\
&- \left(-\frac{b}{bx+cy} + \frac{(ax+by) c}{(bx+cy)^2}\right)(x b_2 + y b_3 + b_1) = 0
\end{aligned} \tag{5E}
$$

Putting the above in normal form gives

$$
-\frac{a^2 x^2 a_3 - ab\, x^2 a_2 + ab\, x^2 b_3 + 2abxya_3 + ac\, x^2 b_2 - 2acxya_2 + 2acxyb_3 - ac\, y^2 a_3 - 2b^2 x^2 b_2 + 2b^2 y^2 a_3 - 2}{(bx+cy)^2}
$$

$$
= 0
$$

Setting the numerator to zero gives

$$
\begin{aligned}
&-a^2 x^2 a_3 + ab\, x^2 a_2 - ab\, x^2 b_3 - 2abxya_3 - ac\, x^2 b_2 + 2acxya_2 \\
&- 2acxyb_3 + ac\, y^2 a_3 + 2b^2 x^2 b_2 - 2b^2 y^2 a_3 + 2bcxyb_2 + bc\, y^2 a_2 \\
&- bc\, y^2 b_3 + c^2 y^2 b_2 - acxb_1 + acya_1 + b^2 x b_1 - b^2 y a_1 = 0
\end{aligned} \tag{6E}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$-a^2a_3v_1^2 + aba_2v_1^2 - 2aba_3v_1v_2 - abb_3v_1^2 + 2aca_2v_1v_2 + aca_3v_2^2 - acb_2v_1^2 - 2acb_3v_1v_2 - 2b^2a_3v_2^2 + 2b^2b_2v_1^2 + bca_2v_2^2 + 2bcb_2v_1v_2 - bcb_3v_2^2 + c^2b_2v_2^2 + aca_1v_2 - acb_1v_1 - b^2a_1v_2 + b^2b_1v_1 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$(-a^2a_3 + aba_2 - abb_3 - acb_2 + 2b^2b_2)\, v_1^2 + (-2aba_3 + 2aca_2 - 2acb_3 + 2bcb_2)\, v_1v_2 + (-acb_1 + b^2b_1)\, v_1 + (aca_3 - 2b^2a_3 + bca_2 - bcb_3 + c^2b_2)\, v_2^2 + (aca_1 - b^2a_1)\, v_2 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
aca_1 - b^2a_1 &= 0\\
-acb_1 + b^2b_1 &= 0\\
-2aba_3 + 2aca_2 - 2acb_3 + 2bcb_2 &= 0\\
aca_3 - 2b^2a_3 + bca_2 - bcb_3 + c^2b_2 &= 0\\
-a^2a_3 + aba_2 - abb_3 - acb_2 + 2b^2b_2 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= 0\\
a_2 &= \frac{ab_3 - 2bb_2}{a}\\
a_3 &= -\frac{cb_2}{a}\\
b_1 &= 0\\
b_2 &= b_2\\
b_3 &= b_3
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\xi = x$$
$$\eta = y$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(-\frac{ax+by}{bx+cy}\right)(x) \\
&= \frac{a\,x^2+2bxy+c\,y^2}{bx+cy} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta}dy \\
&= \int \frac{1}{\frac{a\,x^2+2bxy+c\,y^2}{bx+cy}}dy
\end{aligned}$$

Which results in

$$S = \frac{\ln\left(a\,x^2+2bxy+c\,y^2\right)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{ax + by}{bx + cy}$$

Evaluating all the partial derivatives gives

$$R_x = 1$$
$$R_y = 0$$
$$S_x = \frac{ax + by}{a\,x^2 + 2bxy + c\,y^2}$$
$$S_y = \frac{bx + cy}{a\,x^2 + 2bxy + c\,y^2}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln\left(cy^2 + 2byx + a\,x^2\right)}{2} = c_1$$

Which simplifies to

$$\frac{\ln\left(cy^2 + 2byx + a\,x^2\right)}{2} = c_1$$

Summary

The solution(s) found are the following

$$\frac{\ln\left(cy^2 + 2byx + a\,x^2\right)}{2} = c_1 \tag{1}$$

Verification of solutions

$$\frac{\ln(cy^2 + 2byx + a\,x^2)}{2} = c_1$$

Verified OK.

5.5.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(bx + cy)\,\mathrm{d}y &= (-ax - by)\,\mathrm{d}x\\ (ax + by)\,\mathrm{d}x + (bx + cy)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x, y) &= ax + by \\
N(x, y) &= bx + cy
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(ax + by) \\
&= b
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(bx + cy) \\
&= b
\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int M \, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int ax + by \, \mathrm{d}x \\
\phi &= \frac{1}{2} a\, x^2 + bxy + f(y) \qquad (3)
\end{aligned}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = bx + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = bx + cy$. Therefore equation (4) becomes

$$bx + cy = bx + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = cy$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (cy)\,\mathrm{d}y$$

$$f(y) = \frac{c\,y^2}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{1}{2}a\,x^2 + bxy + \frac{1}{2}c\,y^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{1}{2}a\,x^2 + bxy + \frac{1}{2}c\,y^2$$

Summary

The solution(s) found are the following

$$\frac{a\,x^2}{2} + byx + \frac{cy^2}{2} = c_1 \tag{1}$$

Verification of solutions

$$\frac{a\,x^2}{2} + byx + \frac{cy^2}{2} = c_1$$

Verified OK.

Section: Section 2.6. Page 100
Problem number: 6.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{y' - \frac{-ax + by}{bx - cy} = 0}$$

5.6.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x + u(x) - \frac{-ax + bu(x)\,x}{bx - cu\,(x)\,x} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{-c\,u^2 + a}{x\,(-cu + b)} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{-c\,u^2+a}{-cu+b}$. Integrating both sides gives

$$\frac{1}{\frac{-c\,u^2+a}{-cu+b}}\,du = -\frac{1}{x}\,dx$$

$$\int \frac{1}{\frac{-c\,u^2+a}{-cu+b}}\,du = \int -\frac{1}{x}\,dx$$

$$\frac{\ln\left(c\,u^2-a\right)}{2}+\frac{b\,\operatorname{arctanh}\left(\frac{uc}{\sqrt{ac}}\right)}{\sqrt{ac}} = -\ln\left(x\right)+c_2$$

The solution is

$$\frac{\ln\left(u(x)^2\,c-a\right)}{2}+\frac{b\,\operatorname{arctanh}\left(\frac{u(x)c}{\sqrt{ac}}\right)}{\sqrt{ac}}+\ln\left(x\right)-c_2 = 0$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\frac{\ln\left(\frac{y^2c}{x^2}-a\right)}{2}+\frac{b\,\operatorname{arctanh}\left(\frac{yc}{x\sqrt{ac}}\right)}{\sqrt{ac}}+\ln\left(x\right)-c_2 = 0$$

$$\frac{\ln\left(\frac{y^2c}{x^2}-a\right)}{2}+\frac{b\,\operatorname{arctanh}\left(\frac{yc}{x\sqrt{ac}}\right)}{\sqrt{ac}}+\ln\left(x\right)-c_2 = 0$$

<u>Summary</u>

The solution(s) found are the following

$$\frac{\ln\left(\frac{y^2c}{x^2}-a\right)}{2}+\frac{b\,\operatorname{arctanh}\left(\frac{yc}{x\sqrt{ac}}\right)}{\sqrt{ac}}+\ln\left(x\right)-c_2 = 0 \tag{1}$$

<u>Verification of solutions</u>

$$\frac{\ln\left(\frac{y^2c}{x^2}-a\right)}{2}+\frac{b\,\operatorname{arctanh}\left(\frac{yc}{x\sqrt{ac}}\right)}{\sqrt{ac}}+\ln\left(x\right)-c_2 = 0$$

Verified OK.

5.6.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{-ax+by}{-bx+cy} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$
\xi = x a_2 + y a_3 + a_1 \tag{1E}
$$

$$
\eta = x b_2 + y b_3 + b_1 \tag{2E}
$$

Where the unknown coefficients are

$$
\{a_1, a_2, a_3, b_1, b_2, b_3\}
$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
&b_2 - \frac{(-ax+by)(b_3-a_2)}{-bx+cy} - \frac{(-ax+by)^2 a_3}{(-bx+cy)^2} \\
&- \left(\frac{a}{-bx+cy} - \frac{(-ax+by)\, b}{(-bx+cy)^2}\right)(x a_2 + y a_3 + a_1) \\
&- \left(-\frac{b}{-bx+cy} + \frac{(-ax+by)\, c}{(-bx+cy)^2}\right)(x b_2 + y b_3 + b_1) = 0
\end{aligned} \tag{5E}
$$

Putting the above in normal form gives

$$
-\frac{a^2x^2a_3 - ab\,x^2a_2 + ab\,x^2b_3 - 2abxya_3 - ac\,x^2b_2 + 2acxya_2 - 2acxyb_3 + ac\,y^2a_3 + 2bcxyb_2 - bc\,y^2a_2 + b}{(bx-cy)^2}
$$

$= 0$

Setting the numerator to zero gives

$$
\begin{aligned}
&-a^2x^2a_3 + ab\,x^2a_2 - ab\,x^2b_3 + 2abxya_3 + ac\,x^2b_2 - 2acxya_2 + 2acxyb_3 - ac\,y^2a_3 \\
&- 2bcxyb_2 + bc\,y^2a_2 - bc\,y^2b_3 + c^2y^2b_2 + acxb_1 - acya_1 - b^2xb_1 + b^2ya_1 = 0
\end{aligned} \tag{6E}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned} -a^2a_3v_1^2 + aba_2v_1^2 + 2aba_3v_1v_2 - abb_3v_1^2 - 2aca_2v_1v_2 \\ - aca_3v_2^2 + acb_2v_1^2 + 2acb_3v_1v_2 + bca_2v_2^2 - 2bcb_2v_1v_2 \\ - bcb_3v_2^2 + c^2b_2v_2^2 - aca_1v_2 + acb_1v_1 + b^2a_1v_2 - b^2b_1v_1 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned} (-a^2a_3 + aba_2 - abb_3 + acb_2)\, v_1^2 + (2aba_3 - 2aca_2 + 2acb_3 - 2bcb_2)\, v_1v_2 \\ + (acb_1 - b^2b_1)\, v_1 + (-aca_3 + bca_2 - bcb_3 + c^2b_2)\, v_2^2 + (-aca_1 + b^2a_1)\, v_2 = 0 \end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} -aca_1 + b^2a_1 &= 0 \\ acb_1 - b^2b_1 &= 0 \\ -aca_3 + bca_2 - bcb_3 + c^2b_2 &= 0 \\ 2aba_3 - 2aca_2 + 2acb_3 - 2bcb_2 &= 0 \\ -a^2a_3 + aba_2 - abb_3 + acb_2 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= b_3 \\ a_3 &= a_3 \\ b_1 &= 0 \\ b_2 &= \frac{a_3a}{c} \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\xi = x$$
$$\eta = y$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= y - \left(-\frac{-ax + by}{-bx + cy}\right)(x) \\
&= \frac{a\,x^2 - c\,y^2}{bx - cy} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{a\,x^2 - c\,y^2}{bx - cy}} dy
\end{aligned}$$

Which results in

$$S = \frac{\ln\left(-a\,x^2 + c\,y^2\right)}{2} + \frac{b \operatorname{arctanh}\left(\frac{yc}{x\sqrt{ac}}\right)}{\sqrt{ac}}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{-ax + by}{-bx + cy}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{ax - by}{a\,x^2 - c\,y^2} \\
S_y &= \frac{bx - cy}{a\,x^2 - c\,y^2}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln\left(cy^2 - a\,x^2\right)\sqrt{a}\,\sqrt{c} + 2b \operatorname{arctanh}\left(\frac{y\sqrt{c}}{x\sqrt{a}}\right)}{2\sqrt{a}\,\sqrt{c}} = c_1$$

Which simplifies to

$$\frac{\ln\left(cy^2-a\,x^2\right)\sqrt{a}\,\sqrt{c}+2b\,\operatorname{arctanh}\left(\frac{y\sqrt{c}}{x\sqrt{a}}\right)}{2\sqrt{a}\,\sqrt{c}}=c_1$$

Summary

The solution(s) found are the following

$$\frac{\ln\left(cy^2-a\,x^2\right)\sqrt{a}\,\sqrt{c}+2b\,\operatorname{arctanh}\left(\frac{y\sqrt{c}}{x\sqrt{a}}\right)}{2\sqrt{a}\,\sqrt{c}}=c_1 \tag{1}$$

Verification of solutions

$$\frac{\ln\left(cy^2-a\,x^2\right)\sqrt{a}\,\sqrt{c}+2b\,\operatorname{arctanh}\left(\frac{y\sqrt{c}}{x\sqrt{a}}\right)}{2\sqrt{a}\,\sqrt{c}}=c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

```
[_exact]
```

$$\boxed{e^{x} \sin \left(y\right)-2 \sin \left(x\right) y+\left(2 \cos \left(x\right)+e^{x} \cos \left(y\right)\right) y^{\prime}=0}$$

5.7.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x}=M$$
$$\frac{\partial \phi}{\partial y}=N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned} (2\cos(x) + \mathrm{e}^x\cos(y))\,\mathrm{d}y &= (-\mathrm{e}^x\sin(y) + 2\sin(x)\,y)\,\mathrm{d}x \\ (\mathrm{e}^x\sin(y) - 2\sin(x)\,y)\,\mathrm{d}x + (2\cos(x) + \mathrm{e}^x\cos(y))\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x,y) &= \mathrm{e}^x\sin(y) - 2\sin(x)\,y \\ N(x,y) &= 2\cos(x) + \mathrm{e}^x\cos(y) \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(\mathrm{e}^x\sin(y) - 2\sin(x)\,y) \\ &= -2\sin(x) + \mathrm{e}^x\cos(y) \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2\cos(x) + \mathrm{e}^x\cos(y)) \\ &= -2\sin(x) + \mathrm{e}^x\cos(y) \end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = M \tag{1}$$

$$\frac{\partial\phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \mathrm{e}^{x} \sin(y) - 2\sin(x)\, y \,\mathrm{d}x$$
$$\phi = \mathrm{e}^{x} \sin(y) + 2\cos(x)\, y + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2\cos(x) + \mathrm{e}^{x}\cos(y) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2\cos(x) + \mathrm{e}^{x}\cos(y)$. Therefore equation (4) becomes

$$2\cos(x) + \mathrm{e}^{x}\cos(y) = 2\cos(x) + \mathrm{e}^{x}\cos(y) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \mathrm{e}^{x}\sin(y) + 2\cos(x)\, y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \mathrm{e}^{x}\sin(y) + 2\cos(x)\, y$$

Summary

The solution(s) found are the following

$$\mathrm{e}^{x}\sin(y) + 2\cos(x)\, y = c_1 \tag{1}$$

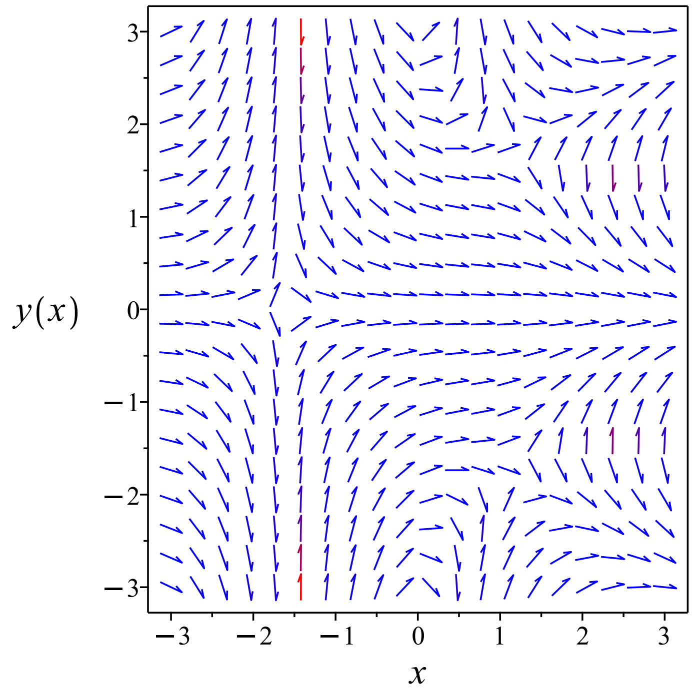

Figure 237: Slope field plot

Verification of solutions

$$e^{x} \sin (y)+2 \cos (x) y = c_1$$

Verified OK.

5.7.2 Maple step by step solution

Let's solve

$e^{x} \sin (y)-2 \sin (x) y+(2 \cos (x)+e^{x} \cos (y)) y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact

  - ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$

  - Compute derivative of lhs

    $F'(x, y)+\left(\frac{\partial}{\partial y}F(x, y)\right) y' = 0$

- Evaluate derivatives

  $-2\sin(x) + e^x \cos(y) = -2\sin(x) + e^x \cos(y)$

- Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y) = c_1, M(x,y) = F'(x,y), N(x,y) = \frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y) = \int (e^x \sin(y) - 2\sin(x)\, y)\, dx + f_1(y)$

- Evaluate integral

  $F(x,y) = e^x \sin(y) + 2\cos(x)\, y + f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y) = \frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $2\cos(x) + e^x \cos(y) = e^x \cos(y) + 2\cos(x) + \frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y) = 0$

- Solve for $f_1(y)$

  $f_1(y) = 0$

- Substitute $f_1(y)$ into equation for $F(x,y)$

  $F(x,y) = e^x \sin(y) + 2\cos(x)\, y$

- Substitute $F(x,y)$ into the solution of the ODE

  $e^x \sin(y) + 2\cos(x)\, y = c_1$

- Solve for y

  $y = \mathit{RootOf}(-e^x \sin(\_Z) - 2\_Z\cos(x) + c_1)$

$$\boxed{-2\,\mathrm{e}^{yx}\sin(2x)+\mathrm{e}^{yx}\cos(2x)\,y+\left(-3+\mathrm{e}^{yx}x\cos(2x)\right)y'=-2x}$$

5.9.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\,\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(-3 + \mathrm{e}^{yx} x \cos(2x))\,\mathrm{d}y = (-2x + 2\,\mathrm{e}^{yx} \sin(2x) - \mathrm{e}^{yx} \cos(2x)\, y)$$

$$(2x - 2\,\mathrm{e}^{yx} \sin(2x) + \mathrm{e}^{yx} \cos(2x)\, y)\,\mathrm{d}x + (-3 + \mathrm{e}^{yx} x \cos(2x))\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x, y) &= 2x - 2\,\mathrm{e}^{yx} \sin(2x) + \mathrm{e}^{yx} \cos(2x)\, y \\
N(x, y) &= -3 + \mathrm{e}^{yx} x \cos(2x)
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(2x - 2\,\mathrm{e}^{yx} \sin(2x) + \mathrm{e}^{yx} \cos(2x)\, y) \\
&= \mathrm{e}^{yx}(yx \cos(2x) + \cos(2x) - 2x \sin(2x))
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-3 + \mathrm{e}^{yx} x \cos(2x)) \\
&= \mathrm{e}^{yx}(yx \cos(2x) + \cos(2x) - 2x \sin(2x))
\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int M \,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int 2x - 2\,\mathrm{e}^{yx} \sin(2x) + \mathrm{e}^{yx} \cos(2x)\, y \,\mathrm{d}x \\
\phi &= \mathrm{e}^{yx} \cos(2x) + x^2 + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = \mathrm{e}^{yx} x \cos(2x) + f'(y) \qquad (4)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -3 + \mathrm{e}^{yx} x \cos(2x)$. Therefore equation (4) becomes

$$
-3 + \mathrm{e}^{yx} x \cos(2x) = \mathrm{e}^{yx} x \cos(2x) + f'(y) \qquad (5)
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = -3
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \,\mathrm{d}y &= \int (-3) \,\mathrm{d}y \\
f(y) &= -3y + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$
\phi = \mathrm{e}^{yx} \cos(2x) + x^2 - 3y + c_1
$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$
c_1 = \mathrm{e}^{yx} \cos(2x) + x^2 - 3y
$$

The solution becomes

$$y = -\frac{-x^3 + c_1 x + 3\,\mathrm{LambertW}\left(-\frac{x\cos(2x)\mathrm{e}^{\frac{1}{3}x^3 - \frac{1}{3}c_1 x}}{3}\right)}{3x}$$

Summary

The solution(s) found are the following

$$y = -\frac{-x^3 + c_1 x + 3\,\mathrm{LambertW}\left(-\frac{x\cos(2x)\mathrm{e}^{\frac{1}{3}x^3 - \frac{1}{3}c_1 x}}{3}\right)}{3x} \tag{1}$$

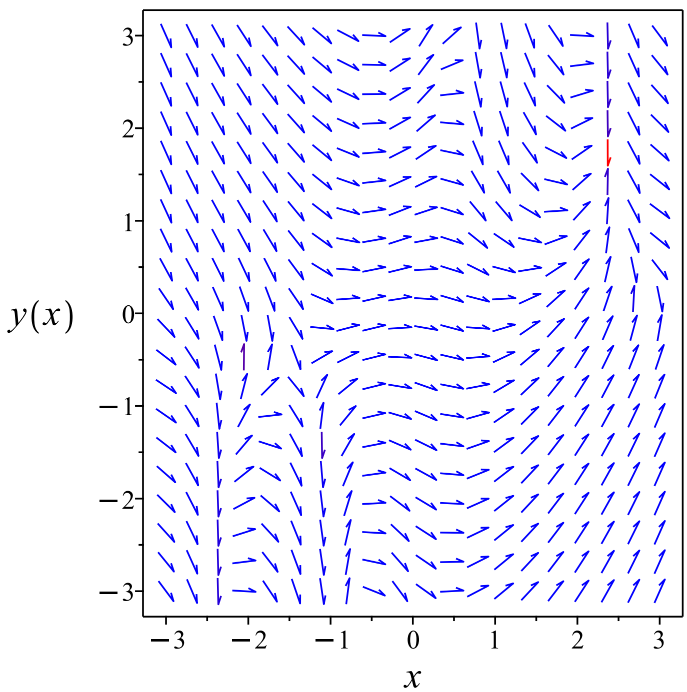

Figure 238: Slope field plot

Verification of solutions

$$y = -\frac{-x^3 + c_1 x + 3\,\mathrm{LambertW}\left(-\frac{x\cos(2x)\mathrm{e}^{\frac{1}{3}x^3 - \frac{1}{3}c_1 x}}{3}\right)}{3x}$$

Verified OK.

5.9.2 Maple step by step solution

Let's solve

$-2\,\mathrm{e}^{yx}\sin(2x)+\mathrm{e}^{yx}\cos(2x)\,y+(-3+\mathrm{e}^{yx}x\cos(2x))\,y'=-2x$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

  ◦ ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x,y)=0$

  ◦ Compute derivative of lhs

    $F'(x,y)+\left(\frac{\partial}{\partial y}F(x,y)\right)y'=0$

  ◦ Evaluate derivatives

    $\mathrm{e}^{yx}yx\cos(2x)+\mathrm{e}^{yx}\cos(2x)-2\,\mathrm{e}^{yx}x\sin(2x)=\mathrm{e}^{yx}yx\cos(2x)+\mathrm{e}^{yx}\cos(2x)-2\,\mathrm{e}^{yx}x\sin(2x)$

  ◦ Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y)=c_1, M(x,y)=F'(x,y), N(x,y)=\frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y)=\int(2x-2\,\mathrm{e}^{yx}\sin(2x)+\mathrm{e}^{yx}\cos(2x)\,y)\,dx+f_1(y)$

- Evaluate integral

  $F(x,y)=y\left(\frac{y\,\mathrm{e}^{yx}\cos(2x)}{y^2+4}+\frac{2\,\mathrm{e}^{yx}\sin(2x)}{y^2+4}\right)+x^2+\frac{4\,\mathrm{e}^{yx}\cos(2x)}{y^2+4}-\frac{2y\,\mathrm{e}^{yx}\sin(2x)}{y^2+4}+f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y)=\frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $-3+\mathrm{e}^{yx}x\cos(2x)=\frac{y\,\mathrm{e}^{yx}\cos(2x)}{y^2+4}+y\left(\frac{\mathrm{e}^{yx}\cos(2x)}{y^2+4}-\frac{2y^2\mathrm{e}^{yx}\cos(2x)}{(y^2+4)^2}+\frac{y\,\mathrm{e}^{yx}x\cos(2x)}{y^2+4}-\frac{4\,\mathrm{e}^{yx}\sin(2x)y}{(y^2+4)^2}+\frac{2\,\mathrm{e}^{yx}x\sin}{y^2+}\right.$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y)=-3+\mathrm{e}^{yx}x\cos(2x)-\frac{y\,\mathrm{e}^{yx}\cos(2x)}{y^2+4}-y\left(\frac{\mathrm{e}^{yx}\cos(2x)}{y^2+4}-\frac{2y^2\mathrm{e}^{yx}\cos(2x)}{(y^2+4)^2}+\frac{y\,\mathrm{e}^{yx}x\cos(2x)}{y^2+4}-\frac{4\,\mathrm{e}^{yx}\sin(2x)}{(y^2+4)^2}\right.$

- Solve for $f_1(y)$

  $f_1(y)=-3y$

- Substitute $f_1(y)$ into equation for $F(x,y)$

$$F(x,y)=y\left(\frac{y\,e^{yx}\cos(2x)}{y^2+4}+\frac{2\,e^{yx}\sin(2x)}{y^2+4}\right)+x^2+\frac{4\,e^{yx}\cos(2x)}{y^2+4}-\frac{2y\,e^{yx}\sin(2x)}{y^2+4}-3y$$

- Substitute $F(x,y)$ into the solution of the ODE

$$y\left(\frac{y\,e^{yx}\cos(2x)}{y^2+4}+\frac{2\,e^{yx}\sin(2x)}{y^2+4}\right)+x^2+\frac{4\,e^{yx}\cos(2x)}{y^2+4}-\frac{2y\,e^{yx}\sin(2x)}{y^2+4}-3y=c_1$$

- Solve for y

$$y=-\frac{-x^3+c_1x+3\mathit{LambertW}\left(-\frac{x\cos(2x)\mathrm{e}^{\frac{1}{3}x^3-\frac{1}{3}c_1x}}{3}\right)}{3x}$$

Problem number: 10.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{\frac{y}{x}+(\ln (x)-2)\, y'=-6x}$$

5.10.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$p(x)=\frac{1}{(\ln (x)-2)\, x}$$
$$q(x)=-\frac{6x}{\ln (x)-2}$$

Hence the ode is

$$y'+\frac{y}{(\ln (x)-2)\, x}=-\frac{6x}{\ln (x)-2}$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int \frac{1}{(\ln(x)-2)x}dx} \\
&= \ln(x) - 2
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(-\frac{6x}{\ln(x)-2}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}((\ln(x)-2)\, y) &= (\ln(x)-2)\left(-\frac{6x}{\ln(x)-2}\right) \\
\mathrm{d}((\ln(x)-2)\, y) &= (-6x)\, \mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
(\ln(x)-2)\, y &= \int -6x\, \mathrm{d}x \\
(\ln(x)-2)\, y &= -3x^2 + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \ln(x) - 2$ results in

$$
y = -\frac{3x^2}{\ln(x)-2} + \frac{c_1}{\ln(x)-2}
$$

which simplifies to

$$
y = \frac{-3x^2 + c_1}{\ln(x)-2}
$$

Summary

The solution(s) found are the following

$$
y = \frac{-3x^2 + c_1}{\ln(x)-2} \tag{1}
$$

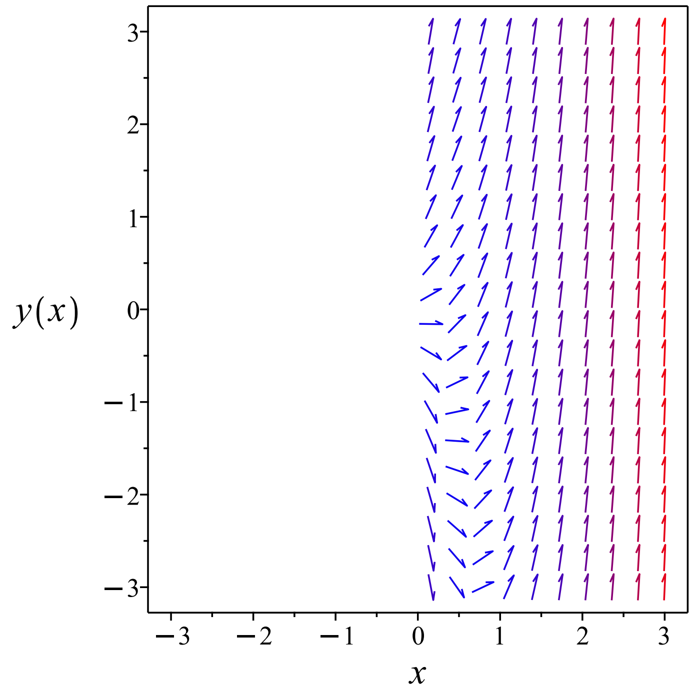

Figure 239: Slope field plot

Verification of solutions

$$y = \frac{-3x^2 + c_1}{\ln(x) - 2}$$

Verified OK.

5.10.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{6x^2 + y}{(\ln(x) - 2)x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 243: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{1}{\ln(x) - 2}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{\ln(x)-2}} dy \end{aligned}$$

Which results in

$$S = (\ln (x) - 2)\, y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{6x^2 + y}{(\ln (x) - 2)\, x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{y}{x} \\ S_y &= \ln (x) - 2 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -6x \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -6R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -3R^2 + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$(\ln(x) - 2)\, y = -3x^2 + c_1$$

Which simplifies to

$$(\ln(x) - 2)\, y = -3x^2 + c_1$$

Which gives

$$y = \frac{-3x^2 + c_1}{\ln(x) - 2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{6x^2+y}{(\ln(x)-2)x}$ 	$R = x$ $S = (\ln(x) - 2)\, y$	$\frac{dS}{dR} = -6R$ 
Summary
The solution(s) found are the following

$$y = \frac{-3x^2 + c_1}{\ln(x) - 2} \tag{1}$$

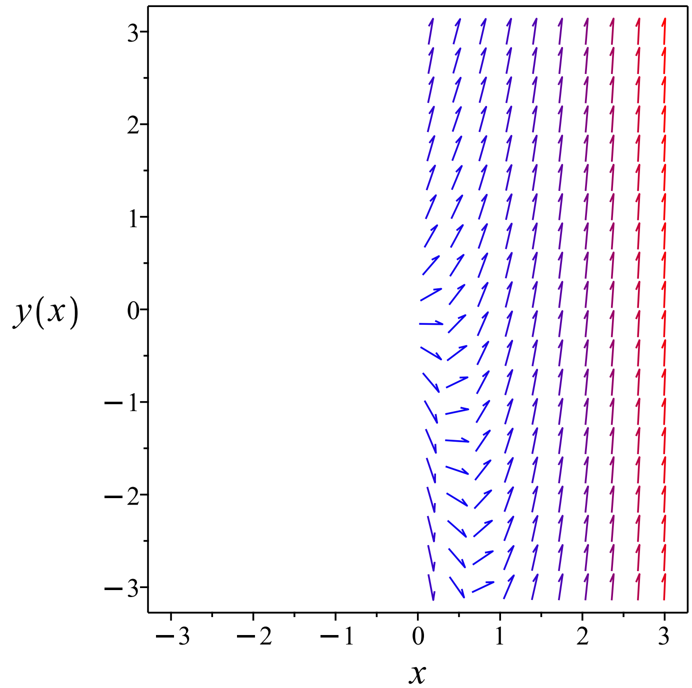

Figure 240: Slope field plot

Verification of solutions

$$y = \frac{-3x^2 + c_1}{\ln(x) - 2}$$

Verified OK.

5.10.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(\ln(x) - 2)\,\mathrm{d}y = \left(-\frac{y}{x} - 6x\right)\mathrm{d}x$$
$$\left(\frac{y}{x} + 6x\right)\mathrm{d}x + (\ln(x) - 2)\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = \frac{y}{x} + 6x$$
$$N(x,y) = \ln(x) - 2$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(\frac{y}{x} + 6x\right)$$
$$= \frac{1}{x}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(\ln(x) - 2)\\ &= \frac{1}{x}\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int M\,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \frac{y}{x} + 6x\,\mathrm{d}x$$

$$\phi = \ln(x)\,y + 3x^2 + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \ln(x) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \ln(x) - 2$. Therefore equation (4) becomes

$$\ln(x) - 2 = \ln(x) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -2$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (-2)\,\mathrm{d}y$$

$$f(y) = -2y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \ln(x)\, y + 3x^2 - 2y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \ln(x)\, y + 3x^2 - 2y$$

The solution becomes

$$y = \frac{-3x^2 + c_1}{\ln(x) - 2}$$

Summary
The solution(s) found are the following

$$y = \frac{-3x^2 + c_1}{\ln(x) - 2} \tag{1}$$

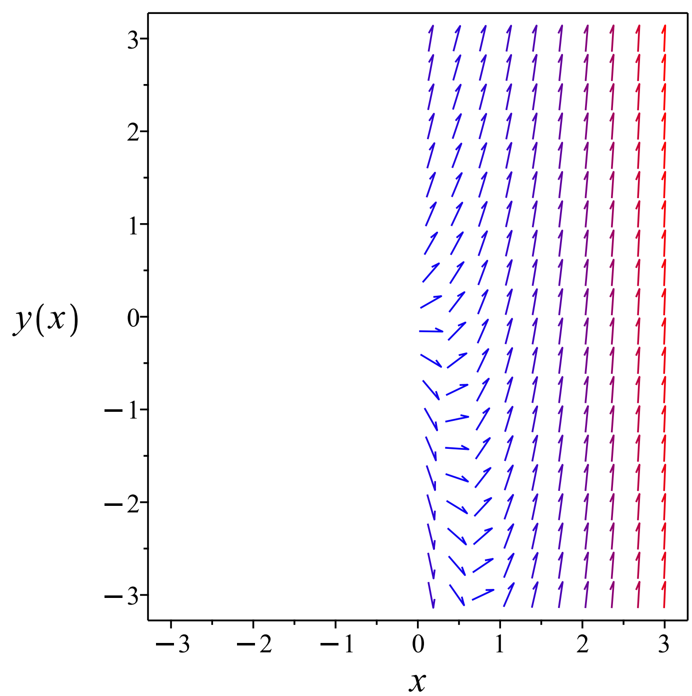

Figure 241: Slope field plot

Verification of solutions

$$y = \frac{-3x^2 + c_1}{\ln(x) - 2}$$

Verified OK.

5.10.4 Maple step by step solution

Let's solve

$\frac{y}{x} + (\ln(x) - 2)\, y' = -6x$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{y}{(\ln(x)-2)x} - \frac{6x}{\ln(x)-2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{y}{(\ln(x)-2)x} = -\frac{6x}{\ln(x)-2}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' + \frac{y}{(\ln(x)-2)x}\right) = -\frac{6\mu(x)x}{\ln(x)-2}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\left(y' + \frac{y}{(\ln(x)-2)x}\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

  $\mu'(x) = \frac{\mu(x)}{(\ln(x)-2)x}$

- Solve to find the integrating factor

  $\mu(x) = \ln(x) - 2$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int -\frac{6\mu(x)x}{\ln(x)-2} dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\, y = \int -\frac{6\mu(x)x}{\ln(x)-2} dx + c_1$

- Solve for y

  $y = \frac{\int -\frac{6\mu(x)x}{\ln(x)-2} dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \ln(x) - 2$

  $y = \frac{\int -6x dx + c_1}{\ln(x) - 2}$

- Evaluate the integrals on the rhs

  $y = \frac{-3x^2 + c_1}{\ln(x) - 2}$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "differentialType", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{\frac{x}{(x^2+y^2)^{\frac{3}{2}}}+\frac{yy'}{(x^2+y^2)^{\frac{3}{2}}}=0}$$

5.12.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x,y)\\ &= f(x)g(y)\\ &= -\frac{x}{y}\end{aligned}$$

Where $f(x) = -x$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y}}\,dy = -x\,dx$$

$$\int \frac{1}{\frac{1}{y}}\,dy = \int -x\,dx$$

$$\frac{y^2}{2} = -\frac{x^2}{2} + c_1$$

Which results in

$$y = \sqrt{-x^2 + 2c_1}$$

$$y = -\sqrt{-x^2 + 2c_1}$$

Summary

The solution(s) found are the following

$$y = \sqrt{-x^2 + 2c_1} \tag{1}$$

$$y = -\sqrt{-x^2 + 2c_1} \tag{2}$$

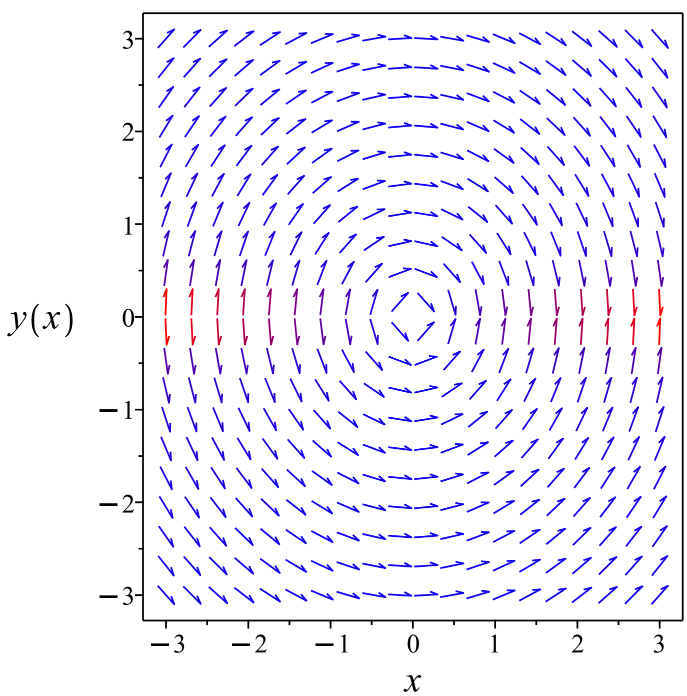

Figure 242: Slope field plot

Verification of solutions

$$y = \sqrt{-x^2 + 2c_1}$$

Verified OK.

$$y = -\sqrt{-x^2 + 2c_1}$$

Verified OK.

5.12.2 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$\frac{x}{\left(x^2 + u\left(x\right)^2 x^2\right)^{\frac{3}{2}}} + \frac{u(x)\,x(u'(x)\,x + u(x))}{\left(x^2 + u\left(x\right)^2 x^2\right)^{\frac{3}{2}}} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{u^2+1}{ux} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{u^2+1}{u}$. Integrating both sides gives

$$\begin{aligned} \frac{1}{\frac{u^2+1}{u}}\,du &= -\frac{1}{x}\,dx \\ \int \frac{1}{\frac{u^2+1}{u}}\,du &= \int -\frac{1}{x}\,dx \\ \frac{\ln\left(u^2+1\right)}{2} &= -\ln\left(x\right) + c_2 \end{aligned}$$

Raising both side to exponential gives

$$\sqrt{u^2+1} = \mathrm{e}^{-\ln(x)+c_2}$$

Which simplifies to

$$\sqrt{u^2+1} = \frac{c_3}{x}$$

Which simplifies to

$$\sqrt{u\left(x\right)^2 + 1} = \frac{c_3 \mathrm{e}^{c_2}}{x}$$

The solution is

$$\sqrt{u(x)^2+1} = \frac{c_3 e^{c_2}}{x}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\sqrt{\frac{y^2}{x^2}+1} = \frac{c_3 e^{c_2}}{x}$$
$$\sqrt{\frac{x^2+y^2}{x^2}} = \frac{c_3 e^{c_2}}{x}$$

Summary
The solution(s) found are the following

$$\sqrt{\frac{x^2+y^2}{x^2}} = \frac{c_3 e^{c_2}}{x} \tag{1}$$

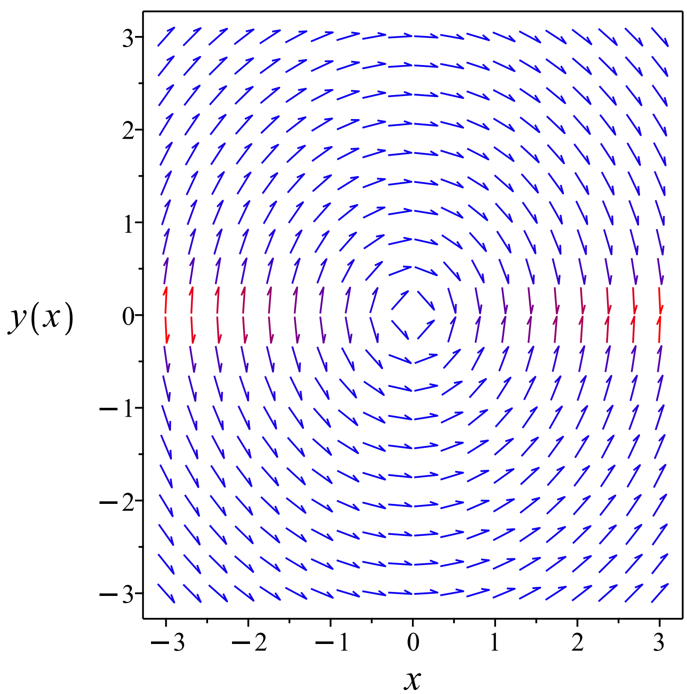

Figure 243: Slope field plot

Verification of solutions

$$\sqrt{\frac{x^2+y^2}{x^2}} = \frac{c_3 e^{c_2}}{x}$$

Verified OK.

5.12.3 Solving as differentialType ode

Writing the ode as

$$y' = -\frac{x}{y} \tag{1}$$

Which becomes

$$(y)\, dy = (-x)\, dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\, dx = d\left(-\frac{x^2}{2}\right)$$

Hence (2) becomes

$$(y)\, dy = d\left(-\frac{x^2}{2}\right)$$

Integrating both sides gives gives these solutions

$$y = \sqrt{-x^2 + 2c_1} + c_1$$
$$y = -\sqrt{-x^2 + 2c_1} + c_1$$

<u>Summary</u>
The solution(s) found are the following

$$y = \sqrt{-x^2 + 2c_1} + c_1 \tag{1}$$
$$y = -\sqrt{-x^2 + 2c_1} + c_1 \tag{2}$$

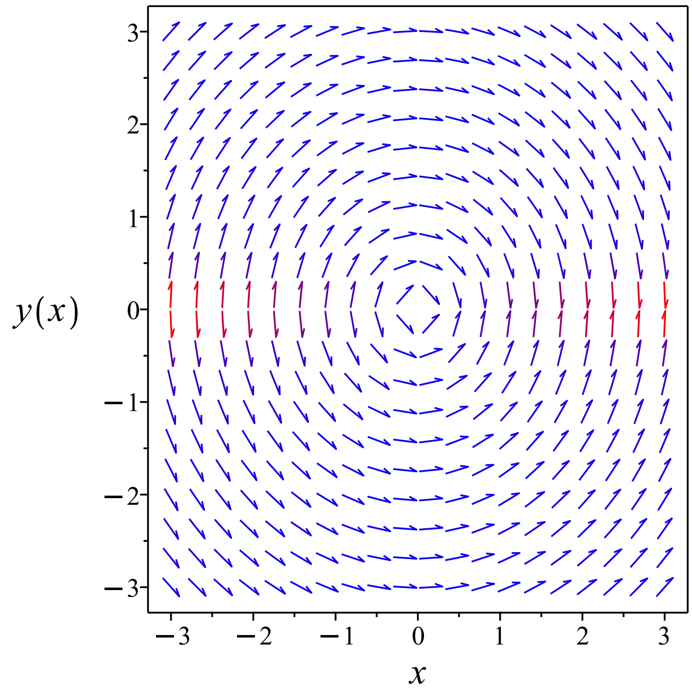

Figure 244: Slope field plot

Verification of solutions

$$y = \sqrt{-x^2 + 2c_1} + c_1$$

Verified OK.

$$y = -\sqrt{-x^2 + 2c_1} + c_1$$

Verified OK.

5.12.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{x}{y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 246: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int(n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= -\frac{1}{x}\\
\eta(x,y) &= 0
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{-\frac{1}{x}} dx \end{aligned}$$

Which results in

$$S = -\frac{x^2}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{x}{y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= -x \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = y \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{x^2}{2} = \frac{y^2}{2} + c_1$$

Which simplifies to

$$-\frac{x^2}{2} = \frac{y^2}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{x}{y}$ 	$R = y$ $S = -\frac{x^2}{2}$	$\frac{dS}{dR} = R$ 
Summary
The solution(s) found are the following

$$-\frac{x^2}{2} = \frac{y^2}{2} + c_1 \tag{1}$$

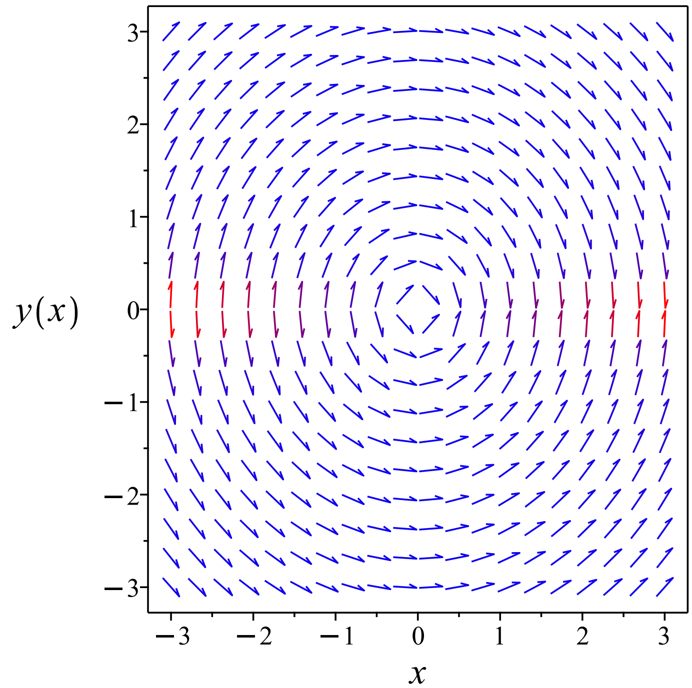

Figure 245: Slope field plot

Verification of solutions

$$-\frac{x^2}{2} = \frac{y^2}{2} + c_1$$

Verified OK.

5.12.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(-y)\,\mathrm{d}y = (x)\,\mathrm{d}x$$
$$(-x)\,\mathrm{d}x + (-y)\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -x$$
$$N(x, y) = -y$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}(-x)$$
$$= 0$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}(-y)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -x \, \mathrm{d}x$$
$$\phi = -\frac{x^2}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -y$. Therefore equation (4) becomes

$$-y = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -y$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (-y) \, \mathrm{d}y$$
$$f(y) = -\frac{y^2}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x^2}{2} - \frac{y^2}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x^2}{2} - \frac{y^2}{2}$$

Summary

The solution(s) found are the following

$$-\frac{x^2}{2} - \frac{y^2}{2} = c_1 \tag{1}$$

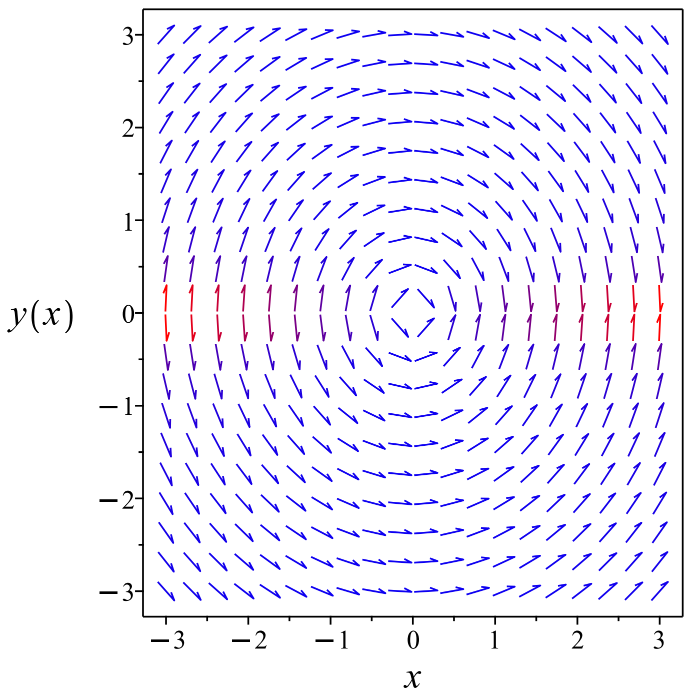

Figure 246: Slope field plot

Verification of solutions

$$-\frac{x^2}{2} - \frac{y^2}{2} = c_1$$

Verified OK.

5.12.6 Maple step by step solution

Let's solve

$\frac{x}{(x^2+y^2)^{\frac{3}{2}}}+\frac{yy'}{(x^2+y^2)^{\frac{3}{2}}}=0$

- Highest derivative means the order of the ODE is 1

  y'

- Integrate both sides with respect to x

  $\int \left(\frac{x}{(x^2+y^2)^{\frac{3}{2}}}+\frac{yy'}{(x^2+y^2)^{\frac{3}{2}}}\right)dx=\int 0dx+c_1$

- Evaluate integral

  $-\frac{1}{\sqrt{x^2+y^2}}=c_1$

- Solve for y

  $\left\{y=\frac{\sqrt{-c_1^2x^2+1}}{c_1}, y=-\frac{\sqrt{-c_1^2x^2+1}}{c_1}\right\}$

