$$y_2(x) = e^{2x}\left(\int e^{-\left(\int \frac{-4x-4}{2x+1}dx\right)} e^{-4x} dx\right)$$

$$y_2(x) = e^{2x}\int \frac{e^{2x+\ln(2x+1)}}{e^{4x}}, dx$$

$$y_2(x) = e^{2x}\left(\int (2x+1)\,e^{-2x} dx\right)$$

$$y_2(x) = -e^{2x}(1+x)\,e^{-2x}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 e^{2x} - c_2 e^{2x}(1+x)\,e^{-2x} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{2x} - c_2 e^{2x}(1+x)\,e^{-2x} \tag{1}$$

Verification of solutions

$$y = c_1 e^{2x} - c_2 e^{2x}(1+x)\,e^{-2x}$$

Verified OK.

9.5.1 Maple step by step solution

Let's solve

$(2x+1)\,y'' + (-4x-4)\,y' + 4y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{4y}{2x+1} + \frac{4(1+x)y'}{2x+1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{4(1+x)y'}{2x+1} + \frac{4y}{2x+1} = 0$

□ Check to see if $x_0 = -\frac{1}{2}$ is a regular singular point

  ◦ Define functions

$\left[P_2(x) = -\frac{4(1+x)}{2x+1}, P_3(x) = \frac{4}{2x+1}\right]$

- $\left(x+\frac{1}{2}\right) \cdot P_2(x)$ is analytic at $x = -\frac{1}{2}$

  $\left(\left(x+\frac{1}{2}\right) \cdot P_2(x)\right)\bigg|_{x=-\frac{1}{2}} = -1$

- $\left(x+\frac{1}{2}\right)^2 \cdot P_3(x)$ is analytic at $x = -\frac{1}{2}$

  $\left(\left(x+\frac{1}{2}\right)^2 \cdot P_3(x)\right)\bigg|_{x=-\frac{1}{2}} = 0$

- $x = -\frac{1}{2}$is a regular singular point

  Check to see if $x_0 = -\frac{1}{2}$ is a regular singular point

  $x_0 = -\frac{1}{2}$

- Multiply by denominators

  $(2x+1)\, y'' + (-4x-4)\, y' + 4y = 0$

- Change variables using $x = u - \frac{1}{2}$ so that the regular singular point is at $u = 0$

  $2u\left(\frac{d^2}{du^2}y(u)\right) + (-4u-2)\left(\frac{d}{du}y(u)\right) + 4y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

  $u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, u^{k+r-1}$

- Shift index using $k->k+1$

  $u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\, u^{k+r}$

  Rewrite ODE with series expansions

$$2a_0r(-2+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(2a_{k+1}(k+1+r)\,(k+r-1)-4a_k(k+r-1)\right)u^{k+r}\right)=0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$2r(-2+r)=0$$

- Values of r that satisfy the indicial equation

$$r\in\{0,2\}$$

- Each term in the series must be 0, giving the recursion relation

$$2(a_{k+1}(k+1+r)-2a_k)\,(k+r-1)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=\frac{2a_k}{k+1+r}$$

- Recursion relation for $r=0$

$$a_{k+1}=\frac{2a_k}{k+1}$$

- Solution for $r=0$

$$\left[y(u)=\sum_{k=0}^{\infty}a_ku^k, a_{k+1}=\frac{2a_k}{k+1}\right]$$

- Revert the change of variables $u=x+\frac{1}{2}$

$$\left[y=\sum_{k=0}^{\infty}a_k\left(x+\frac{1}{2}\right)^k, a_{k+1}=\frac{2a_k}{k+1}\right]$$

- Recursion relation for $r=2$

$$a_{k+1}=\frac{2a_k}{k+3}$$

- Solution for $r=2$

$$\left[y(u)=\sum_{k=0}^{\infty}a_ku^{k+2}, a_{k+1}=\frac{2a_k}{k+3}\right]$$

- Revert the change of variables $u=x+\frac{1}{2}$

$$\left[y=\sum_{k=0}^{\infty}a_k\left(x+\frac{1}{2}\right)^{k+2}, a_{k+1}=\frac{2a_k}{k+3}\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}a_k\left(x+\frac{1}{2}\right)^k\right)+\left(\sum_{k=0}^{\infty}b_k\left(x+\frac{1}{2}\right)^{k+2}\right), a_{1+k}=\frac{2a_k}{1+k}, b_{1+k}=\frac{2b_k}{k+3}\right]$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.1. Basic theory of linear differential equations. Exercises page 124
Problem number: 6.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{\left(x^{3}-x^{2}\right) y''-\left(x^{3}+2 x^{2}-2 x\right) y'+\left(2 x^{2}+2 x -2\right) y=0}$$

Given that one solution of the ode is

$$y_1 = x^2$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{\mathrm{e}^{-\left(\int p dx\right)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{-x^3 - 2x^2 + 2x}{x^3 - x^2}$$

Therefore

$$y_2(x) = x^2 \left(\int \frac{\mathrm{e}^{-\left(\int \frac{-x^3-2x^2+2x}{x^3-x^2}dx\right)}}{x^4}dx\right)$$

$$y_2(x) = x^2 \int \frac{\mathrm{e}^{x+\ln(x-1)+2\ln(x)}}{x^4}, dx$$

$$y_2(x) = x^2 \left(\int \frac{(x-1)\,\mathrm{e}^x}{x^2}dx\right)$$

$$y_2(x) = x\,\mathrm{e}^x$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^2 + c_2 x\,\mathrm{e}^x \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x^2 + c_2 x\,\mathrm{e}^x \tag{1}$$

Verification of solutions

$$y = c_1 x^2 + c_2 x\,\mathrm{e}^x$$

Verified OK.

9.6.1 Maple step by step solution

Let's solve

$y''x^2(x-1) + (-x^3 - 2x^2 + 2x)\,y' + (2x^2 + 2x - 2)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{2(x^2+x-1)y}{x^2(x-1)} + \frac{(x^2+2x-2)y'}{x(x-1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{(x^2+2x-2)y'}{x(x-1)} + \frac{2(x^2+x-1)y}{x^2(x-1)} = 0$

□ Check to see if x_0 is a regular singular point

- Define functions

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 3y' + 2y = 4x^2}$$

9.7.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -3, C = 2, f(x) = 4x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 3y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -3, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 3\lambda \, \mathrm{e}^{\lambda x} + 2 \, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 3\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -3, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{3}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-3^2 - (4)\,(1)\,(2)} \\ &= \frac{3}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= \frac{3}{2} + \frac{1}{2} \\ \lambda_2 &= \frac{3}{2} - \frac{1}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2 \\ \lambda_2 &= 1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(2)x} + c_2 e^{(1)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_3 x^2 + A_2 x + A_1$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_3 x^2 + 2A_2 x - 6x A_3 + 2A_1 - 3A_2 + 2A_3 = 4x^2$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 7, A_2 = 6, A_3 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2x^2 + 6x + 7$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{2x} + c_2 e^x\right) + \left(2x^2 + 6x + 7\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{2x} + c_2 e^x + 2x^2 + 6x + 7 \tag{1}$$

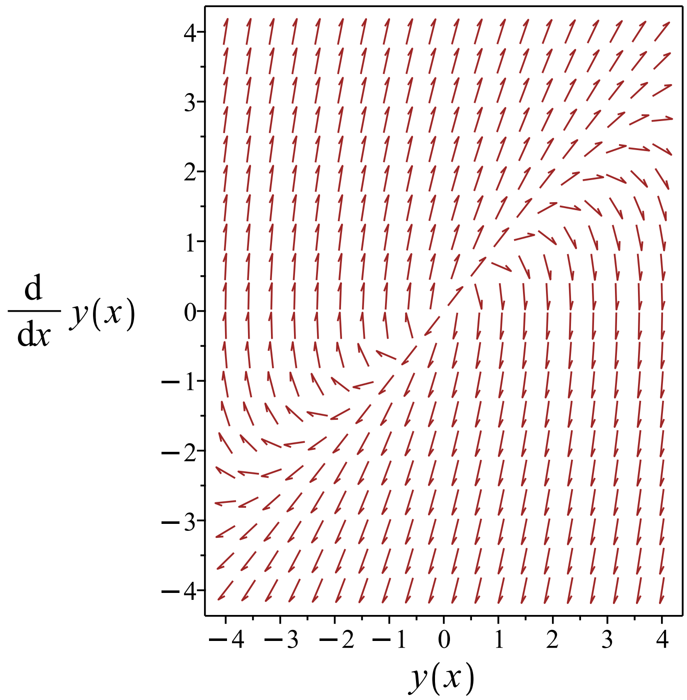

Figure 353: Slope field plot

Verification of solutions

$$y = c_1 e^{2x} + c_2 e^{x} + 2x^2 + 6x + 7$$

Verified OK.

9.7.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 3y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -3 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 275: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3}{1}\,dx} \\
&= z_1 e^{\frac{3x}{2}} \\
&= z_1\left(\mathrm{e}^{\frac{3x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{3x}}{(y_1)^2}\,dx \\
&= y_1(\mathrm{e}^{x})
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1(e^x) + c_2(e^x(e^x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 3y' + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = e^x c_1 + c_2 e^{2x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
x^2
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{1, x, x^2\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{e^x, e^{2x}\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_3x^2 + A_2x + A_1
$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
2A_3x^2 + 2A_2x - 6xA_3 + 2A_1 - 3A_2 + 2A_3 = 4x^2
$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 7, A_2 = 6, A_3 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2x^2 + 6x + 7$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^x c_1 + c_2 e^{2x}\right) + \left(2x^2 + 6x + 7\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^x c_1 + c_2 e^{2x} + 2x^2 + 6x + 7 \tag{1}$$

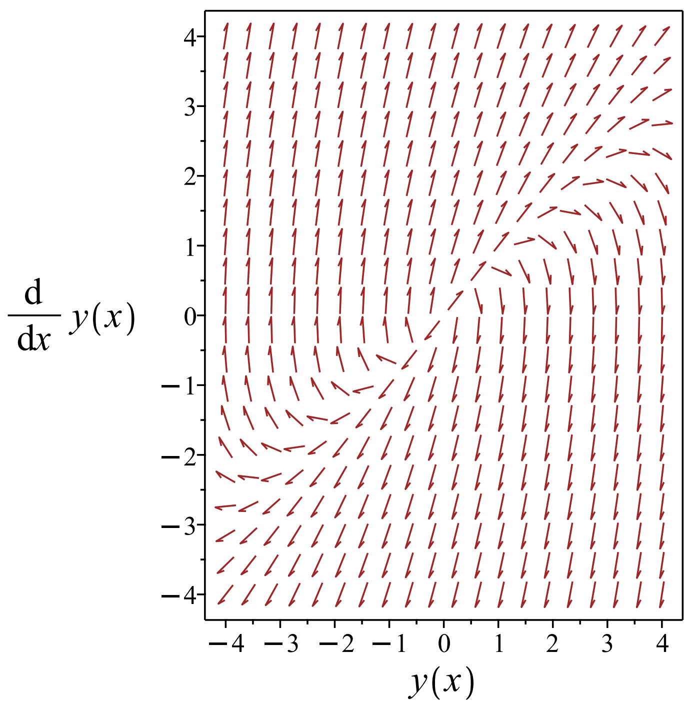

Figure 354: Slope field plot

Verification of solutions

$$y = e^x c_1 + c_2 e^{2x} + 2x^2 + 6x + 7$$

Verified OK.

9.7.3 Maple step by step solution

Let's solve

$y'' - 3y' + 2y = 4x^2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 3r + 2 = 0$

- Factor the characteristic polynomial

  $(r-1)(r-2) = 0$

- Roots of the characteristic polynomial

  $r = (1, 2)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^x$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^x c_1 + c_2 e^{2x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 4x^2\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^x & e^{2x} \\ e^x & 2\,e^{2x} \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{3x}$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -4\,e^x\left(\int x^2 e^{-x} dx\right) + 4\,e^{2x}\left(\int x^2 e^{-2x} dx\right)$

- ◦ Compute integrals

  $y_p(x) = 2x^2 + 6x + 7$

- Substitute particular solution into general solution to ODE

  $y = e^x c_1 + c_2 e^{2x} + 2x^2 + 6x + 7$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 5y' + 6y = 2 - 12x + 6\,\mathrm{e}^{x}}$$

9.8.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -5, C = 6, f(x) = 2 - 12x + 6\,\mathrm{e}^{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 5y' + 6y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -5, C = 6$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 5\lambda \,\mathrm{e}^{\lambda x} + 6\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 5\lambda + 6 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -5, C = 6$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{5}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-5^2 - (4)\,(1)\,(6)} \\
&= \frac{5}{2} \pm \frac{1}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
\lambda_1 &= \frac{5}{2} + \frac{1}{2} \\
\lambda_2 &= \frac{5}{2} - \frac{1}{2}
\end{aligned}$$

Which simplifies to

$$\begin{aligned}
\lambda_1 &= 3 \\
\lambda_2 &= 2
\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}
y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\
y &= c_1 e^{(3)x} + c_2 e^{(2)x}
\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{3x} + c_2 \mathrm{e}^{2x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{3x} + c_2 \mathrm{e}^{2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2 - 12x + 6\,\mathrm{e}^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{x}\}, \{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{2x}, \mathrm{e}^{3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\mathrm{e}^{x} + A_2 + A_3x$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1\mathrm{e}^{x} - 5A_3 + 6A_2 + 6A_3x = 2 - 12x + 6\,\mathrm{e}^{x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 3, A_2 = -\frac{4}{3}, A_3 = -2\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3\,\mathrm{e}^{x} - \frac{4}{3} - 2x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{3x} + c_2\mathrm{e}^{2x}\right) + \left(3\,\mathrm{e}^{x} - \frac{4}{3} - 2x\right) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1\mathrm{e}^{3x} + c_2\mathrm{e}^{2x} + 3\,\mathrm{e}^{x} - \frac{4}{3} - 2x \tag{1}$$

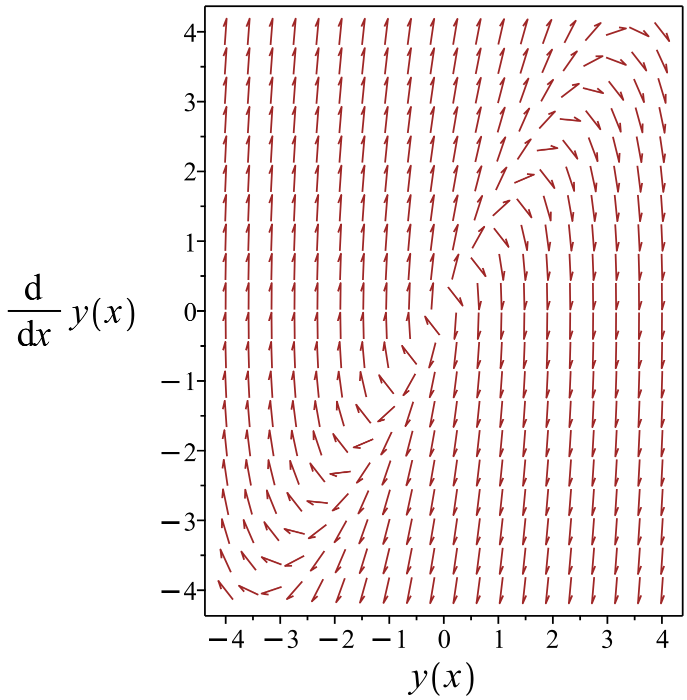

Figure 355: Slope field plot

Verification of solutions

$$y = c_1 e^{3x} + c_2 e^{2x} + 3 e^{x} - \frac{4}{3} - 2x$$

Verified OK.

9.8.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 5y' + 6y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -5 \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 277: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-5}{1}\, dx} \\
&= z_1 e^{\frac{5x}{2}} \\
&= z_1 \left(\mathrm{e}^{\frac{5x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-5}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{5x}}{(y_1)^2}\, dx \\
&= y_1 (\mathrm{e}^{x})
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(e^{2x}\right) + c_2 \left(e^{2x} \left(e^{x}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
y'' - 5y' + 6y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 e^{2x} + e^{3x} c_2
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
2 - 12x + 6\,e^{x}
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{e^{x}\}, \{1, x\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{e^{2x}, e^{3x}\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 e^{x} + A_2 + A_3 x
$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
2A_1 e^{x} - 5A_3 + 6A_2 + 6A_3 x = 2 - 12x + 6\,e^{x}
$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 3, A_2 = -\frac{4}{3}, A_3 = -2\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3\,\mathrm{e}^{x} - \frac{4}{3} - 2x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{2x} + \mathrm{e}^{3x} c_2\right) + \left(3\,\mathrm{e}^{x} - \frac{4}{3} - 2x\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{2x} + \mathrm{e}^{3x} c_2 + 3\,\mathrm{e}^{x} - \frac{4}{3} - 2x \tag{1}$$

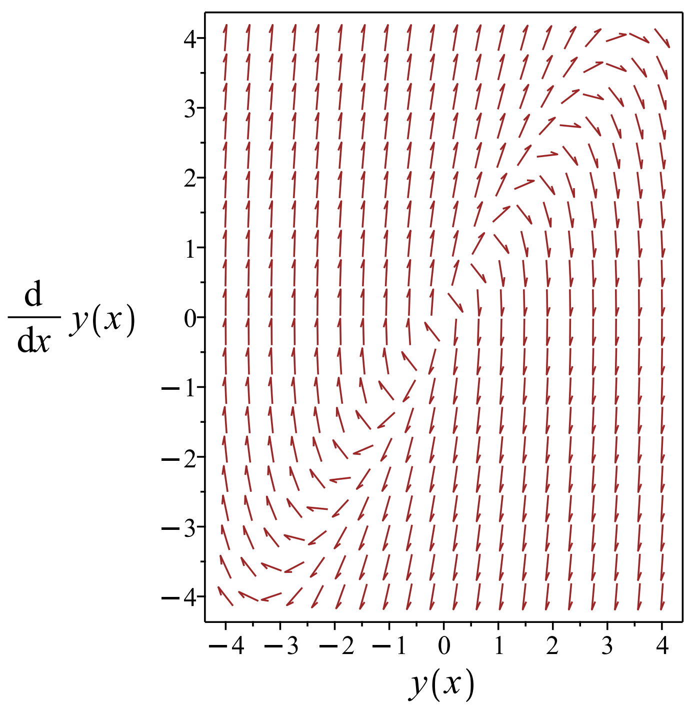

Figure 356: Slope field plot

Verification of solutions

$$y = c_1 e^{2x} + e^{3x} c_2 + 3\,e^{x} - \frac{4}{3} - 2x$$

Verified OK.

9.8.3 Maple step by step solution

Let's solve

$y'' - 5y' + 6y = 2 - 12x + 6\,e^{x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 5r + 6 = 0$

- Factor the characteristic polynomial

  $(r-2)(r-3) = 0$

- Roots of the characteristic polynomial

  $r = (2, 3)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{2x} + e^{3x} c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 2 - 12x + 6\,e^{x}\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{2x} & e^{3x} \\ 2\,e^{2x} & 3\,e^{3x} \end{bmatrix}$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{5x}$
- Substitute functions into equation for $y_p(x)$

  $y_p(x) = -2\,e^{2x}\left(\int (1-6x+3\,e^x)\,e^{-2x}dx\right) + 2\,e^{3x}\left(\int (1-6x+3\,e^x)\,e^{-3x}dx\right)$
- Compute integrals

  $y_p(x) = 3\,e^x - \frac{4}{3} - 2x$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{2x} + e^{3x} c_2 + 3\,e^x - \frac{4}{3} - 2x$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 5y' + 6y = 0}$$

10.1.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -5, C = 6$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 5\lambda e^{\lambda x} + 6 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 5\lambda + 6 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -5, C = 6$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{5}{(2)(1)} \pm \frac{1}{(2)(1)} \sqrt{-5^2 - (4)(1)(6)} \\ &= \frac{5}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\lambda_1 = \frac{5}{2} + \frac{1}{2}$$
$$\lambda_2 = \frac{5}{2} - \frac{1}{2}$$

Which simplifies to

$$\lambda_1 = 3$$
$$\lambda_2 = 2$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(3)x} + c_2 e^{(2)x}$$

Or

$$y = c_1 \mathrm{e}^{3x} + c_2 \mathrm{e}^{2x}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{3x} + c_2 \mathrm{e}^{2x} \tag{1}$$

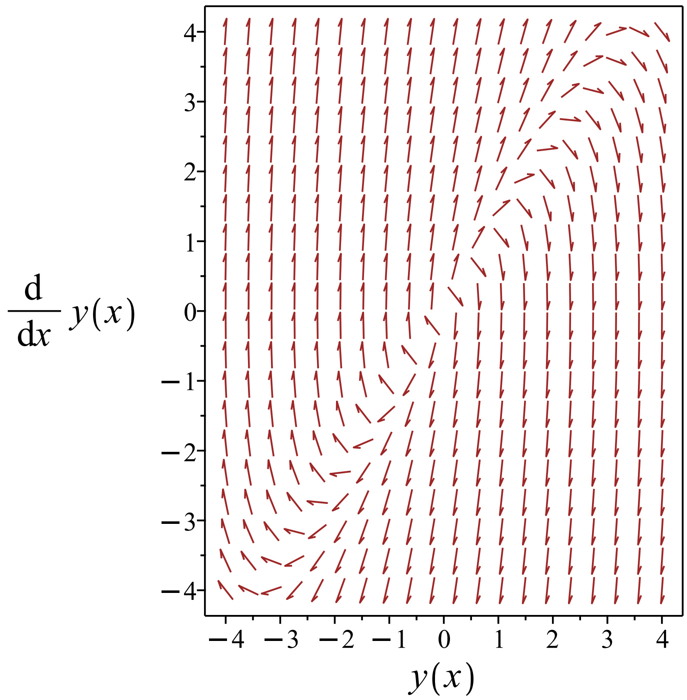

Figure 357: Slope field plot

Verification of solutions

$$y = c_1 e^{3x} + c_2 e^{2x}$$

Verified OK.

10.1.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 5y' + 6y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -5 \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 279: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-5}{1}\, dx} \\ &= z_1 e^{\frac{5x}{2}} \\ &= z_1 \left(\mathrm{e}^{\frac{5x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-5}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{5x}}{(y_1)^2}\, dx \\ &= y_1(\mathrm{e}^{x}) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{2x}\right) + c_2\left(\mathrm{e}^{2x}(\mathrm{e}^{x})\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{2x} + \mathrm{e}^{3x} c_2 \tag{1}
$$

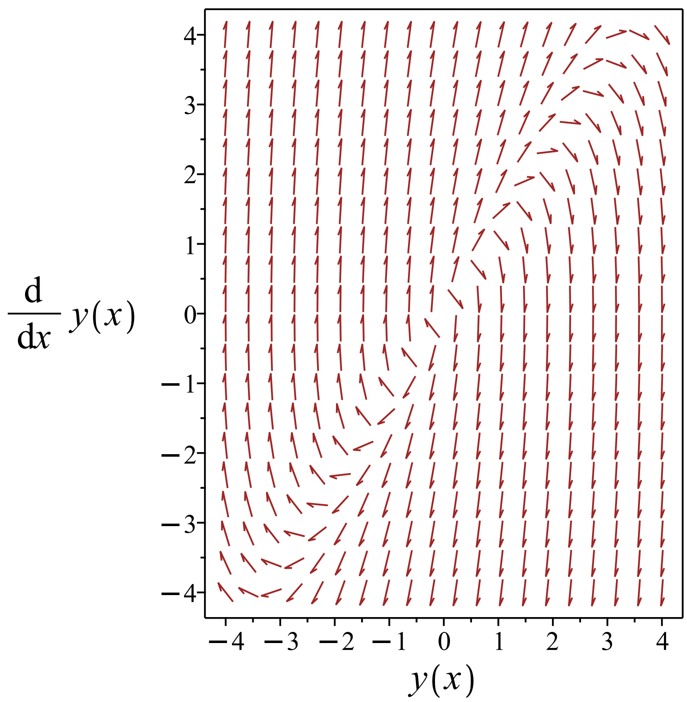

Figure 358: Slope field plot

Verification of solutions

$$
y = c_1 \mathrm{e}^{2x} + \mathrm{e}^{3x} c_2
$$

Verified OK.

10.1.3 Maple step by step solution

Let's solve

$y'' - 5y' + 6y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 5r + 6 = 0$

- Factor the characteristic polynomial

  $(r-2)(r-3) = 0$

- Roots of the characteristic polynomial

  $r = (2, 3)$

- 1st solution of the ODE

  $y_1(x) = e^{2x}$

- 2nd solution of the ODE

  $y_2(x) = e^{3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{2x} + e^{3x} c_2$

Problem number: 2.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 2y' - 3y = 0}$$

10.2.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = -3$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda e^{\lambda x} - 3 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda - 3 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = -3$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-2^2 - (4)(1)(-3)} \\
&= 1 \pm 2
\end{aligned}$$

Hence

$$\lambda_1 = 1 + 2$$
$$\lambda_2 = 1 - 2$$

Which simplifies to

$$\lambda_1 = 3$$
$$\lambda_2 = -1$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(3)x} + c_2 e^{(-1)x}$$

Or

$$y = c_1 \mathrm{e}^{3x} + c_2 \mathrm{e}^{-x}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{3x} + c_2 \mathrm{e}^{-x} \tag{1}$$

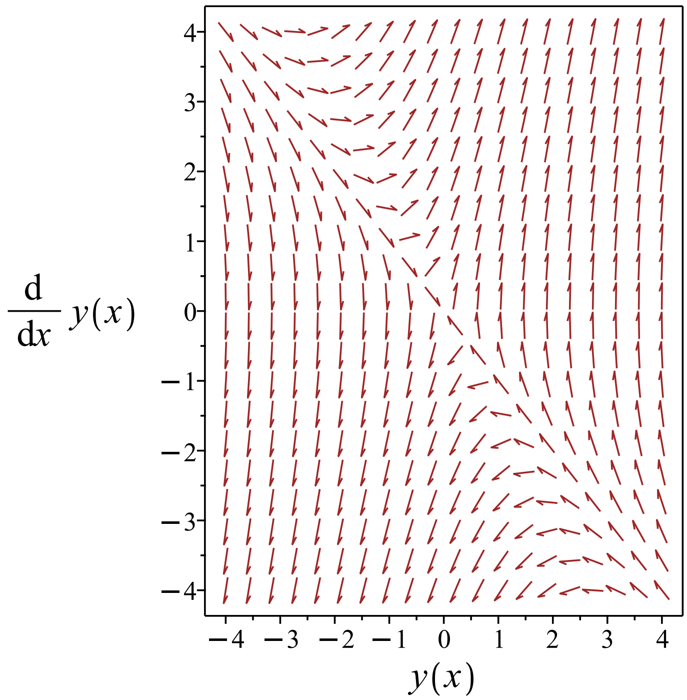

Figure 359: Slope field plot

Verification of solutions

$$y = c_1 e^{3x} + c_2 e^{-x}$$

Verified OK.

10.2.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' - 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= -3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 281: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-2x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\ &= z_1 e^{x} \\ &= z_1(\mathrm{e}^{x}) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{\mathrm{e}^{4x}}{4}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(e^{-x}\right) + c_2 \left(e^{-x} \left(\frac{e^{4x}}{4}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^{-x} + \frac{e^{3x} c_2}{4} \tag{1}
$$

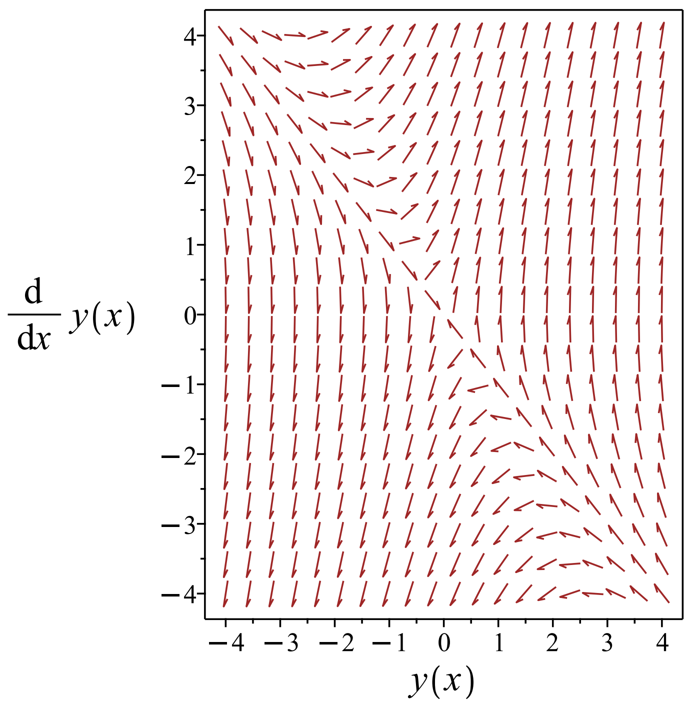

Figure 360: Slope field plot

Verification of solutions

$$
y = c_1 e^{-x} + \frac{e^{3x} c_2}{4}
$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{4y'' - 12y' + 5y = 0}$$

10.3.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 4, B = -12, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$4\lambda^2 e^{\lambda x} - 12\lambda e^{\lambda x} + 5 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$4\lambda^2 - 12\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 4, B = -12, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{12}{(2)\,(4)} \pm \frac{1}{(2)\,(4)}\sqrt{-12^2 - (4)\,(4)\,(5)} \\ &= \frac{3}{2} \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= \frac{3}{2} + 1 \\ \lambda_2 &= \frac{3}{2} - 1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \frac{5}{2} \\ \lambda_2 &= \frac{1}{2}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{\left(\frac{5}{2}\right)x} + c_2 e^{\left(\frac{1}{2}\right)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{\frac{5x}{2}} + \mathrm{e}^{\frac{x}{2}} c_2$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{\frac{5x}{2}} + \mathrm{e}^{\frac{x}{2}} c_2 \tag{1}$$

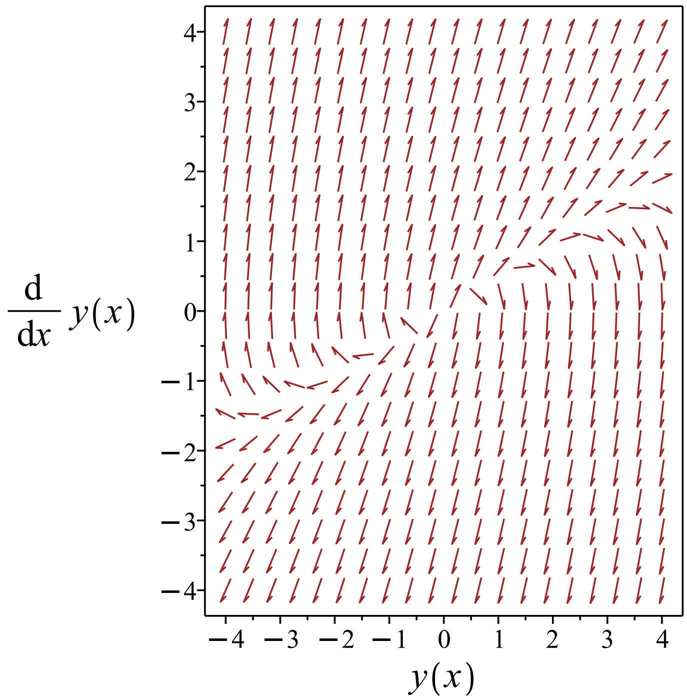

Figure 361: Slope field plot

Verification of solutions

$$y = c_1 e^{\frac{5x}{2}} + e^{\frac{x}{2}} c_2$$

Verified OK.

10.3.2 Solving using Kovacic algorithm

Writing the ode as

$$4y'' - 12y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4 \\ B &= -12 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 283: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-12}{4}\,dx} \\ &= z_1 e^{\frac{3x}{2}} \\ &= z_1\left(\mathrm{e}^{\frac{3x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\frac{x}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-12}{4}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{3x}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\mathrm{e}^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(e^{\frac{x}{2}}\right) + c_2\left(e^{\frac{x}{2}}\left(\frac{e^{2x}}{2}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^{\frac{x}{2}} + \frac{c_2 e^{\frac{5x}{2}}}{2} \tag{1}
$$

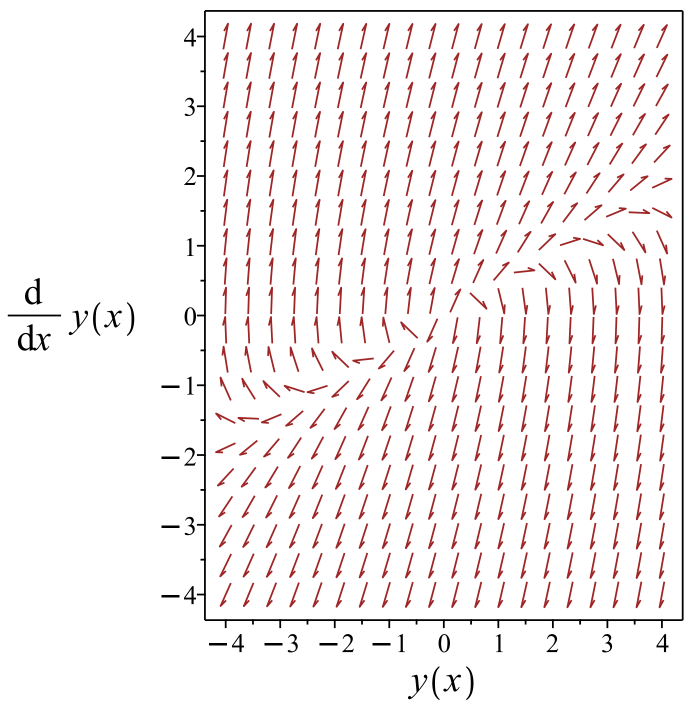

Figure 362: Slope field plot

Verification of solutions

$$
y = c_1 e^{\frac{x}{2}} + \frac{c_2 e^{\frac{5x}{2}}}{2}
$$

Verified OK.

10.3.3 Maple step by step solution

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{3y'' - 14y' - 5y = 0}$$

10.4.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 3, B = -14, C = -5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$3\lambda^2 e^{\lambda x} - 14\lambda e^{\lambda x} - 5 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$3\lambda^2 - 14\lambda - 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 3, B = -14, C = -5$ into the above gives

$$
\begin{aligned}
\lambda_{1,2} &= \frac{14}{(2)(3)} \pm \frac{1}{(2)(3)}\sqrt{-14^2 - (4)(3)(-5)} \\
&= \frac{7}{3} \pm \frac{8}{3}
\end{aligned}
$$

Hence

$$
\begin{aligned}
\lambda_1 &= \frac{7}{3} + \frac{8}{3} \\
\lambda_2 &= \frac{7}{3} - \frac{8}{3}
\end{aligned}
$$

Which simplifies to

$$
\begin{aligned}
\lambda_1 &= 5 \\
\lambda_2 &= -\frac{1}{3}
\end{aligned}
$$

Since roots are real and distinct, then the solution is

$$
\begin{aligned}
y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\
y &= c_1 e^{(5)x} + c_2 e^{\left(-\frac{1}{3}\right)x}
\end{aligned}
$$

Or

$$
y = c_1 \mathrm{e}^{5x} + c_2 \mathrm{e}^{-\frac{x}{3}}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{5x} + c_2 \mathrm{e}^{-\frac{x}{3}} \tag{1}
$$

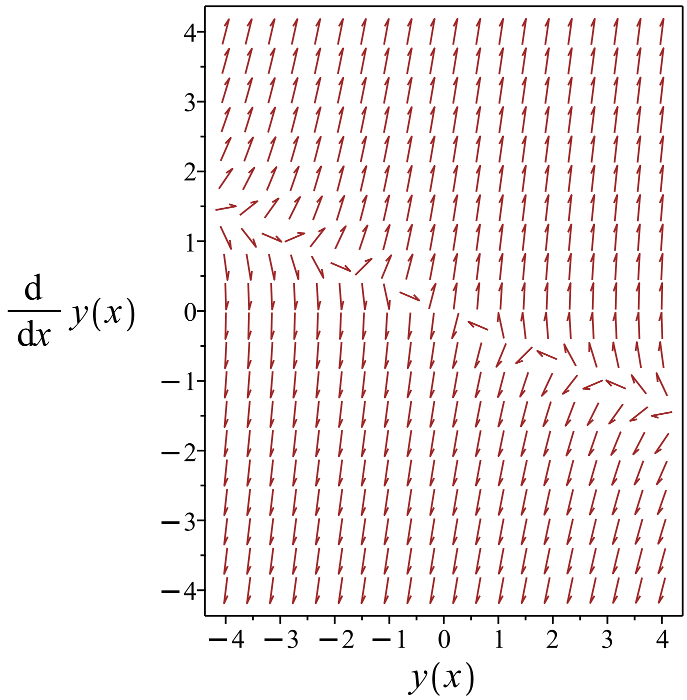

Figure 363: Slope field plot

Verification of solutions

$$y = c_1 e^{5x} + c_2 e^{-\frac{x}{3}}$$

Verified OK.

10.4.2 Solving using Kovacic algorithm

Writing the ode as

$$3y'' - 14y' - 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3 \\ B &= -14 \\ C &= -5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{64}{9} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 64 \\ t &= 9 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{64z(x)}{9} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 285: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{64}{9}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{8x}{3}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-14}{3}\,dx} \\ &= z_1 e^{\frac{7x}{3}} \\ &= z_1 \left(\mathrm{e}^{\frac{7x}{3}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x}{3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-14}{3}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{\frac{14x}{3}}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{3\,\mathrm{e}^{\frac{16x}{3}}}{16}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-\frac{x}{3}}\right) + c_2\left(\mathrm{e}^{-\frac{x}{3}}\left(\frac{3\,\mathrm{e}^{\frac{16x}{3}}}{16}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-\frac{x}{3}} + \frac{3c_2 \mathrm{e}^{5x}}{16} \tag{1}
$$

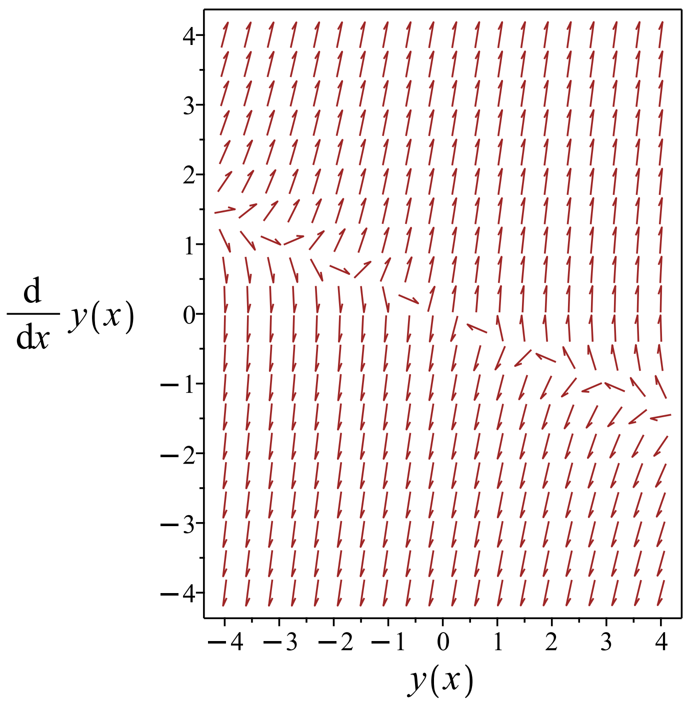

Figure 364: Slope field plot

Verification of solutions

$$
y = c_1 \mathrm{e}^{-\frac{x}{3}} + \frac{3c_2 \mathrm{e}^{5x}}{16}
$$

Verified OK.

10.4.3 Maple step by step solution

Let's solve

$3y'' - 14y' - 5y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{14y'}{3} + \frac{5y}{3}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{14y'}{3} - \frac{5y}{3} = 0$

- Characteristic polynomial of ODE

  $r^2 - \frac{14}{3}r - \frac{5}{3} = 0$

- Factor the characteristic polynomial

  $\frac{(3r+1)(r-5)}{3} = 0$

- Roots of the characteristic polynomial

  $r = \left(5, -\frac{1}{3}\right)$

- 1st solution of the ODE

  $y_1(x) = \mathrm{e}^{5x}$

- 2nd solution of the ODE

  $y_2(x) = \mathrm{e}^{-\frac{x}{3}}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 \mathrm{e}^{5x} + c_2 \mathrm{e}^{-\frac{x}{3}}$

Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 7.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 8y' + 16y = 0}$$

10.7.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -8, C = 16$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 8\lambda e^{\lambda x} + 16 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 8\lambda + 16 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -8, C = 16$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{8}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{(-8)^2 - (4)\,(1)\,(16)} \\ &= 4\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -4$. Therefore the solution is

$$y = c_1 e^{4x} + c_2 x\, e^{4x} \tag{1}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{4x} + c_2 x\, e^{4x} \tag{1}$$

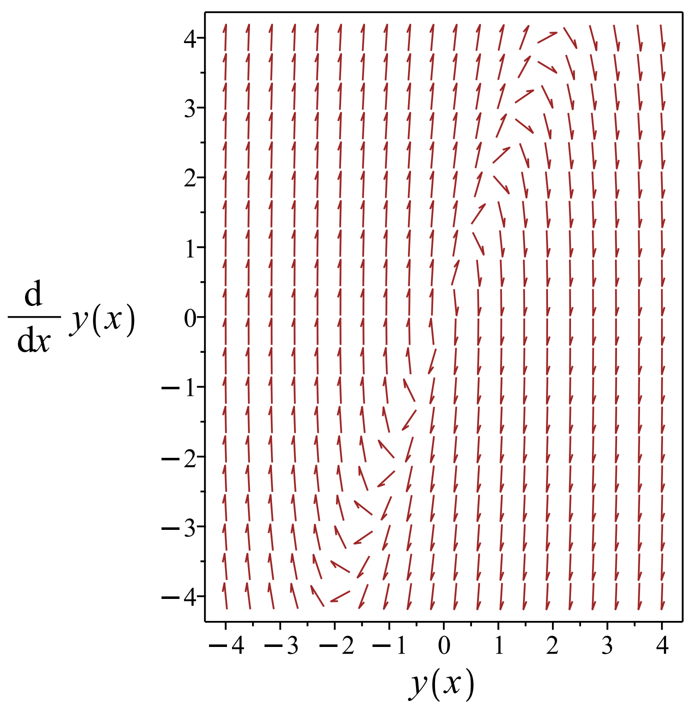

Figure 365: Slope field plot

Verification of solutions

$$y = c_1 e^{4x} + c_2 x\, e^{4x}$$

Verified OK.

10.7.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)$$

Where $p(x) = -8$. Therefore, there is an integrating factor given by

$$\begin{aligned}M(x) &= e^{\frac{1}{2}\int p\,dx}\\&= e^{\int -8\,dx}\\&= \mathrm{e}^{-4x}\end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned}(M(x)y)'' &= 0\\\left(\mathrm{e}^{-4x}y\right)'' &= 0\end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{-4x}y\right)' = c_1$$

Integrating again gives

$$\left(\mathrm{e}^{-4x}y\right) = c_1x + c_2$$

Hence the solution is

$$y = \frac{c_1x + c_2}{\mathrm{e}^{-4x}}$$

Or

$$y = c_1x\,\mathrm{e}^{4x} + c_2\mathrm{e}^{4x}$$

Summary

The solution(s) found are the following

$$y = c_1x\,\mathrm{e}^{4x} + c_2\mathrm{e}^{4x} \tag{1}$$

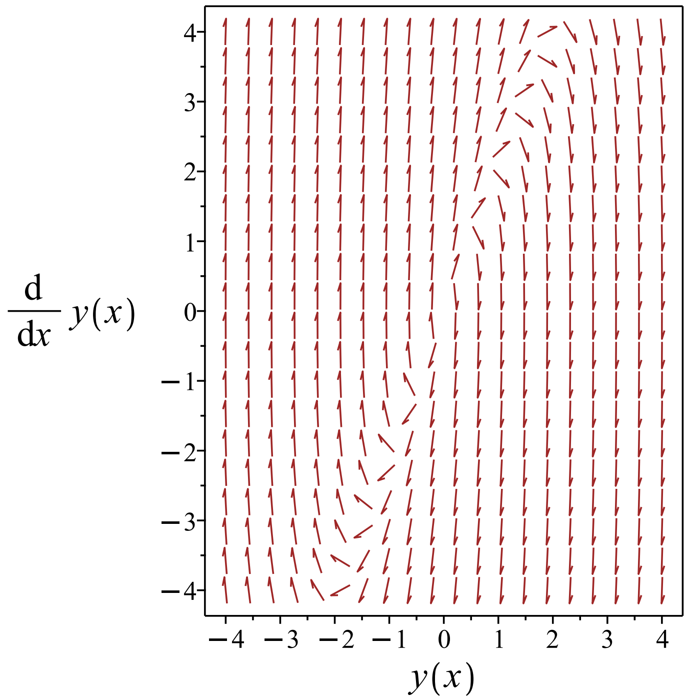

Figure 366: Slope field plot

Verification of solutions

$$y = c_1 x\, e^{4x} + c_2 e^{4x}$$

Verified OK.

10.7.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 8y' + 16y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -8 \\ C &= 16 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 289: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-8}{1}\,dx} \\ &= z_1 e^{4x} \\ &= z_1\left(\mathrm{e}^{4x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{4x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-8}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{8x}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{4x}\right) + c_2\left(\mathrm{e}^{4x}(x)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{4x} + c_2 x\, \mathrm{e}^{4x} \tag{1}$$

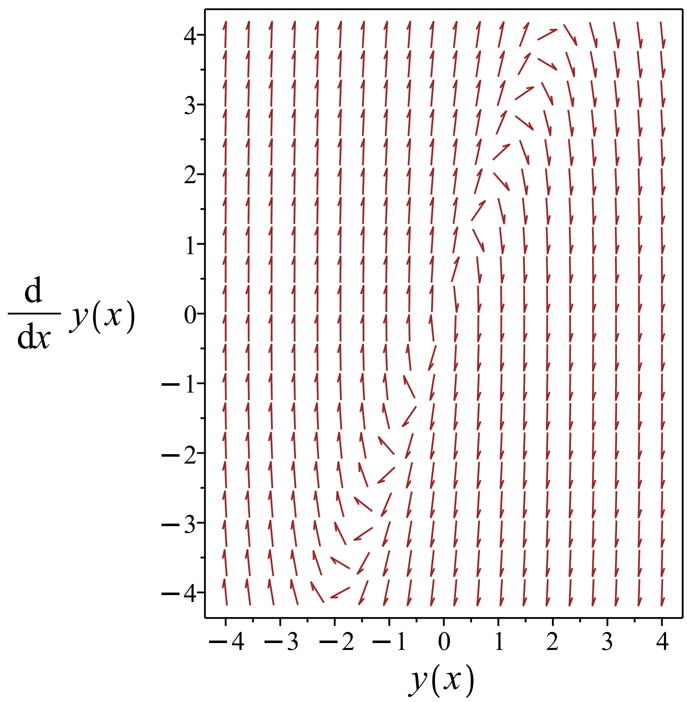

Figure 367: Slope field plot

Verification of solutions

$$y = c_1 \mathrm{e}^{4x} + c_2 x\, \mathrm{e}^{4x}$$

Verified OK.

10.7.4 Maple step by step solution

Let's solve

$y'' - 8y' + 16y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 8r + 16 = 0$

- Factor the characteristic polynomial

  $(r-4)^2 = 0$

- Root of the characteristic polynomial

  $r = 4$

- 1st solution of the ODE

  $y_1(x) = e^{4x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^{4x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{4x} + c_2 x\,e^{4x}$

Problem number: 8.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{4y'' + 4y' + y = 0}$$

10.8.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 4, B = 4, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$4\lambda^2 e^{\lambda x} + 4\lambda\, e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$4\lambda^2 + 4\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 4, B = 4, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-4}{(2)(4)} \pm \frac{1}{(2)(4)}\sqrt{(4)^2 - (4)(4)(1)} \\ &= -\frac{1}{2}\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = \frac{1}{2}$. Therefore the solution is

$$y = c_1 e^{-\frac{x}{2}} + c_2 x\, e^{-\frac{x}{2}} \tag{1}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-\frac{x}{2}} + c_2 x\, e^{-\frac{x}{2}} \tag{1}$$

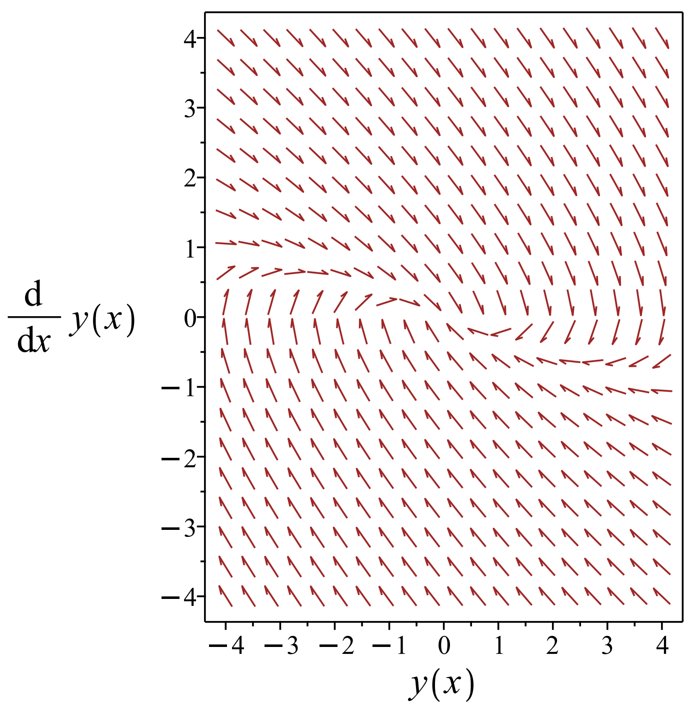

Figure 368: Slope field plot

Verification of solutions

$$y = c_1 e^{-\frac{x}{2}} + c_2 x\, e^{-\frac{x}{2}}$$

Verified OK.