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.6. Page 100
Problem number: 13.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "differentialType", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _exact, _rational, [_Abel, `2nd
   type`, `class A`]]
```

$$\boxed{-y + (-x + 2y)\, y' = -2x}$$

With initial conditions

$$[y(1) = 3]$$

5.13.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= \frac{-2x + y}{-x + 2y} \end{aligned}$$

The x domain of $f(x,y)$ when $y=3$ is

$$\{x<6\vee 6<x\}$$

And the point $x_0=1$ is inside this domain. The y domain of $f(x,y)$ when $x=1$ is

$$\left\{y<\frac{1}{2}\vee\frac{1}{2}<y\right\}$$

And the point $y_0=3$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y}&=\frac{\partial}{\partial y}\left(\frac{-2x+y}{-x+2y}\right)\\&=\frac{1}{-x+2y}-\frac{2(-2x+y)}{(-x+2y)^2}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y=3$ is

$$\{x<6\vee 6<x\}$$

And the point $x_0=1$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x=1$ is

$$\left\{y<\frac{1}{2}\vee\frac{1}{2}<y\right\}$$

And the point $y_0=3$ is inside this domain. Therefore solution exists and is unique.

5.13.2 Solving as homogeneousTypeD2 ode

Using the change of variables $y=u(x)\,x$ on the above ode results in new ode in $u(x)$

$$-u(x)\,x+(-x+2u(x)\,x)\,(u'(x)\,x+u(x))=-2x$$

In canonical form the ODE is

$$\begin{aligned}u'&=F(x,u)\\&=f(x)g(u)\\&=-\frac{2(u^2-u+1)}{x\,(2u-1)}\end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = \frac{u^2-u+1}{2u-1}$. Integrating both sides gives

$$\frac{1}{\frac{u^2-u+1}{2u-1}}\,du = -\frac{2}{x}\,dx$$
$$\int \frac{1}{\frac{u^2-u+1}{2u-1}}\,du = \int -\frac{2}{x}\,dx$$
$$\ln\left(u^2-u+1\right) = -2\ln(x) + c_2$$

Raising both side to exponential gives

$$u^2 - u + 1 = \mathrm{e}^{-2\ln(x)+c_2}$$

Which simplifies to

$$u^2 - u + 1 = \frac{c_3}{x^2}$$

Which simplifies to

$$u(x)^2 - u(x) + 1 = \frac{c_3 \mathrm{e}^{c_2}}{x^2}$$

The solution is

$$u(x)^2 - u(x) + 1 = \frac{c_3 \mathrm{e}^{c_2}}{x^2}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\frac{y^2}{x^2} - \frac{y}{x} + 1 = \frac{c_3 \mathrm{e}^{c_2}}{x^2}$$
$$\frac{y^2}{x^2} - \frac{y}{x} + 1 = \frac{c_3 \mathrm{e}^{c_2}}{x^2}$$

Which simplifies to

$$y^2 - yx + x^2 = c_3 \mathrm{e}^{c_2}$$

Substituting initial conditions and solving for c_2 gives $c_2 = \ln\left(\frac{7}{c_3}\right)$. Hence the solution becomes

Summary

The solution(s) found are the following

$$y^2 - yx + x^2 = 7 \tag{1}$$

Verification of solutions

$$y^2 - yx + x^2 = 7$$

Verified OK.

5.13.3 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-2x + y}{-x + 2y} \tag{1}$$

Which becomes

$$(-2y)\,dy = (-x)\,dy + (2x - y)\,dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\,dy + (2x - y)\,dx = d\left(x^2 - yx\right)$$

Hence (2) becomes

$$(-2y)\,dy = d\left(x^2 - yx\right)$$

Integrating both sides gives gives these solutions

$$y = \frac{x}{2} + \frac{\sqrt{-3x^2 - 4c_1}}{2} + c_1$$
$$y = \frac{x}{2} - \frac{\sqrt{-3x^2 - 4c_1}}{2} + c_1$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 3$ in the above solution gives an equation to solve for the constant of integration.

$$3 = \frac{1}{2} - \frac{\sqrt{-3 - 4c_1}}{2} + c_1$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 3$ in the above solution gives an equation to solve for the constant of integration.

$$3 = \frac{1}{2} + \frac{\sqrt{-3 - 4c_1}}{2} + c_1$$

$$c_1 = 2 - i\sqrt{3}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{x}{2} + \frac{\sqrt{-3x^2 - 8 + 4i\sqrt{3}}}{2} + 2 - i\sqrt{3}$$

Summary

The solution(s) found are the following

$$y = \frac{x}{2} + \frac{\sqrt{-3x^2 - 8 + 4i\sqrt{3}}}{2} + 2 - i\sqrt{3} \tag{1}$$

Verification of solutions

$$y = \frac{x}{2} + \frac{\sqrt{-3x^2 - 8 + 4i\sqrt{3}}}{2} + 2 - i\sqrt{3}$$

Verified OK.

5.13.4 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= \frac{-2x + y}{-x + 2y} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} & b_2 + \frac{(-2x + y)(b_3 - a_2)}{-x + 2y} - \frac{(-2x + y)^2 a_3}{(-x + 2y)^2} \\ & - \left(-\frac{2}{-x + 2y} + \frac{-2x + y}{(-x + 2y)^2} \right) (x a_2 + y a_3 + a_1) \\ & - \left(\frac{1}{-x + 2y} - \frac{2(-2x + y)}{(-x + 2y)^2} \right) (x b_2 + y b_3 + b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{2x^2a_2+4x^2a_3+2x^2b_2-2x^2b_3-8xya_2-4xya_3+4xyb_2+8xyb_3+2y^2a_2-2y^2a_3-4y^2b_2-2y^2b_3+3}{(x-2y)^2}$$
$$=0$$

Setting the numerator to zero gives

$$-2x^2a_2-4x^2a_3-2x^2b_2+2x^2b_3+8xya_2+4xya_3-4xyb_2 \\ -8xyb_3-2y^2a_2+2y^2a_3+4y^2b_2+2y^2b_3-3xb_1+3ya_1=0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x,y\}$ in them.

$$\{x,y\}$$

The following substitution is now made to be able to collect on all terms with $\{x,y\}$ in them

$$\{x=v_1,y=v_2\}$$

The above PDE (6E) now becomes

$$-2a_2v_1^2+8a_2v_1v_2-2a_2v_2^2-4a_3v_1^2+4a_3v_1v_2+2a_3v_2^2-2b_2v_1^2 \\ -4b_2v_1v_2+4b_2v_2^2+2b_3v_1^2-8b_3v_1v_2+2b_3v_2^2+3a_1v_2-3b_1v_1=0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1,v_2\}$$

Equation (7E) now becomes

$$(-2a_2-4a_3-2b_2+2b_3)v_1^2+(8a_2+4a_3-4b_2-8b_3)v_1v_2 \\ -3b_1v_1+(-2a_2+2a_3+4b_2+2b_3)v_2^2+3a_1v_2=0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}3a_1&=0\\-3b_1&=0\\-2a_2-4a_3-2b_2+2b_3&=0\\-2a_2+2a_3+4b_2+2b_3&=0\\8a_2+4a_3-4b_2-8b_3&=0\end{aligned}$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= b_2 + b_3 \\
a_3 &= -b_2 \\
b_1 &= 0 \\
b_2 &= b_2 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= y - \left(\frac{-2x + y}{-x + 2y}\right)(x) \\
&= \frac{-2x^2 + 2yx - 2y^2}{x - 2y} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-2x^2 + 2yx - 2y^2}{x - 2y}} dy
\end{aligned}
$$

Which results in

$$S = \frac{\ln(x^2 - yx + y^2)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{-2x + y}{-x + 2y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{2x - y}{2x^2 - 2yx + 2y^2} \\
S_y &= \frac{-x + 2y}{2x^2 - 2yx + 2y^2}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(y^2 - yx + x^2)}{2} = c_1$$

Which simplifies to

$$\frac{\ln \left(y^{2}-y x+x^{2}\right)}{2} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{-2x+y}{-x+2y}$ 	$R = x$ $S = \frac{\ln \left(x^{2}-y x+y^{2}\right)}{2}$	$\frac{dS}{dR} = 0$ 
Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 3$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{\ln \left(7\right)}{2} = c_1$$

$$c_1 = \frac{\ln \left(7\right)}{2}$$

Substituting c_1 found above in the general solution gives

$$\frac{\ln \left(x^{2}-y x+y^{2}\right)}{2} = \frac{\ln \left(7\right)}{2}$$

Summary

The solution(s) found are the following

$$\frac{\ln \left(y^{2}-y x+x^{2}\right)}{2} = \frac{\ln \left(7\right)}{2} \tag{1}$$

Verification of solutions

$$\frac{\ln\left(y^2 - yx + x^2\right)}{2} = \frac{\ln\left(7\right)}{2}$$

Verified OK.

5.13.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(-x + 2y)\,\mathrm{d}y = (-2x + y)\,\mathrm{d}x$$
$$(2x - y)\,\mathrm{d}x + (-x + 2y)\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x,y) &= 2x - y \\
N(x,y) &= -x + 2y
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(2x - y) \\
&= -1
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-x + 2y) \\
&= -1
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \qquad (1) \\
\frac{\partial \phi}{\partial y} &= N \qquad (2)
\end{aligned}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int M \, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int 2x - y \, \mathrm{d}x \\
\phi &= x(x - y) + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = -x + f'(y) \qquad (4)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -x + 2y$. Therefore equation (4) becomes

$$-x + 2y = -x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 2y$$

Integrating the above w.r.t y gives

$$\int f'(y)\, \mathrm{d}y = \int (2y)\, \mathrm{d}y$$
$$f(y) = y^2 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = x(x - y) + y^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x(x - y) + y^2$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 3$ in the above solution gives an equation to solve for the constant of integration.

$$7 = c_1$$

$$c_1 = 7$$

Substituting c_1 found above in the general solution gives

$$x(x - y) + y^2 = 7$$

Summary

The solution(s) found are the following

$$y^2 - yx + x^2 = 7 \tag{1}$$

Verification of solutions

$$y^2 - yx + x^2 = 7$$

Verified OK.

The solution

$$\frac{\ln (y^2 - yx + x^2)}{2} = \frac{\ln (7)}{2}$$

can be simplified to

$$\ln \left(y^2 - yx + x^2\right) = \ln (7)$$

5.13.6 Maple step by step solution

Let's solve

$[-y + (-x + 2y)\, y' = -2x, y(1) = 3]$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact
  - ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$
  - Compute derivative of lhs

    $F'(x, y) + \left(\frac{\partial}{\partial y} F(x, y)\right) y' = 0$
  - Evaluate derivatives

    $-1 = -1$
  - Condition met, ODE is exact
- Exact ODE implies solution will be of this form

  $\left[F(x, y) = c_1, M(x, y) = F'(x, y)\, , N(x, y) = \frac{\partial}{\partial y} F(x, y)\right]$
- Solve for $F(x, y)$ by integrating $M(x, y)$ with respect to x

  $F(x, y) = \int (2x - y)\, dx + f_1(y)$
- Evaluate integral

  $F(x, y) = x^2 - yx + f_1(y)$
- Take derivative of $F(x, y)$ with respect to y

  $N(x, y) = \frac{\partial}{\partial y} F(x, y)$

- Compute derivative

  $-x+2y=-x+\frac{d}{dy}f_1(y)$
- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y)=2y$
- Solve for $f_1(y)$

  $f_1(y)=y^2$
- Substitute $f_1(y)$ into equation for $F(x,y)$

  $F(x,y)=x^2-yx+y^2$
- Substitute $F(x,y)$ into the solution of the ODE

  $x^2-yx+y^2=c_1$
- Solve for y

  $\left\{y=\frac{x}{2}-\frac{\sqrt{-3x^2+4c_1}}{2}, y=\frac{x}{2}+\frac{\sqrt{-3x^2+4c_1}}{2}\right\}$
- Use initial condition $y(1)=3$

  $3=\frac{1}{2}-\frac{\sqrt{4c_1-3}}{2}$
- Solution does not satisfy initial condition
- Use initial condition $y(1)=3$

  $3=\frac{1}{2}+\frac{\sqrt{4c_1-3}}{2}$
- Solve for c_1

  $c_1=7$
- Substitute $c_1=7$ into general solution and simplify

  $y=\frac{x}{2}+\frac{\sqrt{-3x^2+28}}{2}$
- Solution to the IVP

  $y=\frac{x}{2}+\frac{\sqrt{-3x^2+28}}{2}$

$$\boxed{y + (x - 4y)\, y' = -9x^2 + 1}$$

With initial conditions

$$[y(1) = 0]$$

5.14.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= \frac{9x^2 + y - 1}{-x + 4y} \end{aligned}$$

The x domain of $f(x, y)$ when $y = 0$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The y domain of $f(x, y)$ when $x = 1$ is

$$\left\{y < \frac{1}{4} \vee \frac{1}{4} < y\right\}$$

And the point $y_0 = 0$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{9x^2 + y - 1}{-x + 4y}\right) \\ &= \frac{1}{-x + 4y} - \frac{4(9x^2 + y - 1)}{(-x + 4y)^2}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 0$ is

$$\{x < 0 \vee 0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 1$ is

$$\left\{y < \frac{1}{4} \vee \frac{1}{4} < y\right\}$$

And the point $y_0 = 0$ is inside this domain. Therefore solution exists and is unique.

5.14.2 Solving as differentialType ode

Writing the ode as

$$y' = \frac{1 - 9x^2 - y}{x - 4y} \tag{1}$$

Which becomes

$$(-4y)\, dy = (-x)\, dy + \left(-9x^2 - y + 1\right) dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\, dy + \left(-9x^2 - y + 1\right) dx = d\left(-3x^3 - yx + x\right)$$

Hence (2) becomes

$$(-4y)\, dy = d\left(-3x^3 - yx + x\right)$$

Integrating both sides gives gives these solutions

$$y = \frac{x}{4} + \frac{\sqrt{24x^3 + x^2 - 8c_1 - 8x}}{4} + c_1$$
$$y = \frac{x}{4} - \frac{\sqrt{24x^3 + x^2 - 8c_1 - 8x}}{4} + c_1$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{1}{4} - \frac{\sqrt{17 - 8c_1}}{4} + c_1$$

$$c_1 = \frac{\sqrt{5}}{2} - \frac{1}{2}$$

Substituting c_1 found above in the general solution gives

$$y = \frac{x}{4} - \frac{\sqrt{24x^3 + x^2 - 4\sqrt{5} + 4 - 8x}}{4} + \frac{\sqrt{5}}{2} - \frac{1}{2}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{1}{4} + \frac{\sqrt{17 - 8c_1}}{4} + c_1$$

$$c_1 = -\frac{1}{2} - \frac{\sqrt{5}}{2}$$

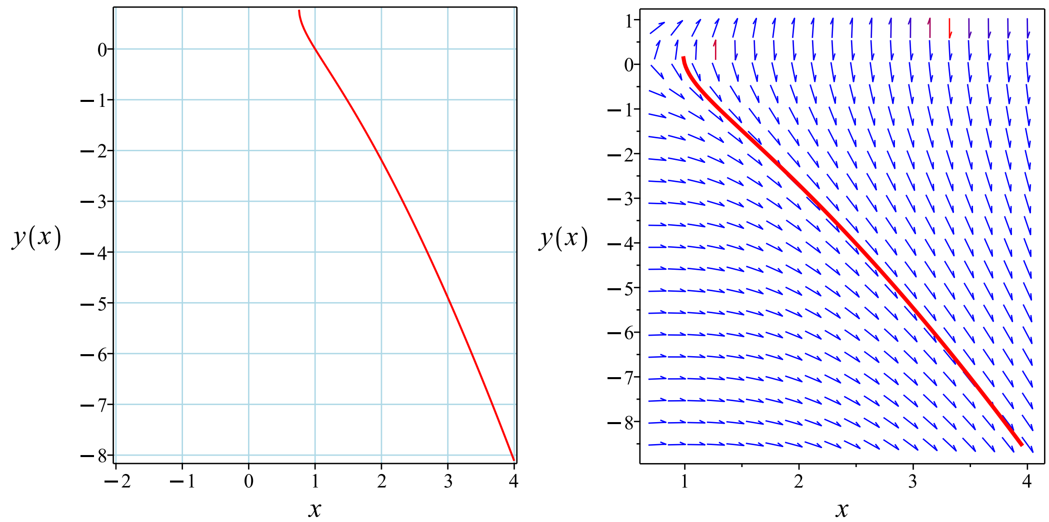
Substituting c_1 found above in the general solution gives

$$y = \frac{x}{4} + \frac{\sqrt{24x^3 + x^2 + 4 + 4\sqrt{5} - 8x}}{4} - \frac{1}{2} - \frac{\sqrt{5}}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{x}{4} + \frac{\sqrt{24x^3 + x^2 + 4 + 4\sqrt{5} - 8x}}{4} - \frac{1}{2} - \frac{\sqrt{5}}{2} \tag{1}$$
$$y = \frac{x}{4} - \frac{\sqrt{24x^3 + x^2 - 4\sqrt{5} + 4 - 8x}}{4} + \frac{\sqrt{5}}{2} - \frac{1}{2} \tag{2}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \frac{x}{4} + \frac{\sqrt{24x^3 + x^2 + 4 + 4\sqrt{5} - 8x}}{4} - \frac{1}{2} - \frac{\sqrt{5}}{2}$$

Verified OK.

$$y = \frac{x}{4} - \frac{\sqrt{24x^3 + x^2 - 4\sqrt{5} + 4 - 8x}}{4} + \frac{\sqrt{5}}{2} - \frac{1}{2}$$

Verified OK.

5.14.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(x - 4y)\, \mathrm{d}y = \left(-9x^2 - y + 1\right) \mathrm{d}x$$
$$\left(9x^2 + y - 1\right) \mathrm{d}x + (x - 4y)\, \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = 9x^2 + y - 1$$
$$N(x, y) = x - 4y$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(9x^2 + y - 1\right)$$
$$= 1$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}(x - 4y)$$
$$= 1$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x}=M \tag{1}$$
$$\frac{\partial \phi}{\partial y}=N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x=\int M\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x=\int 9x^2+y-1\,\mathrm{d}x$$
$$\phi=x\left(3x^2+y-1\right)+f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y}=x+f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y}=x-4y$. Therefore equation (4) becomes

$$x-4y=x+f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y)=-4y$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y=\int (-4y)\,\mathrm{d}y$$
$$f(y)=-2y^2+c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi=x\left(3x^2+y-1\right)-2y^2+c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x(3x^2 + y - 1) - 2y^2$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$2 = c_1$$

$$c_1 = 2$$

Substituting c_1 found above in the general solution gives

$$x(3x^2 + y - 1) - 2y^2 = 2$$

Summary

The solution(s) found are the following

$$3x^3 + (y - 1)x - 2y^2 = 2 \tag{1}$$

Verification of solutions

$$3x^3 + (y - 1)x - 2y^2 = 2$$

Verified OK.

5.14.4 Maple step by step solution

Let's solve

$[y + (x - 4y)y' = -9x^2 + 1, y(1) = 0]$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact
  - ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$
  - Compute derivative of lhs

    $F'(x, y) + \left(\frac{\partial}{\partial y}F(x, y)\right)y' = 0$

- Evaluate derivatives
  $1 = 1$
- Condition met, ODE is exact

- Exact ODE implies solution will be of this form
  $\left[F(x,y) = c_1, M(x,y) = F'(x,y), N(x,y) = \frac{\partial}{\partial y}F(x,y)\right]$
- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x
  $F(x,y) = \int (9x^2 + y - 1)\, dx + f_1(y)$
- Evaluate integral
  $F(x,y) = 3x^3 + yx - x + f_1(y)$
- Take derivative of $F(x,y)$ with respect to y
  $N(x,y) = \frac{\partial}{\partial y}F(x,y)$
- Compute derivative
  $x - 4y = x + \frac{d}{dy}f_1(y)$
- Isolate for $\frac{d}{dy}f_1(y)$
  $\frac{d}{dy}f_1(y) = -4y$
- Solve for $f_1(y)$
  $f_1(y) = -2y^2$
- Substitute $f_1(y)$ into equation for $F(x,y)$
  $F(x,y) = 3x^3 + yx - 2y^2 - x$
- Substitute $F(x,y)$ into the solution of the ODE
  $3x^3 + yx - 2y^2 - x = c_1$
- Solve for y
  $\left\{y = \frac{x}{4} - \frac{\sqrt{24x^3+x^2-8c_1-8x}}{4}, y = \frac{x}{4} + \frac{\sqrt{24x^3+x^2-8c_1-8x}}{4}\right\}$
- Use initial condition $y(1) = 0$
  $0 = \frac{1}{4} - \frac{\sqrt{17-8c_1}}{4}$
- Solve for c_1
  $c_1 = 2$
- Substitute $c_1 = 2$ into general solution and simplify

$y = \frac{x}{4} - \frac{\sqrt{24x^3+x^2-8x-16}}{4}$

- Use initial condition $y(1) = 0$

  $0 = \frac{1}{4} + \frac{\sqrt{17-8c_1}}{4}$
- Solution does not satisfy initial condition
- Solution to the IVP

  $y = \frac{x}{4} - \frac{\sqrt{24x^3+x^2-8x-16}}{4}$

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{y^3x^2 + x(1 + y^2)\, y' = 0}$$

5.15.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= f(x)g(y) \\ &= -\frac{y^3x}{y^2 + 1} \end{aligned}$$

Where $f(x) = -x$ and $g(y) = \frac{y^3}{y^2+1}$. Integrating both sides gives

$$\frac{1}{\frac{y^3}{y^2+1}}\, dy = -x\, dx$$

$$\int \frac{1}{\frac{y^3}{y^2+1}}\, dy = \int -x\, dx$$

$$\ln(y) - \frac{1}{2y^2} = -\frac{x^2}{2} + c_1$$

Which results in

$$y = e^{\frac{\text{LambertW}\left(e^{x^2 - 2c_1}\right)}{2} - \frac{x^2}{2} + c_1}$$

Summary

The solution(s) found are the following

$$y = e^{\frac{\text{LambertW}\left(e^{x^2 - 2c_1}\right)}{2} - \frac{x^2}{2} + c_1} \tag{1}$$

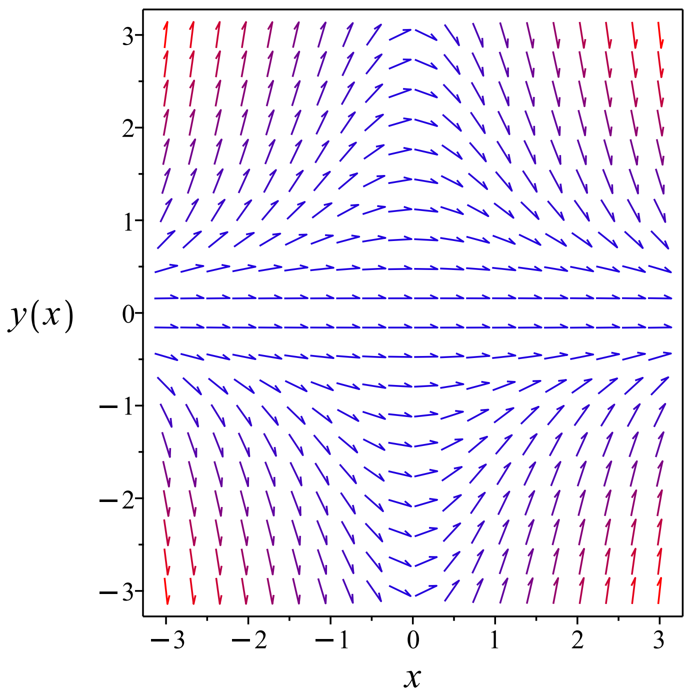

Figure 248: Slope field plot

Verification of solutions

$$y = e^{\frac{\text{LambertW}\left(e^{x^2 - 2c_1}\right)}{2} - \frac{x^2}{2} + c_1}$$

Verified OK.

5.15.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{y^3 x}{y^2+1} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 251: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= -\frac{1}{x} \\
\eta(x,y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{-\frac{1}{x}} dx
\end{aligned}
$$

Which results in

$$
S = -\frac{x^2}{2}
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = -\frac{y^3 x}{y^2 + 1}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= -x \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{y^2+1}{y^3} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{R^2+1}{R^3}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \ln(R) - \frac{1}{2R^2} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
-\frac{x^2}{2} = \ln(y) - \frac{1}{2y^2} + c_1
$$

Which simplifies to

$$
-\frac{x^2}{2} = \ln(y) - \frac{1}{2y^2} + c_1
$$

Which gives

$$
y = \mathrm{e}^{\frac{\mathrm{LambertW}\left(\mathrm{e}^{x^2+2c_1}\right)}{2} - \frac{x^2}{2} - c_1}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y^3 x}{y^2+1}$ 	$R = y$ $S = -\frac{x^2}{2}$	$\frac{dS}{dR} = \frac{R^2+1}{R^3}$ 
Summary

The solution(s) found are the following

$$y = e^{\frac{\mathrm{LambertW}\left(e^{x^2+2c_1}\right)}{2} - \frac{x^2}{2} - c_1} \tag{1}$$

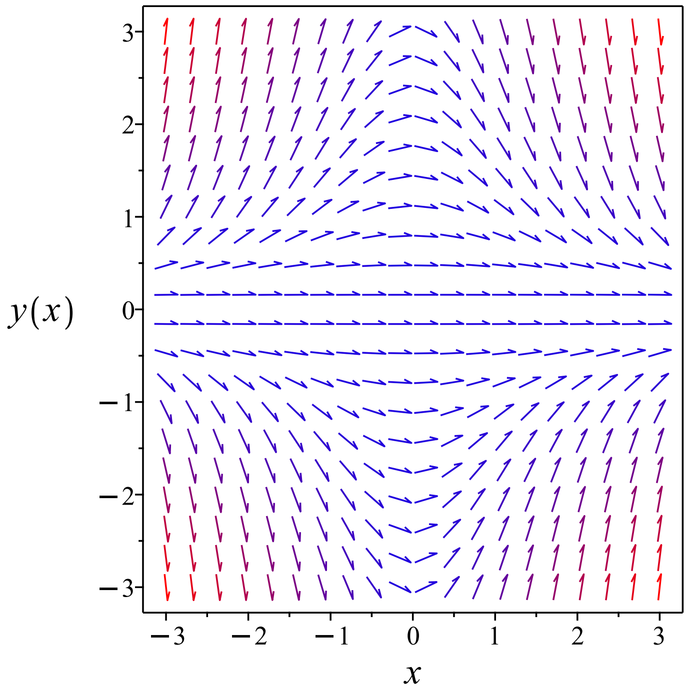

Figure 249: Slope field plot

Verification of solutions

$$y = e^{\frac{\text{LambertW}\left(e^{x^2+2c_1}\right)}{2}-\frac{x^2}{2}-c_1}$$

Verified OK.

5.15.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(-\frac{y^2+1}{y^3}\right)\mathrm{d}y = (x)\,\mathrm{d}x$$
$$(-x)\,\mathrm{d}x + \left(-\frac{y^2+1}{y^3}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -x$$
$$N(x, y) = -\frac{y^2+1}{y^3}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-x)\\ &= 0\end{aligned}$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}\left(-\frac{y^2+1}{y^3}\right)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int M \,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int -x \,\mathrm{d}x$$
$$\phi = -\frac{x^2}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{y^2+1}{y^3}$. Therefore equation (4) becomes

$$-\frac{y^2+1}{y^3} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{y^2+1}{y^3}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{-y^2-1}{y^3}\right)\mathrm{d}y$$
$$f(y) = -\ln(y) + \frac{1}{2y^2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x^2}{2} - \ln(y) + \frac{1}{2y^2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x^2}{2} - \ln(y) + \frac{1}{2y^2}$$

The solution becomes

$$y = \mathrm{e}^{\frac{\mathrm{LambertW}\left(\mathrm{e}^{x^2+2c_1}\right)}{2} - \frac{x^2}{2} - c_1}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{\frac{\mathrm{LambertW}\left(\mathrm{e}^{x^2+2c_1}\right)}{2} - \frac{x^2}{2} - c_1} \tag{1}$$

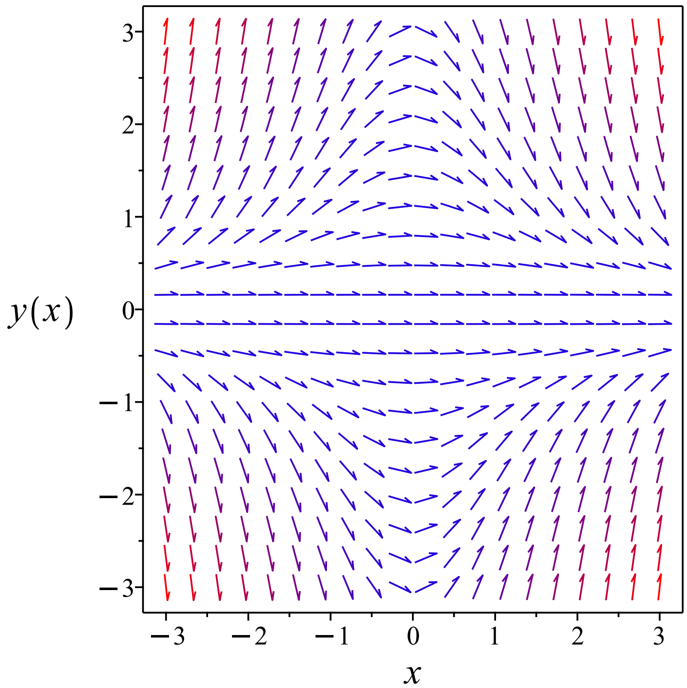

Figure 250: Slope field plot

Verification of solutions

$$y = e^{\frac{\operatorname{LambertW}\left(e^{x^2+2c_1}\right)}{2}-\frac{x^2}{2}-c_1}$$

Verified OK.

5.15.4 Maple step by step solution

Let's solve

$y^3x^2 + x(1+y^2)\,y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'(1+y^2)}{y^3} = -x$

- Integrate both sides with respect to x

  $\int \frac{y'(1+y^2)}{y^3}dx = \int -xdx + c_1$

- Evaluate integral

$$\ln (y)-\frac{1}{2y^2}=-\frac{x^2}{2}+c_1$$

- Solve for y

$$y=\mathrm{e}^{\frac{\mathit{LambertW}\left(\mathrm{e}^{x^2-2c_1}\right)}{2}-\frac{x^2}{2}+c_1}$$

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor"**

Maple gives the following as the ode type

`[[_1st_order, `_with_symmetry_[F(x)*G(y),0]`]]`

$$\boxed{y + (2x - e^{y} y) y' = 0}$$

5.16.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(2x - \mathrm{e}^y y)\,\mathrm{d}y &= (-y)\,\mathrm{d}x\\ (y)\,\mathrm{d}x + (2x - \mathrm{e}^y y)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= y\\ N(x,y) &= 2x - \mathrm{e}^y y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(y)\\ &= 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2x - \mathrm{e}^y y)\\ &= 2\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{2x - \mathrm{e}^y y}((1) - (2))\\ &= \frac{1}{\mathrm{e}^y y - 2x}\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned} B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\ &= \frac{1}{y}((2) - (1)) \\ &= \frac{1}{y} \end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned} \mu &= e^{\int B \, \mathrm{d}y} \\ &= e^{\int \frac{1}{y} \, \mathrm{d}y} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{\ln(y)} \\ &= y \end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= y(y) \\ &= y^2 \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= y(2x - \mathrm{e}^y y) \\ &= -y^2 \mathrm{e}^y + 2yx \end{aligned}$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N} \frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ (y^2) + (-y^2 \mathrm{e}^y + 2yx) \frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int y^2 \, \mathrm{d}x$$
$$\phi = x\,y^2 + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2yx + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -y^2 \mathrm{e}^y + 2yx$. Therefore equation (4) becomes

$$-y^2 \mathrm{e}^y + 2yx = 2yx + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -y^2 \mathrm{e}^y$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int \left(-y^2 \mathrm{e}^y\right) \mathrm{d}y$$
$$f(y) = -\left(y^2 - 2y + 2\right) \mathrm{e}^y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = x\,y^2 - \left(y^2 - 2y + 2\right) \mathrm{e}^y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x\,y^2 - \left(y^2 - 2y + 2\right) \mathrm{e}^{y}$$

Summary

The solution(s) found are the following

$$xy^2 - \left(y^2 - 2y + 2\right) \mathrm{e}^{y} = c_1 \tag{1}$$

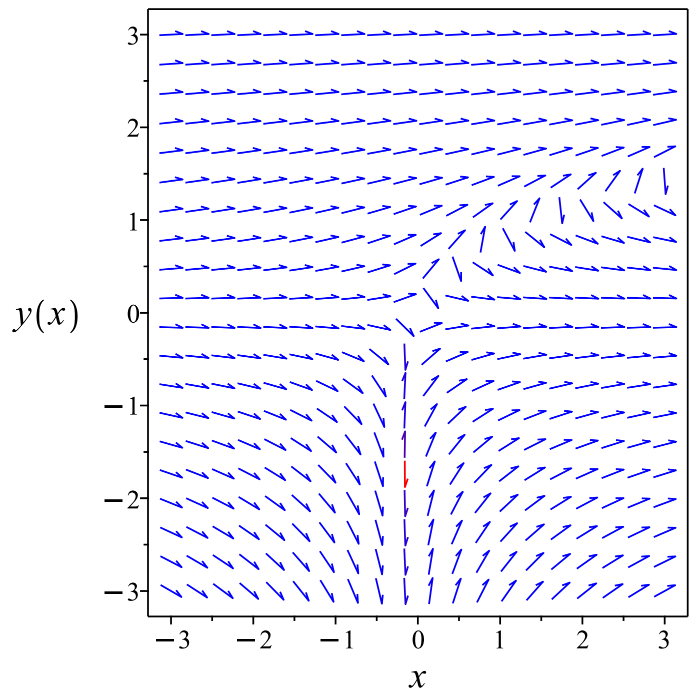

Figure 251: Slope field plot

Verification of solutions

$$xy^2 - \left(y^2 - 2y + 2\right) \mathrm{e}^{y} = c_1$$

Verified OK.

Problem number: 22.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{(2+x)\sin(y)+x\cos(y)\,y'=0}$$

5.17.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y)\\ &= f(x)g(y)\\ &= -\frac{(2+x)\tan(y)}{x} \end{aligned}$$

Where $f(x)=-\frac{2+x}{x}$ and $g(y)=\tan(y)$. Integrating both sides gives

$$\begin{aligned} \frac{1}{\tan(y)}\,dy &= -\frac{2+x}{x}\,dx\\ \int \frac{1}{\tan(y)}\,dy &= \int -\frac{2+x}{x}\,dx\\ \ln(\sin(y)) &= -x-2\ln(x)+c_1 \end{aligned}$$

Raising both side to exponential gives

$$\sin(y) = e^{-x-2\ln(x)+c_1}$$

Which simplifies to

$$\sin(y) = c_2 e^{-x-2\ln(x)}$$

Summary

The solution(s) found are the following

$$y = \arcsin\left(\frac{c_2 e^{-x+c_1}}{x^2}\right) \tag{1}$$

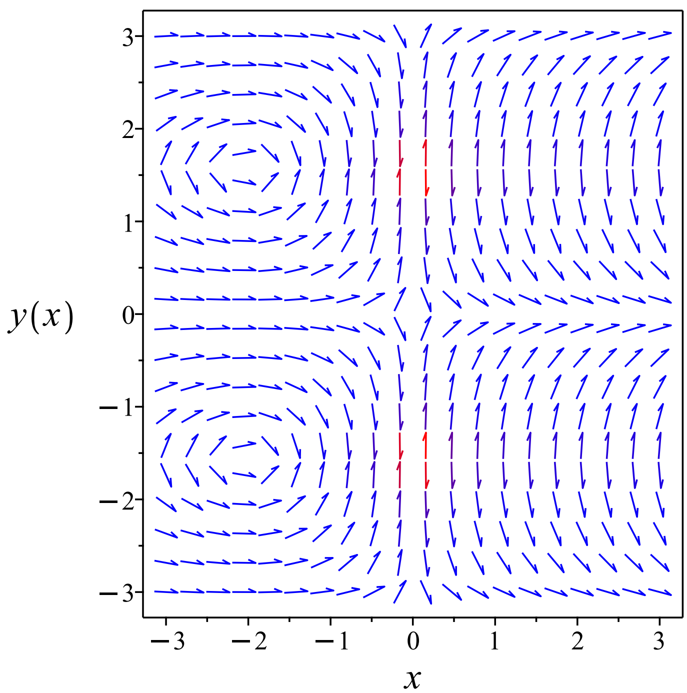

Figure 252: Slope field plot

Verification of solutions

$$y = \arcsin\left(\frac{c_2 e^{-x+c_1}}{x^2}\right)$$

Verified OK.

5.17.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{(2+x)\sin(y)}{x\cos(y)} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 254: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\xi(x, y) = -\frac{x}{2+x}$$
$$\eta(x, y) = 0 \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{-\frac{x}{2+x}} dx \end{aligned}$$

Which results in

$$S = -x - 2\ln(x)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{(2+x)\sin(y)}{x\cos(y)}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= \frac{-x-2}{x} \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \cot(y) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \cot(R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \ln(\sin(R)) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-x - 2\ln(x) = \ln(\sin(y)) + c_1$$

Which simplifies to

$$-x - 2\ln(x) = \ln(\sin(y)) + c_1$$

Which gives

$$y = \arcsin\left(\frac{e^{-x-c_1}}{x^2}\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{(2+x)\sin(y)}{x\cos(y)}$ 	$R = y$ $S = -x - 2\ln(x)$	$\frac{dS}{dR} = \cot(R)$ 
Summary

The solution(s) found are the following

$$y = \arcsin\left(\frac{e^{-x-c_1}}{x^2}\right) \tag{1}$$

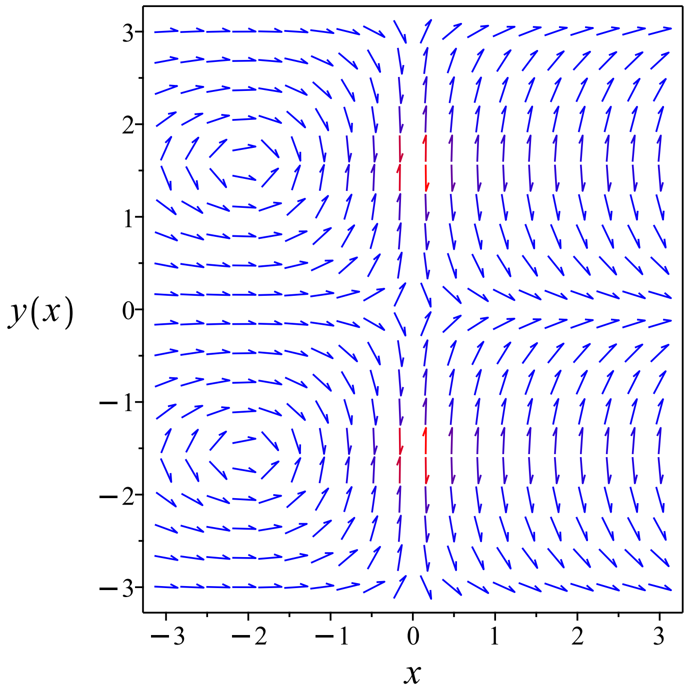

Figure 253: Slope field plot

Verification of solutions

$$y = \arcsin\left(\frac{e^{-x-c_1}}{x^2}\right)$$

Verified OK.

5.17.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(-\frac{\cos(y)}{\sin(y)}\right) \mathrm{d}y &= \left(\frac{2 + x}{x}\right) \mathrm{d}x \\
\left(-\frac{2 + x}{x}\right) \mathrm{d}x + \left(-\frac{\cos(y)}{\sin(y)}\right) \mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -\frac{2 + x}{x} \\
N(x, y) &= -\frac{\cos(y)}{\sin(y)}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{2 + x}{x}\right) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{\cos(y)}{\sin(y)}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int M \, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int -\frac{2+x}{x} \, \mathrm{d}x
\end{aligned}
$$

$$
\phi = -x - 2\ln(x) + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{\cos(y)}{\sin(y)}$. Therefore equation (4) becomes

$$
-\frac{\cos(y)}{\sin(y)} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
\begin{aligned}
f'(y) &= -\frac{\cos(y)}{\sin(y)} \\
&= -\cot(y)
\end{aligned}
$$

Integrating the above w.r.t y results in

$$\int f'(y)\,dy = \int (-\cot(y))\,dy$$
$$f(y) = -\ln(\sin(y)) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -x - 2\ln(x) - \ln(\sin(y)) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x - 2\ln(x) - \ln(\sin(y))$$

Summary
The solution(s) found are the following

$$-x - 2\ln(x) - \ln(\sin(y)) = c_1 \tag{1}$$

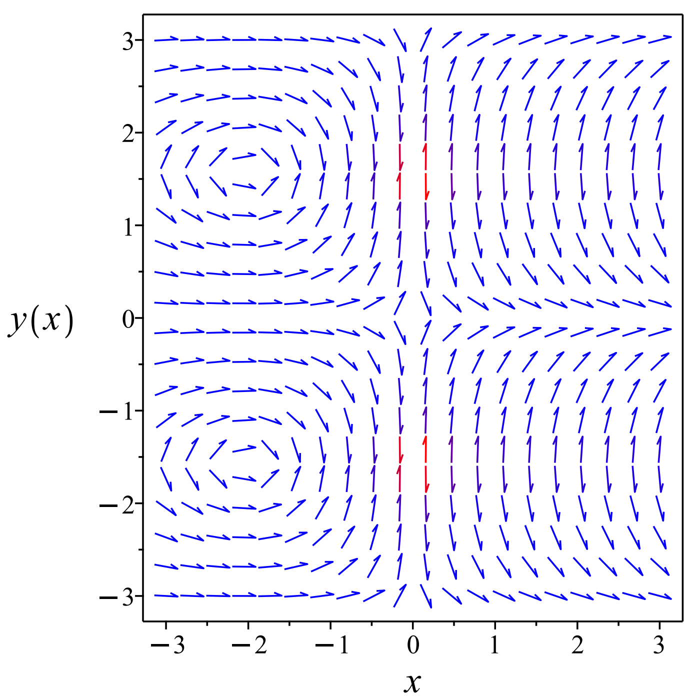

Figure 254: Slope field plot

Verification of solutions

$$-x-2\ln(x)-\ln(\sin(y))=c_1$$

Verified OK.

5.17.4 Maple step by step solution

Let's solve

$(2+x)\sin(y)+x\cos(y)\,y'=0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'\cos(y)}{\sin(y)}=-\frac{2+x}{x}$

- Integrate both sides with respect to x

  $\int\frac{y'\cos(y)}{\sin(y)}dx=\int-\frac{2+x}{x}dx+c_1$

- Evaluate integral

  $\ln(\sin(y))=-x-2\ln(x)+c_1$

- Solve for y

  $y=\arcsin\left(\frac{e^{-x+c_1}}{x^2}\right)$

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.6. Page 100
Problem number: 25.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"homogeneousTypeD2", "exactWithIntegrationFactor"**

Maple gives the following as the ode type

```
[[_homogeneous, `class D`], _rational]
```

$$\boxed{2yx + 3x^2y + y^3 + (x^2 + y^2)\, y' = 0}$$

5.18.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$2u(x)\, x^2 + 3x^3u(x) + u(x)^3\, x^3 + \left(x^2 + u(x)^2\, x^2\right)(u'(x)\, x + u(x)) = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{u(u^2+3)\,(x+1)}{x\,(u^2+1)} \end{aligned}$$

Where $f(x) = -\frac{x+1}{x}$ and $g(u) = \frac{(u^2+3)u}{u^2+1}$. Integrating both sides gives

$$\frac{1}{\frac{(u^2+3)u}{u^2+1}}\, du = -\frac{x+1}{x}\, dx$$

$$
\int \frac{1}{\frac{(u^2+3)u}{u^2+1}} du = \int -\frac{x+1}{x} dx
$$

$$
\frac{\ln\left(\left(u^2+3\right)u\right)}{3} = -x - \ln\left(x\right) + c_2
$$

Raising both side to exponential gives

$$
\left(\left(u^2+3\right)u\right)^{\frac{1}{3}} = \mathrm{e}^{-x-\ln(x)+c_2}
$$

Which simplifies to

$$
\left(\left(u^2+3\right)u\right)^{\frac{1}{3}} = c_3 \mathrm{e}^{-x-\ln(x)}
$$

Which simplifies to

$$
\left(\left(u(x)^2+3\right)u(x)\right)^{\frac{1}{3}} = \frac{c_3 \mathrm{e}^{-x} \mathrm{e}^{c_2}}{x}
$$

The solution is

$$
\left(\left(u(x)^2+3\right)u(x)\right)^{\frac{1}{3}} = \frac{c_3 \mathrm{e}^{-x} \mathrm{e}^{c_2}}{x}
$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$
\left(\frac{\left(\frac{y^2}{x^2}+3\right)y}{x}\right)^{\frac{1}{3}} = \frac{c_3 \mathrm{e}^{-x} \mathrm{e}^{c_2}}{x}
$$

$$
\left(\frac{\left(y^2+3x^2\right)y}{x^3}\right)^{\frac{1}{3}} = \frac{c_3 \mathrm{e}^{-x+c_2}}{x}
$$

Summary

The solution(s) found are the following

$$
\left(\frac{\left(y^2+3x^2\right)y}{x^3}\right)^{\frac{1}{3}} = \frac{c_3 \mathrm{e}^{-x+c_2}}{x} \tag{1}
$$

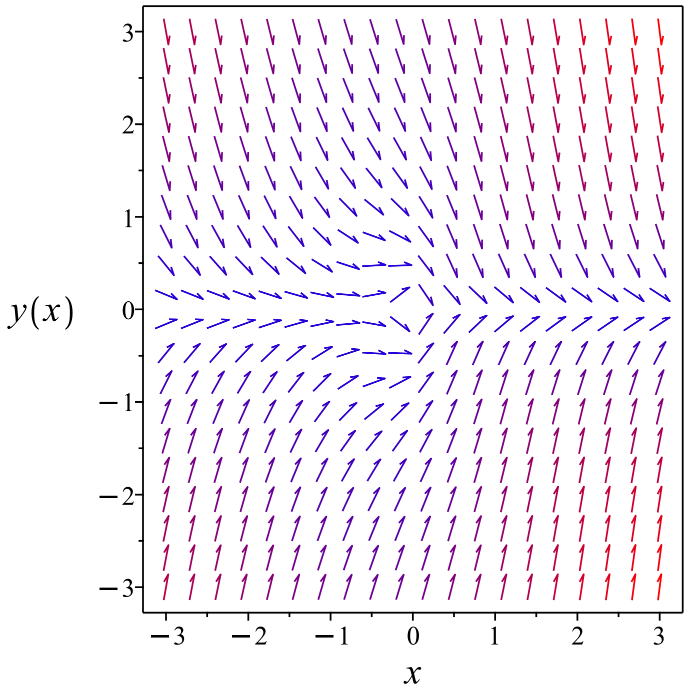

Figure 255: Slope field plot

Verification of solutions

$$\left(\frac{(y^2+3x^2)\,y}{x^3}\right)^{\frac{1}{3}} = \frac{c_3 \mathrm{e}^{-x+c_2}}{x}$$

Verified OK.

5.18.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\,\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned} (x^2 + y^2)\,\mathrm{d}y &= (-3y\,x^2 - y^3 - 2yx)\,\mathrm{d}x \\ (3y\,x^2 + y^3 + 2yx)\,\mathrm{d}x + (x^2 + y^2)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x, y) &= 3y\,x^2 + y^3 + 2yx \\ N(x, y) &= x^2 + y^2 \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(3y\,x^2 + y^3 + 2yx) \\ &= 3x^2 + 3y^2 + 2x \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x^2 + y^2) \\ &= 2x \end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{x^2+y^2}\left((3x^2+3y^2+2x) - (2x)\right) \\
&= 3
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int 3 \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{3x} \\
&= \mathrm{e}^{3x}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{3x}\left(3y\,x^2 + y^3 + 2yx\right) \\
&= y\left(3x^2 + y^2 + 2x\right)\mathrm{e}^{3x}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{3x}\left(x^2 + y^2\right) \\
&= \left(x^2 + y^2\right)\mathrm{e}^{3x}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(y\left(3x^2 + y^2 + 2x\right)\mathrm{e}^{3x}\right) + \left(\left(x^2 + y^2\right)\mathrm{e}^{3x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x}=\overline{M} \tag{1}$$
$$\frac{\partial\phi}{\partial y}=\overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int\frac{\partial\phi}{\partial x}\,\mathrm{d}x&=\int\overline{M}\,\mathrm{d}x\\ \int\frac{\partial\phi}{\partial x}\,\mathrm{d}x&=\int y\left(3x^2+y^2+2x\right)\mathrm{e}^{3x}\,\mathrm{d}x\\ \phi&=\frac{(3x^2+y^2)\,y\,\mathrm{e}^{3x}}{3}+f(y)\end{aligned} \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\begin{aligned}\frac{\partial\phi}{\partial y}&=\frac{2y^2\mathrm{e}^{3x}}{3}+\frac{(3x^2+y^2)\,\mathrm{e}^{3x}}{3}+f'(y) \\ &=\left(x^2+y^2\right)\mathrm{e}^{3x}+f'(y)\end{aligned} \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y}=(x^2+y^2)\,\mathrm{e}^{3x}$. Therefore equation (4) becomes

$$\left(x^2+y^2\right)\mathrm{e}^{3x}=\left(x^2+y^2\right)\mathrm{e}^{3x}+f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y)=0$$

Therefore

$$f(y)=c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi=\frac{(3x^2+y^2)\,y\,\mathrm{e}^{3x}}{3}+c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{(3x^2 + y^2)\, y\, e^{3x}}{3}$$

Summary

The solution(s) found are the following

$$\frac{(y^2 + 3x^2)\, y\, e^{3x}}{3} = c_1 \tag{1}$$

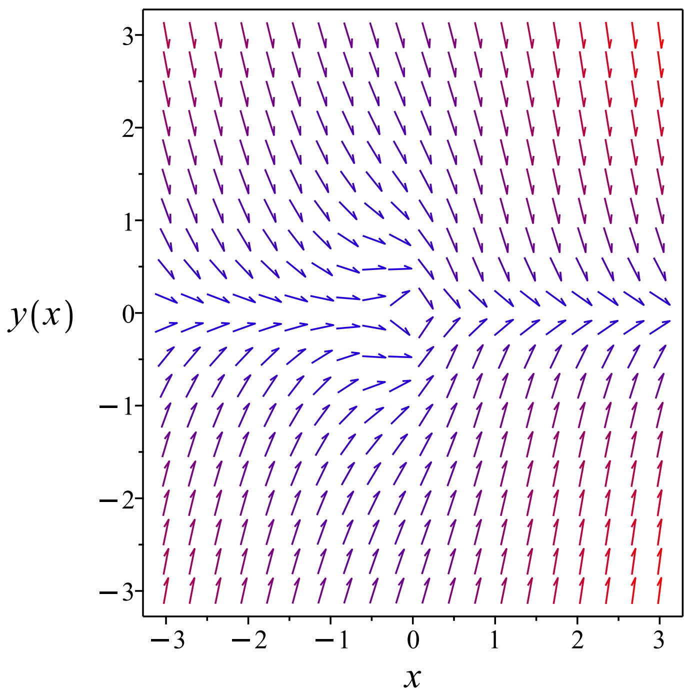

Figure 256: Slope field plot

Verification of solutions

$$\frac{(y^2 + 3x^2)\, y\, e^{3x}}{3} = c_1$$

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.6. Page 100
Problem number: 26.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' - y = -1 + e^{2x}}$$

5.19.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -1 \\ q(x) &= -1 + e^{2x} \end{aligned}$$

Hence the ode is

$$y' - y = -1 + e^{2x}$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int (-1)dx} \\
&= e^{-x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(-1+e^{2x}\right) \\
\frac{d}{dx}\left(e^{-x} y\right) &= \left(e^{-x}\right)\left(-1+e^{2x}\right) \\
d\left(e^{-x} y\right) &= \left(e^{x}-e^{-x}\right)\, dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
e^{-x} y &= \int e^{x}-e^{-x}\, dx \\
e^{-x} y &= e^{x}+e^{-x}+c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{-x}$ results in

$$
y = e^{x}\left(e^{x}+e^{-x}\right)+c_1 e^{x}
$$

which simplifies to

$$
y = e^{2x}+1+c_1 e^{x}
$$

<u>Summary</u>
The solution(s) found are the following

$$
y = e^{2x}+1+c_1 e^{x} \tag{1}
$$

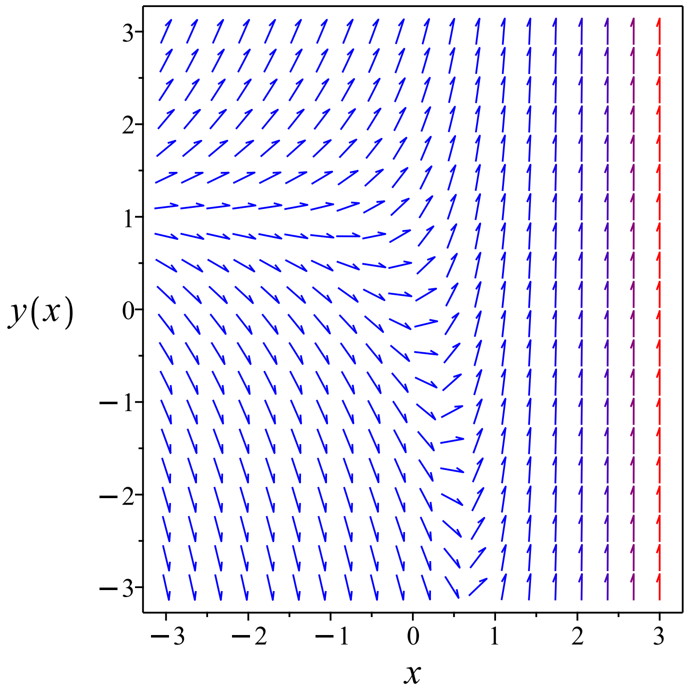

Figure 257: Slope field plot

Verification of solutions

$$y = e^{2x} + 1 + c_1 e^x$$

Verified OK.

5.19.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= -1 + e^{2x} + y \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 257: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x) dx - h(x)}}{g(x)}$	$\frac{f(x) e^{-\int b f(x) dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= e^x
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^x} dy \end{aligned}$$

Which results in

$$S = e^{-x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -1 + e^{2x} + y$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -e^{-x} y \\ S_y &= e^{-x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = e^x - e^{-x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = e^R - e^{-R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = e^{R} + e^{-R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$y\, e^{-x} = e^{x} + e^{-x} + c_1$$

Which simplifies to

$$y\, e^{-x} = e^{x} + e^{-x} + c_1$$

Which gives

$$y = \left(e^{x} + e^{-x} + c_1\right) e^{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -1 + e^{2x} + y$ 	$R = x$ $S = e^{-x} y$	$\frac{dS}{dR} = e^{R} - e^{-R}$ 
Summary

The solution(s) found are the following

$$y = \left(e^{x} + e^{-x} + c_1\right) e^{x} \tag{1}$$

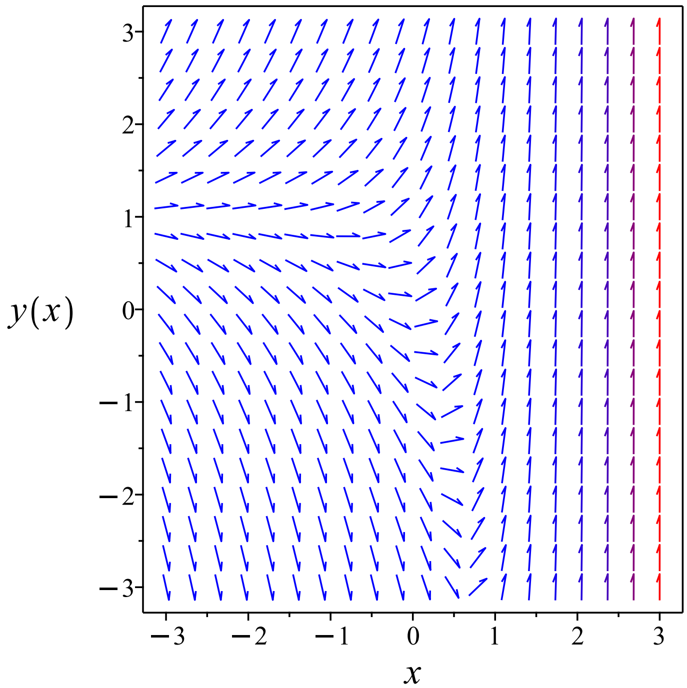

Figure 258: Slope field plot

Verification of solutions

$$y = \left(e^x + e^{-x} + c_1\right) e^x$$

Verified OK.

5.19.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\mathrm{d}y &= \left(-1 + \mathrm{e}^{2x} + y\right) \mathrm{d}x \\
\left(1 - \mathrm{e}^{2x} - y\right) \mathrm{d}x + \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= 1 - \mathrm{e}^{2x} - y \\
N(x, y) &= 1
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(1 - \mathrm{e}^{2x} - y\right) \\
&= -1
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= 1((-1) - (0)) \\ &= -1 \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int -1 \, \mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-x} \\ &= \mathrm{e}^{-x} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{-x}\left(1 - \mathrm{e}^{2x} - y\right) \\ &= \mathrm{e}^{-x} - \mathrm{e}^{x} - \mathrm{e}^{-x} y \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{-x}(1) \\ &= \mathrm{e}^{-x} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(\mathrm{e}^{-x} - \mathrm{e}^{x} - \mathrm{e}^{-x} y\right) + \left(\mathrm{e}^{-x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \mathrm{e}^{-x} - \mathrm{e}^{x} - \mathrm{e}^{-x} y\,\mathrm{d}x$$
$$\phi = (y-1)\,\mathrm{e}^{-x} - \mathrm{e}^{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x}$. Therefore equation (4) becomes

$$\mathrm{e}^{-x} = \mathrm{e}^{-x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = (y-1)\,\mathrm{e}^{-x} - \mathrm{e}^{x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = (y-1)\,\mathrm{e}^{-x} - \mathrm{e}^{x}$$

The solution becomes

$$y = \left(\mathrm{e}^{x} + \mathrm{e}^{-x} + c_1\right)\mathrm{e}^{x}$$

Summary

The solution(s) found are the following

$$y = \left(\mathrm{e}^{x} + \mathrm{e}^{-x} + c_1\right)\mathrm{e}^{x} \tag{1}$$

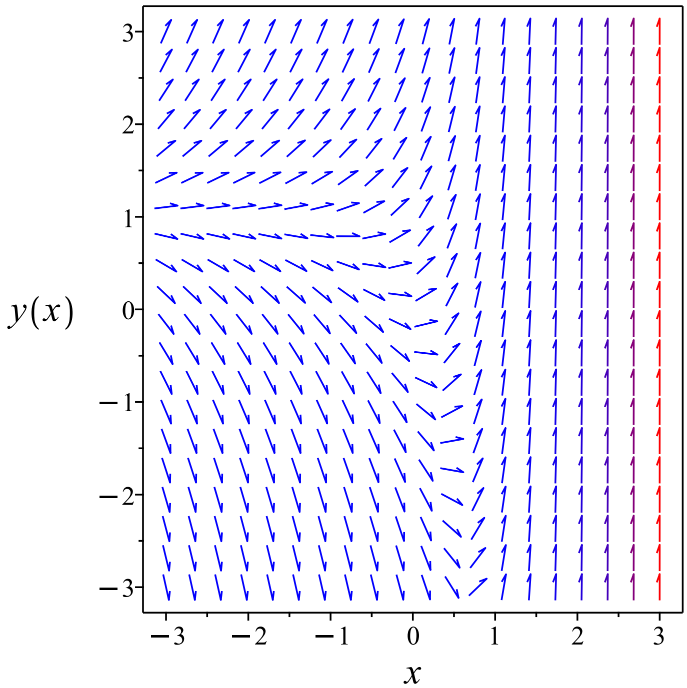

Figure 259: Slope field plot

Verification of solutions

$$y = \left(e^{x} + e^{-x} + c_1\right) e^{x}$$

Verified OK.

5.19.4 Maple step by step solution

Let's solve

$y' - y = -1 + e^{2x}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -1 + e^{2x} + y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - y = -1 + e^{2x}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' - y\right) = \mu(x)\left(-1 + e^{2x}\right)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\,(y' - y) = \mu'(x)\, y + \mu(x)\, y'$
- Isolate $\mu'(x)$

  $\mu'(x) = -\mu(x)$
- Solve to find the integrating factor

  $\mu(x) = \mathrm{e}^{-x}$
- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int \mu(x)\,(-1 + \mathrm{e}^{2x})\, dx + c_1$
- Evaluate the integral on the lhs

  $\mu(x)\, y = \int \mu(x)\,(-1 + \mathrm{e}^{2x})\, dx + c_1$
- Solve for y

  $y = \frac{\int \mu(x)(-1+\mathrm{e}^{2x})dx+c_1}{\mu(x)}$
- Substitute $\mu(x) = \mathrm{e}^{-x}$

  $y = \frac{\int \mathrm{e}^{-x}(-1+\mathrm{e}^{2x})dx+c_1}{\mathrm{e}^{-x}}$
- Evaluate the integrals on the rhs

  $y = \frac{\mathrm{e}^{x}+\frac{1}{\mathrm{e}^{x}}+c_1}{\mathrm{e}^{-x}}$
- Simplify

  $y = \mathrm{e}^{2x} + 1 + c_1\mathrm{e}^{x}$

Section: Section 2.6. Page 100
Problem number: 27.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "differentialType"**

Maple gives the following as the ode type

```
[[_1st_order, `_with_symmetry_[F(x)*G(y),0]`]]
```

$$\boxed{\left(-\sin\left(y\right)+\frac{x}{y}\right)y'=-1}$$

5.20.1 Solving as differentialType ode

Writing the ode as

$$y'=-\frac{1}{-\sin\left(y\right)+\frac{x}{y}} \tag{1}$$

Which becomes

$$\left(y\sin\left(y\right)\right)dy=\left(x\right)dy+\left(y\right)dx \tag{2}$$

But the RHS is complete differential because

$$\left(x\right)dy+\left(y\right)dx=d(yx)$$

Hence (2) becomes

$$\left(y\sin\left(y\right)\right)dy=d(yx)$$

Integrating both sides gives gives the solution as

$$\sin(y) - y\cos(y) = yx + c_1$$

Summary

The solution(s) found are the following

$$\sin(y) - y\cos(y) = yx + c_1 \tag{1}$$

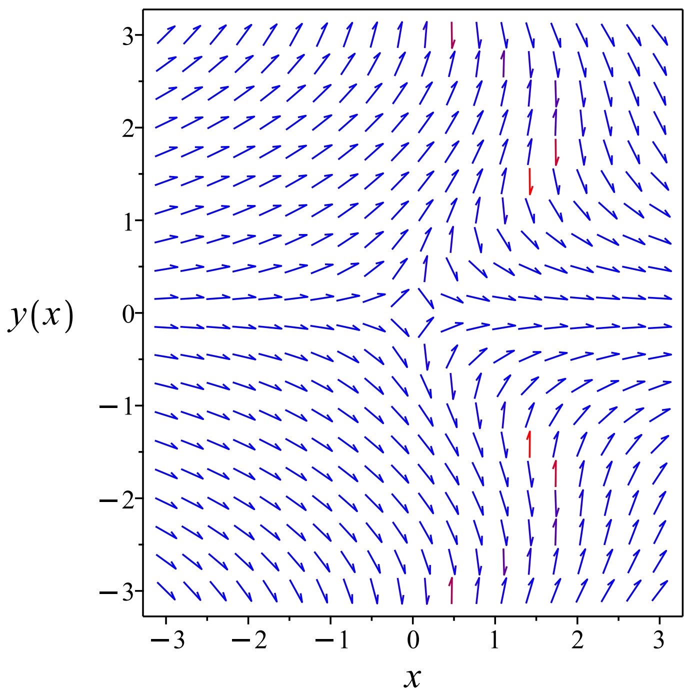

Figure 260: Slope field plot

Verification of solutions

$$\sin(y) - y\cos(y) = yx + c_1$$

Verified OK.

5.20.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(y\sin(y)-x)\,\mathrm{d}y&=(y)\,\mathrm{d}x\\ (-y)\,\mathrm{d}x+(y\sin(y)-x)\,\mathrm{d}y&=0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=-y\\ N(x,y)&=y\sin(y)-x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-y) \\ &= -1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(y \sin(y) - x) \\ &= -1\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, dx = \int M \, dx$$

$$\int \frac{\partial \phi}{\partial x} \, dx = \int -y \, dx$$

$$\phi = -yx + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y \sin(y) - x$. Therefore equation (4) becomes

$$y \sin(y) - x = -x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = y \sin(y)$$

Integrating the above w.r.t y gives

$$\int f'(y) \,\mathrm{d}y = \int (y \sin(y)) \,\mathrm{d}y$$
$$f(y) = \sin(y) - y \cos(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -yx + \sin(y) - y \cos(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -yx + \sin(y) - y \cos(y)$$

Summary

The solution(s) found are the following

$$\sin(y) - y \cos(y) - yx = c_1 \tag{1}$$

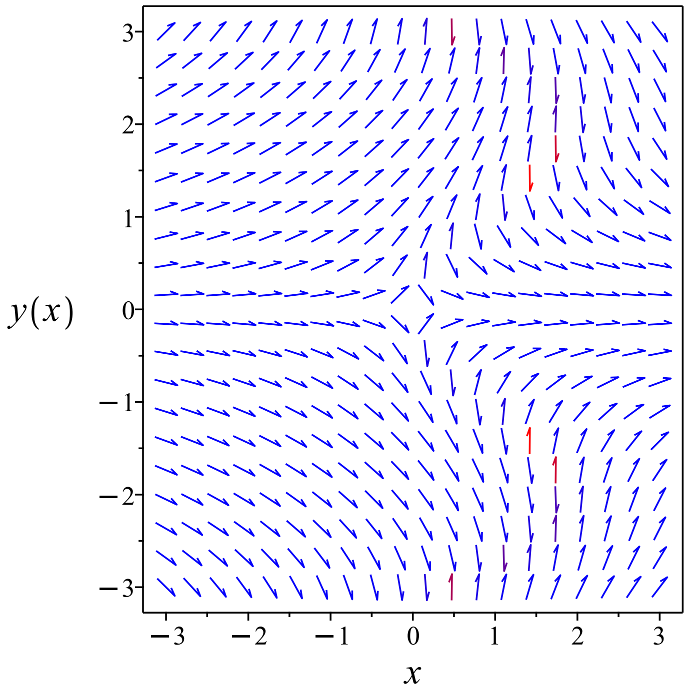

Figure 261: Slope field plot

Verification of solutions

$$\sin(y) - y\cos(y) - yx = c_1$$

Verified OK.

ODE degree: 1.

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_1st_order, _with_exponential_symmetries]]
```

$$\boxed{y + \left(-\mathrm{e}^{-2y} + 2yx\right) y' = 0}$$

5.21.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -\frac{y}{-\mathrm{e}^{-2y} + 2yx}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 2 to use as anstaz gives

$$\xi = x^2 a_4 + yxa_5 + y^2 a_6 + xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = x^2 b_4 + yxb_5 + y^2 b_6 + xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, a_4, a_5, a_6, b_1, b_2, b_3, b_4, b_5, b_6\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} &2xb_4 + yb_5 + b_2 - \frac{y(-2xa_4 + xb_5 - ya_5 + 2yb_6 - a_2 + b_3)}{-\mathrm{e}^{-2y} + 2yx} \\ &- \frac{y^2(xa_5 + 2ya_6 + a_3)}{(-\mathrm{e}^{-2y} + 2yx)^2} - \frac{2y^2(x^2a_4 + yxa_5 + y^2a_6 + xa_2 + ya_3 + a_1)}{(-\mathrm{e}^{-2y} + 2yx)^2} \\ &- \left(-\frac{1}{-\mathrm{e}^{-2y} + 2yx} + \frac{y(2\,\mathrm{e}^{-2y} + 2x)}{(-\mathrm{e}^{-2y} + 2yx)^2}\right)\left(x^2b_4 \right. \\ &\left. + yxb_5 + y^2b_6 + xb_2 + yb_3 + b_1\right) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{-10\,\mathrm{e}^{-2y}x^2yb_4 - 6\,\mathrm{e}^{-2y}x\,y^2b_5 - 2\,\mathrm{e}^{-2y}xya_4 - 6\,\mathrm{e}^{-2y}xyb_2 + \mathrm{e}^{-4y}yb_5 + 8x^3y^2b_4 + 4x^2y^3b_5 - 2y^4a_6 - 2y^3a_6 -}{}$$

$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} &-10\,\mathrm{e}^{-2y}x^2yb_4 - 6\,\mathrm{e}^{-2y}x\,y^2b_5 - 2\,\mathrm{e}^{-2y}xya_4 - 6\,\mathrm{e}^{-2y}xyb_2 + \mathrm{e}^{-4y}yb_5 \\ &+ 8x^3y^2b_4 + 4x^2y^3b_5 - 2y^4a_6 - 2y^3a_6 - 4x\,y^3b_6 + 2x^2y^2a_4 - 2x^2y^2b_5 \\ &- y^2a_3 + 4x^2y^2b_2 - 2x\,y^2b_3 - 2\,\mathrm{e}^{-2y}y^2b_3 - \mathrm{e}^{-2y}xb_2 - \mathrm{e}^{-2y}ya_2 \\ &- 2\,\mathrm{e}^{-2y}yb_1 - 2y^3a_3 - 2y^2a_1 - \mathrm{e}^{-2y}b_1 + 2\,\mathrm{e}^{-4y}xb_4 - x\,y^2a_5 \\ &- 2\,\mathrm{e}^{-2y}y^3b_6 - \mathrm{e}^{-2y}x^2b_4 - \mathrm{e}^{-2y}y^2a_5 + \mathrm{e}^{-2y}y^2b_6 + \mathrm{e}^{-4y}b_2 = 0 \end{aligned} \tag{6E}$$

Simplifying the above gives

$$\begin{aligned} &-10\,\mathrm{e}^{-2y}x^2yb_4 - 6\,\mathrm{e}^{-2y}x\,y^2b_5 - 2\,\mathrm{e}^{-2y}xya_4 - 6\,\mathrm{e}^{-2y}xyb_2 + \mathrm{e}^{-4y}yb_5 \\ &+ 8x^3y^2b_4 + 4x^2y^3b_5 - 2y^4a_6 - 2y^3a_6 - 4x\,y^3b_6 + 2x^2y^2a_4 - 2x^2y^2b_5 \\ &- y^2a_3 + 4x^2y^2b_2 - 2x\,y^2b_3 - 2\,\mathrm{e}^{-2y}y^2b_3 - \mathrm{e}^{-2y}xb_2 - \mathrm{e}^{-2y}ya_2 \\ &- 2\,\mathrm{e}^{-2y}yb_1 - 2y^3a_3 - 2y^2a_1 - \mathrm{e}^{-2y}b_1 + 2\,\mathrm{e}^{-4y}xb_4 - x\,y^2a_5 \\ &- 2\,\mathrm{e}^{-2y}y^3b_6 - \mathrm{e}^{-2y}x^2b_4 - \mathrm{e}^{-2y}y^2a_5 + \mathrm{e}^{-2y}y^2b_6 + \mathrm{e}^{-4y}b_2 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y, \mathrm{e}^{-4y}, \mathrm{e}^{-2y}\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2, \mathrm{e}^{-4y} = v_3, \mathrm{e}^{-2y} = v_4\}$$

The above PDE (6E) now becomes

$$\begin{aligned}
&8v_1^3v_2^2b_4 + 4v_1^2v_2^3b_5 + 2v_1^2v_2^2a_4 - 2v_2^4a_6 + 4v_1^2v_2^2b_2 - 10v_4v_1^2v_2b_4 - 2v_1^2v_2^2b_5 \\
&- 6v_4v_1v_2^2b_5 - 4v_1v_2^3b_6 - 2v_4v_2^3b_6 - 2v_2^3a_3 - 2v_4v_1v_2a_4 - v_1v_2^2a_5 - v_4v_2^2a_5 \\
&- 2v_2^3a_6 - 6v_4v_1v_2b_2 - 2v_1v_2^2b_3 - 2v_4v_2^2b_3 - v_4v_1^2b_4 + v_4v_2^2b_6 - 2v_2^2a_1 \\
&- v_4v_2a_2 - v_2^2a_3 - 2v_4v_2b_1 - v_4v_1b_2 + 2v_3v_1b_4 + v_3v_2b_5 - v_4b_1 + v_3b_2 = 0
\end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3, v_4\}$$

Equation (7E) now becomes

$$\begin{aligned}
&8v_1^3v_2^2b_4 + 4v_1^2v_2^3b_5 + (2a_4 + 4b_2 - 2b_5)\, v_1^2v_2^2 - 10v_4v_1^2v_2b_4 - v_4v_1^2b_4 \\
&- 4v_1v_2^3b_6 - 6v_4v_1v_2^2b_5 + (-a_5 - 2b_3)\, v_1v_2^2 + (-2a_4 - 6b_2)\, v_1v_2v_4 + 2v_3v_1b_4 \\
&- v_4v_1b_2 - 2v_2^4a_6 - 2v_4v_2^3b_6 + (-2a_3 - 2a_6)\, v_2^3 + (-a_5 - 2b_3 + b_6)\, v_2^2v_4 \\
&+ (-2a_1 - a_3)\, v_2^2 + v_3v_2b_5 + (-a_2 - 2b_1)\, v_2v_4 + v_3b_2 - v_4b_1 = 0
\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
b_2 &= 0 \\
b_5 &= 0 \\
-2a_6 &= 0 \\
-b_1 &= 0 \\
-b_2 &= 0 \\
-10b_4 &= 0 \\
-b_4 &= 0 \\
2b_4 &= 0 \\
8b_4 &= 0 \\
-6b_5 &= 0 \\
4b_5 &= 0 \\
-4b_6 &= 0 \\
-2b_6 &= 0 \\
-2a_1 - a_3 &= 0 \\
-a_2 - 2b_1 &= 0 \\
-2a_3 - 2a_6 &= 0 \\
-2a_4 - 6b_2 &= 0 \\
-a_5 - 2b_3 &= 0 \\
2a_4 + 4b_2 - 2b_5 &= 0 \\
-a_5 - 2b_3 + b_6 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= 0 \\
a_3 &= 0 \\
a_4 &= 0 \\
a_5 &= -2b_3 \\
a_6 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3 \\
b_4 &= 0 \\
b_5 &= 0 \\
b_6 &= 0
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= -2yx \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(-\frac{y}{-\mathrm{e}^{-2y} + 2yx}\right)(-2yx) \\
&= \frac{y\,\mathrm{e}^{-2y}}{-2yx + \mathrm{e}^{-2y}} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x}+\eta \frac{\partial}{\partial y}\right) S(x, y)=1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi=0$ then in this special case

$$R=x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{y\,\mathrm{e}^{-2y}}{-2yx+\mathrm{e}^{-2y}}} dy \end{aligned}$$

Which results in

$$S=\ln(y)-\mathrm{e}^{2y} x$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR}=\frac{S_x+\omega(x, y) S_y}{R_x+\omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y)=-\frac{y}{-\mathrm{e}^{-2y}+2yx}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\mathrm{e}^{2y} \\ S_y &= \frac{-2\,\mathrm{e}^{2y} xy+1}{y} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR}=0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR}=0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\ln(y) - e^{2y}x = c_1$$

Which simplifies to

$$\ln(y) - e^{2y}x = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y}{-e^{-2y}+2yx}$ 	$R = x$ $S = \ln(y) - e^{2y}x$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\ln(y) - e^{2y}x = c_1 \tag{1}$$

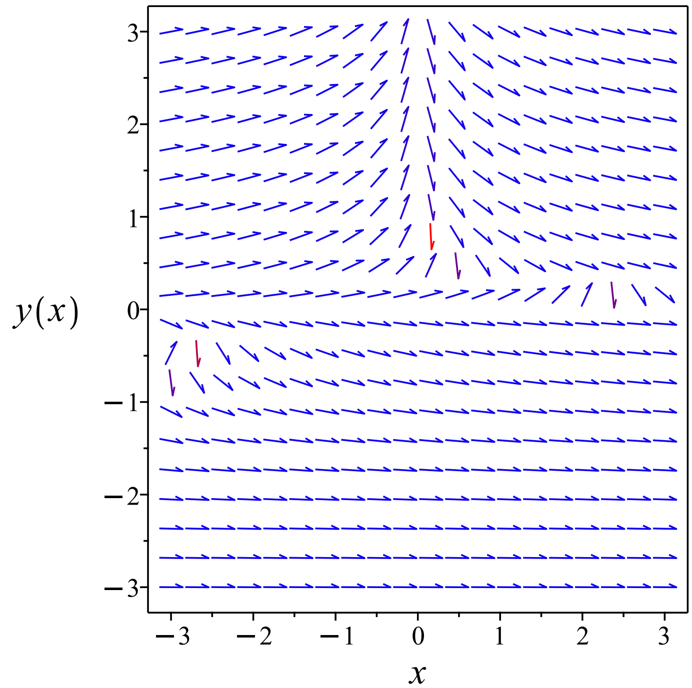

Figure 262: Slope field plot

Verification of solutions

$$\ln(y) - e^{2y}x = c_1$$

Verified OK.

5.21.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \, dx + N(x, y) \, dy = 0 \tag{1A}$$

Therefore

$$\begin{aligned} (-e^{-2y} + 2yx) \, dy &= (-y) \, dx \\ (y) \, dx + (-e^{-2y} + 2yx) \, dy &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x, y) &= y \\ N(x, y) &= -e^{-2y} + 2yx \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(y) \\ &= 1 \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-e^{-2y} + 2yx) \\ &= 2y \end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{-\mathrm{e}^{-2y} + 2yx}((1) - (2y)) \\
&= \frac{-1 + 2y}{-2yx + \mathrm{e}^{-2y}}
\end{aligned}
$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$
\begin{aligned}
B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\
&= \frac{1}{y}((2y) - (1)) \\
&= \frac{-1 + 2y}{y}
\end{aligned}
$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$
\begin{aligned}
\mu &= e^{\int B \, \mathrm{d}y} \\
&= e^{\int \frac{-1+2y}{y} \, \mathrm{d}y}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{2y - \ln(y)} \\
&= \frac{\mathrm{e}^{2y}}{y}
\end{aligned}
$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \frac{\mathrm{e}^{2y}}{y}(y) \\
&= \mathrm{e}^{2y}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{\mathrm{e}^{2y}}{y}\left(-\mathrm{e}^{-2y} + 2yx\right) \\
&= \frac{2\,\mathrm{e}^{2y} xy - 1}{y}
\end{aligned}
$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$

$$(\mathrm{e}^{2y}) + \left(\frac{2\,\mathrm{e}^{2y} xy - 1}{y}\right)\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int \overline{M} \,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int \mathrm{e}^{2y} \,\mathrm{d}x$$

$$\phi = \mathrm{e}^{2y} x + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2\,\mathrm{e}^{2y} x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{2\,\mathrm{e}^{2y} xy - 1}{y}$. Therefore equation (4) becomes

$$\frac{2\,\mathrm{e}^{2y} xy - 1}{y} = 2\,\mathrm{e}^{2y} x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{1}{y}$$

Integrating the above w.r.t y gives

$$\int f'(y) \,\mathrm{d}y = \int \left(-\frac{1}{y}\right) \mathrm{d}y$$

$$f(y) = -\ln(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = e^{2y}x - \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = e^{2y}x - \ln(y)$$

Summary

The solution(s) found are the following

$$-\ln(y) + e^{2y}x = c_1 \tag{1}$$

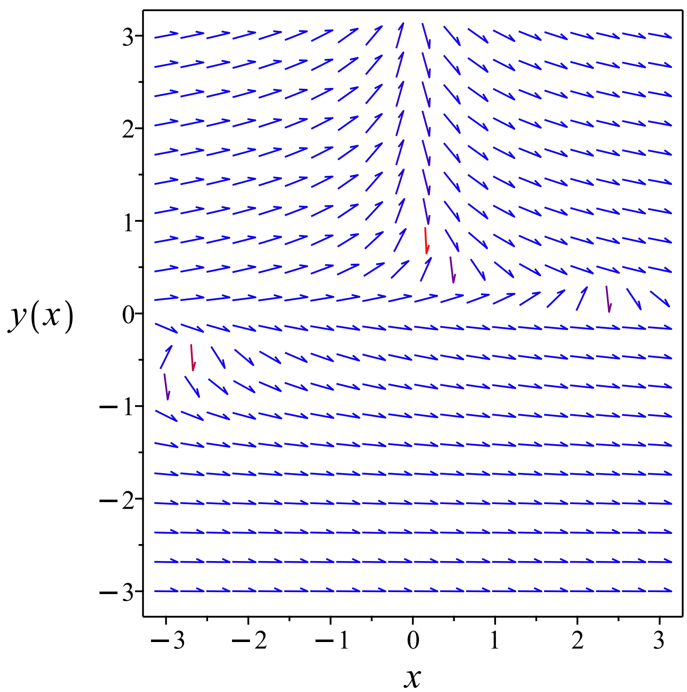

Figure 263: Slope field plot

Verification of solutions

$$-\ln(y) + e^{2y}x = c_1$$

Verified OK.

$$\boxed{(e^{x} \cot(y) + 2 \csc(y) y) y' = -e^{x}}$$

5.22.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\mathrm{e}^{x} \cot\left(y\right)+2 \csc\left(y\right) y\right)\mathrm{d}y &= \left(-\mathrm{e}^{x}\right)\mathrm{d}x\\ \left(\mathrm{e}^{x}\right)\mathrm{d}x + \left(\mathrm{e}^{x} \cot\left(y\right)+2 \csc\left(y\right) y\right)\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= \mathrm{e}^{x}\\ N(x, y) &= \mathrm{e}^{x} \cot\left(y\right)+2 \csc\left(y\right) y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\mathrm{e}^{x}\right)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\mathrm{e}^{x} \cot\left(y\right)+2 \csc\left(y\right) y\right)\\ &= \mathrm{e}^{x} \cot\left(y\right)\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{\sin(y)}{e^x \cos(y) + 2y}((0) - (e^x \cot(y))) \\
&= -\frac{\cos(y)\, e^x}{e^x \cos(y) + 2y}
\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned}
B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\
&= e^{-x}((e^x \cot(y)) - (0)) \\
&= \cot(y)
\end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned}
\mu &= e^{\int B \, \mathrm{d}y} \\
&= e^{\int \cot(y) \, \mathrm{d}y}
\end{aligned}$$

The result of integrating gives

$$\begin{aligned}
\mu &= e^{\ln(\sin(y))} \\
&= \sin(y)
\end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned}
\overline{M} &= \mu M \\
&= \sin(y)(e^x) \\
&= e^x \sin(y)
\end{aligned}$$

And

$$\begin{aligned}
\overline{N} &= \mu N \\
&= \sin(y)(e^x \cot(y) + 2\csc(y)\, y) \\
&= e^x \cos(y) + 2y
\end{aligned}$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$
$$(\mathrm{e}^{x}\sin(y)) + (\mathrm{e}^{x}\cos(y) + 2y)\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$
$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int \mathrm{e}^{x}\sin(y)\,\mathrm{d}x$$
$$\phi = \mathrm{e}^{x}\sin(y) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial\phi}{\partial y} = \mathrm{e}^{x}\cos(y) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = \mathrm{e}^{x}\cos(y) + 2y$. Therefore equation (4) becomes

$$\mathrm{e}^{x}\cos(y) + 2y = \mathrm{e}^{x}\cos(y) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 2y$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (2y)\,\mathrm{d}y$$
$$f(y) = y^{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = e^x \sin(y) + y^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = e^x \sin(y) + y^2$$

<u>Summary</u>
The solution(s) found are the following

$$e^x \sin(y) + y^2 = c_1 \tag{1}$$

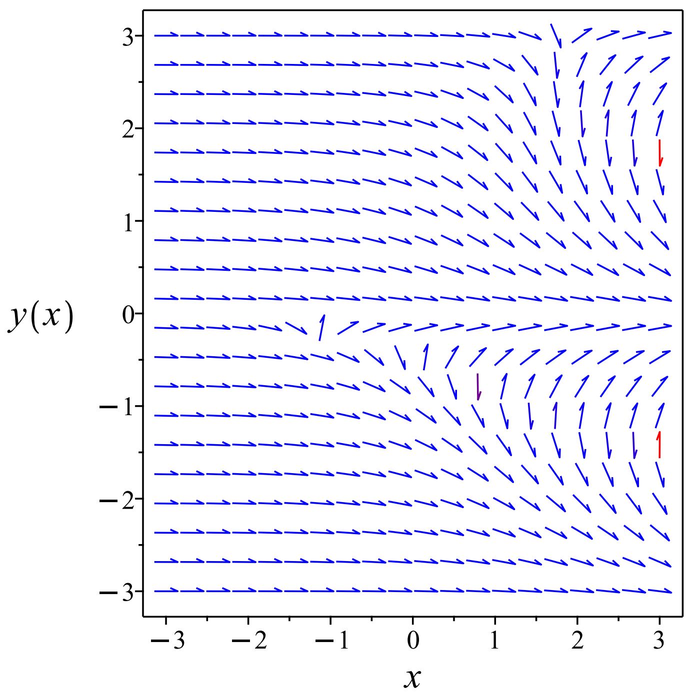

Figure 264: Slope field plot

<u>Verification of solutions</u>

$$e^x \sin(y) + y^2 = c_1$$

Verified OK.

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "differentialType"**

Maple gives the following as the ode type

`[_rational]`

$$\boxed{\frac{4x^3}{y^2}+\frac{3}{y}+\left(\frac{3x}{y^2}+4y\right)y'=0}$$

5.23.1 Solving as differentialType ode

Writing the ode as

$$y'=\frac{-\frac{4x^3}{y^2}-\frac{3}{y}}{\frac{3x}{y^2}+4y} \tag{1}$$

Which becomes

$$\left(4y^3\right)dy=(-3x)\,dy+\left(-4x^3-3y\right)dx \tag{2}$$

But the RHS is complete differential because

$$(-3x)\,dy+\left(-4x^3-3y\right)dx=d\left(-x^4-3yx\right)$$

Hence (2) becomes

$$\left(4y^3\right)dy=d\left(-x^4-3yx\right)$$

Integrating both sides gives gives the solution as

$$y^4 = -x^4 - 3yx + c_1$$

Summary
The solution(s) found are the following

$$y^4 = -x^4 - 3yx + c_1 \tag{1}$$

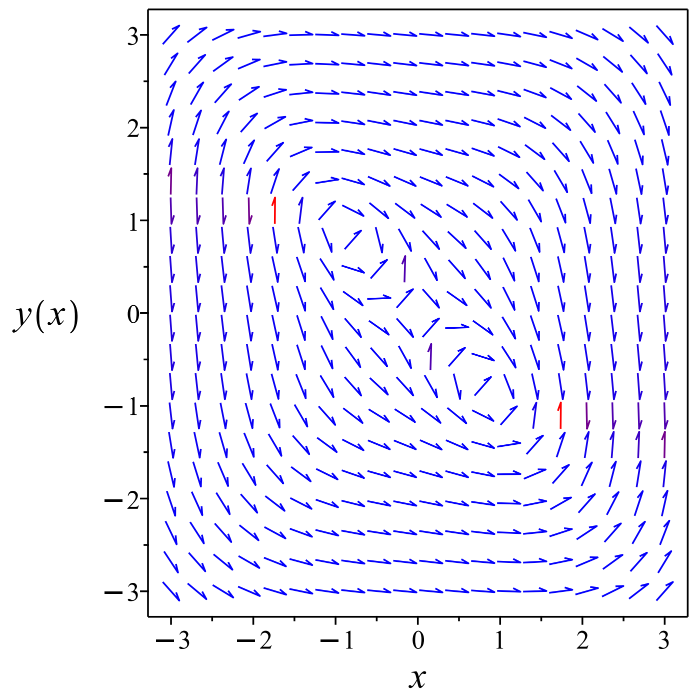

Figure 265: Slope field plot

Verification of solutions

$$y^4 = -x^4 - 3yx + c_1$$

Verified OK.

5.23.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(4y^3 + 3x\right)\mathrm{d}y &= \left(-4x^3 - 3y\right)\mathrm{d}x\\ \left(4x^3 + 3y\right)\mathrm{d}x + \left(4y^3 + 3x\right)\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= 4x^3 + 3y\\ N(x,y) &= 4y^3 + 3x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(4x^3 + 3y)\\ &= 3\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(4y^3 + 3x)\\ &= 3\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int 4x^3 + 3y\,\mathrm{d}x\\ \phi &= x(x^3 + 3y) + f(y)\end{aligned} \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 3x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 4y^3 + 3x$. Therefore equation (4) becomes

$$4y^3 + 3x = 3x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 4y^3$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (4y^3)\,\mathrm{d}y$$
$$f(y) = y^4 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = x(x^3 + 3y) + y^4 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x(x^3 + 3y) + y^4$$

Summary

The solution(s) found are the following

$$x(3y + x^3) + y^4 = c_1 \tag{1}$$

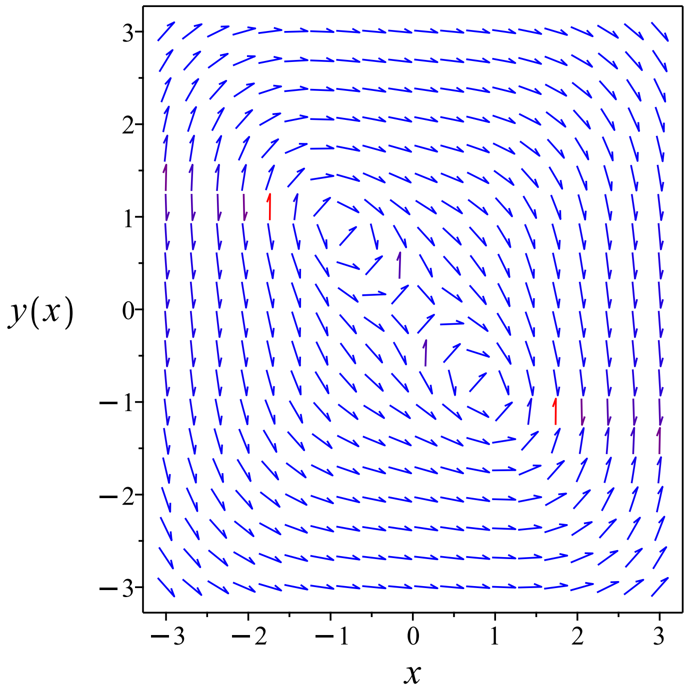

Figure 266: Slope field plot

Verification of solutions

$$x(3y + x^3) + y^4 = c_1$$

Verified OK.

Problem number: 30.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "differentialType"**

Maple gives the following as the ode type

`[_rational]`

$$\boxed{\frac{6}{y}+\left(\frac{x^{2}}{y}+\frac{3y}{x}\right)y'=-3x}$$

5.24.1 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-3x-\frac{6}{y}}{\frac{x^{2}}{y}+\frac{3y}{x}} \tag{1}$$

Which becomes

$$(3y^{2})\,dy = (-x^{3})\,dy + (-3x(yx+2))\,dx \tag{2}$$

But the RHS is complete differential because

$$(-x^{3})\,dy + (-3x(yx+2))\,dx = d\left(-y\,x^{3}-3x^{2}\right)$$

Hence (2) becomes

$$(3y^{2})\,dy = d\left(-y\,x^{3}-3x^{2}\right)$$

Integrating both sides gives gives these solutions

$$y = \frac{\left(-324x^2 + 108c_1 + 12\sqrt{12x^9 + 729x^4 - 486c_1x^2 + 81c_1^2}\right)^{\frac{1}{3}}}{6} - \frac{2x^3}{\left(-324x^2 + 108c_1 + 12\sqrt{12x^9 + 729x^4}\right.}$$

$$y = -\frac{\left(-324x^2 + 108c_1 + 12\sqrt{12x^9 + 729x^4 - 486c_1x^2 + 81c_1^2}\right)^{\frac{1}{3}}}{12} + \frac{x^3}{\left(-324x^2 + 108c_1 + 12\sqrt{12x^9 + 729\right.}$$

$$y = -\frac{\left(-324x^2 + 108c_1 + 12\sqrt{12x^9 + 729x^4 - 486c_1x^2 + 81c_1^2}\right)^{\frac{1}{3}}}{12} + \frac{x^3}{\left(-324x^2 + 108c_1 + 12\sqrt{12x^9 + 729\right.}$$

Summary
The solution(s) found are the following

$$y = \frac{\left(-324x^2+108c_1+12\sqrt{12x^9+729x^4-486c_1x^2+81c_1^2}\right)^{\frac{1}{3}}}{6} - \frac{2x^3}{\left(-324x^2+108c_1+12\sqrt{12x^9+729x^4-486c_1x^2+81c_1^2}\right)^{\frac{1}{3}}} + c_1 \tag{1}$$

$$y = -\frac{\left(-324x^2+108c_1+12\sqrt{12x^9+729x^4-486c_1x^2+81c_1^2}\right)^{\frac{1}{3}}}{12} + \frac{x^3}{\left(-324x^2+108c_1+12\sqrt{12x^9+729x^4-486c_1x^2+81c_1^2}\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(\frac{\left(-324x^2+108c_1+12\sqrt{12x^9+729x^4-486c_1x^2+81c_1^2}\right)^{\frac{1}{3}}}{6} + \frac{2x^3}{\left(-324x^2+108c_1+12\sqrt{12x^9+729x^4-486c_1x^2+81c_1^2}\right)^{\frac{1}{3}}}\right)}{2} + c_1 \tag{2}$$

$$y = -\frac{\left(-324x^2+108c_1+12\sqrt{12x^9+729x^4-486c_1x^2+81c_1^2}\right)^{\frac{1}{3}}}{12} + \frac{x^3}{\left(-324x^2+108c_1+12\sqrt{12x^9+729x^4-486c_1x^2+81c_1^2}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(\frac{\left(-324x^2+108c_1+12\sqrt{12x^9+729x^4-486c_1x^2+81c_1^2}\right)^{\frac{1}{3}}}{6} + \frac{2x^3}{\left(-324x^2+108c_1+12\sqrt{12x^9+729x^4-486c_1x^2+81c_1^2}\right)^{\frac{1}{3}}}\right)}{2} + c_1 \tag{3}$$

Verified OK.

5.24.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(x^3+3y^2\right)\mathrm{d}y&=(-3x(yx+2))\,\mathrm{d}x\\ (3x(yx+2))\,\mathrm{d}x+\left(x^3+3y^2\right)\mathrm{d}y&=0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=3x(yx+2)\\ N(x,y)&=x^3+3y^2\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(3x(yx+2)) \\ &= 3x^2\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x^3+3y^2) \\ &= 3x^2\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int 3x(yx+2) \mathrm{d}x$$

$$\phi = y x^3 + 3x^2 + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x^3 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x^3 + 3y^2$. Therefore equation (4) becomes

$$x^3 + 3y^2 = x^3 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 3y^2$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (3y^2) \, \mathrm{d}y$$
$$f(y) = y^3 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = y\,x^3 + y^3 + 3x^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = y\,x^3 + y^3 + 3x^2$$

Summary
The solution(s) found are the following

$$yx^3 + y^3 + 3x^2 = c_1 \tag{1}$$

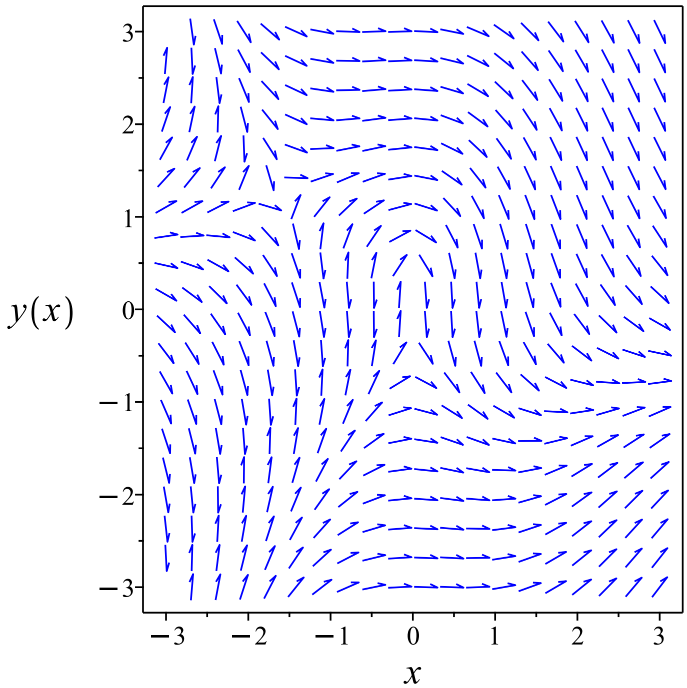

Figure 268: Slope field plot

Verification of solutions

$$
y x^{3}+y^{3}+3 x^{2}=c_{1}
$$

Verified OK.

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Section 2.6. Page 100
Problem number: 32.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"homogeneousTypeD2", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, [_Abel, `2nd type`, `
   class B`]]
```

$$\boxed{3yx + y^2 + (x^2 + yx)\, y' = 0}$$

5.25.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$3u(x)\, x^2 + u(x)^2\, x^2 + (x^2 + u(x)\, x^2)\, (u'(x)\, x + u(x)) = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{2u(u+2)}{x\,(u+1)} \end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = \frac{u(u+2)}{u+1}$. Integrating both sides gives

$$\frac{1}{\frac{u(u+2)}{u+1}}\, du = -\frac{2}{x}\, dx$$

$$\int \frac{1}{\frac{u(u+2)}{u+1}}\, du = \int -\frac{2}{x}\, dx$$

$$\frac{\ln\left(u(u+2)\right)}{2} = -2\ln\left(x\right) + c_2$$

Raising both side to exponential gives

$$\sqrt{u\left(u+2\right)} = \mathrm{e}^{-2\ln(x)+c_2}$$

Which simplifies to

$$\sqrt{u\left(u+2\right)} = \frac{c_3}{x^2}$$

Which simplifies to

$$\sqrt{u\left(x\right)\left(u\left(x\right)+2\right)} = \frac{c_3 \mathrm{e}^{c_2}}{x^2}$$

The solution is

$$\sqrt{u\left(x\right)\left(u\left(x\right)+2\right)} = \frac{c_3 \mathrm{e}^{c_2}}{x^2}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\sqrt{\frac{y\left(\frac{y}{x}+2\right)}{x}} = \frac{c_3 \mathrm{e}^{c_2}}{x^2}$$

$$\sqrt{\frac{y\left(2x+y\right)}{x^2}} = \frac{c_3 \mathrm{e}^{c_2}}{x^2}$$

Summary

The solution(s) found are the following

$$\sqrt{\frac{y\left(2x+y\right)}{x^2}} = \frac{c_3 \mathrm{e}^{c_2}}{x^2} \tag{1}$$

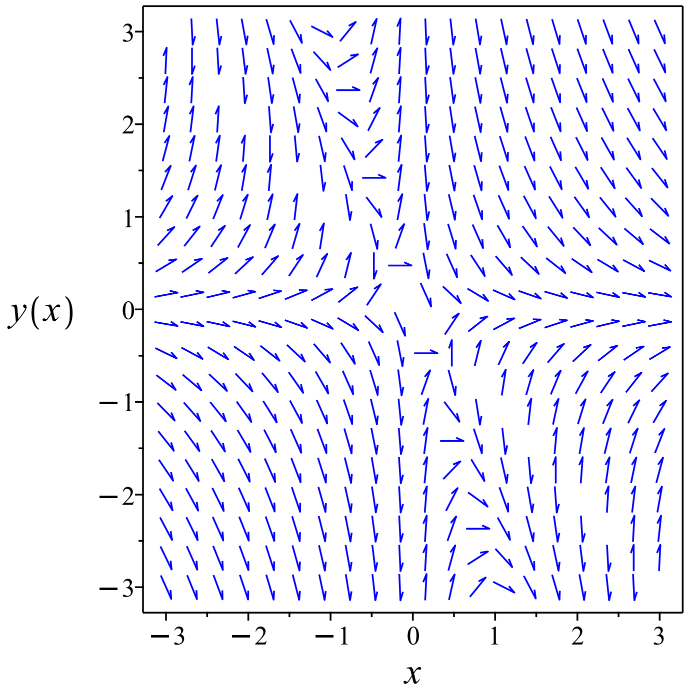

Figure 269: Slope field plot

Verification of solutions

$$\sqrt{\frac{y\left(2x+y\right)}{x^{2}}}=\frac{c_{3}\mathrm{e}^{c_{2}}}{x^{2}}$$

Verified OK.

5.25.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=-\frac{y(3x+y)}{x\left(x+y\right)}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} &b_2 - \frac{y(3x+y)\,(b_3-a_2)}{x\,(x+y)} - \frac{y^2(3x+y)^2\,a_3}{x^2\,(x+y)^2} \\ &- \left(-\frac{3y}{x\,(x+y)} + \frac{y(3x+y)}{x^2\,(x+y)} + \frac{y(3x+y)}{x\,(x+y)^2}\right)(xa_2 + ya_3 + a_1) \\ &- \left(-\frac{3x+y}{x\,(x+y)} - \frac{y}{x\,(x+y)} + \frac{y(3x+y)}{x\,(x+y)^2}\right)(xb_2 + yb_3 + b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{4x^4b_2 + 4x^3yb_2 + 2x^2y^2a_2 - 12x^2y^2a_3 + 2x^2y^2b_2 - 2x^2y^2b_3 - 8x\,y^3a_3 - 2y^4a_3 + 3x^3b_1 - 3x^2ya_1 + 2x^2yb_1}{x^2\,(x+y)^2}$$
$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} &4x^4b_2 + 4x^3yb_2 + 2x^2y^2a_2 - 12x^2y^2a_3 + 2x^2y^2b_2 - 2x^2y^2b_3 - 8x\,y^3a_3 \\ &- 2y^4a_3 + 3x^3b_1 - 3x^2ya_1 + 2x^2yb_1 - 2x\,y^2a_1 + x\,y^2b_1 - y^3a_1 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned} &2a_2v_1^2v_2^2 - 12a_3v_1^2v_2^2 - 8a_3v_1v_2^3 - 2a_3v_2^4 + 4b_2v_1^4 + 4b_2v_1^3v_2 + 2b_2v_1^2v_2^2 \\ &- 2b_3v_1^2v_2^2 - 3a_1v_1^2v_2 - 2a_1v_1v_2^2 - a_1v_2^3 + 3b_1v_1^3 + 2b_1v_1^2v_2 + b_1v_1v_2^2 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$4b_2v_1^4 + 4b_2v_1^3v_2 + 3b_1v_1^3 + (2a_2 - 12a_3 + 2b_2 - 2b_3)\, v_1^2v_2^2 \\ + (-3a_1 + 2b_1)\, v_1^2v_2 - 8a_3v_1v_2^3 + (-2a_1 + b_1)\, v_1v_2^2 - 2a_3v_2^4 - a_1v_2^3 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} -a_1 &= 0 \\ -8a_3 &= 0 \\ -2a_3 &= 0 \\ 3b_1 &= 0 \\ 4b_2 &= 0 \\ -3a_1 + 2b_1 &= 0 \\ -2a_1 + b_1 &= 0 \\ 2a_2 - 12a_3 + 2b_2 - 2b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= b_3 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= x \\ \eta &= y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}\eta &= \eta - \omega(x,y)\,\xi \\ &= y - \left(-\frac{y(3x+y)}{x\,(x+y)}\right)(x) \\ &= \frac{4yx+2y^2}{x+y} \\ \xi &= 0\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{4yx+2y^2}{x+y}} dy\end{aligned}$$

Which results in

$$S = \frac{\ln\left(y(2x+y)\right)}{4}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{y(3x+y)}{x\,(x+y)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{1}{4x + 2y} \\
S_y &= \frac{x + y}{2y\,(2x + y)}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{2x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{2R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{\ln(R)}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(y)}{4} + \frac{\ln(2x + y)}{4} = -\frac{\ln(x)}{2} + c_1$$

Which simplifies to

$$\frac{\ln(y)}{4} + \frac{\ln(2x + y)}{4} = -\frac{\ln(x)}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y(3x+y)}{x(x+y)}$ 	$R = x$ $S = \frac{\ln(y)}{4} + \frac{\ln(2x+y)}{4}$	$\frac{dS}{dR} = -\frac{1}{2R}$ 
Summary

The solution(s) found are the following

$$\frac{\ln(y)}{4} + \frac{\ln(2x+y)}{4} = -\frac{\ln(x)}{2} + c_1 \tag{1}$$

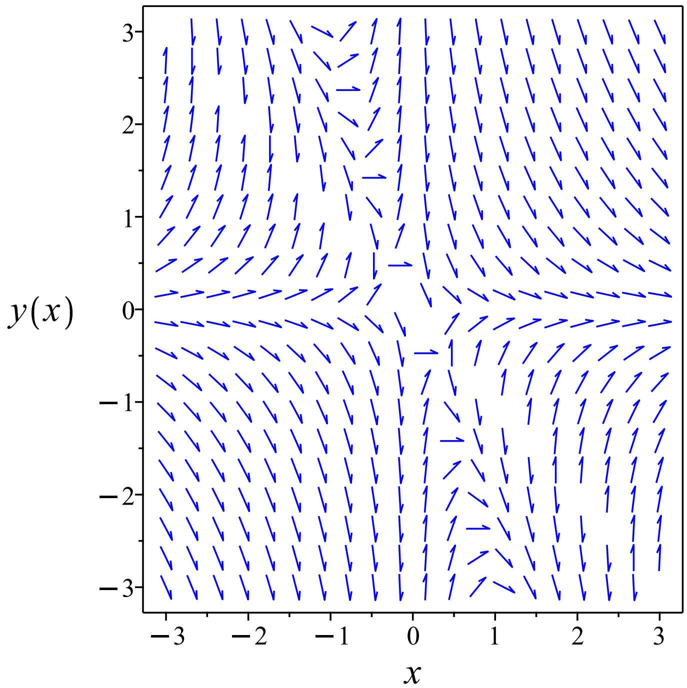

Figure 270: Slope field plot

Verification of solutions

$$\frac{\ln(y)}{4} + \frac{\ln(2x+y)}{4} = -\frac{\ln(x)}{2} + c_1$$

Verified OK.

5.25.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(x^2 + yx)\,\mathrm{d}y &= (-3yx - y^2)\,\mathrm{d}x\\ (3yx + y^2)\,\mathrm{d}x + (x^2 + yx)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = 3yx + y^2$$
$$N(x,y) = x^2 + yx$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(3yx + y^2)\\ &= 3x + 2y\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x^2 + yx)\\ &= 2x + y\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{x\left(x+y\right)}\left(\left(3x+2y\right)-\left(2x+y\right)\right) \\
&= \frac{1}{x}
\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int \frac{1}{x} \, \mathrm{d}x}
\end{aligned}$$

The result of integrating gives

$$\begin{aligned}
\mu &= e^{\ln(x)} \\
&= x
\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}
\overline{M} &= \mu M \\
&= x\left(3yx+y^2\right) \\
&= y(3x+y)\,x
\end{aligned}$$

And

$$\begin{aligned}
\overline{N} &= \mu N \\
&= x\left(x^2+yx\right) \\
&= x^2(x+y)
\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(y(3x+y)\,x\right) + \left(x^2(x+y)\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int y(3x+y)\, x \, \mathrm{d}x$$
$$\phi = \frac{y\, x^2(2x+y)}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{x^2(2x+y)}{2} + \frac{y\, x^2}{2} + f'(y) \tag{4}$$
$$= x^2(x+y) + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x^2(x+y)$. Therefore equation (4) becomes

$$x^2(x+y) = x^2(x+y) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{y\, x^2(2x+y)}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{y\,x^2(2x + y)}{2}$$

Summary

The solution(s) found are the following

$$\frac{yx^2(2x + y)}{2} = c_1 \tag{1}$$

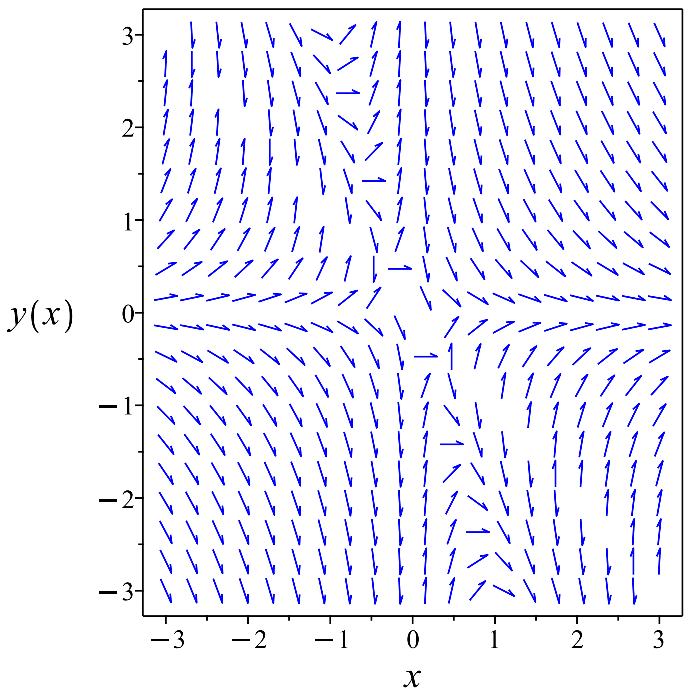

Figure 271: Slope field plot

Verification of solutions

$$\frac{yx^2(2x + y)}{2} = c_1$$

Verified OK.

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Miscellaneous problems, end of chapter 2. Page 133
Problem number: 1.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_linear]
```

$$\boxed{y' - \frac{x^3 - 2y}{x} = 0}$$

6.1.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{2}{x}$$
$$q(x) = x^2$$

Hence the ode is

$$y' + \frac{2y}{x} = x^2$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int \frac{2}{x}dx} \\
&= x^2
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(x^2\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(y\, x^2\right) &= \left(x^2\right)\left(x^2\right) \\
\mathrm{d}\left(y\, x^2\right) &= x^4\, \mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
y\, x^2 &= \int x^4\, \mathrm{d}x \\
y\, x^2 &= \frac{x^5}{5} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = x^2$ results in

$$
y = \frac{x^3}{5} + \frac{c_1}{x^2}
$$

Summary
The solution(s) found are the following

$$
y = \frac{x^3}{5} + \frac{c_1}{x^2} \tag{1}
$$

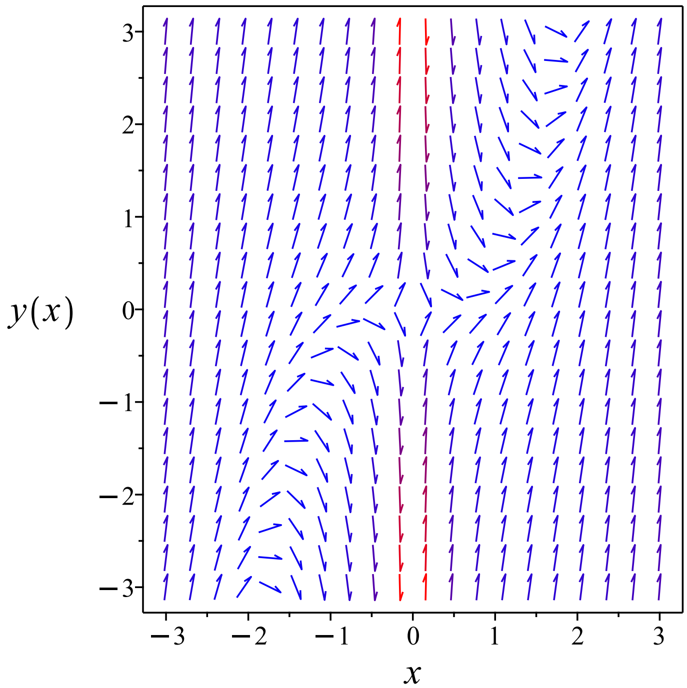

Figure 272: Slope field plot

Verification of solutions

$$y = \frac{x^3}{5} + \frac{c_1}{x^2}$$

Verified OK.

6.1.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{-x^3 + 2y}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 260: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{1}{x^2}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{x^2}} dy \end{aligned}$$

Which results in

$$S = y\,x^2$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{-x^3 + 2y}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= 2yx \\ S_y &= x^2 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = x^4 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R^4$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^5}{5} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$x^2 y = \frac{x^5}{5} + c_1$$

Which simplifies to

$$x^2 y = \frac{x^5}{5} + c_1$$

Which gives

$$y = \frac{x^5 + 5c_1}{5x^2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{-x^3+2y}{x}$ 	$R = x$ $S = y\,x^2$	$\frac{dS}{dR} = R^4$ 
Summary

The solution(s) found are the following

$$y = \frac{x^5 + 5c_1}{5x^2} \tag{1}$$

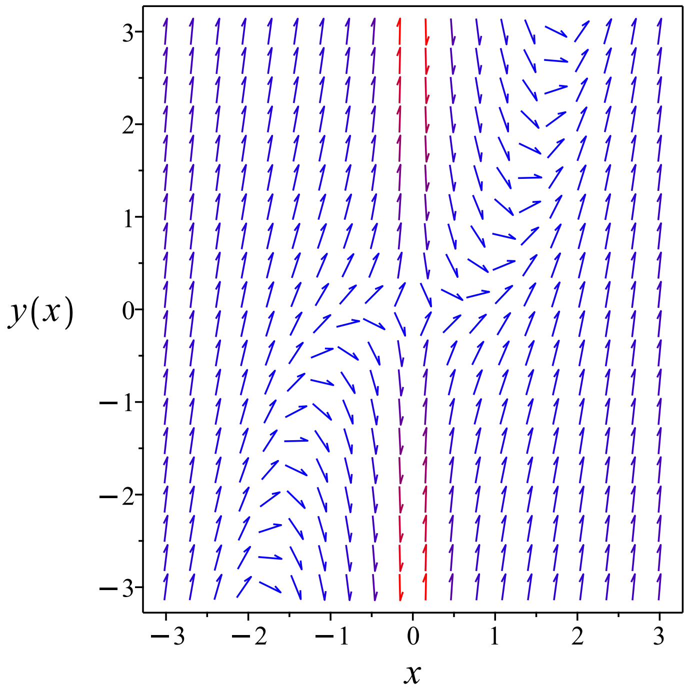

Figure 273: Slope field plot

Verification of solutions

$$y = \frac{x^5 + 5c_1}{5x^2}$$

Verified OK.

6.1.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = \left(\frac{x^3 - 2y}{x}\right) \mathrm{d}x$$
$$\left(-\frac{x^3 - 2y}{x}\right) \mathrm{d}x + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\frac{x^3 - 2y}{x}$$
$$N(x, y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-\frac{x^3 - 2y}{x}\right)$$
$$= \frac{2}{x}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= 1\left(\left(\frac{2}{x}\right) - (0)\right) \\
&= \frac{2}{x}
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int \frac{2}{x} \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{2\ln(x)} \\
&= x^2
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= x^2\left(-\frac{x^3 - 2y}{x}\right) \\
&= -x\left(x^3 - 2y\right)
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= x^2(1) \\
&= x^2
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$
$$\left(-x\left(x^{3}-2y\right)\right) + \left(x^{2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int -x\left(x^{3}-2y\right) \mathrm{d}x$$
$$\phi = -\frac{1}{5}x^{5} + y\,x^{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x^{2} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x^{2}$. Therefore equation (4) becomes

$$x^{2} = x^{2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_{1}$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{1}{5}x^5 + y\,x^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{1}{5}x^5 + y\,x^2$$

The solution becomes

$$y = \frac{x^5 + 5c_1}{5x^2}$$

Summary

The solution(s) found are the following

$$y = \frac{x^5 + 5c_1}{5x^2} \tag{1}$$

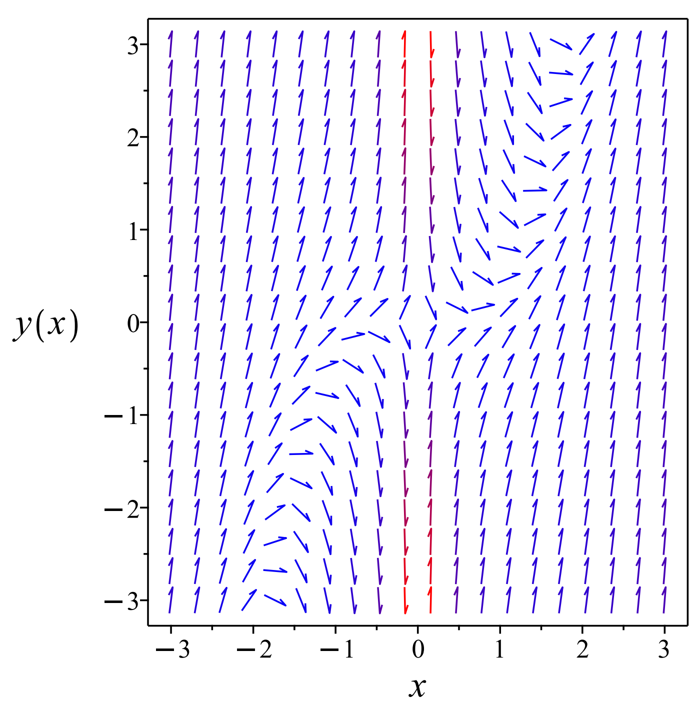

Figure 274: Slope field plot

Verification of solutions

$$y = \frac{x^5 + 5c_1}{5x^2}$$

6.1.4 Maple step by step solution

Let's solve

$y' - \frac{x^3-2y}{x} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{2y}{x} + x^2$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{2y}{x} = x^2$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' + \frac{2y}{x}\right) = \mu(x)\, x^2$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\left(y' + \frac{2y}{x}\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

  $\mu'(x) = \frac{2\mu(x)}{x}$

- Solve to find the integrating factor

  $\mu(x) = x^2$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int \mu(x)\, x^2 dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\, y = \int \mu(x)\, x^2 dx + c_1$

- Solve for y

  $y = \frac{\int \mu(x)x^2 dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = x^2$

$y = \frac{\int x^4 dx + c_1}{x^2}$

- Evaluate the integrals on the rhs

$y = \frac{\frac{x^5}{5} + c_1}{x^2}$

- Simplify

$y = \frac{x^5 + 5c_1}{5x^2}$

Problem number: 2.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{y' - \frac{\cos(x) + 1}{2 - \sin(y)} = 0}$$

6.2.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{-\cos(x) - 1}{-2 + \sin(y)} \end{aligned}$$

Where $f(x) = -\cos(x) - 1$ and $g(y) = \frac{1}{-2+\sin(y)}$. Integrating both sides gives

$$\frac{1}{\frac{1}{-2+\sin(y)}}\,dy = -\cos(x) - 1\,dx$$

$$\int \frac{1}{\frac{1}{-2+\sin(y)}}\, dy = \int -\cos(x) - 1\, dx$$

$$-2y - \cos(y) = -x - \sin(x) + c_1$$

Which results in

$$y = \text{RootOf}\left(2\_Z + \cos(\_Z) - x - \sin(x) + c_1\right)$$

Summary

The solution(s) found are the following

$$y = \text{RootOf}\left(2\_Z + \cos(\_Z) - x - \sin(x) + c_1\right) \tag{1}$$

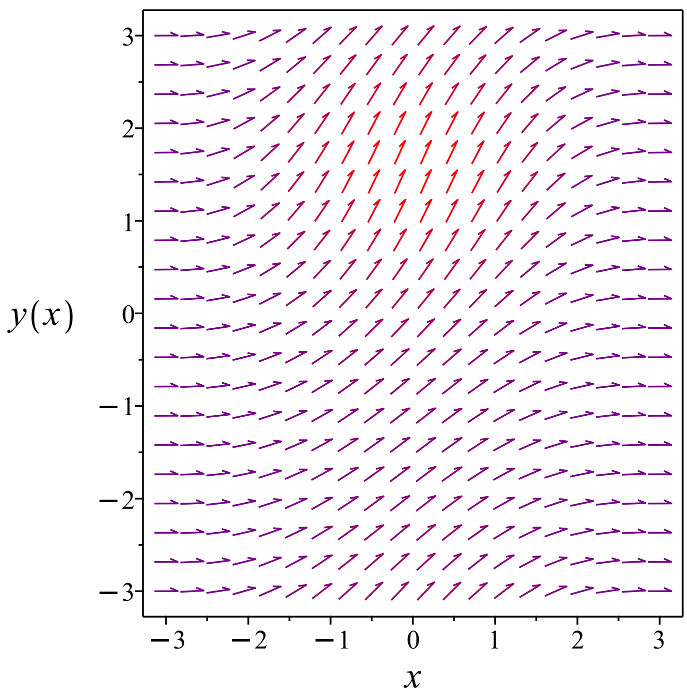

Figure 275: Slope field plot

$$y = \text{RootOf}\left(2\_Z + \cos(\_Z) - x - \sin(x) + c_1\right)$$

Verified OK.

6.2.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{\cos(x)+1}{-2+\sin(y)} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 263: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a+bx+cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= \frac{1}{-\cos(x)-1} \\
\eta(x,y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{\frac{1}{-\cos(x)-1}} dx
\end{aligned}
$$

Which results in

$$
S = -x - \sin(x)
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = -\frac{\cos(x)+1}{-2+\sin(y)}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= -\cos(x) - 1 \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -2 + \sin(y) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -2 + \sin(R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\cos(R) - 2R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-x - \sin(x) = -\cos(y) - 2y + c_1$$

Which simplifies to

$$-x - \sin(x) = -\cos(y) - 2y + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in x, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>

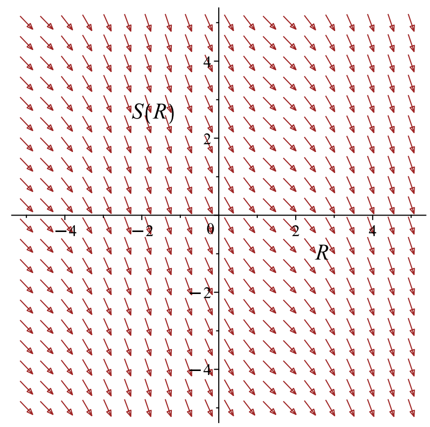
$R = y$

$S = -x - \sin(x)$

</td><td>

$\frac{dS}{dR} = -2 + \sin(R)$



</td></tr>
</table>

Summary

The solution(s) found are the following

$$-x - \sin(x) = -\cos(y) - 2y + c_1 \tag{1}$$

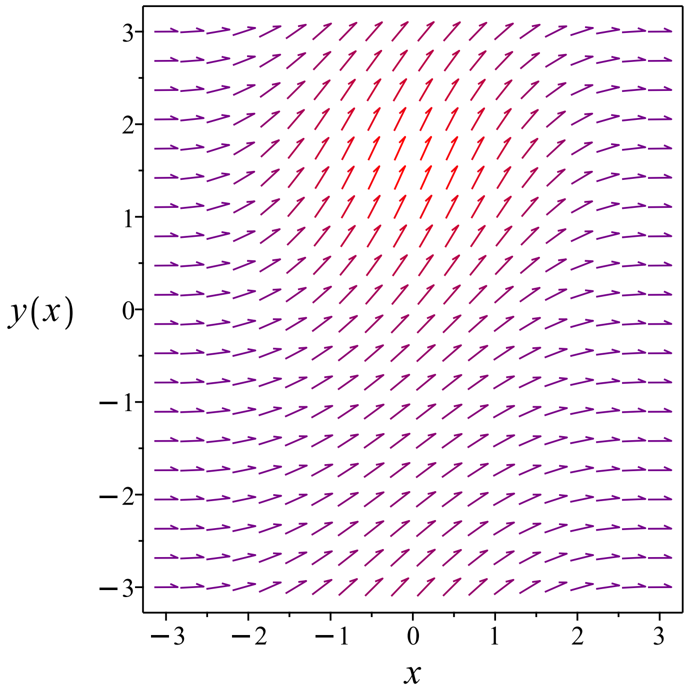


Figure 276: Slope field plot

Verification of solutions

$$-x - \sin(x) = -\cos(y) - 2y + c_1$$

Verified OK.

6.2.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y) \,\mathrm{d}x + N(x, y) \,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
(2 - \sin(y)) \,\mathrm{d}y &= (\cos(x) + 1) \,\mathrm{d}x \\
(-\cos(x) - 1) \,\mathrm{d}x + (2 - \sin(y)) \,\mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -\cos(x) - 1 \\
N(x, y) &= 2 - \sin(y)
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-\cos(x) - 1) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2 - \sin(y)) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int -\cos(x) - 1 \mathrm{d}x$$
$$\phi = -x - \sin(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2 - \sin(y)$. Therefore equation (4) becomes

$$2 - \sin(y) = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 2 - \sin(y)$$

Integrating the above w.r.t y gives

$$\int f'(y) \mathrm{d}y = \int (2 - \sin(y)) \mathrm{d}y$$
$$f(y) = 2y + \cos(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -x - \sin(x) + 2y + \cos(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x - \sin(x) + 2y + \cos(y)$$

Summary
The solution(s) found are the following

$$2y + \cos(y) - x - \sin(x) = c_1 \tag{1}$$

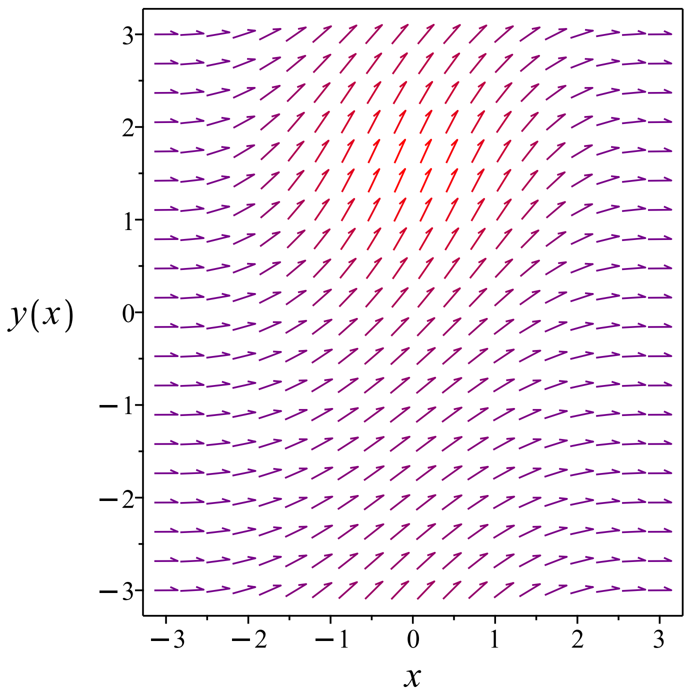

Figure 277: Slope field plot

Verification of solutions

$$2y + \cos(y) - x - \sin(x) = c_1$$

Verified OK.

6.2.4 Maple step by step solution

Let's solve

$y' - \frac{\cos(x)+1}{2-\sin(y)} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $(2-\sin(y))\, y' = \cos(x) + 1$

- Integrate both sides with respect to x

  $\int (2-\sin(y))\, y' dx = \int (\cos(x) + 1)\, dx + c_1$

- Evaluate integral

  $2y + \cos(y) = x + \sin(x) + c_1$

Problem number: 3.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "differentialType"**

Maple gives the following as the ode type

`[_rational]`

$$\boxed{y' - \frac{2x+y}{3-x+3y^2} = 0}$$

With initial conditions

$$[y(0) = 0]$$

6.3.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= \frac{2x+y}{3y^2-x+3} \end{aligned}$$

The x domain of $f(x,y)$ when $y=0$ is

$$\{x < 3 \lor 3 < x\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x,y)$ when $x=0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 0$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{2x+y}{3y^2-x+3}\right) \\ &= \frac{1}{3y^2-x+3} - \frac{6(2x+y)\,y}{(3y^2-x+3)^2}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 0$ is

$$\{x < 3 \lor 3 < x\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 0$ is inside this domain. Therefore solution exists and is unique.

6.3.2 Solving as differentialType ode

Writing the ode as

$$y' = \frac{2x+y}{3-x+3y^2} \tag{1}$$

Which becomes

$$\left(-3y^2-3\right) dy = (-x)\, dy + (-2x-y)\, dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\, dy + (-2x-y)\, dx = d\left(-x^2-yx\right)$$

Hence (2) becomes

$$\left(-3y^2-3\right) dy = d\left(-x^2-yx\right)$$

Integrating both sides gives gives these solutions

$$y = \frac{\left(108x^2 - 108c_1 + 12\sqrt{81x^4 - 162c_1x^2 - 12x^3 + 81c_1^2 + 108x^2 - 324x + 324}\right)^{\frac{1}{3}}}{6} - \frac{}{\left(108x^2 - 108c_1 + \right.}$$

$$y = -\frac{\left(108x^2 - 108c_1 + 12\sqrt{81x^4 - 162c_1x^2 - 12x^3 + 81c_1^2 + 108x^2 - 324x + 324}\right)^{\frac{1}{3}}}{12} + \frac{}{\left(108x^2 - 108c_1 \right.}$$

$$y = -\frac{\left(108x^2 - 108c_1 + 12\sqrt{81x^4 - 162c_1x^2 - 12x^3 + 81c_1^2 + 108x^2 - 324x + 324}\right)^{\frac{1}{3}}}{12} + \frac{}{\left(108x^2 - 108c_1 \right.}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{-i\sqrt{3}\left(-4c_1 + 4\sqrt{c_1^2 + 4}\right)^{\frac{2}{3}} - 4i\sqrt{3} - \left(-4c_1 + 4\sqrt{c_1^2 + 4}\right)^{\frac{2}{3}} + 4c_1\left(-4c_1 + 4\sqrt{c_1^2 + 4}\right)^{\frac{1}{3}} + 4}{4\left(-4c_1 + 4\sqrt{c_1^2 + 4}\right)^{\frac{1}{3}}}$$

$$c_1 = \frac{i(2\sqrt{3} - 2i)\sqrt{3} + 4i\sqrt{3} + 2\sqrt{3} - 4 - 2i}{4\sqrt{2\sqrt{3} - 2i}}$$

Substituting c_1 found above in the general solution gives

$$y = \lim_{c_1 \to \frac{i(2\sqrt{3}-2i)\sqrt{3}+4i\sqrt{3}+2\sqrt{3}-4-2i}{4\sqrt{2\sqrt{3}-2i}}} \left(-\frac{\left(108x^2 - 108c_1 + 12\sqrt{81x^4 - 162c_1x^2 - 12x^3 + 81c_1^2 + 108x^2 - 324x \right.}}{12} \right.$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{i\sqrt{3}\left(-4c_1 + 4\sqrt{c_1^2 + 4}\right)^{\frac{2}{3}} + 4i\sqrt{3} - \left(-4c_1 + 4\sqrt{c_1^2 + 4}\right)^{\frac{2}{3}} + 4c_1\left(-4c_1 + 4\sqrt{c_1^2 + 4}\right)^{\frac{1}{3}} + 4}{4\left(-4c_1 + 4\sqrt{c_1^2 + 4}\right)^{\frac{1}{3}}}$$

$$c_1 = -\frac{i\left(2i+2\sqrt{3}\right)\sqrt{3}+4i\sqrt{3}+4-2i-2\sqrt{3}}{4\sqrt{2i+2\sqrt{3}}}$$

Substituting c_1 found above in the general solution gives

$$y = \text{Expression too large to display}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{\left(-4c_1+4\sqrt{c_1^2+4}\right)^{\frac{2}{3}}+2c_1\left(-4c_1+4\sqrt{c_1^2+4}\right)^{\frac{1}{3}}-4}{2\left(-4c_1+4\sqrt{c_1^2+4}\right)^{\frac{1}{3}}}$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$y = \frac{\left(108x^2+12\sqrt{81x^4-12x^3+108x^2-324x+324}\right)^{\frac{2}{3}}+12x-36}{6\left(108x^2+12\sqrt{81x^4-12x^3+108x^2-324x+324}\right)^{\frac{1}{3}}}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(108x^2+12\sqrt{81x^4-12x^3+108x^2-324x+324}\right)^{\frac{2}{3}}+12x-36}{6\left(108x^2+12\sqrt{81x^4-12x^3+108x^2-324x+324}\right)^{\frac{1}{3}}} \tag{1}$$

Expression too large to display (2)

$$y \tag{3}$$

6.3.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the

ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(3y^2 - x + 3\right)\mathrm{d}y &= (2x + y)\,\mathrm{d}x \\ (-2x - y)\,\mathrm{d}x + \left(3y^2 - x + 3\right)\mathrm{d}y &= 0 \qquad \text{(2A)}\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -2x - y \\ N(x,y) &= 3y^2 - x + 3\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-2x - y)\\ &= -1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(3y^2 - x + 3\right)\\ &= -1\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -2x - y \, \mathrm{d}x$$

$$\phi = -x(x + y) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 3y^2 - x + 3$. Therefore equation (4) becomes

$$3y^2 - x + 3 = -x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 3y^2 + 3$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(3y^2+3\right)\mathrm{d}y$$
$$f(y) = y^3+3y+c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -x(x+y)+y^3+3y+c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x(x+y)+y^3+3y$$

Initial conditions are used to solve for c_1. Substituting $x=0$ and $y=0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$-x(x+y)+y^3+3y = 0$$

Summary

The solution(s) found are the following

$$y^3+(3-x)\,y-x^2 = 0 \tag{1}$$

Verification of solutions

$$y^3+(3-x)\,y-x^2 = 0$$

Verified OK.

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - y + 2yx = -6x + 3}$$

6.4.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= (2x-1)(-y-3) \end{aligned}$$

Where $f(x) = 2x - 1$ and $g(y) = -y - 3$. Integrating both sides gives

$$\frac{1}{-y-3}\,dy = 2x - 1\,dx$$

$$\int \frac{1}{-y-3}\,dy = \int 2x - 1\,dx$$

$$-\ln(3+y) = x^2 + c_1 - x$$

Raising both side to exponential gives

$$\frac{1}{3+y} = \mathrm{e}^{x^2+c_1-x}$$

Which simplifies to

$$\frac{1}{3+y} = c_2 \mathrm{e}^{x^2-x}$$

Summary
The solution(s) found are the following

$$y = -\frac{\left(3c_2 \mathrm{e}^{x^2+c_1-x} - 1\right) \mathrm{e}^{-x^2-c_1+x}}{c_2} \tag{1}$$

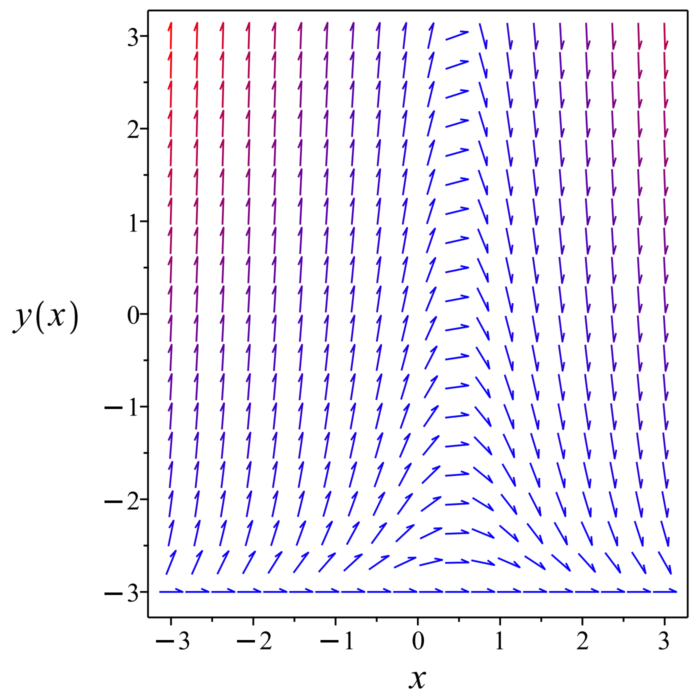

Figure 279: Slope field plot

Verification of solutions

$$y = -\frac{\left(3c_2 \mathrm{e}^{x^2+c_1-x} - 1\right) \mathrm{e}^{-x^2-c_1+x}}{c_2}$$

Verified OK.

6.4.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= 2x - 1\\ q(x) &= -6x + 3\end{aligned}$$

Hence the ode is

$$y' + y(2x - 1) = -6x + 3$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int (2x-1)dx}\\ &= \mathrm{e}^{x^2 - x}\end{aligned}$$

Which simplifies to

$$\mu = \mathrm{e}^{x(x-1)}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)(-6x + 3)\\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{x(x-1)} y\right) &= \left(\mathrm{e}^{x(x-1)}\right)(-6x + 3)\\ \mathrm{d}\left(\mathrm{e}^{x(x-1)} y\right) &= \left((-6x + 3)\,\mathrm{e}^{x(x-1)}\right)\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\mathrm{e}^{x(x-1)} y &= \int (-6x + 3)\,\mathrm{e}^{x(x-1)}\,\mathrm{d}x\\ \mathrm{e}^{x(x-1)} y &= -3\,\mathrm{e}^{x(x-1)} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{x(x-1)}$ results in

$$y = -3\,\mathrm{e}^{-x(x-1)}\mathrm{e}^{x(x-1)} + c_1 \mathrm{e}^{-x(x-1)}$$

which simplifies to

$$y = -3 + c_1 \mathrm{e}^{-x(x-1)}$$

Summary
The solution(s) found are the following

$$y = -3 + c_1 e^{-x(x-1)} \tag{1}$$

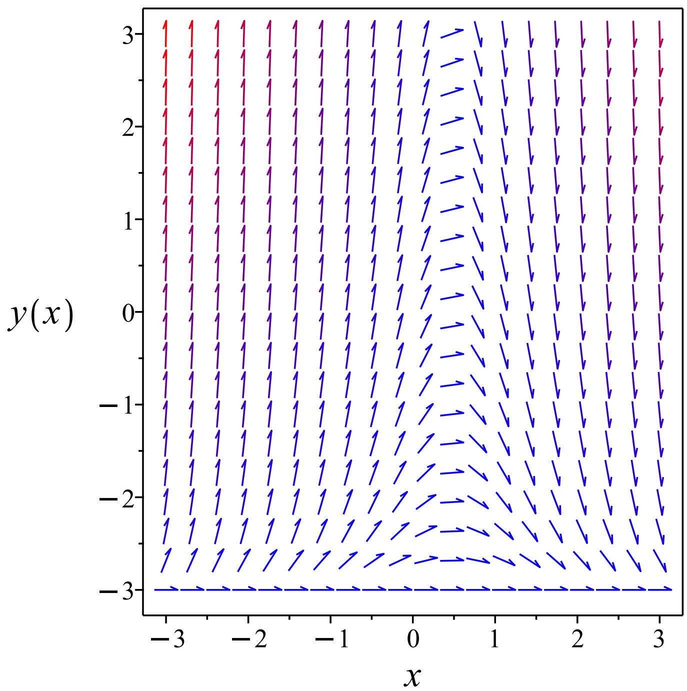

Figure 280: Slope field plot

Verification of solutions

$$y = -3 + c_1 e^{-x(x-1)}$$

Verified OK.

6.4.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -2yx - 6x + y + 3$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 266: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \mathrm{e}^{-x^2+x}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{-x^2+x}} dy \end{aligned}$$

Which results in

$$S = \mathrm{e}^{x^2-x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -2yx - 6x + y + 3$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= (2x-1)\,\mathrm{e}^{x(x-1)} y \\ S_y &= \mathrm{e}^{x(x-1)} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = (-6x+3)\,\mathrm{e}^{x(x-1)} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = (-6R+3)\,\mathrm{e}^{R(R-1)}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -3\,\mathrm{e}^{R(R-1)} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\mathrm{e}^{x(x-1)} y = -3\,\mathrm{e}^{x(x-1)} + c_1$$

Which simplifies to

$$(3 + y)\,\mathrm{e}^{x(x-1)} - c_1 = 0$$

Which gives

$$y = -\left(3\,\mathrm{e}^{x(x-1)} - c_1\right) \mathrm{e}^{-x(x-1)}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -2yx - 6x + y + 3$ 	$R = x$ $S = \mathrm{e}^{x(x-1)} y$	$\frac{dS}{dR} = (-6R + 3)\,\mathrm{e}^{R(R-1)}$ 
Summary
The solution(s) found are the following

$$y = -\left(3\,\mathrm{e}^{x(x-1)} - c_1\right) \mathrm{e}^{-x(x-1)} \tag{1}$$

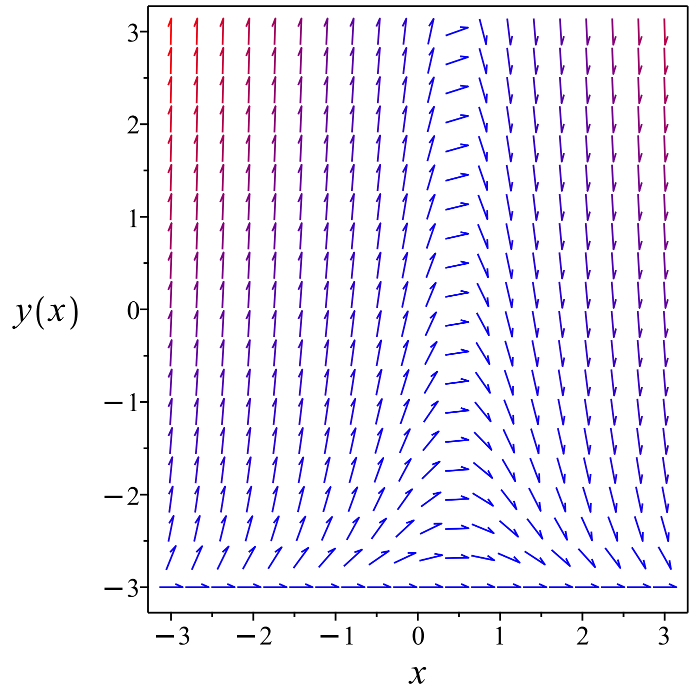

Figure 281: Slope field plot

Verification of solutions

$$y = -\left(3\,\mathrm{e}^{x(x-1)} - c_1\right)\mathrm{e}^{-x(x-1)}$$

Verified OK.

6.4.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\,\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(\frac{1}{-y-3}\right) \mathrm{d}y &= (2x - 1)\, \mathrm{d}x \\
(1 - 2x)\, \mathrm{d}x + \left(\frac{1}{-y-3}\right) \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= 1 - 2x \\
N(x, y) &= \frac{1}{-y-3}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(1 - 2x) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{-y-3}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \qquad (1) \\
\frac{\partial \phi}{\partial y} &= N \qquad (2)
\end{aligned}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int M \, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int 1 - 2x \, \mathrm{d}x \\
\phi &= -x^2 + x + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \qquad (4)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{-y-3}$. Therefore equation (4) becomes

$$
\frac{1}{-y-3} = 0 + f'(y) \qquad (5)
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = -\frac{1}{3+y}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \, \mathrm{d}y &= \int \left(-\frac{1}{3+y}\right) \mathrm{d}y \\
f(y) &= -\ln(3+y) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -x^2 + x - \ln(3+y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x^2 + x - \ln(3+y)$$

The solution becomes

$$y = e^{-x^2-c_1+x} - 3$$

Summary

The solution(s) found are the following

$$y = e^{-x^2-c_1+x} - 3 \tag{1}$$

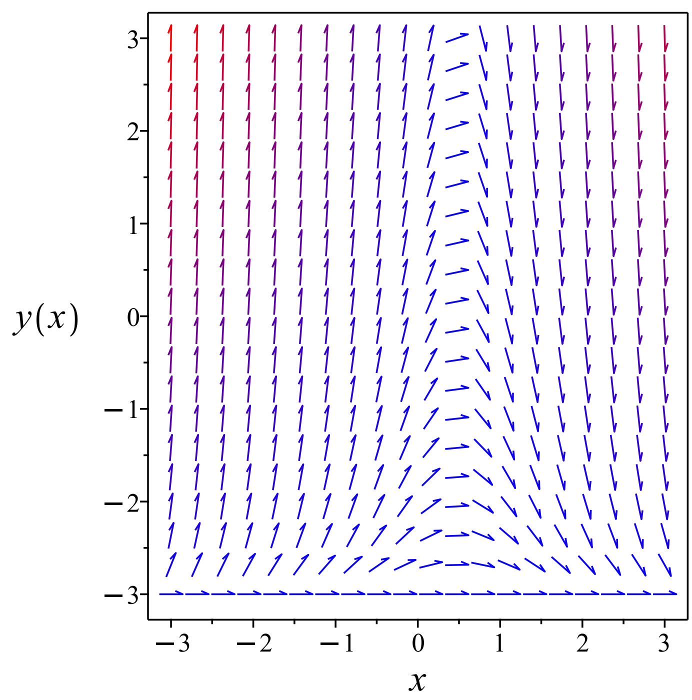

Figure 282: Slope field plot

Verification of solutions

$$y = e^{-x^2-c_1+x} - 3$$

Verified OK.

6.4.5 Maple step by step solution

Let's solve

$y' - y + 2yx = -6x + 3$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{3+y} = 1 - 2x$

- Integrate both sides with respect to x

  $\int \frac{y'}{3+y}dx = \int (1 - 2x)\,dx + c_1$

- Evaluate integral

  $\ln(3 + y) = -x^2 + c_1 + x$

- Solve for y

  $y = \mathrm{e}^{-x^2+c_1+x} - 3$

Problem number: 5.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

`[_rational, [_Abel, `2nd type`, `class B`]]`

$$\boxed{y' - \frac{-1 - 2yx - y^2}{x^2 + 2yx} = 0}$$

6.5.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(x(x+2y))\,\mathrm{d}y &= \left(-2yx - y^2 - 1\right)\mathrm{d}x\\ \left(2yx + y^2 + 1\right)\mathrm{d}x + (x(x+2y))\,\mathrm{d}y &= 0 \qquad (2\mathrm{A})\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= 2yx + y^2 + 1\\ N(x,y) &= x(x+2y)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(2yx + y^2 + 1\right)\\ &= 2x + 2y\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x(x+2y))\\ &= 2x + 2y\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial\phi}{\partial x} = M \tag{1}$$

$$\frac{\partial\phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int M \,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int 2yx + y^2 + 1 \,\mathrm{d}x$$
$$\phi = y\,x^2 + x\,y^2 + x + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x^2 + 2yx + f'(y) \tag{4}$$
$$= x(x + 2y) + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x(x + 2y)$. Therefore equation (4) becomes

$$x(x + 2y) = x(x + 2y) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = y\,x^2 + x\,y^2 + x + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = y\,x^2 + x\,y^2 + x$$

Summary

The solution(s) found are the following

$$x^2y + xy^2 + x = c_1 \tag{1}$$

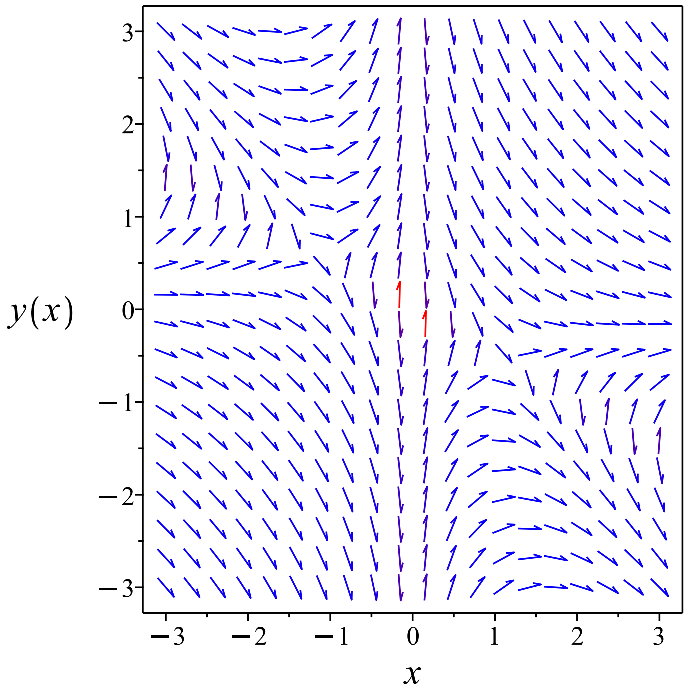

Figure 283: Slope field plot

Verification of solutions

$$x^2y + xy^2 + x = c_1$$

Problem number: 6.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{yx + y'x + y = 1}$$

With initial conditions

$$[y(1) = 0]$$

6.6.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-x-1}{x}$$
$$q(x) = \frac{1}{x}$$

Hence the ode is

$$y' - \frac{(-x-1)\,y}{x} = \frac{1}{x}$$

The domain of $p(x) = -\frac{-x-1}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $q(x) = \frac{1}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

6.6.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{-x-1}{x}dx} \\ &= \mathrm{e}^{x+\ln(x)}\end{aligned}$$

Which simplifies to

$$\mu = x\,\mathrm{e}^{x}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{1}{x}\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}(x\,\mathrm{e}^{x} y) &= (x\,\mathrm{e}^{x})\left(\frac{1}{x}\right) \\ \mathrm{d}(x\,\mathrm{e}^{x} y) &= \mathrm{e}^{x}\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}x\,\mathrm{e}^{x} y &= \int \mathrm{e}^{x}\,\mathrm{d}x \\ x\,\mathrm{e}^{x} y &= \mathrm{e}^{x} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = x\,\mathrm{e}^{x}$ results in

$$y = \frac{\mathrm{e}^{-x}\mathrm{e}^{x}}{x} + \frac{c_1\mathrm{e}^{-x}}{x}$$

which simplifies to

$$y = \frac{c_1 e^{-x} + 1}{x}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = e^{-1} c_1 + 1$$

$$c_1 = -e$$

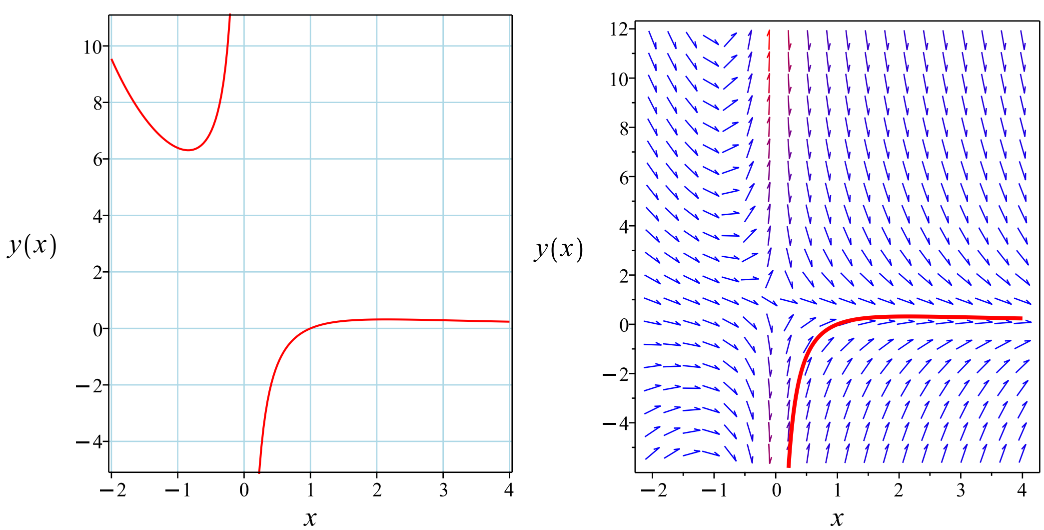
Substituting c_1 found above in the general solution gives

$$y = \frac{-e^{1-x} + 1}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{-e^{1-x} + 1}{x} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \frac{-e^{1-x} + 1}{x}$$

Verified OK.

6.6.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{yx + y - 1}{x} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 269: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= 0 \\ \eta(x,y) &= \mathrm{e}^{-x-\ln(x)} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{-x-\ln(x)}} dy \end{aligned}$$

Which results in

$$S = x\,\mathrm{e}^{x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{yx + y - 1}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \mathrm{e}^{x} y(x+1) \\ S_y &= x\,\mathrm{e}^{x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \mathrm{e}^{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \mathrm{e}^{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \mathrm{e}^{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$y\,\mathrm{e}^{x} x = \mathrm{e}^{x} + c_1$$

Which simplifies to

$$y\,\mathrm{e}^{x} x = \mathrm{e}^{x} + c_1$$

Which gives

$$y = \frac{(\mathrm{e}^{x} + c_1)\,\mathrm{e}^{-x}}{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{yx+y-1}{x}$ 	$R = x$ $S = x\,\mathrm{e}^{x} y$	$\frac{dS}{dR} = \mathrm{e}^{R}$ 
Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \mathrm{e}^{-1} c_1 + 1$$

$$c_1 = -\mathrm{e}$$

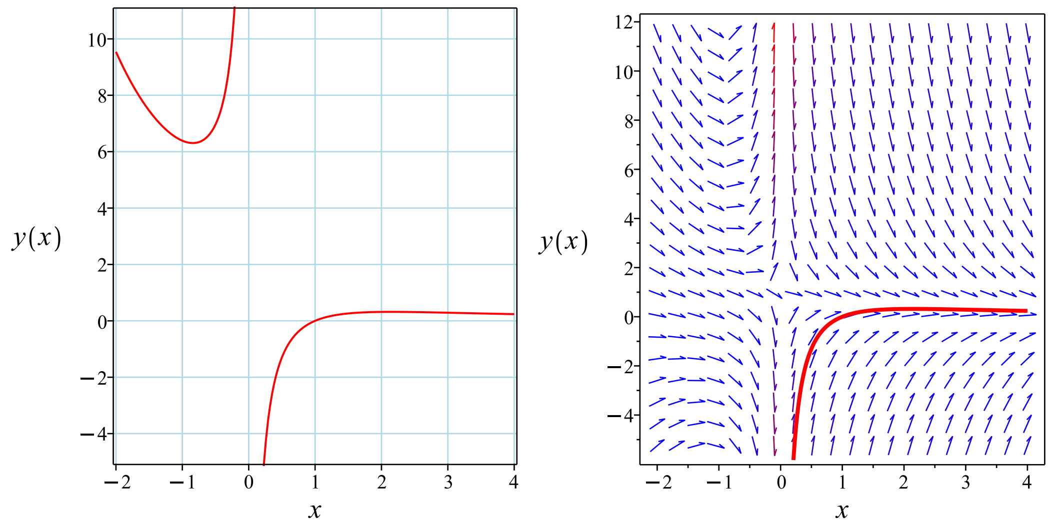
Substituting c_1 found above in the general solution gives

$$y = \frac{\mathrm{e}^{-x}\mathrm{e}^{x} - \mathrm{e}\,\mathrm{e}^{-x}}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{\mathrm{e}^{-x}\mathrm{e}^{x} - \mathrm{e}\,\mathrm{e}^{-x}}{x} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \frac{e^{-x} e^{x} - e\, e^{-x}}{x}$$

Verified OK.