10.8.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^{2} + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = 1$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2} \int p \, dx} \\ &= e^{\int 1 \, dx} \\ &= \mathrm{e}^{\frac{x}{2}} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= 0 \\ \left(\mathrm{e}^{\frac{x}{2}} y\right)'' &= 0 \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{\frac{x}{2}} y\right)' = c_1$$

Integrating again gives

$$\left(\mathrm{e}^{\frac{x}{2}} y\right) = c_1 x + c_2$$

Hence the solution is

$$y = \frac{c_1 x + c_2}{\mathrm{e}^{\frac{x}{2}}}$$

Or

$$y = c_1 x \,\mathrm{e}^{-\frac{x}{2}} + c_2 \mathrm{e}^{-\frac{x}{2}}$$

Summary

The solution(s) found are the following

$$y = c_1 x \,\mathrm{e}^{-\frac{x}{2}} + c_2 \mathrm{e}^{-\frac{x}{2}} \tag{1}$$

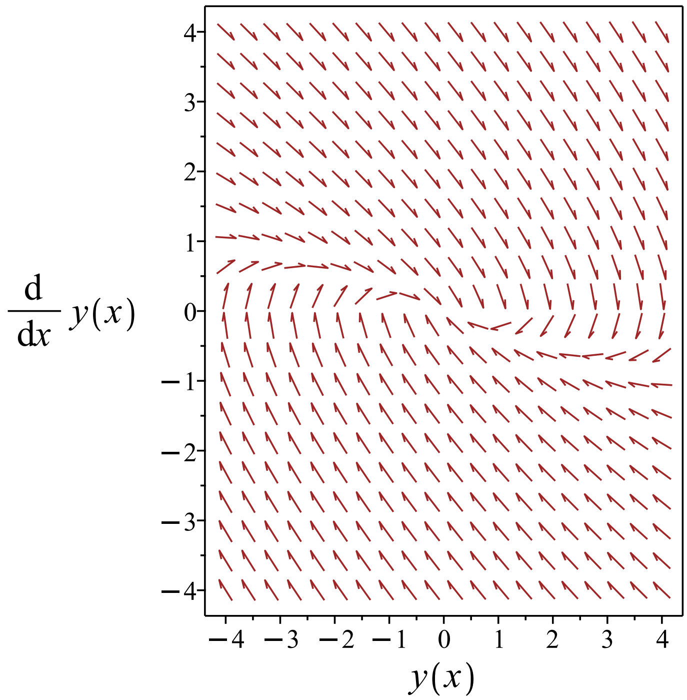

Figure 369: Slope field plot

Verification of solutions

$$y = c_1 x\, \mathrm{e}^{-\frac{x}{2}} + c_2 \mathrm{e}^{-\frac{x}{2}}$$

Verified OK.

10.8.3 Solving using Kovacic algorithm

Writing the ode as

$$4y'' + 4y' + y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4 \\ B &= 4 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 291: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4}{4}\,dx} \\
&= z_1 e^{-\frac{x}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-\frac{x}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4}{4}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-\frac{x}{2}}\right) + c_2\left(\mathrm{e}^{-\frac{x}{2}}(x)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-\frac{x}{2}} + c_2 x \,\mathrm{e}^{-\frac{x}{2}} \tag{1}
$$

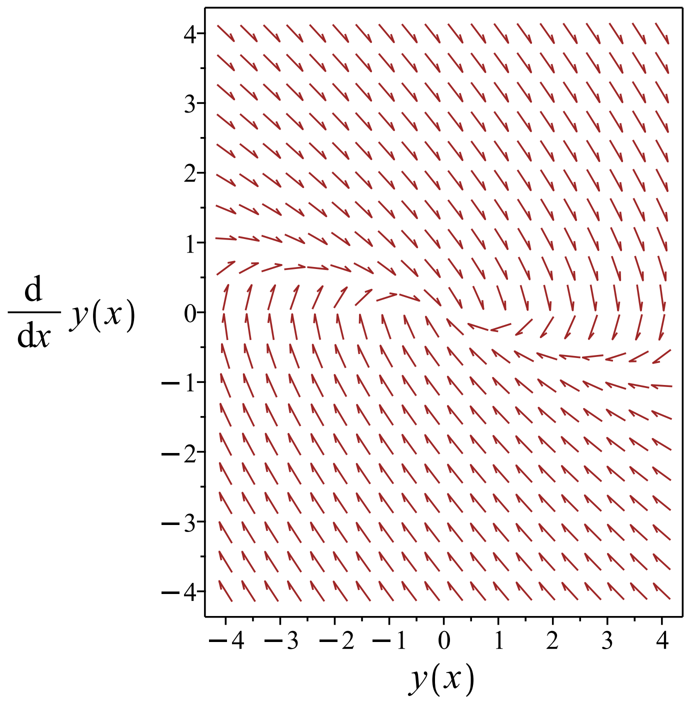

Figure 370: Slope field plot

Verification of solutions

$$
y = c_1 \mathrm{e}^{-\frac{x}{2}} + c_2 x \,\mathrm{e}^{-\frac{x}{2}}
$$

Verified OK.

10.8.4 Maple step by step solution

Let's solve

$4y'' + 4y' + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -y' - \frac{y}{4}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + y' + \frac{y}{4} = 0$

- Characteristic polynomial of ODE

  $r^2 + r + \frac{1}{4} = 0$

- Factor the characteristic polynomial

  $\frac{(2r+1)^2}{4} = 0$

- Root of the characteristic polynomial

  $r = -\frac{1}{2}$

- 1st solution of the ODE

  $y_1(x) = e^{-\frac{x}{2}}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\, e^{-\frac{x}{2}}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{-\frac{x}{2}} + c_2 x\, e^{-\frac{x}{2}}$

Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 9.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 4y' + 13y = 0}$$

10.9.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 13$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 4\lambda\, e^{\lambda x} + 13\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 13 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 13$ into the above gives

$$
\begin{aligned}
\lambda_{1,2} &= \frac{4}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-4^2 - (4)(1)(13)} \\
&= 2 \pm 3i
\end{aligned}
$$

Hence

$$
\begin{aligned}
\lambda_1 &= 2 + 3i \\
\lambda_2 &= 2 - 3i
\end{aligned}
$$

Which simplifies to

$$
\begin{aligned}
\lambda_1 &= 2 + 3i \\
\lambda_2 &= 2 - 3i
\end{aligned}
$$

Since roots are complex conjugate of each others, then let the roots be

$$
\lambda_{1,2} = \alpha \pm i\beta
$$

Where $\alpha = 2$ and $\beta = 3$. Therefore the final solution, when using Euler relation, can be written as

$$
y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))
$$

Which becomes

$$
y = e^{2x}(c_1 \cos(3x) + c_2 \sin(3x))
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = \mathrm{e}^{2x}(c_1 \cos(3x) + c_2 \sin(3x)) \tag{1}
$$

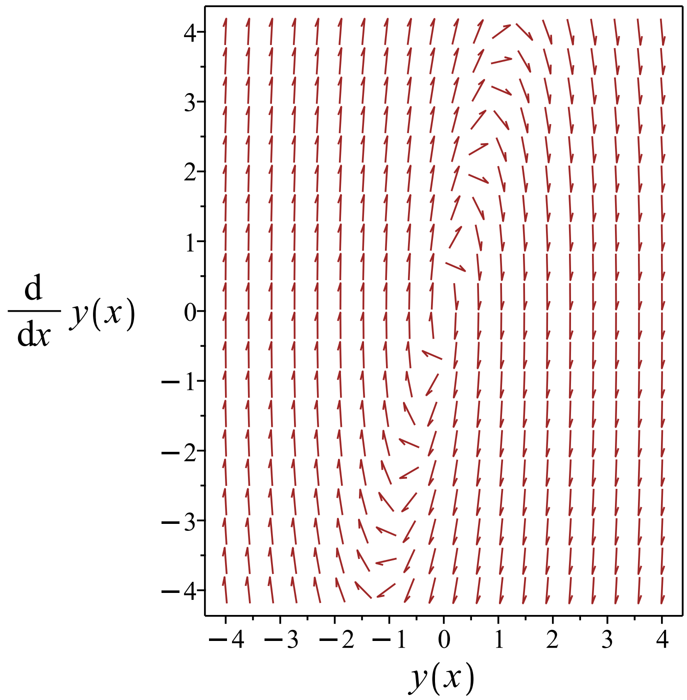

Figure 371: Slope field plot

<u>Verification of solutions</u>

$$y = e^{2x}(c_1 \cos(3x) + c_2 \sin(3x))$$

Verified OK.

10.9.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 13y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 13 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-9}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -9 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -9z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 293: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -9$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(3x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-4}{1} \, dx} \\
&= z_1 e^{2x} \\
&= z_1 \left(\mathrm{e}^{2x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{2x} \cos(3x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{4x}}{(y_1)^2} \, dx \\
&= y_1 \left(\frac{\tan(3x)}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(e^{2x} \cos(3x)\right) + c_2\left(e^{2x} \cos(3x) \left(\frac{\tan(3x)}{3}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^{2x} \cos(3x) + \frac{c_2 e^{2x} \sin(3x)}{3} \tag{1}
$$

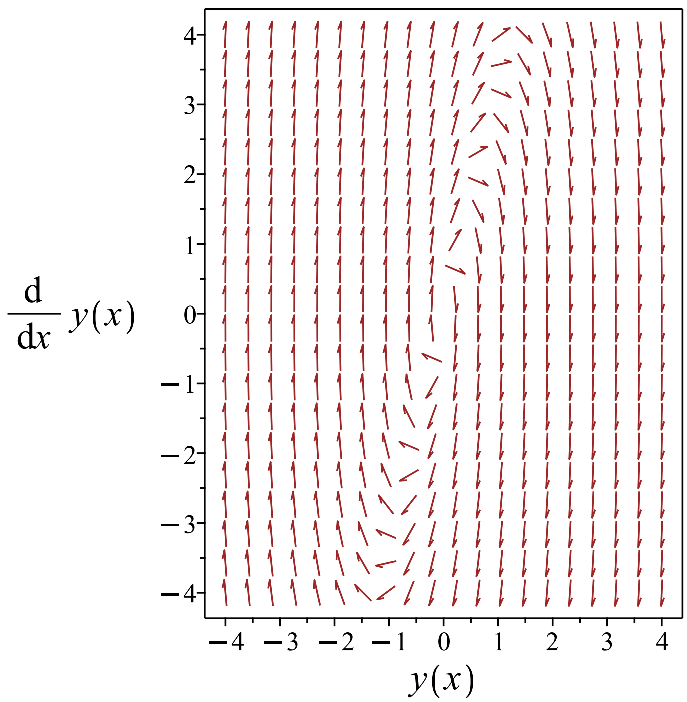

Figure 372: Slope field plot

Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 10.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 6y' + 25y = 0}$$

10.10.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 6, C = 25$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 6\lambda\, e^{\lambda x} + 25\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 6\lambda + 25 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 6, C = 25$ into the above gives

$$\lambda_{1,2} = \frac{-6}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{6^2 - (4)(1)(25)}$$
$$= -3 \pm 4i$$

Hence

$$\lambda_1 = -3 + 4i$$
$$\lambda_2 = -3 - 4i$$

Which simplifies to

$$\lambda_1 = -3 + 4i$$
$$\lambda_2 = -3 - 4i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -3$ and $\beta = 4$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-3x}(c_1 \cos(4x) + c_2 \sin(4x))$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-3x}(c_1 \cos(4x) + c_2 \sin(4x)) \tag{1}$$

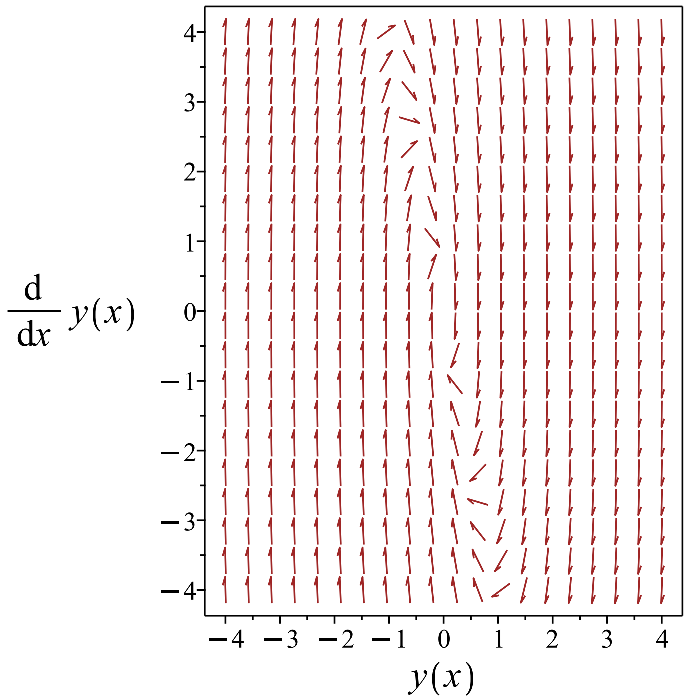

Figure 373: Slope field plot

Verification of solutions

$$y = e^{-3x}(c_1 \cos(4x) + c_2 \sin(4x))$$

Verified OK.

10.10.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 6y' + 25y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 6 \\ C &= 25 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-16}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -16 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -16z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 295: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - 0\\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -16$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(4x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{6}{1}\,dx}\\ &= z_1 e^{-3x}\\ &= z_1\left(\mathrm{e}^{-3x}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x}\cos(4x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{6}{1}\,dx}}{(y_1)^2}\,dx\\ &= y_1 \int \frac{e^{-6x}}{(y_1)^2}\,dx\\ &= y_1\left(\frac{\tan(4x)}{4}\right)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(e^{-3x} \cos(4x)\right) + c_2 \left(e^{-3x} \cos(4x) \left(\frac{\tan(4x)}{4}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^{-3x} \cos(4x) + \frac{c_2 e^{-3x} \sin(4x)}{4} \tag{1}
$$

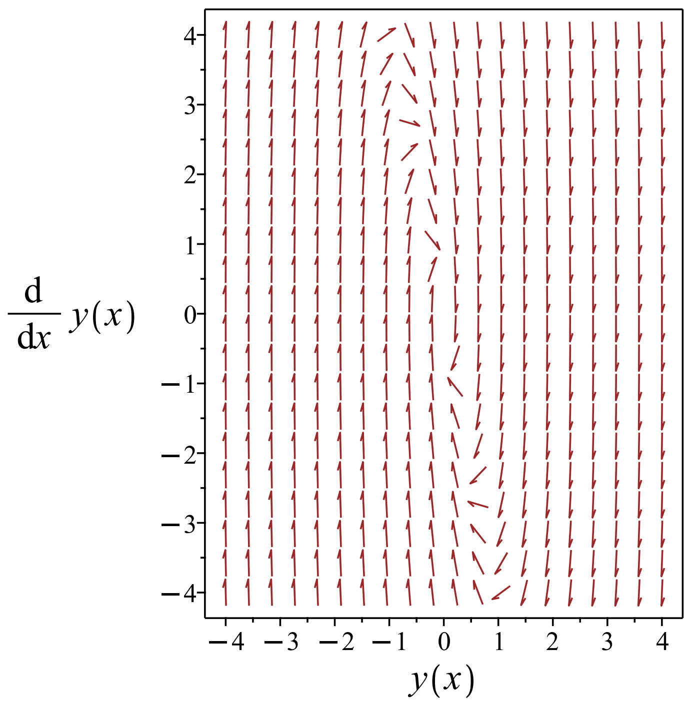

Figure 374: Slope field plot

Verification of solutions

$$
y = c_1 e^{-3x} \cos(4x) + \frac{c_2 e^{-3x} \sin(4x)}{4}
$$

Verified OK.

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 11.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 9y = 0}$$

10.11.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 9\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(9)}\\ &= \pm 3i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +3i\\ \lambda_2 &= -3i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 3i\\ \lambda_2 &= -3i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 3$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(3x) + c_2 \sin(3x))$$

Or

$$y = c_1 \cos(3x) + c_2 \sin(3x)$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(3x) + c_2 \sin(3x) \tag{1}$$

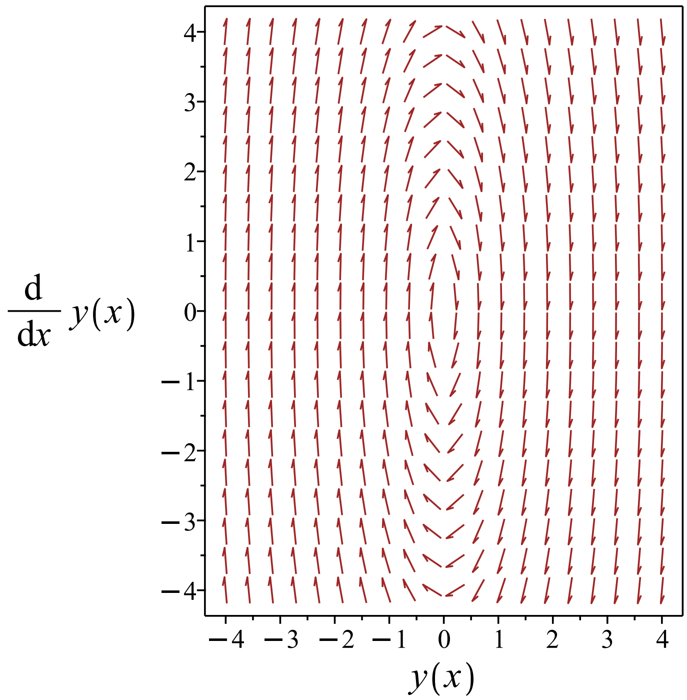

Figure 375: Slope field plot

<u>Verification of solutions</u>

$$y = c_1 \cos(3x) + c_2 \sin(3x)$$

Verified OK.

10.11.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + 9yy' = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' + 9yy')\, dx = 0$$

$$\frac{y'^2}{2} + \frac{9y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-9y^2 + 2c_1} \tag{1}$$

$$y' = -\sqrt{-9y^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-9y^2 + 2c_1}} dy = \int dx$$
$$\frac{\arctan\left(\frac{3y}{\sqrt{-9y^2+2c_1}}\right)}{3} = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-9y^2 + 2c_1}} dy = \int dx$$
$$-\frac{\arctan\left(\frac{3y}{\sqrt{-9y^2+2c_1}}\right)}{3} = c_3 + x$$

Summary

The solution(s) found are the following

$$\frac{\arctan\left(\frac{3y}{\sqrt{-9y^2+2c_1}}\right)}{3} = x + c_2 \tag{1}$$
$$-\frac{\arctan\left(\frac{3y}{\sqrt{-9y^2+2c_1}}\right)}{3} = c_3 + x \tag{2}$$

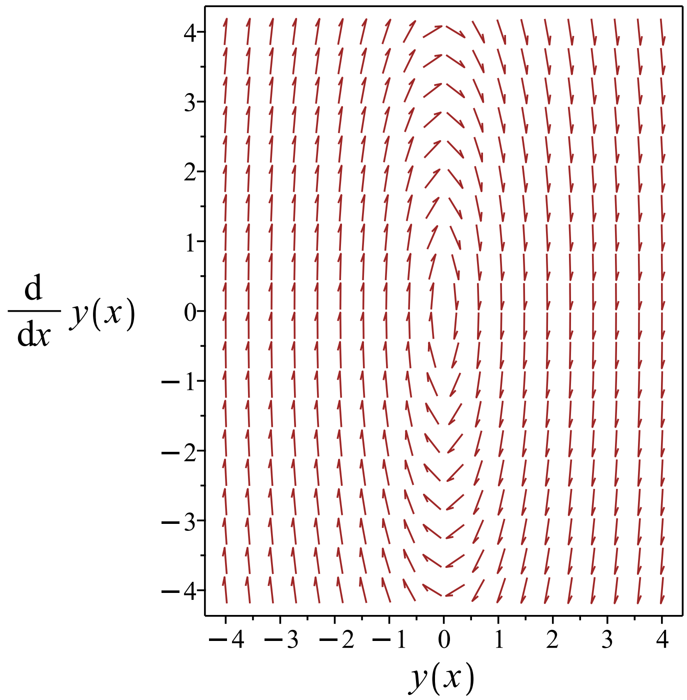

Figure 376: Slope field plot

Verification of solutions

$$\frac{\arctan\left(\frac{3y}{\sqrt{-9y^2+2c_1}}\right)}{3} = x + c_2$$

Verified OK.

$$-\frac{\arctan\left(\frac{3y}{\sqrt{-9y^2+2c_1}}\right)}{3} = c_3 + x$$

Verified OK.

10.11.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-9}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -9 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -9z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 297: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -9$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(3x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(3x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(3x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(3x) \int \frac{1}{\cos(3x)^2}\,dx \\ &= \cos(3x)\left(\frac{\tan(3x)}{3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(3x)) + c_2\left(\cos(3x)\left(\frac{\tan(3x)}{3}\right)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3} \tag{1}$$

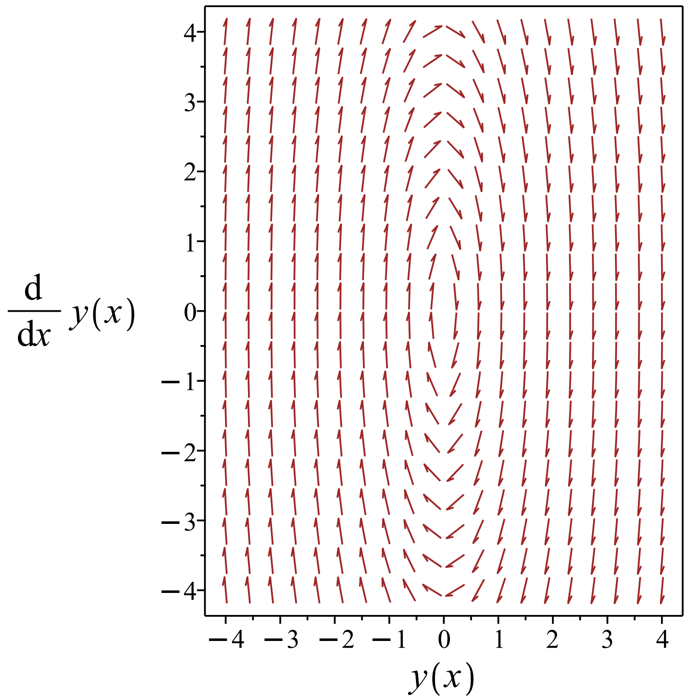

Figure 377: Slope field plot

Verification of solutions

$$y = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3}$$

Verified OK.

10.11.4 Maple step by step solution

Let's solve

$y'' + 9y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 + 9 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-36})}{2}$

- Roots of the characteristic polynomial

$$r = (-3\,\mathrm{I}, 3\,\mathrm{I})$$

- 1st solution of the ODE

$$y_1(x) = \cos(3x)$$

- 2nd solution of the ODE

$$y_2(x) = \sin(3x)$$

- General solution of the ODE

$$y = c_1 y_1(x) + c_2 y_2(x)$$

- Substitute in solutions

$$y = c_1 \cos(3x) + c_2 \sin(3x)$$

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{4y'' + y = 0}$$

10.12.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 4, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$4\lambda^2 \mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$4\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 4, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(4)} \pm \frac{1}{(2)(4)}\sqrt{0^2 - (4)(4)(1)} \\ &= \pm\frac{i}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\frac{i}{2} \\ \lambda_2 &= -\frac{i}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \frac{i}{2} \\ \lambda_2 &= -\frac{i}{2}\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = \frac{1}{2}$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0\left(c_1 \cos\left(\frac{x}{2}\right) + c_2 \sin\left(\frac{x}{2}\right)\right)$$

Or

$$y = c_1 \cos\left(\frac{x}{2}\right) + c_2 \sin\left(\frac{x}{2}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \cos\left(\frac{x}{2}\right) + c_2 \sin\left(\frac{x}{2}\right) \tag{1}$$

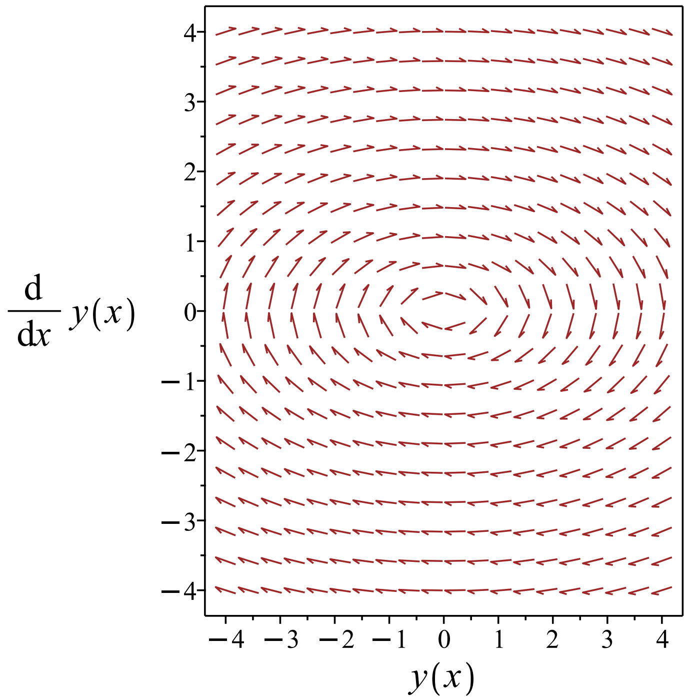

Figure 378: Slope field plot

<u>Verification of solutions</u>

$$y = c_1 \cos\left(\frac{x}{2}\right) + c_2 \sin\left(\frac{x}{2}\right)$$

Verified OK.

10.12.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$4y'y'' + yy' = 0$$

Integrating the above w.r.t x gives

$$\int (4y'y'' + yy')\, dx = 0$$
$$\frac{y^2}{2} + 2y'^2 = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{\sqrt{-y^2+2c_1}}{2} \tag{1}$$
$$y' = -\frac{\sqrt{-y^2+2c_1}}{2} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{2}{\sqrt{-y^2+2c_1}} dy = \int dx$$
$$2\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{2}{\sqrt{-y^2+2c_1}} dy = \int dx$$
$$-2\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = c_3 + x$$

Summary

The solution(s) found are the following

$$2\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = x + c_2 \tag{1}$$
$$-2\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = c_3 + x \tag{2}$$

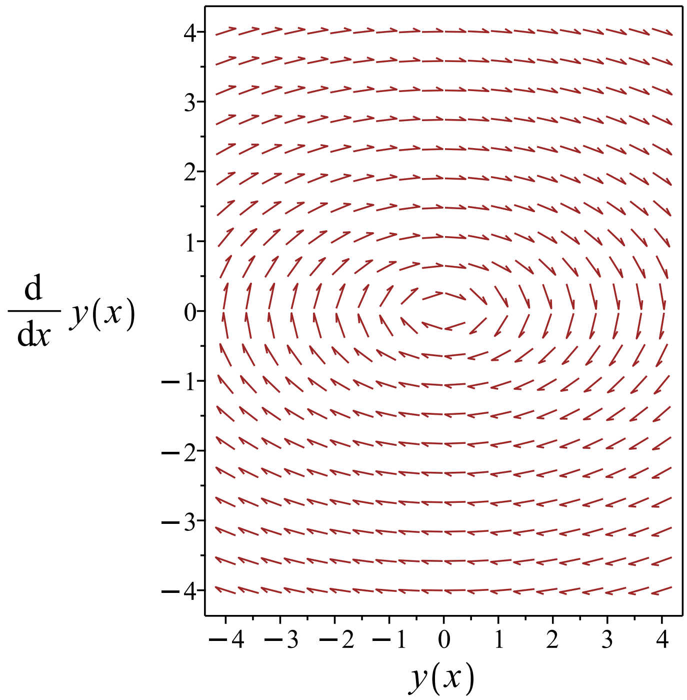

Figure 379: Slope field plot

Verification of solutions

$$2\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right)=x+c_2$$

Verified OK.

$$-2\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right)=c_3+x$$

Verified OK.

10.12.3 Solving using Kovacic algorithm

Writing the ode as

$$4y''+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -\frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 299: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -\frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos\left(\frac{x}{2}\right)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos\left(\frac{x}{2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \cos\left(\frac{x}{2}\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \cos\left(\frac{x}{2}\right) \int \frac{1}{\cos\left(\frac{x}{2}\right)^2}\, dx \\ &= \cos\left(\frac{x}{2}\right) \left(2\tan\left(\frac{x}{2}\right)\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\cos\left(\frac{x}{2}\right)\right) + c_2\left(\cos\left(\frac{x}{2}\right)\left(2\tan\left(\frac{x}{2}\right)\right)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos\left(\frac{x}{2}\right) + 2c_2 \sin\left(\frac{x}{2}\right) \tag{1}$$

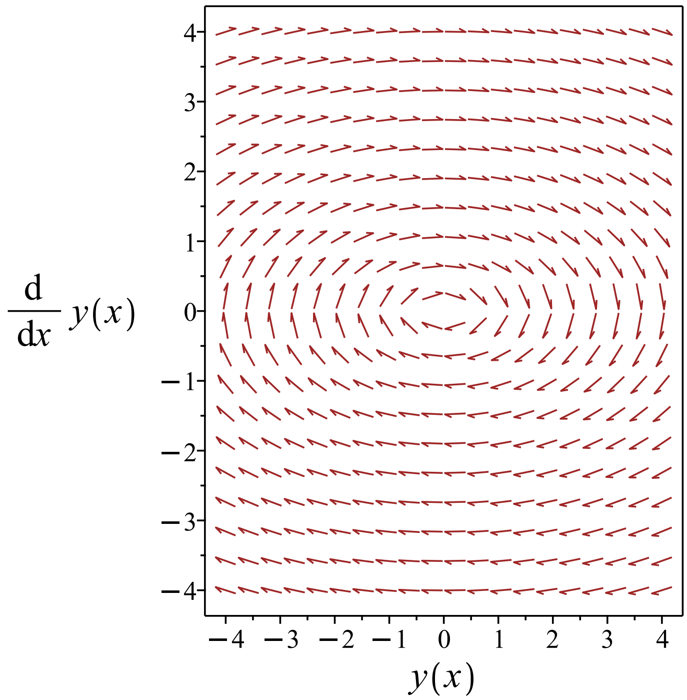

Figure 380: Slope field plot

Verification of solutions

$$y = c_1 \cos\left(\frac{x}{2}\right) + 2c_2 \sin\left(\frac{x}{2}\right)$$

Verified OK.

10.12.4 Maple step by step solution

Let's solve

$4y'' + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y}{4}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y}{4} = 0$

- Characteristic polynomial of ODE

$r^2 + \frac{1}{4} = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-1})}{2}$
- Roots of the characteristic polynomial

  $r = \left(-\frac{I}{2}, \frac{I}{2}\right)$
- 1st solution of the ODE

  $y_1(x) = \cos\left(\frac{x}{2}\right)$
- 2nd solution of the ODE

  $y_2(x) = \sin\left(\frac{x}{2}\right)$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$
- Substitute in solutions

  $y = c_1 \cos\left(\frac{x}{2}\right) + c_2 \sin\left(\frac{x}{2}\right)$

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' - 5y'' + 7y' - 3y = 0}$$

The characteristic equation is

$$\lambda^3 - 5\lambda^2 + 7\lambda - 3 = 0$$

The roots of the above equation are

$$\lambda_1 = 3$$
$$\lambda_2 = 1$$
$$\lambda_3 = 1$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + c_2 x\, e^x + c_3 e^{3x}$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^x$$
$$y_2 = x\, e^x$$
$$y_3 = e^{3x}$$

Summary
The solution(s) found are the following

$$y = e^{x} c_1 + c_2 x\, e^{x} + c_3 e^{3x} \tag{1}$$

Verification of solutions

$$y = e^{x} c_1 + c_2 x\, e^{x} + c_3 e^{3x}$$

Verified OK.

10.13.1 Maple step by step solution

Let's solve

$y''' - 5y'' + 7y' - 3y = 0$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = 5y_3(x) - 7y_2(x) + 3y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 5y_3(x) - 7y_2(x) + 3y_1(x)]$

- Define vector

  $\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$

- System to solve

$$\overrightarrow{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 3 & -7 & 5 \end{bmatrix} \cdot \overrightarrow{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 3 & -7 & 5 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{y}'(x) = A \cdot \overrightarrow{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[3, \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- First solution from eigenvalue 1

$$\overrightarrow{y}_1(x) = \mathrm{e}^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\overrightarrow{p}$ is to be solved for, $\lambda = 1$ is the eigenvalue, an

$$\overrightarrow{y}_2(x) = \mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Note that the x multiplying $\overrightarrow{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\overrightarrow{y}_2(x)$ into the homogeneous system

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda x}\overrightarrow{v} = \left(\mathrm{e}^{\lambda x} A\right) \cdot \left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Use the fact that $\overrightarrow{v}$ is an eigenvector of A

  $$\lambda \mathrm{e}^{\lambda x}\left(x\overrightarrow{v}+\overrightarrow{p}\right)+\mathrm{e}^{\lambda x}\overrightarrow{v}=\mathrm{e}^{\lambda x}\left(\lambda x\overrightarrow{v}+A\cdot\overrightarrow{p}\right)$$

- Simplify equation

  $$\lambda\overrightarrow{p}+\overrightarrow{v}=A\cdot\overrightarrow{p}$$

- Make use of the identity matrix I

  $$(\lambda\cdot I)\cdot\overrightarrow{p}+\overrightarrow{v}=A\cdot\overrightarrow{p}$$

- Condition $\overrightarrow{p}$ must meet for $\overrightarrow{y}_2(x)$ to be a solution to the homogeneous system

  $$(A-\lambda\cdot I)\cdot\overrightarrow{p}=\overrightarrow{v}$$

- Choose $\overrightarrow{p}$ to use in the second solution to the homogeneous system from eigenvalue 1

  $$\left(\begin{bmatrix}0 & 1 & 0\\ 0 & 0 & 1\\ 3 & -7 & 5\end{bmatrix}-1\cdot\begin{bmatrix}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{bmatrix}\right)\cdot\overrightarrow{p}=\begin{bmatrix}1\\ 1\\ 1\end{bmatrix}$$

- Choice of $\overrightarrow{p}$

  $$\overrightarrow{p}=\begin{bmatrix}-1\\ 0\\ 0\end{bmatrix}$$

- Second solution from eigenvalue 1

  $$\overrightarrow{y}_2(x)=\mathrm{e}^{x}\cdot\left(x\cdot\begin{bmatrix}1\\ 1\\ 1\end{bmatrix}+\begin{bmatrix}-1\\ 0\\ 0\end{bmatrix}\right)$$

- Consider eigenpair

  $$\left[3,\begin{bmatrix}\frac{1}{9}\\ \frac{1}{3}\\ 1\end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

  $$\overrightarrow{y}_3=\mathrm{e}^{3x}\cdot\begin{bmatrix}\frac{1}{9}\\ \frac{1}{3}\\ 1\end{bmatrix}$$

- General solution to the system of ODEs

  $\overrightarrow{y} = c_1 \overrightarrow{y}_1(x) + c_2 \overrightarrow{y}_2(x) + c_3 \overrightarrow{y}_3$
- Substitute solutions into the general solution

  $$\overrightarrow{y} = e^x c_1 \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + c_2 e^x \cdot \left(x \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \end{bmatrix} \right) + c_3 e^{3x} \cdot \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}$$
- First component of the vector is the solution to the ODE

  $y = \frac{c_3 e^{3x}}{9} + e^x (c_2(x-1) + c_1)$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 14.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_3rd_order, _missing_x]]`

$$\boxed{4y''' + 4y'' - 7y' + 2y = 0}$$

The characteristic equation is

$$4\lambda^3 + 4\lambda^2 - 7\lambda + 2 = 0$$

The roots of the above equation are

$$\lambda_1 = -2$$
$$\lambda_2 = \frac{1}{2}$$
$$\lambda_3 = \frac{1}{2}$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-2x} + e^{\frac{x}{2}} c_2 + x\, e^{\frac{x}{2}} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-2x}$$
$$y_2 = e^{\frac{x}{2}}$$
$$y_3 = e^{\frac{x}{2}} x$$

Summary
The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-2x} + \mathrm{e}^{\frac{x}{2}} c_2 + x \,\mathrm{e}^{\frac{x}{2}} c_3 \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-2x} + \mathrm{e}^{\frac{x}{2}} c_2 + x \,\mathrm{e}^{\frac{x}{2}} c_3$$

Verified OK.

10.14.1 Maple step by step solution

Let's solve

$4y''' + 4y'' - 7y' + 2y = 0$

- Highest derivative means the order of the ODE is 3

  y'''

- Isolate 3rd derivative

  $y''' = -y'' + \frac{7y'}{4} - \frac{y}{2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''' + y'' - \frac{7y'}{4} + \frac{y}{2} = 0$

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

  ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$

  ◦ Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = -y_3(x) + \frac{7y_2(x)}{4} - \frac{y_1(x)}{2}$

  Convert linear ODE into a system of first order ODEs

  $\left[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = -y_3(x) + \frac{7y_2(x)}{4} - \frac{y_1(x)}{2}\right]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -\frac{1}{2} & \frac{7}{4} & -1 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -\frac{1}{2} & \frac{7}{4} & -1 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2, \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}\right], \left[\frac{1}{2}, \begin{bmatrix} 4 \\ 2 \\ 1 \end{bmatrix}\right], \left[\frac{1}{2}, \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-2, \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = e^{-2x} \cdot \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[\frac{1}{2}, \begin{bmatrix} 4 \\ 2 \\ 1 \end{bmatrix}\right]$$

- First solution from eigenvalue $\frac{1}{2}$

$$\vec{y}_2(x) = \mathrm{e}^{\frac{x}{2}} \cdot \begin{bmatrix} 4 \\ 2 \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\vec{p}$ is to be solved for, $\lambda = \frac{1}{2}$ is the eigenvalue, an

$$\vec{y}_3(x) = \mathrm{e}^{\lambda x}\left(x\vec{v} + \vec{p}\right)$$

- Note that the x multiplying $\vec{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\vec{y}_3(x)$ into the homogeneous system

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\vec{v} + \vec{p}\right) + \mathrm{e}^{\lambda x}\vec{v} = \left(\mathrm{e}^{\lambda x}A\right) \cdot \left(x\vec{v} + \vec{p}\right)$$

- Use the fact that $\vec{v}$ is an eigenvector of A

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\vec{v} + \vec{p}\right) + \mathrm{e}^{\lambda x}\vec{v} = \mathrm{e}^{\lambda x}\left(\lambda x\vec{v} + A \cdot \vec{p}\right)$$

- Simplify equation

$$\lambda\vec{p} + \vec{v} = A \cdot \vec{p}$$

- Make use of the identity matrix I

$$(\lambda \cdot I) \cdot \vec{p} + \vec{v} = A \cdot \vec{p}$$

- Condition $\vec{p}$ must meet for $\vec{y}_3(x)$ to be a solution to the homogeneous system

$$(A - \lambda \cdot I) \cdot \vec{p} = \vec{v}$$

- Choose $\vec{p}$ to use in the second solution to the homogeneous system from eigenvalue $\frac{1}{2}$

$$\left(\begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -\frac{1}{2} & \frac{7}{4} & -1 \end{bmatrix} - \frac{1}{2} \cdot \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) \cdot \vec{p} = \begin{bmatrix} 4 \\ 2 \\ 1 \end{bmatrix}$$

- Choice of $\vec{p}$

$$\vec{p} = \begin{bmatrix} -8 \\ 0 \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue $\frac{1}{2}$

$$\vec{y}_3(x) = e^{\frac{x}{2}} \cdot \left(x \cdot \begin{bmatrix} 4 \\ 2 \\ 1 \end{bmatrix} + \begin{bmatrix} -8 \\ 0 \\ 0 \end{bmatrix}\right)$$

- General solution to the system of ODEs

$$\vec{y} = c_1 \vec{y}_1 + c_2 \vec{y}_2(x) + c_3 \vec{y}_3(x)$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 e^{-2x} \cdot \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix} + e^{\frac{x}{2}} c_2 \cdot \begin{bmatrix} 4 \\ 2 \\ 1 \end{bmatrix} + c_3 e^{\frac{x}{2}} \cdot \left(x \cdot \begin{bmatrix} 4 \\ 2 \\ 1 \end{bmatrix} + \begin{bmatrix} -8 \\ 0 \\ 0 \end{bmatrix}\right)$$

- First component of the vector is the solution to the ODE

$$y = 4\,e^{-2x}\left(\left((x-2)\,c_3 + c_2\right) e^{\frac{5x}{2}} + \frac{c_1}{16}\right)$$

Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 16.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' + 4y'' + 5y' + 6y = 0}$$

The characteristic equation is

$$\lambda^3 + 4\lambda^2 + 5\lambda + 6 = 0$$

The roots of the above equation are

$$\lambda_1 = -3$$
$$\lambda_2 = -\frac{1}{2} - \frac{i\sqrt{7}}{2}$$
$$\lambda_3 = -\frac{1}{2} + \frac{i\sqrt{7}}{2}$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 \mathrm{e}^{-3x} + \mathrm{e}^{\left(-\frac{1}{2}-\frac{i\sqrt{7}}{2}\right)x} c_2 + \mathrm{e}^{\left(-\frac{1}{2}+\frac{i\sqrt{7}}{2}\right)x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-3x}$$
$$y_2 = e^{\left(-\frac{1}{2}-\frac{i\sqrt{7}}{2}\right)x}$$
$$y_3 = e^{\left(-\frac{1}{2}+\frac{i\sqrt{7}}{2}\right)x}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-3x} + e^{\left(-\frac{1}{2}-\frac{i\sqrt{7}}{2}\right)x} c_2 + e^{\left(-\frac{1}{2}+\frac{i\sqrt{7}}{2}\right)x} c_3 \tag{1}$$

Verification of solutions

$$y = c_1 e^{-3x} + e^{\left(-\frac{1}{2}-\frac{i\sqrt{7}}{2}\right)x} c_2 + e^{\left(-\frac{1}{2}+\frac{i\sqrt{7}}{2}\right)x} c_3$$

Verified OK.

10.16.1 Maple step by step solution

Let's solve

$y''' + 4y'' + 5y' + 6y = 0$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

  ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$

  ◦ Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = -4y_3(x) - 5y_2(x) - 6y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = -4y_3(x) - 5y_2(x) - 6y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -6 & -5 & -4 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -6 & -5 & -4 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-3, \begin{bmatrix} \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{bmatrix}\right], \left[-\frac{1}{2} - \frac{\mathrm{I}\sqrt{7}}{2}, \begin{bmatrix} \frac{1}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{7}}{2}\right)^2} \\ \frac{1}{-\frac{1}{2}-\frac{\mathrm{I}\sqrt{7}}{2}} \\ 1 \end{bmatrix}\right], \left[-\frac{1}{2} + \frac{\mathrm{I}\sqrt{7}}{2}, \begin{bmatrix} \frac{1}{\left(-\frac{1}{2}+\frac{\mathrm{I}\sqrt{7}}{2}\right)^2} \\ \frac{1}{-\frac{1}{2}+\frac{\mathrm{I}\sqrt{7}}{2}} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-3, \begin{bmatrix} \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{-3x} \cdot \begin{bmatrix} \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\frac{1}{2}-\frac{I\sqrt{7}}{2}, \left[\begin{array}{c}\frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{7}}{2}\right)^{2}} \\ \frac{1}{-\frac{1}{2}-\frac{I\sqrt{7}}{2}} \\ 1\end{array}\right]\right]$$

- Solution from eigenpair

$$e^{\left(-\frac{1}{2}-\frac{I\sqrt{7}}{2}\right)x}\cdot\left[\begin{array}{c}\frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{7}}{2}\right)^{2}} \\ \frac{1}{-\frac{1}{2}-\frac{I\sqrt{7}}{2}} \\ 1\end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$e^{-\frac{x}{2}}\cdot\left(\cos\left(\frac{\sqrt{7}\,x}{2}\right)-I\sin\left(\frac{\sqrt{7}\,x}{2}\right)\right)\cdot\left[\begin{array}{c}\frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{7}}{2}\right)^{2}} \\ \frac{1}{-\frac{1}{2}-\frac{I\sqrt{7}}{2}} \\ 1\end{array}\right]$$

- Simplify expression

$$e^{-\frac{x}{2}}\cdot\left[\begin{array}{c}\frac{\cos\left(\frac{\sqrt{7}\,x}{2}\right)-I\sin\left(\frac{\sqrt{7}\,x}{2}\right)}{\left(-\frac{1}{2}-\frac{I\sqrt{7}}{2}\right)^{2}} \\ \frac{\cos\left(\frac{\sqrt{7}\,x}{2}\right)-I\sin\left(\frac{\sqrt{7}\,x}{2}\right)}{-\frac{1}{2}-\frac{I\sqrt{7}}{2}} \\ \cos\left(\frac{\sqrt{7}\,x}{2}\right)-I\sin\left(\frac{\sqrt{7}\,x}{2}\right)\end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_{2}(x)=e^{-\frac{x}{2}}\cdot\left[\begin{array}{c}-\frac{3\cos\left(\frac{\sqrt{7}\,x}{2}\right)}{8}-\frac{\sin\left(\frac{\sqrt{7}\,x}{2}\right)\sqrt{7}}{8} \\ -\frac{\cos\left(\frac{\sqrt{7}\,x}{2}\right)}{4}+\frac{\sin\left(\frac{\sqrt{7}\,x}{2}\right)\sqrt{7}}{4} \\ \cos\left(\frac{\sqrt{7}\,x}{2}\right)\end{array}\right], \vec{y}_{3}(x)=e^{-\frac{x}{2}}\cdot\left[\begin{array}{c}-\frac{\cos\left(\frac{\sqrt{7}\,x}{2}\right)\sqrt{7}}{8}+\frac{3\sin\left(\frac{\sqrt{7}\,x}{2}\right)}{8} \\ \frac{\cos\left(\frac{\sqrt{7}\,x}{2}\right)\sqrt{7}}{4}+\frac{\sin\left(\frac{\sqrt{7}\,x}{2}\right)}{4} \\ -\sin\left(\frac{\sqrt{7}\,x}{2}\right)\end{array}\right]\right]$$

- General solution to the system of ODEs

$$\vec{y}=c_{1}\vec{y}_{1}+c_{2}\vec{y}_{2}(x)+c_{3}\vec{y}_{3}(x)$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 \mathrm{e}^{-3x} \cdot \begin{bmatrix} \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{bmatrix} + c_2 \mathrm{e}^{-\frac{x}{2}} \cdot \begin{bmatrix} -\frac{3\cos\left(\frac{\sqrt{7}\,x}{2}\right)}{8} - \frac{\sin\left(\frac{\sqrt{7}\,x}{2}\right)\sqrt{7}}{8} \\ -\frac{\cos\left(\frac{\sqrt{7}\,x}{2}\right)}{4} + \frac{\sin\left(\frac{\sqrt{7}\,x}{2}\right)\sqrt{7}}{4} \\ \cos\left(\frac{\sqrt{7}\,x}{2}\right) \end{bmatrix} + c_3 \mathrm{e}^{-\frac{x}{2}} \cdot \begin{bmatrix} -\frac{\cos\left(\frac{\sqrt{7}\,x}{2}\right)\sqrt{7}}{8} + \frac{3\sin\left(\frac{\sqrt{7}\,x}{2}\right)}{8} \\ \frac{\cos\left(\frac{\sqrt{7}\,x}{2}\right)\sqrt{7}}{4} + \frac{\sin\left(\frac{\sqrt{7}\,x}{2}\right)}{4} \\ -\sin\left(\frac{\sqrt{7}\,x}{2}\right) \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = -\frac{3\left(\frac{c_3\sqrt{7}}{3}+c_2\right)\mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{\sqrt{7}\,x}{2}\right)}{8} - \frac{\mathrm{e}^{-\frac{x}{2}}\left(c_2\sqrt{7}-3c_3\right)\sin\left(\frac{\sqrt{7}\,x}{2}\right)}{8} + \frac{c_1\mathrm{e}^{-3x}}{9}$$

Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 17.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' - y'' + y' - y = 0}$$

The characteristic equation is

$$\lambda^3 - \lambda^2 + \lambda - 1 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = i$$
$$\lambda_3 = -i$$

Therefore the homogeneous solution is

$$y_h(x) = \mathrm{e}^{x} c_1 + \mathrm{e}^{ix} c_2 + \mathrm{e}^{-ix} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = \mathrm{e}^{x}$$
$$y_2 = \mathrm{e}^{ix}$$
$$y_3 = \mathrm{e}^{-ix}$$

Summary
The solution(s) found are the following

$$y = e^{x} c_1 + e^{ix} c_2 + e^{-ix} c_3 \tag{1}$$

Verification of solutions

$$y = e^{x} c_1 + e^{ix} c_2 + e^{-ix} c_3$$

Verified OK.