6.6.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx} \phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y} \frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(x)\,\mathrm{d}y &= (-yx - y + 1)\,\mathrm{d}x\\ (yx + y - 1)\,\mathrm{d}x + (x)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= yx + y - 1\\ N(x,y) &= x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(yx + y - 1)\\ &= x + 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x)\\ &= 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{x}((x+1) - (1))\\ &= 1\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int 1 \, \mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{x} \\ &= \mathrm{e}^{x}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \mathrm{e}^{x}(yx + y - 1) \\ &= \mathrm{e}^{x}(yx + y - 1)\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N \\ &= \mathrm{e}^{x}(x) \\ &= x\,\mathrm{e}^{x}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(\mathrm{e}^{x}(yx + y - 1)\right) + \left(x\,\mathrm{e}^{x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int \overline{M} \, \mathrm{d}x \\ \int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int \mathrm{e}^{x}(yx + y - 1) \, \mathrm{d}x\end{aligned}$$

$$\phi = (yx - 1)\,\mathrm{e}^{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x\,\mathrm{e}^{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x\,\mathrm{e}^{x}$. Therefore equation (4) becomes

$$x\,\mathrm{e}^{x} = x\,\mathrm{e}^{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = (yx - 1)\,\mathrm{e}^{x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = (yx - 1)\,\mathrm{e}^{x}$$

The solution becomes

$$y = \frac{(\mathrm{e}^{x} + c_1)\,\mathrm{e}^{-x}}{x}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \mathrm{e}^{-1}c_1 + 1$$

$$c_1 = -\mathrm{e}$$

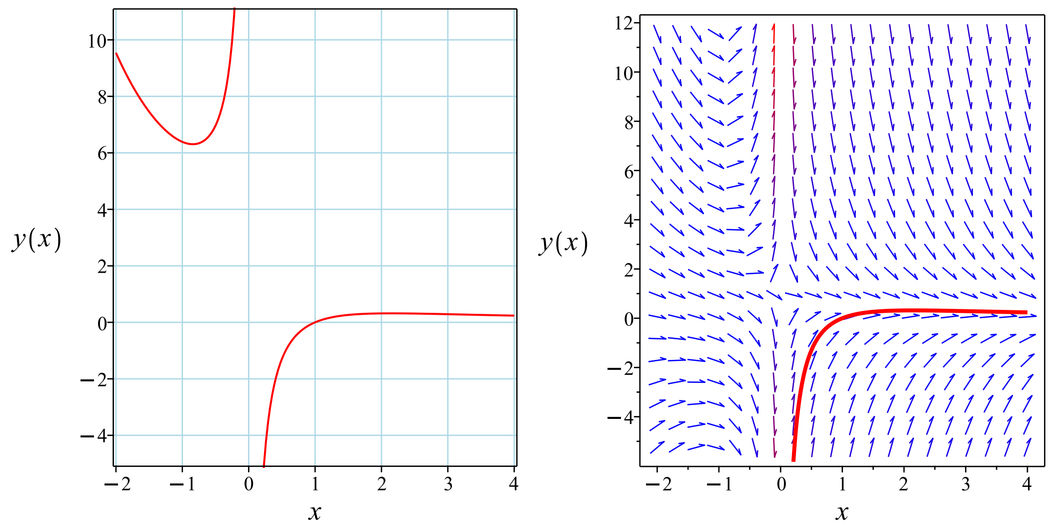
Substituting c_1 found above in the general solution gives

$$y = \frac{\mathrm{e}^{-x}\mathrm{e}^{x} - \mathrm{e}\,\mathrm{e}^{-x}}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{e^{-x}e^{x} - e\,e^{-x}}{x} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \frac{e^{-x}e^{x} - e\,e^{-x}}{x}$$

Verified OK.

6.6.5 Maple step by step solution

Let's solve

$[yx + y'x + y = 1, y(1) = 0]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{(x+1)y}{x} + \frac{1}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{(x+1)y}{x} = \frac{1}{x}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y'+\frac{(x+1)y}{x}\right)=\frac{\mu(x)}{x}$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y'+\frac{(x+1)y}{x}\right)=\mu'(x)\,y+\mu(x)\,y'$
- Isolate $\mu'(x)$

  $\mu'(x)=\frac{\mu(x)(x+1)}{x}$
- Solve to find the integrating factor

  $\mu(x)=x\,\mathrm{e}^{x}$
- Integrate both sides with respect to x

  $\int\left(\frac{d}{dx}(\mu(x)\,y)\right)dx=\int\frac{\mu(x)}{x}dx+c_1$
- Evaluate the integral on the lhs

  $\mu(x)\,y=\int\frac{\mu(x)}{x}dx+c_1$
- Solve for y

  $y=\frac{\int\frac{\mu(x)}{x}dx+c_1}{\mu(x)}$
- Substitute $\mu(x)=x\mathrm{e}^{x}$

  $y=\frac{\int\mathrm{e}^{x}dx+c_1}{x\,\mathrm{e}^{x}}$
- Evaluate the integrals on the rhs

  $y=\frac{\mathrm{e}^{x}+c_1}{\mathrm{e}^{x}x}$
- Simplify

  $y=\frac{c_1\mathrm{e}^{-x}+1}{x}$
- Use initial condition $y(1)=0$

  $0=\mathrm{e}^{-1}c_1+1$
- Solve for c_1

  $c_1=-\frac{1}{\mathrm{e}^{-1}}$
- Substitute $c_1=-\frac{1}{\mathrm{e}^{-1}}$ into general solution and simplify

  $y=\frac{-\mathrm{e}^{1-x}+1}{x}$
- Solution to the IVP

  $y=\frac{-\mathrm{e}^{1-x}+1}{x}$

The type(s) of ODE detected by this program : **"exact", "separable", "differentialType", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{4x^3 + 1}{y(2 + 3y)} = 0}$$

6.7.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= f(x)g(y) \\ &= \frac{4x^3 + 1}{y(2 + 3y)} \end{aligned}$$

Where $f(x) = 4x^3 + 1$ and $g(y) = \frac{1}{y(2+3y)}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y(2+3y)}}\, dy = 4x^3 + 1\, dx$$

$$\int \frac{1}{\frac{1}{y(2+3y)}}\,dy = \int 4x^3+1\,dx$$

$$y^3+y^2 = x^4+c_1+x$$

Which results in

$$y = \frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1-\cdots}\right.}{6} + \frac{2}{3\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c\cdots}\right.} - \frac{1}{3}$$

$$y = -\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1\cdots}\right.}{12} - \frac{1}{3\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c\cdots}\right.} - \frac{1}{3} + \frac{i\sqrt{3}\left(\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1-12x}\right)^{\frac{1}{3}}}{6} - \frac{\cdots}{3\left(-8+108x^4+108c_1+10\cdots\right.}\right.}{2}$$

$$y = -\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1\cdots}\right.}{12} - \frac{1}{3\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c\cdots}\right.} - \frac{1}{3} - \frac{i\sqrt{3}\left(\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1-12x}\right)^{\frac{1}{3}}}{6} - \frac{\cdots}{3\left(-8+108x^4+108c_1+10\cdots\right.}\right.}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1-}\right.}{6} + \frac{2}{3\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c\right.} - \frac{1}{3} \tag{1}$$

$$y = -\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1}\right.}{12} - \frac{1}{3\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c\right.} - \frac{1}{3} + \frac{i\sqrt{3}\left(\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1-12x}\right)^{\frac{1}{3}}}{6} - \frac{}{3\left(-8+108x^4+108c_1+10\right.}\right.}{2} \tag{2}$$

$$y = -\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1}\right.}{12} - \frac{1}{3\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c\right.} - \frac{1}{3} - \frac{i\sqrt{3}\left(\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1-12x}\right)^{\frac{1}{3}}}{6} - \frac{}{3\left(-8+108x^4+108c_1+10\right.}\right.}{2} \tag{3}$$

$$y = -\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1}\right.}{12} - \frac{1}{3\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c}\right.} - \frac{1}{3} + \frac{i\sqrt{3}\left(\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1-12x}\right)^{\frac{1}{3}}}{6} - \frac{}{3\left(-8+108x^4+108c_1+10\right.}\right.}{2}$$

Verified OK.

$$y = -\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1}\right.}{12} - \frac{1}{3\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c}\right.} - \frac{1}{3} - \frac{i\sqrt{3}\left(\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1-12x}\right)^{\frac{1}{3}}}{6} - \frac{}{3\left(-8+108x^4+108c_1+10\right.}\right.}{2}$$

Verified OK.

6.7.2 Solving as differentialType ode

Writing the ode as

$$y' = \frac{4x^3 + 1}{y\,(2 + 3y)} \tag{1}$$

Which becomes

$$\left(3y^2 + 2y\right) dy = \left(4x^3 + 1\right) dx \tag{2}$$

But the RHS is complete differential because

$$\left(4x^3 + 1\right) dx = d\left(x^4 + x\right)$$

Hence (2) becomes

$$\left(3y^2 + 2y\right) dy = d\left(x^4 + x\right)$$

Integrating both sides gives gives these solutions

$$y = \frac{\left(-8 + 108x^4 + 108c_1 + 108x + 12\sqrt{81x^8 + 162c_1x^4 + 162x^5 - 12x^4 + 81c_1^2 + 162c_1x + 81x^2 - 12c_1}\right.}{6}$$

$$y = -\frac{\left(-8 + 108x^4 + 108c_1 + 108x + 12\sqrt{81x^8 + 162c_1x^4 + 162x^5 - 12x^4 + 81c_1^2 + 162c_1x + 81x^2 - 12c}\right.}{12}$$

$$y = -\frac{\left(-8 + 108x^4 + 108c_1 + 108x + 12\sqrt{81x^8 + 162c_1x^4 + 162x^5 - 12x^4 + 81c_1^2 + 162c_1x + 81x^2 - 12c}\right.}{12}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(-8 + 108x^4 + 108c_1 + 108x + 12\sqrt{81x^8 + 162c_1x^4 + 162x^5 - 12x^4 + 81c_1^2 + 162c_1x + 81x^2 - 12c_1 -}\right.}{6} + \frac{2}{3\left(-8 + 108x^4 + 108c_1 + 108x + 12\sqrt{81x^8 + 162c_1x^4 + 162x^5 - 12x^4 + 81c_1^2 + 162c_1x + 81x^2 - 12c}\right.} - \frac{1}{3} + c_1 \tag{1}$$

$$y = -\frac{\left(-8 + 108x^4 + 108c_1 + 108x + 12\sqrt{81x^8 + 162c_1x^4 + 162x^5 - 12x^4 + 81c_1^2 + 162c_1x + 81x^2 - 12c_1}\right.}{12} - \frac{1}{3\left(-8 + 108x^4 + 108c_1 + 108x + 12\sqrt{81x^8 + 162c_1x^4 + 162x^5 - 12x^4 + 81c_1^2 + 162c_1x + 81x^2 - 12c}\right.} - \frac{1}{3} + \frac{i\sqrt{3}\left(\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1-12x}\right)^{\frac{1}{3}}}{6} - \frac{}{3\left(-8+108x^4+108c_1+10\right.}\right.}{2} + c_1 \tag{2}$$

$$y = -\frac{\left(-8 + 108x^4 + 108c_1 + 108x + 12\sqrt{81x^8 + 162c_1x^4 + 162x^5 - 12x^4 + 81c_1^2 + 162c_1x + 81x^2 - 12c_1}\right.}{12} - \frac{1}{3\left(-8 + 108x^4 + 108c_1 + 108x + 12\sqrt{81x^8 + 162c_1x^4 + 162x^5 - 12x^4 + 81c_1^2 + 162c_1x + 81x^2 - 12c}\right.} - \frac{1}{3} - \frac{i\sqrt{3}\left(\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1-12x}\right)^{\frac{1}{3}}}{6} - \frac{}{3\left(-8+108x^4+108c_1+10\right.}\right.}{2} + c_1 \tag{3}$$

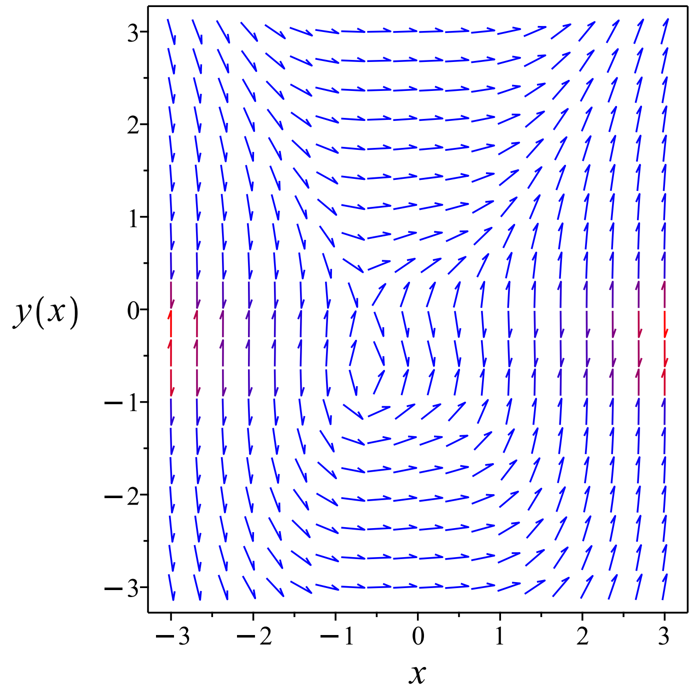

Figure 288: Slope field plot

Verification of solutions

$$y = \frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1-}\right.}{6} + \frac{2}{3\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c}\right.} - \frac{1}{3} + c_1$$

Verified OK.

$$y = -\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1}\right.}{12} - \frac{1}{3\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c}\right.} - \frac{1}{3} - \frac{i\sqrt{3}\left(\frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1-12x}\right)^{\frac{1}{3}}}{6} - \frac{}{3\left(-8+108x^4+108c_1+10\right.}\right.}{2} + c_1$$

Verified OK.

6.7.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{4x^3+1}{y(2+3y)} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 272: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a+bx+cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= \frac{1}{4x^3+1} \\
\eta(x, y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{\frac{1}{4x^3+1}} dx
\end{aligned}
$$

Which results in

$$
S = x^4 + x
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$
\omega(x, y) = \frac{4x^3+1}{y\,(2+3y)}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= 4x^3 + 1 \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = 3y^2 + 2y \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = 3R^2 + 2R
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = R^3 + R^2 + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
x^4 + x = y^3 + y^2 + c_1
$$

Which simplifies to

$$
x^4 + x = y^3 + y^2 + c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{4x^3+1}{y(2+3y)}$ 	$R = y$ $S = x^4 + x$	$\frac{dS}{dR} = 3R^2 + 2R$ 
Summary

The solution(s) found are the following

$$x^4 + x = y^3 + y^2 + c_1 \tag{1}$$

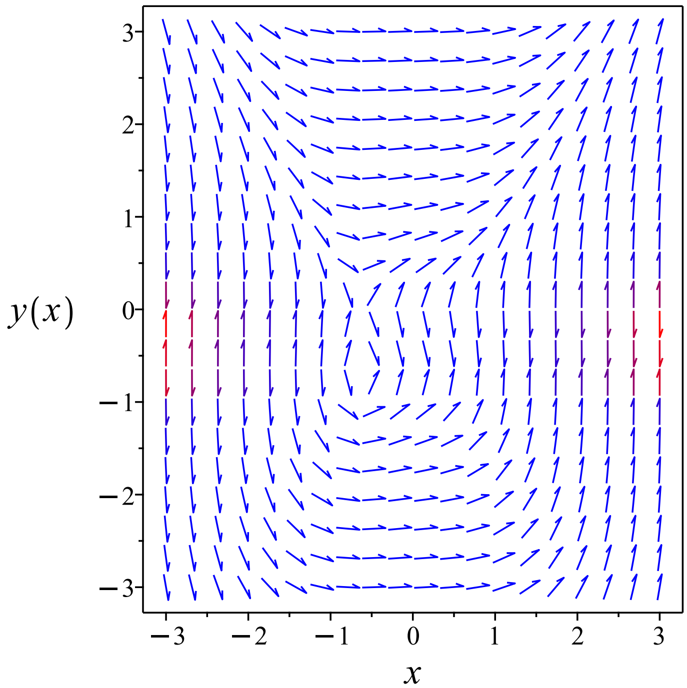

Figure 289: Slope field plot

Verification of solutions

$$x^4 + x = y^3 + y^2 + c_1$$

Verified OK.

6.7.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(y(2 + 3y))\,\mathrm{d}y = \left(4x^3 + 1\right)\mathrm{d}x$$
$$\left(-4x^3 - 1\right)\mathrm{d}x + (y(2 + 3y))\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -4x^3 - 1$$
$$N(x, y) = y(2 + 3y)$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-4x^3 - 1\right)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(y(2 + 3y))\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -4x^3 - 1 \, \mathrm{d}x$$

$$\phi = -x^4 - x + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y(2 + 3y)$. Therefore equation (4) becomes

$$y(2 + 3y) = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = y(2 + 3y)$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (3y^2 + 2y) \, \mathrm{d}y$$

$$f(y) = y^3 + y^2 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -x^4 + y^3 + y^2 - x + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x^4 + y^3 + y^2 - x$$

Summary
The solution(s) found are the following

$$y^3 + y^2 - x^4 - x = c_1 \tag{1}$$

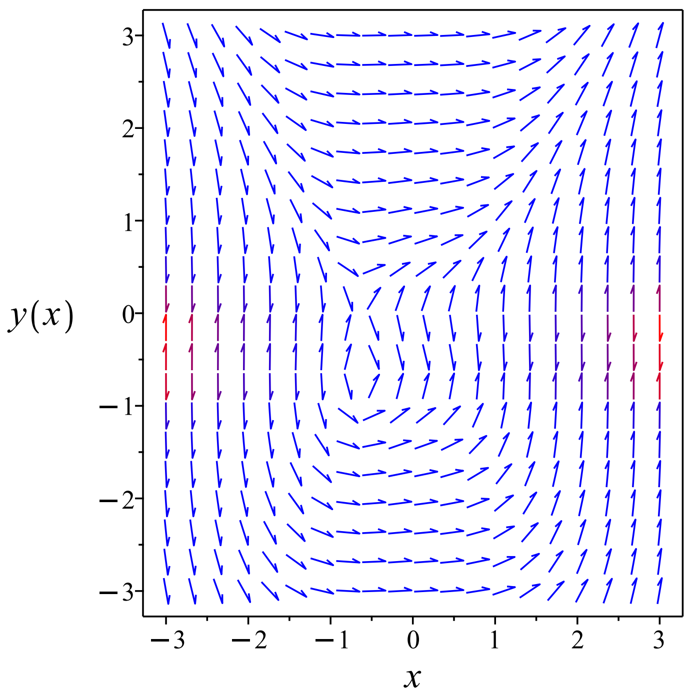

Figure 290: Slope field plot

Verification of solutions

$$y^3 + y^2 - x^4 - x = c_1$$

Verified OK.

6.7.5 Maple step by step solution

Let's solve

$y' - \frac{4x^3+1}{y(2+3y)} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $y'y(2+3y) = 4x^3+1$

- Integrate both sides with respect to x

  $\int y'y(2+3y)\,dx = \int (4x^3+1)\,dx + c_1$

- Evaluate integral

  $y^3+y^2 = x^4+c_1+x$

- Solve for y

  $y = \frac{\left(-8+108x^4+108c_1+108x+12\sqrt{81x^8+162c_1x^4+162x^5-12x^4+81c_1^2+162c_1x+81x^2-12c_1-12x}\right)^{\frac{1}{3}}}{6} + \frac{}{3\left(-8+108x^4+108c_1+10\right.}$

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{2y + y'x = \frac{\sin(x)}{x}}$$

With initial conditions

$$[y(2) = 1]$$

6.8.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{2}{x}$$
$$q(x) = \frac{\sin(x)}{x^2}$$

Hence the ode is

$$y' + \frac{2y}{x} = \frac{\sin(x)}{x^2}$$

The domain of $p(x) = \frac{2}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 2$ is inside this domain. The domain of $q(x) = \frac{\sin(x)}{x^2}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 2$ is also inside this domain. Hence solution exists and is unique.

6.8.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{2}{x} dx} \\ &= x^2\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{\sin(x)}{x^2}\right) \\ \frac{d}{dx}\left(y\,x^2\right) &= \left(x^2\right)\left(\frac{\sin(x)}{x^2}\right) \\ d\left(y\,x^2\right) &= \sin(x)\,dx\end{aligned}$$

Integrating gives

$$\begin{aligned}y\,x^2 &= \int \sin(x)\,dx \\ y\,x^2 &= -\cos(x) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = x^2$ results in

$$y = -\frac{\cos(x)}{x^2} + \frac{c_1}{x^2}$$

which simplifies to

$$y = \frac{-\cos(x) + c_1}{x^2}$$

Initial conditions are used to solve for c_1. Substituting $x = 2$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{\cos(2)}{4} + \frac{c_1}{4}$$

$$c_1 = \cos(2) + 4$$

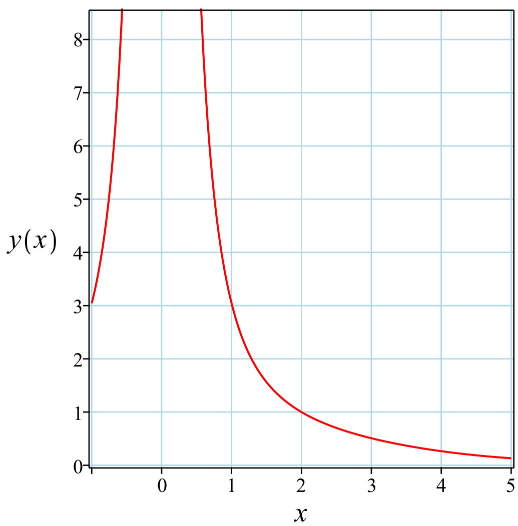
Substituting c_1 found above in the general solution gives

$$y = -\frac{\cos(x) - 4 - \cos(2)}{x^2}$$

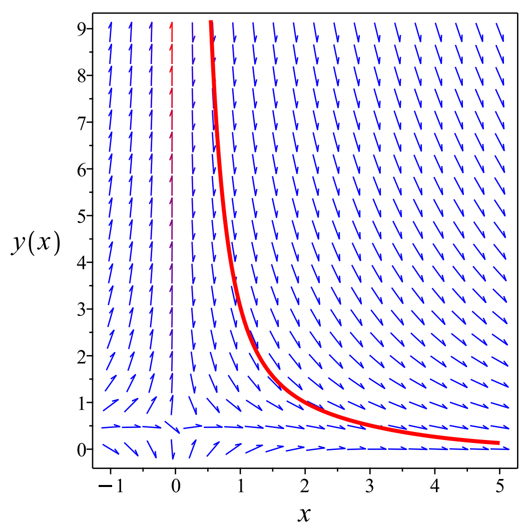
Summary

The solution(s) found are the following

$$y = -\frac{\cos(x) - 4 - \cos(2)}{x^2} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -\frac{\cos(x) - 4 - \cos(2)}{x^2}$$

Verified OK.

6.8.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{-2yx + \sin(x)}{x^2}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 275: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \frac{1}{x^2}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{1}{x^2}} dy
\end{aligned}
$$

Which results in

$$
S = y\,x^2
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = \frac{-2yx + \sin(x)}{x^2}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= 2yx \\
S_y &= x^2
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \sin(x) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \sin(R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\cos(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$x^2 y = -\cos(x) + c_1$$

Which simplifies to

$$x^2 y = -\cos(x) + c_1$$

Which gives

$$y = -\frac{\cos(x) - c_1}{x^2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{-2yx+\sin(x)}{x^2}$ 	$R = x$ $S = y\,x^2$	$\frac{dS}{dR} = \sin(R)$ 
Initial conditions are used to solve for c_1. Substituting $x = 2$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{\cos(2)}{4} + \frac{c_1}{4}$$

$$c_1 = \cos(2) + 4$$

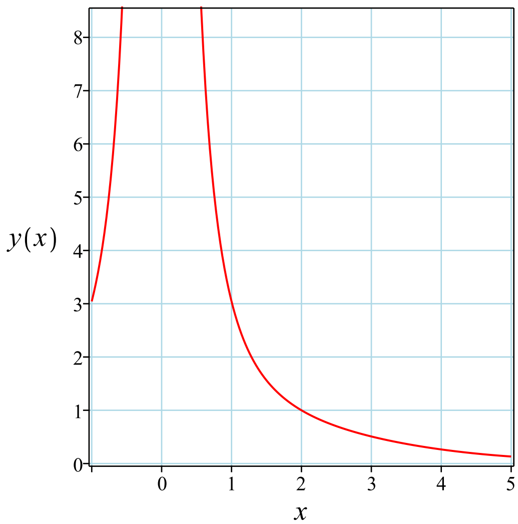
Substituting c_1 found above in the general solution gives

$$y = -\frac{\cos(x) - 4 - \cos(2)}{x^2}$$

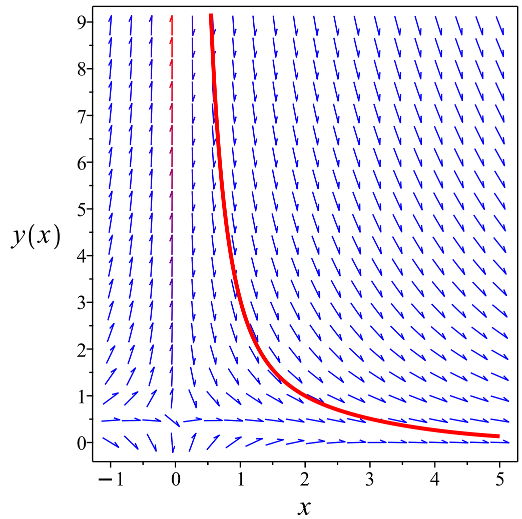
Summary

The solution(s) found are the following

$$y = -\frac{\cos(x) - 4 - \cos(2)}{x^2} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -\frac{\cos(x) - 4 - \cos(2)}{x^2}$$

Verified OK.

6.8.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(x^2)\,\mathrm{d}y &= (-2yx + \sin(x))\,\mathrm{d}x\\ (2yx - \sin(x))\,\mathrm{d}x + (x^2)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= 2yx - \sin(x)\\ N(x, y) &= x^2\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(2yx - \sin(x))\\ &= 2x\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x^2)\\ &= 2x\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int 2yx - \sin(x) \mathrm{d}x$$
$$\phi = y\,x^2 + \cos(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x^2 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x^2$. Therefore equation (4) becomes

$$x^2 = x^2 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = y\,x^2 + \cos(x) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = y\,x^2 + \cos(x)$$

The solution becomes

$$y = -\frac{\cos(x) - c_1}{x^2}$$

Initial conditions are used to solve for c_1. Substituting $x = 2$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{\cos(2)}{4} + \frac{c_1}{4}$$

$$c_1 = \cos(2) + 4$$

Substituting c_1 found above in the general solution gives

$$y = -\frac{\cos(x) - 4 - \cos(2)}{x^2}$$

Summary

The solution(s) found are the following

$$y = -\frac{\cos(x) - 4 - \cos(2)}{x^2} \tag{1}$$

6.8.5 Maple step by step solution

Let's solve

$\left[2y+y'x=\frac{\sin(x)}{x}, y(2)=1\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y'=-\frac{2y}{x}+\frac{\sin(x)}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y'+\frac{2y}{x}=\frac{\sin(x)}{x^2}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y'+\frac{2y}{x}\right)=\frac{\mu(x)\sin(x)}{x^2}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y'+\frac{2y}{x}\right)=\mu'(x)\,y+\mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x)=\frac{2\mu(x)}{x}$

- Solve to find the integrating factor

  $\mu(x)=x^2$

- Integrate both sides with respect to x

  $\int\left(\frac{d}{dx}(\mu(x)\,y)\right)dx=\int\frac{\mu(x)\sin(x)}{x^2}dx+c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y=\int\frac{\mu(x)\sin(x)}{x^2}dx+c_1$

- Solve for y

  $y=\frac{\int\frac{\mu(x)\sin(x)}{x^2}dx+c_1}{\mu(x)}$

- Substitute $\mu(x)=x^2$

  $y=\frac{\int\sin(x)dx+c_1}{x^2}$

- Evaluate the integrals on the rhs

  $y=\frac{-\cos(x)+c_1}{x^2}$

- Use initial condition $y(2)=1$

$$1 = -\frac{\cos(2)}{4} + \frac{c_1}{4}$$

- Solve for c_1

$$c_1 = \cos(2) + 4$$

- Substitute $c_1 = \cos(2) + 4$ into general solution and simplify

$$y = \frac{-\cos(x) + 4 + \cos(2)}{x^2}$$

- Solution to the IVP

$$y = \frac{-\cos(x) + 4 + \cos(2)}{x^2}$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "differentialType"**

Maple gives the following as the ode type

```
[_rational, [_1st_order, `_with_symmetry_[F(x),G(x)]`], [_Abel,
    `2nd type`, `class A`]]
```

$$\boxed{y' - \frac{-1 - 2yx}{x^2 + 2y} = 0}$$

6.9.1 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-1 - 2yx}{x^2 + 2y} \tag{1}$$

Which becomes

$$(2y)\, dy = \left(-x^2\right) dy + \left(-2yx - 1\right) dx \tag{2}$$

But the RHS is complete differential because

$$\left(-x^2\right) dy + \left(-2yx - 1\right) dx = d\left(-y\, x^2 - x\right)$$

Hence (2) becomes

$$(2y)\, dy = d\left(-y\, x^2 - x\right)$$

Integrating both sides gives gives these solutions

$$y = -\frac{x^2}{2} + \frac{\sqrt{x^4 + 4c_1 - 4x}}{2} + c_1$$
$$y = -\frac{x^2}{2} - \frac{\sqrt{x^4 + 4c_1 - 4x}}{2} + c_1$$

Summary

The solution(s) found are the following

$$y = -\frac{x^2}{2} + \frac{\sqrt{x^4 + 4c_1 - 4x}}{2} + c_1 \tag{1}$$
$$y = -\frac{x^2}{2} - \frac{\sqrt{x^4 + 4c_1 - 4x}}{2} + c_1 \tag{2}$$

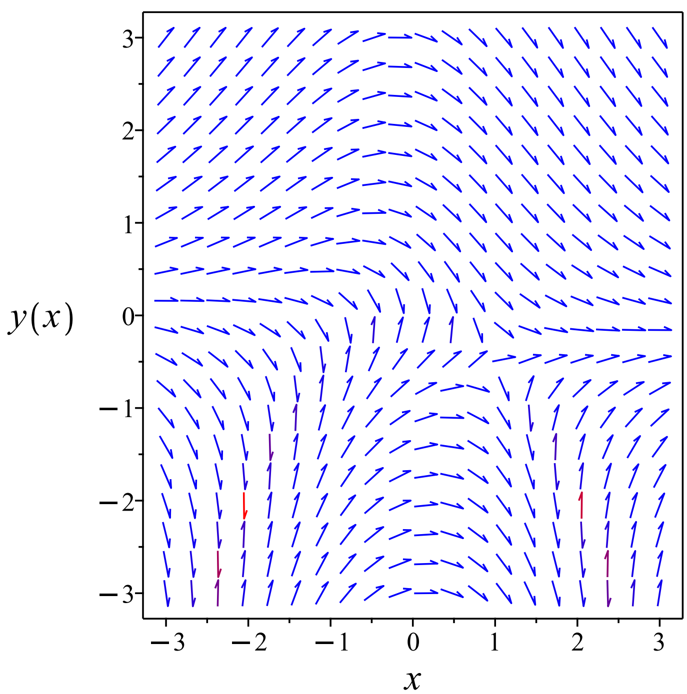

Figure 294: Slope field plot

Verification of solutions

$$y = -\frac{x^2}{2} + \frac{\sqrt{x^4 + 4c_1 - 4x}}{2} + c_1$$

Verified OK.

$$y = -\frac{x^2}{2} - \frac{\sqrt{x^4 + 4c_1 - 4x}}{2} + c_1$$

Verified OK.

6.9.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$
\begin{aligned}
\left(x^{2}+2y\right) \mathrm{d}y &= (-2yx-1) \mathrm{d}x \\
(2yx+1) \mathrm{d}x+\left(x^{2}+2y\right) \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x,y) &= 2yx+1 \\
N(x,y) &= x^{2}+2y
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(2yx+1) \\
&= 2x
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(x^{2}+2y\right) \\
&= 2x
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \qquad (1) \\
\frac{\partial \phi}{\partial y} &= N \qquad (2)
\end{aligned}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int M \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int 2yx+1 \mathrm{d}x \\
\phi &= y\,x^{2}+x+f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x^2 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x^2 + 2y$. Therefore equation (4) becomes

$$x^2 + 2y = x^2 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 2y$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (2y)\,\mathrm{d}y$$
$$f(y) = y^2 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = y\,x^2 + y^2 + x + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = y\,x^2 + y^2 + x$$

Summary

The solution(s) found are the following

$$x^2y + y^2 + x = c_1 \tag{1}$$

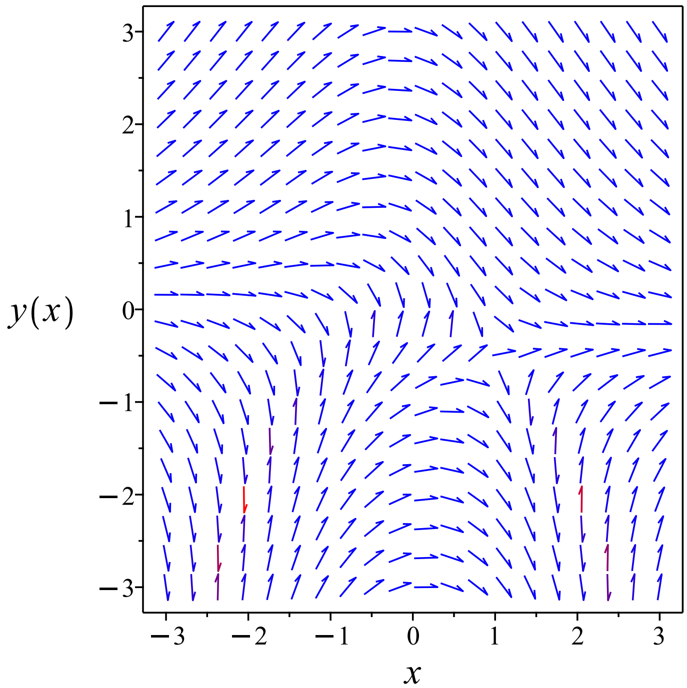

Figure 295: Slope field plot

Verification of solutions

$$x^2y + y^2 + x = c_1$$

Verified OK.

Problem number: 10.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{\frac{yy'}{y-2} = -\frac{-x^2+x+1}{x^2}}$$

6.10.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}
y' &= F(x,y) \\
&= f(x)g(y) \\
&= \frac{(x^2-x-1)(y-2)}{y\,x^2}
\end{aligned}$$

Where $f(x) = \frac{x^2-x-1}{x^2}$ and $g(y) = \frac{y-2}{y}$. Integrating both sides gives

$$\frac{1}{\frac{y-2}{y}}\,dy = \frac{x^2-x-1}{x^2}\,dx$$

$$\int \frac{1}{\frac{y-2}{y}}\, dy = \int \frac{x^2 - x - 1}{x^2}\, dx$$

$$y + 2\ln(y-2) = x - \ln(x) + \frac{1}{x} + c_1$$

Which results in

$$y = \mathrm{e}^{-\frac{x\ln(x) + 2\,\mathrm{LambertW}\left(\frac{\mathrm{e}^{-\frac{-1 - c_1 x - x^2 + x\ln(x) + 2x}{2x}}}{2}\right)x - c_1 x - x^2 + 2x - 1}{2x}} + 2$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\frac{x\ln(x) + 2\,\mathrm{LambertW}\left(\frac{\mathrm{e}^{-\frac{-1 - c_1 x - x^2 + x\ln(x) + 2x}{2x}}}{2}\right)x - c_1 x - x^2 + 2x - 1}{2x}} + 2 \tag{1}$$

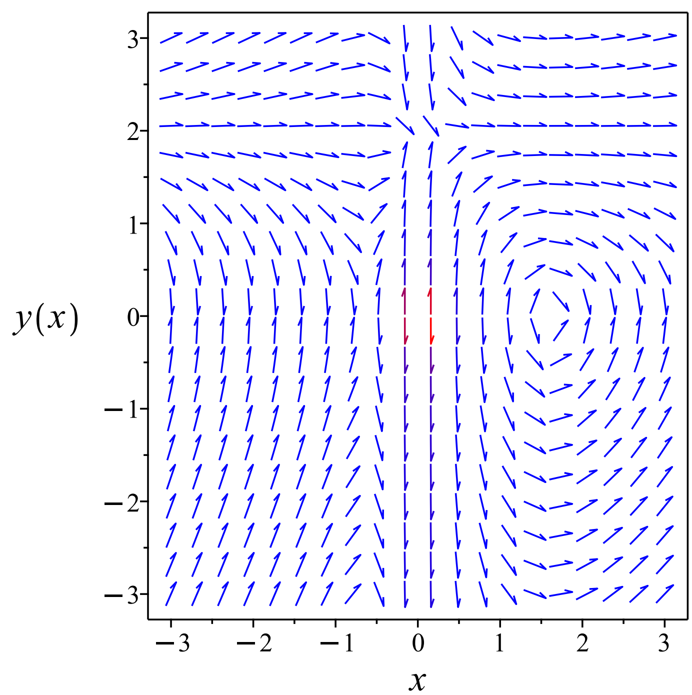

Figure 296: Slope field plot

Verification of solutions

$$
y = \mathrm{e}^{-\frac{x\ln(x)+2\,\mathrm{LambertW}\left(\frac{\mathrm{e}^{-\frac{-1-c_1x-x^2+x\ln(x)+2x}{2x}}}{2}\right)x-c_1x-x^2+2x-1}{2x}}+2
$$

Verified OK.

6.10.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{y\,x^2-2x^2-yx+2x-y+2}{y\,x^2} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ,η

Table 278: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int(n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,y) &= \frac{x^2}{x^2 - x - 1}\\ \eta(x,y) &= 0 \end{aligned}\tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{x^2}{x^2-x-1}} dx \end{aligned}$$

Which results in

$$S = x - \ln(x) + \frac{1}{x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y\,x^2 - 2x^2 - yx + 2x - y + 2}{y\,x^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= \frac{x^2 - x - 1}{x^2} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{y}{y-2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{R}{R-2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = R + 2\ln(R-2) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{-x\ln(x) + x^2 + 1}{x} = y + 2\ln(y-2) + c_1$$

Which simplifies to

$$\frac{-x\ln(x) + x^2 + 1}{x} = y + 2\ln(y-2) + c_1$$

Which gives

$$y = 2\,\mathrm{LambertW}\left(\frac{\mathrm{e}^{-\frac{x\ln(x)+c_1x-x^2+2x-1}{2x}}}{2}\right) + 2$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y\,x^2-2x^2-yx+2x-y+2}{y\,x^2}$  	$R = y$ $S = \frac{-x\ln(x) + x^2 + 1}{x}$	$\frac{dS}{dR} = \frac{R}{R-2}$ 
Summary

The solution(s) found are the following

$$y = 2\,\mathrm{LambertW}\left(\frac{\mathrm{e}^{-\frac{x\ln(x)+c_1x-x^2+2x-1}{2x}}}{2}\right)+2 \tag{1}$$

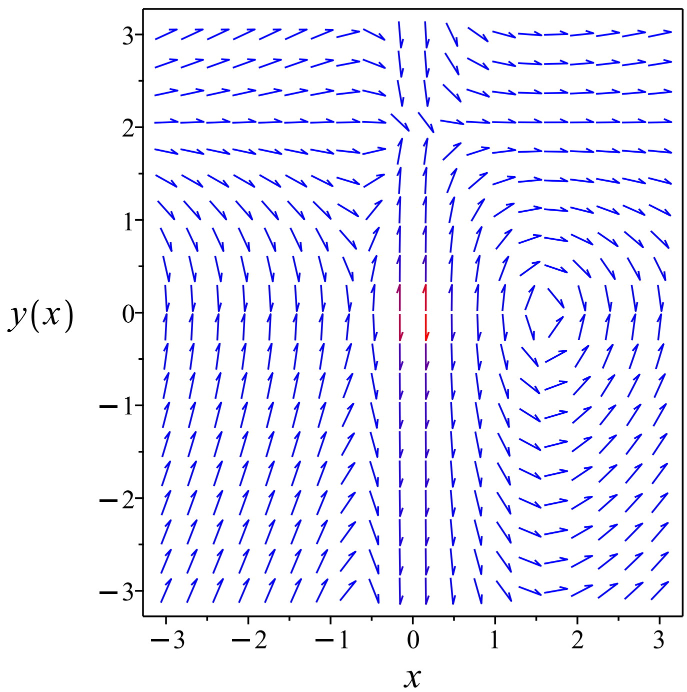

Figure 297: Slope field plot

$$y = 2\,\mathrm{LambertW}\left(\frac{\mathrm{e}^{-\frac{x\ln(x)+c_1x-x^2+2x-1}{2x}}}{2}\right)+2$$

Verified OK.

6.10.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\frac{y}{y-2}\right)\mathrm{d}y&=\left(\frac{x^2-x-1}{x^2}\right)\mathrm{d}x\\ \left(-\frac{x^2-x-1}{x^2}\right)\mathrm{d}x+\left(\frac{y}{y-2}\right)\mathrm{d}y&=0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -\frac{x^2-x-1}{x^2}\\ N(x,y) &= \frac{y}{y-2}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{x^2-x-1}{x^2}\right)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{y}{y-2}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int M\,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int -\frac{x^2-x-1}{x^2}\,\mathrm{d}x$$

$$\phi = -x + \ln(x) - \frac{1}{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = \frac{y}{y-2}$. Therefore equation (4) becomes

$$\frac{y}{y-2} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{y}{y-2}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{y}{y-2}\right) \mathrm{d}y$$
$$f(y) = y + 2\ln(y-2) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -x + \ln(x) - \frac{1}{x} + y + 2\ln(y-2) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x + \ln(x) - \frac{1}{x} + y + 2\ln(y-2)$$

The solution becomes

$$y = \mathrm{e}^{-\frac{x\ln(x)+2\,\mathrm{LambertW}\left(\frac{\mathrm{e}^{-\frac{-1-c_1x-x^2+x\ln(x)+2x}{2x}}}{2}\right)x-c_1x-x^2+2x-1}{2x}} + 2$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\frac{x\ln(x)+2\,\mathrm{LambertW}\left(\frac{\mathrm{e}^{-\frac{-1-c_1x-x^2+x\ln(x)+2x}{2x}}}{2}\right)x-c_1x-x^2+2x-1}{2x}} + 2 \tag{1}$$

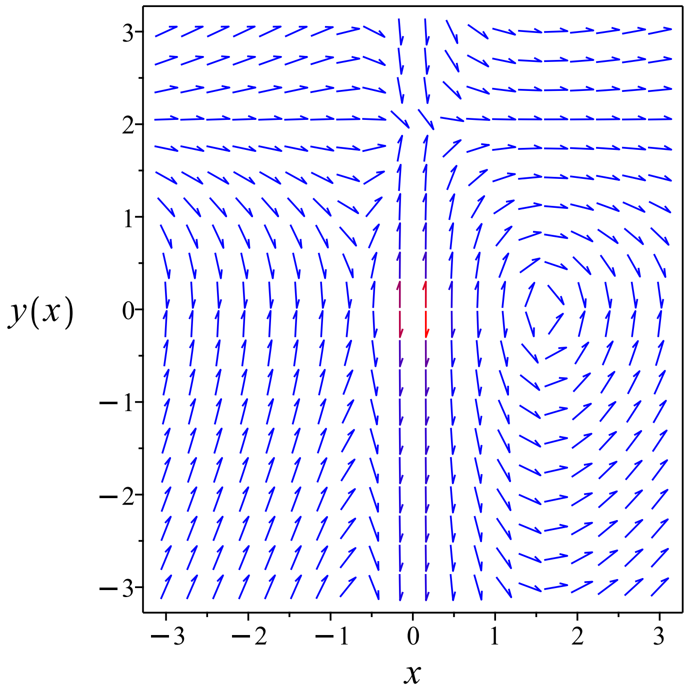

Figure 298: Slope field plot

Verification of solutions

$$y = \mathrm{e}^{-\frac{x \ln(x)+2 \,\mathrm{LambertW}\left(\frac{\mathrm{e}^{-\frac{-1-c_1 x-x^2+x \ln(x)+2x}{2x}}}{2}\right) x-c_1 x-x^2+2x-1}{2x}}+2$$

Verified OK.

6.10.4 Maple step by step solution

Let's solve

$\frac{yy'}{y-2} = -\frac{-x^2+x+1}{x^2}$

- Highest derivative means the order of the ODE is 1

  y'

- Integrate both sides with respect to x

  $\int \frac{yy'}{y-2}dx = \int -\frac{-x^2+x+1}{x^2}dx + c_1$

- Evaluate integral

  $y + 2\ln(y-2) = x - \ln(x) + \frac{1}{x} + c_1$

- Solve for y

$$y = \mathrm{e}^{-\frac{x\ln(x)+2\,LambertW\left(\frac{\mathrm{e}^{-\frac{-1-c_1x-x^2+x\ln(x)+2x}{2x}}}{2}\right)x-c_1x-x^2+2x-1}{2x}}+2$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "differentialType"**

Maple gives the following as the ode type

`[_exact]`

$$\boxed{y + (e^y + x)\, y' = -x^2}$$

6.11.1 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-x^2 - y}{e^y + x} \tag{1}$$

Which becomes

$$(e^y)\, dy = (-x)\, dy + \left(-x^2 - y\right) dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\, dy + \left(-x^2 - y\right) dx = d\left(-\frac{1}{3}x^3 - yx\right)$$

Hence (2) becomes

$$(e^y)\, dy = d\left(-\frac{1}{3}x^3 - yx\right)$$

Integrating both sides gives gives these solutions

$$y = -\operatorname{LambertW}\left(\frac{e^{\frac{-x^3+3c_1}{3x}}}{x}\right) + \frac{-x^3+3c_1}{3x} + c_1$$

Summary

The solution(s) found are the following

$$y = -\operatorname{LambertW}\left(\frac{e^{\frac{-x^3+3c_1}{3x}}}{x}\right) + \frac{-x^3+3c_1}{3x} + c_1 \tag{1}$$

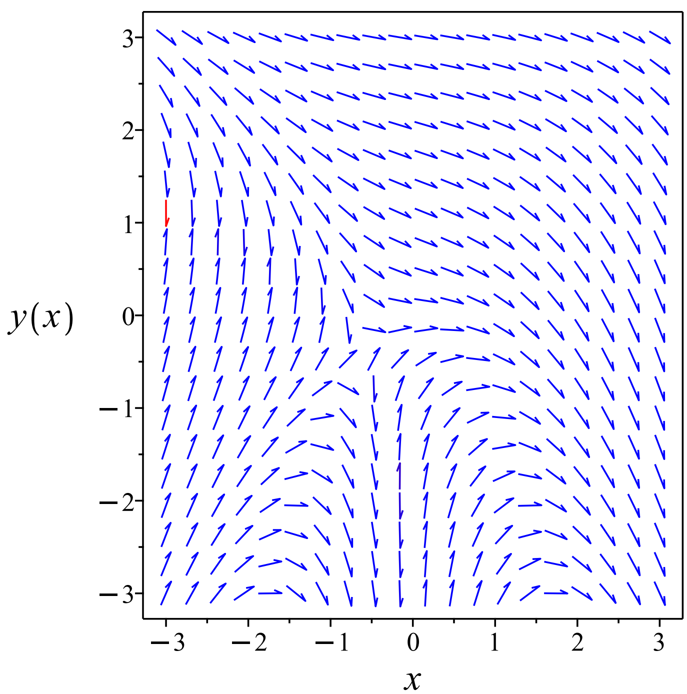

Figure 299: Slope field plot

Verification of solutions

$$y = -\operatorname{LambertW}\left(\frac{e^{\frac{-x^3+3c_1}{3x}}}{x}\right) + \frac{-x^3+3c_1}{3x} + c_1$$

Verified OK.

6.11.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(\mathrm{e}^y+x)\,\mathrm{d}y&=\left(-x^2-y\right)\mathrm{d}x\\ \left(x^2+y\right)\mathrm{d}x+(\mathrm{e}^y+x)\,\mathrm{d}y&=0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=x^2+y\\ N(x,y)&=\mathrm{e}^y+x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(x^2 + y)\\ &= 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(\mathrm{e}^y + x)\\ &= 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int x^2 + y \,\mathrm{d}x$$

$$\phi = \frac{1}{3}x^3 + yx + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^y + x$. Therefore equation (4) becomes

$$\mathrm{e}^y + x = x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = e^y$$

Integrating the above w.r.t y gives

$$\int f'(y)\, dy = \int (e^y)\, dy$$
$$f(y) = e^y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{x^3}{3} + yx + e^y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{x^3}{3} + yx + e^y$$

The solution becomes

$$y = -\operatorname{LambertW}\left(\frac{e^{\frac{-x^3+3c_1}{3x}}}{x}\right) + \frac{-x^3 + 3c_1}{3x}$$

<u>Summary</u>
The solution(s) found are the following

$$y = -\operatorname{LambertW}\left(\frac{e^{\frac{-x^3+3c_1}{3x}}}{x}\right) + \frac{-x^3 + 3c_1}{3x} \tag{1}$$

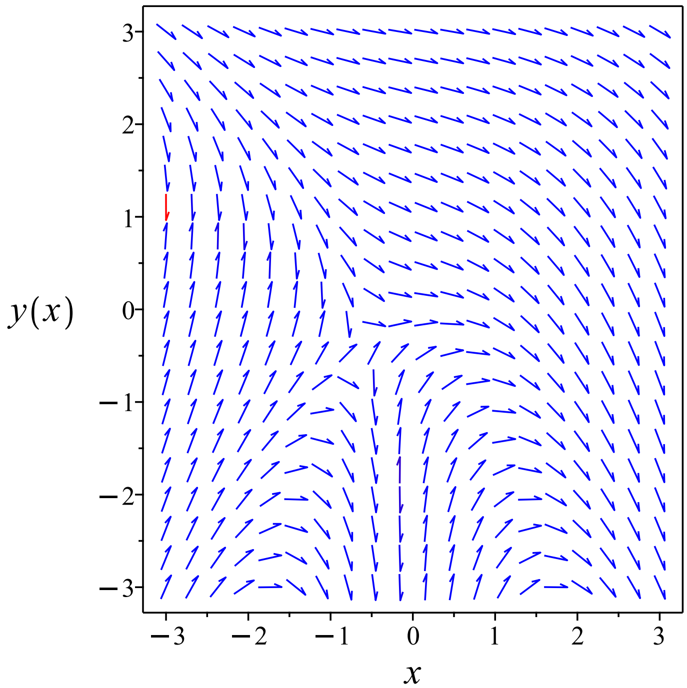

Figure 300: Slope field plot

Verification of solutions

$$y = -\operatorname{LambertW}\left(\frac{e^{\frac{-x^3+3c_1}{3x}}}{x}\right) + \frac{-x^3+3c_1}{3x}$$

Verified OK.

6.11.3 Maple step by step solution

Let's solve

$y + (e^y + x)\, y' = -x^2$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

  ◦ ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$

  ◦ Compute derivative of lhs

$F'(x,y)+\left(\frac{\partial}{\partial y}F(x,y)\right)y'=0$

- Evaluate derivatives

  $1=1$

- Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y)=c_1, M(x,y)=F'(x,y), N(x,y)=\frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y)=\int (x^2+y)\,dx+f_1(y)$

- Evaluate integral

  $F(x,y)=\frac{x^3}{3}+yx+f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y)=\frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $e^y+x=x+\frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y)=e^y$

- Solve for $f_1(y)$

  $f_1(y)=e^y$

- Substitute $f_1(y)$ into equation for $F(x,y)$

  $F(x,y)=\frac{x^3}{3}+yx+e^y$

- Substitute $F(x,y)$ into the solution of the ODE

  $\frac{x^3}{3}+yx+e^y=c_1$

- Solve for y

  $y=-LambertW\left(\frac{e^{\frac{-x^3+3c_1}{3x}}}{x}\right)+\frac{-x^3+3c_1}{3x}$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_linear]
```

$$\boxed{y' + y = \frac{1}{1 + e^{x}}}$$

6.12.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 1$$
$$q(x) = \frac{1}{1 + e^{x}}$$

Hence the ode is

$$y' + y = \frac{1}{1 + e^{x}}$$

The integrating factor μ is

$$\mu = e^{\int 1 dx}$$
$$= e^x$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{1}{1+e^x}\right)$$
$$\frac{d}{dx}(e^x y) = (e^x)\left(\frac{1}{1+e^x}\right)$$
$$d(e^x y) = \left(\frac{e^x}{1+e^x}\right) dx$$

Integrating gives

$$e^x y = \int \frac{e^x}{1+e^x} dx$$
$$e^x y = \ln(1+e^x) + c_1$$

Dividing both sides by the integrating factor $\mu = e^x$ results in

$$y = e^{-x}\ln(1+e^x) + c_1 e^{-x}$$

which simplifies to

$$y = e^{-x}(\ln(1+e^x) + c_1)$$

Summary

The solution(s) found are the following

$$y = e^{-x}(\ln(1+e^x) + c_1) \tag{1}$$

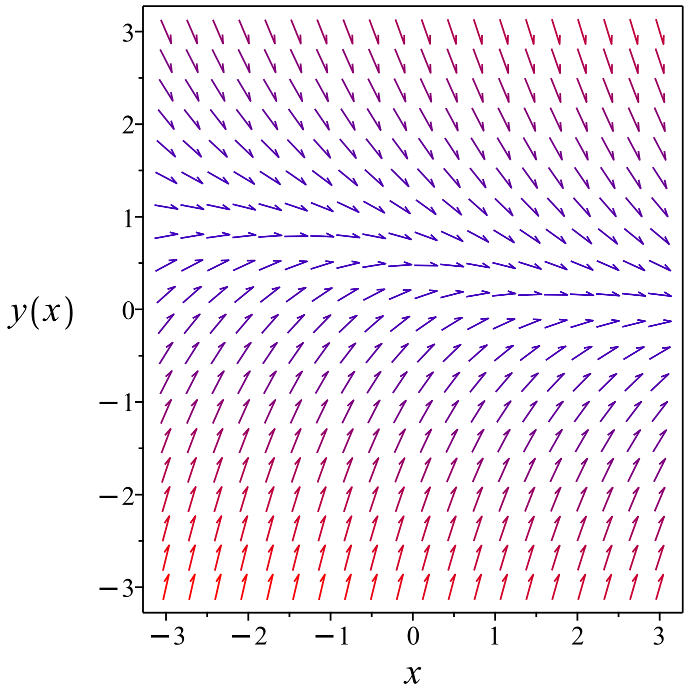

Figure 301: Slope field plot

Verification of solutions

$$y = e^{-x}(\ln(1 + e^x) + c_1)$$

Verified OK.

6.12.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{e^x y + y - 1}{1 + e^x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 282: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= e^{-x}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{-x}} dy \end{aligned}$$

Which results in

$$S = e^x y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{e^x y + y - 1}{1 + e^x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= e^x y \\ S_y &= e^x \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{e^x}{1 + e^x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{e^R}{1 + e^R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \ln\left(1 + e^{R}\right) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$e^{x} y = \ln\left(1 + e^{x}\right) + c_1$$

Which simplifies to

$$e^{x} y = \ln\left(1 + e^{x}\right) + c_1$$

Which gives

$$y = e^{-x}\left(\ln\left(1 + e^{x}\right) + c_1\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{e^{x} y + y - 1}{1 + e^{x}}$ 	$R = x$ $S = e^{x} y$	$\frac{dS}{dR} = \frac{e^{R}}{1 + e^{R}}$ 
Summary

The solution(s) found are the following

$$y = e^{-x}\left(\ln\left(1 + e^{x}\right) + c_1\right) \tag{1}$$

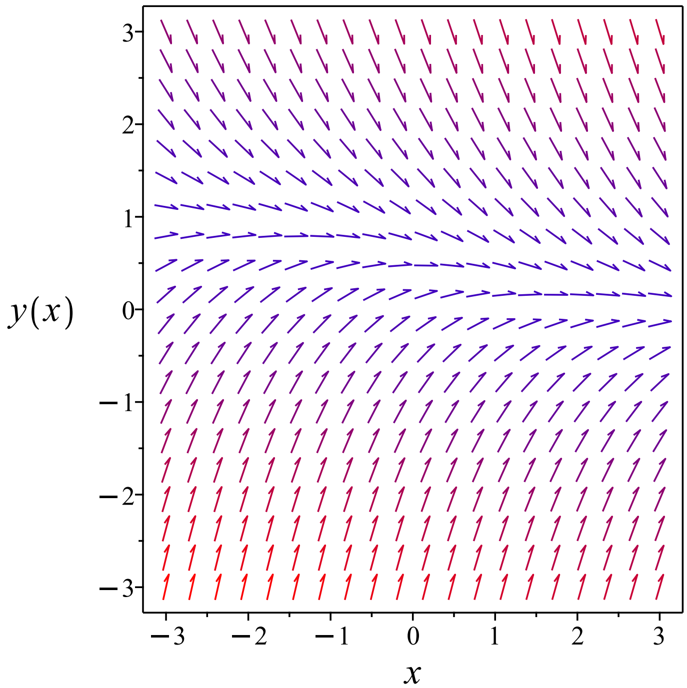

Figure 302: Slope field plot

Verification of solutions

$$y = e^{-x}(\ln(1 + e^x) + c_1)$$

Verified OK.

6.12.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = \left(-y + \frac{1}{1+\mathrm{e}^x}\right)\mathrm{d}x$$
$$\left(y - \frac{1}{1+\mathrm{e}^x}\right)\mathrm{d}x + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = y - \frac{1}{1+\mathrm{e}^x}$$
$$N(x,y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(y - \frac{1}{1+\mathrm{e}^x}\right)\\ &= 1\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1) \\
&= 0
\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= 1((1) - (0)) \\
&= 1
\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int A \,\mathrm{d}x} \\
&= e^{\int 1 \,\mathrm{d}x}
\end{aligned}$$

The result of integrating gives

$$\begin{aligned}
\mu &= e^{x} \\
&= \mathrm{e}^{x}
\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{x}\left(y - \frac{1}{1 + \mathrm{e}^{x}}\right) \\
&= \frac{\mathrm{e}^{x}(\mathrm{e}^{x} y + y - 1)}{1 + \mathrm{e}^{x}}
\end{aligned}$$

And

$$\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{x}(1) \\
&= \mathrm{e}^{x}
\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{\mathrm{e}^{x}(\mathrm{e}^{x} y + y - 1)}{1 + \mathrm{e}^{x}}\right) + (\mathrm{e}^{x})\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int \overline{M} \,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int \frac{\mathrm{e}^x(\mathrm{e}^x y + y - 1)}{1 + \mathrm{e}^x} \,\mathrm{d}x$$

$$\phi = \mathrm{e}^x y - \ln(1 + \mathrm{e}^x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^x$. Therefore equation (4) becomes

$$\mathrm{e}^x = \mathrm{e}^x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \mathrm{e}^x y - \ln(1 + \mathrm{e}^x) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \mathrm{e}^x y - \ln(1 + \mathrm{e}^x)$$

The solution becomes

$$y = \mathrm{e}^{-x}(\ln(1+\mathrm{e}^{x}) + c_1)$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-x}(\ln(1+\mathrm{e}^{x}) + c_1) \tag{1}$$

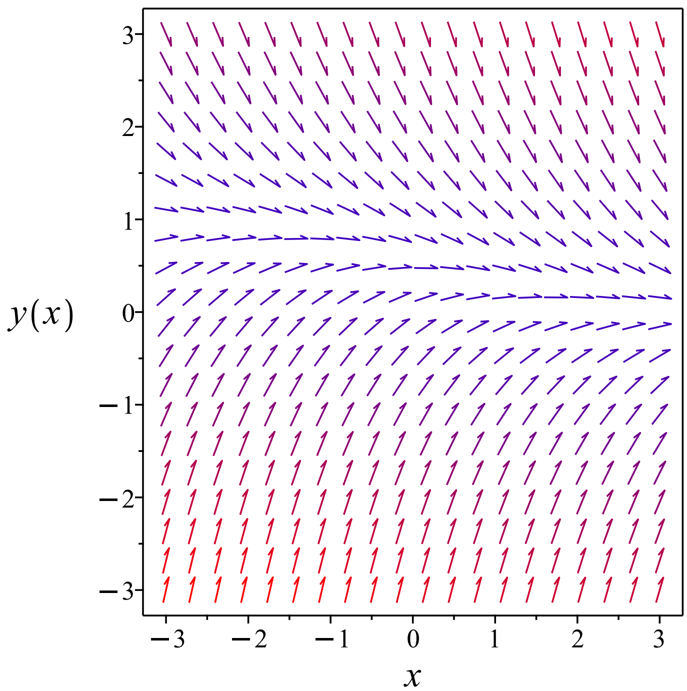

Figure 303: Slope field plot

Verification of solutions

$$y = \mathrm{e}^{-x}(\ln(1+\mathrm{e}^{x}) + c_1)$$

Verified OK.

6.12.4 Maple step by step solution

Let's solve

$y' + y = \frac{1}{1+e^x}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -y + \frac{1}{1+e^x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + y = \frac{1}{1+e^x}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' + y\right) = \frac{\mu(x)}{1+e^x}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\left(y' + y\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

  $\mu'(x) = \mu(x)$

- Solve to find the integrating factor

  $\mu(x) = e^x$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int \frac{\mu(x)}{1+e^x} dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\, y = \int \frac{\mu(x)}{1+e^x} dx + c_1$

- Solve for y

  $y = \frac{\int \frac{\mu(x)}{1+e^x} dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = e^x$

  $y = \frac{\int \frac{e^x}{1+e^x} dx + c_1}{e^x}$

- Evaluate the integrals on the rhs

  $y = \frac{\ln(1+e^x) + c_1}{e^x}$

- Simplify

$$y = e^{-x}(\ln(1 + e^x) + c_1)$$

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Miscellaneous problems, end of chapter 2. Page 133
Problem number: 13.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "riccati", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - y^2 - 2x y^2 = 1 + 2x}$$

6.13.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= (y^2+1)(1+2x) \end{aligned}$$

Where $f(x) = 1 + 2x$ and $g(y) = y^2 + 1$. Integrating both sides gives

$$\frac{1}{y^2+1}\,dy = 1 + 2x\,dx$$

$$\int \frac{1}{y^2+1}\,dy = \int 1 + 2x\,dx$$

$$\arctan(y) = x^2 + c_1 + x$$

Which results in

$$y = \tan\left(x^2 + c_1 + x\right)$$

Summary

The solution(s) found are the following

$$y = \tan\left(x^2 + c_1 + x\right) \tag{1}$$

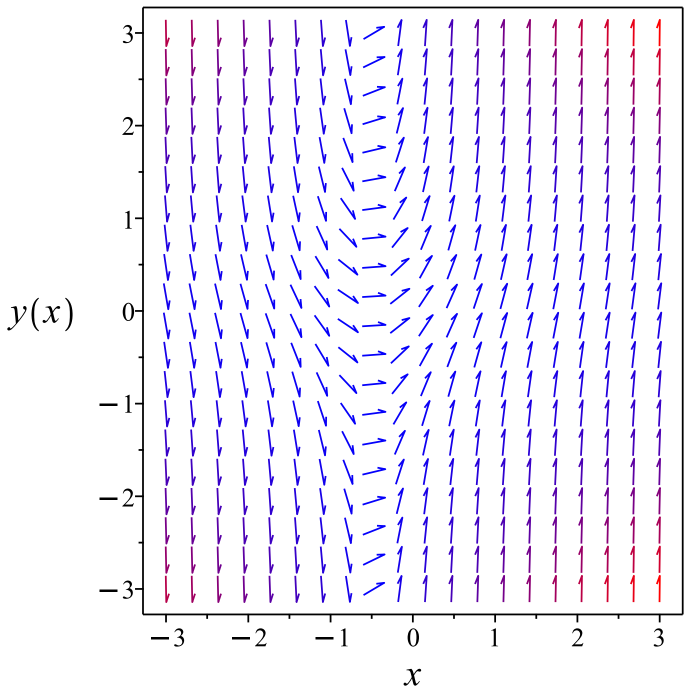

Figure 304: Slope field plot

Verification of solutions

$$y = \tan\left(x^2 + c_1 + x\right)$$

Verified OK.

6.13.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= 2x\,y^2 + y^2 + 2x + 1 \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 285: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= \frac{1}{1+2x} \\
\eta(x,y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{\frac{1}{1+2x}} dx
\end{aligned}
$$

Which results in

$$
S = x^2 + x
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = 2x\,y^2 + y^2 + 2x + 1
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= 1 + 2x \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{y^2 + 1} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R^2 + 1}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \arctan(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$x^2 + x = \arctan(y) + c_1$$

Which simplifies to

$$x^2 + x = \arctan(y) + c_1$$

Which gives

$$y = -\tan\left(-x^2 + c_1 - x\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = 2x\,y^2 + y^2 + 2x + 1$ 	$R = y$ $S = x^2 + x$	$\frac{dS}{dR} = \frac{1}{R^2+1}$ 
Summary

The solution(s) found are the following

$$y = -\tan\left(-x^2 + c_1 - x\right) \tag{1}$$

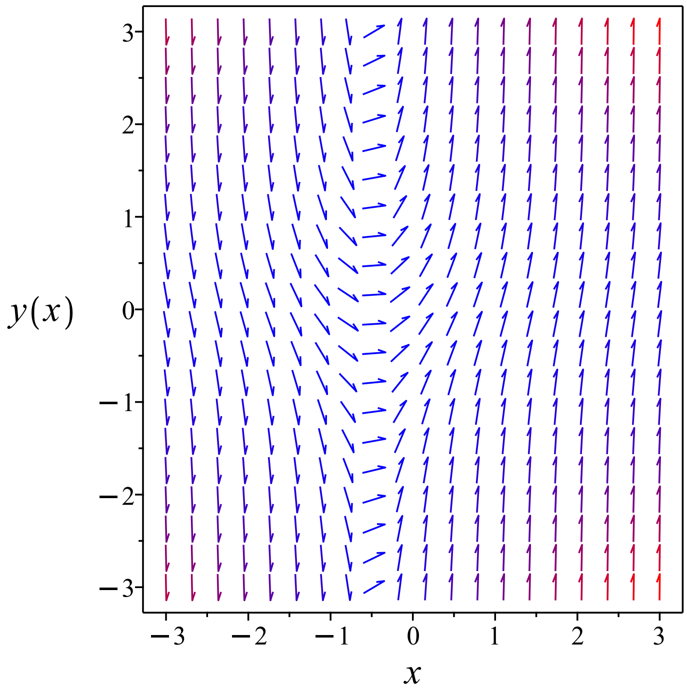

Figure 305: Slope field plot

Verification of solutions

$$y = -\tan\left(-x^2 + c_1 - x\right)$$

Verified OK.

6.13.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{y^2+1}\right)\mathrm{d}y = (1+2x)\,\mathrm{d}x$$
$$(-1-2x)\,\mathrm{d}x + \left(\frac{1}{y^2+1}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = -1-2x$$
$$N(x,y) = \frac{1}{y^2+1}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-1-2x)\\ &= 0\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{y^2+1}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$
\begin{align}
\frac{\partial \phi}{\partial x} &= M \tag{1} \\
\frac{\partial \phi}{\partial y} &= N \tag{2}
\end{align}
$$

Integrating (1) w.r.t. x gives

$$
\begin{align}
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int M \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int -1 - 2x \mathrm{d}x \\
\phi &= -x^2 - x + f(y) \tag{3}
\end{align}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y^2+1}$. Therefore equation (4) becomes

$$
\frac{1}{y^2+1} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{y^2+1}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \mathrm{d}y &= \int \left(\frac{1}{y^2+1}\right) \mathrm{d}y \\
f(y) &= \arctan(y) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -x^2 - x + \arctan(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x^2 - x + \arctan(y)$$

The solution becomes

$$y = \tan(x^2 + c_1 + x)$$

Summary

The solution(s) found are the following

$$y = \tan(x^2 + c_1 + x) \tag{1}$$

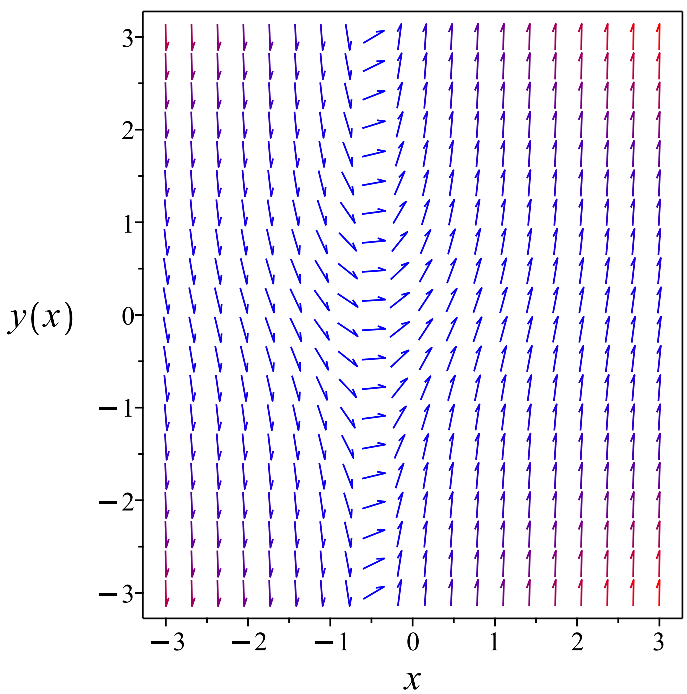

Figure 306: Slope field plot

Verification of solutions

$$y = \tan(x^2 + c_1 + x)$$

Verified OK.

6.13.4 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= 2x\,y^2 + y^2 + 2x + 1 \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = 2x\,y^2 + y^2 + 2x + 1$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 1 + 2x$, $f_1(x) = 0$ and $f_2(x) = 1 + 2x$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{(1+2x)\,u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\,u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 2 \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= (1+2x)^3 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$(1+2x)\,u''(x) - 2u'(x) + (1+2x)^3\,u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = c_1 \sin\left(x^2 + x\right) + c_2 \cos\left(x^2 + x\right)$$

The above shows that

$$u'(x) = (1+2x)\left(c_1 \cos\left(x^2 + x\right) - c_2 \sin\left(x^2 + x\right)\right)$$

Using the above in (1) gives the solution

$$y = -\frac{c_1 \cos(x^2 + x) - c_2 \sin(x^2 + x)}{c_1 \sin(x^2 + x) + c_2 \cos(x^2 + x)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{-c_3 \cos(x^2 + x) + \sin(x^2 + x)}{c_3 \sin(x^2 + x) + \cos(x^2 + x)}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \frac{-c_3 \cos(x^2 + x) + \sin(x^2 + x)}{c_3 \sin(x^2 + x) + \cos(x^2 + x)} \tag{1}$$

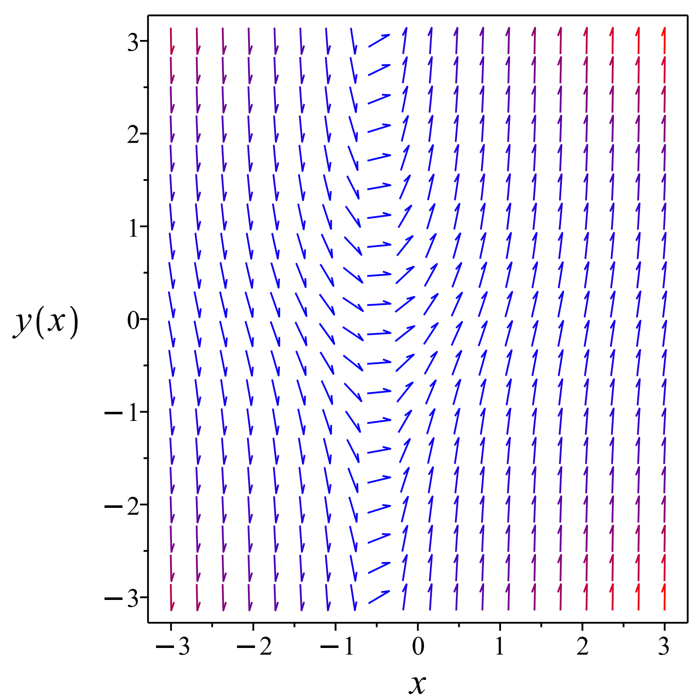

Figure 307: Slope field plot

<u>Verification of solutions</u>

$$y = \frac{-c_3 \cos(x^2 + x) + \sin(x^2 + x)}{c_3 \sin(x^2 + x) + \cos(x^2 + x)}$$

Verified OK.

6.13.5 Maple step by step solution

Let's solve

$y' - y^2 - 2xy^2 = 1 + 2x$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{1+y^2} = 1 + 2x$

- Integrate both sides with respect to x

  $\int \frac{y'}{1+y^2}dx = \int (1 + 2x)\, dx + c_1$

- Evaluate integral

  $\arctan(y) = x^2 + c_1 + x$

- Solve for y

  $y = \tan(x^2 + c_1 + x)$

The type(s) of ODE detected by this program : **"exact", "differentialType", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _exact, _rational, [_Abel, `2nd
   type`, `class A`]]
```

$$\boxed{y + (x + 2y)\, y' = -x}$$

With initial conditions

$$[y(2) = 3]$$

6.14.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= -\frac{x + y}{x + 2y} \end{aligned}$$

The x domain of $f(x,y)$ when $y=3$ is

$$\{x<-6\vee -6<x\}$$

And the point $x_0=2$ is inside this domain. The y domain of $f(x,y)$ when $x=2$ is

$$\{y<-1\vee -1<y\}$$

And the point $y_0=3$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y}&=\frac{\partial}{\partial y}\left(-\frac{x+y}{x+2y}\right)\\&=-\frac{1}{x+2y}+\frac{2x+2y}{(x+2y)^2}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y=3$ is

$$\{x<-6\vee -6<x\}$$

And the point $x_0=2$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x=2$ is

$$\{y<-1\vee -1<y\}$$

And the point $y_0=3$ is inside this domain. Therefore solution exists and is unique.