10.17.1 Maple step by step solution

Let's solve

$y''' - y'' + y' - y = 0$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(x)$

    $y_1(x) = y$

  - Define new variable $y_2(x)$

    $y_2(x) = y'$

  - Define new variable $y_3(x)$

    $y_3(x) = y''$

  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = y_3(x) - y_2(x) + y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = y_3(x) - y_2(x) + y_1(x)]$

- Define vector

  $\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & -1 & 1 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & -1 & 1 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} -1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-Ix} \cdot \begin{bmatrix} -1 \\ I \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$(\cos(x) - I\sin(x)) \cdot \begin{bmatrix} -1 \\ I \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\cos(x) + I\sin(x) \\ I(\cos(x) - I\sin(x)) \\ \cos(x) - I\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_3(x) = \begin{bmatrix} \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$\vec{y} = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x)$

- Substitute solutions into the general solution

$$\vec{y} = e^x c_1 \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} -c_2\cos(x) + c_3\sin(x) \\ c_2\sin(x) + c_3\cos(x) \\ c_2\cos(x) - c_3\sin(x) \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$y = e^x c_1 + c_3\sin(x) - c_2\cos(x)$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 18.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_x]]
```

$$\boxed{y'''' + 8y'' + 16y = 0}$$

The characteristic equation is

$$\lambda^4 + 8\lambda^2 + 16 = 0$$

The roots of the above equation are

$$\lambda_1 = 2i$$
$$\lambda_2 = -2i$$
$$\lambda_3 = 2i$$
$$\lambda_4 = -2i$$

Therefore the homogeneous solution is

$$y_h(x) = \mathrm{e}^{2ix} c_1 + x\,\mathrm{e}^{2ix} c_2 + \mathrm{e}^{-2ix} c_3 + x\,\mathrm{e}^{-2ix} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = \mathrm{e}^{2ix}$$
$$y_2 = x\,\mathrm{e}^{2ix}$$
$$y_3 = \mathrm{e}^{-2ix}$$
$$y_4 = x\,\mathrm{e}^{-2ix}$$

Summary
The solution(s) found are the following

$$y = e^{2ix} c_1 + x\, e^{2ix} c_2 + e^{-2ix} c_3 + x\, e^{-2ix} c_4 \tag{1}$$

Verification of solutions

$$y = e^{2ix} c_1 + x\, e^{2ix} c_2 + e^{-2ix} c_3 + x\, e^{-2ix} c_4$$

Verified OK.

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 19.
ODE order: 5.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_x]]
```

$$\boxed{y^{(5)} - 2y'''' + y''' = 0}$$

The characteristic equation is

$$\lambda^5 - 2\lambda^4 + \lambda^3 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$
$$\lambda_4 = 1$$
$$\lambda_5 = 1$$

Therefore the homogeneous solution is

$$y_h(x) = c_3x^2 + c_2x + c_1 + \mathrm{e}^x c_4 + x\,\mathrm{e}^x c_5$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= 1 \\
y_2 &= x \\
y_3 &= x^2 \\
y_4 &= e^x \\
y_5 &= x\,e^x
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_3x^2 + c_2x + c_1 + e^x c_4 + x\,e^x c_5 \tag{1}$$

Verification of solutions

$$y = c_3x^2 + c_2x + c_1 + e^x c_4 + x\,e^x c_5$$

Verified OK.

10.19.1 Maple step by step solution

Let's solve

$y^{(5)} - 2y'''' + y''' = 0$

- Highest derivative means the order of the ODE is 5

  $y^{(5)}$

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

  ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$

  ◦ Define new variable $y_4(x)$

    $y_4(x) = y'''$

  ◦ Define new variable $y_5(x)$

    $y_5(x) = y''''$

- Isolate for $y_5'(x)$ using original ODE

  $y_5'(x) = 2y_5(x) - y_4(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_5(x) = y_4'(x), y_5'(x) = 2y_5(x) - y_4(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \\ y_5(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & -1 & 2 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & -1 & 2 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix}1\\0\\0\\0\\0\end{bmatrix}\right], \left[0, \begin{bmatrix}0\\0\\0\\0\\0\end{bmatrix}\right], \left[0, \begin{bmatrix}0\\0\\0\\0\\0\end{bmatrix}\right], \left[1, \begin{bmatrix}1\\1\\1\\1\\1\end{bmatrix}\right], \left[1, \begin{bmatrix}0\\0\\0\\0\\0\end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix}1\\0\\0\\0\\0\end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \begin{bmatrix}1\\0\\0\\0\\0\end{bmatrix}$$

- Consider eigenpair

$$\left[0, \begin{bmatrix}0\\0\\0\\0\\0\end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 0, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\begin{bmatrix} 1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} \end{bmatrix}$$

- First solution from eigenvalue 1

$$\overrightarrow{y}_4(x) = e^x \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\overrightarrow{p}$ is to be solved for, $\lambda = 1$ is the eigenvalue, an

$$\overrightarrow{y}_5(x) = e^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Note that the x multiplying $\overrightarrow{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\overrightarrow{y}_5(x)$ into the homogeneous system

$$\lambda e^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right) + e^{\lambda x}\overrightarrow{v} = \left(e^{\lambda x}A\right) \cdot \left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Use the fact that $\overrightarrow{v}$ is an eigenvector of A

$$\lambda e^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right) + e^{\lambda x}\overrightarrow{v} = e^{\lambda x}\left(\lambda x\overrightarrow{v} + A \cdot \overrightarrow{p}\right)$$

- Simplify equation

$$\lambda\overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$$

- Make use of the identity matrix I

$$(\lambda \cdot I) \cdot \overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$$

- Condition $\overrightarrow{p}$ must meet for $\overrightarrow{y}_5(x)$ to be a solution to the homogeneous system

$$(A - \lambda \cdot I) \cdot \overrightarrow{p} = \overrightarrow{v}$$

- Choose $\overrightarrow{p}$ to use in the second solution to the homogeneous system from eigenvalue 1

$$\left(\begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & -1 & 2 \end{bmatrix} - 1 \cdot \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}\right) \cdot \overrightarrow{p} = \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$$

- Choice of $\overrightarrow{p}$

$$\vec{p} = \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue 1

$$\vec{y}_5(x) = e^x \cdot \left(x \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \right)$$

- General solution to the system of ODEs

$$\vec{y} = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3 + c_4 \vec{y}_4(x) + c_5 \vec{y}_5(x)$$

- Substitute solutions into the general solution

$$\vec{y} = e^x c_4 \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} + c_5 e^x \cdot \left(x \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \right) + \begin{bmatrix} c_1 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = ((x-1) c_5 + c_4) e^x + c_1$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 21.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_x]]
```

$$\boxed{y'''' - 3y''' - 2y'' + 2y' + 12y = 0}$$

The characteristic equation is

$$\lambda^4 - 3\lambda^3 - 2\lambda^2 + 2\lambda + 12 = 0$$

The roots of the above equation are

$$\begin{aligned}
\lambda_1 &= 2 \\
\lambda_2 &= 3 \\
\lambda_3 &= -1 - i \\
\lambda_4 &= -1 + i
\end{aligned}$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 \mathrm{e}^{2x} + \mathrm{e}^{3x} c_2 + \mathrm{e}^{(-1+i)x} c_3 + \mathrm{e}^{(-1-i)x} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= e^{2x} \\
y_2 &= e^{3x} \\
y_3 &= e^{(-1+i)x} \\
y_4 &= e^{(-1-i)x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1 e^{2x} + e^{3x} c_2 + e^{(-1+i)x} c_3 + e^{(-1-i)x} c_4 \tag{1}$$

Verification of solutions

$$y = c_1 e^{2x} + e^{3x} c_2 + e^{(-1+i)x} c_3 + e^{(-1-i)x} c_4$$

Verified OK.

10.21.1 Maple step by step solution

Let's solve

$y'''' - 3y''' - 2y'' + 2y' + 12y = 0$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Define new variable $y_4(x)$

    $y_4(x) = y'''$
  - Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = 3y_4(x) + 2y_3(x) - 2y_2(x) - 12y_1(x)$

  Convert linear ODE into a system of first order ODEs

$$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = 3y_4(x) + 2y_3(x) - 2y_2(x) - 12y_1(x)]$$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -12 & -2 & 2 & 3 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -12 & -2 & 2 & 3 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[2, \begin{bmatrix} \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} \frac{1}{27} \\ \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right], \left[-1 - \mathrm{I}, \begin{bmatrix} \frac{1}{4} + \frac{\mathrm{I}}{4} \\ -\frac{\mathrm{I}}{2} \\ -\frac{1}{2} + \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right], \left[-1 + \mathrm{I}, \begin{bmatrix} \frac{1}{4} - \frac{\mathrm{I}}{4} \\ \frac{\mathrm{I}}{2} \\ -\frac{1}{2} - \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[2, \left[\begin{array}{c}\frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = e^{2x} \cdot \left[\begin{array}{c}\frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1\end{array}\right]$$

- Consider eigenpair

$$\left[3, \left[\begin{array}{c}\frac{1}{27} \\ \frac{1}{9} \\ \frac{1}{3} \\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{3x} \cdot \left[\begin{array}{c}\frac{1}{27} \\ \frac{1}{9} \\ \frac{1}{3} \\ 1\end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-1 - \mathrm{I}, \left[\begin{array}{c}\frac{1}{4} + \frac{\mathrm{I}}{4} \\ -\frac{\mathrm{I}}{2} \\ -\frac{1}{2} + \frac{\mathrm{I}}{2} \\ 1\end{array}\right]\right]$$

- Solution from eigenpair

$$e^{(-1-I)x} \cdot \begin{bmatrix} \frac{1}{4}+\frac{I}{4} \\ -\frac{I}{2} \\ -\frac{1}{2}+\frac{I}{2} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$e^{-x} \cdot (\cos(x) - I\sin(x)) \cdot \begin{bmatrix} \frac{1}{4}+\frac{I}{4} \\ -\frac{I}{2} \\ -\frac{1}{2}+\frac{I}{2} \\ 1 \end{bmatrix}$$

- Simplify expression

$$e^{-x} \cdot \begin{bmatrix} \left(\frac{1}{4}+\frac{I}{4}\right)(\cos(x) - I\sin(x)) \\ -\frac{I}{2}(\cos(x) - I\sin(x)) \\ \left(-\frac{1}{2}+\frac{I}{2}\right)(\cos(x) - I\sin(x)) \\ \cos(x) - I\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = e^{-x} \cdot \begin{bmatrix} \frac{\cos(x)}{4}+\frac{\sin(x)}{4} \\ -\frac{\sin(x)}{2} \\ -\frac{\cos(x)}{2}+\frac{\sin(x)}{2} \\ \cos(x) \end{bmatrix}, \vec{y}_4(x) = e^{-x} \cdot \begin{bmatrix} \frac{\cos(x)}{4}-\frac{\sin(x)}{4} \\ -\frac{\cos(x)}{2} \\ \frac{\sin(x)}{2}+\frac{\cos(x)}{2} \\ -\sin(x) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x)$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 e^{2x} \cdot \begin{bmatrix} \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix} + e^{3x} c_2 \cdot \begin{bmatrix} \frac{1}{27} \\ \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix} + c_3 e^{-x} \cdot \begin{bmatrix} \frac{\cos(x)}{4}+\frac{\sin(x)}{4} \\ -\frac{\sin(x)}{2} \\ -\frac{\cos(x)}{2}+\frac{\sin(x)}{2} \\ \cos(x) \end{bmatrix} + c_4 e^{-x} \cdot \begin{bmatrix} \frac{\cos(x)}{4}-\frac{\sin(x)}{4} \\ -\frac{\cos(x)}{2} \\ \frac{\sin(x)}{2}+\frac{\cos(x)}{2} \\ -\sin(x) \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = \frac{((c_3+c_4)\cos(x)+\sin(x)(c_3-c_4))\mathrm{e}^{-x}}{4} + \frac{\mathrm{e}^{3x}c_2}{27} + \frac{c_1\mathrm{e}^{2x}}{8}$$

$$

Verification of solutions

$$
y = c_1\mathrm{e}^{-2x} + x\,\mathrm{e}^{-2x}c_2 + \mathrm{e}^{\left(i\sqrt{2}-1\right)x}c_3 + \mathrm{e}^{\left(-1-i\sqrt{2}\right)x}c_4
$$

Verified OK.

10.22.1 Maple step by step solution

Let's solve

$y'''' + 6y''' + 15y'' + 20y' + 12y = 0$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Define new variable $y_4(x)$

    $y_4(x) = y'''$
  - Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = -6y_4(x) - 15y_3(x) - 20y_2(x) - 12y_1(x)$

Convert linear ODE into a system of first order ODEs

$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = -6y_4(x) - 15y_3(x) - 20y_2(x) - 12y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -12 & -20 & -15 & -6 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -12 & -20 & -15 & -6 \end{bmatrix}$$

- Rewrite the system as

$\vec{y}'(x) = A \cdot \vec{y}(x)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2, \begin{bmatrix} -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}\right], \left[-2, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[-1 - \mathrm{I}\sqrt{2}, \begin{bmatrix} \frac{1}{\left(-1-\mathrm{I}\sqrt{2}\right)^3} \\ \frac{1}{\left(-1-\mathrm{I}\sqrt{2}\right)^2} \\ \frac{1}{-1-\mathrm{I}\sqrt{2}} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}\sqrt{2} - 1, \begin{bmatrix} \frac{1}{\left(\mathrm{I}\sqrt{2}-1\right)^3} \\ \frac{1}{\left(\mathrm{I}\sqrt{2}-1\right)^2} \\ \frac{1}{\mathrm{I}\sqrt{2}-1} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[-2, \left[\begin{array}{c} -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{array}\right]\right]$$

- First solution from eigenvalue -2

$$\overrightarrow{y}_1(x) = \mathrm{e}^{-2x} \cdot \left[\begin{array}{c} -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{array}\right]$$

- Form of the 2nd homogeneous solution where $\overrightarrow{p}$ is to be solved for, $\lambda = -2$ is the eigenvalue, a

$$\overrightarrow{y}_2(x) = \mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Note that the x multiplying $\overrightarrow{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\overrightarrow{y}_2(x)$ into the homogeneous system

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda x}\overrightarrow{v} = \left(\mathrm{e}^{\lambda x} A\right) \cdot \left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Use the fact that $\overrightarrow{v}$ is an eigenvector of A

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda x}\overrightarrow{v} = \mathrm{e}^{\lambda x}\left(\lambda x\overrightarrow{v} + A \cdot \overrightarrow{p}\right)$$

- Simplify equation

$$\lambda\overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$$

- Make use of the identity matrix I

$$(\lambda \cdot I) \cdot \overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$$

- Condition $\overrightarrow{p}$ must meet for $\overrightarrow{y}_2(x)$ to be a solution to the homogeneous system

$$(A - \lambda \cdot I) \cdot \overrightarrow{p} = \overrightarrow{v}$$

- Choose $\overrightarrow{p}$ to use in the second solution to the homogeneous system from eigenvalue -2

$$\left(\left[\begin{array}{cccc} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -12 & -20 & -15 & -6 \end{array}\right] - (-2) \cdot \left[\begin{array}{cccc} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{array}\right]\right) \cdot \overrightarrow{p} = \left[\begin{array}{c} -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{array}\right]$$

- Choice of $\vec{p}$

$$\vec{p} = \begin{bmatrix} -\frac{1}{16} \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue -2

$$\vec{y}_2(x) = e^{-2x} \cdot \left(x \cdot \begin{bmatrix} -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix} + \begin{bmatrix} -\frac{1}{16} \\ 0 \\ 0 \\ 0 \end{bmatrix}\right)$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-1 - I\sqrt{2}, \begin{bmatrix} \frac{1}{\left(-1-I\sqrt{2}\right)^3} \\ \frac{1}{\left(-1-I\sqrt{2}\right)^2} \\ \frac{1}{-1-I\sqrt{2}} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{\left(-1-I\sqrt{2}\right)x} \cdot \begin{bmatrix} \frac{1}{\left(-1-I\sqrt{2}\right)^3} \\ \frac{1}{\left(-1-I\sqrt{2}\right)^2} \\ \frac{1}{-1-I\sqrt{2}} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$e^{-x}\cdot\left(\cos\left(\sqrt{2}\,x\right)-\mathrm{I}\sin\left(\sqrt{2}\,x\right)\right)\cdot\begin{bmatrix}\frac{1}{\left(-1-\mathrm{I}\sqrt{2}\right)^{3}}\\ \frac{1}{\left(-1-\mathrm{I}\sqrt{2}\right)^{2}}\\ \frac{1}{-1-\mathrm{I}\sqrt{2}}\\ 1\end{bmatrix}$$

- Simplify expression

$$e^{-x}\cdot\begin{bmatrix}\frac{\cos\left(\sqrt{2}\,x\right)-\mathrm{I}\sin\left(\sqrt{2}\,x\right)}{\left(-1-\mathrm{I}\sqrt{2}\right)^{3}}\\ \frac{\cos\left(\sqrt{2}\,x\right)-\mathrm{I}\sin\left(\sqrt{2}\,x\right)}{\left(-1-\mathrm{I}\sqrt{2}\right)^{2}}\\ \frac{\cos\left(\sqrt{2}\,x\right)-\mathrm{I}\sin\left(\sqrt{2}\,x\right)}{-1-\mathrm{I}\sqrt{2}}\\ \cos\left(\sqrt{2}\,x\right)-\mathrm{I}\sin\left(\sqrt{2}\,x\right)\end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_{3}(x)=e^{-x}\cdot\begin{bmatrix}\frac{5\cos\left(\sqrt{2}\,x\right)}{27}+\frac{\sin\left(\sqrt{2}\,x\right)\sqrt{2}}{27}\\ -\frac{\cos\left(\sqrt{2}\,x\right)}{9}-\frac{2\sin\left(\sqrt{2}\,x\right)\sqrt{2}}{9}\\ -\frac{\cos\left(\sqrt{2}\,x\right)}{3}+\frac{\sin\left(\sqrt{2}\,x\right)\sqrt{2}}{3}\\ \cos\left(\sqrt{2}\,x\right)\end{bmatrix},\vec{y}_{4}(x)=e^{-x}\cdot\begin{bmatrix}\frac{\cos\left(\sqrt{2}\,x\right)\sqrt{2}}{27}-\frac{5\sin\left(\sqrt{2}\,x\right)}{27}\\ -\frac{2\cos\left(\sqrt{2}\,x\right)\sqrt{2}}{9}+\frac{\sin\left(\sqrt{2}\,x\right)}{9}\\ \frac{\cos\left(\sqrt{2}\,x\right)\sqrt{2}}{3}+\frac{\sin\left(\sqrt{2}\,x\right)}{3}\\ -\sin\left(\sqrt{2}\,x\right)\end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\vec{y}=c_{1}\vec{y}_{1}(x)+c_{2}\vec{y}_{2}(x)+c_{3}\vec{y}_{3}(x)+c_{4}\vec{y}_{4}(x)$$

- Substitute solutions into the general solution

$$\vec{y}=c_{1}e^{-2x}\cdot\begin{bmatrix}-\frac{1}{8}\\ \frac{1}{4}\\ -\frac{1}{2}\\ 1\end{bmatrix}+c_{2}e^{-2x}\cdot\left(x\cdot\begin{bmatrix}-\frac{1}{8}\\ \frac{1}{4}\\ -\frac{1}{2}\\ 1\end{bmatrix}+\begin{bmatrix}-\frac{1}{16}\\ 0\\ 0\\ 0\end{bmatrix}\right)+c_{3}e^{-x}\cdot\begin{bmatrix}\frac{5\cos\left(\sqrt{2}\,x\right)}{27}+\frac{\sin\left(\sqrt{2}\,x\right)\sqrt{2}}{27}\\ -\frac{\cos\left(\sqrt{2}\,x\right)}{9}-\frac{2\sin\left(\sqrt{2}\,x\right)\sqrt{2}}{9}\\ -\frac{\cos\left(\sqrt{2}\,x\right)}{3}+\frac{\sin\left(\sqrt{2}\,x\right)\sqrt{2}}{3}\\ \cos\left(\sqrt{2}\,x\right)\end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = \frac{5\,\mathrm{e}^{-x}\left(\frac{c_4\sqrt{2}}{5}+c_3\right)\cos\left(\sqrt{2}\,x\right)}{27} + \frac{\mathrm{e}^{-x}\left(\sqrt{2}\,c_3-5c_4\right)\sin\left(\sqrt{2}\,x\right)}{27} - \frac{\left(\left(x+\frac{1}{2}\right)c_2+c_1\right)\mathrm{e}^{-2x}}{8}$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 23.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_x]]
```

$$\boxed{y'''' + y = 0}$$

The characteristic equation is

$$\lambda^4 + 1 = 0$$

The roots of the above equation are

$$\begin{aligned}
\lambda_1 &= \frac{\sqrt{2}}{2} + \frac{i\sqrt{2}}{2} \\
\lambda_2 &= -\frac{\sqrt{2}}{2} + \frac{i\sqrt{2}}{2} \\
\lambda_3 &= -\frac{\sqrt{2}}{2} - \frac{i\sqrt{2}}{2} \\
\lambda_4 &= \frac{\sqrt{2}}{2} - \frac{i\sqrt{2}}{2}
\end{aligned}$$

Therefore the homogeneous solution is

$$y_h(x) = \mathrm{e}^{\left(\frac{\sqrt{2}}{2} + \frac{i\sqrt{2}}{2}\right)x} c_1 + \mathrm{e}^{\left(-\frac{\sqrt{2}}{2} - \frac{i\sqrt{2}}{2}\right)x} c_2 + \mathrm{e}^{\left(\frac{\sqrt{2}}{2} - \frac{i\sqrt{2}}{2}\right)x} c_3 + \mathrm{e}^{\left(-\frac{\sqrt{2}}{2} + \frac{i\sqrt{2}}{2}\right)x} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= e^{\left(\frac{\sqrt{2}}{2}+\frac{i\sqrt{2}}{2}\right)x} \\
y_2 &= e^{\left(-\frac{\sqrt{2}}{2}-\frac{i\sqrt{2}}{2}\right)x} \\
y_3 &= e^{\left(\frac{\sqrt{2}}{2}-\frac{i\sqrt{2}}{2}\right)x} \\
y_4 &= e^{\left(-\frac{\sqrt{2}}{2}+\frac{i\sqrt{2}}{2}\right)x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = e^{\left(\frac{\sqrt{2}}{2}+\frac{i\sqrt{2}}{2}\right)x} c_1 + e^{\left(-\frac{\sqrt{2}}{2}-\frac{i\sqrt{2}}{2}\right)x} c_2 + e^{\left(\frac{\sqrt{2}}{2}-\frac{i\sqrt{2}}{2}\right)x} c_3 + e^{\left(-\frac{\sqrt{2}}{2}+\frac{i\sqrt{2}}{2}\right)x} c_4 \tag{1}
$$

Verification of solutions

$$
y = e^{\left(\frac{\sqrt{2}}{2}+\frac{i\sqrt{2}}{2}\right)x} c_1 + e^{\left(-\frac{\sqrt{2}}{2}-\frac{i\sqrt{2}}{2}\right)x} c_2 + e^{\left(\frac{\sqrt{2}}{2}-\frac{i\sqrt{2}}{2}\right)x} c_3 + e^{\left(-\frac{\sqrt{2}}{2}+\frac{i\sqrt{2}}{2}\right)x} c_4
$$

Verified OK.

10.23.1 Maple step by step solution

Let's solve

$y'''' + y = 0$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Define new variable $y_4(x)$

    $y_4(x) = y'''$
  - Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = -y_1(x)$

Convert linear ODE into a system of first order ODEs

$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = -y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 \end{bmatrix}$$

- Rewrite the system as

$\vec{y}'(x) = A \cdot \vec{y}(x)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-\frac{\sqrt{2}}{2} - \frac{I\sqrt{2}}{2}, \begin{bmatrix} \frac{1}{\left(-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}\right)^3} \\ \frac{1}{\left(-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}\right)^2} \\ \frac{1}{-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}} \\ 1 \end{bmatrix}\right], \left[-\frac{\sqrt{2}}{2} + \frac{I\sqrt{2}}{2}, \begin{bmatrix} \frac{1}{\left(-\frac{\sqrt{2}}{2}+\frac{I\sqrt{2}}{2}\right)^3} \\ \frac{1}{\left(-\frac{\sqrt{2}}{2}+\frac{I\sqrt{2}}{2}\right)^2} \\ \frac{1}{-\frac{\sqrt{2}}{2}+\frac{I\sqrt{2}}{2}} \\ 1 \end{bmatrix}\right], \left[\frac{\sqrt{2}}{2} - \frac{I\sqrt{2}}{2}, \begin{bmatrix} \frac{1}{\left(\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}\right)^3} \\ \frac{1}{\left(\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}\right)^2} \\ \frac{1}{\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}} \\ 1 \end{bmatrix}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}, \left[\begin{array}{c} \frac{1}{\left(-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}\right)^{3}} \\ \frac{1}{\left(-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}\right)^{2}} \\ \frac{1}{-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$e^{\left(-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}\right)x} \cdot \left[\begin{array}{c} \frac{1}{\left(-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}\right)^{3}} \\ \frac{1}{\left(-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}\right)^{2}} \\ \frac{1}{-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$e^{-\frac{\sqrt{2}\,x}{2}} \cdot \left(\cos\left(\frac{\sqrt{2}\,x}{2}\right) - I\sin\left(\frac{\sqrt{2}\,x}{2}\right)\right) \cdot \left[\begin{array}{c} \frac{1}{\left(-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}\right)^{3}} \\ \frac{1}{\left(-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}\right)^{2}} \\ \frac{1}{-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}} \\ 1 \end{array}\right]$$

- Simplify expression

$$e^{-\frac{\sqrt{2}\,x}{2}} \cdot \left[\begin{array}{c} \frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)-I\sin\left(\frac{\sqrt{2}\,x}{2}\right)}{\left(-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}\right)^{3}} \\ \frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)-I\sin\left(\frac{\sqrt{2}\,x}{2}\right)}{\left(-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}\right)^{2}} \\ \frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)-I\sin\left(\frac{\sqrt{2}\,x}{2}\right)}{-\frac{\sqrt{2}}{2}-\frac{I\sqrt{2}}{2}} \\ \cos\left(\frac{\sqrt{2}\,x}{2}\right) - I\sin\left(\frac{\sqrt{2}\,x}{2}\right) \end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_1(x) = e^{-\frac{\sqrt{2}\,x}{2}} \cdot \left[\begin{array}{c} \frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2}+\frac{\sin\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2} \\ -\sin\left(\frac{\sqrt{2}\,x}{2}\right) \\ -\frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2}+\frac{\sin\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2} \\ \cos\left(\frac{\sqrt{2}\,x}{2}\right) \end{array}\right], \vec{y}_2(x) = e^{-\frac{\sqrt{2}\,x}{2}} \cdot \left[\begin{array}{c} \frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2}-\frac{\sin\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2} \\ -\cos\left(\frac{\sqrt{2}\,x}{2}\right) \\ \frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2}+\frac{\sin\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2} \\ -\sin\left(\frac{\sqrt{2}\,x}{2}\right) \end{array}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[\frac{\sqrt{2}}{2}-\frac{\mathrm{I}\sqrt{2}}{2}, \left[\begin{array}{c} \frac{1}{\left(\frac{\sqrt{2}}{2}-\frac{\mathrm{I}\sqrt{2}}{2}\right)^3} \\ \frac{1}{\left(\frac{\sqrt{2}}{2}-\frac{\mathrm{I}\sqrt{2}}{2}\right)^2} \\ \frac{1}{\frac{\sqrt{2}}{2}-\frac{\mathrm{I}\sqrt{2}}{2}} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$e^{\left(\frac{\sqrt{2}}{2}-\frac{\mathrm{I}\sqrt{2}}{2}\right)x} \cdot \left[\begin{array}{c} \frac{1}{\left(\frac{\sqrt{2}}{2}-\frac{\mathrm{I}\sqrt{2}}{2}\right)^3} \\ \frac{1}{\left(\frac{\sqrt{2}}{2}-\frac{\mathrm{I}\sqrt{2}}{2}\right)^2} \\ \frac{1}{\frac{\sqrt{2}}{2}-\frac{\mathrm{I}\sqrt{2}}{2}} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$e^{\frac{\sqrt{2}\,x}{2}} \cdot \left(\cos\left(\frac{\sqrt{2}\,x}{2}\right)-\mathrm{I}\sin\left(\frac{\sqrt{2}\,x}{2}\right)\right) \cdot \left[\begin{array}{c} \frac{1}{\left(\frac{\sqrt{2}}{2}-\frac{\mathrm{I}\sqrt{2}}{2}\right)^3} \\ \frac{1}{\left(\frac{\sqrt{2}}{2}-\frac{\mathrm{I}\sqrt{2}}{2}\right)^2} \\ \frac{1}{\frac{\sqrt{2}}{2}-\frac{\mathrm{I}\sqrt{2}}{2}} \\ 1 \end{array}\right]$$

- Simplify expression

$$e^{\frac{\sqrt{2}\,x}{2}} \cdot \left[\begin{array}{c} \frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)-\mathrm{I}\sin\left(\frac{\sqrt{2}\,x}{2}\right)}{\left(\frac{\sqrt{2}}{2}-\frac{\mathrm{I}\sqrt{2}}{2}\right)^{3}} \\ \frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)-\mathrm{I}\sin\left(\frac{\sqrt{2}\,x}{2}\right)}{\left(\frac{\sqrt{2}}{2}-\frac{\mathrm{I}\sqrt{2}}{2}\right)^{2}} \\ \frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)-\mathrm{I}\sin\left(\frac{\sqrt{2}\,x}{2}\right)}{\frac{\sqrt{2}}{2}-\frac{\mathrm{I}\sqrt{2}}{2}} \\ \cos\left(\frac{\sqrt{2}\,x}{2}\right)-\mathrm{I}\sin\left(\frac{\sqrt{2}\,x}{2}\right) \end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = e^{\frac{\sqrt{2}\,x}{2}} \cdot \left[\begin{array}{c} -\frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2}+\frac{\sin\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2} \\ \sin\left(\frac{\sqrt{2}\,x}{2}\right) \\ \frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2}+\frac{\sin\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2} \\ \cos\left(\frac{\sqrt{2}\,x}{2}\right) \end{array}\right], \vec{y}_4(x) = e^{\frac{\sqrt{2}\,x}{2}} \cdot \left[\begin{array}{c} \frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2}+\frac{\sin\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2} \\ \cos\left(\frac{\sqrt{2}\,x}{2}\right) \\ \frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2}-\frac{\sin\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2} \\ -\sin\left(\frac{\sqrt{2}\,x}{2}\right) \end{array}\right]\right]$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1(x) + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + c_4\vec{y}_4(x)$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 e^{-\frac{\sqrt{2}\,x}{2}} \cdot \left[\begin{array}{c} \frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2}+\frac{\sin\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2} \\ -\sin\left(\frac{\sqrt{2}\,x}{2}\right) \\ -\frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2}+\frac{\sin\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2} \\ \cos\left(\frac{\sqrt{2}\,x}{2}\right) \end{array}\right] + c_2 e^{-\frac{\sqrt{2}\,x}{2}} \cdot \left[\begin{array}{c} \frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2}-\frac{\sin\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2} \\ -\cos\left(\frac{\sqrt{2}\,x}{2}\right) \\ \frac{\cos\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2}+\frac{\sin\left(\frac{\sqrt{2}\,x}{2}\right)\sqrt{2}}{2} \\ -\sin\left(\frac{\sqrt{2}\,x}{2}\right) \end{array}\right] + c_3 e^{\frac{\sqrt{2}\,x}{2}}$$