6.14.2 Solving as homogeneousTypeD2 ode

Using the change of variables $y=u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u(x)\,x+(x+2u(x)\,x)\,(u'(x)\,x+u(x))=-x$$

In canonical form the ODE is

$$\begin{aligned}u'&=F(x,u)\\&=f(x)g(u)\\&=-\frac{2u^2+2u+1}{x\,(2u+1)}\end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{2u^2+2u+1}{2u+1}$. Integrating both sides gives

$$\frac{1}{\frac{2u^2+2u+1}{2u+1}}\,du = -\frac{1}{x}\,dx$$

$$\int \frac{1}{\frac{2u^2+2u+1}{2u+1}}\,du = \int -\frac{1}{x}\,dx$$

$$\frac{\ln(2u^2+2u+1)}{2} = -\ln(x) + c_2$$

Raising both side to exponential gives

$$\sqrt{2u^2+2u+1} = \mathrm{e}^{-\ln(x)+c_2}$$

Which simplifies to

$$\sqrt{2u^2+2u+1} = \frac{c_3}{x}$$

Which simplifies to

$$\sqrt{2u(x)^2+2u(x)+1} = \frac{c_3\mathrm{e}^{c_2}}{x}$$

The solution is

$$\sqrt{2u(x)^2+2u(x)+1} = \frac{c_3\mathrm{e}^{c_2}}{x}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\sqrt{\frac{2y^2}{x^2}+\frac{2y}{x}+1} = \frac{c_3\mathrm{e}^{c_2}}{x}$$

$$\sqrt{\frac{2y^2+2yx+x^2}{x^2}} = \frac{c_3\mathrm{e}^{c_2}}{x}$$

Substituting initial conditions and solving for c_2 gives $c_2 = \frac{\ln\left(\frac{34}{c_3^2}\right)}{2}$. Hence the solution becomes Initial conditions are used to solve for c_3. Substituting $x = 2$ and $y = 3$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{\sqrt{34}}{2} = \frac{c_3\sqrt{34}\,\sqrt{\frac{1}{c_3^2}}}{2}$$

This solution is valid for any c_3. Hence there are infinite number of solutions.

Summary
The solution(s) found are the following

$$\sqrt{\frac{2y^2+2yx+x^2}{x^2}} = \frac{c_3\sqrt{34}\,\sqrt{\frac{1}{c_3^2}}}{x} \tag{1}$$

Verification of solutions

$$\sqrt{\frac{2y^2+2yx+x^2}{x^2}} = \frac{c_3\sqrt{34}\,\sqrt{\frac{1}{c_3^2}}}{x}$$

Verified OK.

6.14.3 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-x-y}{x+2y} \tag{1}$$

Which becomes

$$(2y)\,dy = (-x)\,dy + (-x-y)\,dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\,dy + (-x-y)\,dx = d\left(-\frac{1}{2}x^2 - yx\right)$$

Hence (2) becomes

$$(2y)\,dy = d\left(-\frac{1}{2}x^2 - yx\right)$$

Integrating both sides gives gives these solutions

$$y = -\frac{x}{2} + \frac{\sqrt{-x^2+4c_1}}{2} + c_1$$
$$y = -\frac{x}{2} - \frac{\sqrt{-x^2+4c_1}}{2} + c_1$$

Initial conditions are used to solve for c_1. Substituting $x = 2$ and $y = 3$ in the above solution gives an equation to solve for the constant of integration.

$$3 = -1 - \sqrt{c_1 - 1} + c_1$$

$$
c_1 = \frac{9}{2} + \frac{\sqrt{13}}{2}
$$

Substituting c_1 found above in the general solution gives

$$
y = -\frac{x}{2} - \frac{\sqrt{-x^2 + 18 + 2\sqrt{13}}}{2} + \frac{9}{2} + \frac{\sqrt{13}}{2}
$$

Initial conditions are used to solve for c_1. Substituting $x = 2$ and $y = 3$ in the above solution gives an equation to solve for the constant of integration.

$$
3 = -1 + \sqrt{c_1 - 1} + c_1
$$

$$
c_1 = \frac{9}{2} - \frac{\sqrt{13}}{2}
$$

Substituting c_1 found above in the general solution gives

$$
y = -\frac{x}{2} + \frac{\sqrt{-x^2 + 18 - 2\sqrt{13}}}{2} + \frac{9}{2} - \frac{\sqrt{13}}{2}
$$

Summary

The solution(s) found are the following

$$
y = -\frac{x}{2} + \frac{\sqrt{-x^2 + 18 - 2\sqrt{13}}}{2} + \frac{9}{2} - \frac{\sqrt{13}}{2} \tag{1}
$$

$$
y = -\frac{x}{2} - \frac{\sqrt{-x^2 + 18 + 2\sqrt{13}}}{2} + \frac{9}{2} + \frac{\sqrt{13}}{2} \tag{2}
$$

6.14.4 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= -\frac{x+y}{x+2y} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2+ya_3+a_1 \tag{1E}$$

$$\eta = xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1,a_2,a_3,b_1,b_2,b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2-\frac{(x+y)(b_3-a_2)}{x+2y}-\frac{(x+y)^2 a_3}{(x+2y)^2}-\left(-\frac{1}{x+2y}+\frac{x+y}{(x+2y)^2}\right)(xa_2+ya_3+a_1) \\ -\left(-\frac{1}{x+2y}+\frac{2x+2y}{(x+2y)^2}\right)(xb_2+yb_3+b_1)=0 \tag{5E}$$

Putting the above in normal form gives

$$\frac{x^2 a_2 - x^2 a_3 - x^2 b_3 + 4xya_2 - 2xya_3 + 4xyb_2 - 4xyb_3 + 2y^2 a_2 + 4y^2 b_2 - 2y^2 b_3 - xb_1 + ya_1}{(x+2y)^2} = 0$$

Setting the numerator to zero gives

$$x^2 a_2 - x^2 a_3 - x^2 b_3 + 4xya_2 - 2xya_3 + 4xyb_2 - 4xyb_3 + 2y^2 a_2 + 4y^2 b_2 - 2y^2 b_3 - xb_1 + ya_1 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$a_2 v_1^2 + 4a_2 v_1 v_2 + 2a_2 v_2^2 - a_3 v_1^2 - 2a_3 v_1 v_2 + 4b_2 v_1 v_2 + 4b_2 v_2^2 - b_3 v_1^2 - 4b_3 v_1 v_2 - 2b_3 v_2^2 + a_1 v_2 - b_1 v_1 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$(a_2 - a_3 - b_3) v_1^2 + (4a_2 - 2a_3 + 4b_2 - 4b_3) v_1 v_2 - b_1 v_1 + (2a_2 + 4b_2 - 2b_3) v_2^2 + a_1 v_2 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} a_1 &= 0 \\ -b_1 &= 0 \\ a_2 - a_3 - b_3 &= 0 \\ 2a_2 + 4b_2 - 2b_3 &= 0 \\ 4a_2 - 2a_3 + 4b_2 - 4b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= 0 \\
a_2 &= -2b_2 + b_3 \\
a_3 &= -2b_2 \\
b_1 &= 0 \\
b_2 &= b_2 \\
b_3 &= b_3
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi &= x \\
\eta &= y
\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= y - \left(-\frac{x+y}{x+2y}\right)(x) \\
&= \frac{x^2 + 2yx + 2y^2}{x + 2y} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{x^2+2yx+2y^2}{x+2y}} dy
\end{aligned}$$

Which results in

$$S = \frac{\ln(x^2 + 2yx + 2y^2)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{x+y}{x+2y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{x+y}{x^2+2yx+2y^2} \\ S_y &= \frac{x+2y}{x^2+2yx+2y^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(2y^2 + 2yx + x^2)}{2} = c_1$$

Which simplifies to

$$\frac{\ln\left(2y^2+2yx+x^2\right)}{2}=c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx}=-\frac{x+y}{x+2y}$ 	$R=x$ $S=\frac{\ln\left(x^2+2yx+2y^2\right)}{2}$	$\frac{dS}{dR}=0$ 
Initial conditions are used to solve for c_1. Substituting $x=2$ and $y=3$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{\ln(2)}{2}+\frac{\ln(17)}{2}=c_1$$

$$c_1=\frac{\ln(2)}{2}+\frac{\ln(17)}{2}$$

Substituting c_1 found above in the general solution gives

$$\frac{\ln\left(x^2+2yx+2y^2\right)}{2}=\frac{\ln(2)}{2}+\frac{\ln(17)}{2}$$

Summary

The solution(s) found are the following

$$\frac{\ln\left(2y^2+2yx+x^2\right)}{2}=\frac{\ln(2)}{2}+\frac{\ln(17)}{2} \tag{1}$$

Verification of solutions

$$\frac{\ln(2y^2+2yx+x^2)}{2} = \frac{\ln(2)}{2} + \frac{\ln(17)}{2}$$

Verified OK.

6.14.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(x+2y)\,\mathrm{d}y = (-x-y)\,\mathrm{d}x$$
$$(x+y)\,\mathrm{d}x + (x+2y)\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x,y) &= x+y \\
N(x,y) &= x+2y
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(x+y) \\
&= 1
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x+2y) \\
&= 1
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int M \,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int x+y \,\mathrm{d}x \\
\phi &= \frac{x(x+2y)}{2} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = x + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x + 2y$. Therefore equation (4) becomes

$$x + 2y = x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 2y$$

Integrating the above w.r.t y gives

$$\int f'(y) \, dy = \int (2y) \, dy$$

$$f(y) = y^2 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{x(x + 2y)}{2} + y^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{x(x + 2y)}{2} + y^2$$

Initial conditions are used to solve for c_1. Substituting $x = 2$ and $y = 3$ in the above solution gives an equation to solve for the constant of integration.

$$17 = c_1$$

$$c_1 = 17$$

Substituting c_1 found above in the general solution gives

$$\frac{x(x + 2y)}{2} + y^2 = 17$$

Summary
The solution(s) found are the following

$$\frac{x^2}{2} + yx + y^2 = 17 \tag{1}$$

Verification of solutions

$$\frac{x^2}{2}+yx+y^2=17$$

Verified OK.

6.14.6 Maple step by step solution

Let's solve

$[y+(x+2y)\,y'=-x, y(2)=3]$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact
  - ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x,y)=0$
  - Compute derivative of lhs

    $F'(x,y)+\left(\frac{\partial}{\partial y}F(x,y)\right)y'=0$
  - Evaluate derivatives

    $1=1$
  - Condition met, ODE is exact
- Exact ODE implies solution will be of this form

  $\left[F(x,y)=c_1, M(x,y)=F'(x,y), N(x,y)=\frac{\partial}{\partial y}F(x,y)\right]$
- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y)=\int (x+y)\,dx+f_1(y)$
- Evaluate integral

  $F(x,y)=\frac{x^2}{2}+yx+f_1(y)$
- Take derivative of $F(x,y)$ with respect to y

  $N(x,y)=\frac{\partial}{\partial y}F(x,y)$
- Compute derivative

  $x+2y=x+\frac{d}{dy}f_1(y)$
- Isolate for $\frac{d}{dy}f_1(y)$

$\frac{d}{dy}f_1(y) = 2y$

- Solve for $f_1(y)$

  $f_1(y) = y^2$

- Substitute $f_1(y)$ into equation for $F(x, y)$

  $F(x, y) = \frac{1}{2}x^2 + yx + y^2$

- Substitute $F(x, y)$ into the solution of the ODE

  $\frac{1}{2}x^2 + yx + y^2 = c_1$

- Solve for y

  $\left\{y = -\frac{x}{2} - \frac{\sqrt{-x^2+4c_1}}{2}, y = -\frac{x}{2} + \frac{\sqrt{-x^2+4c_1}}{2}\right\}$

- Use initial condition $y(2) = 3$

  $3 = -1 - \frac{\sqrt{-4+4c_1}}{2}$

- Solution does not satisfy initial condition
- Use initial condition $y(2) = 3$

  $3 = -1 + \frac{\sqrt{-4+4c_1}}{2}$

- Solve for c_1

  $c_1 = 17$

- Substitute $c_1 = 17$ into general solution and simplify

  $y = -\frac{x}{2} + \frac{\sqrt{-x^2+68}}{2}$

- Solution to the IVP

  $y = -\frac{x}{2} + \frac{\sqrt{-x^2+68}}{2}$

Section: Miscellaneous problems, end of chapter 2. Page 133
Problem number: 15.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{(1+\mathrm{e}^{x})\, y' - y + \mathrm{e}^{x} y = 0}$$

6.15.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= -\frac{y(\mathrm{e}^{x}-1)}{1+\mathrm{e}^{x}} \end{aligned}$$

Where $f(x) = -\frac{e^x - 1}{1 + e^x}$ and $g(y) = y$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{y}\, dy &= -\frac{e^x - 1}{1 + e^x}\, dx \\
\int \frac{1}{y}\, dy &= \int -\frac{e^x - 1}{1 + e^x}\, dx \\
\ln(y) &= \ln(e^x) - 2\ln(1 + e^x) + c_1 \\
y &= e^{\ln(e^x) - 2\ln(1+e^x) + c_1} \\
&= c_1 e^{\ln(e^x) - 2\ln(1+e^x)}
\end{aligned}$$

Which simplifies to

$$y = \frac{c_1 e^x}{(1 + e^x)^2}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 e^x}{(1 + e^x)^2} \tag{1}$$

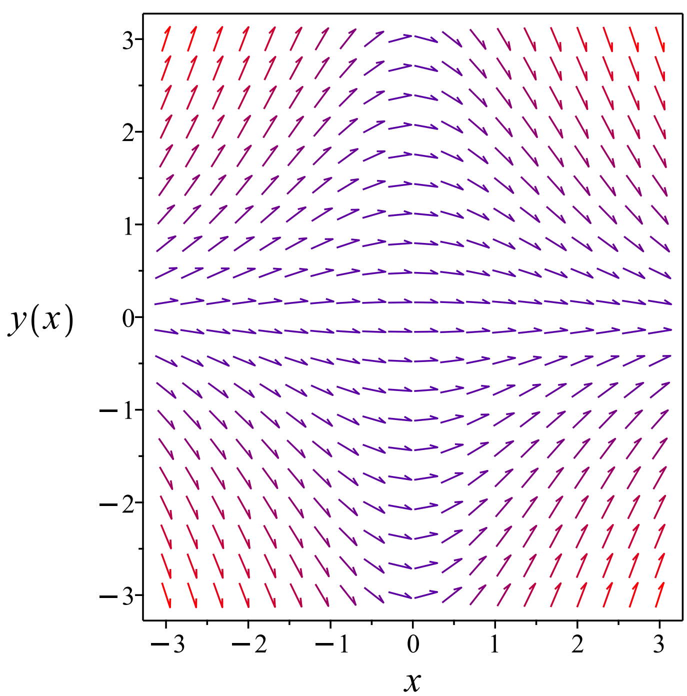

Figure 309: Slope field plot

Verification of solutions

$$y = \frac{c_1 \mathrm{e}^{x}}{(1+\mathrm{e}^{x})^{2}}$$

Verified OK.

6.15.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-\mathrm{e}^{x}+1}{1+\mathrm{e}^{x}}$$
$$q(x) = 0$$

Hence the ode is

$$y' - \frac{(-\mathrm{e}^{x}+1)\, y}{1+\mathrm{e}^{x}} = 0$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int -\frac{-\mathrm{e}^{x}+1}{1+\mathrm{e}^{x}}dx}$$
$$= \mathrm{e}^{-\ln(\mathrm{e}^{x})+2\ln(1+\mathrm{e}^{x})}$$

Which simplifies to

$$\mu = \mathrm{e}^{-x}(1+\mathrm{e}^{x})^{2}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}\mu y = 0$$
$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{-x}(1+\mathrm{e}^{x})^{2}\, y\right) = 0$$

Integrating gives

$$\mathrm{e}^{-x}(1+\mathrm{e}^{x})^{2}\, y = c_1$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-x}(1+\mathrm{e}^{x})^{2}$ results in

$$y = \frac{c_1 \mathrm{e}^{x}}{(1+\mathrm{e}^{x})^{2}}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 e^x}{(1 + e^x)^2} \tag{1}$$

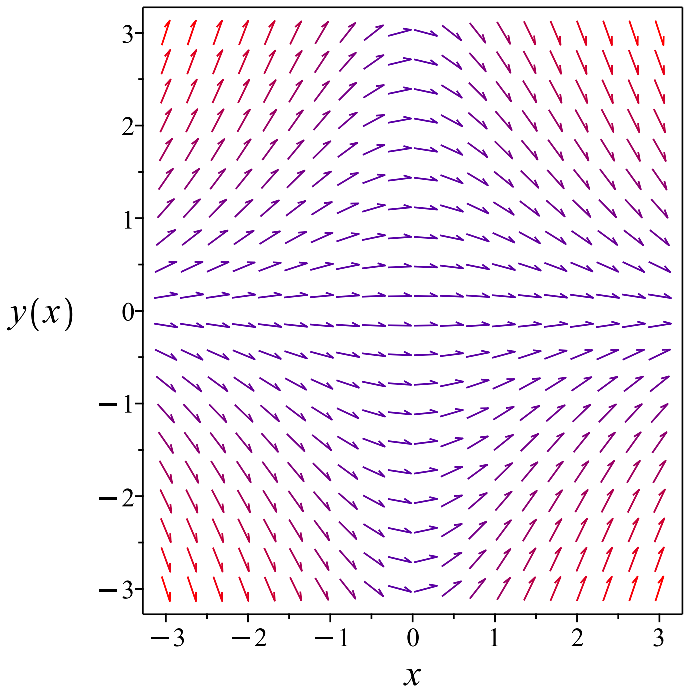

Figure 310: Slope field plot

Verification of solutions

$$y = \frac{c_1 e^x}{(1 + e^x)^2}$$

Verified OK.

6.15.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$(1 + e^x)\,(u'(x)\, x + u(x)) - u(x)\, x + e^x u(x)\, x = 0$$

In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= -\frac{u(x\,\mathrm{e}^{x}+\mathrm{e}^{x}-x+1)}{(1+\mathrm{e}^{x})\,x}
\end{aligned}
$$

Where $f(x) = -\frac{x\,\mathrm{e}^{x}+\mathrm{e}^{x}-x+1}{x(1+\mathrm{e}^{x})}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= -\frac{x\,\mathrm{e}^{x}+\mathrm{e}^{x}-x+1}{x\,(1+\mathrm{e}^{x})}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{x\,\mathrm{e}^{x}+\mathrm{e}^{x}-x+1}{x\,(1+\mathrm{e}^{x})}\,dx \\
\ln(u) &= x-\ln(x)-2\ln(1+\mathrm{e}^{x})+c_{2} \\
u &= \mathrm{e}^{x-\ln(x)-2\ln(1+\mathrm{e}^{x})+c_{2}} \\
&= c_{2}\mathrm{e}^{x-\ln(x)-2\ln(1+\mathrm{e}^{x})}
\end{aligned}
$$

Which simplifies to

$$
u(x) = \frac{c_{2}\mathrm{e}^{x}}{x\,(1+\mathrm{e}^{x})^{2}}
$$

Therefore the solution y is

$$
\begin{aligned}
y &= ux \\
&= \frac{c_{2}\mathrm{e}^{x}}{(1+\mathrm{e}^{x})^{2}}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_{2}\mathrm{e}^{x}}{(1+\mathrm{e}^{x})^{2}} \tag{1}
$$

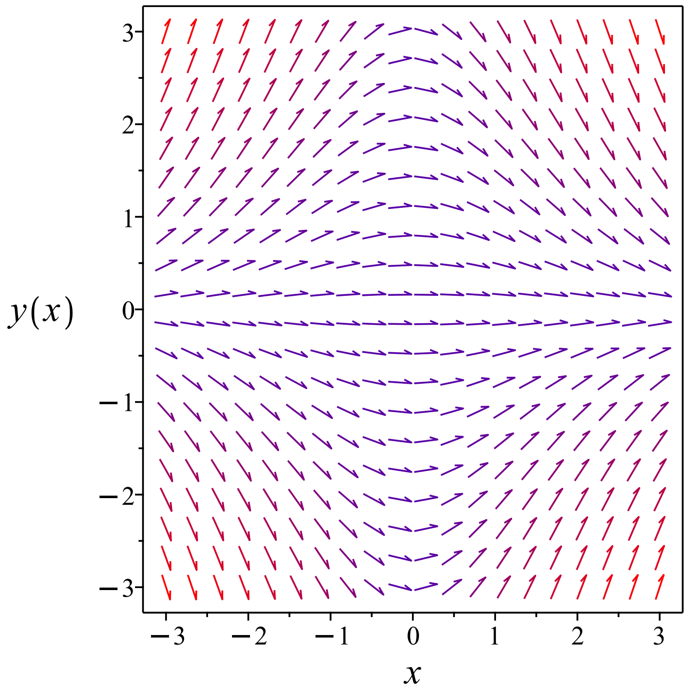

Figure 311: Slope field plot

Verification of solutions

$$y = \frac{c_2 e^x}{(1 + e^x)^2}$$

Verified OK.

6.15.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{y(e^x - 1)}{1 + e^x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 289: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x, y) &= 0 \\ \eta(x, y) &= \mathrm{e}^{\ln(\mathrm{e}^x)-2\ln(1+\mathrm{e}^x)} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{\ln(e^x) - 2\ln(1+e^x)}} dy \end{aligned}$$

Which results in

$$S = e^{-x}(1 + e^x)^2 y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{y(e^x - 1)}{1 + e^x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= y(e^x - e^{-x}) \\ S_y &= e^{-x}(1 + e^x)^2 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$e^{-x}(1 + e^{x})^2 y = c_1$$

Which simplifies to

$$e^{-x}(1 + e^{x})^2 y = c_1$$

Which gives

$$y = \frac{c_1 e^{x}}{e^{2x} + 2e^{x} + 1}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y(e^{x}-1)}{1+e^{x}}$ 	$R = x$ $S = e^{-x}(1 + e^{x})^2 y$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$y = \frac{c_1 e^{x}}{e^{2x} + 2e^{x} + 1} \tag{1}$$

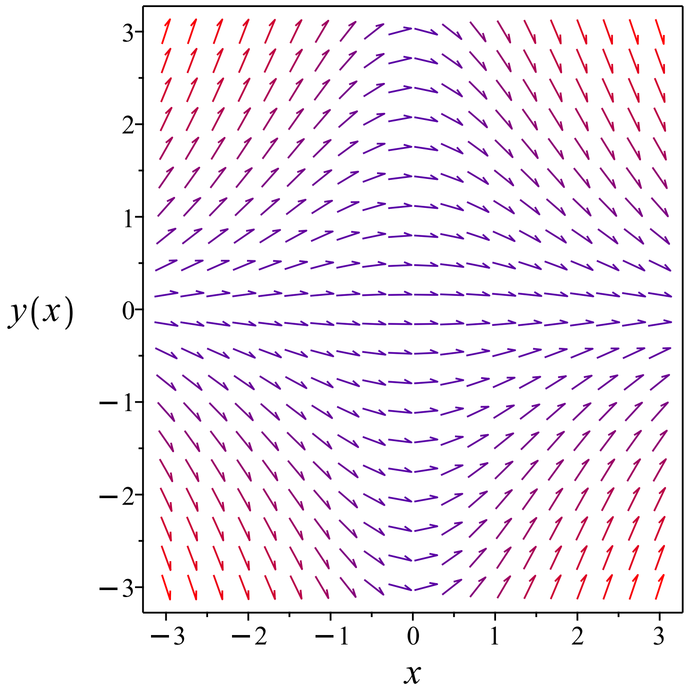

Figure 312: Slope field plot

Verification of solutions

$$y = \frac{c_1 e^x}{e^{2x} + 2 e^x + 1}$$

Verified OK.

6.15.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(-\frac{1}{y}\right) \mathrm{d}y &= \left(\frac{\mathrm{e}^x - 1}{1 + \mathrm{e}^x}\right) \mathrm{d}x \\
\left(-\frac{\mathrm{e}^x - 1}{1 + \mathrm{e}^x}\right) \mathrm{d}x + \left(-\frac{1}{y}\right) \mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -\frac{\mathrm{e}^x - 1}{1 + \mathrm{e}^x} \\
N(x, y) &= -\frac{1}{y}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{\mathrm{e}^x - 1}{1 + \mathrm{e}^x}\right) \\
&= 0
\end{aligned}
$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}\left(-\frac{1}{y}\right)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -\frac{\mathrm{e}^x - 1}{1 + \mathrm{e}^x} \, \mathrm{d}x$$
$$\phi = \ln(\mathrm{e}^x) - 2\ln(1 + \mathrm{e}^x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{1}{y}$. Therefore equation (4) becomes

$$-\frac{1}{y} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{1}{y}$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int \left(-\frac{1}{y}\right) \mathrm{d}y$$
$$f(y) = -\ln(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \ln(e^x) - 2\ln(1 + e^x) - \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \ln(e^x) - 2\ln(1 + e^x) - \ln(y)$$

The solution becomes

$$y = \frac{e^{x-c_1}}{(1 + e^x)^2}$$

Summary

The solution(s) found are the following

$$y = \frac{e^{x-c_1}}{(1 + e^x)^2} \tag{1}$$

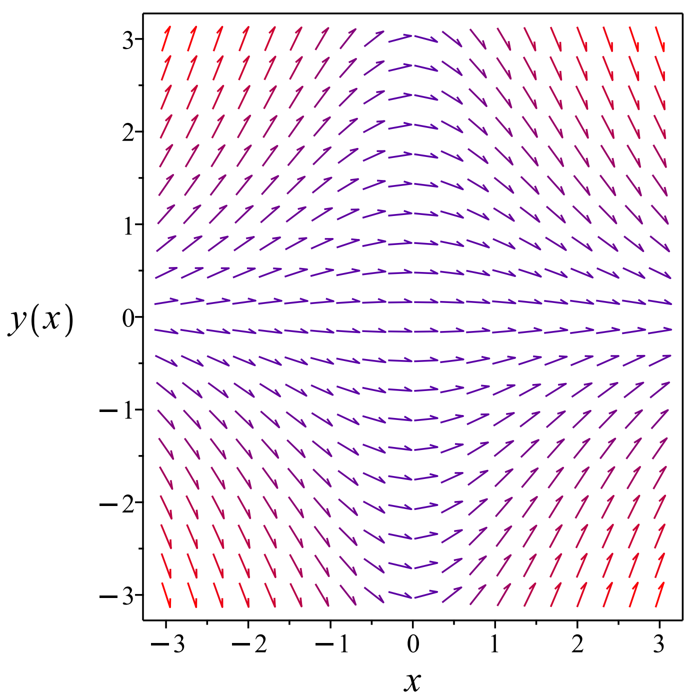

Figure 313: Slope field plot

Verification of solutions

$$y = \frac{e^{x-c_1}}{(1+e^x)^2}$$

Verified OK.

6.15.6 Maple step by step solution

Let's solve

$(1+e^x)\,y' - y + e^x y = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = -\frac{e^x-1}{1+e^x}$

- Integrate both sides with respect to x

  $\int \frac{y'}{y}dx = \int -\frac{e^x-1}{1+e^x}dx + c_1$

- Evaluate integral

  $\ln(y) = \ln(e^x) - 2\ln(1+e^x) + c_1$

- Solve for y

  $y = \frac{e^{x+c_1}}{(1+e^x)^2}$

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor"**

Maple gives the following as the ode type

`[NONE]`

$$\boxed{y' - \frac{-\mathrm{e}^{2y}\cos(x) + \cos(y)\,\mathrm{e}^{-x}}{2\,\mathrm{e}^{2y}\sin(x) - \sin(y)\,\mathrm{e}^{-x}} = 0}$$

6.16.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\left(2\,\mathrm{e}^{2y}\sin(x)\,\mathrm{e}^{x}-\sin(y)\right)\mathrm{d}y=\left(-\mathrm{e}^{2y}\cos(x)\,\mathrm{e}^{x}+\cos(y)\right)\mathrm{d}x$$

$$\left(\mathrm{e}^{2y}\cos(x)\,\mathrm{e}^{x}-\cos(y)\right)\mathrm{d}x+\left(2\,\mathrm{e}^{2y}\sin(x)\,\mathrm{e}^{x}-\sin(y)\right)\mathrm{d}y=0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=\mathrm{e}^{2y}\cos(x)\,\mathrm{e}^{x}-\cos(y)\\N(x,y)&=2\,\mathrm{e}^{2y}\sin(x)\,\mathrm{e}^{x}-\sin(y)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}\left(\mathrm{e}^{2y}\cos(x)\,\mathrm{e}^{x}-\cos(y)\right)\\&=2\cos(x)\,\mathrm{e}^{x+2y}+\sin(y)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x}&=\frac{\partial}{\partial x}\left(2\,\mathrm{e}^{2y}\sin(x)\,\mathrm{e}^{x}-\sin(y)\right)\\&=2(\cos(x)+\sin(x))\,\mathrm{e}^{x+2y}\end{aligned}$$

Since $\frac{\partial M}{\partial y}\neq\frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A&=\frac{1}{N}\left(\frac{\partial M}{\partial y}-\frac{\partial N}{\partial x}\right)\\&=\frac{1}{2\sin(x)\,\mathrm{e}^{x+2y}-\sin(y)}\left(\left(2\,\mathrm{e}^{2y}\cos(x)\,\mathrm{e}^{x}+\sin(y)\right)-\left(2\,\mathrm{e}^{2y}\cos(x)\,\mathrm{e}^{x}+2\,\mathrm{e}^{2y}\sin(x)\,\mathrm{e}^{x}\right)\right)\\&=-1\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}x}\\ &= e^{\int -1\,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-x}\\ &= \mathrm{e}^{-x}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \mathrm{e}^{-x}\left(\mathrm{e}^{2y}\cos(x)\,\mathrm{e}^{x} - \cos(y)\right)\\ &= \left(\cos(x)\,\mathrm{e}^{x+2y} - \cos(y)\right)\mathrm{e}^{-x}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \mathrm{e}^{-x}\left(2\,\mathrm{e}^{2y}\sin(x)\,\mathrm{e}^{x} - \sin(y)\right)\\ &= \left(2\sin(x)\,\mathrm{e}^{x+2y} - \sin(y)\right)\mathrm{e}^{-x}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\\ \left(\left(\cos(x)\,\mathrm{e}^{x+2y} - \cos(y)\right)\mathrm{e}^{-x}\right) + \left(\left(2\sin(x)\,\mathrm{e}^{x+2y} - \sin(y)\right)\mathrm{e}^{-x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x\\ \int \frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int \left(\cos(x)\,\mathrm{e}^{x+2y} - \cos(y)\right)\mathrm{e}^{-x}\,\mathrm{d}x\end{aligned}$$

$$\phi = \mathrm{e}^{2y}\sin(x) + \cos(y)\,\mathrm{e}^{-x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2\,\mathrm{e}^{2y} \sin(x) - \sin(y)\,\mathrm{e}^{-x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = (2\sin(x)\,\mathrm{e}^{x+2y} - \sin(y))\,\mathrm{e}^{-x}$. Therefore equation (4) becomes

$$\left(2\sin(x)\,\mathrm{e}^{x+2y} - \sin(y)\right)\mathrm{e}^{-x} = 2\,\mathrm{e}^{2y} \sin(x) - \sin(y)\,\mathrm{e}^{-x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \mathrm{e}^{2y} \sin(x) + \cos(y)\,\mathrm{e}^{-x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \mathrm{e}^{2y} \sin(x) + \cos(y)\,\mathrm{e}^{-x}$$

Summary
The solution(s) found are the following

$$\mathrm{e}^{2y} \sin(x) + \cos(y)\,\mathrm{e}^{-x} = c_1 \tag{1}$$

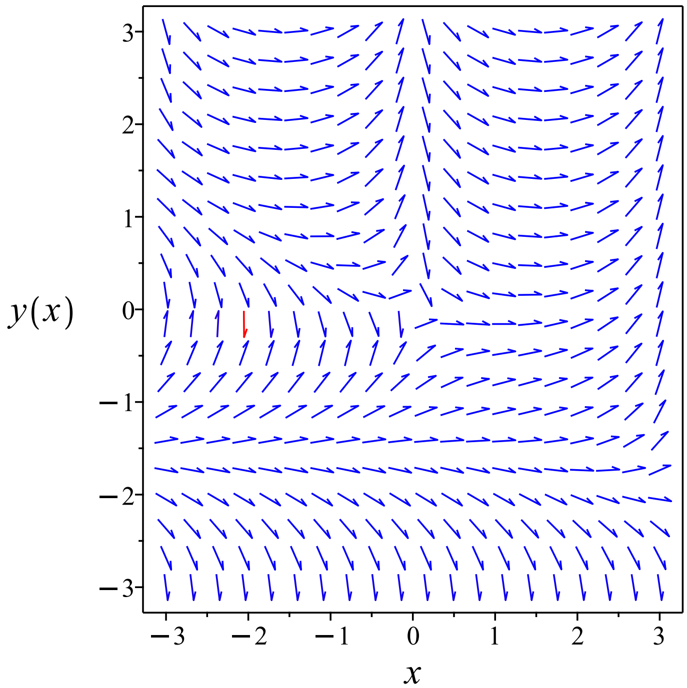

Figure 314: Slope field plot

Problem number: 17.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' - 3y = e^{2x}}$$

6.17.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -3$$
$$q(x) = e^{2x}$$

Hence the ode is

$$y' - 3y = e^{2x}$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int(-3)dx} \\
&= \mathrm{e}^{-3x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\mathrm{e}^{2x}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{-3x} y\right) &= \left(\mathrm{e}^{-3x}\right)\left(\mathrm{e}^{2x}\right) \\
\mathrm{d}\left(\mathrm{e}^{-3x} y\right) &= \mathrm{e}^{-x}\,\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{-3x} y &= \int \mathrm{e}^{-x}\,\mathrm{d}x \\
\mathrm{e}^{-3x} y &= -\mathrm{e}^{-x} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-3x}$ results in

$$
y = -\mathrm{e}^{3x}\mathrm{e}^{-x} + c_1\mathrm{e}^{3x}
$$

which simplifies to

$$
y = -\mathrm{e}^{2x} + c_1\mathrm{e}^{3x}
$$

Summary

The solution(s) found are the following

$$
y = -\mathrm{e}^{2x} + c_1\mathrm{e}^{3x} \tag{1}
$$

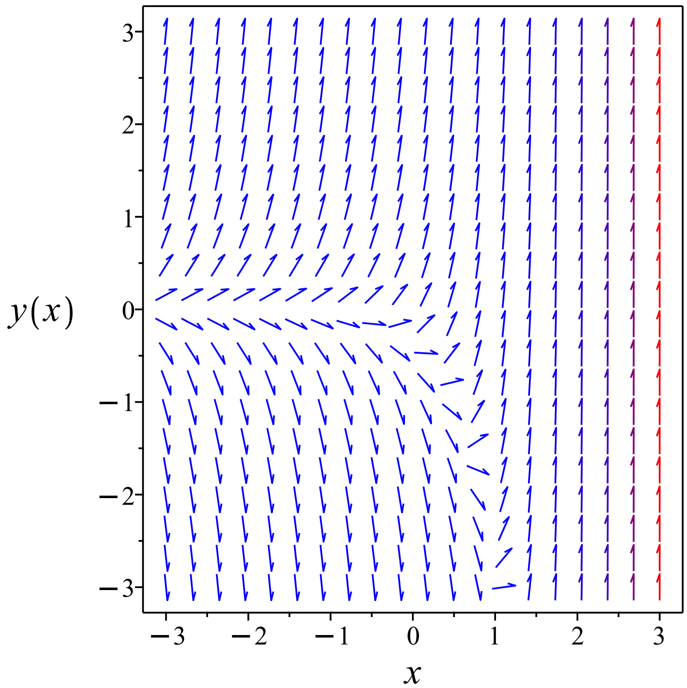

Figure 315: Slope field plot

Verification of solutions

$$y = -e^{2x} + c_1 e^{3x}$$

Verified OK.

6.17.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = e^{2x} + 3y$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 292: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= e^{3x}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{3x}} dy \end{aligned}$$

Which results in

$$S = e^{-3x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = e^{2x} + 3y$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -3 e^{-3x} y \\ S_y &= e^{-3x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = e^{-x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = e^{-R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -e^{-R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$y\,e^{-3x} = -e^{-x} + c_1$$

Which simplifies to

$$y\,e^{-3x} = -e^{-x} + c_1$$

Which gives

$$y = -\left(e^{-x} - c_1\right) e^{3x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = e^{2x} + 3y$ 	$R = x$ $S = e^{-3x}y$	$\frac{dS}{dR} = e^{-R}$ 
Summary
The solution(s) found are the following

$$y = -\left(e^{-x} - c_1\right) e^{3x} \tag{1}$$

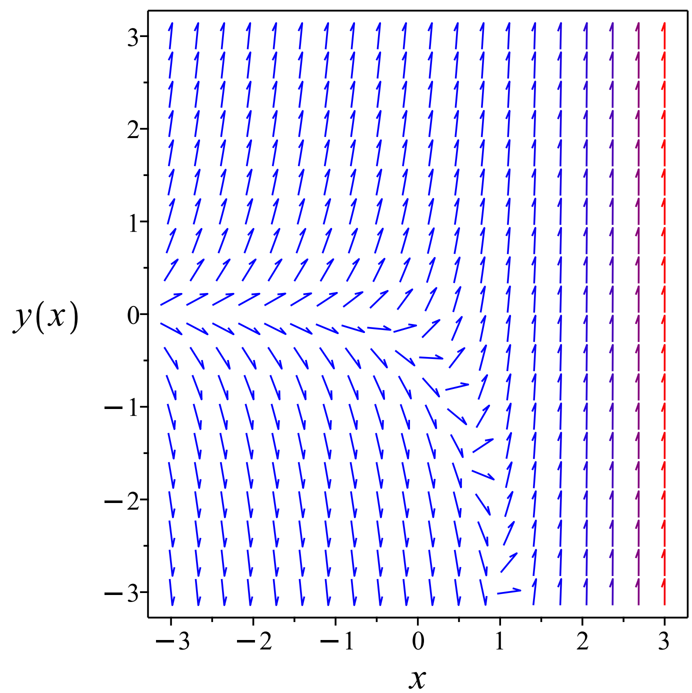

Figure 316: Slope field plot

Verification of solutions

$$y = -\left(\mathrm{e}^{-x} - c_1\right) \mathrm{e}^{3x}$$

Verified OK.

6.17.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = \left(\mathrm{e}^{2x} + 3y\right) \mathrm{d}x$$
$$\left(-\mathrm{e}^{2x} - 3y\right) \mathrm{d}x + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\mathrm{e}^{2x} - 3y$$
$$N(x, y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\mathrm{e}^{2x} - 3y\right) \\ &= -3 \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1) \\ &= 0 \end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= 1((-3) - (0)) \\
&= -3
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int -3 \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-3x} \\
&= \mathrm{e}^{-3x}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{-3x}\left(-\mathrm{e}^{2x} - 3y\right) \\
&= \left(-\mathrm{e}^{2x} - 3y\right) \mathrm{e}^{-3x}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-3x}(1) \\
&= \mathrm{e}^{-3x}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\left(-\mathrm{e}^{2x} - 3y\right) \mathrm{e}^{-3x}\right) + \left(\mathrm{e}^{-3x}\right) \frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \left(-\mathrm{e}^{2x} - 3y\right) \mathrm{e}^{-3x} \, \mathrm{d}x$$

$$\phi = \mathrm{e}^{-x} + \mathrm{e}^{-3x} y + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{-3x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-3x}$. Therefore equation (4) becomes

$$\mathrm{e}^{-3x} = \mathrm{e}^{-3x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \mathrm{e}^{-x} + \mathrm{e}^{-3x} y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \mathrm{e}^{-x} + \mathrm{e}^{-3x} y$$

The solution becomes

$$y = -\left(\mathrm{e}^{-x} - c_1\right) \mathrm{e}^{3x}$$

Summary

The solution(s) found are the following

$$y = -\left(\mathrm{e}^{-x} - c_1\right) \mathrm{e}^{3x} \tag{1}$$

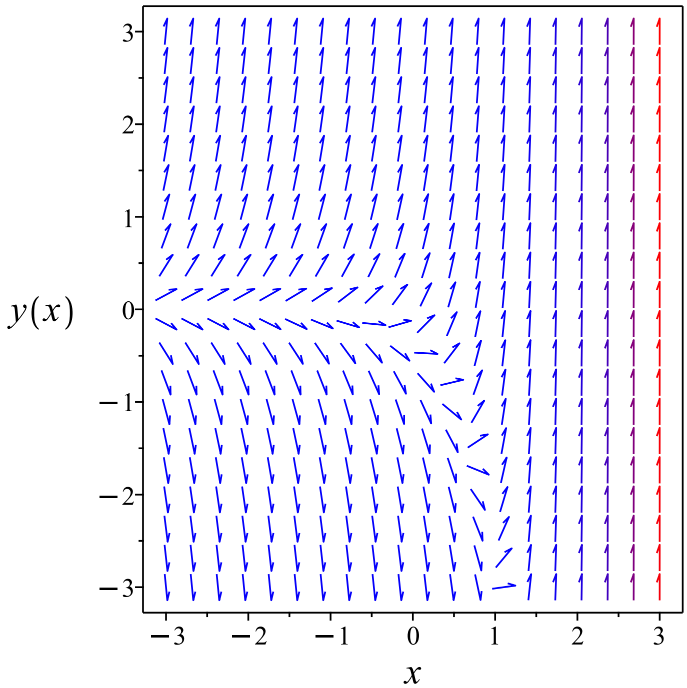

Figure 317: Slope field plot

Verification of solutions

$$y = -\left(e^{-x} - c_1\right) e^{3x}$$

Verified OK.

6.17.4 Maple step by step solution

Let's solve

$y' - 3y = e^{2x}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = e^{2x} + 3y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - 3y = e^{2x}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' - 3y\right) = \mu(x) e^{2x}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\,(y'-3y)=\mu'(x)\,y+\mu(x)\,y'$
- Isolate $\mu'(x)$

  $\mu'(x)=-3\mu(x)$
- Solve to find the integrating factor

  $\mu(x)=\mathrm{e}^{-3x}$
- Integrate both sides with respect to x

  $\int\left(\frac{d}{dx}(\mu(x)\,y)\right)dx=\int\mu(x)\,\mathrm{e}^{2x}dx+c_1$
- Evaluate the integral on the lhs

  $\mu(x)\,y=\int\mu(x)\,\mathrm{e}^{2x}dx+c_1$
- Solve for y

  $y=\frac{\int\mu(x)\mathrm{e}^{2x}dx+c_1}{\mu(x)}$
- Substitute $\mu(x)=\mathrm{e}^{-3x}$

  $y=\frac{\int\mathrm{e}^{2x}\mathrm{e}^{-3x}dx+c_1}{\mathrm{e}^{-3x}}$
- Evaluate the integrals on the rhs

  $y=\frac{-\mathrm{e}^{-x}+c_1}{\mathrm{e}^{-3x}}$
- Simplify

  $y=\mathrm{e}^{2x}(c_1\mathrm{e}^{x}-1)$

Problem number: 18.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{2y + y' = \mathrm{e}^{-x^2-2x}}$$

6.18.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 2 \\ q(x) &= \mathrm{e}^{-x(2+x)} \end{aligned}$$

Hence the ode is

$$2y + y' = \mathrm{e}^{-x(2+x)}$$

The integrating factor μ is

$$\mu = e^{\int 2dx}$$
$$= e^{2x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(e^{-x(2+x)}\right)$$
$$\frac{d}{dx}\left(e^{2x}y\right) = \left(e^{2x}\right)\left(e^{-x(2+x)}\right)$$
$$d\left(e^{2x}y\right) = e^{-x^2}\, dx$$

Integrating gives

$$e^{2x}y = \int e^{-x^2}\, dx$$
$$e^{2x}y = \frac{\sqrt{\pi}\, \operatorname{erf}(x)}{2} + c_1$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$y = \frac{e^{-2x}\sqrt{\pi}\, \operatorname{erf}(x)}{2} + c_1 e^{-2x}$$

which simplifies to

$$y = e^{-2x}\left(\frac{\sqrt{\pi}\, \operatorname{erf}(x)}{2} + c_1\right)$$

Summary

The solution(s) found are the following

$$y = e^{-2x}\left(\frac{\sqrt{\pi}\, \operatorname{erf}(x)}{2} + c_1\right) \tag{1}$$

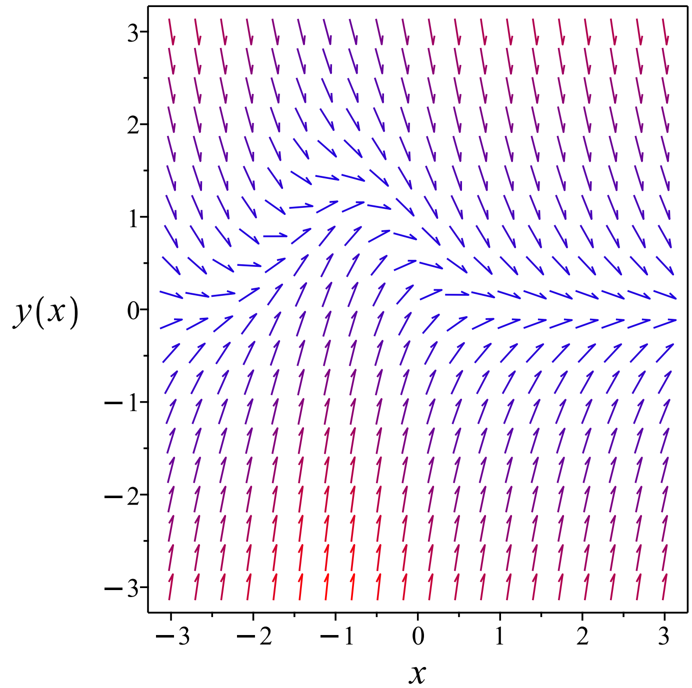

Figure 318: Slope field plot

Verification of solutions

$$y = e^{-2x}\left(\frac{\sqrt{\pi}\,\operatorname{erf}(x)}{2} + c_1\right)$$

Verified OK.

6.18.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= -2y + e^{-x^2-2x} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 295: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= e^{-2x}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{-2x}} dy \end{aligned}$$

Which results in

$$S = \mathrm{e}^{2x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -2y + \mathrm{e}^{-x^2 - 2x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= 2\,\mathrm{e}^{2x} y \\ S_y &= \mathrm{e}^{2x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \mathrm{e}^{-x^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \mathrm{e}^{-R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{\sqrt{\pi}\ \mathrm{erf}\left(R\right)}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$y\,\mathrm{e}^{2x} = \frac{\sqrt{\pi}\ \mathrm{erf}\left(x\right)}{2} + c_1$$

Which simplifies to

$$y\,\mathrm{e}^{2x} = \frac{\sqrt{\pi}\ \mathrm{erf}\left(x\right)}{2} + c_1$$

Which gives

$$y = \frac{\mathrm{e}^{-2x}\left(\sqrt{\pi}\ \mathrm{erf}\left(x\right) + 2c_1\right)}{2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -2y + \mathrm{e}^{-x^2-2x}$ 	$R = x$ $S = \mathrm{e}^{2x} y$	$\frac{dS}{dR} = \mathrm{e}^{-R^2}$ 
Summary

The solution(s) found are the following

$$y = \frac{\mathrm{e}^{-2x}\left(\sqrt{\pi}\ \mathrm{erf}\left(x\right) + 2c_1\right)}{2} \tag{1}$$

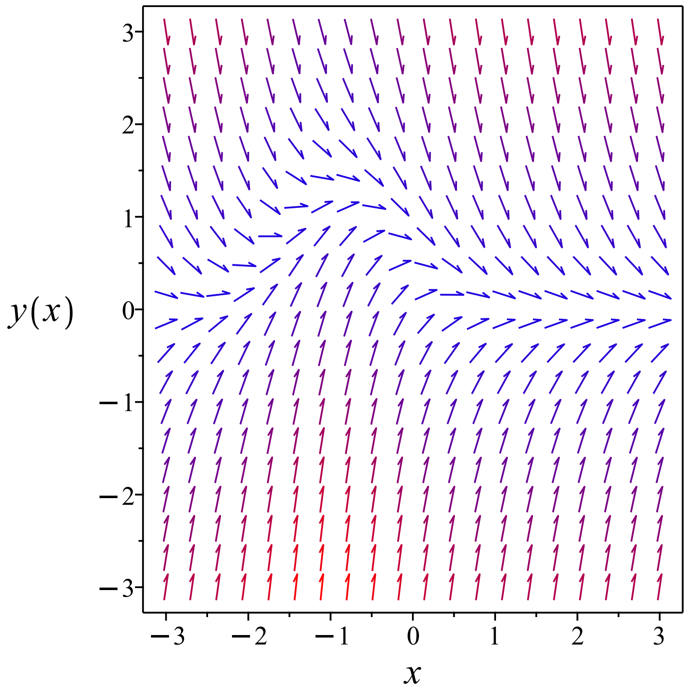

Figure 319: Slope field plot

Verification of solutions

$$y = \frac{e^{-2x}\left(\sqrt{\pi}\,\operatorname{erf}(x) + 2c_1\right)}{2}$$

Verified OK.

6.18.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = \left(-2y + \mathrm{e}^{-x^2-2x}\right) \mathrm{d}x$$
$$\left(2y - \mathrm{e}^{-x^2-2x}\right) \mathrm{d}x + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = 2y - \mathrm{e}^{-x^2-2x}$$
$$N(x, y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(2y - \mathrm{e}^{-x^2-2x}\right)$$
$$= 2$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}(1)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= 1((2) - (0)) \\
&= 2
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \,\mathrm{d}x} \\
&= e^{\int 2 \,\mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{2x} \\
&= \mathrm{e}^{2x}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{2x}\left(2y - \mathrm{e}^{-x^2-2x}\right) \\
&= \left(2y - \mathrm{e}^{-x(2+x)}\right)\mathrm{e}^{2x}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{2x}(1) \\
&= \mathrm{e}^{2x}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\left(2y - \mathrm{e}^{-x(2+x)}\right)\mathrm{e}^{2x}\right) + \left(\mathrm{e}^{2x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \left(2y - \mathrm{e}^{-x(2+x)}\right) \mathrm{e}^{2x} \mathrm{d}x$$

$$\phi = -\frac{\sqrt{\pi}\, \mathrm{erf}\,(x)}{2} + \mathrm{e}^{2x} y + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{2x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{2x}$. Therefore equation (4) becomes

$$\mathrm{e}^{2x} = \mathrm{e}^{2x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\sqrt{\pi}\, \mathrm{erf}\,(x)}{2} + \mathrm{e}^{2x} y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\sqrt{\pi}\, \mathrm{erf}\,(x)}{2} + \mathrm{e}^{2x} y$$

The solution becomes

$$y = \frac{\mathrm{e}^{-2x}\left(\sqrt{\pi}\, \mathrm{erf}\,(x) + 2c_1\right)}{2}$$

Summary
The solution(s) found are the following

$$y = \frac{e^{-2x} \left(\sqrt{\pi}\, \operatorname{erf}(x) + 2c_1\right)}{2} \tag{1}$$

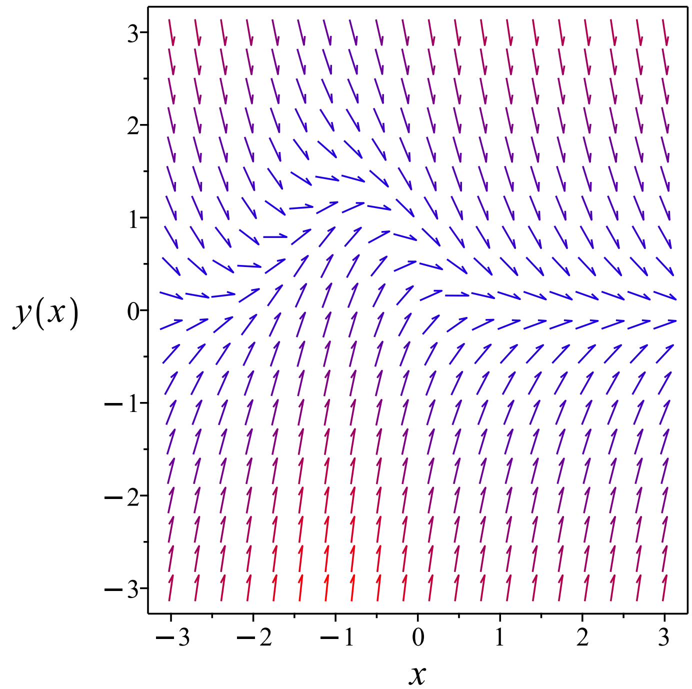

Figure 320: Slope field plot

Verification of solutions

$$y = \frac{e^{-2x} \left(\sqrt{\pi}\, \operatorname{erf}(x) + 2c_1\right)}{2}$$

Verified OK.

6.18.4 Maple step by step solution

Let's solve

$2y + y' = e^{-x^2-2x}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

$$y' = -2y + e^{-x^2-2x}$$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

$$2y + y' = e^{-x^2-2x}$$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

$$\mu(x)\,(2y + y') = \mu(x)\,e^{-x^2-2x}$$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

$$\mu(x)\,(2y + y') = \mu'(x)\,y + \mu(x)\,y'$$

- Isolate $\mu'(x)$

$$\mu'(x) = 2\mu(x)$$

- Solve to find the integrating factor

$$\mu(x) = e^{2x}$$

- Integrate both sides with respect to x

$$\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int \mu(x)\,e^{-x^2-2x} dx + c_1$$

- Evaluate the integral on the lhs

$$\mu(x)\,y = \int \mu(x)\,e^{-x^2-2x} dx + c_1$$

- Solve for y

$$y = \frac{\int \mu(x) e^{-x^2-2x} dx + c_1}{\mu(x)}$$

- Substitute $\mu(x) = e^{2x}$

$$y = \frac{\int e^{2x} e^{-x^2-2x} dx + c_1}{e^{2x}}$$

- Evaluate the integrals on the rhs

$$y = \frac{\frac{\sqrt{\pi}\,\mathrm{erf}(x)}{2} + c_1}{e^{2x}}$$

- Simplify

$$y = \frac{e^{-2x}\left(\sqrt{\pi}\,\mathrm{erf}(x) + 2c_1\right)}{2}$$

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

`[_rational]`

$$\boxed{y' - \frac{3x^2 - 2y - y^3}{2x + 3x y^2} = 0}$$

6.19.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(x\left(3y^2+2\right)\right)\mathrm{d}y &= \left(-y^3+3x^2-2y\right)\mathrm{d}x\\ \left(y^3-3x^2+2y\right)\mathrm{d}x + \left(x\left(3y^2+2\right)\right)\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= y^3-3x^2+2y\\ N(x, y) &= x\left(3y^2+2\right)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(y^3-3x^2+2y\right)\\ &= 3y^2+2\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(x\left(3y^2+2\right)\right)\\ &= 3y^2+2\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial\phi}{\partial x} = M \tag{1}$$

$$\frac{\partial\phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int y^3 - 3x^2 + 2y \mathrm{d}x$$
$$\phi = -x(-y^3 + x^2 - 2y) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -x(-3y^2 - 2) + f'(y) \tag{4}$$
$$= x(3y^2 + 2) + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x(3y^2 + 2)$. Therefore equation (4) becomes

$$x(3y^2 + 2) = x(3y^2 + 2) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -x(-y^3 + x^2 - 2y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x(-y^3 + x^2 - 2y)$$

Summary
The solution(s) found are the following

$$-x(-y^3 + x^2 - 2y) = c_1 \tag{1}$$

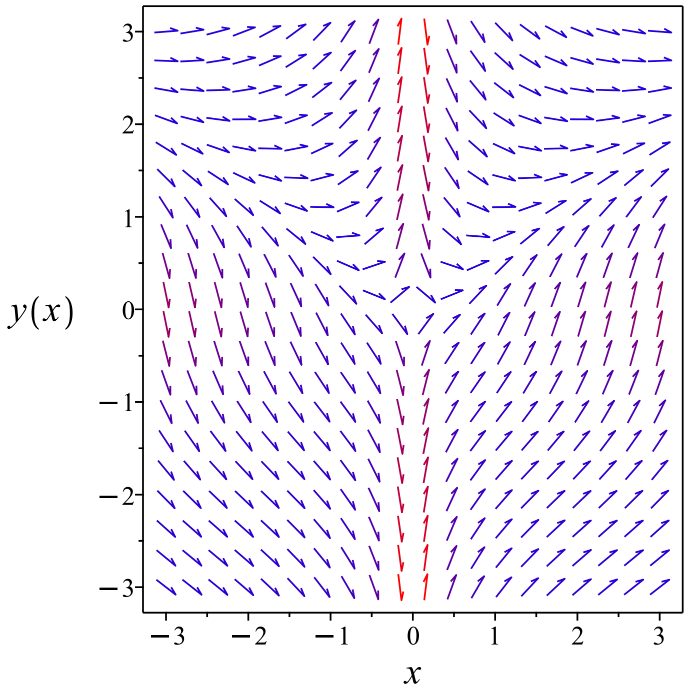

Figure 321: Slope field plot

Verification of solutions

$$-x\left(-y^{3}+x^{2}-2y\right)=c_{1}$$

Verified OK.

The type(s) of ODE detected by this program : **"exact", "separable", "first order special form ID 1", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \mathrm{e}^{x+y} = 0}$$

6.20.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \mathrm{e}^{x}\mathrm{e}^{y} \end{aligned}$$

Where $f(x) = \mathrm{e}^{x}$ and $g(y) = \mathrm{e}^{y}$. Integrating both sides gives

$$\begin{aligned} \frac{1}{\mathrm{e}^{y}}\, dy &= \mathrm{e}^{x}\, dx \\ \int \frac{1}{\mathrm{e}^{y}}\, dy &= \int \mathrm{e}^{x}\, dx \\ -\mathrm{e}^{-y} &= \mathrm{e}^{x} + c_1 \end{aligned}$$

Which results in

$$y = \ln\left(-\frac{1}{e^x + c_1}\right)$$

Summary

The solution(s) found are the following

$$y = \ln\left(-\frac{1}{e^x + c_1}\right) \tag{1}$$

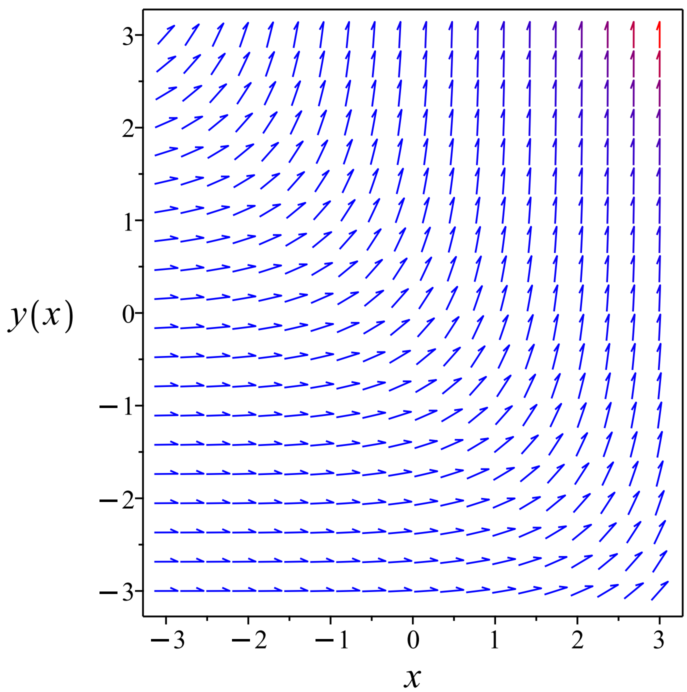

Figure 322: Slope field plot

Verification of solutions

$$y = \ln\left(-\frac{1}{e^x + c_1}\right)$$

Verified OK.

6.20.2 Solving as first order special form ID 1 ode

Writing the ode as

$$y' = e^{x+y} \tag{1}$$

And using the substitution $u = e^{-y}$ then

$$u' = -y' e^{-y}$$

The above shows that

$$\begin{aligned} y' &= -u'(x)\, e^{y} \\ &= -\frac{u'(x)}{u} \end{aligned}$$

Substituting this in (1) gives

$$-\frac{u'(x)}{u} = \frac{e^{x}}{u}$$

The above simplifies to

$$u'(x) = -e^{x} \tag{2}$$

Now ode (2) is solved for $u(x)$ Integrating both sides gives

$$\begin{aligned} u(x) &= \int -e^{x}\, dx \\ &= -e^{x} + c_1 \end{aligned}$$

Substituting the solution found for $u(x)$ in $u = e^{-y}$ gives

$$\begin{aligned} y &= -\ln(u(x)) \\ &= -\ln(-e^{x} + c_1) \\ &= -\ln(-e^{x} + c_1) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\ln(-e^{x} + c_1) \tag{1}$$

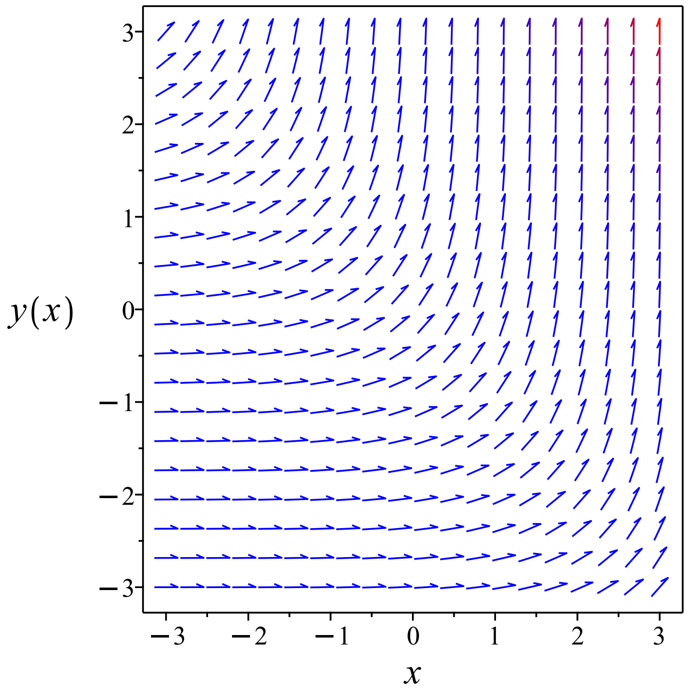

Figure 323: Slope field plot

Verification of solutions

$$y = -\ln\left(-e^{x} + c_1\right)$$

Verified OK.