- First component of the vector is the solution to the ODE

$$y = \frac{\sqrt{2}\left(\left((c_1+c_2)e^{-\frac{\sqrt{2}\,x}{2}}-e^{\frac{\sqrt{2}\,x}{2}}(c_3-c_4)\right)\cos\left(\frac{\sqrt{2}\,x}{2}\right)+\left((c_1-c_2)e^{-\frac{\sqrt{2}\,x}{2}}+e^{\frac{\sqrt{2}\,x}{2}}(c_3+c_4)\right)\sin\left(\frac{\sqrt{2}\,x}{2}\right)\right)}{2}$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 24.
ODE order: 5.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _quadrature]]
```

$$\boxed{y^{(5)} = 0}$$

The characteristic equation is

$$\lambda^5 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$
$$\lambda_4 = 0$$
$$\lambda_5 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_5x^4 + c_4x^3 + c_3x^2 + c_2x + c_1$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = x$$
$$y_3 = x^2$$
$$y_4 = x^3$$
$$y_5 = x^4$$

Summary
The solution(s) found are the following

$$y = c_5 x^4 + c_4 x^3 + c_3 x^2 + c_2 x + c_1 \tag{1}$$

Verification of solutions

$$y = c_5 x^4 + c_4 x^3 + c_3 x^2 + c_2 x + c_1$$

Verified OK.

10.24.1 Maple step by step solution

Let's solve
$y^{(5)} = 0$

- Highest derivative means the order of the ODE is 5
  $y^{(5)}$

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$
    $y_1(x) = y$
  ◦ Define new variable $y_2(x)$
    $y_2(x) = y'$
  ◦ Define new variable $y_3(x)$
    $y_3(x) = y''$
  ◦ Define new variable $y_4(x)$
    $y_4(x) = y'''$
  ◦ Define new variable $y_5(x)$
    $y_5(x) = y''''$

- Isolate for $y_5'(x)$ using original ODE

  $y_5'(x) = 0$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_5(x) = y_4'(x), y_5'(x) = 0]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \\ y_5(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix}1\\0\\0\\0\\0\end{bmatrix}\right], \left[0, \begin{bmatrix}0\\0\\0\\0\\0\end{bmatrix}\right], \left[0, \begin{bmatrix}0\\0\\0\\0\\0\end{bmatrix}\right], \left[0, \begin{bmatrix}0\\0\\0\\0\\0\end{bmatrix}\right], \left[0, \begin{bmatrix}0\\0\\0\\0\\0\end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix}1\\0\\0\\0\\0\end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \begin{bmatrix}1\\0\\0\\0\\0\end{bmatrix}$$

- Consider eigenpair

$$\left[0, \begin{bmatrix}0\\0\\0\\0\\0\end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_4 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_5 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{y} = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3 + c_4 \vec{y}_4 + c_5 \vec{y}_5$$

- Substitute solutions into the general solution

$$\vec{y} = \begin{bmatrix} c_1 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = c_1$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 25.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - y' - 12y = 0}$$

With initial conditions

$$[y(0) = 3, y'(0) = 5]$$

10.25.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -1 \\ q(x) &= -12 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - y' - 12y = 0$$

The domain of $p(x) = -1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -12$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.25.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -1, C = -12$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - \lambda e^{\lambda x} - 12 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \lambda - 12 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -1, C = -12$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{1}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-1^2 - (4)(1)(-12)} \\ &= \frac{1}{2} \pm \frac{7}{2}\end{aligned}$$

Hence

$$\lambda_1 = \frac{1}{2} + \frac{7}{2}$$

$$\lambda_2 = \frac{1}{2} - \frac{7}{2}$$

Which simplifies to

$$\lambda_1 = 4$$
$$\lambda_2 = -3$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(4)x} + c_2 e^{(-3)x}$$

Or

$$y = c_1 \mathrm{e}^{4x} + c_2 \mathrm{e}^{-3x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{4x} + c_2 \mathrm{e}^{-3x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$3 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 4c_1 \mathrm{e}^{4x} - 3c_2 \mathrm{e}^{-3x}$$

substituting $y' = 5$ and $x = 0$ in the above gives

$$5 = 4c_1 - 3c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 2$$
$$c_2 = 1$$

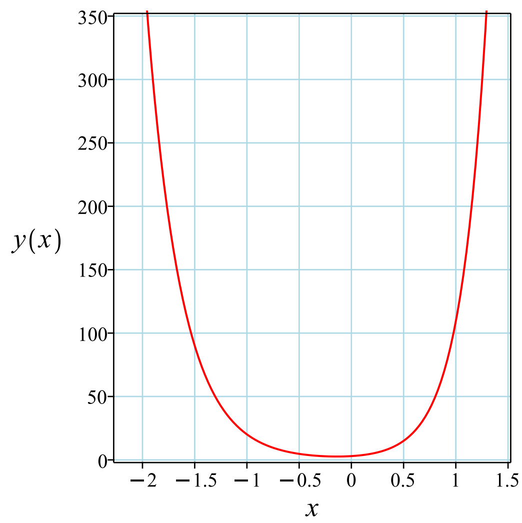
Substituting these values back in above solution results in

$$y = 2\,\mathrm{e}^{4x} + \mathrm{e}^{-3x}$$

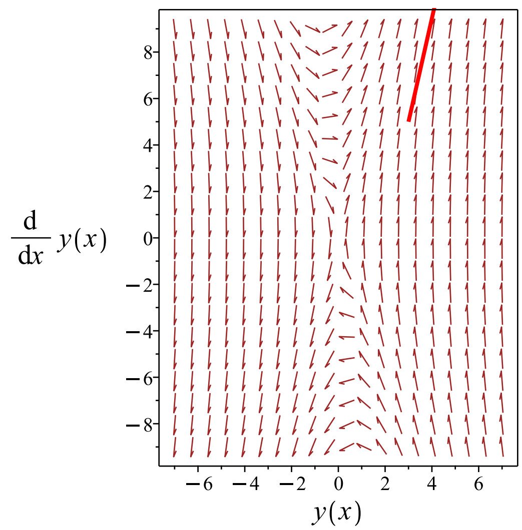
Summary

The solution(s) found are the following

$$y = 2\,\mathrm{e}^{4x} + \mathrm{e}^{-3x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 2\,\mathrm{e}^{4x} + \mathrm{e}^{-3x}$$

Verified OK.

10.25.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y' - 12y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -1 \\ C &= -12 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{49}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = 49$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \frac{49z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 311: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{49}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-\frac{7x}{2}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-1}{1}\,dx} \\
&= z_1 e^{\frac{x}{2}} \\
&= z_1\left(\mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-3x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{x}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{\mathrm{e}^{7x}}{7}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-3x}\right) + c_2 \left(\mathrm{e}^{-3x} \left(\frac{\mathrm{e}^{7x}}{7}\right)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{-3x} + \frac{c_2 \mathrm{e}^{4x}}{7} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$
3 = c_1 + \frac{c_2}{7} \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -3c_1 \mathrm{e}^{-3x} + \frac{4c_2 \mathrm{e}^{4x}}{7}
$$

substituting $y' = 5$ and $x = 0$ in the above gives

$$
5 = -3c_1 + \frac{4c_2}{7} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 1 \\
c_2 &= 14
\end{aligned}
$$

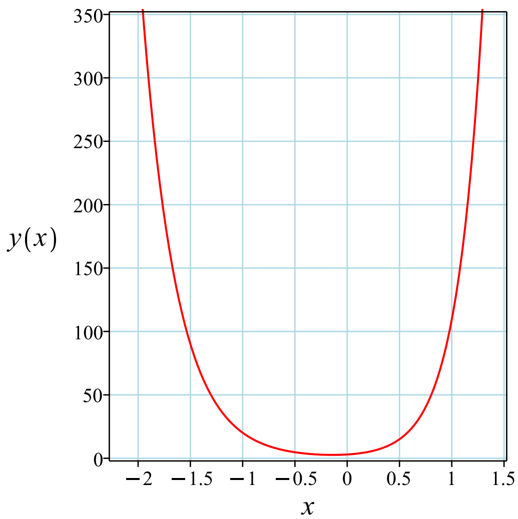
Substituting these values back in above solution results in

$$
y = 2\,\mathrm{e}^{4x} + \mathrm{e}^{-3x}
$$

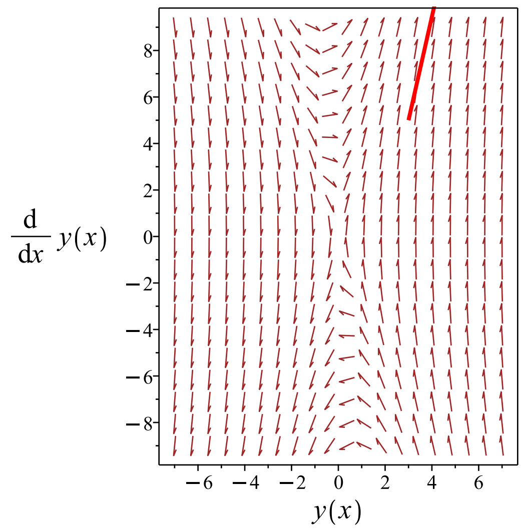
Summary

The solution(s) found are the following

$$
y = 2\,\mathrm{e}^{4x} + \mathrm{e}^{-3x} \tag{1}
$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 2\,e^{4x} + e^{-3x}$$

Verified OK.

10.25.4 Maple step by step solution

Let's solve

$$\left[y'' - y' - 12y = 0, y(0) = 3, y'\Big|_{\{x=0\}} = 5\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - r - 12 = 0$

- Factor the characteristic polynomial

  $(r + 3)(r - 4) = 0$

- Roots of the characteristic polynomial

  $r = (-3, 4)$

- 1st solution of the ODE

$y_1(x) = e^{-3x}$

- 2nd solution of the ODE

  $y_2(x) = e^{4x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{-3x} + c_2 e^{4x}$

- □ Check validity of solution $y = c_1 e^{-3x} + c_2 e^{4x}$
  - Use initial condition $y(0) = 3$

    $3 = c_1 + c_2$
  - Compute derivative of the solution

    $y' = -3c_1 e^{-3x} + 4c_2 e^{4x}$
  - Use the initial condition $y'\Big|_{\{x=0\}} = 5$

    $5 = -3c_1 + 4c_2$
  - Solve for c_1 and c_2

    $\{c_1 = 1, c_2 = 2\}$
  - Substitute constant values into general solution and simplify

    $y = (2\,e^{7x} + 1)\,e^{-3x}$

- Solution to the IVP

  $y = (2\,e^{7x} + 1)\,e^{-3x}$

Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 26.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 7y' + 10y = 0}$$

With initial conditions

$$[y(0) = -4, y'(0) = 2]$$

10.26.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 7 \\ q(x) &= 10 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + 7y' + 10y = 0$$

The domain of $p(x) = 7$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 10$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.26.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 7, C = 10$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 7\lambda\, e^{\lambda x} + 10\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 7\lambda + 10 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 7, C = 10$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-7}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{7^2 - (4)(1)(10)}\\ &= -\frac{7}{2} \pm \frac{3}{2}\end{aligned}$$

Hence

$$\lambda_1 = -\frac{7}{2} + \frac{3}{2}$$

$$\lambda_2 = -\frac{7}{2} - \frac{3}{2}$$

Which simplifies to

$$\lambda_1 = -2$$
$$\lambda_2 = -5$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(-2)x} + c_2 e^{(-5)x}$$

Or

$$y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-5x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-5x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -4$ and $x = 0$ in the above gives

$$-4 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -2c_1 \mathrm{e}^{-2x} - 5c_2 \mathrm{e}^{-5x}$$

substituting $y' = 2$ and $x = 0$ in the above gives

$$2 = -2c_1 - 5c_2 \tag{2A}$$

Equations $\{1\text{A},2\text{A}\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -6$$
$$c_2 = 2$$

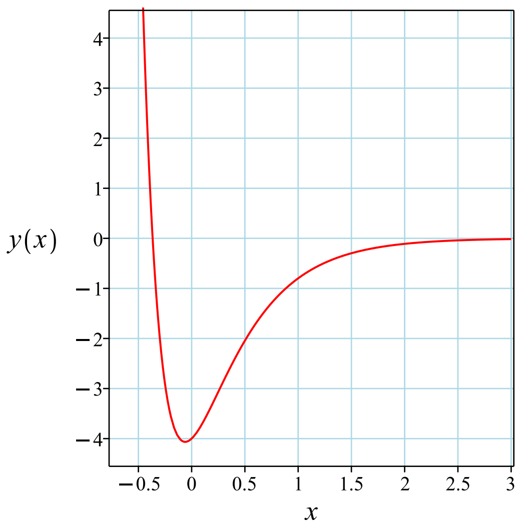
Substituting these values back in above solution results in

$$y = 2\,\mathrm{e}^{-5x} - 6\,\mathrm{e}^{-2x}$$

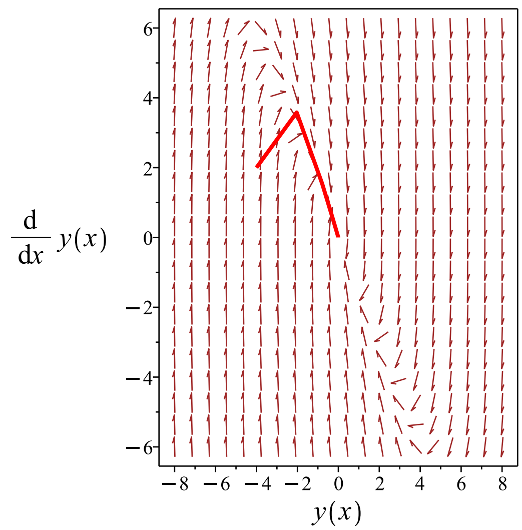
Summary

The solution(s) found are the following

$$y = 2\,e^{-5x} - 6\,e^{-2x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 2\,e^{-5x} - 6\,e^{-2x}$$

Verified OK.

10.26.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 7y' + 10y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 7 \\ C &= 10 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = 9$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 313: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{7}{1}\,dx} \\ &= z_1 e^{-\frac{7x}{2}} \\ &= z_1 \left(\mathrm{e}^{-\frac{7x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-5x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{7}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-7x}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{\mathrm{e}^{3x}}{3}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-5x}\right) + c_2 \left(\mathrm{e}^{-5x} \left(\frac{\mathrm{e}^{3x}}{3}\right)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{-5x} + \frac{c_2 \mathrm{e}^{-2x}}{3} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -4$ and $x = 0$ in the above gives

$$
-4 = c_1 + \frac{c_2}{3} \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -5c_1 \mathrm{e}^{-5x} - \frac{2c_2 \mathrm{e}^{-2x}}{3}
$$

substituting $y' = 2$ and $x = 0$ in the above gives

$$
2 = -5c_1 - \frac{2c_2}{3} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 2 \\
c_2 &= -18
\end{aligned}
$$

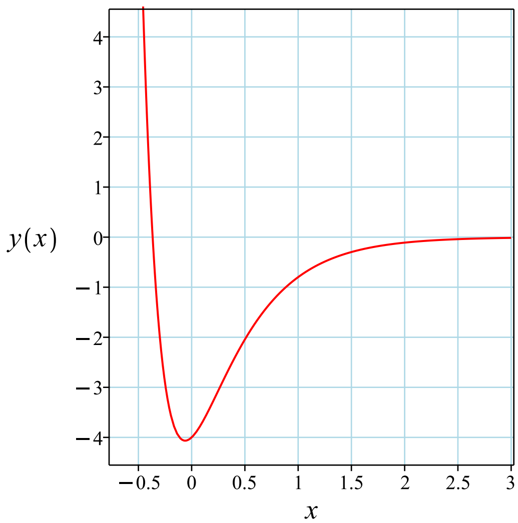
Substituting these values back in above solution results in

$$
y = 2\,\mathrm{e}^{-5x} - 6\,\mathrm{e}^{-2x}
$$

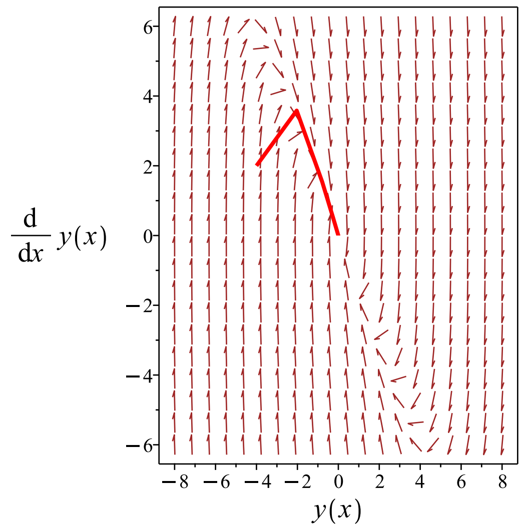
Summary

The solution(s) found are the following

$$
y = 2\,\mathrm{e}^{-5x} - 6\,\mathrm{e}^{-2x} \tag{1}
$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 2\,e^{-5x} - 6\,e^{-2x}$$

Verified OK.

10.26.4 Maple step by step solution

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 6y' + 8y = 0}$$

With initial conditions

$$[y(0) = 1, y'(0) = 6]$$

10.27.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -6 \\ q(x) &= 8 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - 6y' + 8y = 0$$

The domain of $p(x) = -6$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 8$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.27.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -6, C = 8$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 6\lambda\, e^{\lambda x} + 8\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 6\lambda + 8 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -6, C = 8$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{6}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-6^2 - (4)\,(1)\,(8)}\\ &= 3 \pm 1\end{aligned}$$

Hence

$$\lambda_1 = 3 + 1$$
$$\lambda_2 = 3 - 1$$

Which simplifies to

$$\lambda_1 = 4$$
$$\lambda_2 = 2$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(4)x} + c_2 e^{(2)x}$$

Or

$$y = c_1 \mathrm{e}^{4x} + c_2 \mathrm{e}^{2x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{4x} + c_2 \mathrm{e}^{2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 4c_1 \mathrm{e}^{4x} + 2c_2 \mathrm{e}^{2x}$$

substituting $y' = 6$ and $x = 0$ in the above gives

$$6 = 4c_1 + 2c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

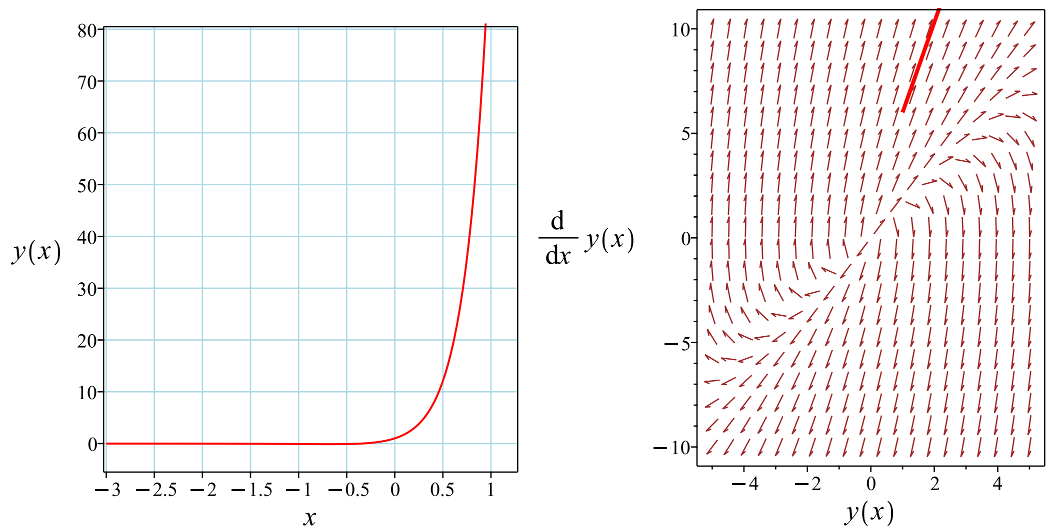
$$c_1 = 2$$
$$c_2 = -1$$

Substituting these values back in above solution results in

$$y = 2\,\mathrm{e}^{4x} - \mathrm{e}^{2x}$$

Summary
The solution(s) found are the following

$$y = 2\,e^{4x} - e^{2x} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = 2\,e^{4x} - e^{2x}$$

Verified OK.

10.27.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 6y' + 8y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -6 \\ C &= 8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 315: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-6}{1}\,dx} \\ &= z_1 e^{3x} \\ &= z_1 \left(\mathrm{e}^{3x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-6}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{6x}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{\mathrm{e}^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{2x}\right) + c_2 \left(\mathrm{e}^{2x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{2x} + \frac{c_2 \mathrm{e}^{4x}}{2} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$
1 = c_1 + \frac{c_2}{2} \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = 2c_1 \mathrm{e}^{2x} + 2c_2 \mathrm{e}^{4x}
$$

substituting $y' = 6$ and $x = 0$ in the above gives

$$
6 = 2c_1 + 2c_2 \tag{2A}
$$

Equations $\{1A,2A\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= -1 \\
c_2 &= 4
\end{aligned}
$$

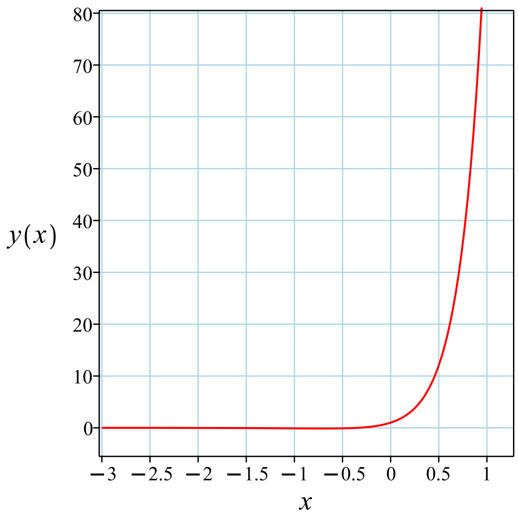
Substituting these values back in above solution results in

$$
y = 2\,\mathrm{e}^{4x} - \mathrm{e}^{2x}
$$

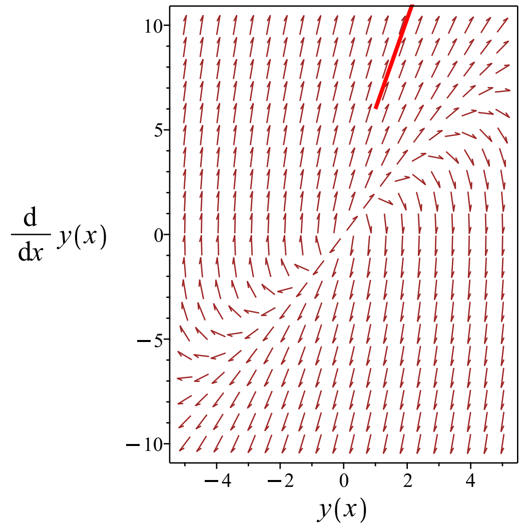
Summary

The solution(s) found are the following

$$
y = 2\,\mathrm{e}^{4x} - \mathrm{e}^{2x} \tag{1}
$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = 2\,e^{4x} - e^{2x}$$

Verified OK.

10.27.4 Maple step by step solution

Let's solve

$$\left[y'' - 6y' + 8y = 0, y(0) = 1, y'\Big|_{\{x=0\}} = 6\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 6r + 8 = 0$

- Factor the characteristic polynomial

  $(r-2)(r-4) = 0$

- Roots of the characteristic polynomial

  $r = (2, 4)$

- 1st solution of the ODE

$$y_1(x) = e^{2x}$$

- 2nd solution of the ODE

$$y_2(x) = e^{4x}$$

- General solution of the ODE

$$y = c_1 y_1(x) + c_2 y_2(x)$$

- Substitute in solutions

$$y = c_1 e^{2x} + c_2 e^{4x}$$

□ Check validity of solution $y = c_1 e^{2x} + c_2 e^{4x}$

  - Use initial condition $y(0) = 1$

    $$1 = c_1 + c_2$$

  - Compute derivative of the solution

    $$y' = 2c_1 e^{2x} + 4c_2 e^{4x}$$

  - Use the initial condition $y'\Big|_{\{x=0\}} = 6$

    $$6 = 2c_1 + 4c_2$$

  - Solve for c_1 and c_2

    $$\{c_1 = -1, c_2 = 2\}$$

  - Substitute constant values into general solution and simplify

    $$y = 2 e^{4x} - e^{2x}$$

- Solution to the IVP

$$y = 2 e^{4x} - e^{2x}$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 28.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _missing_x]]`

$$\boxed{3y'' + 4y' - 4y = 0}$$

With initial conditions

$$[y(0) = 2, y'(0) = -4]$$

10.28.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$p(x) = \frac{4}{3}$$
$$q(x) = -\frac{4}{3}$$
$$F = 0$$

Hence the ode is

$$y'' + \frac{4y'}{3} - \frac{4y}{3} = 0$$

The domain of $p(x) = \frac{4}{3}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -\frac{4}{3}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.28.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 3, B = 4, C = -4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$3\lambda^2 e^{\lambda x} + 4\lambda\, e^{\lambda x} - 4\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$3\lambda^2 + 4\lambda - 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 3, B = 4, C = -4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-4}{(2)\,(3)} \pm \frac{1}{(2)\,(3)}\sqrt{4^2 - (4)\,(3)\,(-4)}\\ &= -\frac{2}{3} \pm \frac{4}{3}\end{aligned}$$

Hence

$$\lambda_1 = -\frac{2}{3} + \frac{4}{3}$$

$$\lambda_2 = -\frac{2}{3} - \frac{4}{3}$$

Which simplifies to

$$\lambda_1 = \frac{2}{3}$$
$$\lambda_2 = -2$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{\left(\frac{2}{3}\right)x} + c_2 e^{(-2)x}$$

Or

$$y = c_1 \mathrm{e}^{\frac{2x}{3}} + c_2 \mathrm{e}^{-2x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{\frac{2x}{3}} + c_2 \mathrm{e}^{-2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{2c_1 \mathrm{e}^{\frac{2x}{3}}}{3} - 2c_2 \mathrm{e}^{-2x}$$

substituting $y' = -4$ and $x = 0$ in the above gives

$$-4 = \frac{2c_1}{3} - 2c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

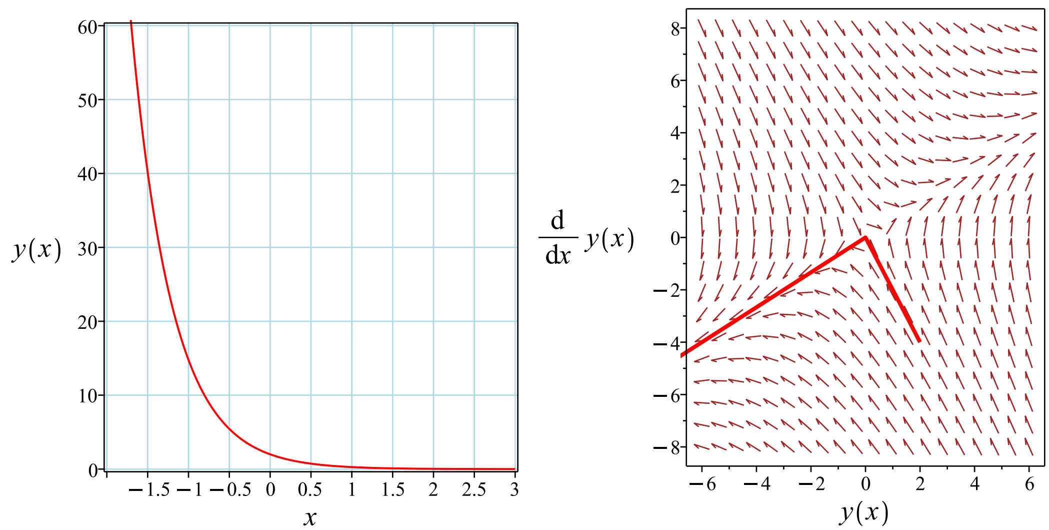
$$c_1 = 0$$
$$c_2 = 2$$

Substituting these values back in above solution results in

$$y = 2\,\mathrm{e}^{-2x}$$

Summary
The solution(s) found are the following

$$y = 2\,\mathrm{e}^{-2x} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = 2\,\mathrm{e}^{-2x}$$

Verified OK.

10.28.3 Solving using Kovacic algorithm

Writing the ode as

$$3y'' + 4y' - 4y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3 \\ B &= 4 \\ C &= -4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{16}{9} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 16 \\ t &= 9 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{16z(x)}{9} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 317: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{16}{9}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = e^{-\frac{4x}{3}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4}{3}\,dx} \\
&= z_1 e^{-\frac{2x}{3}} \\
&= z_1 \left(e^{-\frac{2x}{3}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = e^{-2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4}{3}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{4x}{3}}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{3\,e^{\frac{8x}{3}}}{8}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-2x}\right) + c_2 \left(\mathrm{e}^{-2x} \left(\frac{3\,\mathrm{e}^{\frac{8x}{3}}}{8}\right)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{-2x} + \frac{3 c_2 \mathrm{e}^{\frac{2x}{3}}}{8} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$
2 = c_1 + \frac{3 c_2}{8} \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -2 c_1 \mathrm{e}^{-2x} + \frac{c_2 \mathrm{e}^{\frac{2x}{3}}}{4}
$$

substituting $y' = -4$ and $x = 0$ in the above gives

$$
-4 = -2 c_1 + \frac{c_2}{4} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 2 \\
c_2 &= 0
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = 2\,\mathrm{e}^{-2x}
$$

Summary

The solution(s) found are the following

$$
y = 2\,\mathrm{e}^{-2x} \tag{1}
$$

Verified OK.

10.28.4 Maple step by step solution

Let's solve

$$\left[3y'' + 4y' - 4y = 0, y(0) = 2, y'\Big|_{\{x=0\}} = -4\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{4y'}{3} + \frac{4y}{3}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{4y'}{3} - \frac{4y}{3} = 0$

- Characteristic polynomial of ODE

  $r^2 + \frac{4}{3}r - \frac{4}{3} = 0$

- Factor the characteristic polynomial

$\frac{(r+2)(3r-2)}{3} = 0$

- Roots of the characteristic polynomial

  $r = \left(-2, \frac{2}{3}\right)$

- 1st solution of the ODE

  $y_1(x) = e^{-2x}$

- 2nd solution of the ODE

  $y_2(x) = e^{\frac{2x}{3}}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{-2x} + c_2 e^{\frac{2x}{3}}$

□ Check validity of solution $y = c_1 e^{-2x} + c_2 e^{\frac{2x}{3}}$

  ◦ Use initial condition $y(0) = 2$

    $2 = c_1 + c_2$

  ◦ Compute derivative of the solution

    $y' = -2c_1 e^{-2x} + \frac{2c_2 e^{\frac{2x}{3}}}{3}$

  ◦ Use the initial condition $y'\Big|_{\{x=0\}} = -4$

    $-4 = -2c_1 + \frac{2c_2}{3}$

  ◦ Solve for c_1 and c_2

    $\{c_1 = 2, c_2 = 0\}$

  ◦ Substitute constant values into general solution and simplify

    $y = 2\,e^{-2x}$

- Solution to the IVP

  $y = 2\,e^{-2x}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 6y' + 9y = 0}$$

With initial conditions

$$[y(0) = 2, y'(0) = -3]$$

10.29.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 6 \\ q(x) &= 9 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + 6y' + 9y = 0$$

The domain of $p(x) = 6$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 9$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.29.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 6, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 6\lambda\,\mathrm{e}^{\lambda x} + 9\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 6\lambda + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 6, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-6}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(6)^2 - (4)(1)(9)}\\ &= -3\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 3$. Therefore the solution is

$$y = c_1 e^{-3x} + c_2 x\, e^{-3x} \tag{1}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{-3x} + c_2 x\, e^{-3x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -3c_1 e^{-3x} + c_2 e^{-3x} - 3c_2 x\, e^{-3x}$$

substituting $y' = -3$ and $x = 0$ in the above gives

$$-3 = -3c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned}c_1 &= 2\\ c_2 &= 3\end{aligned}$$

Substituting these values back in above solution results in

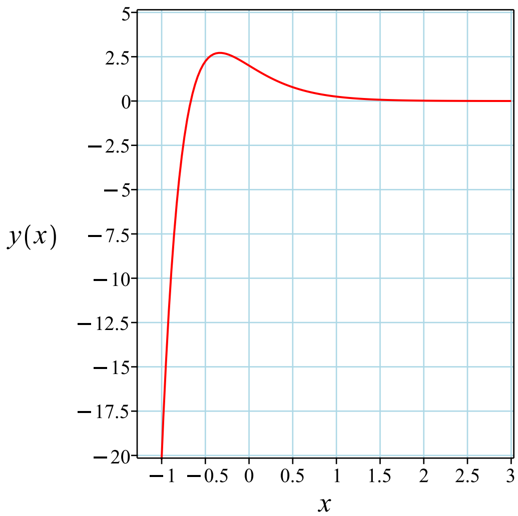
$$y = 3x\, e^{-3x} + 2\, e^{-3x}$$

Which simplifies to

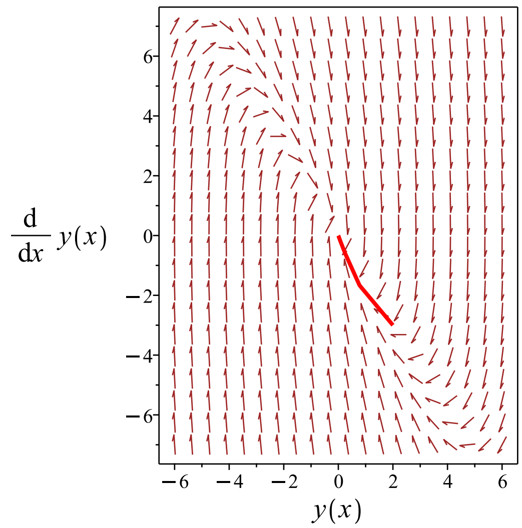
$$y = e^{-3x}(3x + 2)$$

<u>Summary</u>
The solution(s) found are the following

$$y = e^{-3x}(3x + 2) \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = e^{-3x}(3x+2)$$

Verified OK.

10.29.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = 6$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int 6\, dx} \\ &= e^{3x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$(M(x)y)'' = 0$$
$$\left(e^{3x} y\right)'' = 0$$

Integrating once gives

$$\left(e^{3x}y\right)' = c_1$$

Integrating again gives

$$\left(e^{3x}y\right) = c_1x + c_2$$

Hence the solution is

$$y = \frac{c_1x + c_2}{e^{3x}}$$

Or

$$y = c_1x\,e^{-3x} + c_2e^{-3x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1x\,e^{-3x} + c_2e^{-3x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1e^{-3x} - 3c_1x\,e^{-3x} - 3c_2e^{-3x}$$

substituting $y' = -3$ and $x = 0$ in the above gives

$$-3 = c_1 - 3c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 3$$
$$c_2 = 2$$

Substituting these values back in above solution results in

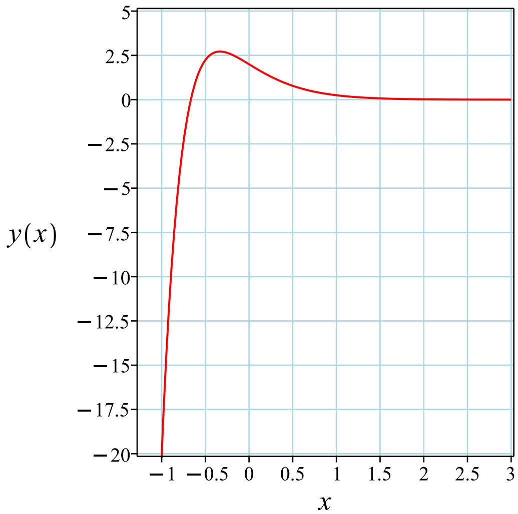
$$y = 3x\,e^{-3x} + 2\,e^{-3x}$$

Which simplifies to

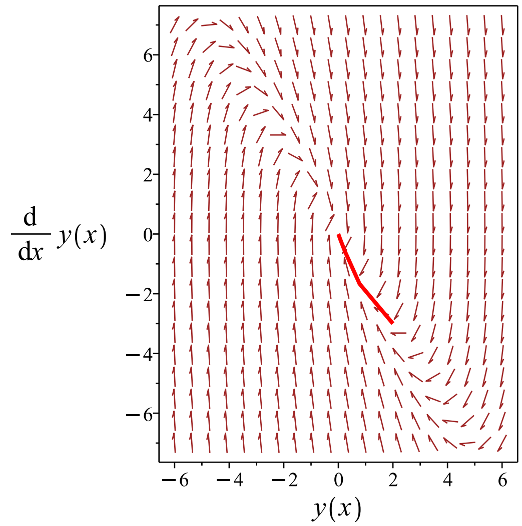
$$y = e^{-3x}(3x + 2)$$

Summary
The solution(s) found are the following

$$y = e^{-3x}(3x + 2) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^{-3x}(3x + 2)$$

Verified OK.

10.29.4 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 6y' + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 6 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 319: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{6}{1}\,dx} \\
&= z_1 e^{-3x} \\
&= z_1\left(\mathrm{e}^{-3x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{6}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-6x}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-3x}\right) + c_2\left(\mathrm{e}^{-3x}(x)\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{-3x} + c_2 x\,\mathrm{e}^{-3x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -3c_1 \mathrm{e}^{-3x} + c_2 \mathrm{e}^{-3x} - 3c_2 x\,\mathrm{e}^{-3x}$$

substituting $y' = -3$ and $x = 0$ in the above gives

$$-3 = -3c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 2 \\ c_2 &= 3 \end{aligned}$$

Substituting these values back in above solution results in

$$y = 3x\,\mathrm{e}^{-3x} + 2\,\mathrm{e}^{-3x}$$

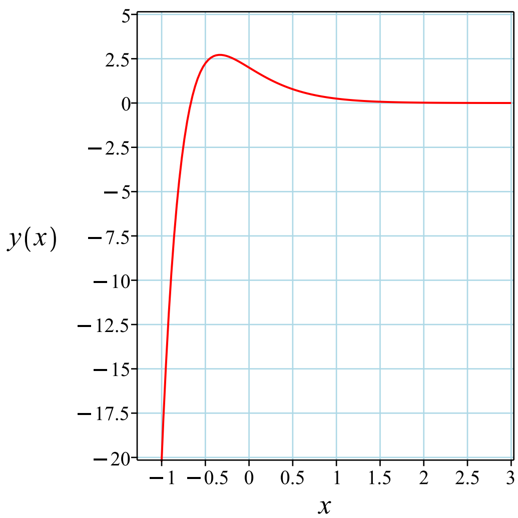
Which simplifies to

$$y = \mathrm{e}^{-3x}(3x + 2)$$

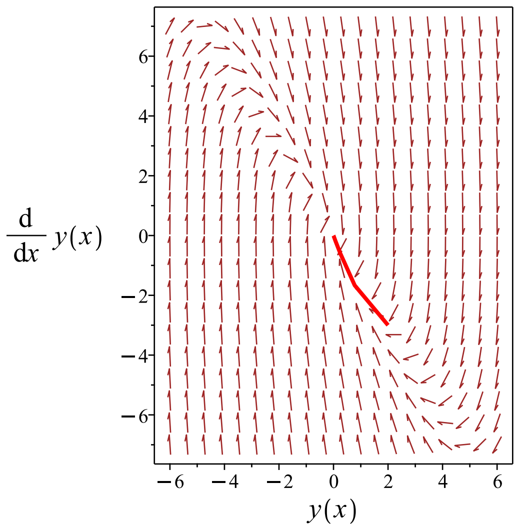
Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-3x}(3x + 2) \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = e^{-3x}(3x + 2)$$

Verified OK.

10.29.5 Maple step by step solution

Let's solve

$$\left[y'' + 6y' + 9y = 0, y(0) = 2, y'\Big|_{\{x=0\}} = -3\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 + 6r + 9 = 0$

- Factor the characteristic polynomial

  $(r + 3)^2 = 0$

- Root of the characteristic polynomial

  $r = -3$

- 1st solution of the ODE

$y_1(x) = \mathrm{e}^{-3x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,\mathrm{e}^{-3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 \mathrm{e}^{-3x} + c_2 x\,\mathrm{e}^{-3x}$

□ Check validity of solution $y = c_1 \mathrm{e}^{-3x} + c_2 x \mathrm{e}^{-3x}$

  - Use initial condition $y(0) = 2$

    $2 = c_1$

  - Compute derivative of the solution

    $y' = -3c_1 \mathrm{e}^{-3x} + c_2 \mathrm{e}^{-3x} - 3c_2 x\,\mathrm{e}^{-3x}$

  - Use the initial condition $y'\Big|_{\{x=0\}} = -3$

    $-3 = -3c_1 + c_2$

  - Solve for c_1 and c_2

    $\{c_1 = 2, c_2 = 3\}$

  - Substitute constant values into general solution and simplify

    $y = \mathrm{e}^{-3x}(3x + 2)$

- Solution to the IVP

  $y = \mathrm{e}^{-3x}(3x + 2)$

Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 30.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{4y'' - 12y' + 9y = 0}$$

With initial conditions

$$[y(0) = 4, y'(0) = 9]$$

10.30.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -3 \\ q(x) &= \frac{9}{4} \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - 3y' + \frac{9y}{4} = 0$$

The domain of $p(x) = -3$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \frac{9}{4}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.30.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 4, B = -12, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$4\lambda^2 \mathrm{e}^{\lambda x} - 12\lambda\, \mathrm{e}^{\lambda x} + 9\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$4\lambda^2 - 12\lambda + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 4, B = -12, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{12}{(2)(4)} \pm \frac{1}{(2)(4)}\sqrt{(-12)^2 - (4)(4)(9)} \\ &= \frac{3}{2}\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -\frac{3}{2}$. Therefore the solution is

$$y = c_1 e^{\frac{3x}{2}} + c_2 x\, e^{\frac{3x}{2}} \tag{1}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{\frac{3x}{2}} + c_2 x\, e^{\frac{3x}{2}} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 0$ in the above gives

$$4 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{3c_1 e^{\frac{3x}{2}}}{2} + e^{\frac{3x}{2}} c_2 + \frac{3c_2 x\, e^{\frac{3x}{2}}}{2}$$

substituting $y' = 9$ and $x = 0$ in the above gives

$$9 = \frac{3c_1}{2} + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned}c_1 &= 4 \\ c_2 &= 3\end{aligned}$$

Substituting these values back in above solution results in

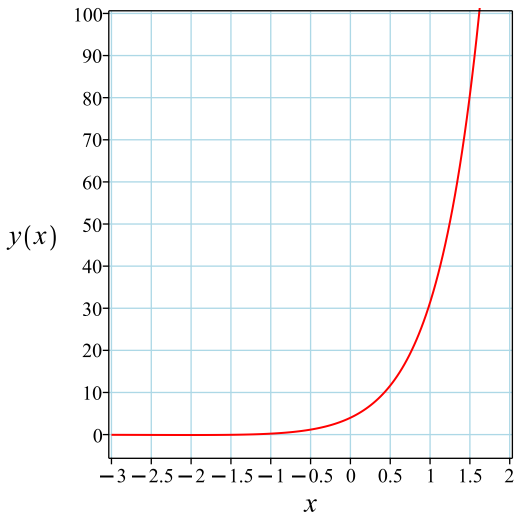
$$y = 3x\, e^{\frac{3x}{2}} + 4\, e^{\frac{3x}{2}}$$

Which simplifies to

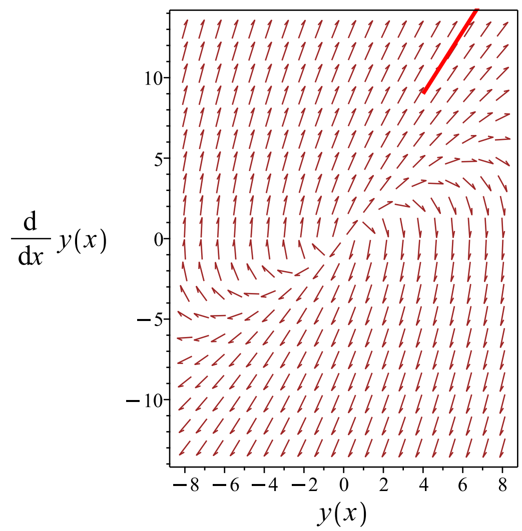
$$y = e^{\frac{3x}{2}}(4 + 3x)$$

Summary
The solution(s) found are the following

$$y = e^{\frac{3x}{2}}(4+3x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^{\frac{3x}{2}}(4+3x)$$

Verified OK.

10.30.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -3$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int -3\,dx} \\ &= e^{-\frac{3x}{2}} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= 0 \\
\left(\mathrm{e}^{-\frac{3x}{2}} y\right)'' &= 0
\end{aligned}
$$

Integrating once gives

$$
\left(\mathrm{e}^{-\frac{3x}{2}} y\right)' = c_1
$$

Integrating again gives

$$
\left(\mathrm{e}^{-\frac{3x}{2}} y\right) = c_1 x + c_2
$$

Hence the solution is

$$
y = \frac{c_1 x + c_2}{\mathrm{e}^{-\frac{3x}{2}}}
$$

Or

$$
y = c_1 x \,\mathrm{e}^{\frac{3x}{2}} + \mathrm{e}^{\frac{3x}{2}} c_2
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 x \,\mathrm{e}^{\frac{3x}{2}} + \mathrm{e}^{\frac{3x}{2}} c_2 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 0$ in the above gives

$$
4 = c_2 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = c_1 \mathrm{e}^{\frac{3x}{2}} + \frac{3 c_1 x \,\mathrm{e}^{\frac{3x}{2}}}{2} + \frac{3 \,\mathrm{e}^{\frac{3x}{2}} c_2}{2}
$$

substituting $y' = 9$ and $x = 0$ in the above gives

$$
9 = c_1 + \frac{3 c_2}{2} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 3\\
c_2 &= 4
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = 3x\,\mathrm{e}^{\frac{3x}{2}} + 4\,\mathrm{e}^{\frac{3x}{2}}
$$

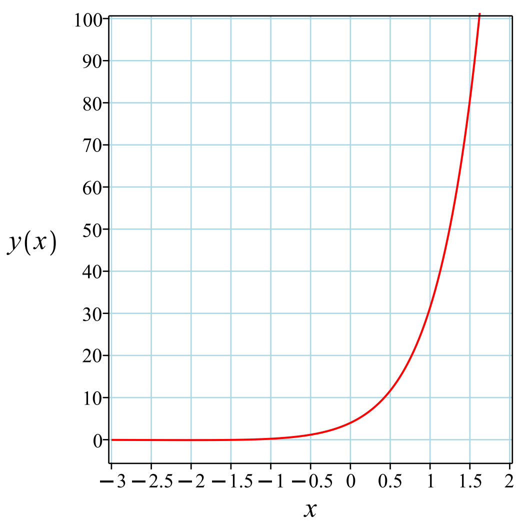
Which simplifies to

$$
y = \mathrm{e}^{\frac{3x}{2}}(4 + 3x)
$$

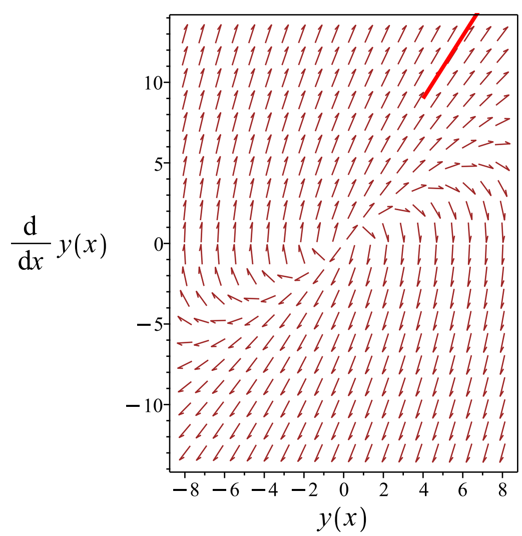
Summary

The solution(s) found are the following

$$
y = \mathrm{e}^{\frac{3x}{2}}(4 + 3x) \tag{1}
$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$
y = \mathrm{e}^{\frac{3x}{2}}(4 + 3x)
$$

Verified OK.

10.30.4 Solving using Kovacic algorithm

Writing the ode as

$$4y'' - 12y' + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4 \\ B &= -12 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 321: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-12}{4}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{\frac{3x}{2}} \\
&= z_1 \left(\mathrm{e}^{\frac{3x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{\frac{3x}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-12}{4}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{3x}}{(y_1)^2}\, dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{\frac{3x}{2}}\right) + c_2 \left(\mathrm{e}^{\frac{3x}{2}} (x)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{\frac{3x}{2}} + c_2 x\, \mathrm{e}^{\frac{3x}{2}} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 0$ in the above gives

$$
4 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = \frac{3c_1 \mathrm{e}^{\frac{3x}{2}}}{2} + \mathrm{e}^{\frac{3x}{2}} c_2 + \frac{3c_2 x\, \mathrm{e}^{\frac{3x}{2}}}{2}
$$

substituting $y' = 9$ and $x = 0$ in the above gives

$$9 = \frac{3c_1}{2} + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 4$$
$$c_2 = 3$$

Substituting these values back in above solution results in

$$y = 3x\,\mathrm{e}^{\frac{3x}{2}} + 4\,\mathrm{e}^{\frac{3x}{2}}$$

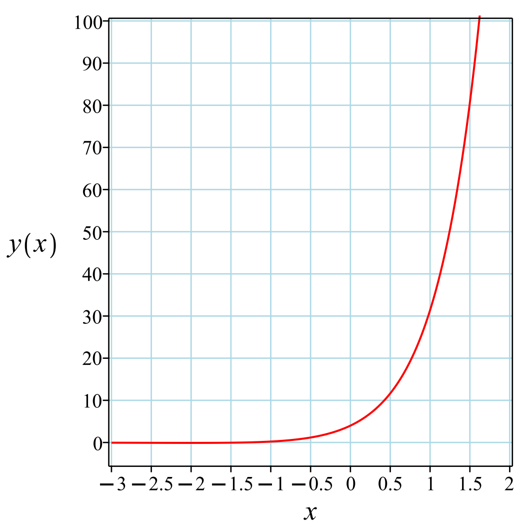
Which simplifies to

$$y = \mathrm{e}^{\frac{3x}{2}}(4 + 3x)$$

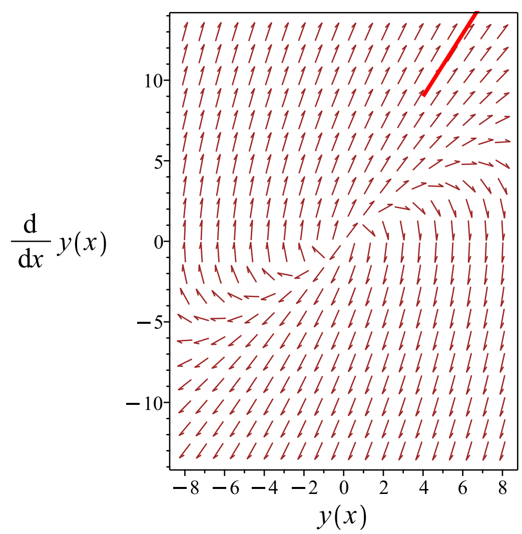
Summary

The solution(s) found are the following

$$y = \mathrm{e}^{\frac{3x}{2}}(4 + 3x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \mathrm{e}^{\frac{3x}{2}}(4 + 3x)$$

Verified OK.

10.30.5 Maple step by step solution

Let's solve

$\left[4y''-12y'+9y=0, y(0)=4, y'\Big|_{\{x=0\}}=9\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=3y'-\frac{9y}{4}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-3y'+\frac{9y}{4}=0$

- Characteristic polynomial of ODE

  $r^2-3r+\frac{9}{4}=0$

- Factor the characteristic polynomial

  $\frac{(2r-3)^2}{4}=0$

- Root of the characteristic polynomial

  $r=\frac{3}{2}$

- 1st solution of the ODE

  $y_1(x)=e^{\frac{3x}{2}}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x)=x\,e^{\frac{3x}{2}}$

- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)$

- Substitute in solutions

  $y=c_1e^{\frac{3x}{2}}+c_2x\,e^{\frac{3x}{2}}$

□ Check validity of solution $y=c_1e^{\frac{3x}{2}}+c_2xe^{\frac{3x}{2}}$

  - Use initial condition $y(0)=4$

    $4=c_1$

  - Compute derivative of the solution

    $y'=\frac{3c_1e^{\frac{3x}{2}}}{2}+e^{\frac{3x}{2}}c_2+\frac{3c_2x\,e^{\frac{3x}{2}}}{2}$

- Use the initial condition $y'\Big|_{\{x=0\}} = 9$

  $9 = \frac{3c_1}{2} + c_2$

- Solve for c_1 and c_2

  $\{c_1 = 4, c_2 = 3\}$

- Substitute constant values into general solution and simplify

  $y = e^{\frac{3x}{2}}(4 + 3x)$

- Solution to the IVP

  $y = e^{\frac{3x}{2}}(4 + 3x)$

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 4y' + 4y = 0}$$

With initial conditions

$$[y(0) = 3, y'(0) = 7]$$

10.31.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 4 \\ q(x) &= 4 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + 4y' + 4y = 0$$

The domain of $p(x) = 4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.31.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 4, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4\lambda\, e^{\lambda x} + 4\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4\lambda + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 4, C = 4$ into the above gives

$$
\begin{aligned}
\lambda_{1,2} &= \frac{-4}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(4)^2 - (4)(1)(4)} \\
&= -2
\end{aligned}
$$

Hence this is the case of a double root $\lambda_{1,2} = 2$. Therefore the solution is

$$
y = c_1 e^{-2x} + c_2 x\, e^{-2x} \tag{1}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 e^{-2x} + x\, e^{-2x} c_2 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$
3 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -2c_1 e^{-2x} + c_2 e^{-2x} - 2x\, e^{-2x} c_2
$$

substituting $y' = 7$ and $x = 0$ in the above gives

$$
7 = -2c_1 + c_2 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 3 \\
c_2 &= 13
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = 13x\, e^{-2x} + 3\, e^{-2x}
$$

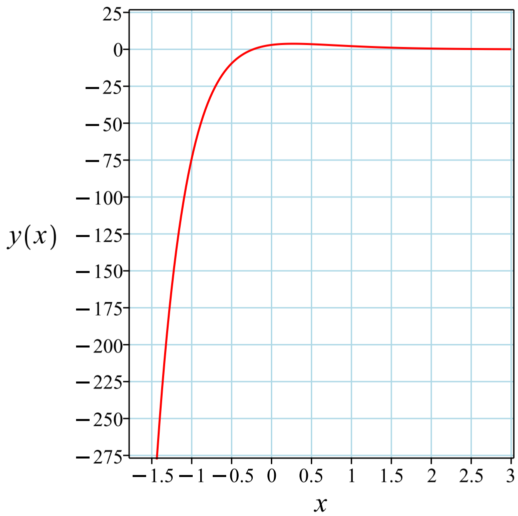
Which simplifies to

$$
y = e^{-2x}(3 + 13x)
$$

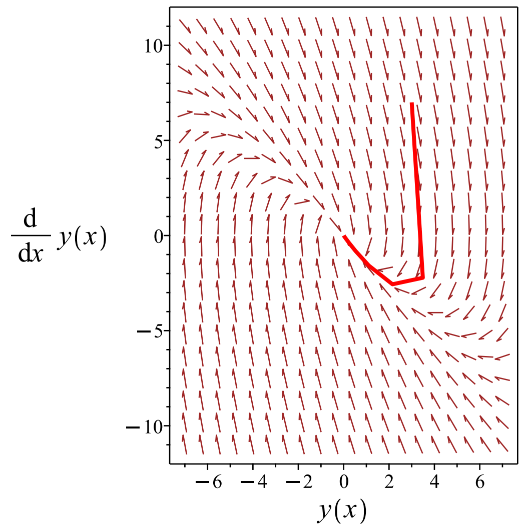
Summary

The solution(s) found are the following

$$
y = e^{-2x}(3 + 13x) \tag{1}
$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^{-2x}(3 + 13x)$$

Verified OK.

10.31.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)$$

Where $p(x) = 4$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int 4\,dx} \\ &= e^{2x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= 0 \\ \left(y\,e^{2x}\right)'' &= 0 \end{aligned}$$

Integrating once gives

$$\left(y\,\mathrm{e}^{2x}\right)' = c_1$$

Integrating again gives

$$\left(y\,\mathrm{e}^{2x}\right) = c_1 x + c_2$$

Hence the solution is

$$y = \frac{c_1 x + c_2}{\mathrm{e}^{2x}}$$

Or

$$y = c_1 x\,\mathrm{e}^{-2x} + c_2 \mathrm{e}^{-2x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 x\,\mathrm{e}^{-2x} + c_2 \mathrm{e}^{-2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$3 = c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 \mathrm{e}^{-2x} - 2c_1 x\,\mathrm{e}^{-2x} - 2c_2 \mathrm{e}^{-2x}$$

substituting $y' = 7$ and $x = 0$ in the above gives

$$7 = c_1 - 2c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 13$$
$$c_2 = 3$$

Substituting these values back in above solution results in

$$y = 13x\,\mathrm{e}^{-2x} + 3\,\mathrm{e}^{-2x}$$

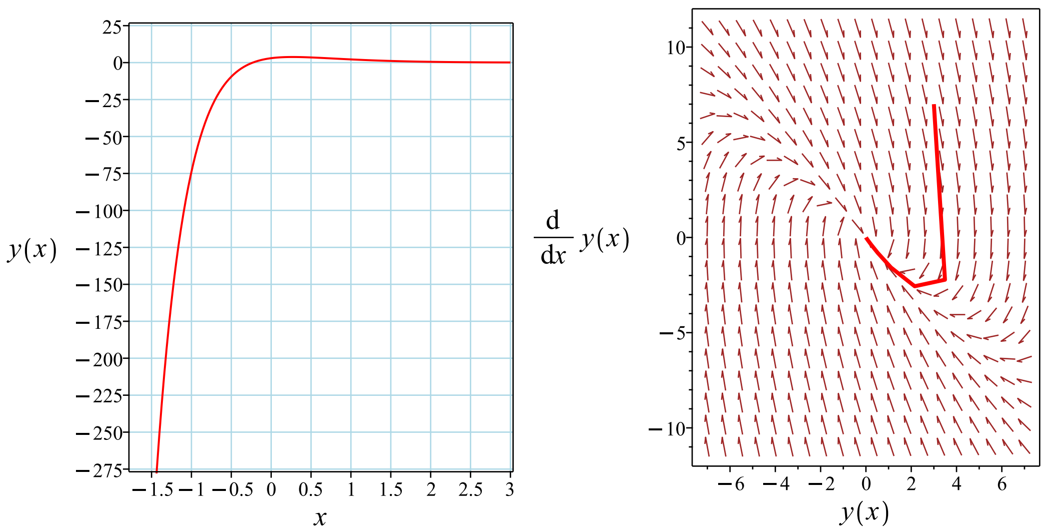
Which simplifies to

$$y = \mathrm{e}^{-2x}(3 + 13x)$$

Summary

The solution(s) found are the following

$$y = e^{-2x}(3 + 13x) \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = e^{-2x}(3 + 13x)$$

Verified OK.

10.31.4 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 323: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4}{1}\,dx} \\ &= z_1 e^{-2x} \\ &= z_1 \left(\mathrm{e}^{-2x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{4}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{\mathrm{e}^{-4x}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-2x}\right) + c_2\left(\mathrm{e}^{-2x}(x)\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{-2x} + x\,\mathrm{e}^{-2x} c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$3 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -2c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-2x} - 2x\,\mathrm{e}^{-2x} c_2$$

substituting $y' = 7$ and $x = 0$ in the above gives

$$7 = -2c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 3 \\ c_2 &= 13 \end{aligned}$$

Substituting these values back in above solution results in

$$y = 13x\,\mathrm{e}^{-2x} + 3\,\mathrm{e}^{-2x}$$

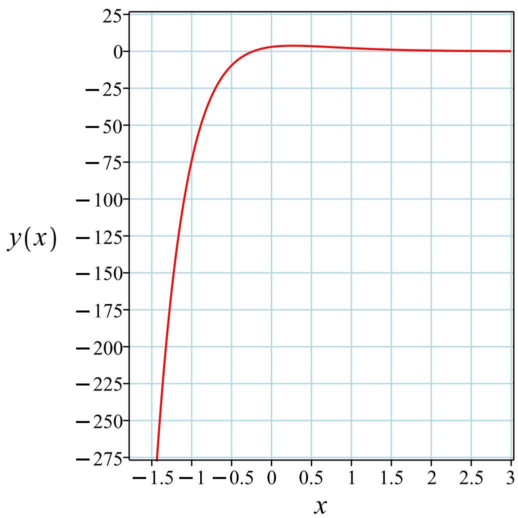
Which simplifies to

$$y = \mathrm{e}^{-2x}(3 + 13x)$$

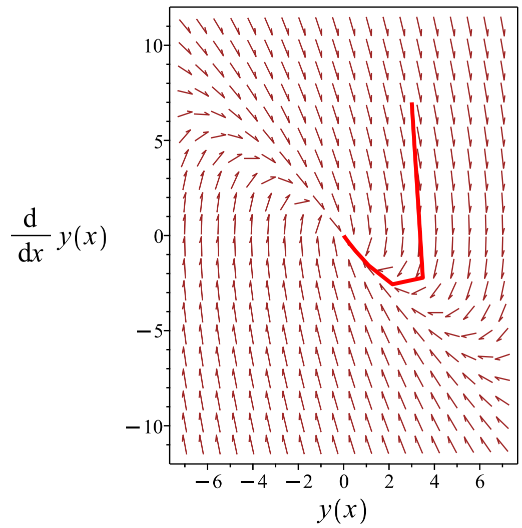
Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-2x}(3 + 13x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = e^{-2x}(3 + 13x)$$

Verified OK.

10.31.5 Maple step by step solution

Let's solve

$$\left[y'' + 4y' + 4y = 0, y(0) = 3, y'\Big|_{\{x=0\}} = 7\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 + 4r + 4 = 0$

- Factor the characteristic polynomial

  $(r + 2)^2 = 0$

- Root of the characteristic polynomial

  $r = -2$

- 1st solution of the ODE

$y_1(x) = e^{-2x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^{-2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{-2x} + x\,e^{-2x} c_2$

- ☐ Check validity of solution $y = c_1 e^{-2x} + x e^{-2x} c_2$
  - Use initial condition $y(0) = 3$

    $3 = c_1$
  - Compute derivative of the solution

    $y' = -2c_1 e^{-2x} + c_2 e^{-2x} - 2x\,e^{-2x} c_2$
  - Use the initial condition $y'\Big|_{\{x=0\}} = 7$

    $7 = -2c_1 + c_2$
  - Solve for c_1 and c_2

    $\{c_1 = 3, c_2 = 13\}$
  - Substitute constant values into general solution and simplify

    $y = e^{-2x}(3 + 13x)$

- Solution to the IVP

  $y = e^{-2x}(3 + 13x)$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{9y'' - 6y' + y = 0}$$

With initial conditions

$$[y(0) = 3, y'(0) = -1]$$

10.32.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -\frac{2}{3} \\ q(x) &= \frac{1}{9} \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - \frac{2y'}{3} + \frac{y}{9} = 0$$

The domain of $p(x) = -\frac{2}{3}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \frac{1}{9}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.32.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 9, B = -6, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$9\lambda^2 e^{\lambda x} - 6\lambda e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$9\lambda^2 - 6\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 9, B = -6, C = 1$ into the above gives

$$
\begin{aligned}
\lambda_{1,2} &= \frac{6}{(2)(9)} \pm \frac{1}{(2)(9)}\sqrt{(-6)^2 - (4)(9)(1)} \\
&= \frac{1}{3}
\end{aligned}
$$

Hence this is the case of a double root $\lambda_{1,2} = -\frac{1}{3}$. Therefore the solution is

$$
y = c_1 e^{\frac{x}{3}} + c_2 x\, e^{\frac{x}{3}} \tag{1}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 e^{\frac{x}{3}} + c_2 x\, e^{\frac{x}{3}} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$
3 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = \frac{c_1 e^{\frac{x}{3}}}{3} + c_2 e^{\frac{x}{3}} + \frac{c_2 x\, e^{\frac{x}{3}}}{3}
$$

substituting $y' = -1$ and $x = 0$ in the above gives

$$
-1 = \frac{c_1}{3} + c_2 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 3 \\
c_2 &= -2
\end{aligned}
$$

Substituting these values back in above solution results in

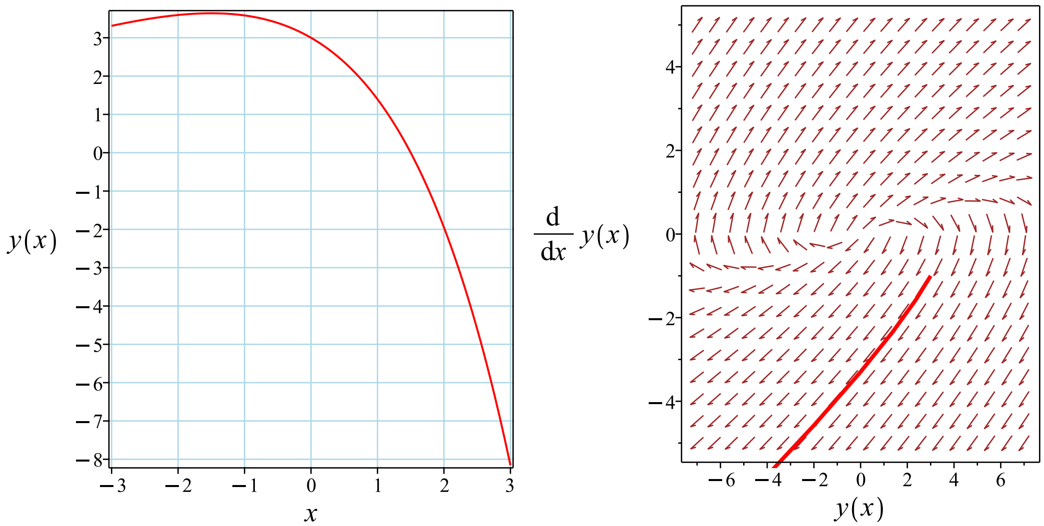
$$
y = -2x\, e^{\frac{x}{3}} + 3\, e^{\frac{x}{3}}
$$

Which simplifies to

$$
y = e^{\frac{x}{3}}(-2x + 3)
$$

Summary
The solution(s) found are the following

$$y = e^{\frac{x}{3}}(-2x+3) \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = e^{\frac{x}{3}}(-2x+3)$$

Verified OK.

10.32.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)$$

Where $p(x) = -\frac{2}{3}$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int -\frac{2}{3}\,dx} \\ &= e^{-\frac{x}{3}} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= 0 \\
\left(e^{-\frac{x}{3}}y\right)'' &= 0
\end{aligned}
$$

Integrating once gives

$$
\left(e^{-\frac{x}{3}}y\right)' = c_1
$$

Integrating again gives

$$
\left(e^{-\frac{x}{3}}y\right) = c_1x + c_2
$$

Hence the solution is

$$
y = \frac{c_1x + c_2}{e^{-\frac{x}{3}}}
$$

Or

$$
y = c_1x\,e^{\frac{x}{3}} + c_2e^{\frac{x}{3}}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1x\,e^{\frac{x}{3}} + c_2e^{\frac{x}{3}} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$
3 = c_2 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = c_1e^{\frac{x}{3}} + \frac{c_1x\,e^{\frac{x}{3}}}{3} + \frac{c_2e^{\frac{x}{3}}}{3}
$$

substituting $y' = -1$ and $x = 0$ in the above gives

$$
-1 = c_1 + \frac{c_2}{3} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= -2 \\
c_2 &= 3
\end{aligned}
$$

Substituting these values back in above solution results in

$$y = -2x\,e^{\frac{x}{3}} + 3\,e^{\frac{x}{3}}$$

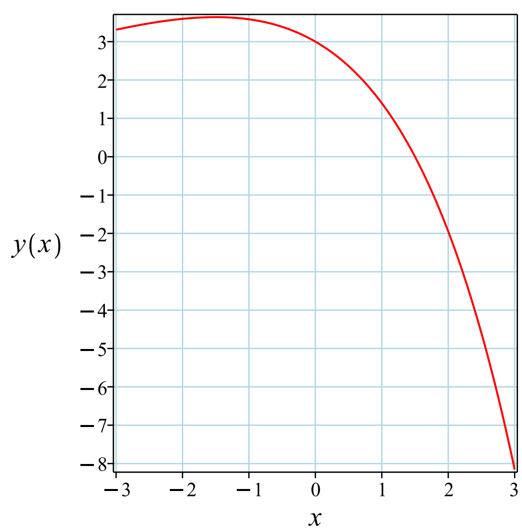
Which simplifies to

$$y = e^{\frac{x}{3}}(-2x+3)$$

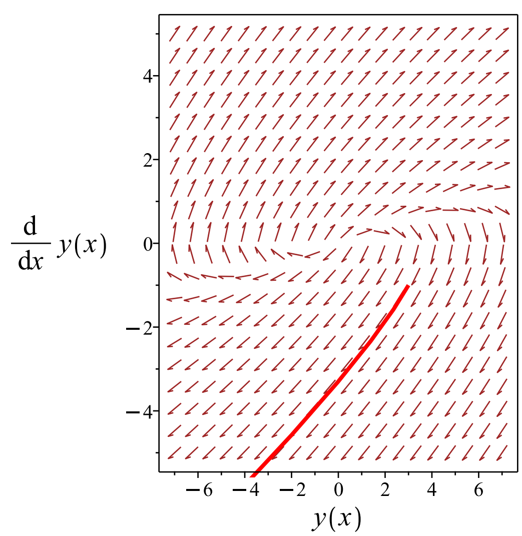
Summary

The solution(s) found are the following

$$y = e^{\frac{x}{3}}(-2x+3) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^{\frac{x}{3}}(-2x+3)$$

Verified OK.

10.32.4 Solving using Kovacic algorithm

Writing the ode as

$$9y'' - 6y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9 \\ B &= -6 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 325: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-6}{9}\,dx} \end{aligned}$$

$$
\begin{aligned}
&= z_1 e^{\frac{x}{3}} \\
&= z_1 \left(\mathrm{e}^{\frac{x}{3}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{\frac{x}{3}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-6}{9} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{\frac{2x}{3}}}{(y_1)^2} \, dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{\frac{x}{3}}\right) + c_2 \left(\mathrm{e}^{\frac{x}{3}}(x)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{\frac{x}{3}} + c_2 x \, \mathrm{e}^{\frac{x}{3}} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$
3 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = \frac{c_1 \mathrm{e}^{\frac{x}{3}}}{3} + c_2 \mathrm{e}^{\frac{x}{3}} + \frac{c_2 x \, \mathrm{e}^{\frac{x}{3}}}{3}
$$

substituting $y' = -1$ and $x = 0$ in the above gives

$$-1 = \frac{c_1}{3} + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 3$$
$$c_2 = -2$$

Substituting these values back in above solution results in

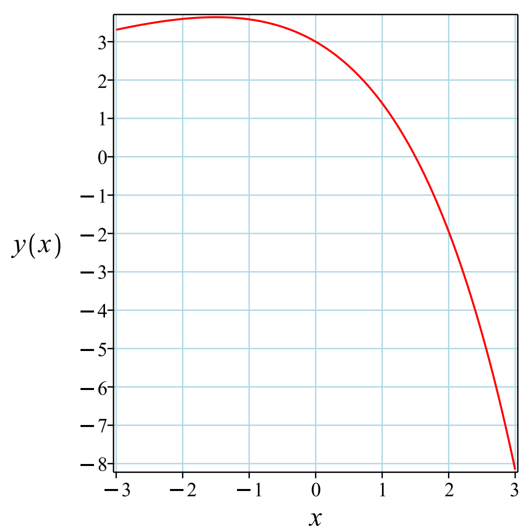
$$y = -2x\,\mathrm{e}^{\frac{x}{3}} + 3\,\mathrm{e}^{\frac{x}{3}}$$

Which simplifies to

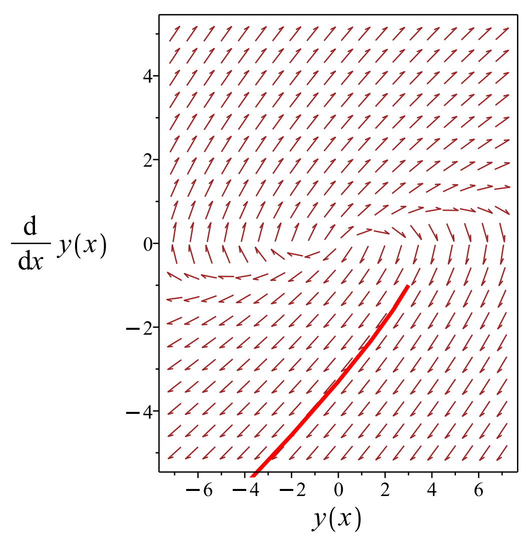
$$y = \mathrm{e}^{\frac{x}{3}}(-2x + 3)$$

Summary
The solution(s) found are the following

$$y = \mathrm{e}^{\frac{x}{3}}(-2x + 3) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \mathrm{e}^{\frac{x}{3}}(-2x + 3)$$

Verified OK.

10.32.5 Maple step by step solution

Let's solve

$\left[9y''-6y'+y=0, y(0)=3, y'\Big|_{\{x=0\}}=-1\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{2y'}{3}-\frac{y}{9}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{2y'}{3}+\frac{y}{9}=0$

- Characteristic polynomial of ODE

  $r^2-\frac{2}{3}r+\frac{1}{9}=0$

- Factor the characteristic polynomial

  $\frac{(3r-1)^2}{9}=0$

- Root of the characteristic polynomial

  $r=\frac{1}{3}$

- 1st solution of the ODE

  $y_1(x)=e^{\frac{x}{3}}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x)=x\,e^{\frac{x}{3}}$

- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)$

- Substitute in solutions

  $y=c_1e^{\frac{x}{3}}+c_2x\,e^{\frac{x}{3}}$

□ Check validity of solution $y=c_1e^{\frac{x}{3}}+c_2xe^{\frac{x}{3}}$

  ◦ Use initial condition $y(0)=3$

    $3=c_1$

  ◦ Compute derivative of the solution

    $y'=\frac{c_1e^{\frac{x}{3}}}{3}+c_2e^{\frac{x}{3}}+\frac{c_2x\,e^{\frac{x}{3}}}{3}$

- Use the initial condition $y'\Big|_{\{x=0\}} = -1$

  $-1 = \frac{c_1}{3} + c_2$
- Solve for c_1 and c_2

  $\{c_1 = 3, c_2 = -2\}$
- Substitute constant values into general solution and simplify

  $y = e^{\frac{x}{3}}(-2x + 3)$

- Solution to the IVP

  $y = e^{\frac{x}{3}}(-2x + 3)$

10.33.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -4 \\ q(x) &= 29 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - 4y' + 29y = 0$$

The domain of $p(x) = -4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 29$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.33.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 29$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 4\lambda\, e^{\lambda x} + 29\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 29 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 29$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-4^2 - (4)\,(1)\,(29)} \\
&= 2 \pm 5i
\end{aligned}$$

Hence

$$\begin{aligned}
\lambda_1 &= 2 + 5i \\
\lambda_2 &= 2 - 5i
\end{aligned}$$

Which simplifies to

$$\lambda_1 = 2 + 5i$$
$$\lambda_2 = 2 - 5i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 2$ and $\beta = 5$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{2x}(c_1 \cos(5x) + c_2 \sin(5x))$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{2x}(c_1 \cos(5x) + c_2 \sin(5x)) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2\,e^{2x}(c_1 \cos(5x) + c_2 \sin(5x)) + e^{2x}(-5c_1 \sin(5x) + 5c_2 \cos(5x))$$

substituting $y' = 5$ and $x = 0$ in the above gives

$$5 = 2c_1 + 5c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

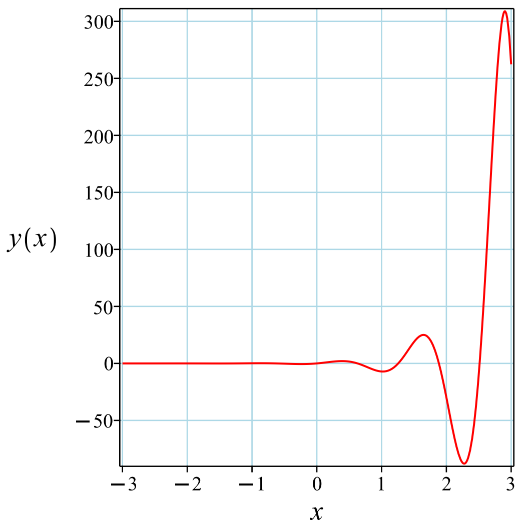
$$c_1 = 0$$
$$c_2 = 1$$

Substituting these values back in above solution results in

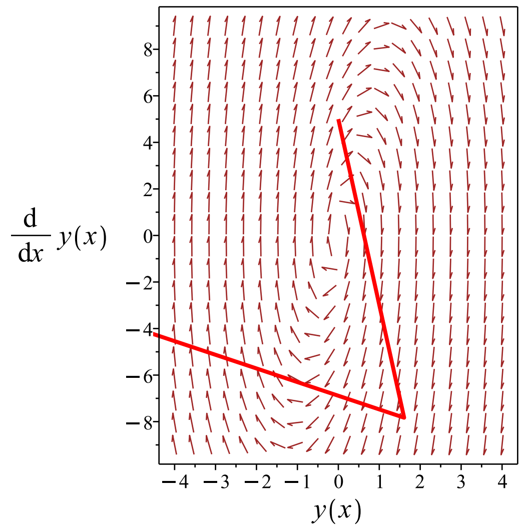
$$y = e^{2x}\sin(5x)$$

Summary
The solution(s) found are the following

$$y = e^{2x} \sin(5x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^{2x} \sin(5x)$$

Verified OK.

10.33.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 29y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 29 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-25}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -25 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -25z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 327: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -25$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(5x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx} \\
&= z_1 e^{2x} \\
&= z_1 \left(\mathrm{e}^{2x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2x}\cos(5x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{4x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\tan(5x)}{5}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{2x}\cos(5x)\right) + c_2\left(\mathrm{e}^{2x}\cos(5x)\left(\frac{\tan(5x)}{5}\right)\right)
\end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{2x}\cos(5x) + \frac{\mathrm{e}^{2x} c_2 \sin(5x)}{5} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2c_1 \mathrm{e}^{2x}\cos(5x) - 5c_1 \mathrm{e}^{2x}\sin(5x) + \frac{2\,\mathrm{e}^{2x} c_2 \sin(5x)}{5} + \mathrm{e}^{2x} c_2 \cos(5x)$$

substituting $y' = 5$ and $x = 0$ in the above gives

$$5 = 2c_1 + c_2 \tag{2A}$$

Equations $\{1A, 2A\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned}
c_1 &= 0 \\
c_2 &= 5
\end{aligned}$$

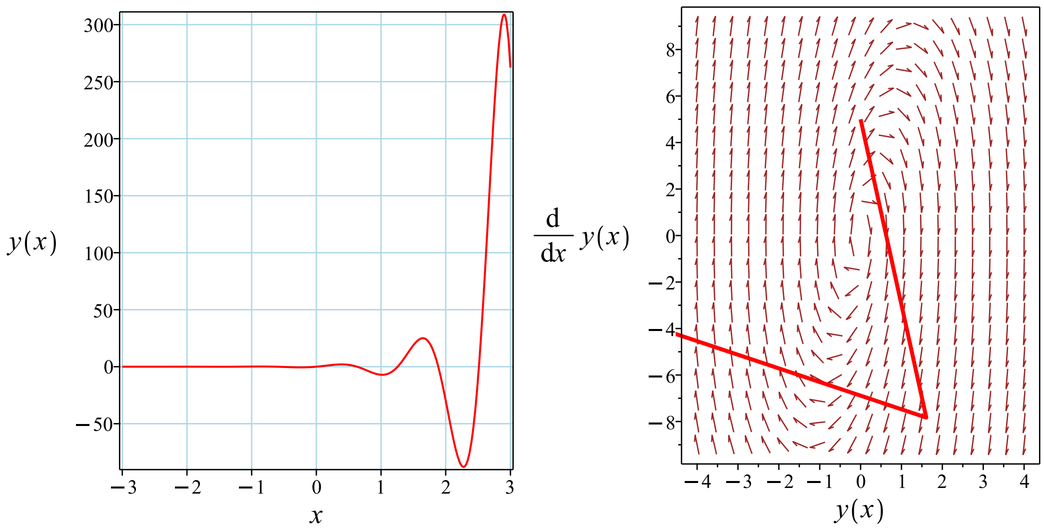
Substituting these values back in above solution results in

$$y = \mathrm{e}^{2x}\sin(5x)$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{2x}\sin(5x) \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = e^{2x} \sin(5x)$$

Verified OK.

10.33.4 Maple step by step solution

Let's solve

$$\left[y'' - 4y' + 29y = 0, y(0) = 0, y'\Big|_{\{x=0\}} = 5\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 4r + 29 = 0$

- Use quadratic formula to solve for r

  $r = \frac{4 \pm (\sqrt{-100})}{2}$

- Roots of the characteristic polynomial

  $r = (2 - 5\,\mathrm{I}, 2 + 5\,\mathrm{I})$

- 1st solution of the ODE

$y_1(x) = e^{2x} \cos(5x)$

- 2nd solution of the ODE

  $y_2(x) = e^{2x} \sin(5x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{2x} \cos(5x) + e^{2x} c_2 \sin(5x)$

- ☐ Check validity of solution $y = c_1 e^{2x} \cos(5x) + e^{2x} c_2 \sin(5x)$

  - Use initial condition $y(0) = 0$

    $0 = c_1$

  - Compute derivative of the solution

    $y' = 2c_1 e^{2x} \cos(5x) - 5c_1 e^{2x} \sin(5x) + 2 e^{2x} c_2 \sin(5x) + 5 e^{2x} c_2 \cos(5x)$

  - Use the initial condition $y'\big|_{\{x=0\}} = 5$

    $5 = 2c_1 + 5c_2$

  - Solve for c_1 and c_2

    $\{c_1 = 0, c_2 = 1\}$

  - Substitute constant values into general solution and simplify

    $y = e^{2x} \sin(5x)$

- Solution to the IVP

  $y = e^{2x} \sin(5x)$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 6y' + 58y = 0}$$

With initial conditions

$$[y(0) = -1, y'(0) = 5]$$

10.34.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 6 \\ q(x) &= 58 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + 6y' + 58y = 0$$

The domain of $p(x) = 6$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 58$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.34.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 6, C = 58$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 6\lambda\,\mathrm{e}^{\lambda x} + 58\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 6\lambda + 58 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 6, C = 58$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-6}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{6^2 - (4)\,(1)\,(58)} \\ &= -3 \pm 7i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -3 + 7i \\ \lambda_2 &= -3 - 7i\end{aligned}$$

Which simplifies to

$$\lambda_1 = -3 + 7i$$
$$\lambda_2 = -3 - 7i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -3$ and $\beta = 7$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-3x}(c_1 \cos(7x) + c_2 \sin(7x))$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \mathrm{e}^{-3x}(c_1 \cos(7x) + c_2 \sin(7x)) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -1$ and $x = 0$ in the above gives

$$-1 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -3\,\mathrm{e}^{-3x}(c_1 \cos(7x) + c_2 \sin(7x)) + \mathrm{e}^{-3x}(-7c_1 \sin(7x) + 7c_2 \cos(7x))$$

substituting $y' = 5$ and $x = 0$ in the above gives

$$5 = -3c_1 + 7c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -1$$
$$c_2 = \frac{2}{7}$$

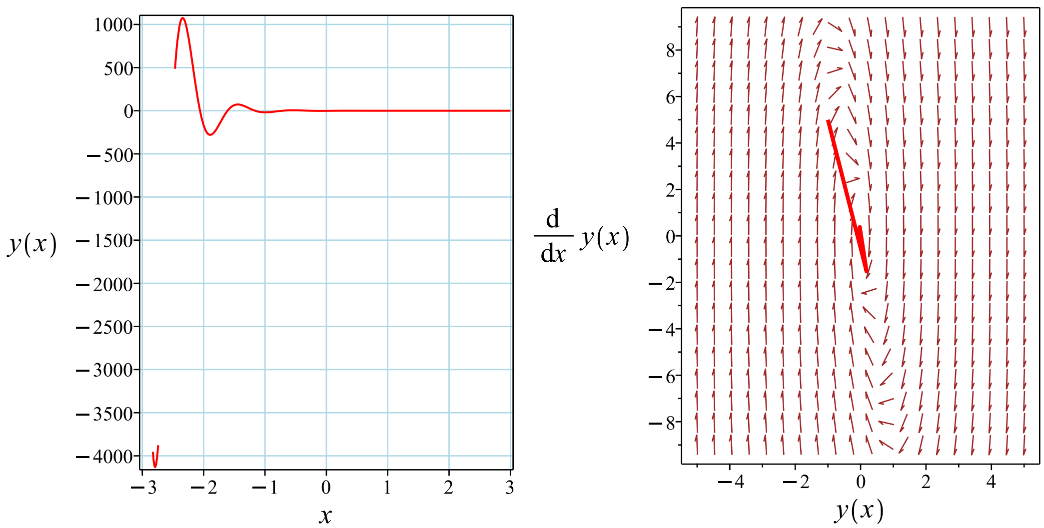
Substituting these values back in above solution results in

$$y = -\frac{e^{-3x}(7\cos(7x) - 2\sin(7x))}{7}$$

Summary

The solution(s) found are the following

$$y = -\frac{e^{-3x}(7\cos(7x) - 2\sin(7x))}{7} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = -\frac{e^{-3x}(7\cos(7x) - 2\sin(7x))}{7}$$

Verified OK.

10.34.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 6y' + 58y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 6 \\
C &= 58
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-49}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -49 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = -49 z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 329: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -49$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(7x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{6}{1}\, dx} \\
&= z_1 e^{-3x} \\
&= z_1 \left(\mathrm{e}^{-3x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x} \cos(7x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{6}{1} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-6x}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{\tan(7x)}{7} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-3x} \cos(7x) \right) + c_2 \left(\mathrm{e}^{-3x} \cos(7x) \left(\frac{\tan(7x)}{7} \right) \right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{-3x} \cos(7x) + \frac{c_2 \mathrm{e}^{-3x} \sin(7x)}{7} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -1$ and $x = 0$ in the above gives

$$-1 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -3c_1 \mathrm{e}^{-3x} \cos(7x) - 7c_1 \mathrm{e}^{-3x} \sin(7x) - \frac{3c_2 \mathrm{e}^{-3x} \sin(7x)}{7} + c_2 \mathrm{e}^{-3x} \cos(7x)$$

substituting $y' = 5$ and $x = 0$ in the above gives

$$5 = -3c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -1$$
$$c_2 = 2$$

Substituting these values back in above solution results in

$$y = -\mathrm{e}^{-3x} \cos(7x) + \frac{2\,\mathrm{e}^{-3x} \sin(7x)}{7}$$

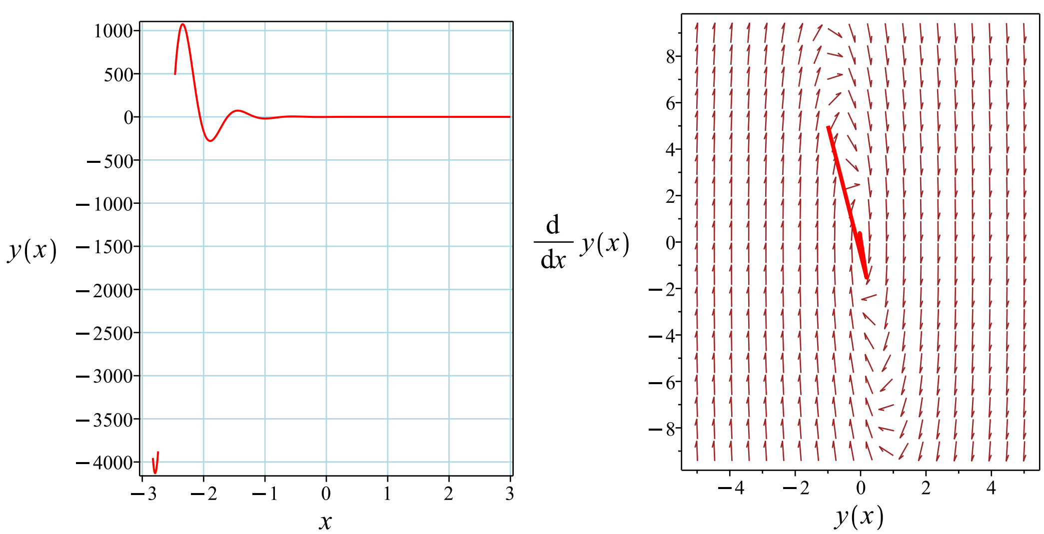
Which simplifies to

$$y = -\frac{\mathrm{e}^{-3x}(7\cos(7x) - 2\sin(7x))}{7}$$

Summary

The solution(s) found are the following

$$y = -\frac{\mathrm{e}^{-3x}(7\cos(7x) - 2\sin(7x))}{7} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = -\frac{\mathrm{e}^{-3x}(7\cos(7x) - 2\sin(7x))}{7}$$

Verified OK.

10.34.4 Maple step by step solution

Let's solve

10.35.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 6 \\ q(x) &= 13 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + 6y' + 13y = 0$$

The domain of $p(x) = 6$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 13$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.35.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 6, C = 13$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 6\lambda\, e^{\lambda x} + 13\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 6\lambda + 13 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 6, C = 13$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-6}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{6^2 - (4)\,(1)\,(13)}\\ &= -3 \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -3 + 2i\\ \lambda_2 &= -3 - 2i\end{aligned}$$

Which simplifies to

$$
\lambda_1 = -3 + 2i
$$
$$
\lambda_2 = -3 - 2i
$$

Since roots are complex conjugate of each others, then let the roots be

$$
\lambda_{1,2} = \alpha \pm i\beta
$$

Where $\alpha = -3$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$
y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))
$$

Which becomes

$$
y = e^{-3x}(c_1 \cos(2x) + c_2 \sin(2x))
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \mathrm{e}^{-3x}(c_1 \cos(2x) + c_2 \sin(2x)) \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$
3 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -3\,\mathrm{e}^{-3x}(c_1 \cos(2x) + c_2 \sin(2x)) + \mathrm{e}^{-3x}(-2c_1 \sin(2x) + 2c_2 \cos(2x))
$$

substituting $y' = -1$ and $x = 0$ in the above gives

$$
-1 = -3c_1 + 2c_2 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
c_1 = 3
$$
$$
c_2 = 4
$$

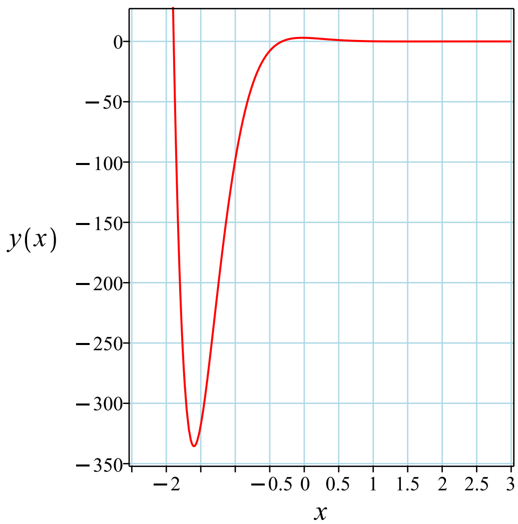
Substituting these values back in above solution results in

$$
y = \mathrm{e}^{-3x}(3\cos(2x) + 4\sin(2x))
$$

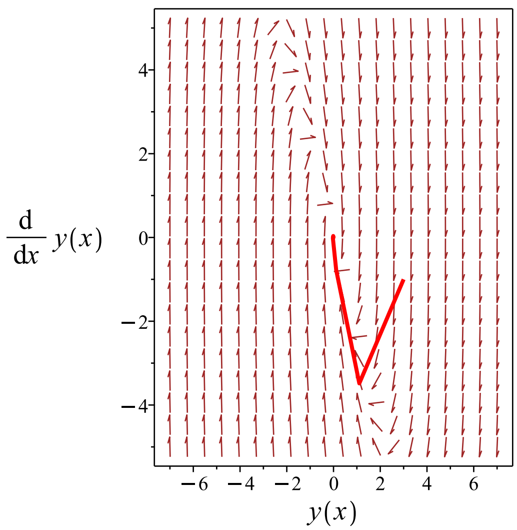
Summary

The solution(s) found are the following

$$y = e^{-3x}(3\cos(2x) + 4\sin(2x)) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^{-3x}(3\cos(2x) + 4\sin(2x))$$

Verified OK.

10.35.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 6y' + 13y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 6 \\ C &= 13 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 331: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{6}{1}\,dx} \\ &= z_1 e^{-3x} \\ &= z_1\left(\mathrm{e}^{-3x}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x}\cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{6}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-6x}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\tan(2x)}{2}\right)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-3x} \cos(2x)\right) + c_2 \left(\mathrm{e}^{-3x} \cos(2x) \left(\frac{\tan(2x)}{2}\right)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{-3x} \cos(2x) + \frac{c_2 \mathrm{e}^{-3x} \sin(2x)}{2} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$
3 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -3c_1 \mathrm{e}^{-3x} \cos(2x) - 2c_1 \mathrm{e}^{-3x} \sin(2x) - \frac{3c_2 \mathrm{e}^{-3x} \sin(2x)}{2} + c_2 \mathrm{e}^{-3x} \cos(2x)
$$

substituting $y' = -1$ and $x = 0$ in the above gives

$$
-1 = -3c_1 + c_2 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 3 \\
c_2 &= 8
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = 3\,\mathrm{e}^{-3x} \cos(2x) + 4\,\mathrm{e}^{-3x} \sin(2x)
$$

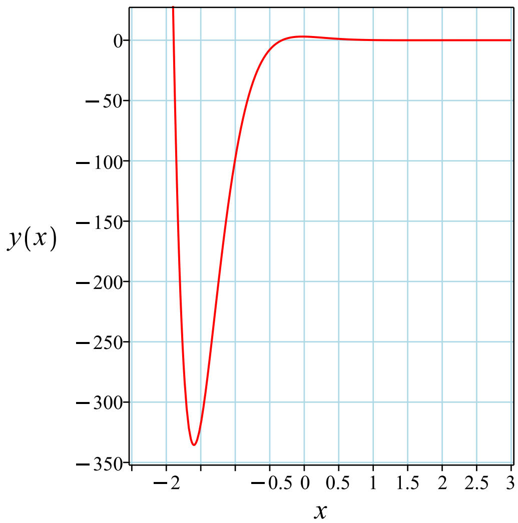
Which simplifies to

$$
y = \mathrm{e}^{-3x} (3 \cos(2x) + 4 \sin(2x))
$$

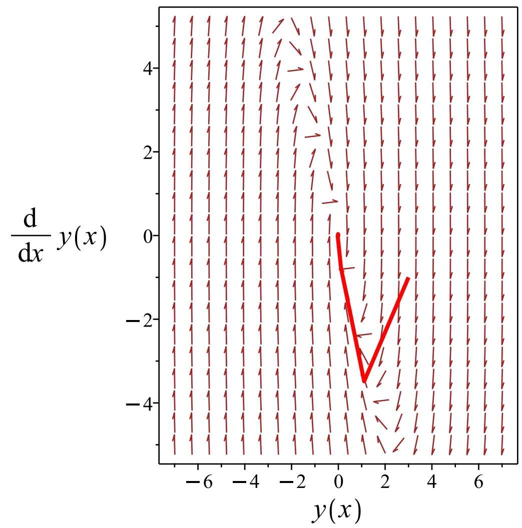
Summary

The solution(s) found are the following

$$
y = \mathrm{e}^{-3x} (3 \cos(2x) + 4 \sin(2x)) \tag{1}
$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^{-3x}(3\cos(2x) + 4\sin(2x))$$

Verified OK.

10.35.4 Maple step by step solution

Let's solve

$\left[y'' + 6y' + 13y = 0, y(0) = 3, y'\Big|_{\{x=0\}} = -1\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 + 6r + 13 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-6)\pm(\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r = (-3 - 2\,\mathrm{I}, -3 + 2\,\mathrm{I})$

- 1st solution of the ODE

$y_1(x) = e^{-3x} \cos(2x)$

- 2nd solution of the ODE

  $y_2(x) = e^{-3x} \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{-3x} \cos(2x) + c_2 e^{-3x} \sin(2x)$

☐ Check validity of solution $y = c_1 e^{-3x} \cos(2x) + c_2 e^{-3x} \sin(2x)$

  ◦ Use initial condition $y(0) = 3$

    $3 = c_1$

  ◦ Compute derivative of the solution

    $y' = -3c_1 e^{-3x} \cos(2x) - 2c_1 e^{-3x} \sin(2x) - 3c_2 e^{-3x} \sin(2x) + 2c_2 e^{-3x} \cos(2x)$

  ◦ Use the initial condition $y'\Big|_{\{x=0\}} = -1$

    $-1 = -3c_1 + 2c_2$

  ◦ Solve for c_1 and c_2

    $\{c_1 = 3, c_2 = 4\}$

  ◦ Substitute constant values into general solution and simplify

    $y = e^{-3x}(3\cos(2x) + 4\sin(2x))$

- Solution to the IVP

  $y = e^{-3x}(3\cos(2x) + 4\sin(2x))$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 2y' + 5y = 0}$$

With initial conditions

$$[y(0) = 2, y'(0) = 6]$$

10.36.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 2 \\ q(x) &= 5 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + 2y' + 5y = 0$$

The domain of $p(x) = 2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 5$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.36.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda\, e^{\lambda x} + 5\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{2^2 - (4)\,(1)\,(5)}\\ &= -1 \pm 2i\end{aligned}$$

Hence

$$\lambda_1 = -1 + 2i$$
$$\lambda_2 = -1 - 2i$$

Which simplifies to

$$\lambda_1 = -1 + 2i$$
$$\lambda_2 = -1 - 2i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -1$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x))$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \mathrm{e}^{-x}(c_1 \cos(2x) + c_2 \sin(2x)) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\mathrm{e}^{-x}(c_1 \cos(2x) + c_2 \sin(2x)) + \mathrm{e}^{-x}(-2c_1 \sin(2x) + 2c_2 \cos(2x))$$

substituting $y' = 6$ and $x = 0$ in the above gives

$$6 = -c_1 + 2c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 2$$
$$c_2 = 4$$

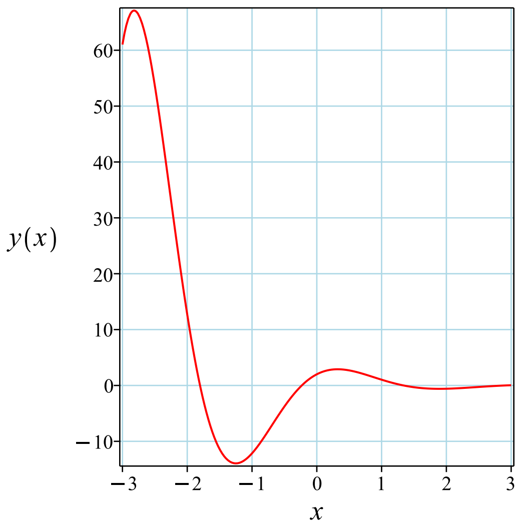
Substituting these values back in above solution results in

$$y = 2\,\mathrm{e}^{-x}(\cos(2x) + 2\sin(2x))$$

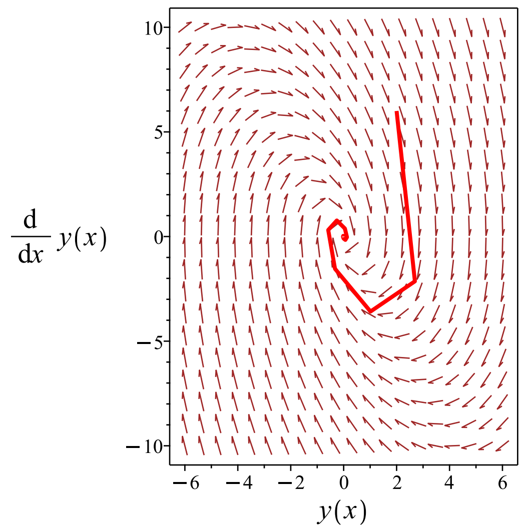
Summary

The solution(s) found are the following

$$y = 2\,e^{-x}(\cos(2x) + 2\sin(2x)) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 2\,e^{-x}(\cos(2x) + 2\sin(2x))$$

Verified OK.

10.36.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 333: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\ &= z_1 e^{-x} \\ &= z_1\left(\mathrm{e}^{-x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}\cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-2x}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\tan(2x)}{2}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-x}\cos(2x)\right) + c_2\left(\mathrm{e}^{-x}\cos(2x)\left(\frac{\tan(2x)}{2}\right)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{-x}\cos(2x) + \frac{c_2 \mathrm{e}^{-x}\sin(2x)}{2} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$
2 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -c_1 \mathrm{e}^{-x}\cos(2x) - 2c_1 \mathrm{e}^{-x}\sin(2x) - \frac{c_2 \mathrm{e}^{-x}\sin(2x)}{2} + c_2 \mathrm{e}^{-x}\cos(2x)
$$

substituting $y' = 6$ and $x = 0$ in the above gives

$$
6 = -c_1 + c_2 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 2 \\
c_2 &= 8
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = 2\,\mathrm{e}^{-x}\cos(2x) + 4\,\mathrm{e}^{-x}\sin(2x)
$$

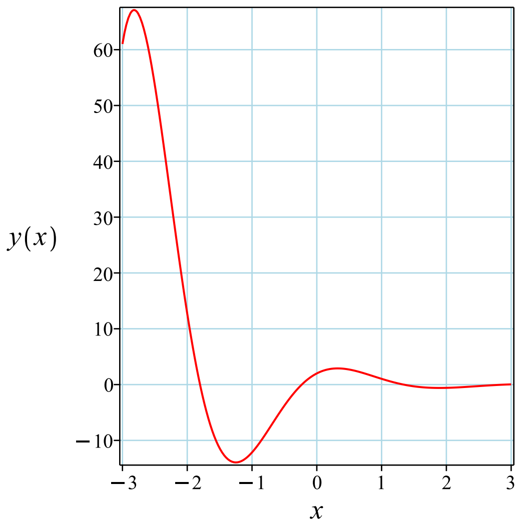
Which simplifies to

$$
y = 2\,\mathrm{e}^{-x}(\cos(2x) + 2\sin(2x))
$$

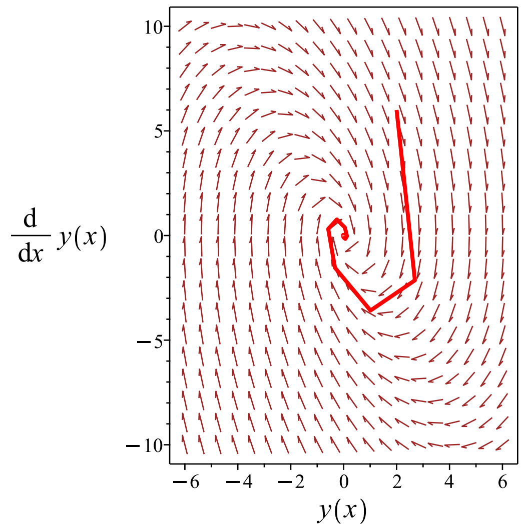
Summary

The solution(s) found are the following

$$
y = 2\,\mathrm{e}^{-x}(\cos(2x) + 2\sin(2x)) \tag{1}
$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 2\,\mathrm{e}^{-x}(\cos(2x) + 2\sin(2x))$$

Verified OK.

10.37.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= \frac{2}{3} \\ q(x) &= \frac{5}{9} \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + \frac{2y'}{3} + \frac{5y}{9} = 0$$

The domain of $p(x) = \frac{2}{3}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \frac{5}{9}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.37.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 9, B = 6, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$9\lambda^2 e^{\lambda x} + 6\lambda \, e^{\lambda x} + 5 \, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$9\lambda^2 + 6\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 9, B = 6, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-6}{(2)\,(9)} \pm \frac{1}{(2)\,(9)}\sqrt{6^2 - (4)\,(9)\,(5)} \\ &= -\frac{1}{3} \pm \frac{2i}{3}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{1}{3} + \frac{2i}{3} \\ \lambda_2 &= -\frac{1}{3} - \frac{2i}{3}\end{aligned}$$

Which simplifies to

$$\lambda_1 = -\frac{1}{3} + \frac{2i}{3}$$
$$\lambda_2 = -\frac{1}{3} - \frac{2i}{3}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -\frac{1}{3}$ and $\beta = \frac{2}{3}$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-\frac{x}{3}}\left(c_1 \cos\left(\frac{2x}{3}\right) + c_2 \sin\left(\frac{2x}{3}\right)\right)$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \mathrm{e}^{-\frac{x}{3}}\left(c_1 \cos\left(\frac{2x}{3}\right) + c_2 \sin\left(\frac{2x}{3}\right)\right) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 6$ and $x = 0$ in the above gives

$$6 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{\mathrm{e}^{-\frac{x}{3}}\left(c_1 \cos\left(\frac{2x}{3}\right) + c_2 \sin\left(\frac{2x}{3}\right)\right)}{3} + \mathrm{e}^{-\frac{x}{3}}\left(-\frac{2c_1 \sin\left(\frac{2x}{3}\right)}{3} + \frac{2c_2 \cos\left(\frac{2x}{3}\right)}{3}\right)$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -\frac{c_1}{3} + \frac{2c_2}{3} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 6 \\
c_2 &= 3
\end{aligned}
$$

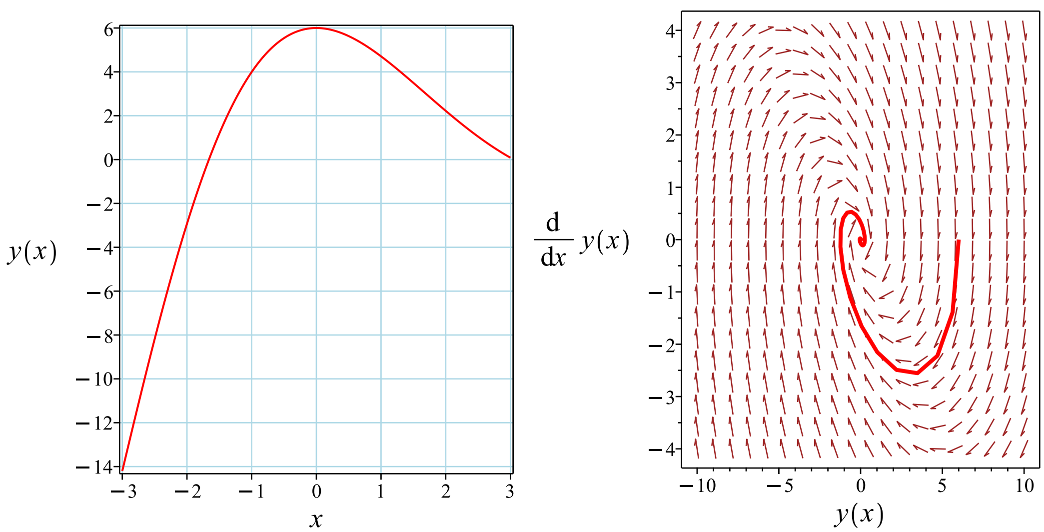
Substituting these values back in above solution results in

$$
y = 3\,\mathrm{e}^{-\frac{x}{3}} \left(2\cos\left(\frac{2x}{3}\right) + \sin\left(\frac{2x}{3}\right)\right)
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = 3\,\mathrm{e}^{-\frac{x}{3}} \left(2\cos\left(\frac{2x}{3}\right) + \sin\left(\frac{2x}{3}\right)\right) \tag{1}
$$



(a) Solution plot

(b) Slope field plot

<u>Verification of solutions</u>

$$
y = 3\,\mathrm{e}^{-\frac{x}{3}} \left(2\cos\left(\frac{2x}{3}\right) + \sin\left(\frac{2x}{3}\right)\right)
$$

Verified OK.

10.37.3 Solving using Kovacic algorithm

Writing the ode as

$$9y'' + 6y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9 \\ B &= 6 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{9} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 9 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -\frac{4z(x)}{9} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 335: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -\frac{4}{9}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos\left(\frac{2x}{3}\right)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{6}{9}\,dx} \\
&= z_1 e^{-\frac{x}{3}} \\
&= z_1 \left(\mathrm{e}^{-\frac{x}{3}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-\frac{x}{3}} \cos\left(\frac{2x}{3}\right)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{6}{9}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{2x}{3}}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{3\tan\left(\frac{2x}{3}\right)}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-\frac{x}{3}}\cos\left(\frac{2x}{3}\right)\right) + c_2\left(\mathrm{e}^{-\frac{x}{3}}\cos\left(\frac{2x}{3}\right)\left(\frac{3\tan\left(\frac{2x}{3}\right)}{2}\right)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{-\frac{x}{3}} \cos\left(\frac{2x}{3}\right) + \frac{3c_2 \mathrm{e}^{-\frac{x}{3}} \sin\left(\frac{2x}{3}\right)}{2} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 6$ and $x = 0$ in the above gives

$$6 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{c_1 \mathrm{e}^{-\frac{x}{3}} \cos\left(\frac{2x}{3}\right)}{3} - \frac{2c_1 \mathrm{e}^{-\frac{x}{3}} \sin\left(\frac{2x}{3}\right)}{3} - \frac{c_2 \mathrm{e}^{-\frac{x}{3}} \sin\left(\frac{2x}{3}\right)}{2} + c_2 \mathrm{e}^{-\frac{x}{3}} \cos\left(\frac{2x}{3}\right)$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -\frac{c_1}{3} + c_2 \tag{2A}$$

Equations $\{1A, 2A\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 6 \\ c_2 &= 2 \end{aligned}$$

Substituting these values back in above solution results in

$$y = 6\,\mathrm{e}^{-\frac{x}{3}} \cos\left(\frac{2x}{3}\right) + 3\,\mathrm{e}^{-\frac{x}{3}} \sin\left(\frac{2x}{3}\right)$$

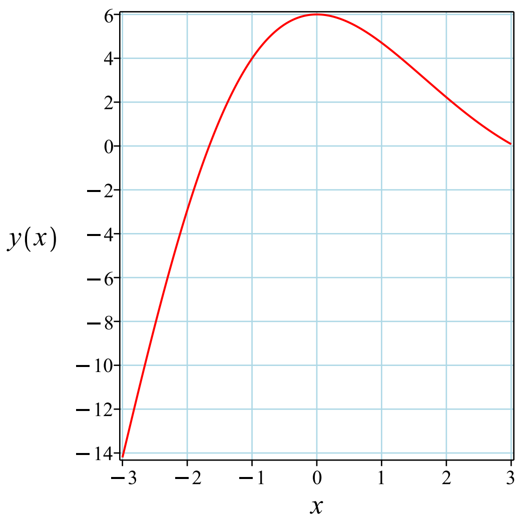
Which simplifies to

$$y = 3\,\mathrm{e}^{-\frac{x}{3}} \left(2 \cos\left(\frac{2x}{3}\right) + \sin\left(\frac{2x}{3}\right)\right)$$

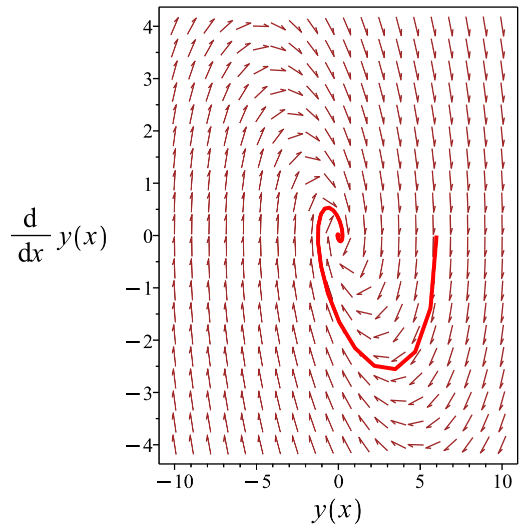
Summary

The solution(s) found are the following

$$y = 3\,\mathrm{e}^{-\frac{x}{3}} \left(2 \cos\left(\frac{2x}{3}\right) + \sin\left(\frac{2x}{3}\right)\right) \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = 3\,\mathrm{e}^{-\frac{x}{3}}\left(2\cos\left(\frac{2x}{3}\right)+\sin\left(\frac{2x}{3}\right)\right)$$

Verified OK.

10.37.4 Maple step by step solution

Let's solve

$$\left[9y''+6y'+5y=0, y(0)=6, y'\Big|_{\{x=0\}}=0\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{2y'}{3}-\frac{5y}{9}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{2y'}{3}+\frac{5y}{9}=0$

- Characteristic polynomial of ODE

  $r^2+\frac{2}{3}r+\frac{5}{9}=0$

- Use quadratic formula to solve for r

$r = \frac{\left(-\frac{2}{3}\right)\pm\left(\sqrt{-\frac{16}{9}}\right)}{2}$

- Roots of the characteristic polynomial

  $r = \left(-\frac{1}{3}-\frac{2\,\mathrm{I}}{3}, -\frac{1}{3}+\frac{2\,\mathrm{I}}{3}\right)$

- 1st solution of the ODE

  $y_1(x) = \mathrm{e}^{-\frac{x}{3}}\cos\left(\frac{2x}{3}\right)$

- 2nd solution of the ODE

  $y_2(x) = \mathrm{e}^{-\frac{x}{3}}\sin\left(\frac{2x}{3}\right)$

- General solution of the ODE

  $y = c_1y_1(x) + c_2y_2(x)$

- Substitute in solutions

  $y = c_1\mathrm{e}^{-\frac{x}{3}}\cos\left(\frac{2x}{3}\right) + c_2\mathrm{e}^{-\frac{x}{3}}\sin\left(\frac{2x}{3}\right)$

☐ Check validity of solution $y = c_1\mathrm{e}^{-\frac{x}{3}}\cos\left(\frac{2x}{3}\right) + c_2\mathrm{e}^{-\frac{x}{3}}\sin\left(\frac{2x}{3}\right)$

  - Use initial condition $y(0) = 6$

    $6 = c_1$

  - Compute derivative of the solution

    $y' = -\frac{c_1\mathrm{e}^{-\frac{x}{3}}\cos\left(\frac{2x}{3}\right)}{3} - \frac{2c_1\mathrm{e}^{-\frac{x}{3}}\sin\left(\frac{2x}{3}\right)}{3} - \frac{c_2\mathrm{e}^{-\frac{x}{3}}\sin\left(\frac{2x}{3}\right)}{3} + \frac{2c_2\mathrm{e}^{-\frac{x}{3}}\cos\left(\frac{2x}{3}\right)}{3}$

  - Use the initial condition $y'\Big|_{\{x=0\}} = 0$

    $0 = -\frac{c_1}{3} + \frac{2c_2}{3}$

  - Solve for c_1 and c_2

    $\{c_1 = 6, c_2 = 3\}$

  - Substitute constant values into general solution and simplify

    $y = 3\,\mathrm{e}^{-\frac{x}{3}}\left(2\cos\left(\frac{2x}{3}\right) + \sin\left(\frac{2x}{3}\right)\right)$

- Solution to the IVP

  $y = 3\,\mathrm{e}^{-\frac{x}{3}}\left(2\cos\left(\frac{2x}{3}\right) + \sin\left(\frac{2x}{3}\right)\right)$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _missing_x]]`

$$\boxed{4y'' + 4y' + 37y = 0}$$

With initial conditions

$$[y(0) = 2, y'(0) = -4]$$

10.38.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$p(x) = 1$$
$$q(x) = \frac{37}{4}$$
$$F = 0$$

Hence the ode is

$$y'' + y' + \frac{37y}{4} = 0$$

The domain of $p(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \frac{37}{4}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.38.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 4, B = 4, C = 37$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$4\lambda^2 e^{\lambda x} + 4\lambda\, e^{\lambda x} + 37\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$4\lambda^2 + 4\lambda + 37 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 4, B = 4, C = 37$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-4}{(2)(4)} \pm \frac{1}{(2)(4)}\sqrt{4^2 - (4)(4)(37)}\\ &= -\frac{1}{2} \pm 3i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{1}{2} + 3i\\ \lambda_2 &= -\frac{1}{2} - 3i\end{aligned}$$

Which simplifies to

$$\lambda_1 = -\frac{1}{2} + 3i$$
$$\lambda_2 = -\frac{1}{2} - 3i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -\frac{1}{2}$ and $\beta = 3$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-\frac{x}{2}}(c_1 \cos(3x) + c_2 \sin(3x))$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \mathrm{e}^{-\frac{x}{2}}(c_1 \cos(3x) + c_2 \sin(3x)) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{\mathrm{e}^{-\frac{x}{2}}(c_1 \cos(3x) + c_2 \sin(3x))}{2} + \mathrm{e}^{-\frac{x}{2}}(-3c_1 \sin(3x) + 3c_2 \cos(3x))$$

substituting $y' = -4$ and $x = 0$ in the above gives

$$-4 = -\frac{c_1}{2} + 3c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 2$$
$$c_2 = -1$$

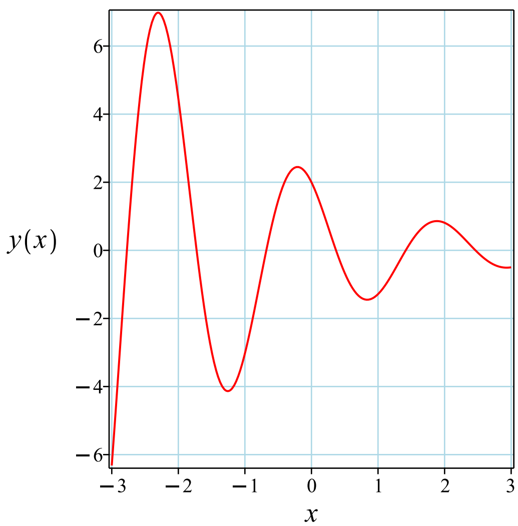
Substituting these values back in above solution results in

$$y = e^{-\frac{x}{2}}(2\cos(3x) - \sin(3x))$$

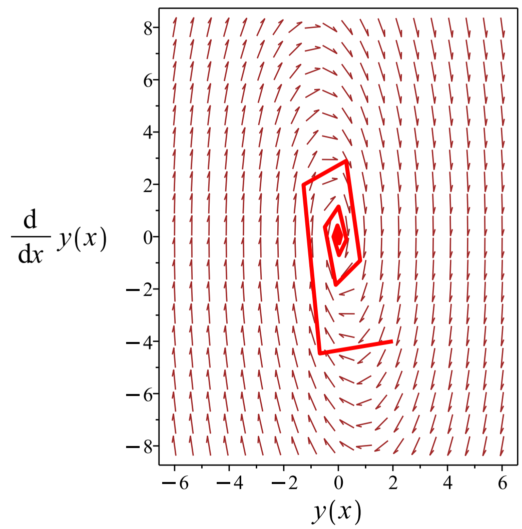
Summary

The solution(s) found are the following

$$y = e^{-\frac{x}{2}}(2\cos(3x) - \sin(3x)) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^{-\frac{x}{2}}(2\cos(3x) - \sin(3x))$$

Verified OK.

10.38.3 Solving using Kovacic algorithm

Writing the ode as

$$4y'' + 4y' + 37y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$A = 4$$
$$B = 4 \tag{3}$$
$$C = 37$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-9}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -9 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -9z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 337: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -9$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(3x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4}{4}\,dx} \\ &= z_1 e^{-\frac{x}{2}} \\ &= z_1\left(\mathrm{e}^{-\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x}{2}} \cos(3x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{4}{4} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-x}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{\tan(3x)}{3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-\frac{x}{2}} \cos(3x)\right) + c_2 \left(\mathrm{e}^{-\frac{x}{2}} \cos(3x) \left(\frac{\tan(3x)}{3}\right)\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{-\frac{x}{2}} \cos(3x) + \frac{c_2 \mathrm{e}^{-\frac{x}{2}} \sin(3x)}{3} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{c_1 \mathrm{e}^{-\frac{x}{2}} \cos(3x)}{2} - 3c_1 \mathrm{e}^{-\frac{x}{2}} \sin(3x) - \frac{c_2 \mathrm{e}^{-\frac{x}{2}} \sin(3x)}{6} + c_2 \mathrm{e}^{-\frac{x}{2}} \cos(3x)$$

substituting $y' = -4$ and $x = 0$ in the above gives

$$-4 = -\frac{c_1}{2} + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 2$$
$$c_2 = -3$$

Substituting these values back in above solution results in

$$y = 2\,\mathrm{e}^{-\frac{x}{2}} \cos(3x) - \mathrm{e}^{-\frac{x}{2}} \sin(3x)$$

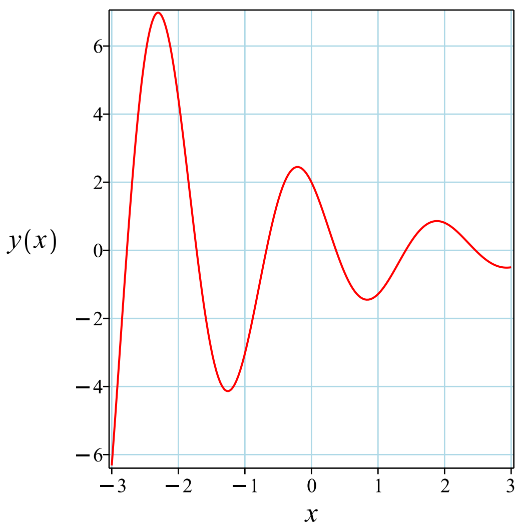
Which simplifies to

$$y = \mathrm{e}^{-\frac{x}{2}} (2\cos(3x) - \sin(3x))$$

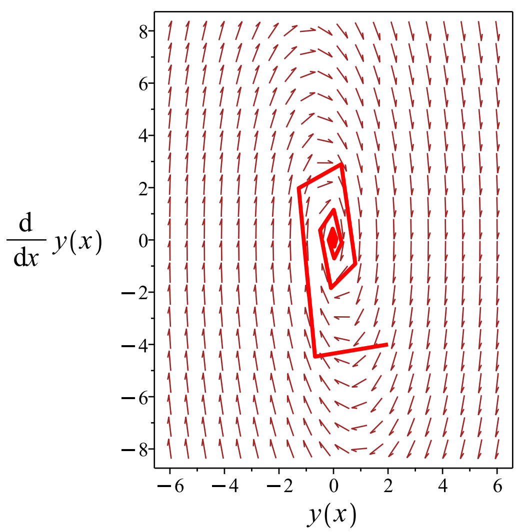
Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\frac{x}{2}} (2\cos(3x) - \sin(3x)) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \mathrm{e}^{-\frac{x}{2}} (2\cos(3x) - \sin(3x))$$

Verified OK.

10.38.4 Maple step by step solution

Let's solve

$$\left[4y'' + 4y' + 37y = 0, y(0) = 2, y'\Big|_{\{x=0\}} = -4\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -y' - \frac{37y}{4}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + y' + \frac{37y}{4} = 0$

- Characteristic polynomial of ODE

  $r^2 + r + \frac{37}{4} = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-1)\pm(\sqrt{-36})}{2}$

- Roots of the characteristic polynomial

  $r = \left(-\frac{1}{2} - 3\,\mathrm{I}, -\frac{1}{2} + 3\,\mathrm{I}\right)$

- 1st solution of the ODE

  $y_1(x) = \mathrm{e}^{-\frac{x}{2}} \cos(3x)$

- 2nd solution of the ODE

  $y_2(x) = \mathrm{e}^{-\frac{x}{2}} \sin(3x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 \mathrm{e}^{-\frac{x}{2}} \cos(3x) + c_2 \mathrm{e}^{-\frac{x}{2}} \sin(3x)$

□ Check validity of solution $y = c_1 \mathrm{e}^{-\frac{x}{2}} \cos(3x) + c_2 \mathrm{e}^{-\frac{x}{2}} \sin(3x)$

  ◦ Use initial condition $y(0) = 2$

    $2 = c_1$

  ◦ Compute derivative of the solution

    $y' = -\frac{c_1 \mathrm{e}^{-\frac{x}{2}} \cos(3x)}{2} - 3c_1 \mathrm{e}^{-\frac{x}{2}} \sin(3x) - \frac{c_2 \mathrm{e}^{-\frac{x}{2}} \sin(3x)}{2} + 3c_2 \mathrm{e}^{-\frac{x}{2}} \cos(3x)$

- Use the initial condition $y'\Big|_{\{x=0\}} = -4$

  $-4 = -\frac{c_1}{2} + 3c_2$
- Solve for c_1 and c_2

  $\{c_1 = 2, c_2 = -1\}$
- Substitute constant values into general solution and simplify

  $y = e^{-\frac{x}{2}}(2\cos(3x) - \sin(3x))$

- Solution to the IVP

  $y = e^{-\frac{x}{2}}(2\cos(3x) - \sin(3x))$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 39.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' - 6y'' + 11y' - 6y = 0}$$

With initial conditions

$$[y(0) = 0, y'(0) = 0, y''(0) = 2]$$

The characteristic equation is

$$\lambda^3 - 6\lambda^2 + 11\lambda - 6 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 2$$
$$\lambda_3 = 3$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + c_2 e^{2x} + c_3 e^{3x}$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= e^{x} \\
y_2 &= e^{2x} \\
y_3 &= e^{3x}
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = e^{x} c_1 + c_2 e^{2x} + c_3 e^{3x} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$
0 = c_1 + c_2 + c_3 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = e^{x} c_1 + 2 c_2 e^{2x} + 3 c_3 e^{3x}
$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$
0 = c_1 + 2c_2 + 3c_3 \tag{2A}
$$

Taking two derivatives of the solution gives

$$
y'' = e^{x} c_1 + 4 c_2 e^{2x} + 9 c_3 e^{3x}
$$

substituting $y'' = 2$ and $x = 0$ in the above gives

$$
2 = c_1 + 4c_2 + 9c_3 \tag{3A}
$$

Equations {1A,2A,3A} are now solved for $\{c_1, c_2, c_3\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 1 \\
c_2 &= -2 \\
c_3 &= 1
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = e^{x} - 2\, e^{2x} + e^{3x}
$$

Summary
The solution(s) found are the following

$$y = e^{x} - 2\,e^{2x} + e^{3x} \tag{1}$$

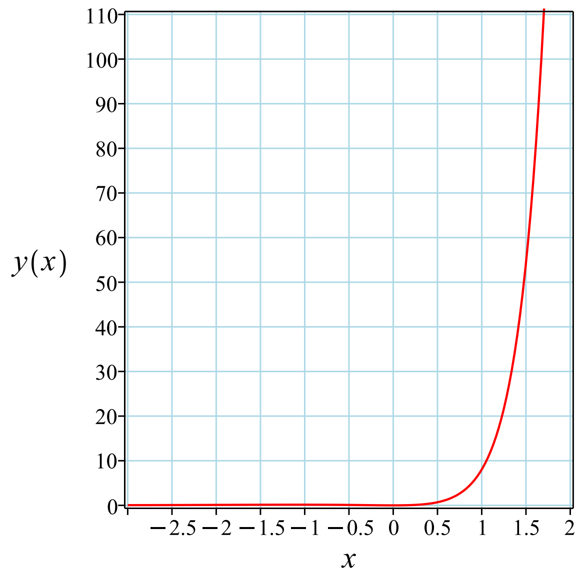

Figure 413: Solution plot

Verification of solutions

$$y = e^{x} - 2\,e^{2x} + e^{3x}$$

Verified OK.

10.39.1 Maple step by step solution

Let's solve

$$\left[y''' - 6y'' + 11y' - 6y = 0, y(0) = 0, y'\Big|_{\{x=0\}} = 0, y''\Big|_{\{x=0\}} = 2\right]$$

ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' - 2y'' + 4y' - 8y = 0}$$

With initial conditions

$$[y(0) = 2, y'(0) = 0, y''(0) = 0]$$

The characteristic equation is

$$\lambda^3 - 2\lambda^2 + 4\lambda - 8 = 0$$

The roots of the above equation are

$$\lambda_1 = 2$$
$$\lambda_2 = 2i$$
$$\lambda_3 = -2i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{2x} + e^{2ix} c_2 + e^{-2ix} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= \mathrm{e}^{2x} \\
y_2 &= \mathrm{e}^{2ix} \\
y_3 &= \mathrm{e}^{-2ix}
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{2x} + \mathrm{e}^{2ix} c_2 + \mathrm{e}^{-2ix} c_3 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$
2 = c_1 + c_2 + c_3 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = 2c_1 \mathrm{e}^{2x} + 2i\mathrm{e}^{2ix} c_2 - 2i\mathrm{e}^{-2ix} c_3
$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$
0 = 2c_2 i - 2c_3 i + 2c_1 \tag{2A}
$$

Taking two derivatives of the solution gives

$$
y'' = 4c_1 \mathrm{e}^{2x} - 4\,\mathrm{e}^{2ix} c_2 - 4\,\mathrm{e}^{-2ix} c_3
$$

substituting $y'' = 0$ and $x = 0$ in the above gives

$$
0 = 4c_1 - 4c_2 - 4c_3 \tag{3A}
$$

Equations {1A,2A,3A} are now solved for $\{c_1, c_2, c_3\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 1 \\
c_2 &= \frac{1}{2} + \frac{i}{2} \\
c_3 &= \frac{1}{2} - \frac{i}{2}
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \mathrm{e}^{2x} + \cos(2x) - \sin(2x)
$$

Summary

The solution(s) found are the following

$$y = e^{2x} + \cos(2x) - \sin(2x) \tag{1}$$

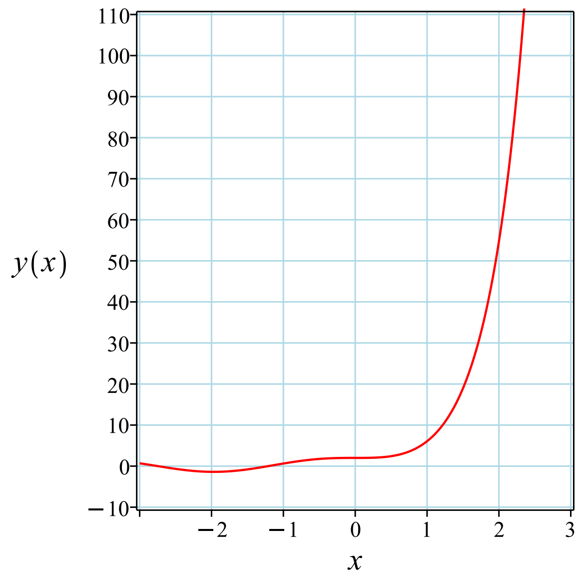

Figure 414: Solution plot

Verification of solutions

$$y = e^{2x} + \cos(2x) - \sin(2x)$$

Verified OK.

10.40.1 Maple step by step solution

Let's solve

$$\left[y''' - 2y'' + 4y' - 8y = 0, y(0) = 2, y'\Big|_{\{x=0\}} = 0, y''\Big|_{\{x=0\}} = 0\right]$$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(x)$

    $y_1(x) = y$

  - Define new variable $y_2(x)$

$y_2(x) = y'$

- Define new variable $y_3(x)$

  $y_3(x) = y''$

- Isolate for $y_3'(x)$ using original ODE

  $y_3'(x) = 2y_3(x) - 4y_2(x) + 8y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 2y_3(x) - 4y_2(x) + 8y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 8 & -4 & 2 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 8 & -4 & 2 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x)$

- To solve the system, find the eigenvalues and eigenvectors of A

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 41.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' - 3y'' + 4y = 0}$$

With initial conditions

$$[y(0) = 1, y'(0) = -8, y''(0) = -4]$$

The characteristic equation is

$$\lambda^3 - 3\lambda^2 + 4 = 0$$

The roots of the above equation are

$$\lambda_1 = -1$$
$$\lambda_2 = 2$$
$$\lambda_3 = 2$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 e^{2x} + x\, e^{2x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= \mathrm{e}^{-x} \\
y_2 &= \mathrm{e}^{2x} \\
y_3 &= \mathrm{e}^{2x} x
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{2x} + x\,\mathrm{e}^{2x} c_3 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$
1 = c_1 + c_2 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -c_1 \mathrm{e}^{-x} + 2c_2 \mathrm{e}^{2x} + \mathrm{e}^{2x} c_3 + 2x\,\mathrm{e}^{2x} c_3
$$

substituting $y' = -8$ and $x = 0$ in the above gives

$$
-8 = -c_1 + 2c_2 + c_3 \tag{2A}
$$

Taking two derivatives of the solution gives

$$
y'' = c_1 \mathrm{e}^{-x} + 4c_2 \mathrm{e}^{2x} + 4\,\mathrm{e}^{2x} c_3 + 4x\,\mathrm{e}^{2x} c_3
$$

substituting $y'' = -4$ and $x = 0$ in the above gives

$$
-4 = c_1 + 4c_2 + 4c_3 \tag{3A}
$$

Equations {1A,2A,3A} are now solved for $\{c_1, c_2, c_3\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= \frac{32}{9} \\
c_2 &= -\frac{23}{9} \\
c_3 &= \frac{2}{3}
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \frac{32\,\mathrm{e}^{-x}}{9} - \frac{23\,\mathrm{e}^{2x}}{9} + \frac{2\,\mathrm{e}^{2x} x}{3}
$$

Which simplifies to

$$y = \frac{(6x - 23)\,\mathrm{e}^{2x}}{9} + \frac{32\,\mathrm{e}^{-x}}{9}$$

Summary

The solution(s) found are the following

$$y = \frac{(6x - 23)\,\mathrm{e}^{2x}}{9} + \frac{32\,\mathrm{e}^{-x}}{9} \tag{1}$$

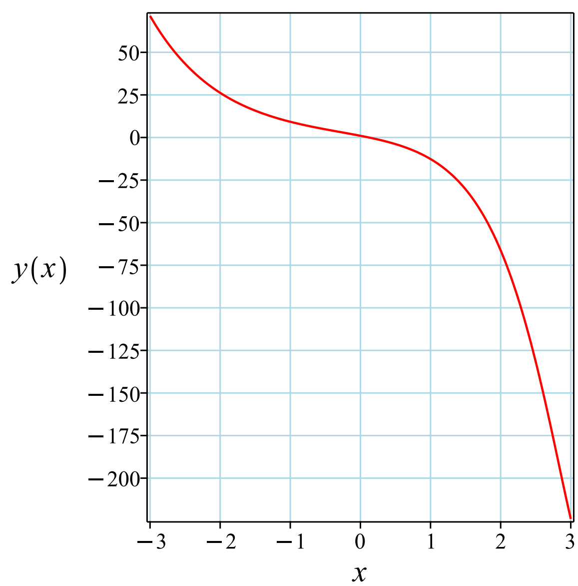

Figure 415: Solution plot

Verification of solutions

$$y = \frac{(6x - 23)\,\mathrm{e}^{2x}}{9} + \frac{32\,\mathrm{e}^{-x}}{9}$$

Verified OK.

  ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$

  ◦ Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = 3y_3(x) - 4y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 3y_3(x) - 4y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -4 & 0 & 3 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -4 & 0 & 3 \end{bmatrix}$$

- Rewrite the system as

$\overrightarrow{y}'(x) = A \cdot \overrightarrow{y}(x)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]\right], \left[2, \left[\begin{array}{c} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]\right], \left[2, \left[\begin{array}{c} 0 \\ 0 \\ 0 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \mathrm{e}^{-x} \cdot \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[2, \left[\begin{array}{c} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]\right]$$

- First solution from eigenvalue 2

$$\overrightarrow{y}_2(x) = \mathrm{e}^{2x} \cdot \left[\begin{array}{c} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]$$

- Form of the 2nd homogeneous solution where $\overrightarrow{p}$ is to be solved for, $\lambda = 2$ is the eigenvalue, an

$\overrightarrow{y}_3(x) = \mathrm{e}^{\lambda x} \left(x \overrightarrow{v} + \overrightarrow{p}\right)$

- Note that the x multiplying $\overrightarrow{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\overrightarrow{y}_3(x)$ into the homogeneous system

$$\lambda \mathrm{e}^{\lambda x}\left(x\vec{v}+\vec{p}\right)+\mathrm{e}^{\lambda x}\vec{v}=\left(\mathrm{e}^{\lambda x}A\right)\cdot\left(x\vec{v}+\vec{p}\right)$$

- Use the fact that $\vec{v}$ is an eigenvector of A

$$\lambda \mathrm{e}^{\lambda x}\left(x\vec{v}+\vec{p}\right)+\mathrm{e}^{\lambda x}\vec{v}=\mathrm{e}^{\lambda x}\left(\lambda x\vec{v}+A\cdot\vec{p}\right)$$

- Simplify equation

$$\lambda\vec{p}+\vec{v}=A\cdot\vec{p}$$

- Make use of the identity matrix I

$$(\lambda\cdot I)\cdot\vec{p}+\vec{v}=A\cdot\vec{p}$$

- Condition $\vec{p}$ must meet for $\vec{y}_3(x)$ to be a solution to the homogeneous system

$$(A-\lambda\cdot I)\cdot\vec{p}=\vec{v}$$

- Choose $\vec{p}$ to use in the second solution to the homogeneous system from eigenvalue 2

$$\left(\left[\begin{array}{ccc}0 & 1 & 0\\ 0 & 0 & 1\\ -4 & 0 & 3\end{array}\right]-2\cdot\left[\begin{array}{ccc}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{array}\right]\right)\cdot\vec{p}=\left[\begin{array}{c}\frac{1}{4}\\ \frac{1}{2}\\ 1\end{array}\right]$$

- Choice of $\vec{p}$

$$\vec{p}=\left[\begin{array}{c}-\frac{1}{8}\\ 0\\ 0\end{array}\right]$$

- Second solution from eigenvalue 2

$$\vec{y}_3(x)=\mathrm{e}^{2x}\cdot\left(x\cdot\left[\begin{array}{c}\frac{1}{4}\\ \frac{1}{2}\\ 1\end{array}\right]+\left[\begin{array}{c}-\frac{1}{8}\\ 0\\ 0\end{array}\right]\right)$$

- General solution to the system of ODEs

$$\vec{y}=c_1\vec{y}_1+c_2\vec{y}_2(x)+c_3\vec{y}_3(x)$$

- Substitute solutions into the general solution

$$\vec{y}=c_1\mathrm{e}^{-x}\cdot\left[\begin{array}{c}1\\ -1\\ 1\end{array}\right]+c_2\mathrm{e}^{2x}\cdot\left[\begin{array}{c}\frac{1}{4}\\ \frac{1}{2}\\ 1\end{array}\right]+\mathrm{e}^{2x}c_3\cdot\left(x\cdot\left[\begin{array}{c}\frac{1}{4}\\ \frac{1}{2}\\ 1\end{array}\right]+\left[\begin{array}{c}-\frac{1}{8}\\ 0\\ 0\end{array}\right]\right)$$

- First component of the vector is the solution to the ODE

  $y = \frac{((2x-1)c_3+2c_2)e^{2x}}{8} + c_1 e^{-x}$

- Use the initial condition $y(0) = 1$

  $1 = -\frac{c_3}{8} + \frac{c_2}{4} + c_1$

- Calculate the 1st derivative of the solution

  $y' = \frac{e^{2x}c_3}{4} + \frac{((2x-1)c_3+2c_2)e^{2x}}{4} - c_1 e^{-x}$

- Use the initial condition $y'\Big|_{\{x=0\}} = -8$

  $-8 = \frac{c_2}{2} - c_1$

- Calculate the 2nd derivative of the solution

  $y'' = e^{2x}c_3 + \frac{((2x-1)c_3+2c_2)e^{2x}}{2} + c_1 e^{-x}$

- Use the initial condition $y''\Big|_{\{x=0\}} = -4$

  $-4 = \frac{c_3}{2} + c_2 + c_1$

- Solve for the unknown coefficients

  $\left\{c_1 = \frac{32}{9}, c_2 = -\frac{80}{9}, c_3 = \frac{8}{3}\right\}$

- Solution to the IVP

  $y = \frac{(6x-23)e^{2x}}{9} + \frac{32\,e^{-x}}{9}$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 42.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' - 5y'' + 9y' - 5y = 0}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1, y''(0) = 6]$$

The characteristic equation is

$$\lambda^3 - 5\lambda^2 + 9\lambda - 5 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 2 - i$$
$$\lambda_3 = 2 + i$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + e^{(2+i)x} c_2 + e^{(2-i)x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= e^{x} \\
y_2 &= e^{(2+i)x} \\
y_3 &= e^{(2-i)x}
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = e^{x} c_1 + e^{(2+i)x} c_2 + e^{(2-i)x} c_3 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$
0 = c_1 + c_2 + c_3 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = e^{x} c_1 + (2+i)\, e^{(2+i)x} c_2 + (2-i)\, e^{(2-i)x} c_3
$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$
1 = c_1 + (2+i)\, c_2 + (2-i)\, c_3 \tag{2A}
$$

Taking two derivatives of the solution gives

$$
y'' = e^{x} c_1 + (3+4i)\, e^{(2+i)x} c_2 + (3-4i)\, e^{(2-i)x} c_3
$$

substituting $y'' = 6$ and $x = 0$ in the above gives

$$
6 = c_1 + (3+4i)\, c_2 + (3-4i)\, c_3 \tag{3A}
$$

Equations {1A,2A,3A} are now solved for $\{c_1, c_2, c_3\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 1 \\
c_2 &= -\frac{1}{2} - i \\
c_3 &= -\frac{1}{2} + i
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = e^{x} - \frac{e^{(2+i)x}}{2} - i e^{(2+i)x} - \frac{e^{(2-i)x}}{2} + i e^{(2-i)x}
$$

Summary

The solution(s) found are the following

$$y = \left(-\frac{1}{2}+i\right) \mathrm{e}^{(2-i)x} + \left(-\frac{1}{2}-i\right) \mathrm{e}^{(2+i)x} + \mathrm{e}^{x} \tag{1}$$

Verification of solutions

$$y = \left(-\frac{1}{2}+i\right) \mathrm{e}^{(2-i)x} + \left(-\frac{1}{2}-i\right) \mathrm{e}^{(2+i)x} + \mathrm{e}^{x}$$

Verified OK.

10.42.1 Maple step by step solution

Let's solve

$\left[y''' - 5y'' + 9y' - 5y = 0, y(0) = 0, y'\Big|_{\{x=0\}} = 1, y''\Big|_{\{x=0\}} = 6\right]$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = 5y_3(x) - 9y_2(x) + 5y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 5y_3(x) - 9y_2(x) + 5y_1(x)]$

- Define vector

  $\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 5 & -9 & 5 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 5 & -9 & 5 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[2-\mathrm{I}, \begin{bmatrix} \frac{3}{25}+\frac{4\,\mathrm{I}}{25} \\ \frac{2}{5}+\frac{\mathrm{I}}{5} \\ 1 \end{bmatrix}\right], \left[2+\mathrm{I}, \begin{bmatrix} \frac{3}{25}-\frac{4\,\mathrm{I}}{25} \\ \frac{2}{5}-\frac{\mathrm{I}}{5} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[2-\mathrm{I}, \begin{bmatrix} \frac{3}{25}+\frac{4\,\mathrm{I}}{25} \\ \frac{2}{5}+\frac{\mathrm{I}}{5} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{(2-I)x} \cdot \begin{bmatrix} \frac{3}{25}+\frac{4\,I}{25} \\ \frac{2}{5}+\frac{I}{5} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$e^{2x} \cdot (\cos(x) - I\sin(x)) \cdot \begin{bmatrix} \frac{3}{25}+\frac{4\,I}{25} \\ \frac{2}{5}+\frac{I}{5} \\ 1 \end{bmatrix}$$

- Simplify expression

$$e^{2x} \cdot \begin{bmatrix} \left(\frac{3}{25}+\frac{4\,I}{25}\right)(\cos(x) - I\sin(x)) \\ \left(\frac{2}{5}+\frac{I}{5}\right)(\cos(x) - I\sin(x)) \\ \cos(x) - I\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = e^{2x} \cdot \begin{bmatrix} \frac{3\cos(x)}{25}+\frac{4\sin(x)}{25} \\ \frac{2\cos(x)}{5}+\frac{\sin(x)}{5} \\ \cos(x) \end{bmatrix}, \vec{y}_3(x) = e^{2x} \cdot \begin{bmatrix} -\frac{3\sin(x)}{25}+\frac{4\cos(x)}{25} \\ -\frac{2\sin(x)}{5}+\frac{\cos(x)}{5} \\ -\sin(x) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x)$$

- Substitute solutions into the general solution

$$\vec{y} = e^{x}c_1 \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + c_2 e^{2x} \cdot \begin{bmatrix} \frac{3\cos(x)}{25}+\frac{4\sin(x)}{25} \\ \frac{2\cos(x)}{5}+\frac{\sin(x)}{5} \\ \cos(x) \end{bmatrix} + e^{2x}c_3 \cdot \begin{bmatrix} -\frac{3\sin(x)}{25}+\frac{4\cos(x)}{25} \\ -\frac{2\sin(x)}{5}+\frac{\cos(x)}{5} \\ -\sin(x) \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = \frac{\left((3c_2+4c_3)\cos(x)+4\left(c_2-\frac{3c_3}{4}\right)\sin(x)\right)e^{2x}}{25} + e^{x}c_1$$

- Use the initial condition $y(0) = 0$

$$0 = \frac{3c_2}{25} + \frac{4c_3}{25} + c_1$$

- Calculate the 1st derivative of the solution

$$y' = \frac{\left(-(3c_2+4c_3)\sin(x)+4\left(c_2-\frac{3c_3}{4}\right)\cos(x)\right)e^{2x}}{25} + \frac{2\left((3c_2+4c_3)\cos(x)+4\left(c_2-\frac{3c_3}{4}\right)\sin(x)\right)e^{2x}}{25} + e^{x}c_1$$

- Use the initial condition $y'\Big|_{\{x=0\}} = 1$

  $1 = \frac{2c_2}{5} + \frac{c_3}{5} + c_1$

- Calculate the 2nd derivative of the solution

  $y'' = \frac{\left(-(3c_2+4c_3)\cos(x)-4\left(c_2-\frac{3c_3}{4}\right)\sin(x)\right)\mathrm{e}^{2x}}{25} + \frac{4\left(-(3c_2+4c_3)\sin(x)+4\left(c_2-\frac{3c_3}{4}\right)\cos(x)\right)\mathrm{e}^{2x}}{25} + \frac{4\left((3c_2+4c_3)\cos(x)+4\left(c\right.\right.}{25}$

- Use the initial condition $y''\Big|_{\{x=0\}} = 6$

  $6 = c_1 + c_2$

- Solve for the unknown coefficients

  $\{c_1 = 1, c_2 = 5, c_3 = -10\}$

- Solution to the IVP

  $y = (-\cos(x) + 2\sin(x))\,\mathrm{e}^{2x} + \mathrm{e}^{x}$

- Solution from eigenpair

$$\mathrm{e}^{(-1-2\mathrm{I})x} \cdot \left[\begin{array}{c} \frac{11}{125}-\frac{2\mathrm{I}}{125} \\ -\frac{3}{25}-\frac{4\mathrm{I}}{25} \\ -\frac{1}{5}+\frac{2\mathrm{I}}{5} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$\mathrm{e}^{-x} \cdot (\cos(2x) - \mathrm{I}\sin(2x)) \cdot \left[\begin{array}{c} \frac{11}{125}-\frac{2\mathrm{I}}{125} \\ -\frac{3}{25}-\frac{4\mathrm{I}}{25} \\ -\frac{1}{5}+\frac{2\mathrm{I}}{5} \\ 1 \end{array}\right]$$

- Simplify expression

$$\mathrm{e}^{-x} \cdot \left[\begin{array}{c} \left(\frac{11}{125}-\frac{2\mathrm{I}}{125}\right)(\cos(2x)-\mathrm{I}\sin(2x)) \\ \left(-\frac{3}{25}-\frac{4\mathrm{I}}{25}\right)(\cos(2x)-\mathrm{I}\sin(2x)) \\ \left(-\frac{1}{5}+\frac{2\mathrm{I}}{5}\right)(\cos(2x)-\mathrm{I}\sin(2x)) \\ \cos(2x)-\mathrm{I}\sin(2x) \end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \mathrm{e}^{-x} \cdot \left[\begin{array}{c} \frac{11\cos(2x)}{125}-\frac{2\sin(2x)}{125} \\ -\frac{3\cos(2x)}{25}-\frac{4\sin(2x)}{25} \\ -\frac{\cos(2x)}{5}+\frac{2\sin(2x)}{5} \\ \cos(2x) \end{array}\right], \vec{y}_4(x) = \mathrm{e}^{-x} \cdot \left[\begin{array}{c} -\frac{11\sin(2x)}{125}-\frac{2\cos(2x)}{125} \\ \frac{3\sin(2x)}{25}-\frac{4\cos(2x)}{25} \\ \frac{\sin(2x)}{5}+\frac{2\cos(2x)}{5} \\ -\sin(2x) \end{array}\right]\right]$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1(x) + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + c_4\vec{y}_4(x)$$

- Substitute solutions into the general solution

$$\vec{y} = c_3 \mathrm{e}^{-x} \cdot \begin{bmatrix} \frac{11\cos(2x)}{125} - \frac{2\sin(2x)}{125} \\ -\frac{3\cos(2x)}{25} - \frac{4\sin(2x)}{25} \\ -\frac{\cos(2x)}{5} + \frac{2\sin(2x)}{5} \\ \cos(2x) \end{bmatrix} + c_4 \mathrm{e}^{-x} \cdot \begin{bmatrix} -\frac{11\sin(2x)}{125} - \frac{2\cos(2x)}{125} \\ \frac{3\sin(2x)}{25} - \frac{4\cos(2x)}{25} \\ \frac{\sin(2x)}{5} + \frac{2\cos(2x)}{5} \\ -\sin(2x) \end{bmatrix} + \begin{bmatrix} -\sin(x)\, c_1 - c_2 \cos(\\ -c_1 \cos(x) + c_2 \sin(\\ \sin(x)\, c_1 + c_2 \cos(x \\ c_1 \cos(x) - c_2 \sin(x \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = \frac{\left((22c_3 - 4c_4)\cos(x)^2 - 4\left(c_3 + \frac{11c_4}{2}\right)\sin(x)\cos(x) - 11c_3 + 2c_4\right)\mathrm{e}^{-x}}{125} - \sin(x)\, c_1 - c_2 \cos(x)$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.2. The homogeneous linear equation with constant coefficients. Exercises page 135
Problem number: 46.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_x]]
```