6.20.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = e^{x+y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 298: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= \mathrm{e}^{-x} \\ \eta(x,y) &= 0 \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{e^{-x}} dx \end{aligned}$$

Which results in

$$S = e^{x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = e^{x+y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= e^{x} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = e^{-y} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = e^{-R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\mathrm{e}^{-R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\mathrm{e}^{x} = -\mathrm{e}^{-y} + c_1$$

Which simplifies to

$$\mathrm{e}^{x} = -\mathrm{e}^{-y} + c_1$$

Which gives

$$y = -\ln\left(-\mathrm{e}^{x} + c_1\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \mathrm{e}^{x+y}$ 	$R = y$ $S = \mathrm{e}^{x}$	$\frac{dS}{dR} = \mathrm{e}^{-R}$ 
Summary

The solution(s) found are the following

$$y = -\ln\left(-\mathrm{e}^{x} + c_1\right) \tag{1}$$

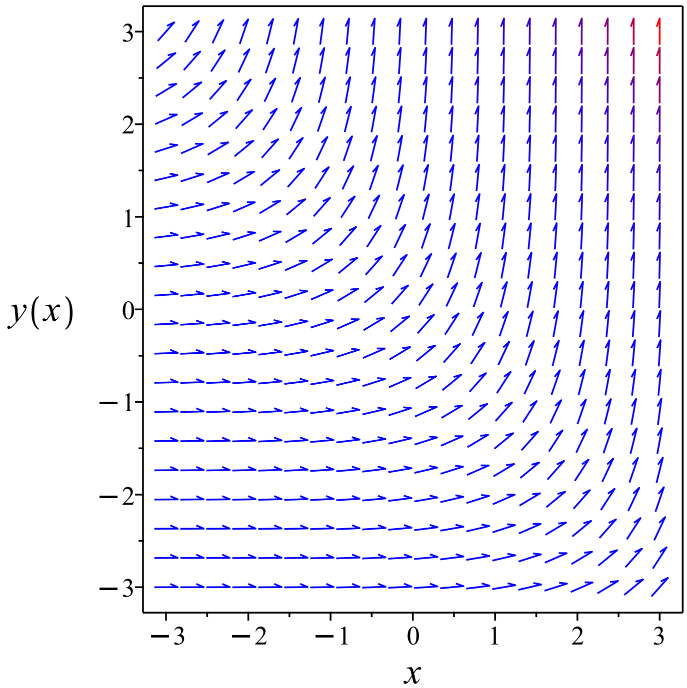

Figure 324: Slope field plot

Verification of solutions

$$y = -\ln\left(-\mathrm{e}^{x} + c_1\right)$$

Verified OK.

6.20.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\mathrm{e}^{-y}\right) \mathrm{d}y = \left(\mathrm{e}^{x}\right) \mathrm{d}x$$
$$\left(-\mathrm{e}^{x}\right) \mathrm{d}x + \left(\mathrm{e}^{-y}\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\mathrm{e}^{x}$$
$$N(x, y) = \mathrm{e}^{-y}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-\mathrm{e}^{x}\right)$$
$$= 0$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}\left(\mathrm{e}^{-y}\right)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int M \,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int -\mathrm{e}^{x} \,\mathrm{d}x$$

$$\phi = -\mathrm{e}^{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-y}$. Therefore equation (4) becomes

$$\mathrm{e}^{-y} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \mathrm{e}^{-y}$$

Integrating the above w.r.t y gives

$$\int f'(y) \,\mathrm{d}y = \int \left(\mathrm{e}^{-y}\right) \mathrm{d}y$$

$$f(y) = -\mathrm{e}^{-y} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\mathrm{e}^{x} - \mathrm{e}^{-y} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -e^{x} - e^{-y}$$

The solution becomes

$$y = -\ln\left(-e^{x} - c_1\right)$$

Summary

The solution(s) found are the following

$$y = -\ln\left(-e^{x} - c_1\right) \tag{1}$$

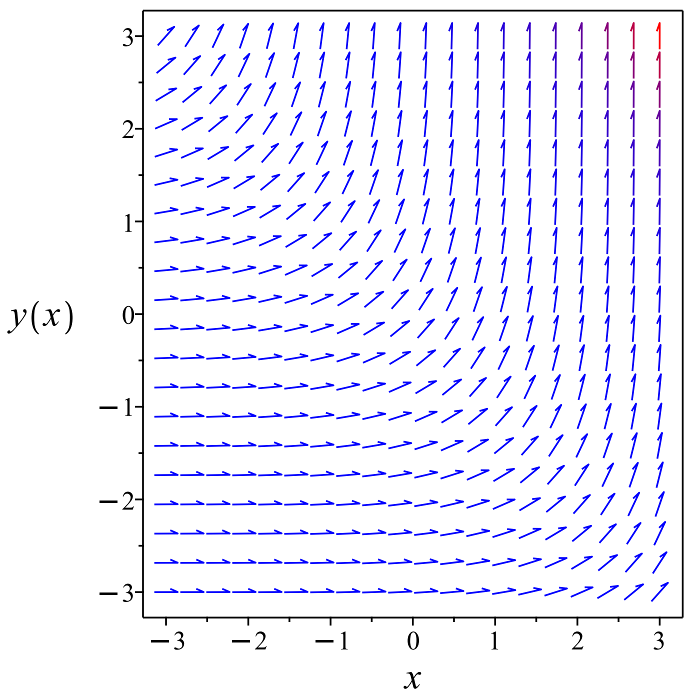

Figure 325: Slope field plot

Verification of solutions

$$y = -\ln\left(-e^{x} - c_1\right)$$

Verified OK.

6.20.5 Maple step by step solution

Let's solve

$y' - e^{x+y} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{e^y} = e^x$

- Integrate both sides with respect to x

  $\int \frac{y'}{e^y} dx = \int e^x dx + c_1$

- Evaluate integral

  $-\frac{1}{e^y} = e^x + c_1$

- Solve for y

  $y = \ln\left(-\frac{1}{e^x + c_1}\right)$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

`[_rational]`

$$\boxed{\frac{-4+6yx+2y^2}{3x^2+4yx+3y^2}+y'=0}$$

6.21.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x}=M$$
$$\frac{\partial\phi}{\partial y}=N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(3x^2 + 4yx + 3y^2)\,\mathrm{d}y &= (-6yx - 2y^2 + 4)\,\mathrm{d}x \\ (6yx + 2y^2 - 4)\,\mathrm{d}x + (3x^2 + 4yx + 3y^2)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x, y) &= 6yx + 2y^2 - 4 \\ N(x, y) &= 3x^2 + 4yx + 3y^2 \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(6yx + 2y^2 - 4) \\ &= 6x + 4y \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(3x^2 + 4yx + 3y^2) \\ &= 6x + 4y \end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int 6yx + 2y^2 - 4 \, \mathrm{d}x$$

$$\phi = 3y\,x^2 + 2x\,y^2 - 4x + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 3x^2 + 4yx + f'(y) \tag{4}$$

$$= x(3x + 4y) + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 3x^2 + 4yx + 3y^2$. Therefore equation (4) becomes

$$3x^2 + 4yx + 3y^2 = x(3x + 4y) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 3y^2$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (3y^2) \, \mathrm{d}y$$

$$f(y) = y^3 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = 3y\,x^2 + 2x\,y^2 + y^3 - 4x + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = 3y\,x^2 + 2x\,y^2 + y^3 - 4x$$

Summary

The solution(s) found are the following

$$3x^2y + 2xy^2 + y^3 - 4x = c_1 \tag{1}$$

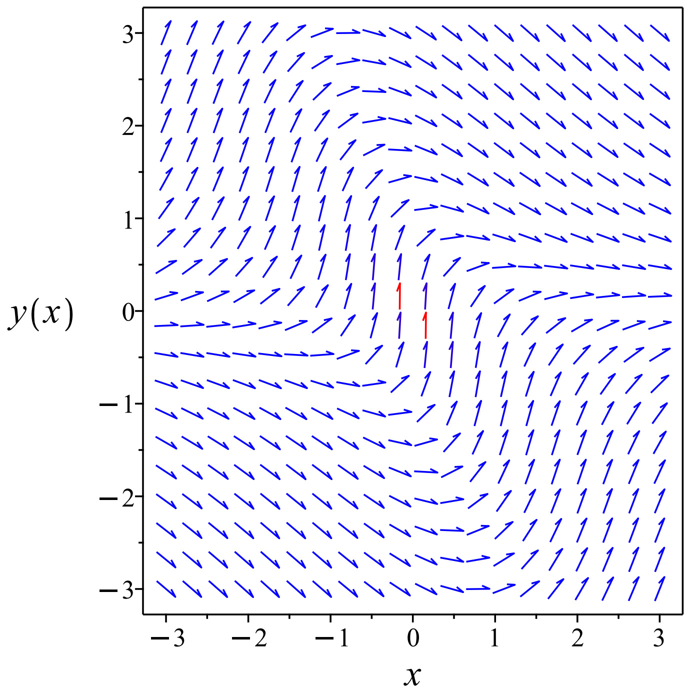

Figure 326: Slope field plot

Verification of solutions

$$3x^2y + 2xy^2 + y^3 - 4x = c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"exact", "separable", "differentialType", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{x^2 - 1}{1 + y^2} = 0}$$

With initial conditions

$$[y(-1) = 1]$$

6.22.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$
\begin{aligned}
y' &= f(x, y) \\
&= \frac{x^2-1}{y^2+1}
\end{aligned}
$$

The x domain of $f(x, y)$ when $y = 1$ is

$$
\{-\infty < x < \infty\}
$$

And the point $x_0 = -1$ is inside this domain. The y domain of $f(x, y)$ when $x = -1$ is

$$
\{-\infty < y < \infty\}
$$

And the point $y_0 = 1$ is inside this domain. Now we will look at the continuity of

$$
\begin{aligned}
\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{x^2-1}{y^2+1}\right) \\
&= -\frac{2(x^2-1)\,y}{\left(y^2+1\right)^2}
\end{aligned}
$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 1$ is

$$
\{-\infty < x < \infty\}
$$

And the point $x_0 = -1$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = -1$ is

$$
\{-\infty < y < \infty\}
$$

And the point $y_0 = 1$ is inside this domain. Therefore solution exists and is unique.

6.22.2 Solving as separable ode

In canonical form the ODE is

$$
\begin{aligned}
y' &= F(x, y) \\
&= f(x)g(y) \\
&= \frac{x^2-1}{y^2+1}
\end{aligned}
$$

Where $f(x) = x^2 - 1$ and $g(y) = \frac{1}{y^2+1}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y^2+1}}\,dy = x^2 - 1\,dx$$

$$\int \frac{1}{\frac{1}{y^2+1}}\,dy = \int x^2 - 1\,dx$$

$$\frac{1}{3}y^3 + y = \frac{1}{3}x^3 - x + c_1$$

Which results in

$$y = \frac{\left(4x^3 + 12c_1 - 12x + 4\sqrt{x^6 + 6c_1x^3 - 6x^4 + 9c_1^2 - 18c_1x + 9x^2 + 4}\right)^{\frac{1}{3}}}{2} - \frac{2}{\left(4x^3 + 12c_1 - 12x + 4\sqrt{x^6 + 6c_1x^3 - 6x^4 + 9c_1^2 - 18c_1x + 9x^2 + 4}\right)^{\frac{1}{3}}}$$

$$y = -\frac{\left(4x^3 + 12c_1 - 12x + 4\sqrt{x^6 + 6c_1x^3 - 6x^4 + 9c_1^2 - 18c_1x + 9x^2 + 4}\right)^{\frac{1}{3}}}{4} + \frac{1}{\left(4x^3 + 12c_1 - 12x + 4\sqrt{x^6 + 6c_1x^3 - 6x^4 + 9c_1^2 - 18c_1x + 9x^2 + 4}\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(\frac{\left(4x^3+12c_1-12x+4\sqrt{x^6+6c_1x^3-6x^4+9c_1^2-18c_1x+9x^2+4}\right)^{\frac{1}{3}}}{2} + \frac{2}{\left(4x^3+12c_1-12x+4\sqrt{x^6+6c_1x^3-6x^4+9c_1^2-18c_1x+9x^2+4}\right)^{\frac{1}{3}}}\right.}{2}$$

$$y = -\frac{\left(4x^3 + 12c_1 - 12x + 4\sqrt{x^6 + 6c_1x^3 - 6x^4 + 9c_1^2 - 18c_1x + 9x^2 + 4}\right)^{\frac{1}{3}}}{4} + \frac{1}{\left(4x^3 + 12c_1 - 12x + 4\sqrt{x^6 + 6c_1x^3 - 6x^4 + 9c_1^2 - 18c_1x + 9x^2 + 4}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(\frac{\left(4x^3+12c_1-12x+4\sqrt{x^6+6c_1x^3-6x^4+9c_1^2-18c_1x+9x^2+4}\right)^{\frac{1}{3}}}{2} + \frac{2}{\left(4x^3+12c_1-12x+4\sqrt{x^6+6c_1x^3-6x^4+9c_1^2-18c_1x+9x^2+4}\right)^{\frac{1}{3}}}\right.}{2}$$

Initial conditions are used to solve for c_1. Substituting $x = -1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{-i\sqrt{3}\left(8+12c_1+4\sqrt{9c_1^2+12c_1+8}\right)^{\frac{2}{3}} - 4i\sqrt{3} - \left(8+12c_1+4\sqrt{9c_1^2+12c_1+8}\right)^{\frac{2}{3}} + 4}{4\left(8+12c_1+4\sqrt{9c_1^2+12c_1+8}\right)^{\frac{1}{3}}}$$

Unable to solve for constant of integration.Initial conditions are used to solve for c_1. Substituting $x = -1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{i\sqrt{3}\left(8+12c_1+4\sqrt{9c_1^2+12c_1+8}\right)^{\frac{2}{3}} - \left(8+12c_1+4\sqrt{9c_1^2+12c_1+8}\right)^{\frac{2}{3}} + 4i\sqrt{3} + 4}{4\left(8+12c_1+4\sqrt{9c_1^2+12c_1+8}\right)^{\frac{1}{3}}}$$

Unable to solve for constant of integration.Initial conditions are used to solve for c_1. Substituting $x = -1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{\left(8+12c_1+4\sqrt{9c_1^2+12c_1+8}\right)^{\frac{2}{3}} - 4}{2\left(8+12c_1+4\sqrt{9c_1^2+12c_1+8}\right)^{\frac{1}{3}}}$$

$$c_1 = \frac{2}{3}$$

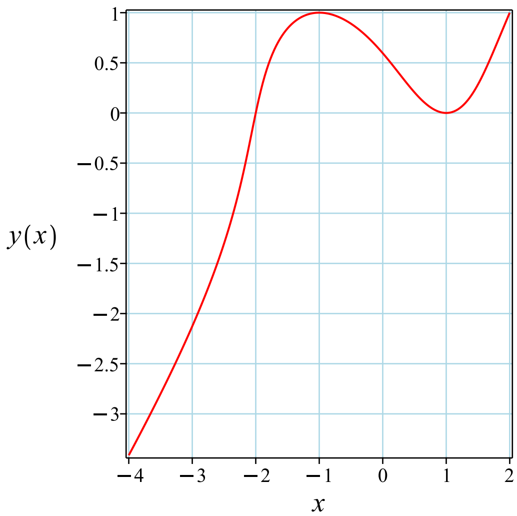
Substituting c_1 found above in the general solution gives

$$y = \frac{\left(4x^3+8-12x+4\sqrt{x^6-6x^4+4x^3+9x^2-12x+8}\right)^{\frac{2}{3}} - 4}{2\left(4x^3+8-12x+4\sqrt{x^6-6x^4+4x^3+9x^2-12x+8}\right)^{\frac{1}{3}}}$$

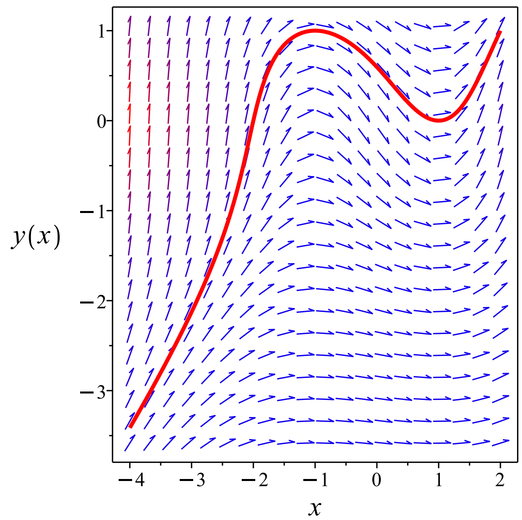
Summary

The solution(s) found are the following

$$y = \frac{\left(4x^3+8-12x+4\sqrt{x^6-6x^4+4x^3+9x^2-12x+8}\right)^{\frac{2}{3}} - 4}{2\left(4x^3+8-12x+4\sqrt{x^6-6x^4+4x^3+9x^2-12x+8}\right)^{\frac{1}{3}}} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{\left(4x^3 + 8 - 12x + 4\sqrt{x^6 - 6x^4 + 4x^3 + 9x^2 - 12x + 8}\right)^{\frac{2}{3}} - 4}{2\left(4x^3 + 8 - 12x + 4\sqrt{x^6 - 6x^4 + 4x^3 + 9x^2 - 12x + 8}\right)^{\frac{1}{3}}}$$

Verified OK.

6.22.3 Solving as differentialType ode

Writing the ode as

$$y' = \frac{x^2 - 1}{1 + y^2} \tag{1}$$

Which becomes

$$(y^2 + 1)\, dy = (x^2 - 1)\, dx \tag{2}$$

But the RHS is complete differential because

$$(x^2 - 1)\, dx = d\left(\frac{1}{3}x^3 - x\right)$$

Hence (2) becomes

$$(y^2 + 1)\, dy = d\left(\frac{1}{3}x^3 - x\right)$$

Integrating both sides gives gives these solutions

$$y = \frac{\left(4x^3 + 12c_1 - 12x + 4\sqrt{x^6 + 6c_1x^3 - 6x^4 + 9c_1^2 - 18c_1x + 9x^2 + 4}\right)^{\frac{1}{3}}}{2} - \frac{}{\left(4x^3 + 12c_1 - 12x + 4\sqrt{x^6}\right.}$$

$$y = -\frac{\left(4x^3 + 12c_1 - 12x + 4\sqrt{x^6 + 6c_1x^3 - 6x^4 + 9c_1^2 - 18c_1x + 9x^2 + 4}\right)^{\frac{1}{3}}}{4} + \frac{}{\left(4x^3 + 12c_1 - 12x + 4\sqrt{\right.}}$$

$$y = -\frac{\left(4x^3 + 12c_1 - 12x + 4\sqrt{x^6 + 6c_1x^3 - 6x^4 + 9c_1^2 - 18c_1x + 9x^2 + 4}\right)^{\frac{1}{3}}}{4} + \frac{}{\left(4x^3 + 12c_1 - 12x + 4\sqrt{\right.}}$$

Initial conditions are used to solve for c_1. Substituting $x = -1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{-i\sqrt{3}\left(8 + 12c_1 + 4\sqrt{9c_1^2 + 12c_1 + 8}\right)^{\frac{2}{3}} - \left(8 + 12c_1 + 4\sqrt{9c_1^2 + 12c_1 + 8}\right)^{\frac{2}{3}} + 4c_1\left(8 + 12c_1 + 4\sqrt{9c_1^2}\right.}{4\left(8 + 12c_1 + 4\sqrt{9c_1^2 + 12c_1 + 8}\right)^{\frac{1}{3}}}$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = -1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{i\sqrt{3}\left(8 + 12c_1 + 4\sqrt{9c_1^2 + 12c_1 + 8}\right)^{\frac{2}{3}} - \left(8 + 12c_1 + 4\sqrt{9c_1^2 + 12c_1 + 8}\right)^{\frac{2}{3}} + 4c_1\left(8 + 12c_1 + 4\sqrt{9c_1^2 -}\right.}{4\left(8 + 12c_1 + 4\sqrt{9c_1^2 + 12c_1 + 8}\right)^{\frac{1}{3}}}$$

Warning: Unable to solve for constant of integration. Initial conditions are used to solve for c_1. Substituting $x = -1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = \frac{\left(8 + 12c_1 + 4\sqrt{9c_1^2 + 12c_1 + 8}\right)^{\frac{2}{3}} + 2c_1\left(8 + 12c_1 + 4\sqrt{9c_1^2 + 12c_1 + 8}\right)^{\frac{1}{3}} - 4}{2\left(8 + 12c_1 + 4\sqrt{9c_1^2 + 12c_1 + 8}\right)^{\frac{1}{3}}}$$

Warning: Unable to solve for constant of integration.

<u>Verification of solutions</u> N/A

6.22.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{x^2 - 1}{y^2 + 1}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 301: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x + b_1y + c_1}{a_2x + b_2y + c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= \frac{1}{x^2 - 1} \\
\eta(x, y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{\frac{1}{x^2-1}} dx
\end{aligned}
$$

Which results in

$$
S = \frac{1}{3} x^3 - x
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$
\omega(x, y) = \frac{x^2 - 1}{y^2 + 1}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= x^2 - 1 \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = y^2 + 1 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R^2 + 1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{1}{3}R^3 + R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{1}{3}x^3 - x = \frac{y^3}{3} + y + c_1$$

Which simplifies to

$$\frac{1}{3}x^3 - x = \frac{y^3}{3} + y + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^2-1}{y^2+1}$ 	$R = y$ $S = \frac{1}{3}x^3 - x$	$\frac{dS}{dR} = R^2 + 1$ 
Initial conditions are used to solve for c_1. Substituting $x = -1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{2}{3} = c_1 + \frac{4}{3}$$

$$c_1 = -\frac{2}{3}$$

Substituting c_1 found above in the general solution gives

$$\frac{1}{3}x^3 - x = \frac{1}{3}y^3 + y - \frac{2}{3}$$

Summary

The solution(s) found are the following

$$\frac{1}{3}x^3 - x = \frac{y^3}{3} + y - \frac{2}{3} \tag{1}$$

Verification of solutions

$$\frac{1}{3}x^3 - x = \frac{y^3}{3} + y - \frac{2}{3}$$

Verified OK.

6.22.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(y^2+1\right)\mathrm{d}y&=\left(x^2-1\right)\mathrm{d}x\\ \left(-x^2+1\right)\mathrm{d}x+\left(y^2+1\right)\mathrm{d}y&=0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=-x^2+1\\ N(x,y)&=y^2+1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-x^2+1)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(y^2+1)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -x^2+1\,\mathrm{d}x\\ \phi &= -\frac{1}{3}x^3 + x + f(y)\end{aligned} \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y^2+1$. Therefore equation (4) becomes

$$y^2 + 1 = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = y^2 + 1$$

Integrating the above w.r.t y gives

$$\int f'(y)\, \mathrm{d}y = \int (y^2 + 1)\, \mathrm{d}y$$

$$f(y) = \frac{1}{3}y^3 + y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{1}{3}x^3 + x + \frac{1}{3}y^3 + y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{1}{3}x^3 + x + \frac{1}{3}y^3 + y$$

Initial conditions are used to solve for c_1. Substituting $x = -1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{2}{3} = c_1$$

$$c_1 = \frac{2}{3}$$

Substituting c_1 found above in the general solution gives

$$-\frac{1}{3}x^3 + x + \frac{1}{3}y^3 + y = \frac{2}{3}$$

Summary

The solution(s) found are the following

$$-\frac{x^3}{3} + x + \frac{y^3}{3} + y = \frac{2}{3} \tag{1}$$

Verification of solutions

$$-\frac{x^3}{3} + x + \frac{y^3}{3} + y = \frac{2}{3}$$

Verified OK.

6.22.6 Maple step by step solution

Let's solve

$\left[y' - \frac{x^2-1}{1+y^2} = 0, y(-1) = 1\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $y'(1+y^2) = x^2 - 1$

- Integrate both sides with respect to x

  $\int y'(1+y^2)\,dx = \int (x^2-1)\,dx + c_1$

- Evaluate integral

  $\frac{y^3}{3} + y = \frac{1}{3}x^3 - x + c_1$

- Solve for y

  $y = \frac{\left(4x^3+12c_1-12x+4\sqrt{x^6+6c_1x^3-6x^4+9c_1^2-18c_1x+9x^2+4}\right)^{\frac{1}{3}}}{2} - \frac{2}{\left(4x^3+12c_1-12x+4\sqrt{x^6+6c_1x^3-6x^4+9c_1^2-18c_1x+9x^2+4}\right)^{\frac{1}{3}}}$

- Use initial condition $y(-1) = 1$

  $1 = \frac{\left(8+12c_1+4\sqrt{9c_1^2+12c_1+8}\right)^{\frac{1}{3}}}{2} - \frac{2}{\left(8+12c_1+4\sqrt{9c_1^2+12c_1+8}\right)^{\frac{1}{3}}}$

- Solve for c_1

  $c_1 = \frac{2}{3}$

- Substitute $c_1 = \frac{2}{3}$ into general solution and simplify

  $y = \frac{\left(4x^3+8-12x+4\sqrt{x^6-6x^4+4x^3+9x^2-12x+8}\right)^{\frac{2}{3}}-4}{2\left(4x^3+8-12x+4\sqrt{x^6-6x^4+4x^3+9x^2-12x+8}\right)^{\frac{1}{3}}}$

- Solution to the IVP

  $y = \frac{\left(4x^3+8-12x+4\sqrt{x^6-6x^4+4x^3+9x^2-12x+8}\right)^{\frac{2}{3}}-4}{2\left(4x^3+8-12x+4\sqrt{x^6-6x^4+4x^3+9x^2-12x+8}\right)^{\frac{1}{3}}}$

6.23 problem 23

Internal problem ID [590]
Internal file name [`OUTPUT/590_Sunday_June_05_2022_01_45_23_AM_42038206/index.tex`]

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Miscellaneous problems, end of chapter 2. Page 133
Problem number: 23.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{(t+1)\, y+t y'={\mathrm e}^{2 t}}$$

6.23.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(t)y=q(t)$$

Where here

$$p(t)=-\frac{-t-1}{t}$$
$$q(t)=\frac{{\mathrm e}^{2 t}}{t}$$

Hence the ode is

$$y'-\frac{(-t-1)\, y}{t}=\frac{{\mathrm e}^{2 t}}{t}$$

The integrating factor μ is

$$\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{-t-1}{t}dt} \\
&= \mathrm{e}^{t+\ln(t)}
\end{aligned}$$

Which simplifies to

$$\mu = t\,\mathrm{e}^{t}$$

The ode becomes

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}t}(\mu y) &= (\mu)\left(\frac{\mathrm{e}^{2t}}{t}\right) \\
\frac{\mathrm{d}}{\mathrm{d}t}\left(t\,\mathrm{e}^{t} y\right) &= \left(t\,\mathrm{e}^{t}\right)\left(\frac{\mathrm{e}^{2t}}{t}\right) \\
\mathrm{d}\left(t\,\mathrm{e}^{t} y\right) &= \mathrm{e}^{3t}\,\mathrm{d}t
\end{aligned}$$

Integrating gives

$$\begin{aligned}
t\,\mathrm{e}^{t} y &= \int \mathrm{e}^{3t}\,\mathrm{d}t \\
t\,\mathrm{e}^{t} y &= \frac{\mathrm{e}^{3t}}{3} + c_1
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = t\,\mathrm{e}^{t}$ results in

$$y = \frac{\mathrm{e}^{-t}\mathrm{e}^{3t}}{3t} + \frac{c_1\mathrm{e}^{-t}}{t}$$

which simplifies to

$$y = \frac{3c_1\mathrm{e}^{-t} + \mathrm{e}^{2t}}{3t}$$

Summary

The solution(s) found are the following

$$y = \frac{3c_1\mathrm{e}^{-t} + \mathrm{e}^{2t}}{3t} \tag{1}$$

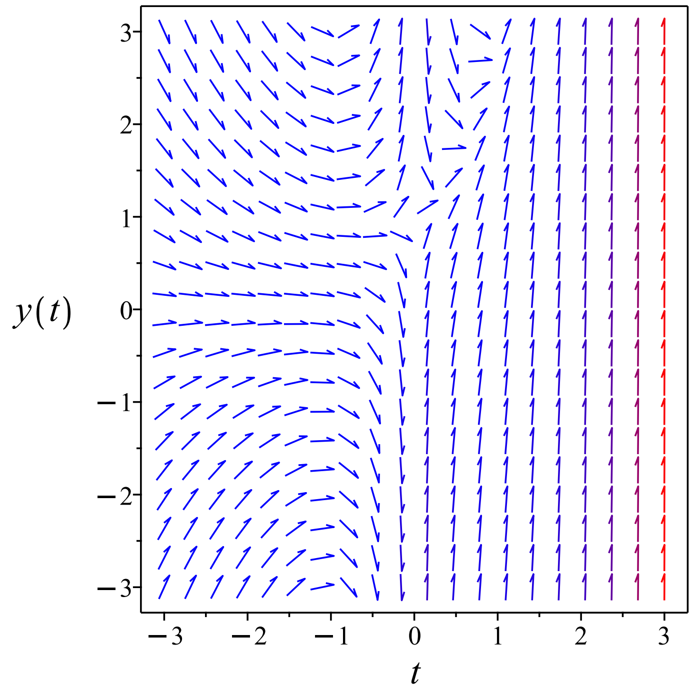

Figure 328: Slope field plot

Verification of solutions

$$y = \frac{3c_1 \mathrm{e}^{-t} + \mathrm{e}^{2t}}{3t}$$

Verified OK.

6.23.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{-ty + \mathrm{e}^{2t} - y}{t}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 304: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(t, y) &= 0 \\ \eta(t, y) &= \mathrm{e}^{-t - \ln(t)} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\mathrm{e}^{-t-\ln(t)}} dy
\end{aligned}$$

Which results in

$$S = t\,\mathrm{e}^{t} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = \frac{-ty + \mathrm{e}^{2t} - y}{t}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_t &= 1 \\
R_y &= 0 \\
S_t &= y\,\mathrm{e}^{t}(t + 1) \\
S_y &= t\,\mathrm{e}^{t}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \mathrm{e}^{3t} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \mathrm{e}^{3R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{e^{3R}}{3} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$t\,e^{t}y = \frac{e^{3t}}{3} + c_1$$

Which simplifies to

$$t\,e^{t}y = \frac{e^{3t}}{3} + c_1$$

Which gives

$$y = \frac{(e^{3t} + 3c_1)\,e^{-t}}{3t}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = \frac{-ty+e^{2t}-y}{t}$ 	$R = t$ $S = t\,e^{t}y$	$\frac{dS}{dR} = e^{3R}$ 
Summary

The solution(s) found are the following

$$y = \frac{(e^{3t} + 3c_1)\,e^{-t}}{3t} \tag{1}$$

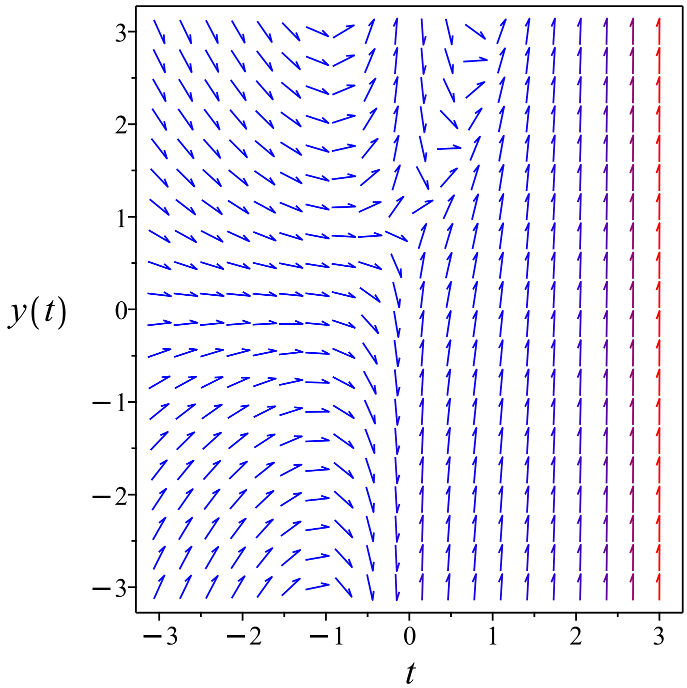

Figure 329: Slope field plot

Verification of solutions

$$y = \frac{\left(\mathrm{e}^{3t} + 3c_1\right)\mathrm{e}^{-t}}{3t}$$

Verified OK.

6.23.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\, \mathrm{d}t + N(t, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(t)\, \mathrm{d}y = \left(-(t+1)\, y + \mathrm{e}^{2t}\right) \mathrm{d}t$$
$$\left(-\mathrm{e}^{2t} + (t+1)\, y\right) \mathrm{d}t + (t)\, \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(t, y) = -\mathrm{e}^{2t} + (t+1)\, y$$
$$N(t, y) = t$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-\mathrm{e}^{2t} + (t+1)\, y\right)$$
$$= t + 1$$

And

$$\frac{\partial N}{\partial t} = \frac{\partial}{\partial t}(t)$$
$$= 1$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\
&= \frac{1}{t}((t+1) - (1)) \\
&= 1
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}t} \\
&= e^{\int 1 \, \mathrm{d}t}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{t} \\
&= \mathrm{e}^{t}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{t}\left(-\mathrm{e}^{2t} + (t+1)\, y\right) \\
&= \left(-\mathrm{e}^{2t} + (t+1)\, y\right) \mathrm{e}^{t}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{t}(t) \\
&= t\,\mathrm{e}^{t}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\
\left(\left(-\mathrm{e}^{2t} + (t+1)\, y\right) \mathrm{e}^{t}\right) + \left(t\,\mathrm{e}^{t}\right) \frac{\mathrm{d}y}{\mathrm{d}t} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(t, y)$

$$
\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \mathrm{d}t = \int \overline{M} \mathrm{d}t$$

$$\int \frac{\partial \phi}{\partial t} \mathrm{d}t = \int \left(-\mathrm{e}^{2t} + (t+1) y\right) \mathrm{e}^{t} \mathrm{d}t$$

$$\phi = t\,\mathrm{e}^{t} y - \frac{\mathrm{e}^{3t}}{3} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = t\,\mathrm{e}^{t} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = t\,\mathrm{e}^{t}$. Therefore equation (4) becomes

$$t\,\mathrm{e}^{t} = t\,\mathrm{e}^{t} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = t\,\mathrm{e}^{t} y - \frac{\mathrm{e}^{3t}}{3} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = t\,\mathrm{e}^{t} y - \frac{\mathrm{e}^{3t}}{3}$$

The solution becomes

$$y = \frac{\left(\mathrm{e}^{3t} + 3c_1\right) \mathrm{e}^{-t}}{3t}$$

Summary

The solution(s) found are the following

$$y = \frac{(e^{3t} + 3c_1) e^{-t}}{3t} \tag{1}$$

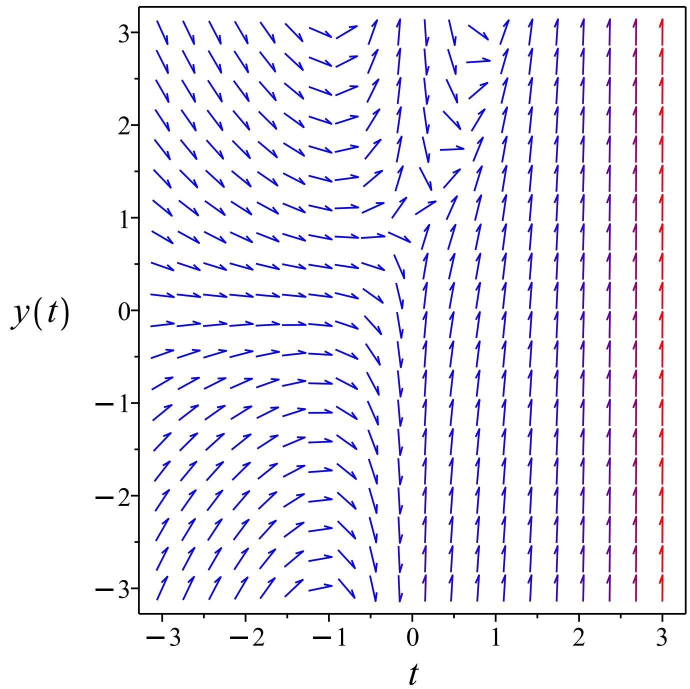

Figure 330: Slope field plot

Verification of solutions

$$y = \frac{(e^{3t} + 3c_1) e^{-t}}{3t}$$

Verified OK.

6.23.4 Maple step by step solution

Let's solve

$(t+1)\,y + ty' = e^{2t}$

- Highest derivative means the order of the ODE is 1

y'

- Isolate the derivative

$y' = -\frac{(t+1)y}{t} + \frac{e^{2t}}{t}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{(t+1)y}{t} = \frac{e^{2t}}{t}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(y' + \frac{(t+1)y}{t}\right) = \frac{\mu(t)e^{2t}}{t}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,y)$

  $\mu(t)\left(y' + \frac{(t+1)y}{t}\right) = \mu'(t)\,y + \mu(t)\,y'$

- Isolate $\mu'(t)$

  $\mu'(t) = \frac{\mu(t)(t+1)}{t}$

- Solve to find the integrating factor

  $\mu(t) = t\,e^{t}$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\,y)\right) dt = \int \frac{\mu(t)e^{2t}}{t} dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\,y = \int \frac{\mu(t)e^{2t}}{t} dt + c_1$

- Solve for y

  $y = \frac{\int \frac{\mu(t)e^{2t}}{t} dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = te^{t}$

  $y = \frac{\int e^{2t}e^{t} dt + c_1}{t\,e^{t}}$

- Evaluate the integrals on the rhs

  $y = \frac{\frac{e^{3t}}{3} + c_1}{t\,e^{t}}$

- Simplify

  $y = \frac{3c_1 e^{-t} + e^{2t}}{3t}$

Section: Miscellaneous problems, end of chapter 2. Page 133
Problem number: 24.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{2\cos(x)\sin(x)\sin(y)+\cos(y)\sin(x)^2 y'=0}$$

6.24.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= -\frac{2\cos(x)\tan(y)}{\sin(x)} \end{aligned}$$

Where $f(x)=-\frac{2\cos(x)}{\sin(x)}$ and $g(y)=\tan(y)$. Integrating both sides gives

$$\begin{aligned} \frac{1}{\tan(y)}\,dy &= -\frac{2\cos(x)}{\sin(x)}\,dx \\ \int \frac{1}{\tan(y)}\,dy &= \int -\frac{2\cos(x)}{\sin(x)}\,dx \\ \ln(\sin(y)) &= -2\ln(\sin(x))+c_1 \end{aligned}$$

Raising both side to exponential gives

$$\sin(y) = e^{-2\ln(\sin(x))+c_1}$$

Which simplifies to

$$\sin(y) = \frac{c_2}{\sin(x)^2}$$

Summary
The solution(s) found are the following

$$y = \arcsin\left(\frac{c_2 e^{c_1}}{\sin(x)^2}\right) \tag{1}$$

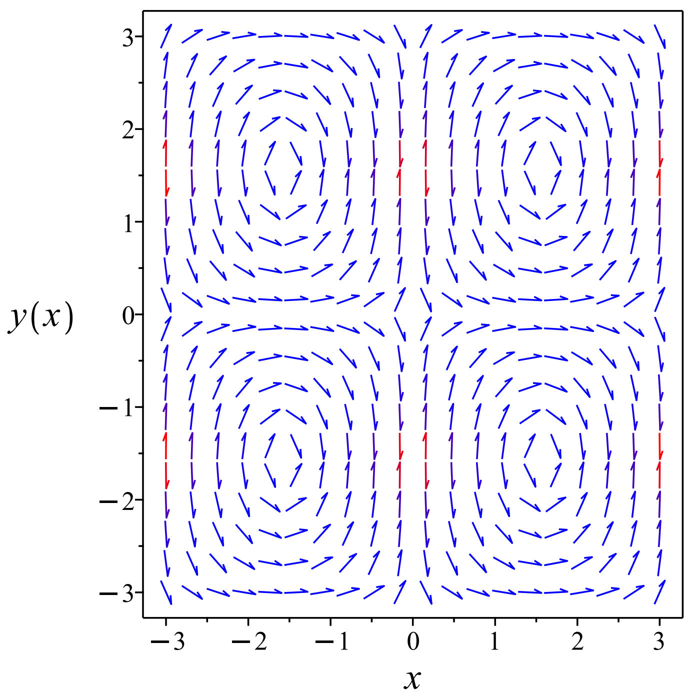

Figure 331: Slope field plot

Verification of solutions

$$y = \arcsin\left(\frac{c_2 e^{c_1}}{\sin(x)^2}\right)$$

Verified OK.

6.24.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{2\cos(x)\sin(y)}{\sin(x)\cos(y)} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 307: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0

Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= -\frac{\sin(x)}{2\cos(x)} \\
\eta(x,y) &= 0 \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R,S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{-\frac{\sin(x)}{2\cos(x)}} dx
\end{aligned}
$$

Which results in

$$
S = -2\ln(\sin(x))
$$

Now that R,S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = -\frac{2\cos(x)\sin(y)}{\sin(x)\cos(y)}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= -2 \cot (x) \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \cot (y) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \cot (R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \ln (\sin (R)) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-2 \ln (\sin (x)) = \ln (\sin (y)) + c_1$$

Which simplifies to

$$-2 \ln (\sin (x)) = \ln (\sin (y)) + c_1$$

Which gives

$$y = \arcsin \left(\frac{\mathrm{e}^{-c_1}}{\sin (x)^2}\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in x, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>
<tr><td>$\frac{dy}{dx} = -\frac{2\cos(x)\sin(y)}{\sin(x)\cos(y)}$
</td><td>$R = y$
$S = -2\ln(\sin(x))$</td><td>$\frac{dS}{dR} = \cot(R)$
</td></tr>
</table>

Summary

The solution(s) found are the following

$$y = \arcsin\left(\frac{e^{-c_1}}{\sin(x)^2}\right) \tag{1}$$

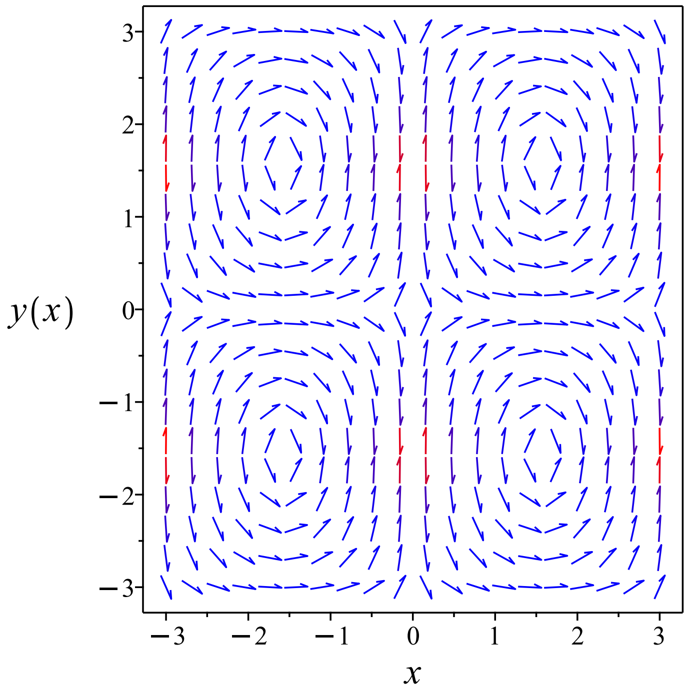

Figure 332: Slope field plot

Verification of solutions

$$y = \arcsin\left(\frac{e^{-c_1}}{\sin(x)^2}\right)$$

Verified OK.

6.24.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(-\frac{\cos(y)}{2\sin(y)}\right)\mathrm{d}y = \left(\frac{\cos(x)}{\sin(x)}\right)\mathrm{d}x$$
$$\left(-\frac{\cos(x)}{\sin(x)}\right)\mathrm{d}x + \left(-\frac{\cos(y)}{2\sin(y)}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\frac{\cos(x)}{\sin(x)}$$
$$N(x, y) = -\frac{\cos(y)}{2\sin(y)}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-\frac{\cos(x)}{\sin(x)}\right)$$
$$= 0$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{\cos(y)}{2\sin(y)}\right)\\&= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\frac{\cos(x)}{\sin(x)}\,\mathrm{d}x\\\phi &= -\ln(\sin(x)) + f(y)\end{aligned} \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{\cos(y)}{2\sin(y)}$. Therefore equation (4) becomes

$$-\frac{\cos(y)}{2\sin(y)} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$\begin{aligned}f'(y) &= -\frac{\cos(y)}{2\sin(y)}\\&= -\frac{\cot(y)}{2}\end{aligned}$$

Integrating the above w.r.t y results in

$$\int f'(y)\,\mathrm{d}y = \int \left(-\frac{\cot(y)}{2}\right) \mathrm{d}y$$

$$f(y) = -\frac{\ln(\sin(y))}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(\sin(x)) - \frac{\ln(\sin(y))}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(\sin(x)) - \frac{\ln(\sin(y))}{2}$$

Summary

The solution(s) found are the following

$$-\ln(\sin(x)) - \frac{\ln(\sin(y))}{2} = c_1 \tag{1}$$

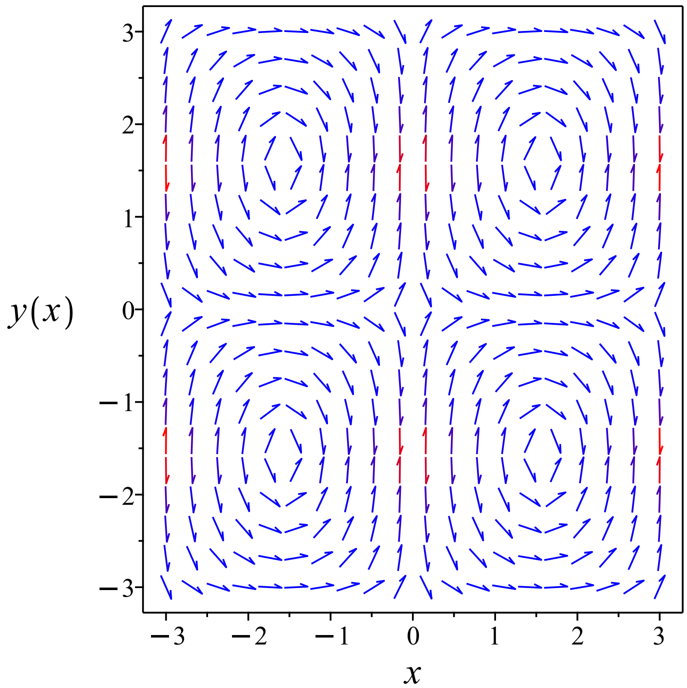

Figure 333: Slope field plot

Verification of solutions

$$-\ln(\sin(x)) - \frac{\ln(\sin(y))}{2} = c_1$$

Verified OK.

6.24.4 Maple step by step solution

Let's solve

$2\cos(x)\sin(x)\sin(y) + \cos(y)\sin(x)^2 y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Integrate both sides with respect to x

  $\int \left(2\cos(x)\sin(x)\sin(y) + \cos(y)\sin(x)^2 y'\right) dx = \int 0 dx + c_1$

- Evaluate integral

  $\sin(x)^2 \sin(y) = c_1$

- Solve for y

$$y = \arcsin\left(\frac{c_1}{\sin(x)^2}\right)$$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

`[_exact, _rational]`

$$\boxed{\frac{2x}{y} - \frac{y}{x^2+y^2} + \left(-\frac{x^2}{y^2} + \frac{x}{x^2+y^2}\right) y' = 0}$$

6.25.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\,\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(-\frac{x^2}{y^2} + \frac{x}{x^2 + y^2}\right)\mathrm{d}y = \left(-\frac{2x}{y} + \frac{y}{x^2 + y^2}\right)\mathrm{d}x$$
$$\left(\frac{2x}{y} - \frac{y}{x^2 + y^2}\right)\mathrm{d}x + \left(-\frac{x^2}{y^2} + \frac{x}{x^2 + y^2}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = \frac{2x}{y} - \frac{y}{x^2 + y^2}$$
$$N(x, y) = -\frac{x^2}{y^2} + \frac{x}{x^2 + y^2}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(\frac{2x}{y} - \frac{y}{x^2 + y^2}\right)$$
$$= -\frac{2x}{y^2} - \frac{1}{x^2 + y^2} + \frac{2y^2}{\left(x^2 + y^2\right)^2}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{x^2}{y^2} + \frac{x}{x^2+y^2}\right) \\
&= -\frac{2x}{y^2} - \frac{2x^2}{\left(x^2+y^2\right)^2} + \frac{1}{x^2+y^2}
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \frac{2x}{y} - \frac{y}{x^2+y^2}\,\mathrm{d}x
\end{aligned}
$$

$$
\phi = \frac{x^2}{y} - \arctan\left(\frac{x}{y}\right) + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = -\frac{x^2}{y^2} + \frac{x}{y^2\left(\frac{x^2}{y^2}+1\right)} + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{x^2}{y^2} + \frac{x}{x^2+y^2}$. Therefore equation (4) becomes

$$
-\frac{x^2}{y^2} + \frac{x}{x^2+y^2} = -\frac{\left((x-1)\,y^2 + x^3\right)x}{y^2\left(x^2+y^2\right)} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = 0
$$

Therefore

$$
f(y) = c_1
$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{x^2}{y} - \arctan\left(\frac{x}{y}\right) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{x^2}{y} - \arctan\left(\frac{x}{y}\right)$$

Summary

The solution(s) found are the following

$$\frac{x^2}{y} - \arctan\left(\frac{x}{y}\right) = c_1 \tag{1}$$

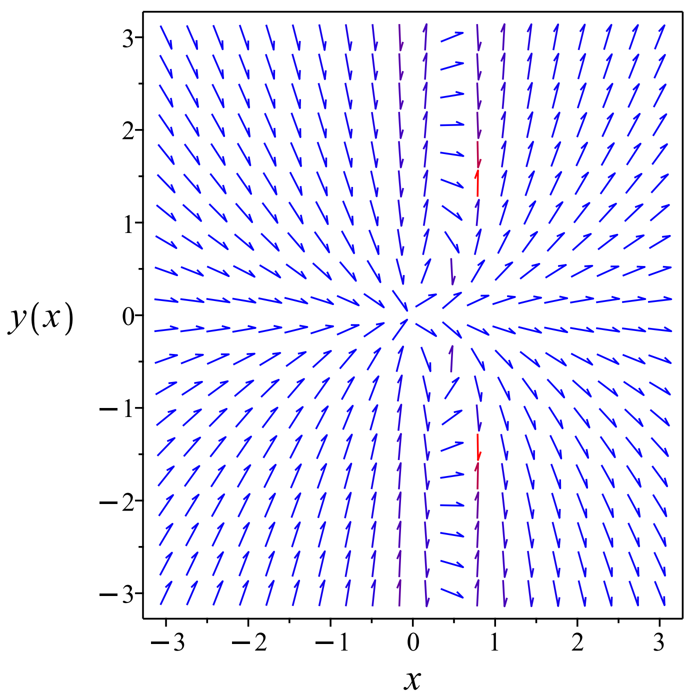

Figure 334: Slope field plot

Verification of solutions

$$\frac{x^2}{y} - \arctan\left(\frac{x}{y}\right) = c_1$$

Verified OK.

6.25.2 Maple step by step solution

Let's solve

$\frac{2x}{y}-\frac{y}{x^2+y^2}+\left(-\frac{x^2}{y^2}+\frac{x}{x^2+y^2}\right)y'=0$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact
  - ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x,y)=0$
  - Compute derivative of lhs

    $F'(x,y)+\left(\frac{\partial}{\partial y}F(x,y)\right)y'=0$
  - Evaluate derivatives

    $-\frac{2x}{y^2}-\frac{1}{x^2+y^2}+\frac{2y^2}{(x^2+y^2)^2}=-\frac{2x}{y^2}-\frac{2x^2}{(x^2+y^2)^2}+\frac{1}{x^2+y^2}$
  - Simplify

    $-\frac{2x}{y^2}-\frac{1}{x^2+y^2}+\frac{2y^2}{(x^2+y^2)^2}=-\frac{2x}{y^2}-\frac{2x^2}{(x^2+y^2)^2}+\frac{1}{x^2+y^2}$
  - Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y)=c_1, M(x,y)=F'(x,y), N(x,y)=\frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y)=\int\left(\frac{2x}{y}-\frac{y}{x^2+y^2}\right)dx+f_1(y)$

- Evaluate integral

  $F(x,y)=\frac{x^2}{y}-\arctan\left(\frac{x}{y}\right)+f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y)=\frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $-\frac{x^2}{y^2}+\frac{x}{x^2+y^2}=-\frac{x^2}{y^2}+\frac{x}{y^2\left(\frac{x^2}{y^2}+1\right)}+\frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

$$\frac{d}{dy}f_1(y) = \frac{x}{x^2+y^2} - \frac{x}{y^2\left(\frac{x^2}{y^2}+1\right)}$$

- Solve for $f_1(y)$

$$f_1(y) = 0$$

- Substitute $f_1(y)$ into equation for $F(x,y)$

$$F(x,y) = \frac{x^2}{y} - \arctan\left(\frac{x}{y}\right)$$

- Substitute $F(x,y)$ into the solution of the ODE

$$\frac{x^2}{y} - \arctan\left(\frac{x}{y}\right) = c_1$$

- Solve for y

$$y = \frac{x}{\tan\left(\mathit{RootOf}\left(\_Z - x\tan\left(\_Z\right) + c_1\right)\right)}$$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"homogeneousTypeD", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _dAlembert]
```

$$\boxed{y'x - \mathrm{e}^{\frac{y}{x}} x - y = 0}$$

6.26.1 Solving as homogeneousTypeD ode

Writing the ode as

$$y' = \mathrm{e}^{\frac{y}{x}} + \frac{y}{x} \tag{A}$$

The given ode has the form

$$y' = \frac{y}{x} + g(x)\, f\left(b\frac{y}{x}\right)^{\frac{n}{m}} \tag{1}$$

Where b is scalar and $g(x)$ is function of x and n, m are integers. The solution is given in Kamke page 20. Using the substitution $y(x) = u(x)\, x$ then

$$\frac{dy}{dx} = \frac{du}{dx} x + u$$

Hence the given ode becomes

$$
\begin{aligned}
\frac{du}{dx}x + u &= u + g(x)\, f(bu)^{\frac{n}{m}} \\
u' &= \frac{1}{x} g(x)\, f(bu)^{\frac{n}{m}} \qquad (2)
\end{aligned}
$$

The above ode is always separable. This is easily solved for u assuming the integration can be resolved, and then the solution to the original ode becomes $y = ux$. Comapring the given ode (A) with the form (1) shows that

$$
\begin{aligned}
g(x) &= 1 \\
b &= 1 \\
f\left(\frac{bx}{y}\right) &= \mathrm{e}^{\frac{y}{x}}
\end{aligned}
$$

Substituting the above in (2) results in the $u(x)$ ode as

$$
u'(x) = \frac{\mathrm{e}^{u(x)}}{x}
$$

Which is now solved as separable In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= \frac{\mathrm{e}^{u}}{x}
\end{aligned}
$$

Where $f(x) = \frac{1}{x}$ and $g(u) = \mathrm{e}^{u}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\mathrm{e}^{u}}\, du &= \frac{1}{x}\, dx \\
\int \frac{1}{\mathrm{e}^{u}}\, du &= \int \frac{1}{x}\, dx \\
-\mathrm{e}^{-u} &= \ln(x) + c_1
\end{aligned}
$$

The solution is

$$
-\mathrm{e}^{-u(x)} - \ln(x) - c_1 = 0
$$

Therefore the solution is found using $y = ux$. Hence

$$
-\mathrm{e}^{-\frac{y}{x}} - \ln(x) - c_1 = 0
$$

Summary

The solution(s) found are the following

$$-\mathrm{e}^{-\frac{y}{x}}-\ln\left(x\right)-c_1=0 \tag{1}$$

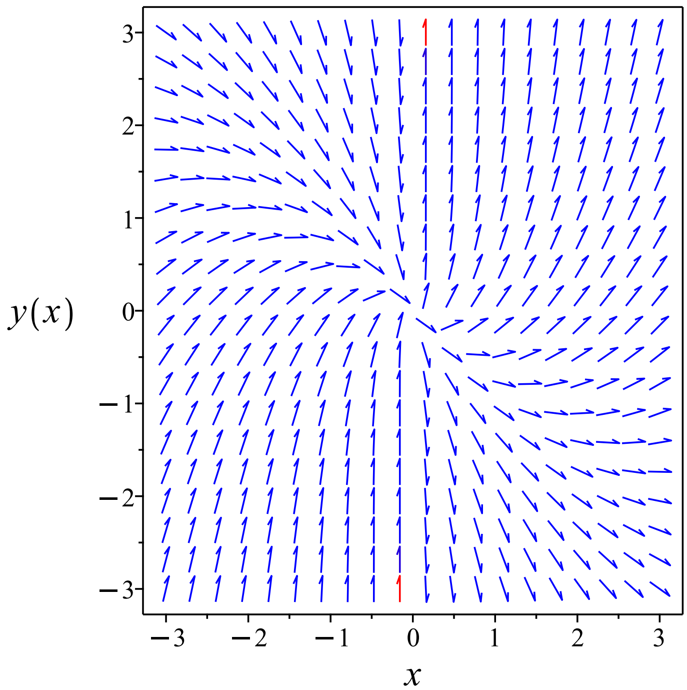

Figure 335: Slope field plot

Verification of solutions

$$-\mathrm{e}^{-\frac{y}{x}}-\ln\left(x\right)-c_1=0$$

Verified OK.

6.26.2 Solving as homogeneousTypeD2 ode

Using the change of variables $y=u(x)\,x$ on the above ode results in new ode in $u(x)$

$$(u'(x)\,x+u(x))\,x-\mathrm{e}^{u(x)}x-u(x)\,x=0$$

In canonical form the ODE is

$$\begin{aligned}u' &= F(x,u)\\ &= f(x)g(u)\\ &= \frac{\mathrm{e}^{u}}{x}\end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(u) = e^u$. Integrating both sides gives

$$\frac{1}{e^u} du = \frac{1}{x} dx$$
$$\int \frac{1}{e^u} du = \int \frac{1}{x} dx$$
$$-e^{-u} = \ln(x) + c_2$$

The solution is

$$-e^{-u(x)} - \ln(x) - c_2 = 0$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$-e^{-\frac{y}{x}} - \ln(x) - c_2 = 0$$
$$-e^{-\frac{y}{x}} - \ln(x) - c_2 = 0$$

Summary
The solution(s) found are the following

$$-e^{-\frac{y}{x}} - \ln(x) - c_2 = 0 \tag{1}$$

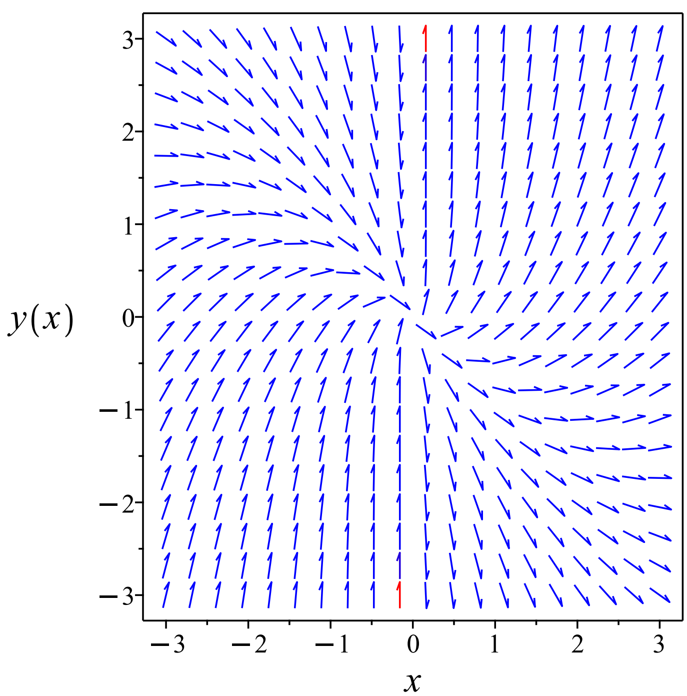

Figure 336: Slope field plot

Verification of solutions

Verified OK.

6.26.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{\mathrm{e}^{\frac{y}{x}} x + y}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `homogeneous Type D`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 311: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= x^2 \\ \eta(x,y) &= yx \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Therefore

$$\frac{dy}{dx} = \frac{\eta}{\xi} = \frac{yx}{x^2} = \frac{y}{x}$$

This is easily solved to give

$$y = c_1 x$$

Where now the coordinate R is taken as the constant of integration. Hence

$$R = \frac{y}{x}$$

And S is found from

$$dS = \frac{dx}{\xi} = \frac{dx}{x^2}$$

Integrating gives

$$S = \int \frac{dx}{T} = -\frac{1}{x}$$

Where the constant of integration is set to zero as we just need one solution. Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{e^{\frac{y}{x}} x + y}{x}$$

Evaluating all the partial derivatives gives

$$R_x = -\frac{y}{x^2}$$
$$R_y = \frac{1}{x}$$
$$S_x = \frac{1}{x^2}$$
$$S_y = 0$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{e^{-\frac{y}{x}}}{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -S(R)\,e^{-R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 e^{e^{-R}} \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{1}{x} = c_1 e^{e^{-\frac{y}{x}}}$$

Which simplifies to

$$-\frac{1}{x} = c_1 e^{e^{-\frac{y}{x}}}$$

Which gives

$$y = -\ln\left(\ln\left(-\frac{1}{c_1 x}\right)\right) x$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{e^{\frac{y}{x}} x+y}{x}$ 	$R = \frac{y}{x}$ $S = -\frac{1}{x}$	$\frac{dS}{dR} = -S(R)\, e^{-R}$ 
Summary

The solution(s) found are the following

$$y = -\ln\left(\ln\left(-\frac{1}{c_1 x}\right)\right) x \tag{1}$$

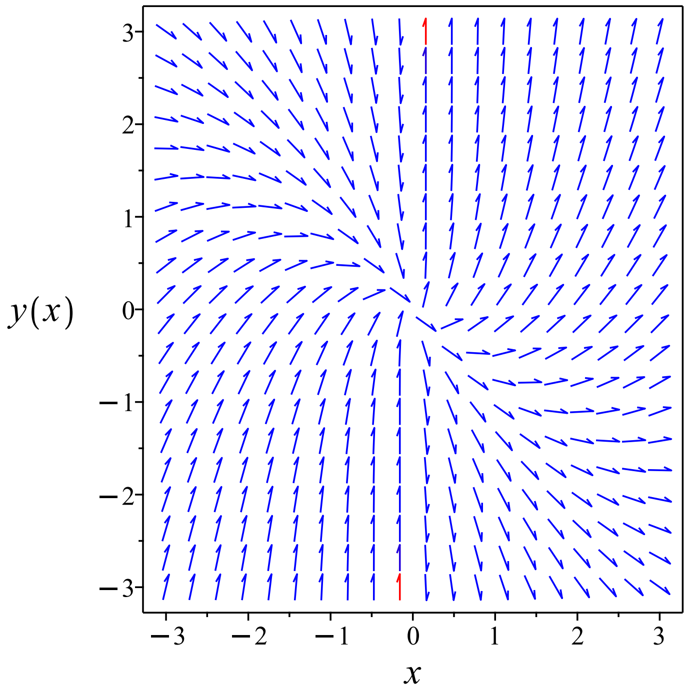

Figure 337: Slope field plot

Verification of solutions

$$y = -\ln\left(\ln\left(-\frac{1}{c_1 x}\right)\right)x$$

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor"**

Maple gives the following as the ode type

```
[_rational, [_1st_order, `_with_symmetry_[F(x)*G(y),0]`]]
```

$$\boxed{y' - \frac{x}{x^2 + y + y^3} = 0}$$

6.27.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(y^3 + x^2 + y)\,\mathrm{d}y &= (x)\,\mathrm{d}x\\ (-x)\,\mathrm{d}x + (y^3 + x^2 + y)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -x\\ N(x, y) &= y^3 + x^2 + y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-x)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(y^3 + x^2 + y)\\ &= 2x\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{y^3 + x^2 + y}((0) - (2x))\\ &= -\frac{2x}{y^3 + x^2 + y}\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned} B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\ &= -\frac{1}{x}((2x) - (0)) \\ &= -2 \end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned} \mu &= e^{\int B \, \mathrm{d}y} \\ &= e^{\int -2 \, \mathrm{d}y} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-2y} \\ &= \mathrm{e}^{-2y} \end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{-2y}(-x) \\ &= -x\,\mathrm{e}^{-2y} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{-2y}\left(y^3 + x^2 + y\right) \\ &= \left(y^3 + x^2 + y\right)\mathrm{e}^{-2y} \end{aligned}$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(-x\,\mathrm{e}^{-2y}\right) + \left(\left(y^3 + x^2 + y\right)\mathrm{e}^{-2y}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= \overline{M} \qquad (1)\\
\frac{\partial \phi}{\partial y} &= \overline{N} \qquad (2)
\end{aligned}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int \overline{M} \,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int -x \,\mathrm{e}^{-2y} \,\mathrm{d}x \\
\phi &= -\frac{x^2 \mathrm{e}^{-2y}}{2} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = x^2 \mathrm{e}^{-2y} + f'(y) \qquad (4)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = (y^3 + x^2 + y) \,\mathrm{e}^{-2y}$. Therefore equation (4) becomes

$$
(y^3 + x^2 + y) \,\mathrm{e}^{-2y} = x^2 \mathrm{e}^{-2y} + f'(y) \qquad (5)
$$

Solving equation (5) for $f'(y)$ gives

$$
\begin{aligned}
f'(y) &= \mathrm{e}^{-2y} y^3 + \mathrm{e}^{-2y} y \\
&= \mathrm{e}^{-2y} (y^3 + y)
\end{aligned}
$$

Integrating the above w.r.t y results in

$$
\begin{aligned}
\int f'(y) \,\mathrm{d}y &= \int \left(\mathrm{e}^{-2y} (y^3 + y)\right) \mathrm{d}y \\
f(y) &= -\frac{\mathrm{e}^{-2y} (4y^3 + 6y^2 + 10y + 5)}{8} + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x^2 e^{-2y}}{2} - \frac{e^{-2y}(4y^3 + 6y^2 + 10y + 5)}{8} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x^2 e^{-2y}}{2} - \frac{e^{-2y}(4y^3 + 6y^2 + 10y + 5)}{8}$$

Summary

The solution(s) found are the following

$$-\frac{x^2 e^{-2y}}{2} - \frac{e^{-2y}(4y^3 + 6y^2 + 10y + 5)}{8} = c_1 \tag{1}$$

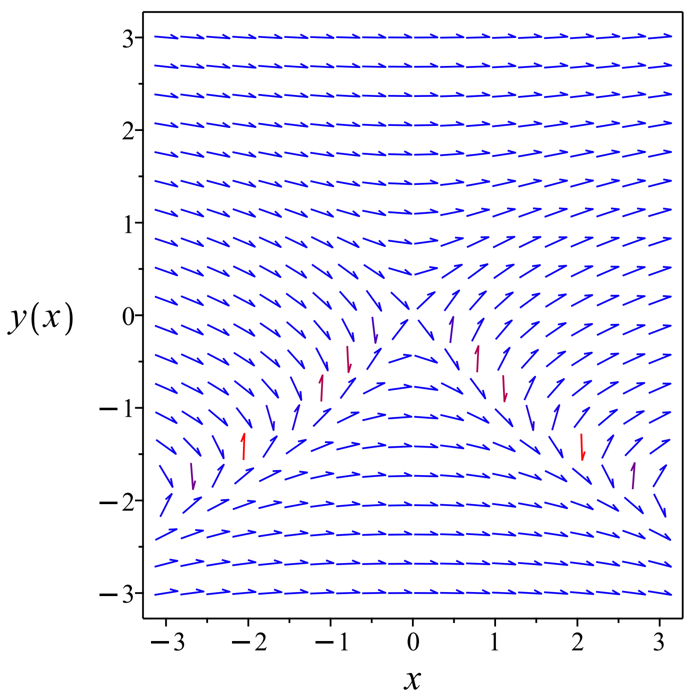

Figure 338: Slope field plot

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "homogeneousTypeD2", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_linear]
```

$$\boxed{2y + ty' = -3t}$$

6.28.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(t)y = q(t)$$

Where here

$$p(t) = \frac{2}{t}$$
$$q(t) = -3$$

Hence the ode is

$$y' + \frac{2y}{t} = -3$$

The integrating factor μ is

$$\mu = e^{\int \frac{2}{t} dt}$$
$$= t^2$$

The ode becomes

$$\frac{d}{dt}(\mu y) = (\mu)(-3)$$
$$\frac{d}{dt}(t^2 y) = (t^2)(-3)$$
$$d(t^2 y) = (-3t^2)\, dt$$

Integrating gives

$$t^2 y = \int -3t^2 \, dt$$
$$t^2 y = -t^3 + c_1$$

Dividing both sides by the integrating factor $\mu = t^2$ results in

$$y = -t + \frac{c_1}{t^2}$$

Summary

The solution(s) found are the following

$$y = -t + \frac{c_1}{t^2} \tag{1}$$

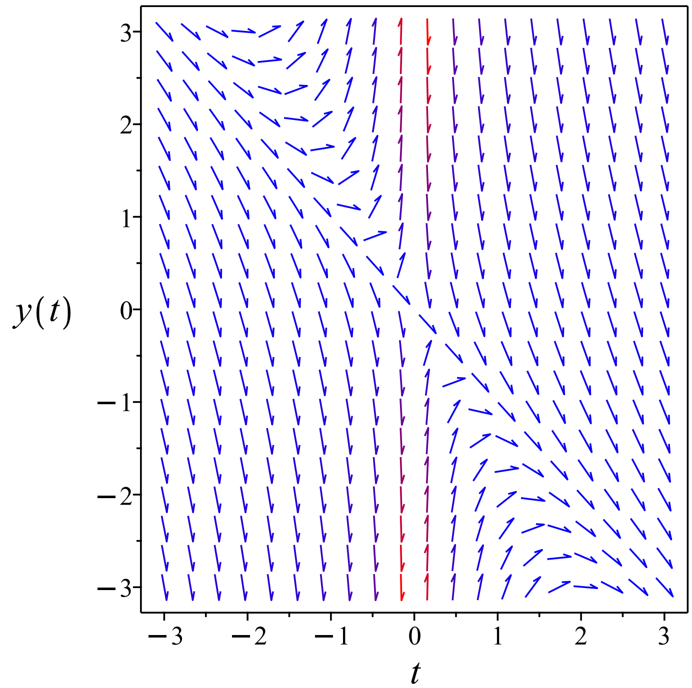

Figure 339: Slope field plot

Verification of solutions

$$y = -t + \frac{c_1}{t^2}$$

Verified OK.