$$\boxed{y'''' + 3y''' + y'' + 13y' + 30y = 0}$$

The characteristic equation is

$$\lambda^4 + 3\lambda^3 + \lambda^2 + 13\lambda + 30 = 0$$

The roots of the above equation are

$$\lambda_1 = -3$$
$$\lambda_2 = -2$$
$$\lambda_3 = 1 - 2i$$
$$\lambda_4 = 1 + 2i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-3x} + \mathrm{e}^{(1+2i)x} c_3 + \mathrm{e}^{(1-2i)x} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= e^{-2x} \\
y_2 &= e^{-3x} \\
y_3 &= e^{(1+2i)x} \\
y_4 &= e^{(1-2i)x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-2x} + c_2 e^{-3x} + e^{(1+2i)x} c_3 + e^{(1-2i)x} c_4 \tag{1}$$

Verification of solutions

$$y = c_1 e^{-2x} + c_2 e^{-3x} + e^{(1+2i)x} c_3 + e^{(1-2i)x} c_4$$

Verified OK.

10.44.1 Maple step by step solution

Let's solve

$y'''' + 3y''' + y'' + 13y' + 30y = 0$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Define new variable $y_4(x)$

    $y_4(x) = y'''$
  - Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = -3y_4(x) - y_3(x) - 13y_2(x) - 30y_1(x)$

  Convert linear ODE into a system of first order ODEs

$$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = -3y_4(x) - y_3(x) - 13y_2(x) - 30y_1(x)]$$

- Define vector

$$\vec{y}(x) = \left[\begin{array}{c} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{array}\right]$$

- System to solve

$$\vec{y}'(x) = \left[\begin{array}{cccc} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -30 & -13 & -1 & -3 \end{array}\right] \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \left[\begin{array}{cccc} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -30 & -13 & -1 & -3 \end{array}\right]$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-3, \left[\begin{array}{c} -\frac{1}{27} \\ \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{array}\right]\right], \left[-2, \left[\begin{array}{c} -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{array}\right]\right], \left[1 - 2\,\mathrm{I}, \left[\begin{array}{c} -\frac{11}{125} - \frac{2\,\mathrm{I}}{125} \\ -\frac{3}{25} + \frac{4\,\mathrm{I}}{25} \\ \frac{1}{5} + \frac{2\,\mathrm{I}}{5} \\ 1 \end{array}\right]\right], \left[1 + 2\,\mathrm{I}, \left[\begin{array}{c} -\frac{11}{125} + \frac{2\,\mathrm{I}}{125} \\ -\frac{3}{25} - \frac{4\,\mathrm{I}}{25} \\ \frac{1}{5} - \frac{2\,\mathrm{I}}{5} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-3, \left[\begin{array}{c} -\frac{1}{27} \\ \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \mathrm{e}^{-3x} \cdot \left[\begin{array}{c} -\frac{1}{27} \\ \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[-2, \left[\begin{array}{c} -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_2 = \mathrm{e}^{-2x} \cdot \left[\begin{array}{c} -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[1 - 2\,\mathrm{I}, \left[\begin{array}{c} -\frac{11}{125} - \frac{2\,\mathrm{I}}{125} \\ -\frac{3}{25} + \frac{4\,\mathrm{I}}{25} \\ \frac{1}{5} + \frac{2\,\mathrm{I}}{5} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$e^{(1-2I)x} \cdot \begin{bmatrix} -\frac{11}{125}-\frac{2I}{125} \\ -\frac{3}{25}+\frac{4I}{25} \\ \frac{1}{5}+\frac{2I}{5} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$e^{x} \cdot (\cos(2x) - I\sin(2x)) \cdot \begin{bmatrix} -\frac{11}{125}-\frac{2I}{125} \\ -\frac{3}{25}+\frac{4I}{25} \\ \frac{1}{5}+\frac{2I}{5} \\ 1 \end{bmatrix}$$

- Simplify expression

$$e^{x} \cdot \begin{bmatrix} \left(-\frac{11}{125}-\frac{2I}{125}\right)(\cos(2x) - I\sin(2x)) \\ \left(-\frac{3}{25}+\frac{4I}{25}\right)(\cos(2x) - I\sin(2x)) \\ \left(\frac{1}{5}+\frac{2I}{5}\right)(\cos(2x) - I\sin(2x)) \\ \cos(2x) - I\sin(2x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = e^{x} \cdot \begin{bmatrix} -\frac{11\cos(2x)}{125}-\frac{2\sin(2x)}{125} \\ -\frac{3\cos(2x)}{25}+\frac{4\sin(2x)}{25} \\ \frac{\cos(2x)}{5}+\frac{2\sin(2x)}{5} \\ \cos(2x) \end{bmatrix}, \vec{y}_4(x) = e^{x} \cdot \begin{bmatrix} \frac{11\sin(2x)}{125}-\frac{2\cos(2x)}{125} \\ \frac{3\sin(2x)}{25}+\frac{4\cos(2x)}{25} \\ -\frac{\sin(2x)}{5}+\frac{2\cos(2x)}{5} \\ -\sin(2x) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x)$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 e^{-3x} \cdot \begin{bmatrix} -\frac{1}{27} \\ \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{bmatrix} + c_2 e^{-2x} \cdot \begin{bmatrix} -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix} + c_3 e^{x} \cdot \begin{bmatrix} -\frac{11\cos(2x)}{125}-\frac{2\sin(2x)}{125} \\ -\frac{3\cos(2x)}{25}+\frac{4\sin(2x)}{25} \\ \frac{\cos(2x)}{5}+\frac{2\sin(2x)}{5} \\ \cos(2x) \end{bmatrix} + e^{x} c_4 \cdot \begin{bmatrix} \frac{11\sin(2x)}{125} - \\ \frac{3\sin(2x)}{25} + \\ -\frac{\sin(2x)}{5} + \\ -\sin(\end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = -\frac{2\,\mathrm{e}^{-3x} \left(\left(\left(\frac{11c_3}{2}+c_4\right)\cos(2x)+\sin(2x)\left(c_3-\frac{11c_4}{2}\right)\right)\mathrm{e}^{4x}+\frac{125c_2\,\mathrm{e}^{x}}{16}+\frac{125c_1}{54}\right)}{125}$$

Problem number: 1.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 3y' + 8y = 4x^2}$$

11.1.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -3, C = 8, f(x) = 4x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 3y' + 8y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -3, C = 8$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 3\lambda\, e^{\lambda x} + 8\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 3\lambda + 8 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -3, C = 8$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{3}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-3^2 - (4)\,(1)\,(8)} \\ &= \frac{3}{2} \pm \frac{i\sqrt{23}}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= \frac{3}{2} + \frac{i\sqrt{23}}{2} \\ \lambda_2 &= \frac{3}{2} - \frac{i\sqrt{23}}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \frac{3}{2} + \frac{i\sqrt{23}}{2} \\ \lambda_2 &= \frac{3}{2} - \frac{i\sqrt{23}}{2}\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = \frac{3}{2}$ and $\beta = \frac{\sqrt{23}}{2}$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{\frac{3x}{2}}\left(c_1 \cos\left(\frac{\sqrt{23}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{23}\, x}{2}\right)\right)$$

Therefore the homogeneous solution y_h is

$$y_h = e^{\frac{3x}{2}} \left(c_1 \cos\left(\frac{\sqrt{23}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{23}\, x}{2}\right)\right)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^{\frac{3x}{2}} \cos\left(\frac{\sqrt{23}\, x}{2}\right), e^{\frac{3x}{2}} \sin\left(\frac{\sqrt{23}\, x}{2}\right)\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_3 x^2 + A_2 x + A_1$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$8A_3 x^2 + 8A_2 x - 6x A_3 + 8A_1 - 3A_2 + 2A_3 = 4x^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{64}, A_2 = \frac{3}{8}, A_3 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{2} x^2 + \frac{3}{8} x + \frac{1}{64}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(e^{\frac{3x}{2}}\left(c_1 \cos\left(\frac{\sqrt{23}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{23}\, x}{2}\right)\right)\right) + \left(\frac{1}{2}x^2 + \frac{3}{8}x + \frac{1}{64}\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = e^{\frac{3x}{2}}\left(c_1 \cos\left(\frac{\sqrt{23}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{23}\, x}{2}\right)\right) + \frac{x^2}{2} + \frac{3x}{8} + \frac{1}{64} \tag{1}
$$

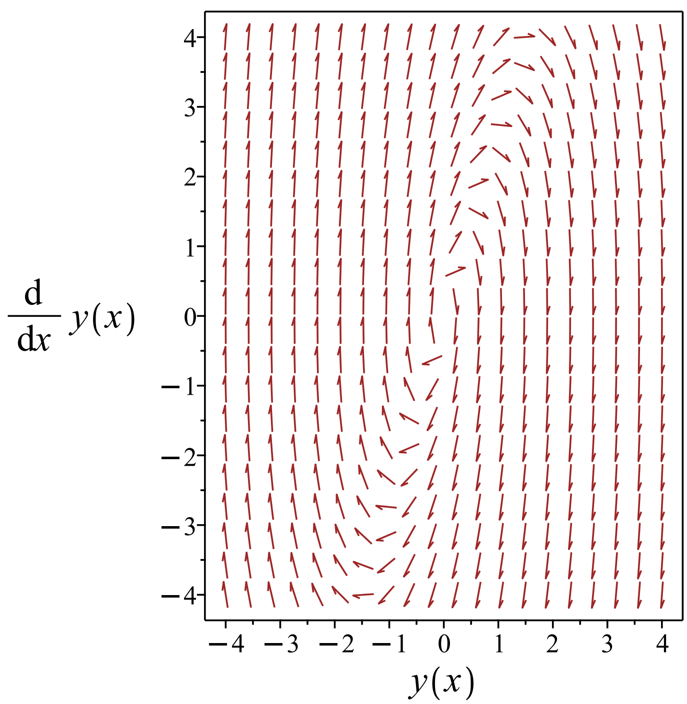

Figure 416: Slope field plot

Verification of solutions

$$
y = e^{\frac{3x}{2}}\left(c_1 \cos\left(\frac{\sqrt{23}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{23}\, x}{2}\right)\right) + \frac{x^2}{2} + \frac{3x}{8} + \frac{1}{64}
$$

Verified OK.

11.1.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 3y' + 8y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -3 \\ C &= 8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-23}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -23 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -\frac{23z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 345: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -\frac{23}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos\left(\frac{\sqrt{23}\, x}{2}\right)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3}{1}\,dx} \\
&= z_1 e^{\frac{3x}{2}} \\
&= z_1 \left(\mathrm{e}^{\frac{3x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{\frac{3x}{2}} \cos\left(\frac{\sqrt{23}\,x}{2}\right)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{3x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{2\sqrt{23}\,\tan\left(\frac{\sqrt{23}\,x}{2}\right)}{23}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{\frac{3x}{2}} \cos\left(\frac{\sqrt{23}\,x}{2}\right)\right) + c_2 \left(\mathrm{e}^{\frac{3x}{2}} \cos\left(\frac{\sqrt{23}\,x}{2}\right) \left(\frac{2\sqrt{23}\,\tan\left(\frac{\sqrt{23}\,x}{2}\right)}{23}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 3y' + 8y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \mathrm{e}^{\frac{3x}{2}} \cos\left(\frac{\sqrt{23}\,x}{2}\right) c_1 + \frac{2c_2 \sin\left(\frac{\sqrt{23}\,x}{2}\right) \mathrm{e}^{\frac{3x}{2}} \sqrt{23}}{23}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\mathrm{e}^{\frac{3x}{2}} \cos\left(\frac{\sqrt{23}\,x}{2}\right), \frac{2\sin\left(\frac{\sqrt{23}\,x}{2}\right) \mathrm{e}^{\frac{3x}{2}} \sqrt{23}}{23}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_3x^2 + A_2x + A_1$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$8A_3x^2 + 8A_2x - 6xA_3 + 8A_1 - 3A_2 + 2A_3 = 4x^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{64}, A_2 = \frac{3}{8}, A_3 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{2}x^2 + \frac{3}{8}x + \frac{1}{64}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{\frac{3x}{2}} \cos\left(\frac{\sqrt{23}\,x}{2}\right) c_1 + \frac{2c_2 \sin\left(\frac{\sqrt{23}\,x}{2}\right) e^{\frac{3x}{2}} \sqrt{23}}{23}\right) + \left(\frac{1}{2}x^2 + \frac{3}{8}x + \frac{1}{64}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{\frac{3x}{2}} \cos\left(\frac{\sqrt{23}\,x}{2}\right) c_1 + \frac{2c_2 \sin\left(\frac{\sqrt{23}\,x}{2}\right) e^{\frac{3x}{2}} \sqrt{23}}{23} + \frac{x^2}{2} + \frac{3x}{8} + \frac{1}{64} \tag{1}$$

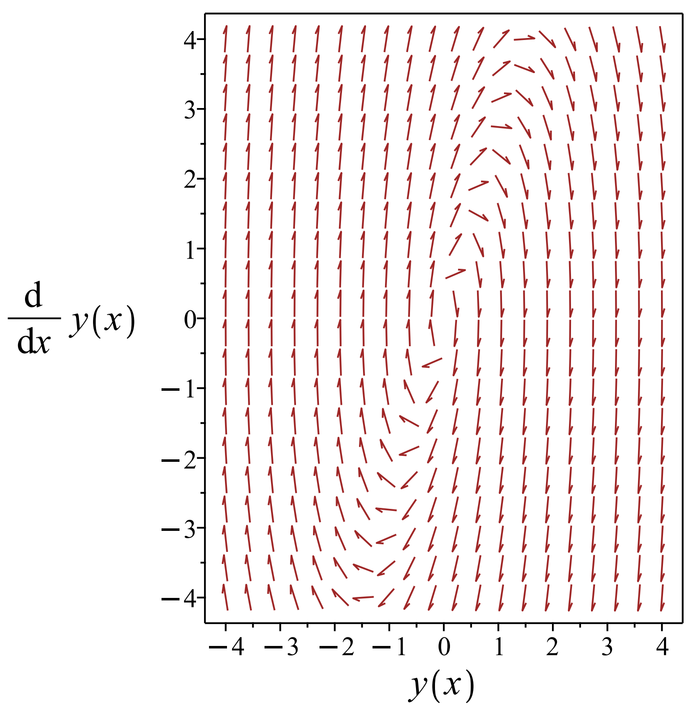

Figure 417: Slope field plot

Verification of solutions

$$y = e^{\frac{3x}{2}} \cos\left(\frac{\sqrt{23}\, x}{2}\right) c_1 + \frac{2c_2 \sin\left(\frac{\sqrt{23}\, x}{2}\right) e^{\frac{3x}{2}} \sqrt{23}}{23} + \frac{x^2}{2} + \frac{3x}{8} + \frac{1}{64}$$

Verified OK.

11.1.3 Maple step by step solution

Let's solve

$y'' - 3y' + 8y = 4x^2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 3r + 8 = 0$

- Use quadratic formula to solve for r

  $r = \frac{3 \pm (\sqrt{-23})}{2}$

- Roots of the characteristic polynomial

  $r = \left(\frac{3}{2} - \frac{I\sqrt{23}}{2}, \frac{3}{2} + \frac{I\sqrt{23}}{2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{\frac{3x}{2}} \cos\left(\frac{\sqrt{23}\, x}{2}\right)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{\frac{3x}{2}} \sin\left(\frac{\sqrt{23}\, x}{2}\right)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{\frac{3x}{2}} \cos\left(\frac{\sqrt{23}\, x}{2}\right) c_1 + e^{\frac{3x}{2}} \sin\left(\frac{\sqrt{23}\, x}{2}\right) c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 4x^2\right]$

  - Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{\frac{3x}{2}} \cos\left(\frac{\sqrt{23}\,x}{2}\right) & e^{\frac{3x}{2}} \sin\left(\frac{\sqrt{23}\,x}{2}\right) \\ \frac{3\,e^{\frac{3x}{2}} \cos\left(\frac{\sqrt{23}\,x}{2}\right)}{2} - \frac{\sin\left(\frac{\sqrt{23}\,x}{2}\right) e^{\frac{3x}{2}} \sqrt{23}}{2} & \frac{3\,e^{\frac{3x}{2}} \sin\left(\frac{\sqrt{23}\,x}{2}\right)}{2} + \frac{e^{\frac{3x}{2}} \sqrt{23}\cos\left(\frac{\sqrt{23}\,x}{2}\right)}{2} \end{bmatrix}$$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = \frac{\sqrt{23}\,e^{3x}}{2}$
- Substitute functions into equation for $y_p(x)$

  $$y_p(x) = -\frac{8\,e^{\frac{3x}{2}} \sqrt{23}\left(\cos\left(\frac{\sqrt{23}\,x}{2}\right)\left(\int x^2 e^{-\frac{3x}{2}} \sin\left(\frac{\sqrt{23}\,x}{2}\right)dx\right) - \sin\left(\frac{\sqrt{23}\,x}{2}\right)\left(\int x^2 e^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{23}\,x}{2}\right)dx\right)\right)}{23}$$
- Compute integrals

  $y_p(x) = \frac{1}{2}x^2 + \frac{3}{8}x + \frac{1}{64}$

- Substitute particular solution into general solution to ODE

  $$y = e^{\frac{3x}{2}} \cos\left(\frac{\sqrt{23}\,x}{2}\right) c_1 + e^{\frac{3x}{2}} \sin\left(\frac{\sqrt{23}\,x}{2}\right) c_2 + \frac{x^2}{2} + \frac{3x}{8} + \frac{1}{64}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 2y' - 8y = 4\,\mathrm{e}^{2x} - 21\,\mathrm{e}^{-3x}}$$

11.2.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = -8, f(x) = (4\,\mathrm{e}^{5x} - 21)\,\mathrm{e}^{-3x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' - 8y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = -8$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 2\lambda\, \mathrm{e}^{\lambda x} - 8\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda - 8 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = -8$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-2^2 - (4)\,(1)\,(-8)}\\ &= 1 \pm 3\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 1 + 3\\ \lambda_2 &= 1 - 3\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 4\\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(4)x} + c_2 e^{(-2)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{4x} + c_2 \mathrm{e}^{-2x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{4x} + c_2 \mathrm{e}^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\left(4\,\mathrm{e}^{5x}-21\right)\mathrm{e}^{-3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{-3x}\},\{\mathrm{e}^{2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-2x},\mathrm{e}^{4x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\mathrm{e}^{-3x} + A_2\mathrm{e}^{2x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$7A_1\mathrm{e}^{-3x} - 8A_2\mathrm{e}^{2x} = \left(4\,\mathrm{e}^{5x}-21\right)\mathrm{e}^{-3x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -3, A_2 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -3\,\mathrm{e}^{-3x} - \frac{\mathrm{e}^{2x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{4x} + c_2\mathrm{e}^{-2x}\right) + \left(-3\,\mathrm{e}^{-3x} - \frac{\mathrm{e}^{2x}}{2}\right) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1\mathrm{e}^{4x} + c_2\mathrm{e}^{-2x} - 3\,\mathrm{e}^{-3x} - \frac{\mathrm{e}^{2x}}{2} \tag{1}$$

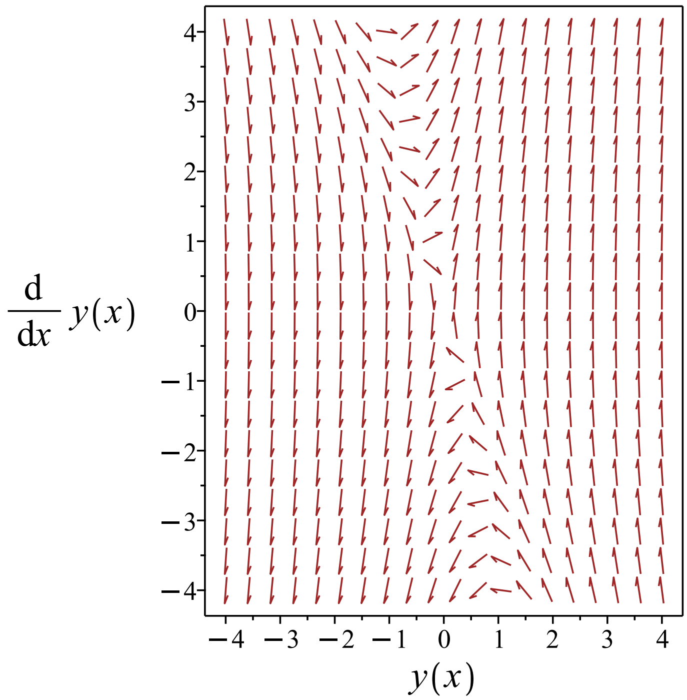

Figure 418: Slope field plot

Verification of solutions

$$y = c_1 e^{4x} + c_2 e^{-2x} - 3\,e^{-3x} - \frac{e^{2x}}{2}$$

Verified OK.

11.2.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' - 8y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= -8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 9z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 347: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 9$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-3x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-2}{1} \, dx} \\ &= z_1 e^{x} \\ &= z_1 (\mathrm{e}^{x}) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{\mathrm{e}^{6x}}{6} \right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(e^{-2x}\right) + c_2 \left(e^{-2x} \left(\frac{e^{6x}}{6}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' - 8y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 e^{-2x} + \frac{c_2 e^{4x}}{6}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
\left(4\,e^{5x} - 21\right) e^{-3x}
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{e^{-3x}\}, \{e^{2x}\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\frac{e^{4x}}{6}, e^{-2x}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 e^{-3x} + A_2 e^{2x}
$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$7A_1 e^{-3x} - 8A_2 e^{2x} = \left(4\,e^{5x} - 21\right) e^{-3x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -3, A_2 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -3\,e^{-3x} - \frac{e^{2x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-2x} + \frac{c_2 e^{4x}}{6}\right) + \left(-3\,e^{-3x} - \frac{e^{2x}}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-2x} + \frac{c_2 e^{4x}}{6} - 3\,e^{-3x} - \frac{e^{2x}}{2} \tag{1}$$

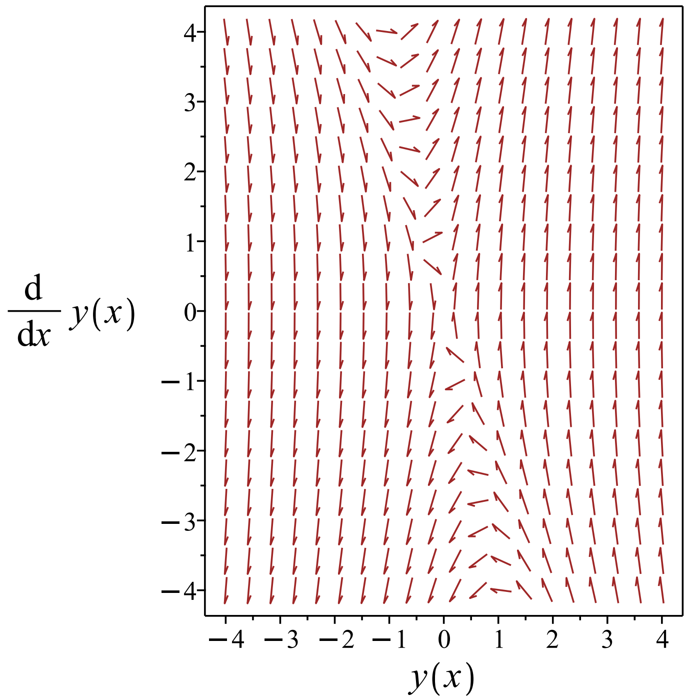

Figure 419: Slope field plot

Verification of solutions

$$y = c_1 e^{-2x} + \frac{c_2 e^{4x}}{6} - 3\,e^{-3x} - \frac{e^{2x}}{2}$$

Verified OK.

11.2.3 Maple step by step solution

Let's solve

$y'' - 2y' - 8y = (4\,e^{5x} - 21)\,e^{-3x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r - 8 = 0$

- Factor the characteristic polynomial

  $(r + 2)(r - 4) = 0$

- Roots of the characteristic polynomial

$r = (-2, 4)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{4x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-2x} + c_2 e^{4x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = (4\,e^{5x} - 21)\,e^{-3x}\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-2x} & e^{4x} \\ -2\,e^{-2x} & 4\,e^{4x} \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 6\,e^{2x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{e^{-2x}\left(\int (4\,e^{4x} - 21\,e^{-x})dx\right)}{6} + \frac{e^{4x}\left(\int (4\,e^{5x} - 21)e^{-7x}dx\right)}{6}$

  ◦ Compute integrals

  $y_p(x) = -\frac{(e^{5x}+6)e^{-3x}}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-2x} + c_2 e^{4x} - \frac{(e^{5x}+6)e^{-3x}}{2}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 2y' + 5y = 6\sin(2x) + 7\cos(2x)}$$

11.3.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 5, f(x) = 6\sin(2x) + 7\cos(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda\, e^{\lambda x} + 5\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{2^2 - (4)\,(1)\,(5)}\\ &= -1 \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -1 + 2i\\ \lambda_2 &= -1 - 2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 + 2i\\ \lambda_2 &= -1 - 2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -1$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$6 \sin(2x) + 7 \cos(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-x} \cos(2x), e^{-x} \sin(2x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(2x) + A_2 \sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 \cos(2x) + A_2 \sin(2x) - 4A_1 \sin(2x) + 4A_2 \cos(2x) = 6 \sin(2x) + 7 \cos(2x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1, A_2 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\cos(2x) + 2 \sin(2x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-x}(c_1 \cos(2x) + c_2 \sin(2x))\right) + (-\cos(2x) + 2 \sin(2x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x)) - \cos(2x) + 2 \sin(2x) \tag{1}$$

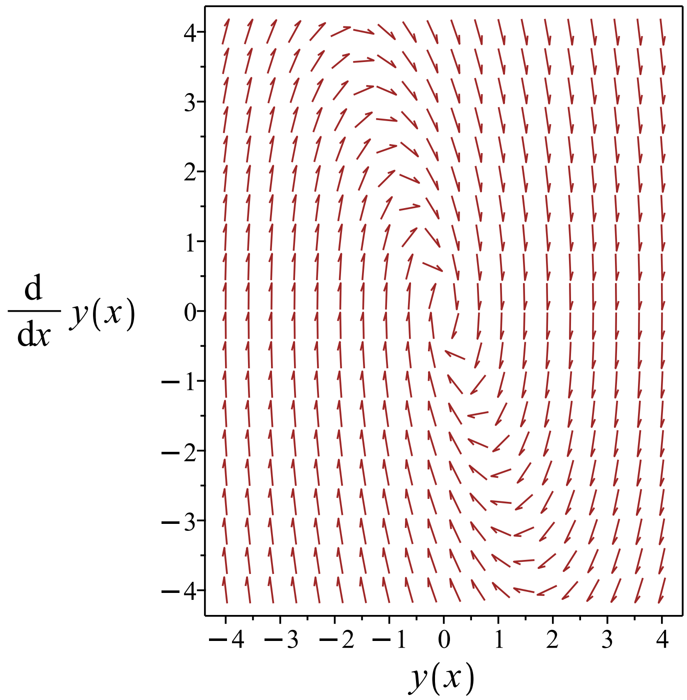

Figure 420: Slope field plot

<u>Verification of solutions</u>

$$y = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x)) - \cos(2x) + 2\sin(2x)$$

Verified OK.

11.3.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 349: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\ &= z_1 e^{-x} \\ &= z_1\left(\mathrm{e}^{-x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}\cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-2x}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\tan(2x)}{2}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-x}\cos\left(2x\right)\right) + c_2\left(\mathrm{e}^{-x}\cos\left(2x\right)\left(\frac{\tan\left(2x\right)}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 2y' + 5y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1\mathrm{e}^{-x}\cos\left(2x\right) + \frac{c_2\mathrm{e}^{-x}\sin\left(2x\right)}{2}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
6\sin\left(2x\right) + 7\cos\left(2x\right)
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\cos\left(2x\right), \sin\left(2x\right)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\mathrm{e}^{-x}\cos\left(2x\right), \frac{\mathrm{e}^{-x}\sin\left(2x\right)}{2}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1\cos\left(2x\right) + A_2\sin\left(2x\right)
$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 \cos(2x) + A_2 \sin(2x) - 4A_1 \sin(2x) + 4A_2 \cos(2x) = 6 \sin(2x) + 7 \cos(2x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1, A_2 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\cos(2x) + 2 \sin(2x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} \cos(2x) + \frac{c_2 e^{-x} \sin(2x)}{2}\right) + (-\cos(2x) + 2 \sin(2x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} \cos(2x) + \frac{c_2 e^{-x} \sin(2x)}{2} - \cos(2x) + 2 \sin(2x) \tag{1}$$

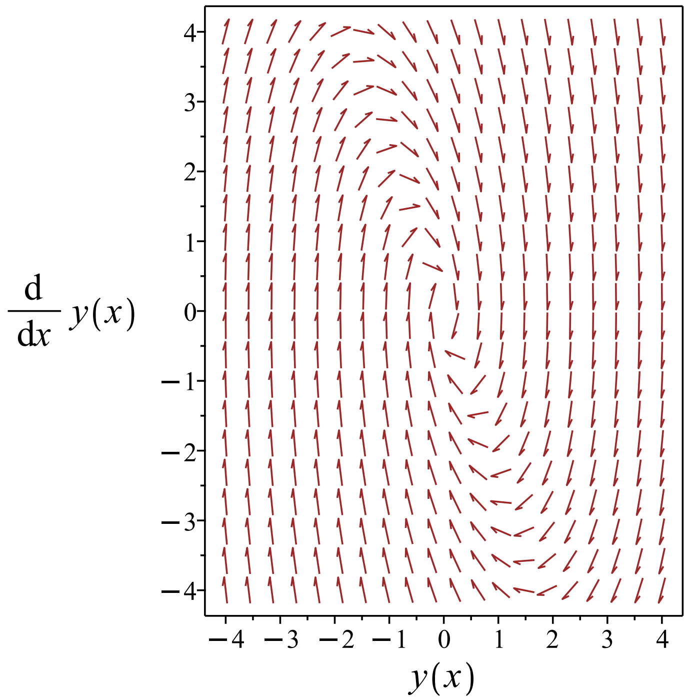

Figure 421: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} \cos(2x) + \frac{c_2 e^{-x} \sin(2x)}{2} - \cos(2x) + 2\sin(2x)$$

Verified OK.

11.3.3 Maple step by step solution

Let's solve

$y'' + 2y' + 5y = 6\sin(2x) + 7\cos(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r + 5 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-2)\pm(\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

$r = (-1 - 2\,\mathrm{I}, -1 + 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-x} \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-x} \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-x} \cos(2x) + c_2 \mathrm{e}^{-x} \sin(2x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 6 \sin(2x) + 7 \cos(2x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-x} \cos(2x) & \mathrm{e}^{-x} \sin(2x) \\ -\mathrm{e}^{-x} \cos(2x) - 2\,\mathrm{e}^{-x} \sin(2x) & -\mathrm{e}^{-x} \sin(2x) + 2\,\mathrm{e}^{-x} \cos(2x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2\,\mathrm{e}^{-2x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = \frac{\mathrm{e}^{-x}\left(\cos(2x)\left(\int(-7\sin(4x)-6+6\cos(4x))\mathrm{e}^{x} dx\right)+\sin(2x)\left(\int(7\cos(4x)+7+6\sin(4x))\mathrm{e}^{x} dx\right)\right)}{4}$

  - Compute integrals

    $y_p(x) = -\cos(2x) + 2\sin(2x)$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-x} \cos(2x) + c_2 \mathrm{e}^{-x} \sin(2x) - \cos(2x) + 2\sin(2x)$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 2y' + 2y = 10\sin(4x)}$$

11.4.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 2, f(x) = 10\sin(4x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 2\lambda \,\mathrm{e}^{\lambda x} + 2 \,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{2^2 - (4)\,(1)\,(2)} \\ &= -1 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -1 + i \\ \lambda_2 &= -1 - i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 + i \\ \lambda_2 &= -1 - i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -1$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x))$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{-x}(c_1 \cos(x) + c_2 \sin(x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$10 \sin (4x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos (4x), \sin (4x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-x} \cos (x), e^{-x} \sin (x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos (4x) + A_2 \sin (4x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-14A_1 \cos (4x) - 14A_2 \sin (4x) - 8A_1 \sin (4x) + 8A_2 \cos (4x) = 10 \sin (4x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{4}{13}, A_2 = -\frac{7}{13}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{4 \cos (4x)}{13} - \frac{7 \sin (4x)}{13}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-x}(c_1 \cos (x) + c_2 \sin (x))\right) + \left(-\frac{4 \cos (4x)}{13} - \frac{7 \sin (4x)}{13}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x)) - \frac{4\cos(4x)}{13} - \frac{7\sin(4x)}{13} \tag{1}$$

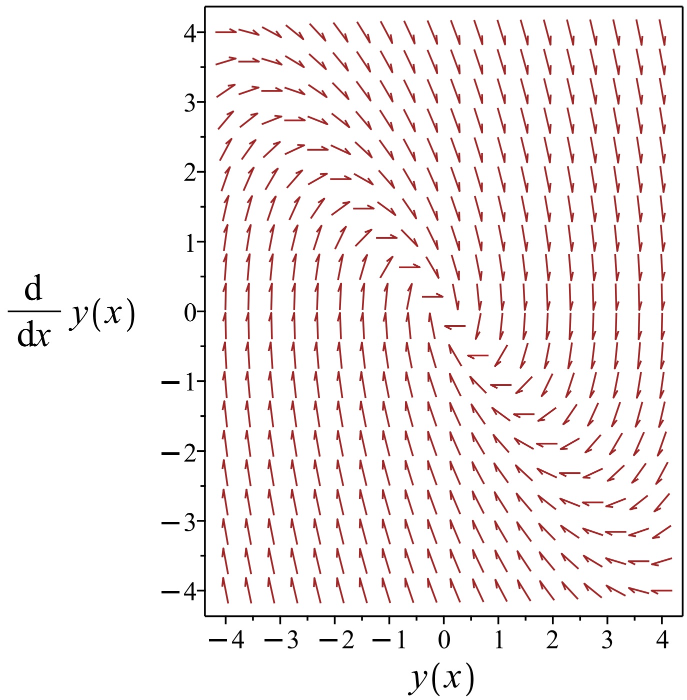

Figure 422: Slope field plot

Verification of solutions

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x)) - \frac{4\cos(4x)}{13} - \frac{7\sin(4x)}{13}$$

Verified OK.

11.4.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 2 \\
C &= 2
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A}\,dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-1}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -1 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = -z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\,dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 351: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\ &= z_1 e^{-x} \\ &= z_1\left(\mathrm{e}^{-x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x} \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-2x}}{(y_1)^2}\, dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-x} \cos(x)\right) + c_2\left(\mathrm{e}^{-x} \cos(x) (\tan(x))\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \cos(x)\,\mathrm{e}^{-x} c_1 + \sin(x)\,\mathrm{e}^{-x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$10 \sin(4x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(4x), \sin(4x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-x}\cos(x), e^{-x}\sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(4x) + A_2 \sin(4x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-14A_1 \cos(4x) - 14A_2 \sin(4x) - 8A_1 \sin(4x) + 8A_2 \cos(4x) = 10\sin(4x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{4}{13}, A_2 = -\frac{7}{13}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{4\cos(4x)}{13} - \frac{7\sin(4x)}{13}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\cos(x)\, e^{-x} c_1 + \sin(x)\, e^{-x} c_2\right) + \left(-\frac{4\cos(4x)}{13} - \frac{7\sin(4x)}{13}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x)) - \frac{4\cos(4x)}{13} - \frac{7\sin(4x)}{13}$$

Summary

The solution(s) found are the following

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x)) - \frac{4\cos(4x)}{13} - \frac{7\sin(4x)}{13} \tag{1}$$

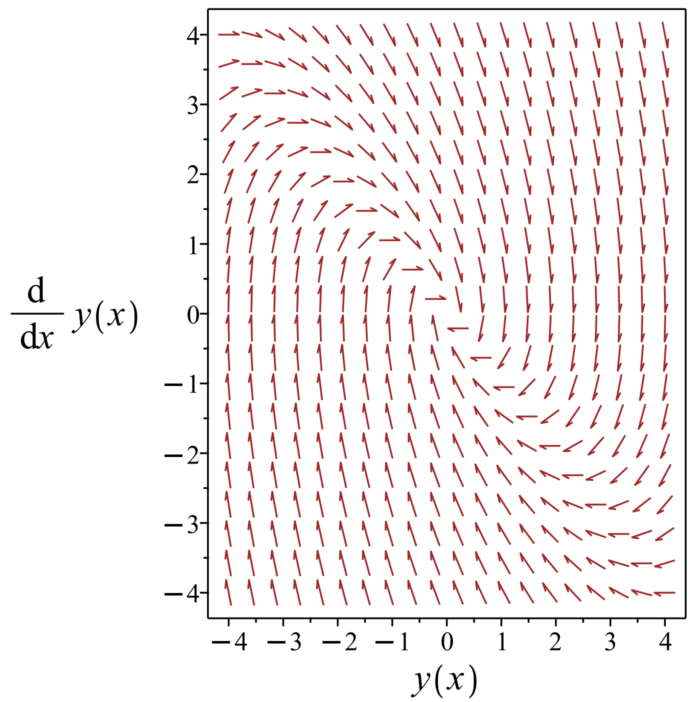

Figure 423: Slope field plot

Verification of solutions

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x)) - \frac{4\cos(4x)}{13} - \frac{7\sin(4x)}{13}$$

Verified OK.

11.4.3 Maple step by step solution

Let's solve

$y'' + 2y' + 2y = 10\sin(4x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2+2r+2=0$

- Use quadratic formula to solve for r

  $r=\frac{(-2)\pm(\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r=(-1-\mathrm{I},-1+\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x)=\mathrm{e}^{-x}\cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x)=\mathrm{e}^{-x}\sin(x)$

- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)+y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y=\cos(x)\,\mathrm{e}^{-x}c_1+\sin(x)\,\mathrm{e}^{-x}c_2+y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x)=-y_1(x)\left(\int\frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right)+y_2(x)\left(\int\frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right),f(x)=10\sin(4x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x),y_2(x))=\left[\begin{array}{cc}\mathrm{e}^{-x}\cos(x) & \mathrm{e}^{-x}\sin(x)\\ -\mathrm{e}^{-x}\cos(x)-\mathrm{e}^{-x}\sin(x) & -\mathrm{e}^{-x}\sin(x)+\mathrm{e}^{-x}\cos(x)\end{array}\right]$

  - Compute Wronskian

    $W(y_1(x),y_2(x))=\mathrm{e}^{-2x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x)=-10\,\mathrm{e}^{-x}\left(\cos(x)\left(\int\sin(x)\sin(4x)\,\mathrm{e}^{x}dx\right)-\sin(x)\left(\int\cos(x)\sin(4x)\,\mathrm{e}^{x}dx\right)\right)$

  - Compute integrals

    $y_p(x)=-\frac{4\cos(4x)}{13}-\frac{7\sin(4x)}{13}$

- Substitute particular solution into general solution to ODE

  $y=\cos(x)\,\mathrm{e}^{-x}c_1+\sin(x)\,\mathrm{e}^{-x}c_2-\frac{7\sin(4x)}{13}-\frac{4\cos(4x)}{13}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 2y' + 4y = \cos(4x)}$$

11.5.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 4, f(x) = \cos(4x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda e^{\lambda x} + 4 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{2^2 - (4)(1)(4)} \\ &= -1 \pm i\sqrt{3}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -1 + i\sqrt{3} \\ \lambda_2 &= -1 - i\sqrt{3}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i\sqrt{3} - 1 \\ \lambda_2 &= -i\sqrt{3} - 1\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -1$ and $\beta = \sqrt{3}$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-x}\left(c_1 \cos\left(\sqrt{3}\, x\right) + c_2 \sin\left(\sqrt{3}\, x\right)\right)$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-x}\left(c_1 \cos\left(\sqrt{3}\, x\right) + c_2 \sin\left(\sqrt{3}\, x\right)\right)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(4x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(4x), \sin(4x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^{-x} \cos\left(\sqrt{3}\, x\right), e^{-x} \sin\left(\sqrt{3}\, x\right)\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(4x) + A_2 \sin(4x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-12A_1 \cos(4x) - 12A_2 \sin(4x) - 8A_1 \sin(4x) + 8A_2 \cos(4x) = \cos(4x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{3}{52}, A_2 = \frac{1}{26}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{3\cos(4x)}{52} + \frac{\sin(4x)}{26}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-x}\left(c_1 \cos\left(\sqrt{3}\, x\right) + c_2 \sin\left(\sqrt{3}\, x\right)\right)\right) + \left(-\frac{3\cos(4x)}{52} + \frac{\sin(4x)}{26}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = e^{-x}\left(c_1 \cos\left(\sqrt{3}\, x\right) + c_2 \sin\left(\sqrt{3}\, x\right)\right) - \frac{3\cos(4x)}{52} + \frac{\sin(4x)}{26} \tag{1}$$

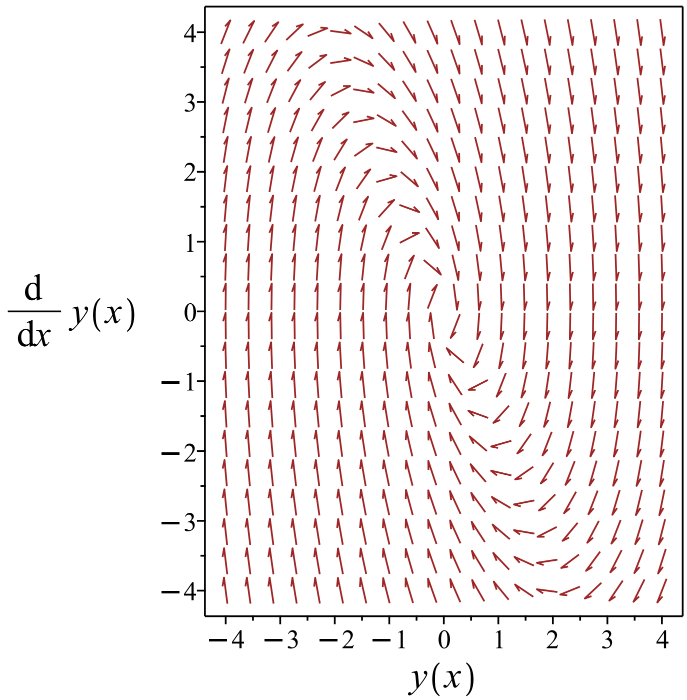

Figure 424: Slope field plot

Verification of solutions

$$y = e^{-x}\left(c_1 \cos\left(\sqrt{3}\, x\right) + c_2 \sin\left(\sqrt{3}\, x\right)\right) - \frac{3\cos(4x)}{52} + \frac{\sin(4x)}{26}$$

Verified OK.

11.5.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 2 \\
C &= 4
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-3}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -3 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = -3z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 353: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -3$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos\left(\sqrt{3}\,x\right)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\ &= z_1 e^{-x} \\ &= z_1\left(\mathrm{e}^{-x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x} \cos\left(\sqrt{3}\, x\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-2x}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\sqrt{3}\, \tan\left(\sqrt{3}\, x\right)}{3}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x} \cos\left(\sqrt{3}\, x\right)\right) + c_2 \left(\mathrm{e}^{-x} \cos\left(\sqrt{3}\, x\right) \left(\frac{\sqrt{3}\, \tan\left(\sqrt{3}\, x\right)}{3}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 4y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \mathrm{e}^{-x} \cos\left(\sqrt{3}\, x\right) c_1 + \frac{c_2 \sin\left(\sqrt{3}\, x\right) \mathrm{e}^{-x} \sqrt{3}}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(4x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(4x), \sin(4x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{ e^{-x} \cos\left(\sqrt{3}\, x\right), \frac{\sin\left(\sqrt{3}\, x\right) e^{-x} \sqrt{3}}{3} \right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(4x) + A_2 \sin(4x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-12A_1 \cos(4x) - 12A_2 \sin(4x) - 8A_1 \sin(4x) + 8A_2 \cos(4x) = \cos(4x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{3}{52}, A_2 = \frac{1}{26}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{3\cos(4x)}{52} + \frac{\sin(4x)}{26}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-x} \cos\left(\sqrt{3}\, x\right) c_1 + \frac{c_2 \sin\left(\sqrt{3}\, x\right) e^{-x} \sqrt{3}}{3} \right) + \left(-\frac{3\cos(4x)}{52} + \frac{\sin(4x)}{26} \right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{-x} \cos\left(\sqrt{3}\, x\right) c_1 + \frac{c_2 \sin\left(\sqrt{3}\, x\right) e^{-x} \sqrt{3}}{3} - \frac{3 \cos(4x)}{52} + \frac{\sin(4x)}{26} \tag{1}$$

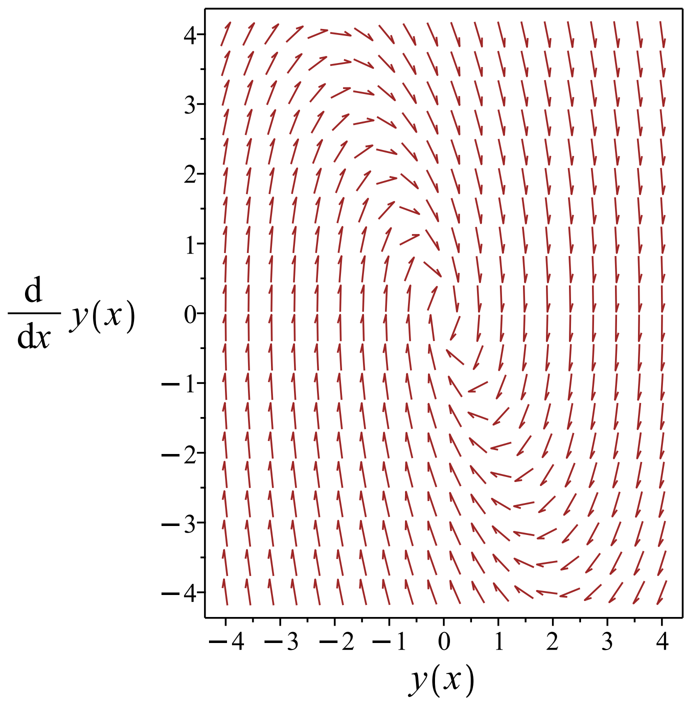

Figure 425: Slope field plot

Verification of solutions

$$y = e^{-x} \cos\left(\sqrt{3}\, x\right) c_1 + \frac{c_2 \sin\left(\sqrt{3}\, x\right) e^{-x} \sqrt{3}}{3} - \frac{3 \cos(4x)}{52} + \frac{\sin(4x)}{26}$$

Verified OK.

11.5.3 Maple step by step solution

Let's solve

$y'' + 2y' + 4y = \cos(4x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 + 2r + 4 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-2)\pm(\sqrt{-12})}{2}$

- Roots of the characteristic polynomial

  $r = \left(-\mathrm{I}\sqrt{3}-1, \mathrm{I}\sqrt{3}-1\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-x}\cos\left(\sqrt{3}\, x\right)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-x}\sin\left(\sqrt{3}\, x\right)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \mathrm{e}^{-x}\cos\left(\sqrt{3}\, x\right) c_1 + \mathrm{e}^{-x}\sin\left(\sqrt{3}\, x\right) c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \cos(4x)\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \left[\begin{array}{cc} \mathrm{e}^{-x}\cos\left(\sqrt{3}\, x\right) & \mathrm{e}^{-x}\sin\left(\sqrt{3}\, x\right) \\ -\mathrm{e}^{-x}\cos\left(\sqrt{3}\, x\right) - \sin\left(\sqrt{3}\, x\right)\mathrm{e}^{-x}\sqrt{3} & -\mathrm{e}^{-x}\sin\left(\sqrt{3}\, x\right) + \mathrm{e}^{-x}\sqrt{3}\cos\left(\sqrt{3}\, x\right) \end{array}\right.$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = \sqrt{3}\,\mathrm{e}^{-2x}$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\mathrm{e}^{-x}\sqrt{3}\left(\cos\left(\sqrt{3}\, x\right)\left(\int \cos(4x)\mathrm{e}^{x}\sin\left(\sqrt{3}\, x\right)dx\right) - \sin\left(\sqrt{3}\, x\right)\left(\int \cos(4x)\mathrm{e}^{x}\cos\left(\sqrt{3}\, x\right)dx\right)\right)}{3}$

- ○ Compute integrals

  $y_p(x) = -\frac{3\cos(4x)}{52} + \frac{\sin(4x)}{26}$

- Substitute particular solution into general solution to ODE

  $y = \mathrm{e}^{-x}\cos\left(\sqrt{3}\, x\right) c_1 + \mathrm{e}^{-x}\sin\left(\sqrt{3}\, x\right) c_2 - \frac{3\cos(4x)}{52} + \frac{\sin(4x)}{26}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 3y' - 4y = 16x - 12\,e^{2x}}$$

11.6.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -3, C = -4, f(x) = 16x - 12\,e^{2x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 3y' - 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A=1, B=-3, C=-4$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 3\lambda\, \mathrm{e}^{\lambda x} - 4\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 3\lambda - 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A=1, B=-3, C=-4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{3}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-3^2 - (4)(1)(-4)}\\ &= \frac{3}{2} \pm \frac{5}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= \frac{3}{2} + \frac{5}{2}\\ \lambda_2 &= \frac{3}{2} - \frac{5}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 4\\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(4)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{4x} + c_2 \mathrm{e}^{-x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{4x} + c_2 \mathrm{e}^{-x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$16x - 12\,\mathrm{e}^{2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{2x}\}, \{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-x}, \mathrm{e}^{4x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \mathrm{e}^{2x} + A_2 + A_3 x$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-6A_1 \mathrm{e}^{2x} - 3A_3 - 4A_2 - 4A_3 x = 16x - 12\,\mathrm{e}^{2x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2, A_2 = 3, A_3 = -4]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2\,\mathrm{e}^{2x} + 3 - 4x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{4x} + c_2 \mathrm{e}^{-x}\right) + \left(2\,\mathrm{e}^{2x} + 3 - 4x\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{4x} + c_2 \mathrm{e}^{-x} + 2\,\mathrm{e}^{2x} + 3 - 4x \tag{1}$$

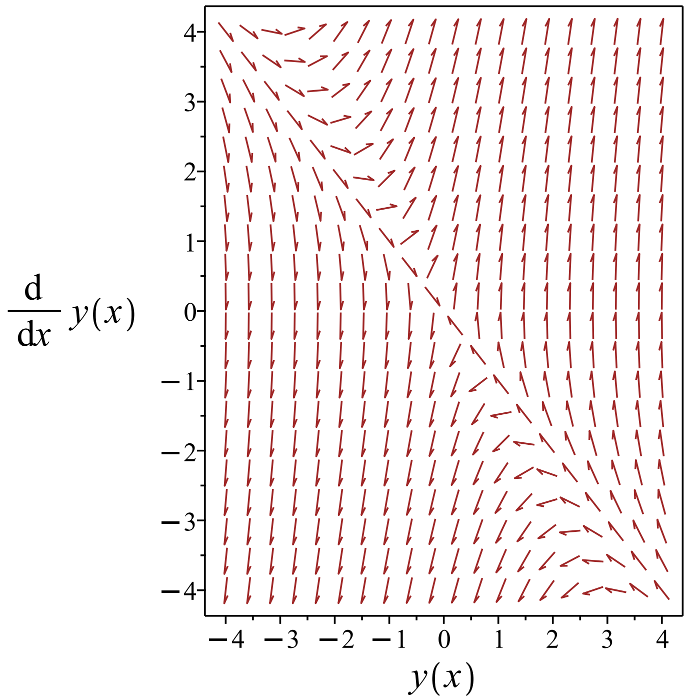

Figure 426: Slope field plot

Verification of solutions

$$y = c_1 e^{4x} + c_2 e^{-x} + 2 e^{2x} + 3 - 4x$$

Verified OK.

11.6.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 3y' - 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -3 \\ C &= -4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{25}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 25 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{25z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 355: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{25}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{5x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-3}{1} \, dx} \\ &= z_1 e^{\frac{3x}{2}} \\ &= z_1 \left(\mathrm{e}^{\frac{3x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-3}{1} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{3x}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{\mathrm{e}^{5x}}{5}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{5x}}{5}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 3y' - 4y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{4x}}{5}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
16x - 12\,\mathrm{e}^{2x}
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\mathrm{e}^{2x}\}, \{1, x\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\frac{\mathrm{e}^{4x}}{5}, \mathrm{e}^{-x}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 \mathrm{e}^{2x} + A_2 + A_3 x
$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-6A_1 e^{2x} - 3A_3 - 4A_2 - 4A_3 x = 16x - 12\,e^{2x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2, A_2 = 3, A_3 = -4]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2\,e^{2x} + 3 - 4x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + \frac{c_2 e^{4x}}{5}\right) + \left(2\,e^{2x} + 3 - 4x\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + \frac{c_2 e^{4x}}{5} + 2\,e^{2x} + 3 - 4x \tag{1}$$

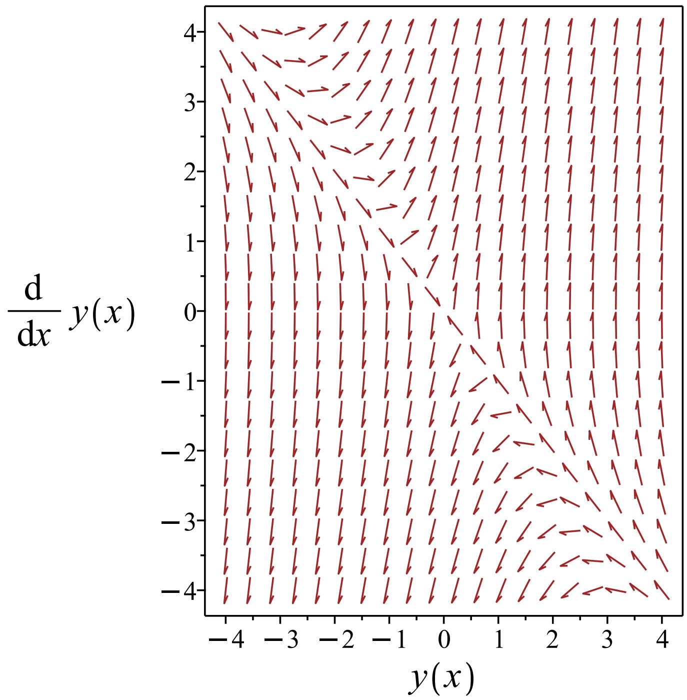

Figure 427: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + \frac{c_2 e^{4x}}{5} + 2\,e^{2x} + 3 - 4x$$

Verified OK.

11.6.3 Maple step by step solution

Let's solve

$y'' - 3y' - 4y = 16x - 12\,e^{2x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 3r - 4 = 0$

- Factor the characteristic polynomial

  $(r + 1)(r - 4) = 0$

- Roots of the characteristic polynomial

$r = (-1, 4)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{4x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-x} + c_2 e^{4x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 16x - 12\,e^{2x}\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x} & e^{4x} \\ -e^{-x} & 4\,e^{4x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 5\,e^{3x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = \frac{4\,e^{-x}\left(\int (3\,e^{2x}-4x)e^{x}dx\right)}{5} - \frac{4\,e^{4x}\left(\int (3\,e^{2x}-4x)e^{-4x}dx\right)}{5}$

  - Compute integrals

    $y_p(x) = 2\,e^{2x} + 3 - 4x$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-x} + c_2 e^{4x} + 2\,e^{2x} + 3 - 4x$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''+6y'+5y=2\,\mathrm{e}^{x}+10\,\mathrm{e}^{5x}}$$

11.7.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=1,B=6,C=5,f(x)=2\,\mathrm{e}^{x}+10\,\mathrm{e}^{5x}$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+6y'+5y=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A = 1, B = 6, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 6\lambda\, e^{\lambda x} + 5\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 6\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 6, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-6}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{6^2 - (4)\,(1)\,(5)} \\ &= -3 \pm 2\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -3 + 2 \\ \lambda_2 &= -3 - 2\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 \\ \lambda_2 &= -5\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(-1)x} + c_2 e^{(-5)x}\end{aligned}$$

Or

$$y = c_1 e^{-x} + c_2 e^{-5x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{-x} + c_2 e^{-5x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2\,e^{x} + 10\,e^{5x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{x}\}, \{e^{5x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-5x}, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{x} + A_2 e^{5x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$12A_1 e^{x} + 60A_2 e^{5x} = 2\,e^{x} + 10\,e^{5x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{6}, A_2 = \frac{1}{6}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{x}}{6} + \frac{e^{5x}}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2 e^{-5x}\right) + \left(\frac{e^{x}}{6} + \frac{e^{5x}}{6}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 e^{-5x} + \frac{e^{x}}{6} + \frac{e^{5x}}{6} \tag{1}$$

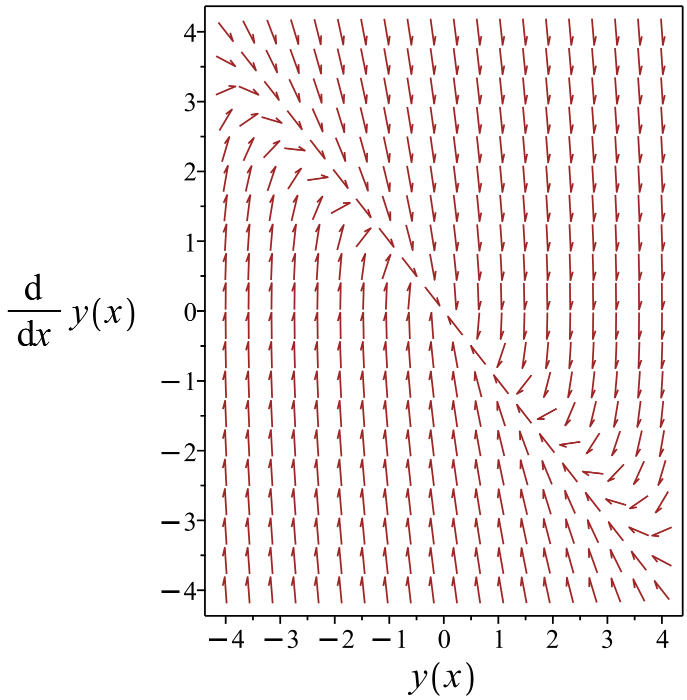

Figure 428: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + c_2 e^{-5x} + \frac{e^x}{6} + \frac{e^{5x}}{6}$$

Verified OK.

11.7.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 6y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 6 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 357: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-2x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{6}{1}\,dx} \\ &= z_1 e^{-3x} \\ &= z_1\left(\mathrm{e}^{-3x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-5x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{6}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-6x}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\mathrm{e}^{4x}}{4}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(e^{-5x}\right) + c_2 \left(e^{-5x} \left(\frac{e^{4x}}{4}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 6y' + 5y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 e^{-5x} + \frac{c_2 e^{-x}}{4}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
2\,e^{x} + 10\,e^{5x}
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{e^{x}\}, \{e^{5x}\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\frac{e^{-x}}{4}, e^{-5x}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 e^{x} + A_2 e^{5x}
$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$12A_1\mathrm{e}^{x} + 60A_2\mathrm{e}^{5x} = 2\,\mathrm{e}^{x} + 10\,\mathrm{e}^{5x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{6}, A_2 = \frac{1}{6}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\mathrm{e}^{x}}{6} + \frac{\mathrm{e}^{5x}}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-5x} + \frac{c_2\mathrm{e}^{-x}}{4}\right) + \left(\frac{\mathrm{e}^{x}}{6} + \frac{\mathrm{e}^{5x}}{6}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\mathrm{e}^{-5x} + \frac{c_2\mathrm{e}^{-x}}{4} + \frac{\mathrm{e}^{x}}{6} + \frac{\mathrm{e}^{5x}}{6} \tag{1}$$

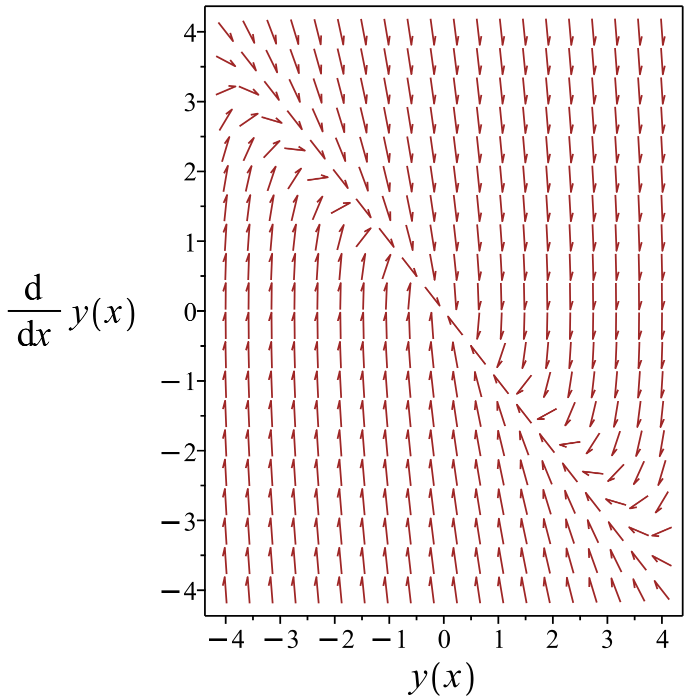

Figure 429: Slope field plot

Verification of solutions

$$y = c_1 e^{-5x} + \frac{c_2 e^{-x}}{4} + \frac{e^x}{6} + \frac{e^{5x}}{6}$$

Verified OK.