6.28.2 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(t)\,t$ on the above ode results in new ode in $u(t)$

$$2u(t)\,t + t(u'(t)\,t + u(t)) = -3t$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(t,u) \\ &= f(t)g(u) \\ &= \frac{-3u-3}{t} \end{aligned}$$

Where $f(t) = \frac{1}{t}$ and $g(u) = -3u - 3$. Integrating both sides gives

$$\frac{1}{-3u-3}\,du = \frac{1}{t}\,dt$$

$$
\int \frac{1}{-3u-3}du = \int \frac{1}{t}dt
$$

$$
-\frac{\ln (u+1)}{3} = \ln (t) + c_2
$$

Raising both side to exponential gives

$$
\frac{1}{(u+1)^{\frac{1}{3}}} = \mathrm{e}^{\ln(t)+c_2}
$$

Which simplifies to

$$
\frac{1}{(u+1)^{\frac{1}{3}}} = c_3 t
$$

Therefore the solution y is

$$
\begin{aligned}
y &= ut \\
&= -\frac{(c_3^3 \mathrm{e}^{3c_2} t^3 - 1)\, \mathrm{e}^{-3c_2}}{t^2 c_3^3}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = -\frac{(c_3^3 \mathrm{e}^{3c_2} t^3 - 1)\, \mathrm{e}^{-3c_2}}{t^2 c_3^3} \tag{1}
$$

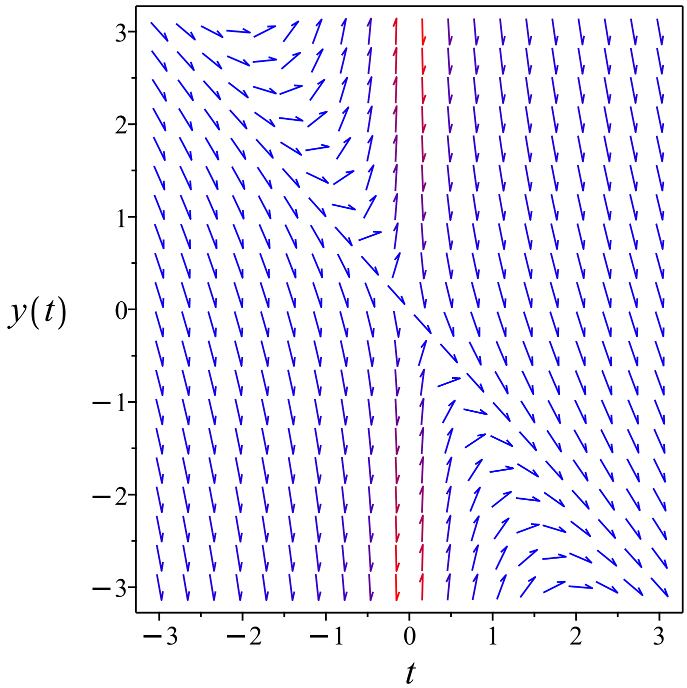

Figure 340: Slope field plot

Verification of solutions

$$y = -\frac{(c_3^3 \mathrm{e}^{3c_2} t^3 - 1)\,\mathrm{e}^{-3c_2}}{t^2 c_3^3}$$

Verified OK.

6.28.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{3t + 2y}{t}$$
$$y' = \omega(t, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_t + \omega(\eta_y - \xi_t) - \omega^2 \xi_y - \omega_t \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 313: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(t, y) &= 0 \\
\eta(t, y) &= \frac{1}{t^2}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(t, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dt}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial y}\right) S(t, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = t$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{t^2}} dy \end{aligned}$$

Which results in

$$S = t^2 y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_t + \omega(t, y) S_y}{R_t + \omega(t, y) R_y} \tag{2}$$

Where in the above R_t, R_y, S_t, S_y are all partial derivatives and $\omega(t, y)$ is the right hand side of the original ode given by

$$\omega(t, y) = -\frac{3t + 2y}{t}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_t &= 1 \\ R_y &= 0 \\ S_t &= 2ty \\ S_y &= t^2 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -3t^2 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for t, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -3R^2$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -R^3 + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to t, y coordinates. This results in

$$yt^2 = -t^3 + c_1$$

Which simplifies to

$$yt^2 = -t^3 + c_1$$

Which gives

$$y = \frac{-t^3 + c_1}{t^2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in t, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dt} = -\frac{3t+2y}{t}$ 	$R = t$ $S = t^2 y$	$\frac{dS}{dR} = -3R^2$ 
Summary

The solution(s) found are the following

$$y = \frac{-t^3 + c_1}{t^2} \tag{1}$$

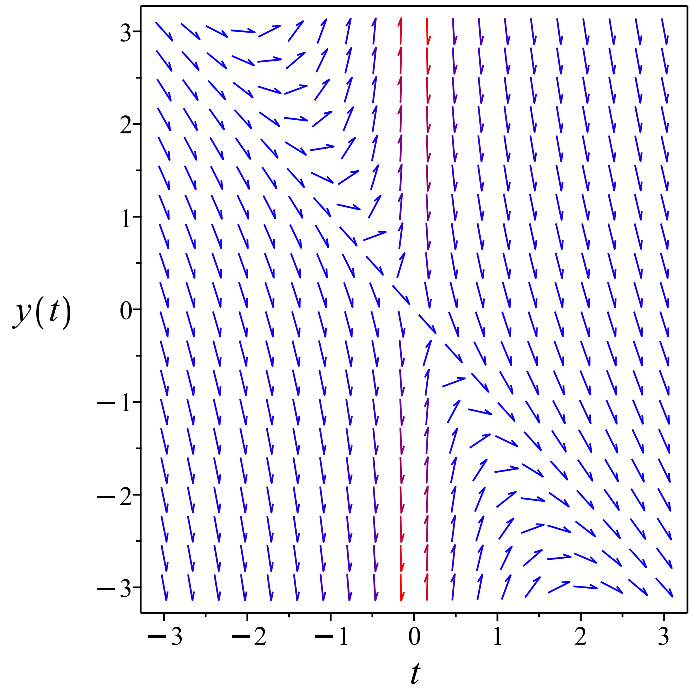

Figure 341: Slope field plot

<u>Verification of solutions</u>

$$y = \frac{-t^3 + c_1}{t^2}$$

6.28.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(t, y)\,\mathrm{d}t + N(t, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(t)\,\mathrm{d}y &= (-3t - 2y)\,\mathrm{d}t \\ (3t + 2y)\,\mathrm{d}t + (t)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(t, y) = 3t + 2y$$
$$N(t, y) = t$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial t}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(3t + 2y) \\ &= 2\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial t} &= \frac{\partial}{\partial t}(t) \\ &= 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial t}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial t}\right) \\
&= \frac{1}{t}((2) - (1)) \\
&= \frac{1}{t}
\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}t} \\
&= e^{\int \frac{1}{t} \, \mathrm{d}t}
\end{aligned}$$

The result of integrating gives

$$\begin{aligned}
\mu &= e^{\ln(t)} \\
&= t
\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}
\overline{M} &= \mu M \\
&= t(3t + 2y) \\
&= t(3t + 2y)
\end{aligned}$$

And

$$\begin{aligned}
\overline{N} &= \mu N \\
&= t(t) \\
&= t^2
\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}t} &= 0 \\
(t(3t + 2y)) + \left(t^2\right)\frac{\mathrm{d}y}{\mathrm{d}t} &= 0
\end{aligned}$$

The following equations are now set up to solve for the function $\phi(t,y)$

$$\frac{\partial \phi}{\partial t} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. t gives

$$\int \frac{\partial \phi}{\partial t} \,\mathrm{d}t = \int \overline{M} \,\mathrm{d}t$$

$$\int \frac{\partial \phi}{\partial t} \,\mathrm{d}t = \int t(3t + 2y) \,\mathrm{d}t$$

$$\phi = t^2(t + y) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both t and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = t^2 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = t^2$. Therefore equation (4) becomes

$$t^2 = t^2 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = t^2(t + y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = t^2(t + y)$$

The solution becomes

$$y = \frac{-t^3 + c_1}{t^2}$$

Summary

The solution(s) found are the following

$$y = \frac{-t^3 + c_1}{t^2} \tag{1}$$

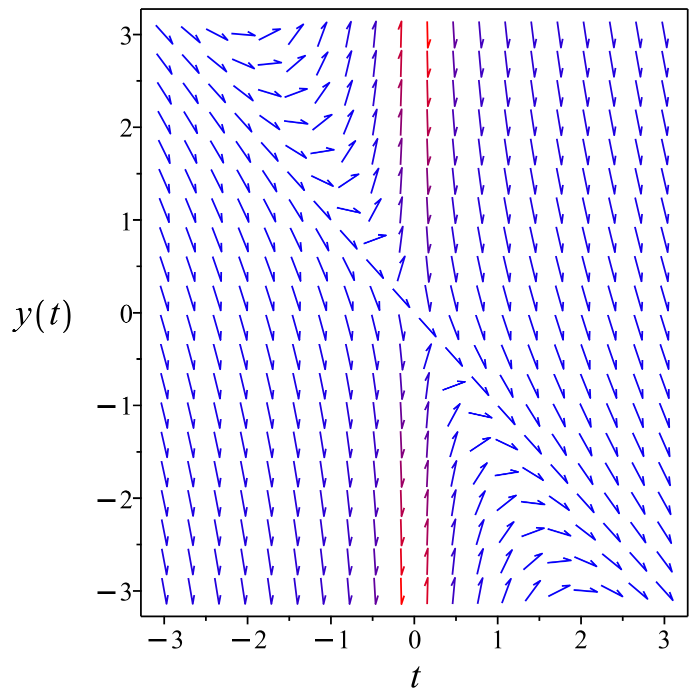

Figure 342: Slope field plot

Verification of solutions

$$y = \frac{-t^3 + c_1}{t^2}$$

Verified OK.

6.28.5 Maple step by step solution

Let's solve

$2y + ty' = -3t$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -3 - \frac{2y}{t}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{2y}{t} = -3$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(y' + \frac{2y}{t}\right) = -3\mu(t)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, y)$

  $\mu(t)\left(y' + \frac{2y}{t}\right) = \mu'(t)\, y + \mu(t)\, y'$

- Isolate $\mu'(t)$

  $\mu'(t) = \frac{2\mu(t)}{t}$

- Solve to find the integrating factor

  $\mu(t) = t^2$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\, y)\right) dt = \int -3\mu(t)\, dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\, y = \int -3\mu(t)\, dt + c_1$

- Solve for y

  $y = \frac{\int -3\mu(t)dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = t^2$

  $y = \frac{\int -3t^2dt + c_1}{t^2}$

- Evaluate the integrals on the rhs

  $y = \frac{-t^3 + c_1}{t^2}$

Problem number: 29.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exactByInspection", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{y' - \frac{x + y}{x - y} = 0}$$

6.29.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x + u(x) - \frac{x + u(x)\,x}{x - u\,(x)\,x} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{u^2 + 1}{x\,(u - 1)} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{u^2+1}{u-1}$. Integrating both sides gives

$$\frac{1}{\frac{u^2+1}{u-1}} \, du = -\frac{1}{x} \, dx$$

$$\int \frac{1}{\frac{u^2+1}{u-1}} \, du = \int -\frac{1}{x} \, dx$$

$$\frac{\ln (u^2+1)}{2} - \arctan (u) = -\ln (x) + c_2$$

The solution is

$$\frac{\ln \left(u(x)^2+1\right)}{2} - \arctan (u(x)) + \ln (x) - c_2 = 0$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\frac{\ln \left(\frac{y^2}{x^2}+1\right)}{2} - \arctan \left(\frac{y}{x}\right) + \ln (x) - c_2 = 0$$

$$\frac{\ln \left(\frac{y^2}{x^2}+1\right)}{2} - \arctan \left(\frac{y}{x}\right) + \ln (x) - c_2 = 0$$

Summary

The solution(s) found are the following

$$\frac{\ln \left(\frac{y^2}{x^2}+1\right)}{2} - \arctan \left(\frac{y}{x}\right) + \ln (x) - c_2 = 0 \tag{1}$$

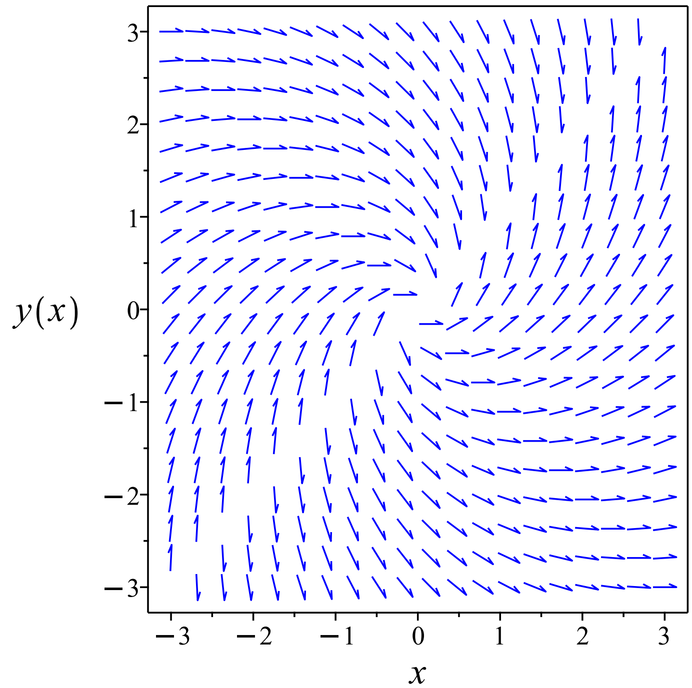

Figure 343: Slope field plot

Verification of solutions

$$\frac{\ln\left(\frac{y^2}{x^2}+1\right)}{2} - \arctan\left(\frac{y}{x}\right) + \ln(x) - c_2 = 0$$

Verified OK.

6.29.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -\frac{x+y}{-x+y}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 - \frac{(x+y)(b_3-a_2)}{-x+y} - \frac{(x+y)^2 a_3}{(-x+y)^2} - \left(-\frac{1}{-x+y} - \frac{x+y}{(-x+y)^2}\right)(xa_2+ya_3+a_1) - \left(-\frac{1}{-x+y} + \frac{x+y}{(-x+y)^2}\right)(xb_2+yb_3+b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{x^2a_2 + x^2a_3 + x^2b_2 - x^2b_3 - 2xya_2 + 2xya_3 + 2xyb_2 + 2xyb_3 - y^2a_2 - y^2a_3 - y^2b_2 + y^2b_3 + 2xb_1 - 2ya}{(x-y)^2} = 0$$

Setting the numerator to zero gives

$$-x^2a_2 - x^2a_3 - x^2b_2 + x^2b_3 + 2xya_2 - 2xya_3 - 2xyb_2 - 2xyb_3 + y^2a_2 + y^2a_3 + y^2b_2 - y^2b_3 - 2xb_1 + 2ya_1 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$-a_2v_1^2 + 2a_2v_1v_2 + a_2v_2^2 - a_3v_1^2 - 2a_3v_1v_2 + a_3v_2^2 - b_2v_1^2 - 2b_2v_1v_2 + b_2v_2^2 + b_3v_1^2 - 2b_3v_1v_2 - b_3v_2^2 + 2a_1v_2 - 2b_1v_1 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}(-a_2 - a_3 - b_2 + b_3)\, v_1^2 + (2a_2 - 2a_3 - 2b_2 - 2b_3)\, v_1 v_2 \\ - 2b_1 v_1 + (a_2 + a_3 + b_2 - b_3)\, v_2^2 + 2a_1 v_2 = 0\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}2a_1 &= 0\\ -2b_1 &= 0\\ -a_2 - a_3 - b_2 + b_3 &= 0\\ a_2 + a_3 + b_2 - b_3 &= 0\\ 2a_2 - 2a_3 - 2b_2 - 2b_3 &= 0\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}a_1 &= 0\\ a_2 &= b_3\\ a_3 &= -b_2\\ b_1 &= 0\\ b_2 &= b_2\\ b_3 &= b_3\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}\xi &= x\\ \eta &= y\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}\eta &= \eta - \omega(x, y)\, \xi\\ &= y - \left(-\frac{x+y}{-x+y}\right)(x)\\ &= \frac{-x^2 - y^2}{x - y}\\ \xi &= 0\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{-x^2-y^2}{x-y}} dy \end{aligned}$$

Which results in

$$S = \frac{\ln(x^2 + y^2)}{2} - \arctan\left(\frac{y}{x}\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{x + y}{-x + y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{x + y}{x^2 + y^2} \\ S_y &= \frac{-x + y}{x^2 + y^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(x^2 + y^2)}{2} - \arctan\left(\frac{y}{x}\right) = c_1$$

Which simplifies to

$$\frac{\ln(x^2 + y^2)}{2} - \arctan\left(\frac{y}{x}\right) = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{x+y}{-x+y}$ 	$R = x$ $S = \frac{\ln(x^2+y^2)}{2} - \arctan$	$\frac{dS}{dR} = 0$ 
Summary
The solution(s) found are the following

$$\frac{\ln(x^2+y^2)}{2} - \arctan\left(\frac{y}{x}\right) = c_1 \tag{1}$$

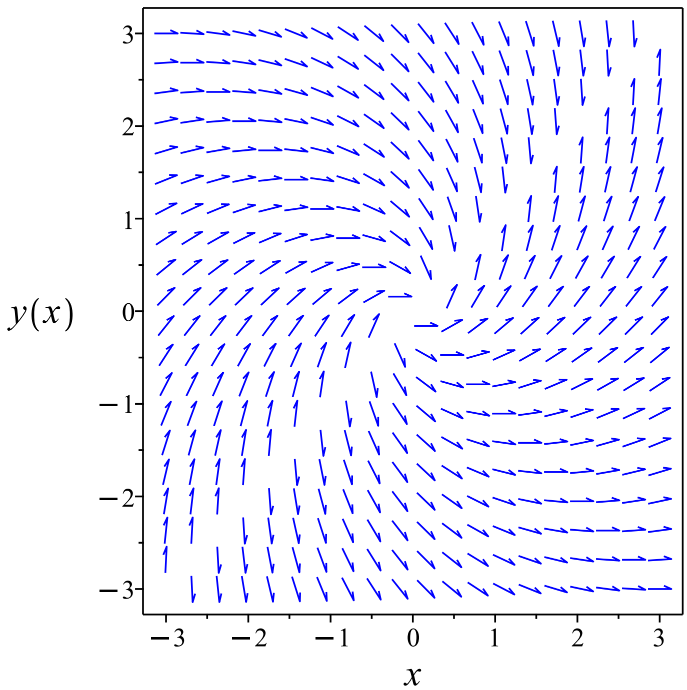

Figure 344: Slope field plot

Verification of solutions

$$\frac{\ln(x^2+y^2)}{2} - \arctan\left(\frac{y}{x}\right) = c_1$$

Verified OK.

6.29.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x}=M$$
$$\frac{\partial\phi}{\partial y}=N$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$(-x+y)\,\mathrm{d}y=(-x-y)\,\mathrm{d}x$$
$$(x+y)\,\mathrm{d}x+(-x+y)\,\mathrm{d}y=0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y)=x+y$$
$$N(x,y)=-x+y$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}(x+y)\\&=1\end{aligned}$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}(-x+y)$$
$$= -1$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. By inspection $\frac{1}{x^2+y^2}$ is an integrating factor. Therefore by multiplying $M = x + y$ and $N = -x + y$ by this integrating factor the ode becomes exact. The new M, N are

$$M = \frac{x+y}{x^2+y^2}$$
$$N = \frac{-x+y}{x^2+y^2}$$

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{-x+y}{x^2+y^2}\right)\mathrm{d}y = \left(-\frac{x+y}{x^2+y^2}\right)\mathrm{d}x$$

$$\left(\frac{x+y}{x^2+y^2}\right)\mathrm{d}x + \left(\frac{-x+y}{x^2+y^2}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = \frac{x+y}{x^2+y^2}$$
$$N(x,y) = \frac{-x+y}{x^2+y^2}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{x+y}{x^2+y^2}\right)\\ &= \frac{x^2-2yx-y^2}{(x^2+y^2)^2}\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{-x+y}{x^2+y^2}\right)\\ &= \frac{x^2-2yx-y^2}{(x^2+y^2)^2}\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \frac{x + y}{x^2 + y^2} \, \mathrm{d}x$$

$$\phi = \frac{\ln(x^2 + y^2)}{2} + \arctan\left(\frac{x}{y}\right) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{y}{x^2 + y^2} - \frac{x}{y^2 \left(\frac{x^2}{y^2} + 1\right)} + f'(y) \tag{4}$$

$$= \frac{-x + y}{x^2 + y^2} + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{-x+y}{x^2+y^2}$. Therefore equation (4) becomes

$$\frac{-x + y}{x^2 + y^2} = \frac{-x + y}{x^2 + y^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{\ln(x^2 + y^2)}{2} + \arctan\left(\frac{x}{y}\right) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{\ln(x^2 + y^2)}{2} + \arctan\left(\frac{x}{y}\right)$$

Summary

The solution(s) found are the following

$$\frac{\ln(x^2+y^2)}{2}+\arctan\left(\frac{x}{y}\right)=c_1 \tag{1}$$

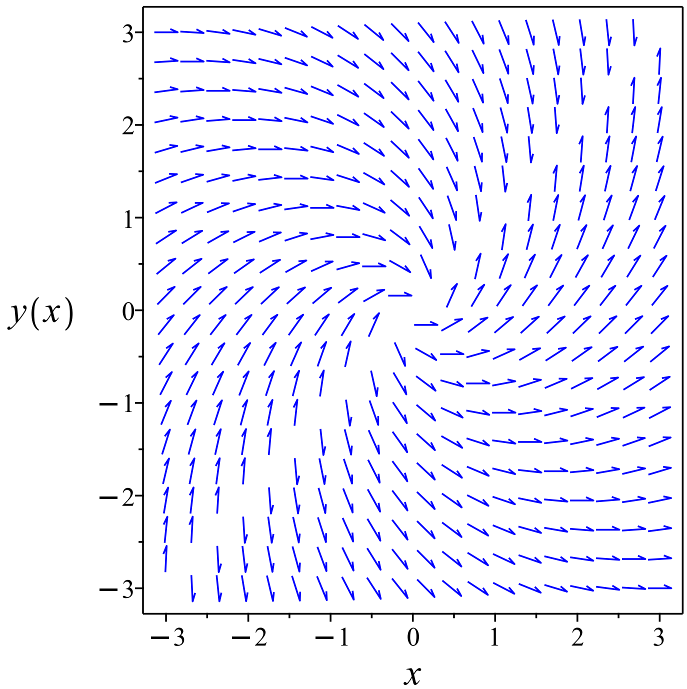

Figure 345: Slope field plot

Verification of solutions

$$\frac{\ln(x^2+y^2)}{2}+\arctan\left(\frac{x}{y}\right)=c_1$$

Verified OK.

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, [_Abel, `2nd type`, `
   class B`]]
```

$$\boxed{2yx + 3y^2 - \left(x^2 + 2yx\right) y' = 0}$$

6.30.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$2u(x)\, x^2 + 3u(x)^2\, x^2 - \left(x^2 + 2u(x)\, x^2\right) \left(u'(x)\, x + u(x)\right) = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x) g(u) \\ &= \frac{u(u+1)}{(2u+1)\, x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(u) = \frac{u(u+1)}{2u+1}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{u(u+1)}{2u+1}}\,du &= \frac{1}{x}\,dx \\
\int \frac{1}{\frac{u(u+1)}{2u+1}}\,du &= \int \frac{1}{x}\,dx \\
\ln\left(u(u+1)\right) &= \ln\left(x\right) + c_2
\end{aligned}
$$

Raising both side to exponential gives

$$
u(u+1) = \mathrm{e}^{\ln(x)+c_2}
$$

Which simplifies to

$$
u(u+1) = c_3 x
$$

Which simplifies to

$$
u(x)\left(u(x)+1\right) = c_3 \mathrm{e}^{c_2} x
$$

The solution is

$$
u(x)\left(u(x)+1\right) = c_3 \mathrm{e}^{c_2} x
$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$
\begin{aligned}
\frac{y\left(1+\frac{y}{x}\right)}{x} &= c_3 \mathrm{e}^{c_2} x \\
\frac{y(x+y)}{x^2} &= c_3 \mathrm{e}^{c_2} x
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
\frac{y(x+y)}{x^2} = c_3 \mathrm{e}^{c_2} x \tag{1}
$$

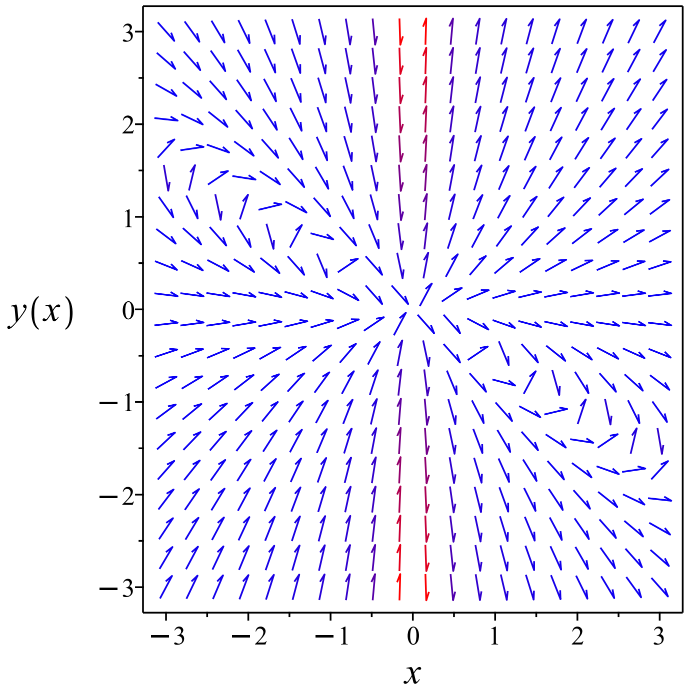

Figure 346: Slope field plot

Verification of solutions

$$\frac{y(x+y)}{x^2} = c_3 e^{c_2} x$$

Verified OK.

6.30.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = \frac{y(2x+3y)}{x(x+2y)}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$
$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned}
&b_2 + \frac{y(2x+3y)\,(b_3-a_2)}{x\,(x+2y)} - \frac{y^2(2x+3y)^2\,a_3}{x^2\,(x+2y)^2} \\
&- \left(\frac{2y}{x\,(x+2y)} - \frac{y(2x+3y)}{x^2\,(x+2y)} - \frac{y(2x+3y)}{x\,(x+2y)^2}\right)(xa_2+ya_3+a_1) \\
&- \left(\frac{2x+3y}{x\,(x+2y)} + \frac{3y}{x\,(x+2y)} - \frac{2y(2x+3y)}{x\,(x+2y)^2}\right)(xb_2+yb_3+b_1) = 0
\end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{x^4b_2 + 2x^3yb_2 + x^2y^2a_2 + 2x^2y^2a_3 + 2x^2y^2b_2 - x^2y^2b_3 + 6x\,y^3a_3 + 3y^4a_3 + 2x^3b_1 - 2x^2ya_1 + 6x^2yb_1 - }{x^2\,(x+2y)^2} = 0$$

Setting the numerator to zero gives

$$\begin{aligned}
&-x^4b_2 - 2x^3yb_2 - x^2y^2a_2 - 2x^2y^2a_3 - 2x^2y^2b_2 + x^2y^2b_3 - 6x\,y^3a_3 \\
&- 3y^4a_3 - 2x^3b_1 + 2x^2ya_1 - 6x^2yb_1 + 6x\,y^2a_1 - 6x\,y^2b_1 + 6y^3a_1 = 0
\end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned}
&-a_2v_1^2v_2^2 - 2a_3v_1^2v_2^2 - 6a_3v_1v_2^3 - 3a_3v_2^4 - b_2v_1^4 - 2b_2v_1^3v_2 - 2b_2v_1^2v_2^2 \\
&+ b_3v_1^2v_2^2 + 2a_1v_1^2v_2 + 6a_1v_1v_2^2 + 6a_1v_2^3 - 2b_1v_1^3 - 6b_1v_1^2v_2 - 6b_1v_1v_2^2 = 0
\end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}
&-b_2 v_1^4 - 2b_2 v_1^3 v_2 - 2b_1 v_1^3 + (-a_2 - 2a_3 - 2b_2 + b_3) v_1^2 v_2^2 \\
&+ (2a_1 - 6b_1) v_1^2 v_2 - 6a_3 v_1 v_2^3 + (6a_1 - 6b_1) v_1 v_2^2 - 3a_3 v_2^4 + 6a_1 v_2^3 = 0
\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
6a_1 &= 0 \\
-6a_3 &= 0 \\
-3a_3 &= 0 \\
-2b_1 &= 0 \\
-2b_2 &= 0 \\
-b_2 &= 0 \\
2a_1 - 6b_1 &= 0 \\
6a_1 - 6b_1 &= 0 \\
-a_2 - 2a_3 - 2b_2 + b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= 0 \\
a_2 &= b_3 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi &= x \\
\eta &= y
\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(\frac{y(2x+3y)}{x\,(x+2y)}\right)(x) \\
&= \frac{-yx-y^2}{x+2y} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-yx-y^2}{x+2y}} dy
\end{aligned}$$

Which results in

$$S = -\ln\left(y(x+y)\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y(2x+3y)}{x\,(x+2y)}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{1}{x+y} \\
S_y &= \frac{-2y-x}{y(x+y)}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = -\frac{3}{x} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = -\frac{3}{R}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = -3\ln(R) + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
-\ln(y) - \ln(x+y) = -3\ln(x) + c_1
$$

Which simplifies to

$$
-\ln(y) - \ln(x+y) = -3\ln(x) + c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y(2x+3y)}{x(x+2y)}$ 	$R = x$ $S = -\ln(y) - \ln(x+y)$	$\frac{dS}{dR} = -\frac{3}{R}$ 
Summary

The solution(s) found are the following

$$-\ln(y) - \ln(x+y) = -3\ln(x) + c_1 \tag{1}$$

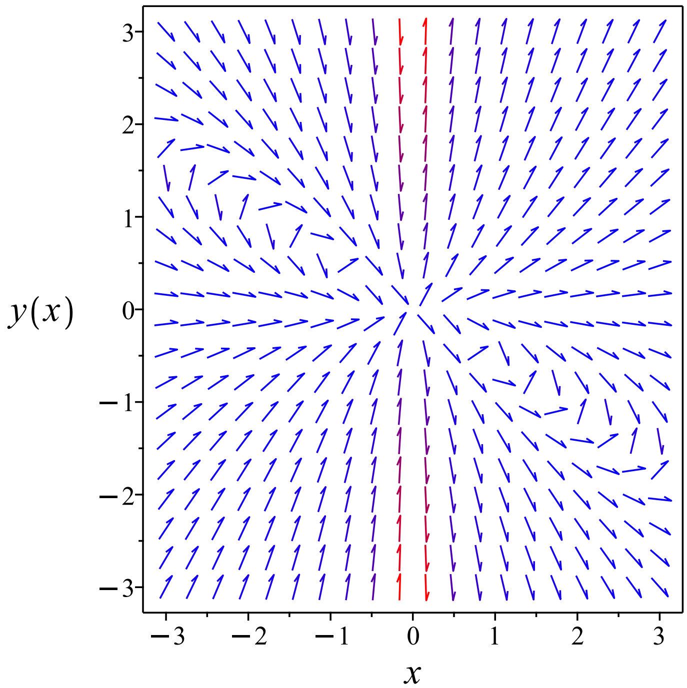

Figure 347: Slope field plot

Verification of solutions

$$-\ln(y) - \ln(x+y) = -3\ln(x) + c_1$$

Verified OK.

6.30.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(-x^2 - 2yx\right) \mathrm{d}y = \left(-2yx - 3y^2\right) \mathrm{d}x$$
$$\left(2yx + 3y^2\right) \mathrm{d}x + \left(-x^2 - 2yx\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = 2yx + 3y^2$$
$$N(x, y) = -x^2 - 2yx$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(2yx + 3y^2\right) \\ &= 2x + 6y\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-x^2 - 2yx\right) \\ &= -2x - 2y\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= -\frac{1}{x\left(x+2y\right)}\left(\left(2x+6y\right) - \left(-2x-2y\right)\right) \\ &= -\frac{4}{x} \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int -\frac{4}{x} \, \mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-4\ln(x)} \\ &= \frac{1}{x^4} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \frac{1}{x^4}\left(2yx+3y^2\right) \\ &= \frac{y(2x+3y)}{x^4} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \frac{1}{x^4}\left(-x^2-2yx\right) \\ &= \frac{-2y-x}{x^3} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(\frac{y(2x+3y)}{x^4}\right) + \left(\frac{-2y-x}{x^3}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, dx = \int \overline{M} \, dx$$
$$\int \frac{\partial \phi}{\partial x} \, dx = \int \frac{y(2x + 3y)}{x^4} \, dx$$
$$\phi = -\frac{y(x + y)}{x^3} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -\frac{x + y}{x^3} - \frac{y}{x^3} + f'(y) \tag{4}$$
$$= \frac{-2y - x}{x^3} + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{-2y-x}{x^3}$. Therefore equation (4) becomes

$$\frac{-2y - x}{x^3} = \frac{-2y - x}{x^3} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{y(x + y)}{x^3} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{y(x+y)}{x^3}$$

Summary
The solution(s) found are the following

$$-\frac{y(x+y)}{x^3} = c_1 \tag{1}$$

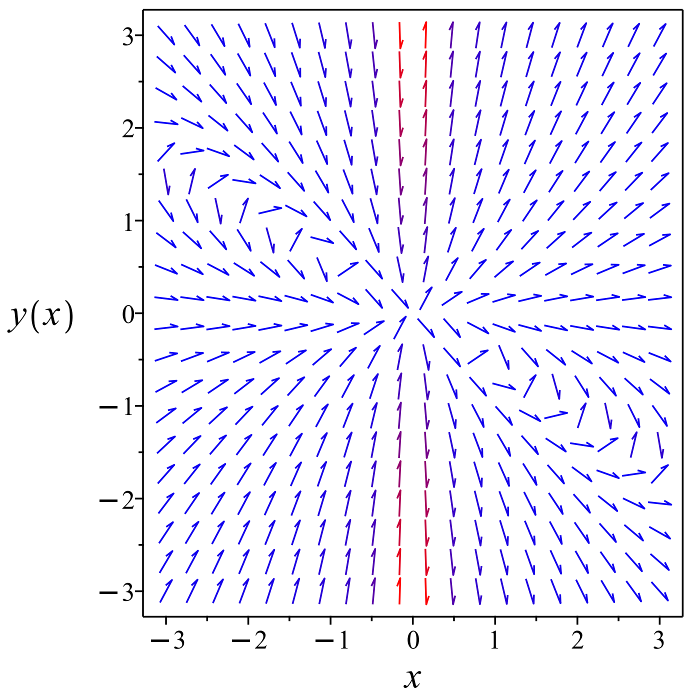

Figure 348: Slope field plot

Verification of solutions

$$-\frac{y(x+y)}{x^3} = c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational, [_Abel, `2nd type`, `
   class B`]]
```

$$\boxed{y' - \frac{-3x^2y - y^2}{2x^3 + 3yx} = 0}$$

With initial conditions

$$[y(1) = -2]$$

6.31.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -\frac{y(3x^2 + y)}{x\,(2x^2 + 3y)}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} b_2 &- \frac{y(3x^2+y)(b_3-a_2)}{x(2x^2+3y)} - \frac{y^2(3x^2+y)^2 a_3}{x^2(2x^2+3y)^2} \\ &- \left(-\frac{6y}{2x^2+3y} + \frac{y(3x^2+y)}{x^2(2x^2+3y)} + \frac{4y(3x^2+y)}{(2x^2+3y)^2}\right)(xa_2+ya_3+a_1) \\ &- \left(-\frac{3x^2+y}{x(2x^2+3y)} - \frac{y}{x(2x^2+3y)} + \frac{3y(3x^2+y)}{x(2x^2+3y)^2}\right)(xb_2+yb_3+b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{10x^6b_2 - 15x^4y^2a_3 + 6x^5b_1 - 6x^4ya_1 + 16x^4yb_2 + 14x^3y^2a_2 - 7x^3y^2b_3 - 3x^2y^3a_3 + 4x^3yb_1 + 3x^2y^2a_1 + 1}{(2x^2+3y)^2 x^2}$$
$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} &10x^6b_2 - 15x^4y^2a_3 + 6x^5b_1 - 6x^4ya_1 + 16x^4yb_2 + 14x^3y^2a_2 - 7x^3y^2b_3 \\ &- 3x^2y^3a_3 + 4x^3yb_1 + 3x^2y^2a_1 + 12x^2y^2b_2 - 4y^4a_3 + 3x\,y^2b_1 - 3y^3a_1 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
-15a_3v_1^4v_2^2 + 10b_2v_1^6 - 6a_1v_1^4v_2 + 14a_2v_1^3v_2^2 - 3a_3v_1^2v_2^3 + 6b_1v_1^5 + 16b_2v_1^4v_2 \\
- 7b_3v_1^3v_2^2 + 3a_1v_1^2v_2^2 - 4a_3v_2^4 + 4b_1v_1^3v_2 + 12b_2v_1^2v_2^2 - 3a_1v_2^3 + 3b_1v_1v_2^2 = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$
\{v_1, v_2\}
$$

Equation (7E) now becomes

$$
\begin{aligned}
10b_2v_1^6 + 6b_1v_1^5 - 15a_3v_1^4v_2^2 + (-6a_1 + 16b_2)\, v_1^4v_2 + (14a_2 - 7b_3)\, v_1^3v_2^2 \\
+ 4b_1v_1^3v_2 - 3a_3v_1^2v_2^3 + (3a_1 + 12b_2)\, v_1^2v_2^2 + 3b_1v_1v_2^2 - 4a_3v_2^4 - 3a_1v_2^3 = 0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-3a_1 &= 0 \\
-15a_3 &= 0 \\
-4a_3 &= 0 \\
-3a_3 &= 0 \\
3b_1 &= 0 \\
4b_1 &= 0 \\
6b_1 &= 0 \\
10b_2 &= 0 \\
-6a_1 + 16b_2 &= 0 \\
3a_1 + 12b_2 &= 0 \\
14a_2 - 7b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= a_2 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= 2a_2
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\xi = x$$
$$\eta = 2y$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}\eta &= \eta - \omega(x, y)\,\xi \\ &= 2y - \left(-\frac{y(3x^2 + y)}{x\,(2x^2 + 3y)}\right)(x) \\ &= \frac{7y\,x^2 + 7y^2}{2x^2 + 3y} \\ \xi &= 0\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{7y\,x^2+7y^2}{2x^2+3y}} dy\end{aligned}$$

Which results in

$$S = \frac{\ln(x^2 + y)}{7} + \frac{2\ln(y)}{7}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{y(3x^2+y)}{x\,(2x^2+3y)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{2x}{7x^2+7y} \\
S_y &= \frac{1}{7x^2+7y} + \frac{2}{7y}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{7x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{7R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{\ln(R)}{7} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(x^2+y)}{7} + \frac{2\ln(y)}{7} = -\frac{\ln(x)}{7} + c_1$$

Which simplifies to

$$\frac{\ln(x^2+y)}{7} + \frac{2\ln(y)}{7} = -\frac{\ln(x)}{7} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y(3x^2+y)}{x(2x^2+3y)}$ 	$R = x$ $S = \frac{\ln(x^2+y)}{7} + \frac{2\ln(y)}{7}$	$\frac{dS}{dR} = -\frac{1}{7R}$ 
Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{3i\pi}{7} + \frac{2\ln(2)}{7} = c_1$$

$$c_1 = \frac{3i\pi}{7} + \frac{2\ln(2)}{7}$$

Substituting c_1 found above in the general solution gives

$$\frac{\ln(x^2+y)}{7} + \frac{2\ln(y)}{7} = -\frac{\ln(x)}{7} + \frac{3i\pi}{7} + \frac{2\ln(2)}{7}$$

Summary

The solution(s) found are the following

$$\frac{\ln(x^2+y)}{7} + \frac{2\ln(y)}{7} = -\frac{\ln(x)}{7} + \frac{3i\pi}{7} + \frac{2\ln(2)}{7} \tag{1}$$

Verification of solutions

$$\frac{\ln(x^2+y)}{7} + \frac{2\ln(y)}{7} = -\frac{\ln(x)}{7} + \frac{3i\pi}{7} + \frac{2\ln(2)}{7}$$

Verified OK.

6.31.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(x\left(2x^2+3y\right)\right)\mathrm{d}y&=\left(-y\left(3x^2+y\right)\right)\mathrm{d}x\\ \left(y\left(3x^2+y\right)\right)\mathrm{d}x+\left(x\left(2x^2+3y\right)\right)\mathrm{d}y&=0\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=y\left(3x^2+y\right)\\ N(x,y)&=x\left(2x^2+3y\right)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\big(y(3x^2 + y)\big)\\ &= 3x^2 + 2y\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\big(x(2x^2 + 3y)\big)\\ &= 6x^2 + 3y\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{2x^3 + 3yx}\big((3x^2 + 2y) - (6x^2 + 3y)\big)\\ &= \frac{-3x^2 - y}{2x^3 + 3yx}\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned}B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right)\\ &= \frac{1}{3y\,x^2 + y^2}\big((6x^2 + 3y) - (3x^2 + 2y)\big)\\ &= \frac{1}{y}\end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned}\mu &= e^{\int B \,\mathrm{d}y}\\ &= e^{\int \frac{1}{y} \,\mathrm{d}y}\end{aligned}$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{\ln(y)} \\
&= y
\end{aligned}
$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= y\left(y\left(3x^2 + y\right)\right) \\
&= y^2\left(3x^2 + y\right)
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= y\left(x\left(2x^2 + 3y\right)\right) \\
&= yx\left(2x^2 + 3y\right)
\end{aligned}
$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(y^2\left(3x^2 + y\right)\right) + \left(yx\left(2x^2 + 3y\right)\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int y^2\left(3x^2 + y\right)\mathrm{d}x
\end{aligned}
$$

$$
\phi = y^2x\left(x^2 + y\right) + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\begin{aligned}
\frac{\partial \phi}{\partial y} &= 2yx(x^2+y) + x\,y^2 + f'(y) \\
&= yx(2x^2+3y) + f'(y)
\end{aligned} \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = yx(2x^2+3y)$. Therefore equation (4) becomes

$$
yx(2x^2+3y) = yx(2x^2+3y) + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = 0
$$

Therefore

$$
f(y) = c_1
$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$
\phi = y^2x(x^2+y) + c_1
$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$
c_1 = y^2x(x^2+y)
$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

$$
-4 = c_1
$$

$$
c_1 = -4
$$

Substituting c_1 found above in the general solution gives

$$
y^2x(x^2+y) = -4
$$

Summary

The solution(s) found are the following

$$
y^2x(x^2+y) = -4 \tag{1}
$$

Verification of solutions

$$y^2x(x^2+y) = -4$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 2y' - 3y = 0}$$

7.1.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = -3$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda e^{\lambda x} - 3 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda - 3 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = -3$ into the above gives

$$\lambda_{1,2} = \frac{-2}{(2)(1)} \pm \frac{1}{(2)(1)} \sqrt{2^2 - (4)(1)(-3)}$$
$$= -1 \pm 2$$

Hence

$$\lambda_1 = -1 + 2$$
$$\lambda_2 = -1 - 2$$

Which simplifies to

$$\lambda_1 = 1$$
$$\lambda_2 = -3$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(1)x} + c_2 e^{(-3)x}$$

Or

$$y = c_1 \mathrm{e}^{x} + \mathrm{e}^{-3x} c_2$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{x} + \mathrm{e}^{-3x} c_2 \tag{1}$$

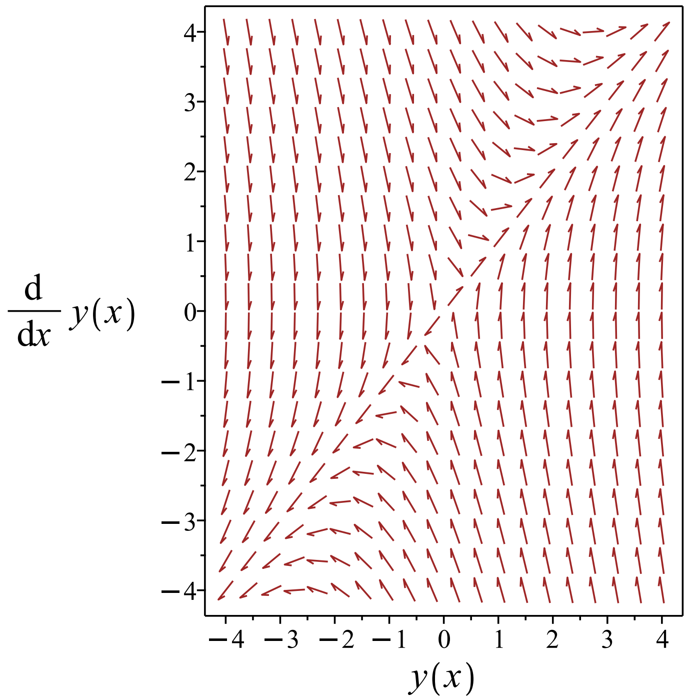

Figure 349: Slope field plot

Verification of solutions

$$y = c_1 e^{x} + e^{-3x} c_2$$

Verified OK.

7.1.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' - 3y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= -3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 316: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-2x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\ &= z_1 e^{-x} \\ &= z_1\left(\mathrm{e}^{-x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-2x}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\mathrm{e}^{4x}}{4}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-3x}\right) + c_2 \left(\mathrm{e}^{-3x} \left(\frac{\mathrm{e}^{4x}}{4}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-3x} + \frac{c_2 \mathrm{e}^{x}}{4} \tag{1}
$$

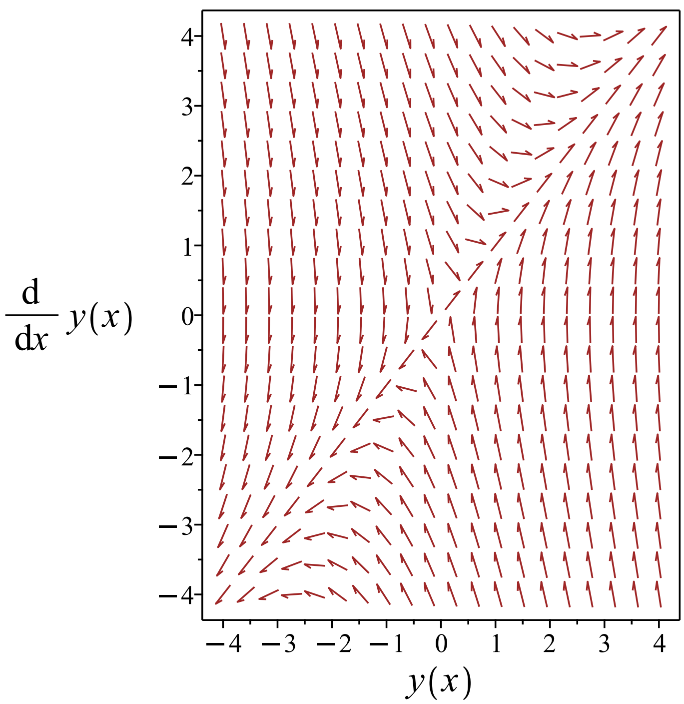

Figure 350: Slope field plot

Verification of solutions

$$
y = c_1 \mathrm{e}^{-3x} + \frac{c_2 \mathrm{e}^{x}}{4}
$$

7.1.3 Maple step by step solution

Let's solve

$y'' + 2y' - 3y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 + 2r - 3 = 0$

- Factor the characteristic polynomial

  $(r + 3)(r - 1) = 0$

- Roots of the characteristic polynomial

  $r = (-3, 1)$

- 1st solution of the ODE

  $y_1(x) = \mathrm{e}^{-3x}$

- 2nd solution of the ODE

  $y_2(x) = \mathrm{e}^{x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 \mathrm{e}^{-3x} + c_2 \mathrm{e}^{x}$

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Chapter 3, Second order linear equations, 3.1 Homogeneous Equations with Constant Coefficients, page 144
Problem number: 2.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 3y' + 2y = 0}$$

7.2.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 3, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 3\lambda\, e^{\lambda x} + 2\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 3\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 3, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-3}{(2)(1)} \pm \frac{1}{(2)(1)} \sqrt{3^2 - (4)(1)(2)} \\ &= -\frac{3}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{3}{2} + \frac{1}{2} \\ \lambda_2 &= -\frac{3}{2} - \frac{1}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 \\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(-1)x} + c_2 e^{(-2)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{-2x}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{-2x} \tag{1}$$

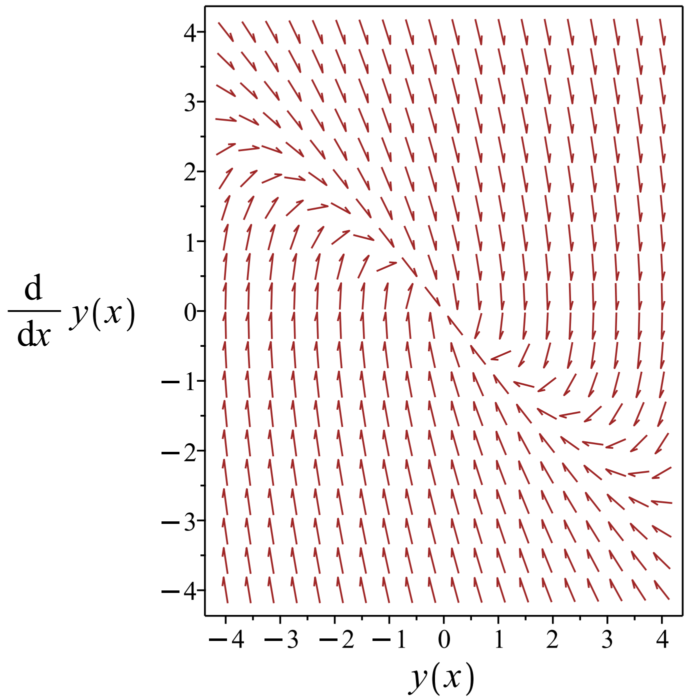

Figure 351: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + c_2 e^{-2x}$$

Verified OK.

7.2.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 3y' + 2y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 3 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 318: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{3}{1}\,dx} \\ &= z_1 e^{-\frac{3x}{2}} \\ &= z_1\left(\mathrm{e}^{-\frac{3x}{2}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{3}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-3x}}{(y_1)^2}\,dx \\ &= y_1(\mathrm{e}^{x})\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-2x}\right) + c_2\left(\mathrm{e}^{-2x}\left(\mathrm{e}^{x}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x} \tag{1}
$$

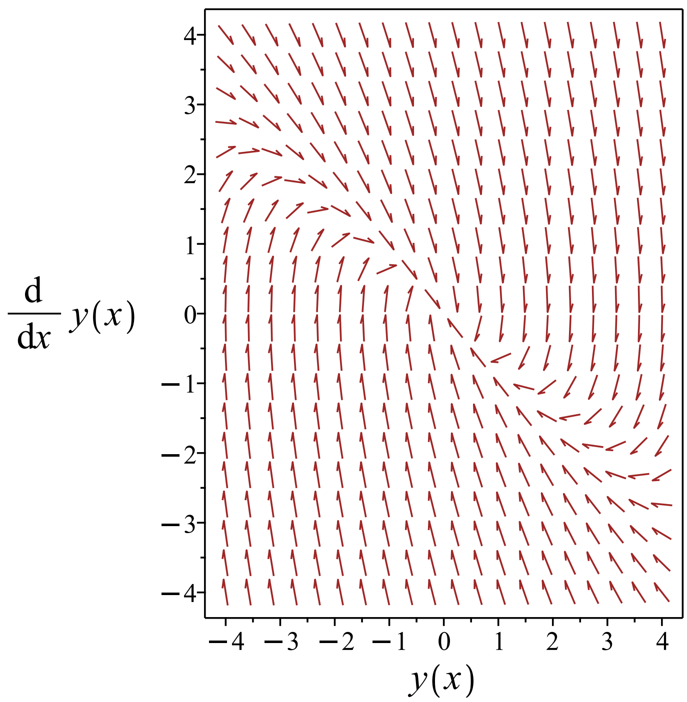

Figure 352: Slope field plot

Verification of solutions

$$
y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x}
$$

Verified OK.

7.2.3 Maple step by step solution

Let's solve

$y'' + 3y' + 2y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 + 3r + 2 = 0$

- Factor the characteristic polynomial

  $(r + 2)(r + 1) = 0$

- Roots of the characteristic polynomial

  $r = (-2, -1)$

- 1st solution of the ODE

  $y_1(x) = e^{-2x}$

- 2nd solution of the ODE

  $y_2(x) = e^{-x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{-2x} + c_2 e^{-x}$

7.3 problem 3

Internal problem ID [601]
Internal file name [`OUTPUT/601_Sunday_June_05_2022_01_45_40_AM_67843365/index.tex`]

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Chapter 3, Second order linear equations, 3.1 Homogeneous Equations with Constant Coefficients, page 144
Problem number: 3.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _missing_x]]`

$$\boxed{6y'' - y' - y = 0}$$

7.3.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 6, B = -1, C = -1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$6\lambda^2 \mathrm{e}^{\lambda x} - \lambda\, \mathrm{e}^{\lambda x} - \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$6\lambda^2 - \lambda - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 6, B = -1, C = -1$ into the above gives

$$\lambda_{1,2} = \frac{1}{(2)(6)} \pm \frac{1}{(2)(6)} \sqrt{-1^2 - (4)(6)(-1)}$$
$$= \frac{1}{12} \pm \frac{5}{12}$$

Hence

$$\lambda_1 = \frac{1}{12} + \frac{5}{12}$$
$$\lambda_2 = \frac{1}{12} - \frac{5}{12}$$

Which simplifies to

$$\lambda_1 = \frac{1}{2}$$
$$\lambda_2 = -\frac{1}{3}$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{\left(\frac{1}{2}\right)x} + c_2 e^{\left(-\frac{1}{3}\right)x}$$

Or

$$y = c_1 \mathrm{e}^{\frac{x}{2}} + c_2 \mathrm{e}^{-\frac{x}{3}}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{\frac{x}{2}} + c_2 \mathrm{e}^{-\frac{x}{3}} \tag{1}$$

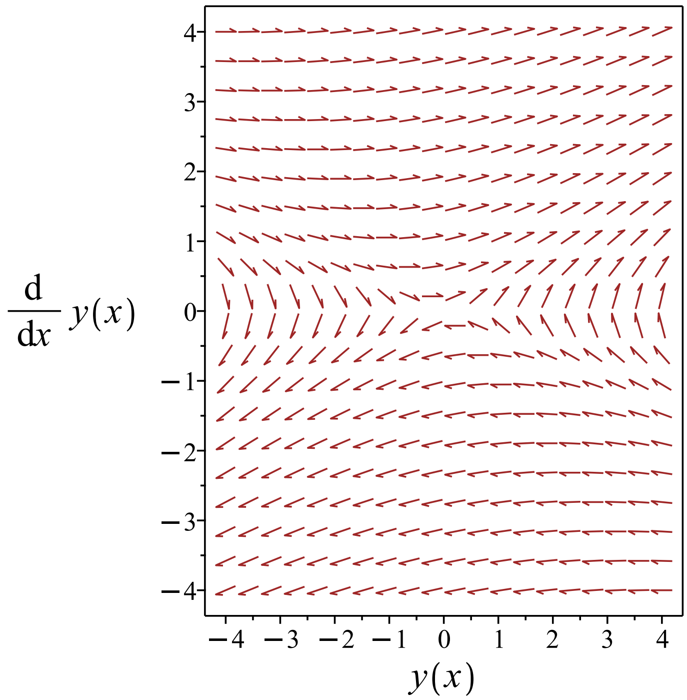

Figure 353: Slope field plot

Verification of solutions

$$y = c_1 e^{\frac{x}{2}} + c_2 e^{-\frac{x}{3}}$$

Verified OK.

7.3.2 Solving using Kovacic algorithm

Writing the ode as

$$6y'' - y' - y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 6 \\ B &= -1 \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{25}{144} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 25 \\ t &= 144 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{25z(x)}{144} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 320: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - 0\\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{25}{144}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{5x}{12}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{-1}{6}\,dx}\\ &= z_1 e^{\frac{x}{12}}\\ &= z_1\left(\mathrm{e}^{\frac{x}{12}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x}{3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{6}\,dx}}{(y_1)^2}\,dx\\ &= y_1 \int \frac{e^{\frac{x}{6}}}{(y_1)^2}\,dx\\ &= y_1\left(\frac{6\,\mathrm{e}^{\frac{5x}{6}}}{5}\right)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-\frac{x}{3}}\right) + c_2\left(\mathrm{e}^{-\frac{x}{3}}\left(\frac{6\,\mathrm{e}^{\frac{5x}{6}}}{5}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-\frac{x}{3}} + \frac{6 c_2 \mathrm{e}^{\frac{x}{2}}}{5} \tag{1}
$$

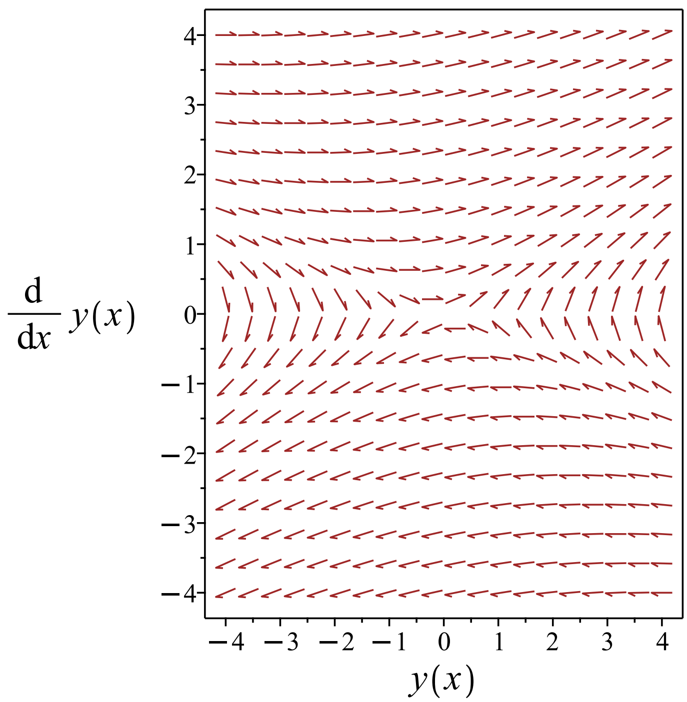

Figure 354: Slope field plot

Verification of solutions

$$
y = c_1 \mathrm{e}^{-\frac{x}{3}} + \frac{6 c_2 \mathrm{e}^{\frac{x}{2}}}{5}
$$

Verified OK.

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Chapter 3, Second order linear equations, 3.1 Homogeneous Equations with Constant Coefficients, page 144
Problem number: 4.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{2y'' - 3y' + y = 0}$$

7.4.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 2, B = -3, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$2\lambda^2 e^{\lambda x} - 3\lambda\, e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$2\lambda^2 - 3\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 2, B = -3, C = 1$ into the above gives

$$
\begin{aligned}
\lambda_{1,2} &= \frac{3}{(2)(2)} \pm \frac{1}{(2)(2)} \sqrt{-3^2 - (4)(2)(1)} \\
&= \frac{3}{4} \pm \frac{1}{4}
\end{aligned}
$$

Hence

$$
\begin{aligned}
\lambda_1 &= \frac{3}{4} + \frac{1}{4} \\
\lambda_2 &= \frac{3}{4} - \frac{1}{4}
\end{aligned}
$$

Which simplifies to

$$
\begin{aligned}
\lambda_1 &= 1 \\
\lambda_2 &= \frac{1}{2}
\end{aligned}
$$

Since roots are real and distinct, then the solution is

$$
\begin{aligned}
y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\
y &= c_1 e^{(1)x} + c_2 e^{\left(\frac{1}{2}\right)x}
\end{aligned}
$$

Or

$$
y = c_1 e^x + c_2 e^{\frac{x}{2}}
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^x + c_2 e^{\frac{x}{2}} \tag{1}
$$

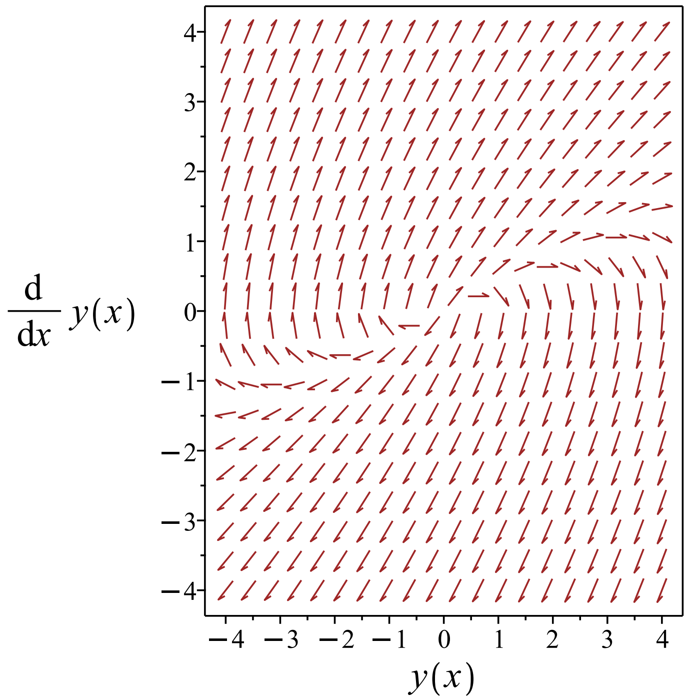

Figure 355: Slope field plot

Verification of solutions

$$y = c_1 e^{x} + c_2 e^{\frac{x}{2}}$$

Verified OK.

7.4.2 Solving using Kovacic algorithm

Writing the ode as

$$2y'' - 3y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2 \\ B &= -3 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{16} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 16 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{16} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 322: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{16}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{4}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-3}{2}\,dx} \\ &= z_1 e^{\frac{3x}{4}} \\ &= z_1 \left(\mathrm{e}^{\frac{3x}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\frac{x}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-3}{2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{\frac{3x}{2}}}{(y_1)^2}\,dx \\ &= y_1 \left(2\,\mathrm{e}^{\frac{x}{2}}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{\frac{x}{2}}\right) + c_2\left(\mathrm{e}^{\frac{x}{2}}\left(2\,\mathrm{e}^{\frac{x}{2}}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{\frac{x}{2}} + 2c_2 \mathrm{e}^{x} \tag{1}
$$

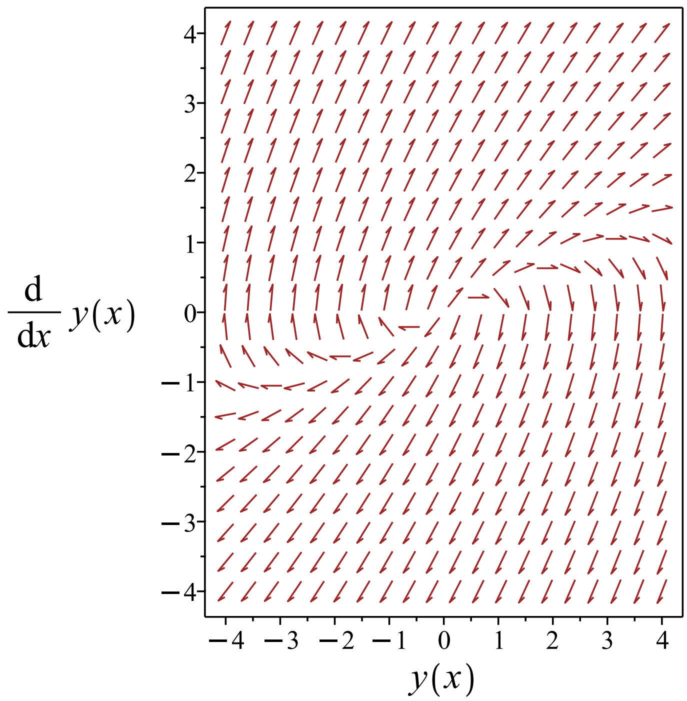

Figure 356: Slope field plot

Verification of solutions

$$
y = c_1 \mathrm{e}^{\frac{x}{2}} + 2c_2 \mathrm{e}^{x}
$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 5y' = 0}$$

7.5.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 5, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 5\lambda\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 5\lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 5, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-5}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{5^2 - (4)(1)(0)} \\ &= -\frac{5}{2} \pm \frac{5}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{5}{2} + \frac{5}{2} \\ \lambda_2 &= -\frac{5}{2} - \frac{5}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 0 \\ \lambda_2 &= -5\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(0)x} + c_2 e^{(-5)x}\end{aligned}$$

Or

$$y = c_1 + c_2 \mathrm{e}^{-5x}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 + c_2 \mathrm{e}^{-5x} \tag{1}$$

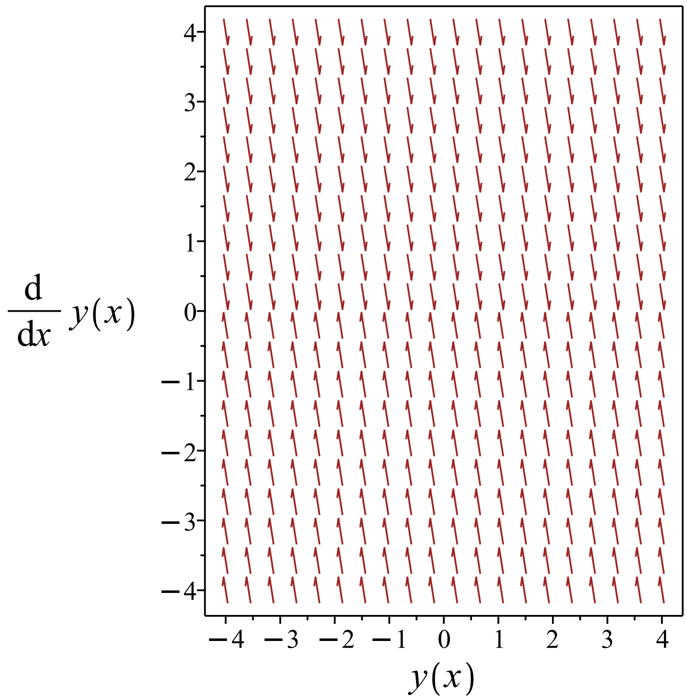

Figure 357: Slope field plot

Verification of solutions

$$y = c_1 + c_2 e^{-5x}$$

Verified OK.

7.5.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 5y')\, dx = 0$$

$$5y + y' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{1}{-5y + c_1} dy = \int dx$$

$$-\frac{\ln(-5y + c_1)}{5} = x + c_2$$

Raising both side to exponential gives

$$\frac{1}{(-5y + c_1)^{\frac{1}{5}}} = e^{x + c_2}$$

Which simplifies to

$$\frac{1}{(-5y+c_1)^{\frac{1}{5}}} = c_3 e^{x}$$

Summary

The solution(s) found are the following

$$y = -\frac{e^{-5x}}{5c_3^5} + \frac{c_1}{5} \tag{1}$$

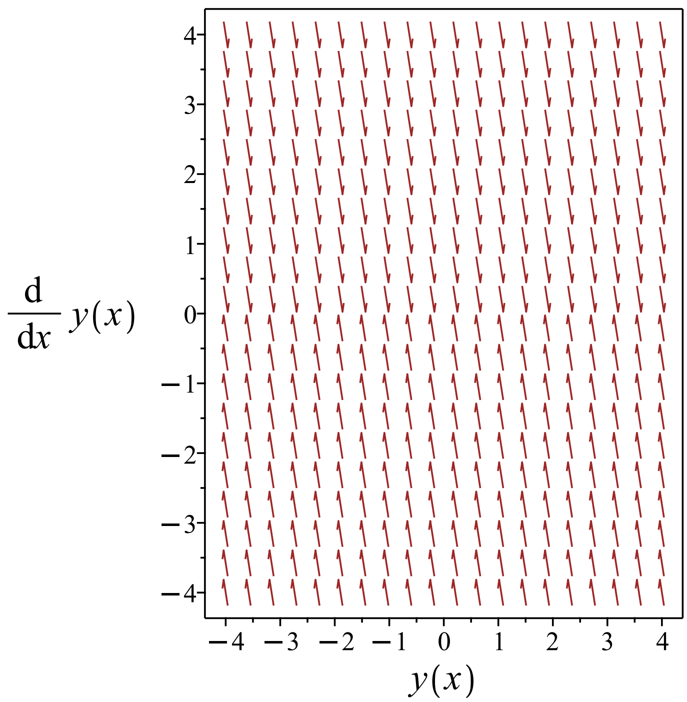

Figure 358: Slope field plot

Verification of solutions

$$y = -\frac{e^{-5x}}{5c_3^5} + \frac{c_1}{5}$$

Verified OK.

7.5.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + 5p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int -\frac{1}{5p}dp = \int dx$$
$$-\frac{\ln(p)}{5} = x + c_1$$

Raising both side to exponential gives

$$\frac{1}{p^{\frac{1}{5}}} = e^{x+c_1}$$

Which simplifies to

$$\frac{1}{p^{\frac{1}{5}}} = c_2 e^{x}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{e^{-5x}}{c_2^5}$$

Integrating both sides gives

$$y = \int \frac{e^{-5x}}{c_2^5}\, dx$$
$$= -\frac{e^{-5x}}{5c_2^5} + c_3$$

Summary
The solution(s) found are the following

$$y = -\frac{e^{-5x}}{5c_2^5} + c_3 \tag{1}$$

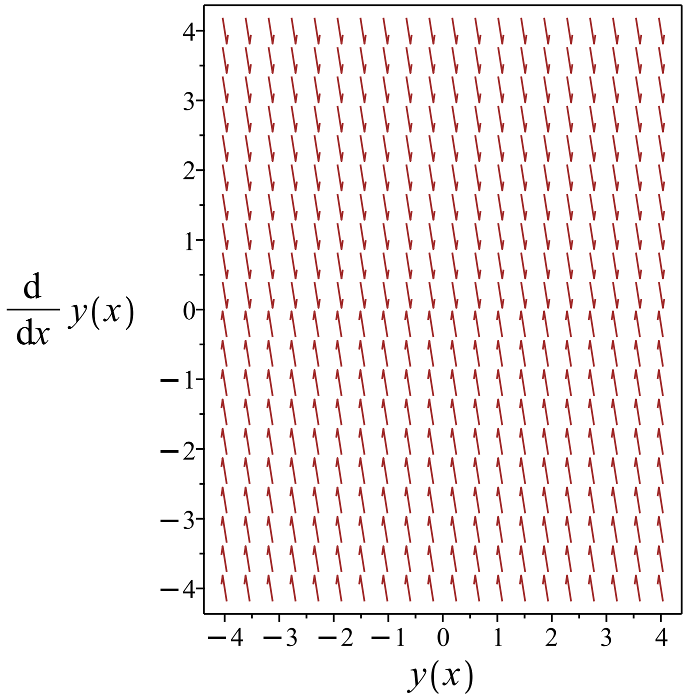

Figure 359: Slope field plot

Verification of solutions

$$y = -\frac{e^{-5x}}{5c_2^5} + c_3$$

Verified OK.

7.5.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + 5y' = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 5y')\, dx = 0$$
$$5y + y' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{1}{-5y+c_1}dy = \int dx$$
$$-\frac{\ln(-5y+c_1)}{5} = x + c_2$$

Raising both side to exponential gives

$$\frac{1}{(-5y+c_1)^{\frac{1}{5}}} = \mathrm{e}^{x+c_2}$$

Which simplifies to

$$\frac{1}{(-5y+c_1)^{\frac{1}{5}}} = c_3\mathrm{e}^{x}$$

Summary

The solution(s) found are the following

$$y = -\frac{\mathrm{e}^{-5x}}{5c_3^5} + \frac{c_1}{5} \tag{1}$$

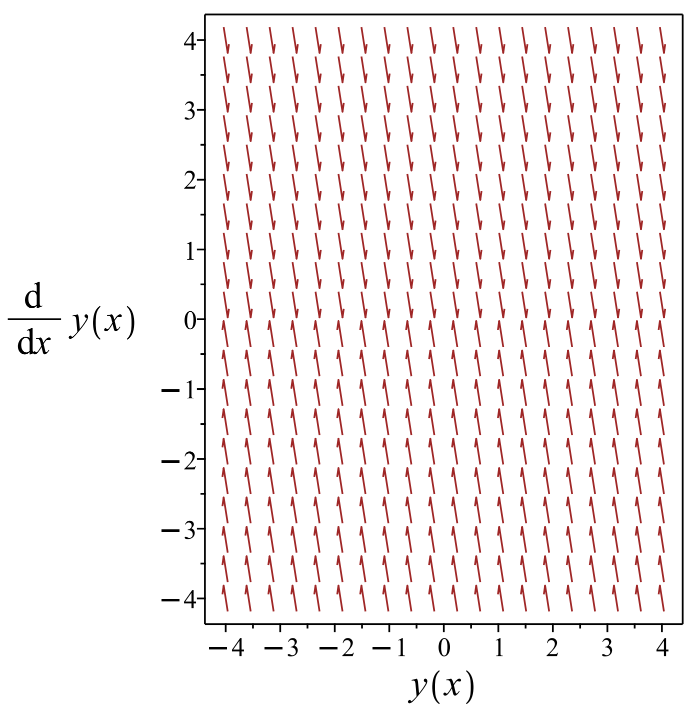

Figure 360: Slope field plot

Verification of solutions

$$y = -\frac{e^{-5x}}{5c_3^5} + \frac{c_1}{5}$$

Verified OK.

7.5.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 5y' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 5 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{25}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 25 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{25z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 324: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{25}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{5x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{5}{1}\,dx} \\
&= z_1 e^{-\frac{5x}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{5x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-5x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{5}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-5x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\mathrm{e}^{5x}}{5}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-5x}\right) + c_2\left(\mathrm{e}^{-5x}\left(\frac{\mathrm{e}^{5x}}{5}\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-5x} + \frac{c_2}{5} \tag{1}$$

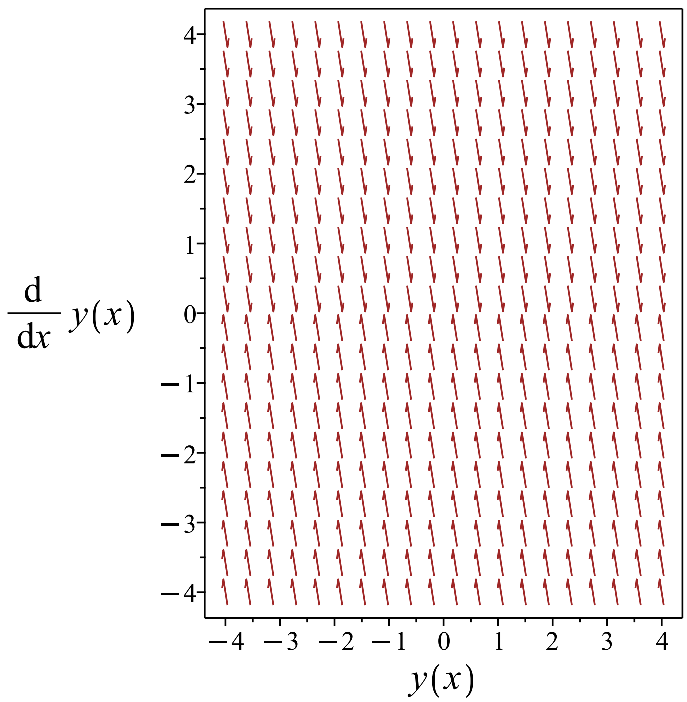

Figure 361: Slope field plot

Verification of solutions

$$y = c_1 e^{-5x} + \frac{c_2}{5}$$

Verified OK.

7.5.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x) y'' + q(x) y' + r(x) y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$
\begin{aligned}
p(x) &= 1 \\
q(x) &= 5 \\
r(x) &= 0 \\
s(x) &= 0
\end{aligned}
$$

Hence

$$
\begin{aligned}
p''(x) &= 0 \\
q'(x) &= 0
\end{aligned}
$$

Therefore (1) becomes

$$
0 - (0) + (0) = 0
$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$
(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)
$$

Integrating gives

$$
p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx
$$

Substituting the above values for p, q, r, s gives

$$
5y + y' = c_1
$$

We now have a first order ode to solve which is

$$
5y + y' = c_1
$$

Integrating both sides gives

$$
\begin{aligned}
\int \frac{1}{-5y + c_1} dy &= \int dx \\
-\frac{\ln(-5y + c_1)}{5} &= x + c_2
\end{aligned}
$$

Raising both side to exponential gives

$$
\frac{1}{(-5y + c_1)^{\frac{1}{5}}} = e^{x + c_2}
$$

Which simplifies to

$$\frac{1}{(-5y+c_1)^{\frac{1}{5}}} = c_3 e^{x}$$

Summary

The solution(s) found are the following

$$y = -\frac{e^{-5x}}{5c_3^5} + \frac{c_1}{5} \tag{1}$$

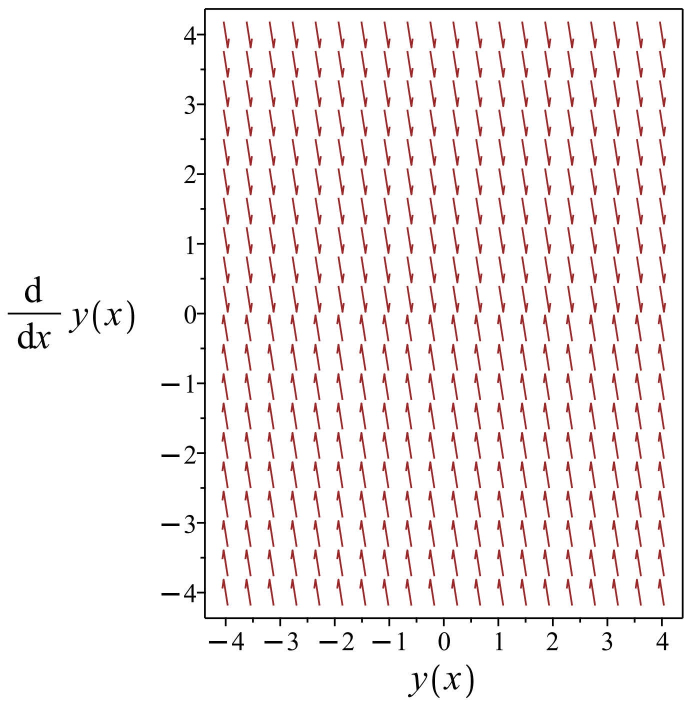

Figure 362: Slope field plot

Verification of solutions

$$y = -\frac{e^{-5x}}{5c_3^5} + \frac{c_1}{5}$$

Verified OK.

7.5.7 Maple step by step solution

Let's solve

$y'' + 5y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 + 5r = 0$

- Factor the characteristic polynomial

  $r(r+5) = 0$

- Roots of the characteristic polynomial

  $r = (-5, 0)$

- 1st solution of the ODE

  $y_1(x) = \mathrm{e}^{-5x}$

- 2nd solution of the ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 \mathrm{e}^{-5x} + c_2$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{4y'' - 9y = 0}$$

7.6.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 4, B = 0, C = -9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$4\lambda^2 e^{\lambda x} - 9 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$4\lambda^2 - 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 4, B = 0, C = -9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(4)} \pm \frac{1}{(2)(4)}\sqrt{0^2 - (4)(4)(-9)} \\ &= \pm\frac{3}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\frac{3}{2} \\ \lambda_2 &= -\frac{3}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \frac{3}{2} \\ \lambda_2 &= -\frac{3}{2}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{\left(\frac{3}{2}\right)x} + c_2 e^{\left(-\frac{3}{2}\right)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{\frac{3x}{2}} + c_2 \mathrm{e}^{-\frac{3x}{2}}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{\frac{3x}{2}} + c_2 \mathrm{e}^{-\frac{3x}{2}} \tag{1}$$

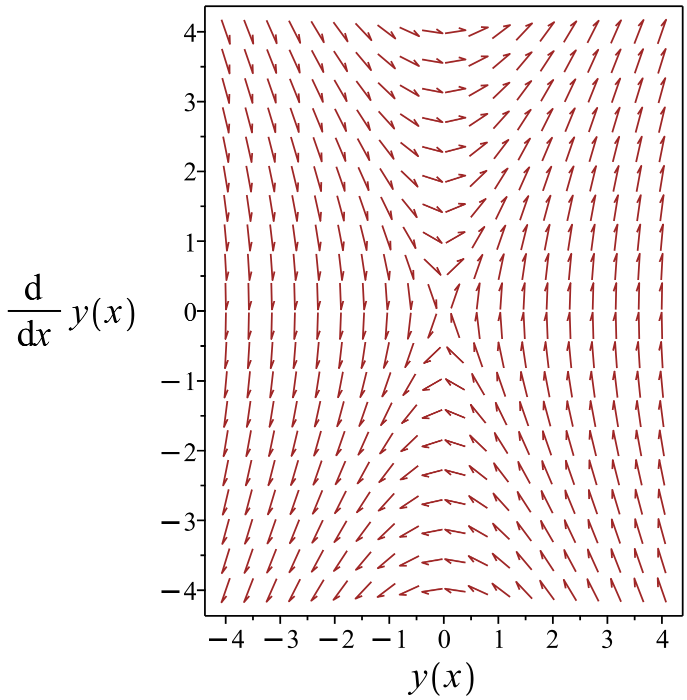

Figure 363: Slope field plot

Verification of solutions

$$y = c_1 e^{\frac{3x}{2}} + c_2 e^{-\frac{3x}{2}}$$

Verified OK.

7.6.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$4y'y'' - 9yy' = 0$$

Integrating the above w.r.t x gives

$$\int (4y'y'' - 9yy')\,dx = 0$$

$$2y'^2 - \frac{9y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{\sqrt{9y^2 + 2c_1}}{2} \tag{1}$$
$$y' = -\frac{\sqrt{9y^2 + 2c_1}}{2} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{2}{\sqrt{9y^2 + 2c_1}} dy = \int dx$$
$$\frac{2 \ln\left(y\sqrt{9} + \sqrt{9y^2 + 2c_1}\right)\sqrt{9}}{9} = x + c_2$$

Raising both side to exponential gives

$$e^{\frac{2 \ln\left(y\sqrt{9} + \sqrt{9y^2 + 2c_1}\right)\sqrt{9}}{9}} = e^{x + c_2}$$

Which simplifies to

$$\left(3y + \sqrt{9y^2 + 2c_1}\right)^{\frac{2}{3}} = c_3 e^x$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{2}{\sqrt{9y^2 + 2c_1}} dy = \int dx$$
$$-\frac{2 \ln\left(y\sqrt{9} + \sqrt{9y^2 + 2c_1}\right)\sqrt{9}}{9} = x + c_4$$

Raising both side to exponential gives

$$e^{-\frac{2 \ln\left(y\sqrt{9} + \sqrt{9y^2 + 2c_1}\right)\sqrt{9}}{9}} = e^{x + c_4}$$

Which simplifies to

$$\frac{1}{\left(3y + \sqrt{9y^2 + 2c_1}\right)^{\frac{2}{3}}} = c_5 e^x$$

Summary
The solution(s) found are the following

$$y = \frac{(c_3^3 e^{3x} - 2c_1) e^{-x}}{6c_3 \sqrt{c_3 e^x}} \tag{1}$$

$$y = -\frac{(2c_1 c_5^3 e^{3x} - 1) e^{-x}}{6c_5 \sqrt{c_5 e^x}} \tag{2}$$

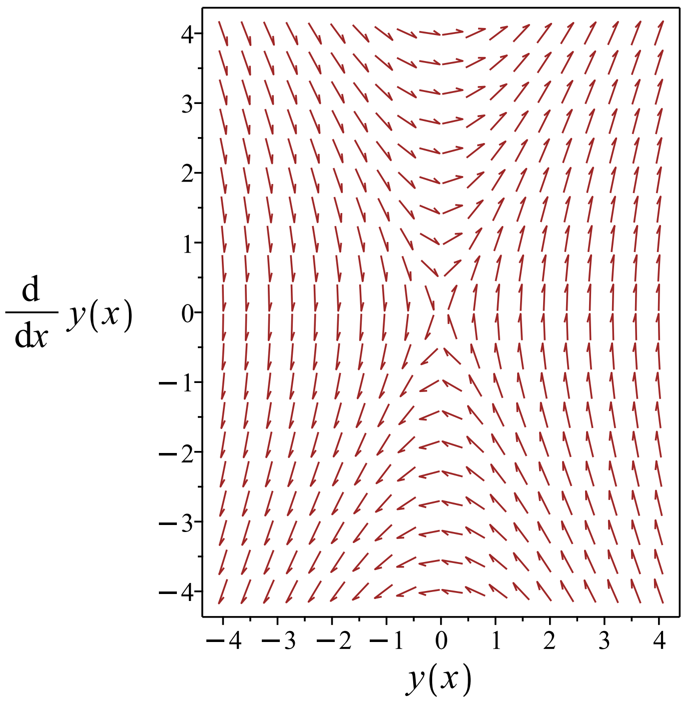

Figure 364: Slope field plot

Verification of solutions

$$y = \frac{(c_3^3 e^{3x} - 2c_1) e^{-x}}{6c_3 \sqrt{c_3 e^x}}$$

Verified OK.

$$y = -\frac{(2c_1 c_5^3 e^{3x} - 1) e^{-x}}{6c_5 \sqrt{c_5 e^x}}$$

Verified OK.

7.6.3 Solving using Kovacic algorithm

Writing the ode as

$$4y'' - 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4 \\ B &= 0 \\ C &= -9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 326: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = e^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= e^{-\frac{3x}{2}}
\end{aligned}
$$

Which simplifies to

$$
y_1 = e^{-\frac{3x}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= e^{-\frac{3x}{2}} \int \frac{1}{e^{-3x}}\, dx \\
&= e^{-\frac{3x}{2}} \left(\frac{e^{3x}}{3} \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(e^{-\frac{3x}{2}} \right) + c_2 \left(e^{-\frac{3x}{2}} \left(\frac{e^{3x}}{3} \right) \right)
\end{aligned}
$$

<u>Summary</u>
The solution(s) found are the following

$$
y = c_1 e^{-\frac{3x}{2}} + \frac{c_2 e^{\frac{3x}{2}}}{3} \tag{1}
$$

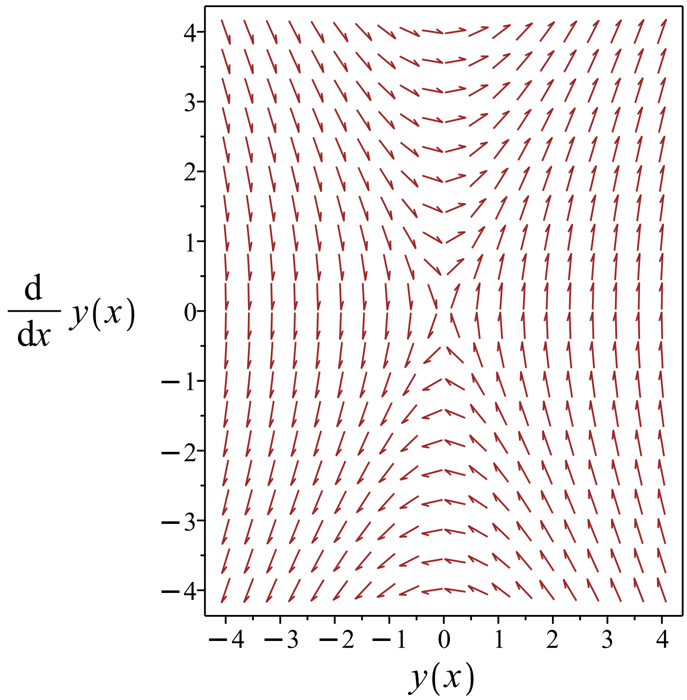

Figure 365: Slope field plot

Verification of solutions

$$y = c_1 e^{-\frac{3x}{2}} + \frac{c_2 e^{\frac{3x}{2}}}{3}$$

Verified OK.

7.6.4 Maple step by step solution

Let's solve

$4y'' - 9y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{9y}{4}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{9y}{4} = 0$

- Characteristic polynomial of ODE

$r^2 - \frac{9}{4} = 0$

- Factor the characteristic polynomial

  $\frac{(2r-3)(2r+3)}{4} = 0$

- Roots of the characteristic polynomial

  $r = \left(-\frac{3}{2}, \frac{3}{2}\right)$

- 1st solution of the ODE

  $y_1(x) = e^{-\frac{3x}{2}}$

- 2nd solution of the ODE

  $y_2(x) = e^{\frac{3x}{2}}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{-\frac{3x}{2}} + c_2 e^{\frac{3x}{2}}$

Problem number: 7.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 9y' + 9y = 0}$$

7.7.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -9, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 9\lambda\, e^{\lambda x} + 9\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 9\lambda + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -9, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{9}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-9^2 - (4)(1)(9)} \\ &= \frac{9}{2} \pm \frac{3\sqrt{5}}{2}\end{aligned}$$

Hence

$$\lambda_1 = \frac{9}{2} + \frac{3\sqrt{5}}{2}$$

$$\lambda_2 = \frac{9}{2} - \frac{3\sqrt{5}}{2}$$

Which simplifies to

$$\lambda_1 = \frac{9}{2} + \frac{3\sqrt{5}}{2}$$

$$\lambda_2 = \frac{9}{2} - \frac{3\sqrt{5}}{2}$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$

$$y = c_1 e^{\left(\frac{9}{2} + \frac{3\sqrt{5}}{2}\right)x} + c_2 e^{\left(\frac{9}{2} - \frac{3\sqrt{5}}{2}\right)x}$$

Or

$$y = c_1 \mathrm{e}^{\left(\frac{9}{2} + \frac{3\sqrt{5}}{2}\right)x} + c_2 \mathrm{e}^{\left(\frac{9}{2} - \frac{3\sqrt{5}}{2}\right)x}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{\left(\frac{9}{2} + \frac{3\sqrt{5}}{2}\right)x} + c_2 \mathrm{e}^{\left(\frac{9}{2} - \frac{3\sqrt{5}}{2}\right)x} \tag{1}$$

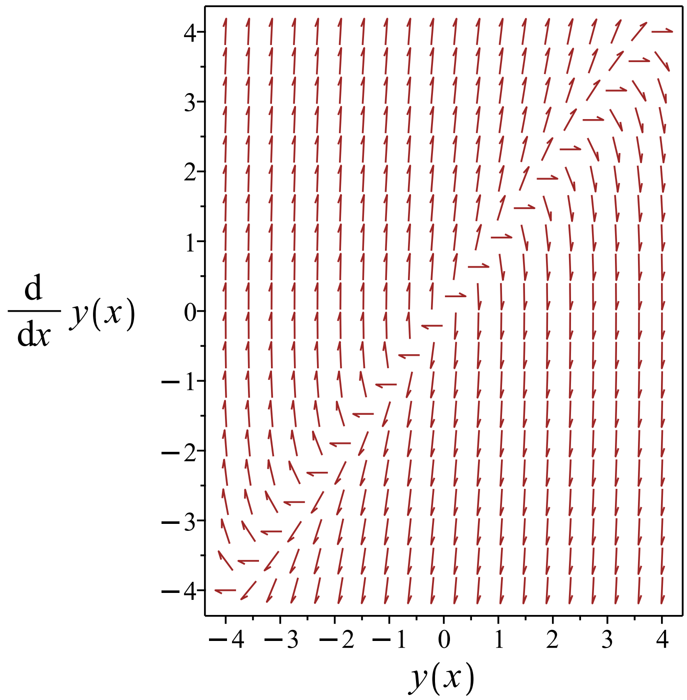

Figure 366: Slope field plot

Verification of solutions

$$y = c_1 e^{\left(\frac{9}{2}+\frac{3\sqrt{5}}{2}\right)x} + c_2 e^{\left(\frac{9}{2}-\frac{3\sqrt{5}}{2}\right)x}$$

Verified OK.

7.7.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 9y' + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -9 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{45}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 45 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{45z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 328: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{45}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{3x\sqrt{5}}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-9}{1}\,dx} \\
&= z_1 e^{\frac{9x}{2}} \\
&= z_1 \left(\mathrm{e}^{\frac{9x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{3\left(\sqrt{5}-3\right)x}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-9}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{9x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\sqrt{5}\,\mathrm{e}^{3x\sqrt{5}}}{15}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-\frac{3\left(\sqrt{5}-3\right)x}{2}}\right) + c_2\left(\mathrm{e}^{-\frac{3\left(\sqrt{5}-3\right)x}{2}}\left(\frac{\sqrt{5}\,\mathrm{e}^{3x\sqrt{5}}}{15}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-\frac{3\left(\sqrt{5}-3\right)x}{2}} + \frac{c_2\sqrt{5}\,\mathrm{e}^{\frac{3\left(3+\sqrt{5}\right)x}{2}}}{15} \tag{1}
$$

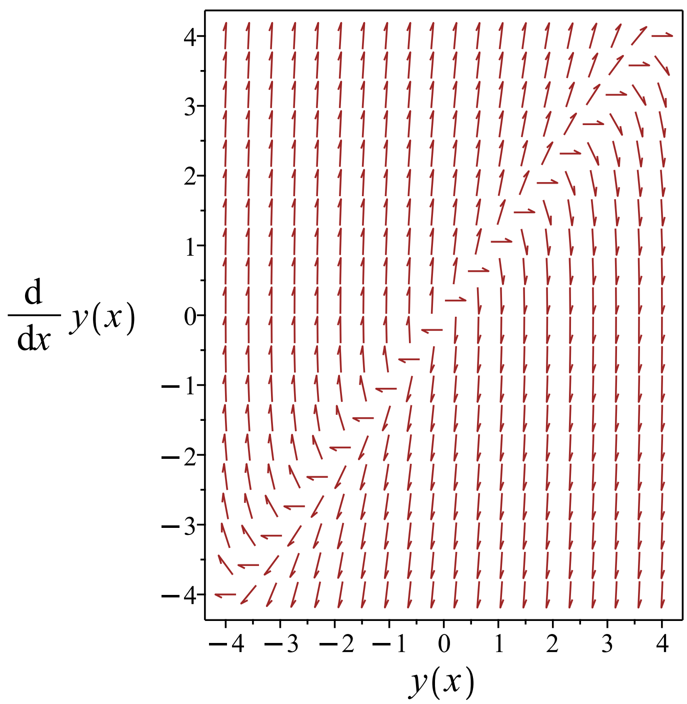

Figure 367: Slope field plot

Verification of solutions

$$
y = c_1 \mathrm{e}^{-\frac{3\left(\sqrt{5}-3\right)x}{2}} + \frac{c_2\sqrt{5}\,\mathrm{e}^{\frac{3\left(3+\sqrt{5}\right)x}{2}}}{15}
$$

Verified OK.

7.7.3 Maple step by step solution

Let's solve

$y'' - 9y' + 9y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 9r + 9 = 0$

- Use quadratic formula to solve for r

  $r = \frac{9 \pm \left(\sqrt{45}\right)}{2}$

- Roots of the characteristic polynomial

  $r = \left(\frac{9}{2} - \frac{3\sqrt{5}}{2}, \frac{9}{2} + \frac{3\sqrt{5}}{2}\right)$

- 1st solution of the ODE

  $y_1(x) = e^{\left(\frac{9}{2} - \frac{3\sqrt{5}}{2}\right)x}$

- 2nd solution of the ODE

  $y_2(x) = e^{\left(\frac{9}{2} + \frac{3\sqrt{5}}{2}\right)x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{\left(\frac{9}{2} - \frac{3\sqrt{5}}{2}\right)x} + c_2 e^{\left(\frac{9}{2} + \frac{3\sqrt{5}}{2}\right)x}$

Section: Chapter 3, Second order linear equations, 3.1 Homogeneous Equations with Constant Coefficients, page 144
Problem number: 8.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 2y' - 2y = 0}$$

7.8.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = -2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 2\lambda\, \mathrm{e}^{\lambda x} - 2\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda - 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = -2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-2^2 - (4)(1)(-2)} \\ &= 1 \pm \sqrt{3}\end{aligned}$$

Hence

$$\lambda_1 = 1 + \sqrt{3}$$
$$\lambda_2 = 1 - \sqrt{3}$$

Which simplifies to

$$\lambda_1 = 1 + \sqrt{3}$$
$$\lambda_2 = -\sqrt{3} + 1$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{\left(1+\sqrt{3}\right)x} + c_2 e^{\left(-\sqrt{3}+1\right)x}$$

Or

$$y = c_1 \mathrm{e}^{\left(1+\sqrt{3}\right)x} + c_2 \mathrm{e}^{\left(-\sqrt{3}+1\right)x}$$

Summary
The solution(s) found are the following

$$y = c_1 \mathrm{e}^{\left(1+\sqrt{3}\right)x} + c_2 \mathrm{e}^{\left(-\sqrt{3}+1\right)x} \tag{1}$$

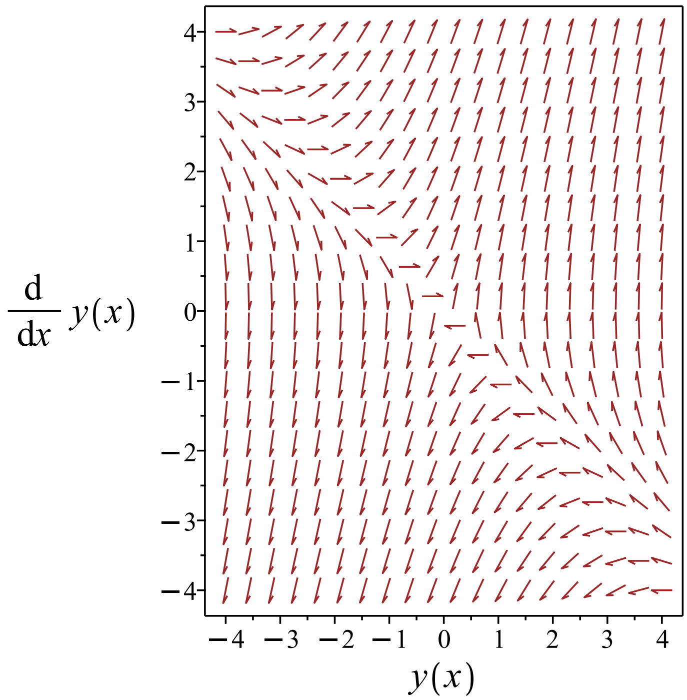

Figure 368: Slope field plot

Verification of solutions

$$y = c_1 e^{(1+\sqrt{3})x} + c_2 e^{(-\sqrt{3}+1)x}$$

Verified OK.

7.8.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' - 2y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 3z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 330: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 3$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-\sqrt{3}\,x}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\
&= z_1 e^{x} \\
&= z_1 \left(\mathrm{e}^{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-\left(\sqrt{3}-1\right)x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{2x}}{\left(y_1\right)^2}\,dx \\
&= y_1 \left(\frac{\sqrt{3}\,\mathrm{e}^{2\sqrt{3}\,x}}{6}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\left(\sqrt{3}-1\right)x}\right) + c_2 \left(\mathrm{e}^{-\left(\sqrt{3}-1\right)x} \left(\frac{\sqrt{3}\,\mathrm{e}^{2\sqrt{3}\,x}}{6}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-\left(\sqrt{3}-1\right)x} + \frac{c_2 \sqrt{3}\,\mathrm{e}^{\left(1+\sqrt{3}\right)x}}{6} \tag{1}
$$

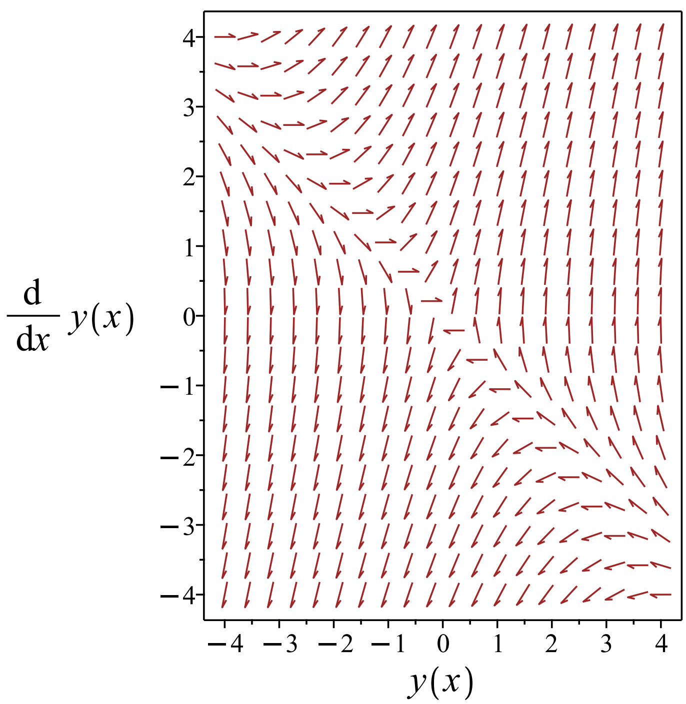

Figure 369: Slope field plot

Verification of solutions

$$
y = c_1 \mathrm{e}^{-\left(\sqrt{3}-1\right)x} + \frac{c_2 \sqrt{3}\,\mathrm{e}^{\left(1+\sqrt{3}\right)x}}{6}
$$

Verified OK.

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Chapter 3, Second order linear equations, 3.1 Homogeneous Equations with Constant Coefficients, page 144
Problem number: 9.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + y' - 2y = 0}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1]$$

7.9.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 1 \\ q(x) &= -2 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + y' - 2y = 0$$

The domain of $p(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

7.9.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 1, C = -2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + \lambda\, e^{\lambda x} - 2\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + \lambda - 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 1, C = -2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-1}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{1^2 - (4)\,(1)\,(-2)}\\ &= -\frac{1}{2} \pm \frac{3}{2}\end{aligned}$$

Hence

$$\lambda_1 = -\frac{1}{2} + \frac{3}{2}$$
$$\lambda_2 = -\frac{1}{2} - \frac{3}{2}$$

Which simplifies to

$$\lambda_1 = 1$$
$$\lambda_2 = -2$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(1)x} + c_2 e^{(-2)x}$$

Or

$$y = c_1 e^x + c_2 e^{-2x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^x + c_2 e^{-2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 e^x - 2c_2 e^{-2x}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = c_1 - 2c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{1}{3}$$
$$c_2 = -\frac{1}{3}$$

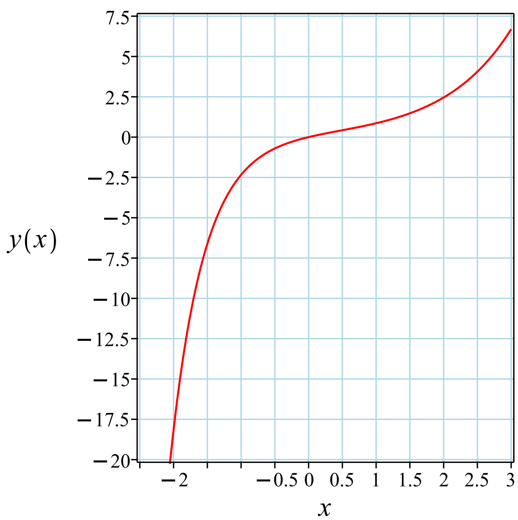
Substituting these values back in above solution results in

$$y = \frac{e^x}{3} - \frac{e^{-2x}}{3}$$

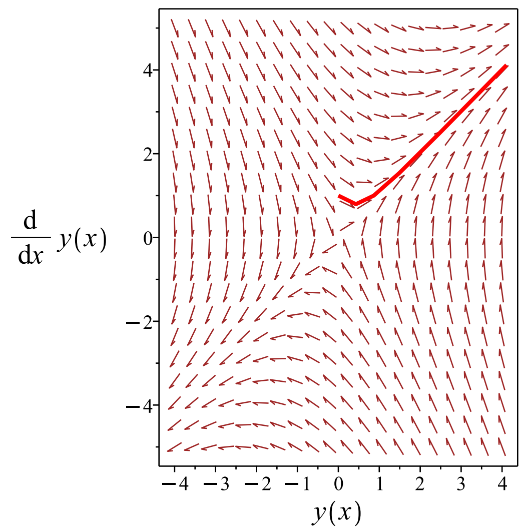
Summary

The solution(s) found are the following

$$y = \frac{e^{x}}{3} - \frac{e^{-2x}}{3} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{e^{x}}{3} - \frac{e^{-2x}}{3}$$

Verified OK.

7.9.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 1 \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 332: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\, dx} \\
&= z_1 e^{-\frac{x}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{1}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-x}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\mathrm{e}^{3x}}{3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-2x}\right) + c_2\left(\mathrm{e}^{-2x}\left(\frac{\mathrm{e}^{3x}}{3}\right)\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1\mathrm{e}^{-2x} + \frac{c_2\mathrm{e}^{x}}{3} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + \frac{c_2}{3} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -2c_1\mathrm{e}^{-2x} + \frac{c_2\mathrm{e}^{x}}{3}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = -2c_1 + \frac{c_2}{3} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -\frac{1}{3}$$
$$c_2 = 1$$

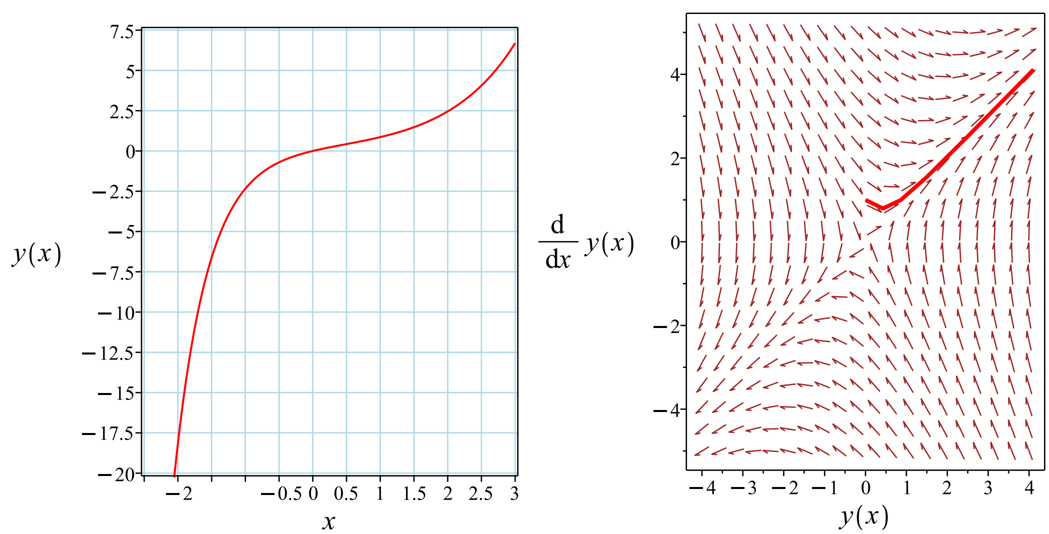
Substituting these values back in above solution results in

$$y = \frac{e^x}{3} - \frac{e^{-2x}}{3}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \frac{e^x}{3} - \frac{e^{-2x}}{3} \tag{1}$$



(a) Solution plot (b) Slope field plot

<u>Verification of solutions</u>

$$y = \frac{e^x}{3} - \frac{e^{-2x}}{3}$$

Verified OK.

7.9.4 Maple step by step solution

Let's solve

$\left[y''+y'-2y=0, y(0)=0, y'\Big|_{\{x=0\}}=1\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2+r-2=0$

- Factor the characteristic polynomial

  $(r+2)(r-1)=0$

- Roots of the characteristic polynomial

  $r=(-2,1)$

- 1st solution of the ODE

  $y_1(x)=\mathrm{e}^{-2x}$

- 2nd solution of the ODE

  $y_2(x)=\mathrm{e}^{x}$

- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)$

- Substitute in solutions

  $y=c_1\mathrm{e}^{-2x}+c_2\mathrm{e}^{x}$

□ Check validity of solution $y=c_1\mathrm{e}^{-2x}+c_2\mathrm{e}^{x}$

  ◦ Use initial condition $y(0)=0$

    $0=c_1+c_2$

  ◦ Compute derivative of the solution

    $y'=-2c_1\mathrm{e}^{-2x}+c_2\mathrm{e}^{x}$

  ◦ Use the initial condition $y'\Big|_{\{x=0\}}=1$

    $1=-2c_1+c_2$

  ◦ Solve for c_1 and c_2

    $\left\{c_1=-\frac{1}{3}, c_2=\frac{1}{3}\right\}$

- Substitute constant values into general solution and simplify

  $y = \frac{(e^{3x}-1)e^{-2x}}{3}$

- Solution to the IVP

  $y = \frac{(e^{3x}-1)e^{-2x}}{3}$

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Chapter 3, Second order linear equations, 3.1 Homogeneous Equations with Constant Coefficients, page 144
Problem number: 10.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 4y' + 3y = 0}$$

With initial conditions

$$[y(0) = 2, y'(0) = -1]$$

7.10.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 4 \\ q(x) &= 3 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + 4y' + 3y = 0$$

The domain of $p(x) = 4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 3$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

7.10.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 4, C = 3$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4\lambda\, e^{\lambda x} + 3\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4\lambda + 3 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 4, C = 3$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{4^2 - (4)\,(1)\,(3)}\\ &= -2 \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -2 + 1\\ \lambda_2 &= -2 - 1\end{aligned}$$

Which simplifies to

$$\lambda_1 = -1$$
$$\lambda_2 = -3$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(-1)x} + c_2 e^{(-3)x}$$

Or

$$y = c_1 \mathrm{e}^{-x} + \mathrm{e}^{-3x} c_2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{-x} + \mathrm{e}^{-3x} c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 \mathrm{e}^{-x} - 3\,\mathrm{e}^{-3x} c_2$$

substituting $y' = -1$ and $x = 0$ in the above gives

$$-1 = -c_1 - 3c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

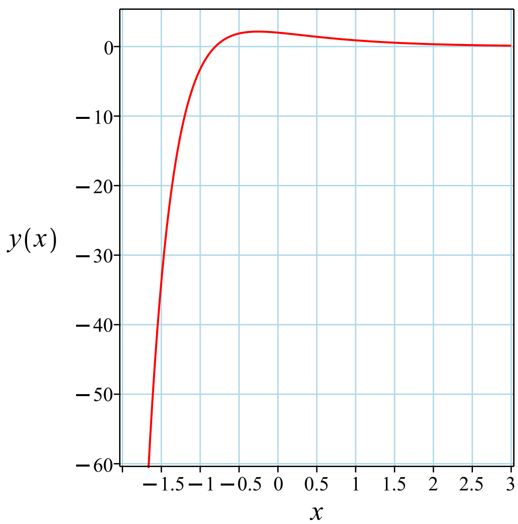
$$c_1 = \frac{5}{2}$$
$$c_2 = -\frac{1}{2}$$

Substituting these values back in above solution results in

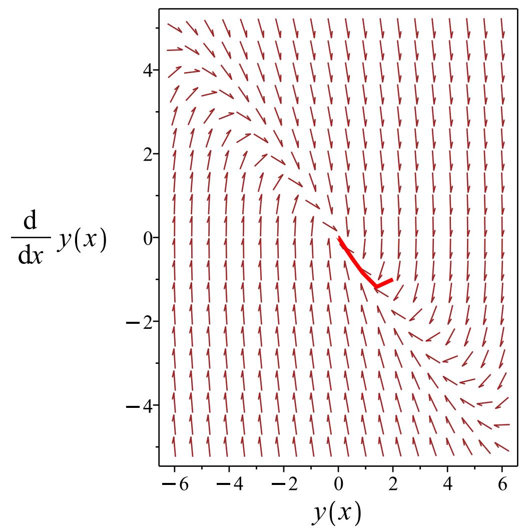
$$y = \frac{5\,\mathrm{e}^{-x}}{2} - \frac{\mathrm{e}^{-3x}}{2}$$

Summary
The solution(s) found are the following

$$y = \frac{5\,e^{-x}}{2} - \frac{e^{-3x}}{2} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{5\,e^{-x}}{2} - \frac{e^{-3x}}{2}$$

Verified OK.

7.10.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y' + 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4 \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 334: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4}{1}\,dx} \\ &= z_1 e^{-2x} \\ &= z_1 \left(\mathrm{e}^{-2x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-4x}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\mathrm{e}^{2x}}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-3x}\right) + c_2 \left(\mathrm{e}^{-3x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{-3x} + \frac{c_2 \mathrm{e}^{-x}}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = c_1 + \frac{c_2}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -3c_1 \mathrm{e}^{-3x} - \frac{c_2 \mathrm{e}^{-x}}{2}$$

substituting $y' = -1$ and $x = 0$ in the above gives

$$-1 = -3c_1 - \frac{c_2}{2} \tag{2A}$$

Equations $\{1A, 2A\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

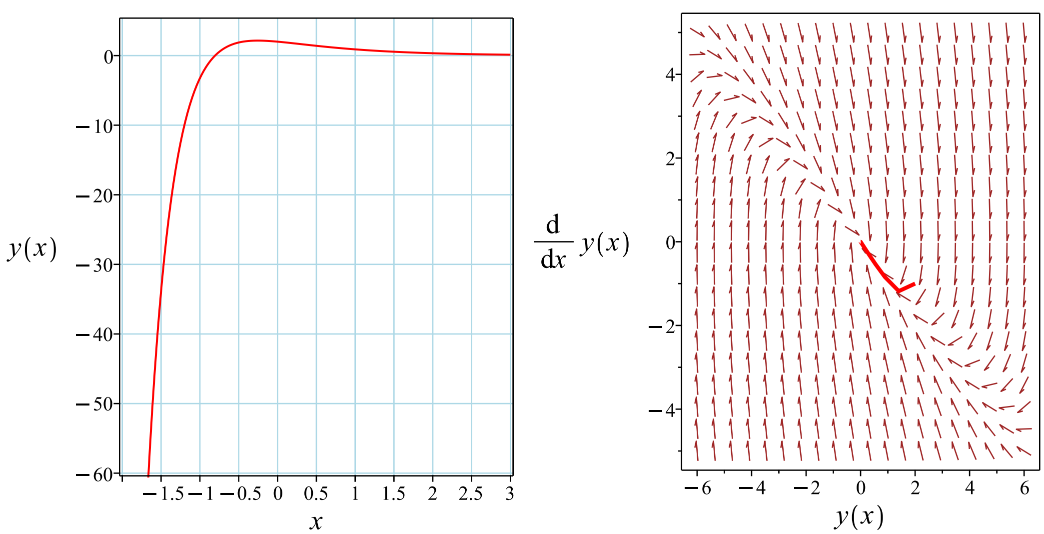
$$c_1 = -\frac{1}{2}$$
$$c_2 = 5$$

Substituting these values back in above solution results in

$$y = \frac{5\,e^{-x}}{2} - \frac{e^{-3x}}{2}$$

Summary
The solution(s) found are the following

$$y = \frac{5\,e^{-x}}{2} - \frac{e^{-3x}}{2} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \frac{5\,e^{-x}}{2} - \frac{e^{-3x}}{2}$$

Verified OK.

7.10.4 Maple step by step solution

Let's solve

$$\left[y''+4y'+3y=0, y(0)=2, y'\Big|_{\{x=0\}}=-1\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2+4r+3=0$

- Factor the characteristic polynomial

  $(r+3)(r+1)=0$

- Roots of the characteristic polynomial

  $r=(-3,-1)$

- 1st solution of the ODE

  $y_1(x)=e^{-3x}$

- 2nd solution of the ODE

  $y_2(x)=e^{-x}$

- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)$

- Substitute in solutions

  $y=c_1e^{-3x}+c_2e^{-x}$

□ Check validity of solution $y=c_1e^{-3x}+c_2e^{-x}$

  ◦ Use initial condition $y(0)=2$

    $2=c_1+c_2$

  ◦ Compute derivative of the solution

    $y'=-3c_1e^{-3x}-c_2e^{-x}$

  ◦ Use the initial condition $y'\Big|_{\{x=0\}}=-1$

    $-1=-3c_1-c_2$

  ◦ Solve for c_1 and c_2

    $\left\{c_1=-\frac{1}{2}, c_2=\frac{5}{2}\right\}$

- Substitute constant values into general solution and simplify

  $y = \frac{5\,e^{-x}}{2} - \frac{e^{-3x}}{2}$

- Solution to the IVP

  $y = \frac{5\,e^{-x}}{2} - \frac{e^{-3x}}{2}$

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Chapter 3, Second order linear equations, 3.1 Homogeneous Equations with Constant Coefficients, page 144
Problem number: 11.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _missing_x]]`

$$\boxed{6y'' - 5y' + y = 0}$$

With initial conditions

$$[y(0) = 4, y'(0) = 0]$$

7.11.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -\frac{5}{6} \\ q(x) &= \frac{1}{6} \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - \frac{5y'}{6} + \frac{y}{6} = 0$$

The domain of $p(x) = -\frac{5}{6}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \frac{1}{6}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

7.11.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 6, B = -5, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$6\lambda^2 e^{\lambda x} - 5\lambda\, e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$6\lambda^2 - 5\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 6, B = -5, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{5}{(2)(6)} \pm \frac{1}{(2)(6)}\sqrt{-5^2 - (4)(6)(1)} \\ &= \frac{5}{12} \pm \frac{1}{12}\end{aligned}$$

Hence

$$\lambda_1 = \frac{5}{12} + \frac{1}{12}$$

$$\lambda_2 = \frac{5}{12} - \frac{1}{12}$$

Which simplifies to

$$\lambda_1 = \frac{1}{2}$$
$$\lambda_2 = \frac{1}{3}$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{\left(\frac{1}{2}\right)x} + c_2 e^{\left(\frac{1}{3}\right)x}$$

Or

$$y = c_1 e^{\frac{x}{2}} + c_2 e^{\frac{x}{3}}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{\frac{x}{2}} + c_2 e^{\frac{x}{3}} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 0$ in the above gives

$$4 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{c_1 e^{\frac{x}{2}}}{2} + \frac{c_2 e^{\frac{x}{3}}}{3}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = \frac{c_1}{2} + \frac{c_2}{3} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -8$$
$$c_2 = 12$$

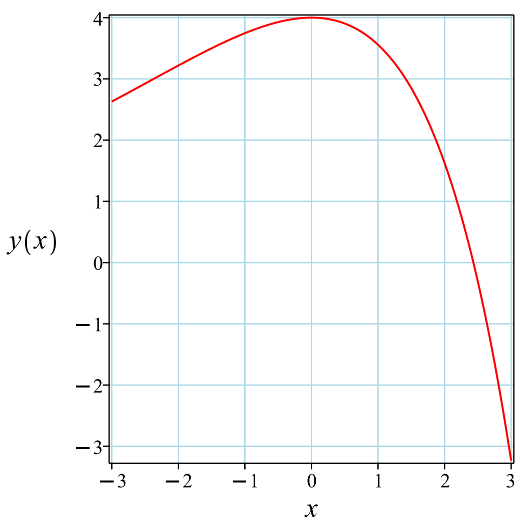
Substituting these values back in above solution results in

$$y = -8\,e^{\frac{x}{2}} + 12\,e^{\frac{x}{3}}$$

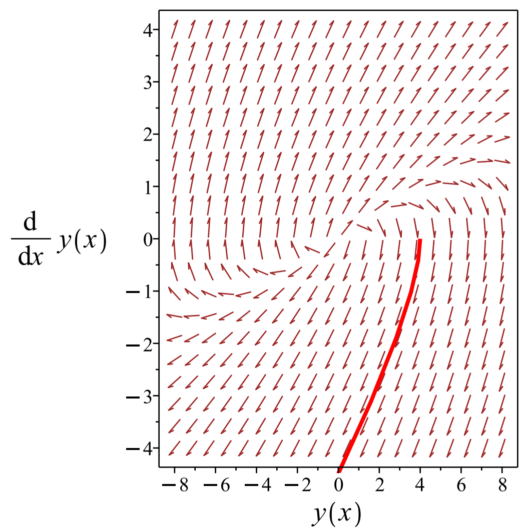
Summary

The solution(s) found are the following

$$y = -8\,e^{\frac{x}{2}} + 12\,e^{\frac{x}{3}} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -8\,e^{\frac{x}{2}} + 12\,e^{\frac{x}{3}}$$

Verified OK.

7.11.3 Solving using Kovacic algorithm

Writing the ode as

$$6y'' - 5y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 6 \\ B &= -5 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{144} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 144 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{144} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 336: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{1}{144}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-\frac{x}{12}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-5}{6}\,dx} \\
&= z_1 e^{\frac{5x}{12}} \\
&= z_1 \left(\mathrm{e}^{\frac{5x}{12}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{\frac{x}{3}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-5}{6}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{5x}{6}}}{(y_1)^2}\,dx \\
&= y_1 \left(6\,\mathrm{e}^{\frac{x}{6}}\right)
\end{aligned}
$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{\frac{x}{3}}\right) + c_2\left(\mathrm{e}^{\frac{x}{3}}\left(6\,\mathrm{e}^{\frac{x}{6}}\right)\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{\frac{x}{3}} + 6c_2 \mathrm{e}^{\frac{x}{2}} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 0$ in the above gives

$$4 = c_1 + 6c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{c_1 \mathrm{e}^{\frac{x}{3}}}{3} + 3c_2 \mathrm{e}^{\frac{x}{2}}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = \frac{c_1}{3} + 3c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 12 \\ c_2 &= -\frac{4}{3} \end{aligned}$$

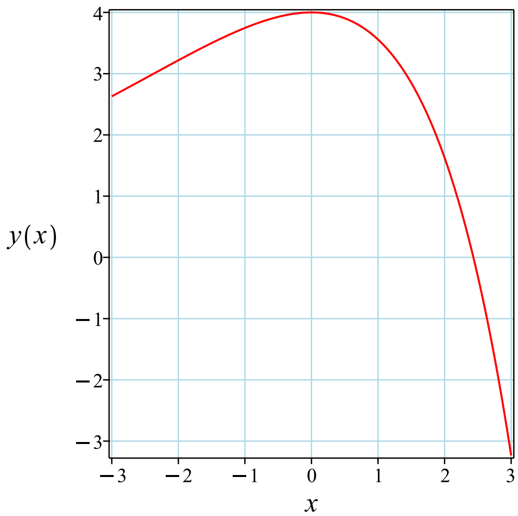
Substituting these values back in above solution results in

$$y = -8\,\mathrm{e}^{\frac{x}{2}} + 12\,\mathrm{e}^{\frac{x}{3}}$$

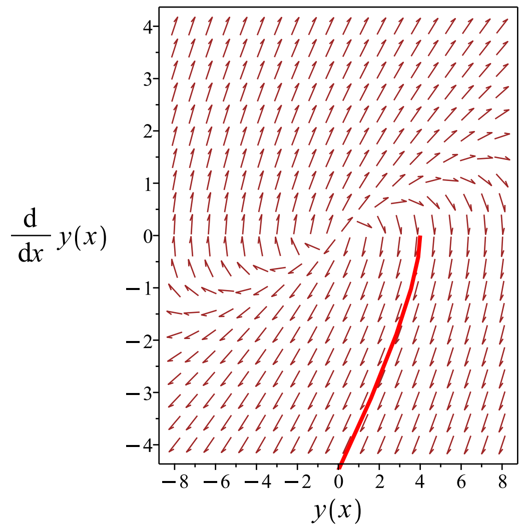
<u>Summary</u>

The solution(s) found are the following

$$y = -8\,\mathrm{e}^{\frac{x}{2}} + 12\,\mathrm{e}^{\frac{x}{3}} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = -8\,\mathrm{e}^{\frac{x}{2}} + 12\,\mathrm{e}^{\frac{x}{3}}$$

Verified OK.

7.11.4 Maple step by step solution

Let's solve

$\left[6y'' - 5y' + y = 0, y(0) = 4, y'\Big|_{\{x=0\}} = 0\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{5y'}{6} - \frac{y}{6}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{5y'}{6} + \frac{y}{6} = 0$

- Characteristic polynomial of ODE

  $r^2 - \frac{5}{6}r + \frac{1}{6} = 0$

- Factor the characteristic polynomial

$\frac{(3r-1)(2r-1)}{6} = 0$

- Roots of the characteristic polynomial

  $r = \left(\frac{1}{2}, \frac{1}{3}\right)$

- 1st solution of the ODE

  $y_1(x) = \mathrm{e}^{\frac{x}{2}}$

- 2nd solution of the ODE

  $y_2(x) = \mathrm{e}^{\frac{x}{3}}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 \mathrm{e}^{\frac{x}{2}} + c_2 \mathrm{e}^{\frac{x}{3}}$

□ Check validity of solution $y = c_1 \mathrm{e}^{\frac{x}{2}} + c_2 \mathrm{e}^{\frac{x}{3}}$

  ◦ Use initial condition $y(0) = 4$

    $4 = c_1 + c_2$

  ◦ Compute derivative of the solution

    $y' = \frac{c_1 \mathrm{e}^{\frac{x}{2}}}{2} + \frac{c_2 \mathrm{e}^{\frac{x}{3}}}{3}$

  ◦ Use the initial condition $y'\Big|_{\{x=0\}} = 0$

    $0 = \frac{c_1}{2} + \frac{c_2}{3}$

  ◦ Solve for c_1 and c_2

    $\{c_1 = -8, c_2 = 12\}$

  ◦ Substitute constant values into general solution and simplify

    $y = -8\,\mathrm{e}^{\frac{x}{2}} + 12\,\mathrm{e}^{\frac{x}{3}}$

- Solution to the IVP

  $y = -8\,\mathrm{e}^{\frac{x}{2}} + 12\,\mathrm{e}^{\frac{x}{3}}$

Book: Elementary differential equations and boundary value problems, 10th ed., Boyce and DiPrima
Section: Chapter 3, Second order linear equations, 3.1 Homogeneous Equations with Constant Coefficients, page 144
Problem number: 12.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 3y' = 0}$$

With initial conditions

$$[y(0) = -2, y'(0) = 3]$$

7.12.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 3 \\ q(x) &= 0 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + 3y' = 0$$

The domain of $p(x) = 3$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. Hence solution exists and is unique.

7.12.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 3, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 3\lambda\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 3\lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 3, C = 0$ into the above gives

$$\begin{aligned} \lambda_{1,2} &= \frac{-3}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{3^2 - (4)\,(1)\,(0)} \\ &= -\frac{3}{2} \pm \frac{3}{2} \end{aligned}$$

Hence

$$\lambda_1 = -\frac{3}{2} + \frac{3}{2}$$
$$\lambda_2 = -\frac{3}{2} - \frac{3}{2}$$

Which simplifies to

$$\lambda_1 = 0$$
$$\lambda_2 = -3$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(0)x} + c_2 e^{(-3)x}$$

Or

$$y = c_1 + \mathrm{e}^{-3x} c_2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 + \mathrm{e}^{-3x} c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -2$ and $x = 0$ in the above gives

$$-2 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -3\,\mathrm{e}^{-3x} c_2$$

substituting $y' = 3$ and $x = 0$ in the above gives

$$3 = -3c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -1$$
$$c_2 = -1$$

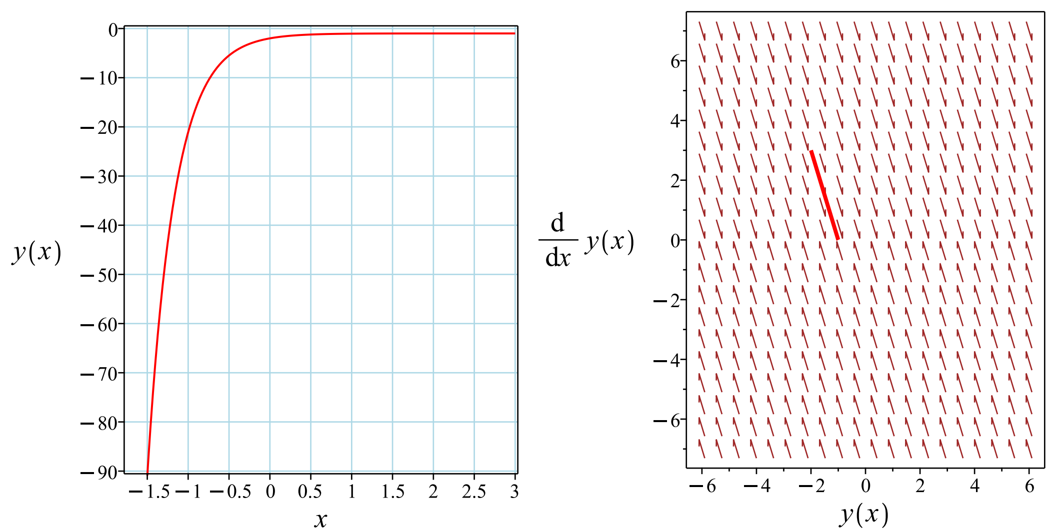
Substituting these values back in above solution results in

$$y = -1 - e^{-3x}$$

Summary

The solution(s) found are the following

$$y = -1 - e^{-3x} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = -1 - e^{-3x}$$

Verified OK.

7.12.3 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 3y')\, dx = 0$$

$$3y + y' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{1}{-3y + c_1} dy = \int dx$$

$$-\frac{\ln(-3y + c_1)}{3} = x + c_2$$

Raising both side to exponential gives

$$\frac{1}{\left(-3y+c_1\right)^{\frac{1}{3}}} = \mathrm{e}^{x+c_2}$$

Which simplifies to

$$\frac{1}{\left(-3y+c_1\right)^{\frac{1}{3}}} = c_3\mathrm{e}^{x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{\mathrm{e}^{-3x}}{3c_3^3} + \frac{c_1}{3} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -2$ and $x = 0$ in the above gives

$$-2 = \frac{c_1c_3^3 - 1}{3c_3^3} \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{\mathrm{e}^{-3x}}{c_3^3}$$

substituting $y' = 3$ and $x = 0$ in the above gives

$$3 = \frac{1}{c_3^3} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. Warning, unable to solve for constants of integrations.

Verification of solutions N/A

7.12.4 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + 3p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int -\frac{1}{3p} dp = \int dx$$
$$-\frac{\ln(p)}{3} = x + c_1$$

Raising both side to exponential gives

$$\frac{1}{p^{\frac{1}{3}}} = e^{x+c_1}$$

Which simplifies to

$$\frac{1}{p^{\frac{1}{3}}} = c_2 e^x$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $p = 3$ in the above solution gives an equation to solve for the constant of integration.

$$3 = \frac{1}{c_2^3}$$

$$c_2 = \frac{3^{\frac{2}{3}}}{3}$$

Substituting c_2 found above in the general solution gives

$$p(x) = 3\,e^{-3x}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = 3\,e^{-3x}$$

Integrating both sides gives

$$y = \int 3\,e^{-3x}\,\mathrm{d}x$$
$$= -e^{-3x} + c_3$$

Initial conditions are used to solve for c_3. Substituting $x = 0$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

$$-2 = -1 + c_3$$

$$c_3 = -1$$

Substituting c_3 found above in the general solution gives

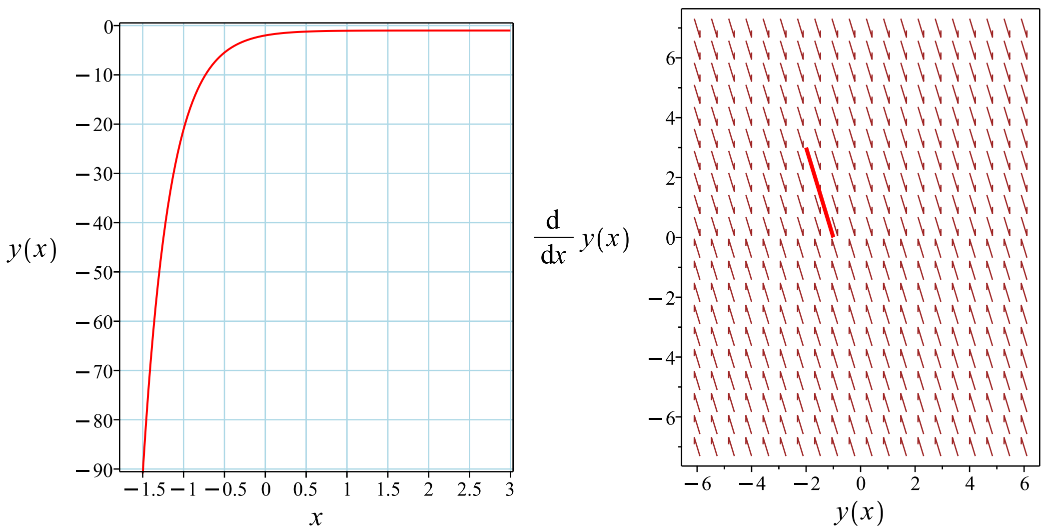
$$y = -1 - e^{-3x}$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$y = -1 - e^{-3x} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = -1 - e^{-3x}$$

Verified OK.

7.12.5 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + 3y' = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 3y')\, dx = 0$$
$$3y + y' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{1}{-3y + c_1} dy = \int dx$$
$$-\frac{\ln(-3y + c_1)}{3} = x + c_2$$

Raising both side to exponential gives

$$\frac{1}{(-3y + c_1)^{\frac{1}{3}}} = \mathrm{e}^{x + c_2}$$

Which simplifies to

$$\frac{1}{(-3y + c_1)^{\frac{1}{3}}} = c_3 \mathrm{e}^{x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{\mathrm{e}^{-3x}}{3c_3^3} + \frac{c_1}{3} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -2$ and $x = 0$ in the above gives

$$-2 = \frac{c_1 c_3^3 - 1}{3c_3^3} \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{\mathrm{e}^{-3x}}{c_3^3}$$

substituting $y' = 3$ and $x = 0$ in the above gives

$$3 = \frac{1}{c_3^3} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. Warning, unable to solve for constants of integrations.

7.12.6 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 3y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 3 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 338: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-\frac{3x}{2}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{3}{1} \, dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{-\frac{3x}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{3x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-3x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-3x}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\mathrm{e}^{3x}}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-3x}\right) + c_2 \left(\mathrm{e}^{-3x} \left(\frac{\mathrm{e}^{3x}}{3}\right)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{-3x} + \frac{c_2}{3} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -2$ and $x = 0$ in the above gives

$$
-2 = c_1 + \frac{c_2}{3} \tag{1A}
$$

Taking derivative of the solution gives

$$y' = -3c_1 e^{-3x}$$

substituting $y' = 3$ and $x = 0$ in the above gives

$$3 = -3c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -1$$
$$c_2 = -3$$

Substituting these values back in above solution results in

$$y = -1 - e^{-3x}$$

Summary

The solution(s) found are the following

$$y = -1 - e^{-3x} \tag{1}$$