11.7.3 Maple step by step solution

Let's solve

$y'' + 6y' + 5y = 2\,e^x + 10\,e^{5x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 6r + 5 = 0$

- Factor the characteristic polynomial

  $(r + 5)(r + 1) = 0$

- Roots of the characteristic polynomial

$r = (-5, -1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-5x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-5x} + c_2 \mathrm{e}^{-x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 2\,\mathrm{e}^{x} + 10\,\mathrm{e}^{5x}\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-5x} & \mathrm{e}^{-x} \\ -5\,\mathrm{e}^{-5x} & -\mathrm{e}^{-x} \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 4\,\mathrm{e}^{-6x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\mathrm{e}^{-5x}\left(\int \mathrm{e}^{6x}(5\,\mathrm{e}^{4x}+1) dx\right)}{2} + \frac{\mathrm{e}^{-x}\left(\int \mathrm{e}^{2x}(5\,\mathrm{e}^{4x}+1) dx\right)}{2}$

  ◦ Compute integrals

  $y_p(x) = \frac{\mathrm{e}^{x}}{6} + \frac{\mathrm{e}^{5x}}{6}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-5x} + c_2 \mathrm{e}^{-x} + \frac{\mathrm{e}^{x}}{6} + \frac{\mathrm{e}^{5x}}{6}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 2y' + 10y = 5x\,\mathrm{e}^{-2x}}$$

11.8.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 10, f(x) = 5x\,\mathrm{e}^{-2x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 10y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 10$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda\, e^{\lambda x} + 10\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 10 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 10$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{2^2 - (4)\,(1)\,(10)}\\ &= -1 \pm 3i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -1 + 3i\\ \lambda_2 &= -1 - 3i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 + 3i\\ \lambda_2 &= -1 - 3i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -1$ and $\beta = 3$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-x}(c_1 \cos(3x) + c_2 \sin(3x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-x}(c_1 \cos(3x) + c_2 \sin(3x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$5x\,\mathrm{e}^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,\mathrm{e}^{-2x}, \mathrm{e}^{-2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-x}\cos(3x), \mathrm{e}^{-x}\sin(3x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,\mathrm{e}^{-2x} + A_2\mathrm{e}^{-2x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1\mathrm{e}^{-2x} + 10A_1 x\,\mathrm{e}^{-2x} + 10A_2\mathrm{e}^{-2x} = 5x\,\mathrm{e}^{-2x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = \frac{1}{10}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x\,\mathrm{e}^{-2x}}{2} + \frac{\mathrm{e}^{-2x}}{10}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{-x}(c_1\cos(3x) + c_2\sin(3x))\right) + \left(\frac{x\,\mathrm{e}^{-2x}}{2} + \frac{\mathrm{e}^{-2x}}{10}\right) \end{aligned}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \mathrm{e}^{-x}(c_1\cos(3x) + c_2\sin(3x)) + \frac{x\,\mathrm{e}^{-2x}}{2} + \frac{\mathrm{e}^{-2x}}{10} \tag{1}$$

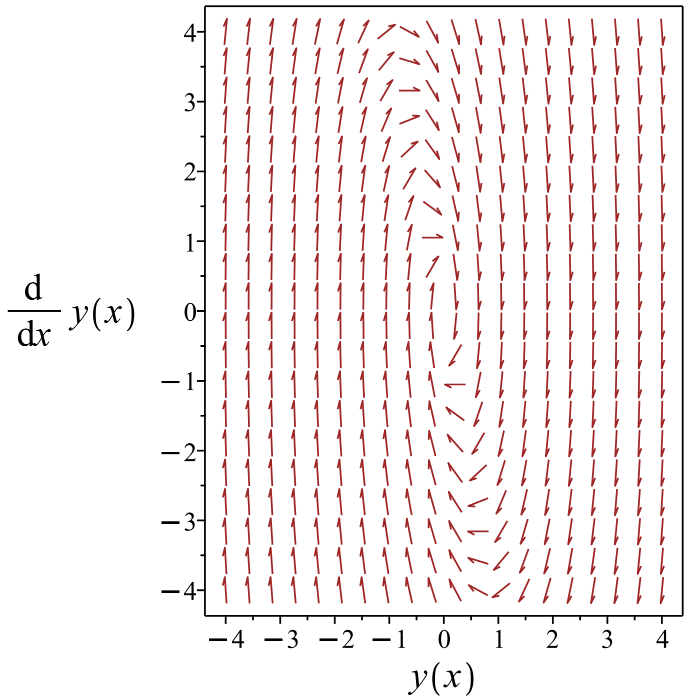

Figure 430: Slope field plot

Verification of solutions

$$y = e^{-x}(c_1 \cos(3x) + c_2 \sin(3x)) + \frac{x\,e^{-2x}}{2} + \frac{e^{-2x}}{10}$$

Verified OK.

11.8.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + 10y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 10 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-9}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -9 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -9z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 359: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -9$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(3x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\
&= z_1 e^{-x} \\
&= z_1 \left(\mathrm{e}^{-x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}\cos(3x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\tan(3x)}{3}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y &= c_1y_1 + c_2y_2\\ &= c_1\left(\mathrm{e}^{-x}\cos(3x)\right) + c_2\left(\mathrm{e}^{-x}\cos(3x)\left(\frac{\tan(3x)}{3}\right)\right)\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 10y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \mathrm{e}^{-x}\cos(3x)\,c_1 + \frac{\mathrm{e}^{-x}\sin(3x)\,c_2}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$5x\,\mathrm{e}^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,\mathrm{e}^{-2x}, \mathrm{e}^{-2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\mathrm{e}^{-x}\cos(3x), \frac{\mathrm{e}^{-x}\sin(3x)}{3}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1x\,\mathrm{e}^{-2x} + A_2\mathrm{e}^{-2x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 e^{-2x} + 10A_1 x\, e^{-2x} + 10A_2 e^{-2x} = 5x\, e^{-2x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = \frac{1}{10}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x\, e^{-2x}}{2} + \frac{e^{-2x}}{10}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-x} \cos(3x)\, c_1 + \frac{e^{-x} \sin(3x)\, c_2}{3}\right) + \left(\frac{x\, e^{-2x}}{2} + \frac{e^{-2x}}{10}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{-x} \cos(3x)\, c_1 + \frac{e^{-x} \sin(3x)\, c_2}{3} + \frac{x\, e^{-2x}}{2} + \frac{e^{-2x}}{10} \tag{1}$$

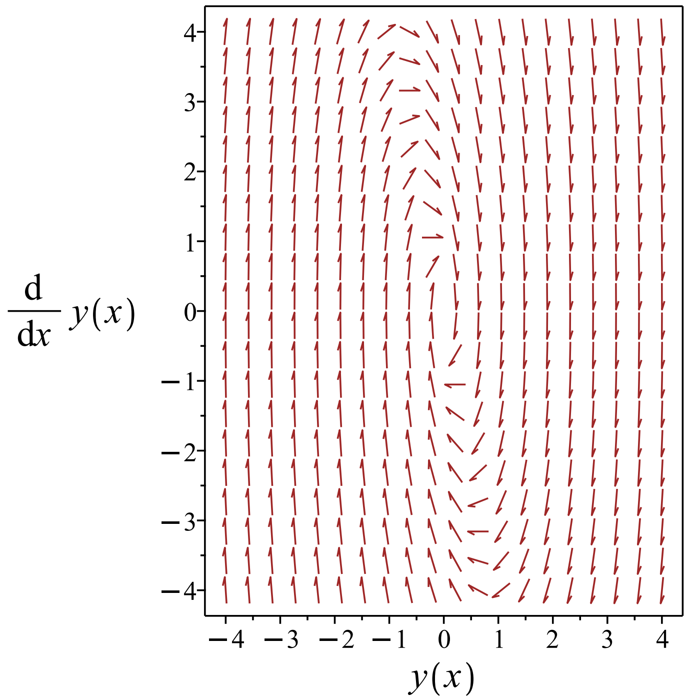

Figure 431: Slope field plot

<u>Verification of solutions</u>

$$y = e^{-x} \cos(3x) c_1 + \frac{e^{-x} \sin(3x) c_2}{3} + \frac{x e^{-2x}}{2} + \frac{e^{-2x}}{10}$$

Verified OK.

11.8.3 Maple step by step solution

Let's solve

$y'' + 2y' + 10y = 5x e^{-2x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r + 10 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-2)\pm(\sqrt{-36})}{2}$

- Roots of the characteristic polynomial

$r = (-1 - 3\,\mathrm{I}, -1 + 3\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-x} \cos(3x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-x} \sin(3x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \mathrm{e}^{-x} \cos(3x)\, c_1 + \mathrm{e}^{-x} \sin(3x)\, c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 5x\, \mathrm{e}^{-2x}\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-x} \cos(3x) & \mathrm{e}^{-x} \sin(3x) \\ -\mathrm{e}^{-x} \cos(3x) - 3\,\mathrm{e}^{-x} \sin(3x) & -\mathrm{e}^{-x} \sin(3x) + 3\,\mathrm{e}^{-x} \cos(3x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 3\,\mathrm{e}^{-2x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\frac{5\,\mathrm{e}^{-x} \left(\cos(3x) \left(\int \mathrm{e}^{-x} \sin(3x) x dx\right) - \sin(3x) \left(\int \mathrm{e}^{-x} \cos(3x) x dx\right)\right)}{3}$

  - Compute integrals

    $y_p(x) = \frac{(5x+1)\mathrm{e}^{-2x}}{10}$

- Substitute particular solution into general solution to ODE

  $y = \mathrm{e}^{-x} \cos(3x)\, c_1 + \mathrm{e}^{-x} \sin(3x)\, c_2 + \frac{(5x+1)\mathrm{e}^{-2x}}{10}$

Problem number: 9.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _with_linear_symmetries]]
```

$$\boxed{y''' + 4y'' + y' - 6y = -18x^2 + 1}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + 4y'' + y' - 6y = 0$$

The characteristic equation is

$$\lambda^3 + 4\lambda^2 + \lambda - 6 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = -3$$
$$\lambda_3 = -2$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-2x} + c_2 e^{x} + e^{-3x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-2x}$$
$$y_2 = e^{x}$$
$$y_3 = e^{-3x}$$

Now the particular solution to the given ODE is found

$$y''' + 4y'' + y' - 6y = -18x^2 + 1$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 + 1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{-3x}, e^{-2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_3 x^2 + A_2 x + A_1$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-6A_3 x^2 - 6A_2 x + 2xA_3 - 6A_1 + A_2 + 8A_3 = -18x^2 + 1$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 4, A_2 = 1, A_3 = 3]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3x^2 + x + 4$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-2x} + c_2 e^{x} + e^{-3x} c_3\right) + \left(3x^2 + x + 4\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-2x} + c_2 e^{x} + e^{-3x} c_3 + 3x^2 + x + 4 \tag{1}$$

Verification of solutions

$$y = c_1 e^{-2x} + c_2 e^{x} + e^{-3x} c_3 + 3x^2 + x + 4$$

Verified OK.

11.9.1 Maple step by step solution

Let's solve

$y''' + 4y'' + y' - 6y = -18x^2 + 1$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - ∘ Define new variable $y_1(x)$

    $y_1(x) = y$
  - ∘ Define new variable $y_2(x)$

    $y_2(x) = y'$
  - ∘ Define new variable $y_3(x)$

    $y_3(x) = y''$
  - ∘ Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = -18x^2 - 4y_3(x) - y_2(x) + 6y_1(x) + 1$

  Convert linear ODE into a system of first order ODEs

$$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = -18x^2 - 4y_3(x) - y_2(x) + 6y_1(x) + 1]$$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 6 & -1 & -4 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ -18x^2 + 1 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ -18x^2 + 1 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 6 & -1 & -4 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-3, \begin{bmatrix} \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{bmatrix}\right], \left[-2, \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-3, \begin{bmatrix} \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \mathrm{e}^{-3x} \cdot \begin{bmatrix} \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} -2, \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_2 = \mathrm{e}^{-2x} \cdot \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_3 = \mathrm{e}^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{y}_p($

$$\overrightarrow{y}(x) = c_1 \overrightarrow{y}_1 + c_2 \overrightarrow{y}_2 + c_3 \overrightarrow{y}_3 + \overrightarrow{y}_p(x)$$

□ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} \frac{\mathrm{e}^{-3x}}{9} & \frac{\mathrm{e}^{-2x}}{4} & \mathrm{e}^{x} \\ -\frac{\mathrm{e}^{-3x}}{3} & -\frac{\mathrm{e}^{-2x}}{2} & \mathrm{e}^{x} \\ \mathrm{e}^{-3x} & \mathrm{e}^{-2x} & \mathrm{e}^{x} \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

  $$\Phi(x) = \begin{bmatrix} \frac{e^{-3x}}{9} & \frac{e^{-2x}}{4} & e^{x} \\ -\frac{e^{-3x}}{3} & -\frac{e^{-2x}}{2} & e^{x} \\ e^{-3x} & e^{-2x} & e^{x} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} \frac{1}{9} & \frac{1}{4} & 1 \\ -\frac{1}{3} & -\frac{1}{2} & 1 \\ 1 & 1 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

  $$\Phi(x) = \begin{bmatrix} \frac{(e^{4x}+2e^{x}-1)e^{-3x}}{2} & -\frac{(-5e^{4x}+8e^{x}-3)e^{-3x}}{12} & \frac{(e^{4x}-4e^{x}+3)e^{-3x}}{12} \\ \frac{(e^{4x}-4e^{x}+3)e^{-3x}}{2} & \frac{(5e^{4x}+16e^{x}-9)e^{-3x}}{12} & \frac{(e^{4x}+8e^{x}-9)e^{-3x}}{12} \\ \frac{(e^{4x}+8e^{x}-9)e^{-3x}}{2} & -\frac{(-5e^{4x}+32e^{x}-27)e^{-3x}}{12} & \frac{(e^{4x}-16e^{x}+27)e^{-3x}}{12} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}'_p(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

$$\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \left[\begin{array}{c} e^{-3x}\left((3x^2+x+4)\,e^{3x} - \frac{4\,e^x}{3} - \frac{35\,e^{4x}}{12} + \frac{1}{4}\right) \\ \frac{(-35\,e^{4x}+72x\,e^{3x}+12\,e^{3x}+32\,e^x-9)e^{-3x}}{12} \\ \frac{(-35\,e^{4x}+72\,e^{3x}-64\,e^x+27)e^{-3x}}{12} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3 + \left[\begin{array}{c} e^{-3x}\left((3x^2+x+4)\,e^{3x} - \frac{4\,e^x}{3} - \frac{35\,e^{4x}}{12} + \frac{1}{4}\right) \\ \frac{(-35\,e^{4x}+72x\,e^{3x}+12\,e^{3x}+32\,e^x-9)e^{-3x}}{12} \\ \frac{(-35\,e^{4x}+72\,e^{3x}-64\,e^x+27)e^{-3x}}{12} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = e^{-3x}\left((3x^2+x+4)\,e^{3x} + \frac{c_2 e^x}{4} + e^{4x}c_3 + \frac{c_1}{9} - \frac{4\,e^x}{3} - \frac{35\,e^{4x}}{12} + \frac{1}{4}\right)$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.3. The method of undetermined coefficients. Exercises page 151
Problem number: 10.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''' + 2y'' - 3y' - 10y = 8x\,\mathrm{e}^{-2x}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + 2y'' - 3y' - 10y = 0$$

The characteristic equation is

$$\lambda^3 + 2\lambda^2 - 3\lambda - 10 = 0$$

The roots of the above equation are

$$\lambda_1 = 2$$
$$\lambda_2 = -2 - i$$
$$\lambda_3 = -2 + i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{2x} + e^{(-2-i)x} c_2 + e^{(-2+i)x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{2x}$$
$$y_2 = e^{(-2-i)x}$$
$$y_3 = e^{(-2+i)x}$$

Now the particular solution to the given ODE is found

$$y''' + 2y'' - 3y' - 10y = 8x\,e^{-2x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8x\,e^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^{-2x}, e^{-2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{(-2-i)x}, e^{(-2+i)x}, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,e^{-2x} + A_2 e^{-2x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 e^{-2x} - 4A_1 x\,e^{-2x} - 4A_2 e^{-2x} = 8x\,e^{-2x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -2, A_2 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2x\,\mathrm{e}^{-2x} - \frac{\mathrm{e}^{-2x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{2x} + \mathrm{e}^{(-2-i)x}c_2 + \mathrm{e}^{(-2+i)x}c_3\right) + \left(-2x\,\mathrm{e}^{-2x} - \frac{\mathrm{e}^{-2x}}{2}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1\mathrm{e}^{2x} + \mathrm{e}^{(-2-i)x}c_2 + \mathrm{e}^{(-2+i)x}c_3 - 2x\,\mathrm{e}^{-2x} - \frac{\mathrm{e}^{-2x}}{2} \tag{1}$$

Verification of solutions

$$y = c_1\mathrm{e}^{2x} + \mathrm{e}^{(-2-i)x}c_2 + \mathrm{e}^{(-2+i)x}c_3 - 2x\,\mathrm{e}^{-2x} - \frac{\mathrm{e}^{-2x}}{2}$$

Verified OK.

11.10.1 Maple step by step solution

Let's solve

$y''' + 2y'' - 3y' - 10y = 8x\,\mathrm{e}^{-2x}$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - ◦ Define new variable $y_1(x)$

    $y_1(x) = y$
  - ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$
  - ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$
  - ◦ Isolate for $y_3'(x)$ using original ODE

$y_3'(x) = 8x\,\mathrm{e}^{-2x} - 2y_3(x) + 3y_2(x) + 10y_1(x)$

Convert linear ODE into a system of first order ODEs

$[y_2(x) = y_1'(x)\,, y_3(x) = y_2'(x)\,, y_3'(x) = 8x\,\mathrm{e}^{-2x} - 2y_3(x) + 3y_2(x) + 10y_1(x)]$

- Define vector

$$\vec{y}(x) = \left[\begin{array}{c} y_1(x) \\ y_2(x) \\ y_3(x) \end{array}\right]$$

- System to solve

$$\vec{y}'(x) = \left[\begin{array}{ccc} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 10 & 3 & -2 \end{array}\right] \cdot \vec{y}(x) + \left[\begin{array}{c} 0 \\ 0 \\ 8x\,\mathrm{e}^{-2x} \end{array}\right]$$

- Define the forcing function

$$\vec{f}(x) = \left[\begin{array}{c} 0 \\ 0 \\ 8x\,\mathrm{e}^{-2x} \end{array}\right]$$

- Define the coefficient matrix

$$A = \left[\begin{array}{ccc} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 10 & 3 & -2 \end{array}\right]$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[2, \left[\begin{array}{c} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]\right], \left[-2-\mathrm{I}, \left[\begin{array}{c} \frac{3}{25} - \frac{4\,\mathrm{I}}{25} \\ -\frac{2}{5} + \frac{\mathrm{I}}{5} \\ 1 \end{array}\right]\right], \left[-2+\mathrm{I}, \left[\begin{array}{c} \frac{3}{25} + \frac{4\,\mathrm{I}}{25} \\ -\frac{2}{5} - \frac{\mathrm{I}}{5} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[2, \left[\begin{array}{c} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = e^{2x} \cdot \left[\begin{array}{c} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-2 - I, \left[\begin{array}{c} \frac{3}{25} - \frac{4\,I}{25} \\ -\frac{2}{5} + \frac{I}{5} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$e^{(-2-I)x} \cdot \left[\begin{array}{c} \frac{3}{25} - \frac{4\,I}{25} \\ -\frac{2}{5} + \frac{I}{5} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$e^{-2x} \cdot (\cos(x) - I\sin(x)) \cdot \left[\begin{array}{c} \frac{3}{25} - \frac{4\,I}{25} \\ -\frac{2}{5} + \frac{I}{5} \\ 1 \end{array}\right]$$

- Simplify expression

$$e^{-2x} \cdot \left[\begin{array}{c} \left(\frac{3}{25} - \frac{4\,I}{25}\right)(\cos(x) - I\sin(x)) \\ \left(-\frac{2}{5} + \frac{I}{5}\right)(\cos(x) - I\sin(x)) \\ \cos(x) - I\sin(x) \end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = e^{-2x} \cdot \left[\begin{array}{c} \frac{3\cos(x)}{25} - \frac{4\sin(x)}{25} \\ -\frac{2\cos(x)}{5} + \frac{\sin(x)}{5} \\ \cos(x) \end{array}\right], \vec{y}_3(x) = e^{-2x} \cdot \left[\begin{array}{c} -\frac{3\sin(x)}{25} - \frac{4\cos(x)}{25} \\ \frac{2\sin(x)}{5} + \frac{\cos(x)}{5} \\ -\sin(x) \end{array}\right]\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{y}_p($

  $\overrightarrow{y}(x) = c_1 \overrightarrow{y}_1 + c_2 \overrightarrow{y}_2(x) + c_3 \overrightarrow{y}_3(x) + \overrightarrow{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} \frac{e^{2x}}{4} & e^{-2x}\left(\frac{3\cos(x)}{25} - \frac{4\sin(x)}{25}\right) & e^{-2x}\left(-\frac{3\sin(x)}{25} - \frac{4\cos(x)}{25}\right) \\ \frac{e^{2x}}{2} & e^{-2x}\left(-\frac{2\cos(x)}{5} + \frac{\sin(x)}{5}\right) & e^{-2x}\left(\frac{2\sin(x)}{5} + \frac{\cos(x)}{5}\right) \\ e^{2x} & \cos(x)\, e^{-2x} & -e^{-2x}\sin(x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} \frac{e^{2x}}{4} & e^{-2x}\left(\frac{3\cos(x)}{25} - \frac{4\sin(x)}{25}\right) & e^{-2x}\left(-\frac{3\sin(x)}{25} - \frac{4\cos(x)}{25}\right) \\ \frac{e^{2x}}{2} & e^{-2x}\left(-\frac{2\cos(x)}{5} + \frac{\sin(x)}{5}\right) & e^{-2x}\left(\frac{2\sin(x)}{5} + \frac{\cos(x)}{5}\right) \\ e^{2x} & \cos(x)\, e^{-2x} & -e^{-2x}\sin(x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} \frac{1}{4} & \frac{3}{25} & -\frac{4}{25} \\ \frac{1}{2} & -\frac{2}{5} & \frac{1}{5} \\ 1 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} \frac{2(6\cos(x)+7\sin(x))e^{-2x}}{17} + \frac{5e^{2x}}{17} & \frac{(-4\cos(x)+\sin(x))e^{-2x}}{17} + \frac{4e^{2x}}{17} & \frac{(-\cos(x)-4\sin(x))e^{-2x}}{17} + \frac{e^{2x}}{17} \\ \frac{10(-\cos(x)-4\sin(x))e^{-2x}}{17} + \frac{10e^{2x}}{17} & \frac{(9\cos(x)+2\sin(x))e^{-2x}}{17} + \frac{8e^{2x}}{17} & \frac{(-2\cos(x)+9\sin(x))e^{-2x}}{17} + \frac{2e^{2x}}{17} \\ \frac{10(-2\cos(x)+9\sin(x))e^{-2x}}{17} + \frac{20e^{2x}}{17} & \frac{(-16\cos(x)-13\sin(x))e^{-2x}}{17} + \frac{16e^{2x}}{17} & \frac{(13\cos(x)-16\sin(x))e^{-2x}}{17} + \frac{4e^{2x}}{17} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(x)$ and solve for $\overrightarrow{v}(x)$

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \overrightarrow{v}(x)$

- Take the derivative of the particular solution

  $\overrightarrow{y}_p'(x) = \Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$$A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$$

- Cancel like terms

  $$\Phi(x) \cdot \overrightarrow{v}'(x) = \overrightarrow{f}(x)$$

- Multiply by the inverse of the fundamental matrix

  $$\overrightarrow{v}'(x) = \frac{1}{\Phi(x)} \cdot \overrightarrow{f}(x)$$

- Integrate to solve for $\overrightarrow{v}(x)$

  $$\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$$

- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $$\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$$

- Plug in the fundamental matrix and the forcing function and compute

  $$\overrightarrow{y}_p(x) = \left[\begin{array}{c} \frac{\mathrm{e}^{-2x}\left(\mathrm{e}^{4x}+16\cos(x)+64\sin(x)-68x-17\right)}{34} \\ \frac{\mathrm{e}^{-2x}\left(\mathrm{e}^{4x}+16\cos(x)-72\sin(x)+68x-17\right)}{17} \\ \frac{2\,\mathrm{e}^{-2x}\left(\mathrm{e}^{4x}-52\cos(x)+64\sin(x)-68x+51\right)}{17} \end{array}\right]$$

- Plug particular solution back into general solution

  $$\overrightarrow{y}(x) = c_1 \overrightarrow{y}_1 + c_2 \overrightarrow{y}_2(x) + c_3 \overrightarrow{y}_3(x) + \left[\begin{array}{c} \frac{\mathrm{e}^{-2x}\left(\mathrm{e}^{4x}+16\cos(x)+64\sin(x)-68x-17\right)}{34} \\ \frac{\mathrm{e}^{-2x}\left(\mathrm{e}^{4x}+16\cos(x)-72\sin(x)+68x-17\right)}{17} \\ \frac{2\,\mathrm{e}^{-2x}\left(\mathrm{e}^{4x}-52\cos(x)+64\sin(x)-68x+51\right)}{17} \end{array}\right]$$

- First component of the vector is the solution to the ODE

  $$y = \frac{\left((204c_2-272c_3+800)\cos(x)+(-272c_2-204c_3+3200)\sin(x)-3400x-850\right)\mathrm{e}^{-2x}}{1700} + \frac{(425c_1+50)\mathrm{e}^{2x}}{1700}$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.3. The method of undetermined coefficients. Exercises page 151
Problem number: 11.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''' + y'' + 3y' - 5y = 5\sin(2x) + 10x^2 + 3x + 7}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + y'' + 3y' - 5y = 0$$

The characteristic equation is

$$\lambda^3 + \lambda^2 + 3\lambda - 5 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = -1 - 2i$$
$$\lambda_3 = -1 + 2i$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + e^{(-1-2i)x} c_2 + e^{(-1+2i)x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^x$$
$$y_2 = e^{(-1-2i)x}$$
$$y_3 = e^{(-1+2i)x}$$

Now the particular solution to the given ODE is found

$$y''' + y'' + 3y' - 5y = 5\sin(2x) + 10x^2 + 3x + 7$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$5\sin(2x) + 10x^2 + 3x + 7$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(2x), \sin(2x)\}, \{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x, e^{(-1-2i)x}, e^{(-1+2i)x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\cos(2x) + A_2\sin(2x) + A_3 + A_4x + A_5x^2$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&2A_1\sin(2x) - 2A_2\cos(2x) - 9A_1\cos(2x) - 9A_2\sin(2x) + 2A_5 \\ &+ 3A_4 + 6A_5x - 5A_3 - 5A_4x - 5A_5x^2 = 5\sin(2x) + 10x^2 + 3x + 7\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{2}{17}, A_2 = -\frac{9}{17}, A_3 = -4, A_4 = -3, A_5 = -2\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{2\cos(2x)}{17} - \frac{9\sin(2x)}{17} - 4 - 3x - 2x^2$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(e^x c_1 + e^{(-1-2i)x} c_2 + e^{(-1+2i)x} c_3\right) + \left(\frac{2\cos(2x)}{17} - \frac{9\sin(2x)}{17} - 4 - 3x - 2x^2\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^x c_1 + e^{(-1-2i)x} c_2 + e^{(-1+2i)x} c_3 + \frac{2\cos(2x)}{17} - \frac{9\sin(2x)}{17} - 4 - 3x - 2x^2 \tag{1}$$

Verification of solutions

$$y = e^x c_1 + e^{(-1-2i)x} c_2 + e^{(-1+2i)x} c_3 + \frac{2\cos(2x)}{17} - \frac{9\sin(2x)}{17} - 4 - 3x - 2x^2$$

Verified OK.

11.11.1 Maple step by step solution

Let's solve

$y''' + y'' + 3y' - 5y = 5\sin(2x) + 10x^2 + 3x + 7$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 5 & -3 & -1 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$
- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \left[\begin{array}{c}1\\1\\1\end{array}\right]\right], \left[-1-2\,\mathrm{I}, \left[\begin{array}{c}-\frac{3}{25}-\frac{4\,\mathrm{I}}{25}\\-\frac{1}{5}+\frac{2\,\mathrm{I}}{5}\\1\end{array}\right]\right], \left[-1+2\,\mathrm{I}, \left[\begin{array}{c}-\frac{3}{25}+\frac{4\,\mathrm{I}}{25}\\-\frac{1}{5}-\frac{2\,\mathrm{I}}{5}\\1\end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c}1\\1\\1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \mathrm{e}^{x} \cdot \left[\begin{array}{c}1\\1\\1\end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-1-2\,\mathrm{I}, \left[\begin{array}{c}-\frac{3}{25}-\frac{4\,\mathrm{I}}{25}\\-\frac{1}{5}+\frac{2\,\mathrm{I}}{5}\\1\end{array}\right]\right]$$

- Solution from eigenpair

$$\mathrm{e}^{(-1-2\,\mathrm{I})x} \cdot \left[\begin{array}{c}-\frac{3}{25}-\frac{4\,\mathrm{I}}{25}\\-\frac{1}{5}+\frac{2\,\mathrm{I}}{5}\\1\end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$\mathrm{e}^{-x} \cdot (\cos(2x) - \mathrm{I}\sin(2x)) \cdot \left[\begin{array}{c}-\frac{3}{25}-\frac{4\,\mathrm{I}}{25}\\-\frac{1}{5}+\frac{2\,\mathrm{I}}{5}\\1\end{array}\right]$$

- Simplify expression

$$\mathrm{e}^{-x} \cdot \left[\begin{array}{c}\left(-\frac{3}{25}-\frac{4\,\mathrm{I}}{25}\right)(\cos(2x)-\mathrm{I}\sin(2x))\\\left(-\frac{1}{5}+\frac{2\,\mathrm{I}}{5}\right)(\cos(2x)-\mathrm{I}\sin(2x))\\\cos(2x)-\mathrm{I}\sin(2x)\end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = e^{-x} \cdot \begin{bmatrix} -\frac{3\cos(2x)}{25} - \frac{4\sin(2x)}{25} \\ -\frac{\cos(2x)}{5} + \frac{2\sin(2x)}{5} \\ \cos(2x) \end{bmatrix}, \vec{y}_3(x) = e^{-x} \cdot \begin{bmatrix} \frac{3\sin(2x)}{25} - \frac{4\cos(2x)}{25} \\ \frac{\sin(2x)}{5} + \frac{2\cos(2x)}{5} \\ -\sin(2x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} e^x & e^{-x}\left(-\frac{3\cos(2x)}{25} - \frac{4\sin(2x)}{25}\right) & e^{-x}\left(\frac{3\sin(2x)}{25} - \frac{4\cos(2x)}{25}\right) \\ e^x & e^{-x}\left(-\frac{\cos(2x)}{5} + \frac{2\sin(2x)}{5}\right) & e^{-x}\left(\frac{\sin(2x)}{5} + \frac{2\cos(2x)}{5}\right) \\ e^x & e^{-x}\cos(2x) & -e^{-x}\sin(2x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} e^x & e^{-x}\left(-\frac{3\cos(2x)}{25} - \frac{4\sin(2x)}{25}\right) & e^{-x}\left(\frac{3\sin(2x)}{25} - \frac{4\cos(2x)}{25}\right) \\ e^x & e^{-x}\left(-\frac{\cos(2x)}{5} + \frac{2\sin(2x)}{5}\right) & e^{-x}\left(\frac{\sin(2x)}{5} + \frac{2\cos(2x)}{5}\right) \\ e^x & e^{-x}\cos(2x) & -e^{-x}\sin(2x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & -\frac{3}{25} & -\frac{4}{25} \\ 1 & -\frac{1}{5} & \frac{2}{5} \\ 1 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} \frac{(-\sin(2x)+3\cos(2x))e^{-x}}{8} + \frac{5e^x}{8} & \frac{(\sin(2x)-\cos(2x))e^{-x}}{4} + \frac{e^x}{4} & \frac{(-\sin(2x)-\cos(2x))e^{-x}}{8} + \frac{e^x}{8} \\ \frac{(-5\sin(2x)-5\cos(2x))e^{-x}}{8} + \frac{5e^x}{8} & \frac{(\sin(2x)+3\cos(2x))e^{-x}}{4} + \frac{e^x}{4} & \frac{(3\sin(2x)-\cos(2x))e^{-x}}{8} + \frac{e^x}{8} \\ \frac{5(3\sin(2x)-\cos(2x))e^{-x}}{8} + \frac{5e^x}{8} & \frac{(-\cos(2x)-7\sin(2x))e^{-x}}{4} + \frac{e^x}{4} & \frac{(7\cos(2x)-\sin(2x))e^{-x}}{8} + \frac{e^x}{8} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

$\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

$\vec{y}'_p(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \left[\begin{array}{c} \frac{(-4\,\mathrm{e}^{-x}+4)\cos(2x)}{34} - 2x^2 - \frac{\mathrm{e}^{-x}\sin(2x)}{34} - 3x + 4\,\mathrm{e}^{x} - \frac{9\sin(2x)}{17} - 4 \\ \frac{(2\,\mathrm{e}^{-x}-36)\cos(2x)}{34} + \frac{9\,\mathrm{e}^{-x}\sin(2x)}{34} - 4x + 4\,\mathrm{e}^{x} - \frac{4\sin(2x)}{17} - 3 \\ -4 + \frac{8(-1+\mathrm{e}^{-x})\cos(2x)}{17} - \frac{13\,\mathrm{e}^{-x}\sin(2x)}{34} + 4\,\mathrm{e}^{x} + \frac{36\sin(2x)}{17} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \left[\begin{array}{c} \frac{(-4\,\mathrm{e}^{-x}+4)\cos(2x)}{34} - 2x^2 - \frac{\mathrm{e}^{-x}\sin(2x)}{34} - 3x + 4\,\mathrm{e}^{x} - \frac{9\sin(2x)}{17} - \\ \frac{(2\,\mathrm{e}^{-x}-36)\cos(2x)}{34} + \frac{9\,\mathrm{e}^{-x}\sin(2x)}{34} - 4x + 4\,\mathrm{e}^{x} - \frac{4\sin(2x)}{17} - 3 \\ -4 + \frac{8(-1+\mathrm{e}^{-x})\cos(2x)}{17} - \frac{13\,\mathrm{e}^{-x}\sin(2x)}{34} + 4\,\mathrm{e}^{x} + \frac{36\sin(2x)}{17} \end{array}\right.$$

- First component of the vector is the solution to the ODE

$$y = -4 + \frac{\left((-50-51c_2-68c_3)\cos(2x)-68\sin(2x)\left(c_2-\frac{3c_3}{4}+\frac{25}{136}\right)\right)\mathrm{e}^{-x}}{425} + \frac{2\cos(2x)}{17} - \frac{9\sin(2x)}{17} + (c_1+4)\,\mathrm{e}^{x} - 2x^2 -$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.3. The method of undetermined coefficients. Exercises page 151
Problem number: 12.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _linear, _nonhomogeneous]]
```

$$\boxed{4y''' - 4y'' - 5y' + 3y = 3x^3 - 8x}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$4y''' - 4y'' - 5y' + 3y = 0$$

The characteristic equation is

$$4\lambda^3 - 4\lambda^2 - 5\lambda + 3 = 0$$

The roots of the above equation are

$$\lambda_1 = \frac{1}{2}$$
$$\lambda_2 = \frac{3}{2}$$
$$\lambda_3 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 \mathrm{e}^{-x} + \mathrm{e}^{\frac{x}{2}} c_2 + c_3 \mathrm{e}^{\frac{3x}{2}}$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = \mathrm{e}^{-x}$$
$$y_2 = \mathrm{e}^{\frac{x}{2}}$$
$$y_3 = \mathrm{e}^{\frac{3x}{2}}$$

Now the particular solution to the given ODE is found

$$4y''' - 4y'' - 5y' + 3y = 3x^3 - 8x$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^3 + x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2, x^3\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\mathrm{e}^{-x}, \mathrm{e}^{\frac{x}{2}}, \mathrm{e}^{\frac{3x}{2}}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_4 x^3 + A_3 x^2 + A_2 x + A_1$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_4x^3 + 3A_3x^2 - 15x^2A_4 + 3A_2x - 10xA_3 - 24xA_4 + 3A_1 - 5A_2 - 8A_3 + 24A_4 \\ = 3x^3 - 8x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 42, A_2 = 22, A_3 = 5, A_4 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x^3 + 5x^2 + 22x + 42$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + e^{\frac{x}{2}} c_2 + c_3 e^{\frac{3x}{2}}\right) + \left(x^3 + 5x^2 + 22x + 42\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-x} + e^{\frac{x}{2}} c_2 + c_3 e^{\frac{3x}{2}} + x^3 + 5x^2 + 22x + 42 \tag{1}$$

Verification of solutions

$$y = c_1 e^{-x} + e^{\frac{x}{2}} c_2 + c_3 e^{\frac{3x}{2}} + x^3 + 5x^2 + 22x + 42$$

Verified OK.

11.12.1 Maple step by step solution

Let's solve

$4y''' - 4y'' - 5y' + 3y = 3x^3 - 8x$

- Highest derivative means the order of the ODE is 3

  y'''

- Isolate 3rd derivative

  $y''' = y'' + \frac{5y'}{4} - \frac{3y}{4} + \frac{3x^3}{4} - 2x$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''' - y'' - \frac{5y'}{4} + \frac{3y}{4} = \frac{3}{4}x^3 - 2x$

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

- Define new variable $y_3(x)$

  $y_3(x) = y''$
- Isolate for $y_3'(x)$ using original ODE

  $y_3'(x) = \frac{3x^3}{4} - 2x + y_3(x) + \frac{5y_2(x)}{4} - \frac{3y_1(x)}{4}$

  Convert linear ODE into a system of first order ODEs

  $\left[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = \frac{3x^3}{4} - 2x + y_3(x) + \frac{5y_2(x)}{4} - \frac{3y_1(x)}{4}\right]$

- Define vector

  $$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

  $$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -\frac{3}{4} & \frac{5}{4} & 1 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ \frac{3}{4}x^3 - 2x \end{bmatrix}$$

- Define the forcing function

  $$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ \frac{3}{4}x^3 - 2x \end{bmatrix}$$

- Define the coefficient matrix

  $$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -\frac{3}{4} & \frac{5}{4} & 1 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$
- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]\right], \left[\frac{1}{2}, \left[\begin{array}{c} 4 \\ 2 \\ 1 \end{array}\right]\right], \left[\frac{3}{2}, \left[\begin{array}{c} \frac{4}{9} \\ \frac{2}{3} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = e^{-x} \cdot \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[\frac{1}{2}, \left[\begin{array}{c} 4 \\ 2 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{\frac{x}{2}} \cdot \left[\begin{array}{c} 4 \\ 2 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[\frac{3}{2}, \left[\begin{array}{c} \frac{4}{9} \\ \frac{2}{3} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = e^{\frac{3x}{2}} \cdot \left[\begin{array}{c} \frac{4}{9} \\ \frac{2}{3} \\ 1 \end{array}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{y}_p($

  $\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2 + c_3\overrightarrow{y}_3 + \overrightarrow{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} \mathrm{e}^{-x} & 4\,\mathrm{e}^{\frac{x}{2}} & \frac{4\,\mathrm{e}^{\frac{3x}{2}}}{9} \\ -\mathrm{e}^{-x} & 2\,\mathrm{e}^{\frac{x}{2}} & \frac{2\,\mathrm{e}^{\frac{3x}{2}}}{3} \\ \mathrm{e}^{-x} & \mathrm{e}^{\frac{x}{2}} & \mathrm{e}^{\frac{3x}{2}} \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} \mathrm{e}^{-x} & 4\,\mathrm{e}^{\frac{x}{2}} & \frac{4\,\mathrm{e}^{\frac{3x}{2}}}{9} \\ -\mathrm{e}^{-x} & 2\,\mathrm{e}^{\frac{x}{2}} & \frac{2\,\mathrm{e}^{\frac{3x}{2}}}{3} \\ \mathrm{e}^{-x} & \mathrm{e}^{\frac{x}{2}} & \mathrm{e}^{\frac{3x}{2}} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & 4 & \frac{4}{9} \\ -1 & 2 & \frac{2}{3} \\ 1 & 1 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} -\frac{\left(\mathrm{e}^{\frac{5x}{2}} - 5\,\mathrm{e}^{\frac{3x}{2}} - 1\right)\mathrm{e}^{-x}}{5} & \frac{\left(3\,\mathrm{e}^{\frac{5x}{2}} + 5\,\mathrm{e}^{\frac{3x}{2}} - 8\right)\mathrm{e}^{-x}}{15} & \frac{2\left(3\,\mathrm{e}^{\frac{5x}{2}} - 5\,\mathrm{e}^{\frac{3x}{2}} + 2\right)\mathrm{e}^{-x}}{15} \\ -\frac{\left(3\,\mathrm{e}^{\frac{5x}{2}} - 5\,\mathrm{e}^{\frac{3x}{2}} + 2\right)\mathrm{e}^{-x}}{10} & \frac{\left(9\,\mathrm{e}^{\frac{5x}{2}} + 5\,\mathrm{e}^{\frac{3x}{2}} + 16\right)\mathrm{e}^{-x}}{30} & \frac{\left(9\,\mathrm{e}^{\frac{5x}{2}} - 5\,\mathrm{e}^{\frac{3x}{2}} - 4\right)\mathrm{e}^{-x}}{15} \\ -\frac{\left(9\,\mathrm{e}^{\frac{5x}{2}} - 5\,\mathrm{e}^{\frac{3x}{2}} - 4\right)\mathrm{e}^{-x}}{20} & \frac{\left(27\,\mathrm{e}^{\frac{5x}{2}} + 5\,\mathrm{e}^{\frac{3x}{2}} - 32\right)\mathrm{e}^{-x}}{60} & \frac{\left(27\,\mathrm{e}^{\frac{5x}{2}} - 5\,\mathrm{e}^{\frac{3x}{2}} + 8\right)\mathrm{e}^{-x}}{30} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(x)$ and solve for $\overrightarrow{v}(x)$

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \overrightarrow{v}(x)$

- Take the derivative of the particular solution

  $\overrightarrow{y}'_p(x) = \Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$$A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$$

- Cancel like terms

$$\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$$

- Multiply by the inverse of the fundamental matrix

$$\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$$

- Integrate to solve for $\vec{v}(x)$

$$\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$$

- Plug $\vec{v}(x)$ into the equation for the particular solution

$$\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \begin{bmatrix} \mathrm{e}^{-x}\left(-\frac{128\,\mathrm{e}^{\frac{3x}{2}}}{3} + \frac{2}{3} + (x^3 + 5x^2 + 22x + 42)\,\mathrm{e}^{x}\right) \\ \frac{\left(9x^2\mathrm{e}^{x} - 64\,\mathrm{e}^{\frac{3x}{2}} + 30x\,\mathrm{e}^{x} + 66\,\mathrm{e}^{x} - 2\right)\mathrm{e}^{-x}}{3} \\ \frac{2\left(-16\,\mathrm{e}^{\frac{3x}{2}} + 9x\,\mathrm{e}^{x} + 15\,\mathrm{e}^{x} + 1\right)\mathrm{e}^{-x}}{3} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3 + \begin{bmatrix} \mathrm{e}^{-x}\left(-\frac{128\,\mathrm{e}^{\frac{3x}{2}}}{3} + \frac{2}{3} + (x^3 + 5x^2 + 22x + 42)\,\mathrm{e}^{x}\right) \\ \frac{\left(9x^2\mathrm{e}^{x} - 64\,\mathrm{e}^{\frac{3x}{2}} + 30x\,\mathrm{e}^{x} + 66\,\mathrm{e}^{x} - 2\right)\mathrm{e}^{-x}}{3} \\ \frac{2\left(-16\,\mathrm{e}^{\frac{3x}{2}} + 9x\,\mathrm{e}^{x} + 15\,\mathrm{e}^{x} + 1\right)\mathrm{e}^{-x}}{3} \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = \mathrm{e}^{-x}\left(\frac{2}{3} + 4\left(-\frac{32}{3} + c_2\right)\mathrm{e}^{\frac{3x}{2}} + \frac{4c_3\mathrm{e}^{\frac{5x}{2}}}{9} + (x^3 + 5x^2 + 22x + 42)\,\mathrm{e}^{x} + c_1\right)$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y' - 6y = 10\,e^{2x} - 18\,e^{3x} - 6x - 11}$$

11.13.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = -6, f(x) = 10\,e^{2x} - 18\,e^{3x} - 6x - 11$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' - 6y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 1, C = -6$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + \lambda e^{\lambda x} - 6 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + \lambda - 6 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 1, C = -6$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{-1}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{1^2 - (4)(1)(-6)} \\
&= -\frac{1}{2} \pm \frac{5}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
\lambda_1 &= -\frac{1}{2} + \frac{5}{2} \\
\lambda_2 &= -\frac{1}{2} - \frac{5}{2}
\end{aligned}$$

Which simplifies to

$$\begin{aligned}
\lambda_1 &= 2 \\
\lambda_2 &= -3
\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}
y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\
y &= c_1 e^{(2)x} + c_2 e^{(-3)x}
\end{aligned}$$

Or

$$y = c_1 e^{2x} + c_2 e^{-3x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{2x} + c_2 e^{-3x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$10\,\mathrm{e}^{2x} - 18\,\mathrm{e}^{3x} - 6x - 11$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{2x}\}, \{\mathrm{e}^{3x}\}, \{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-3x}, \mathrm{e}^{2x}\}$$

Since e^{2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{\mathrm{e}^{2x}x\}, \{\mathrm{e}^{3x}\}, \{1, x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1\mathrm{e}^{2x}x + A_2\mathrm{e}^{3x} + A_3 + A_4x$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$5A_1\mathrm{e}^{2x} + 6A_2\mathrm{e}^{3x} + A_4 - 6A_3 - 6A_4x = 10\,\mathrm{e}^{2x} - 18\,\mathrm{e}^{3x} - 6x - 11$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2, A_2 = -3, A_3 = 2, A_4 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2\,\mathrm{e}^{2x}x - 3\,\mathrm{e}^{3x} + 2 + x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{2x} + c_2\mathrm{e}^{-3x}\right) + \left(2\,\mathrm{e}^{2x}x - 3\,\mathrm{e}^{3x} + 2 + x\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{2x} + c_2 e^{-3x} + 2 e^{2x} x - 3 e^{3x} + 2 + x \tag{1}$$

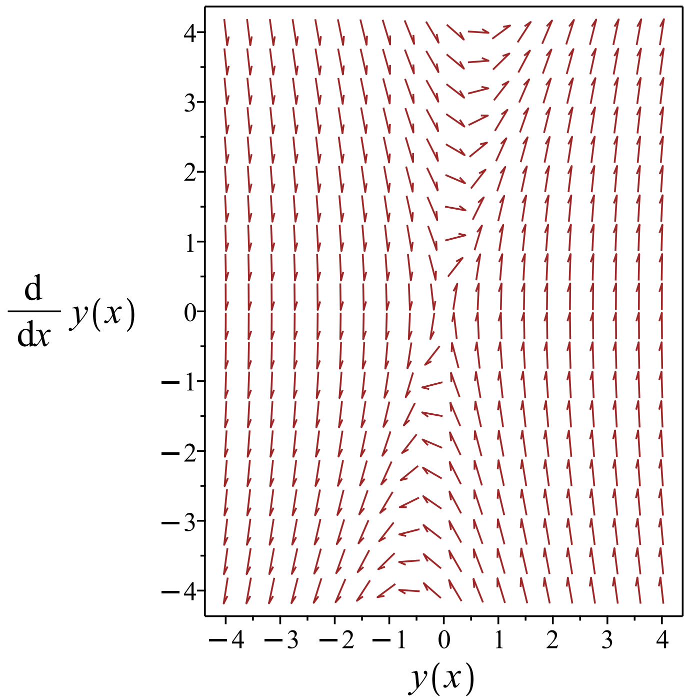

Figure 432: Slope field plot

Verification of solutions

$$y = c_1 e^{2x} + c_2 e^{-3x} + 2 e^{2x} x - 3 e^{3x} + 2 + x$$

Verified OK.

11.13.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y' - 6y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 1 \\ C &= -6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{25}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 25 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{25z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 365: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{25}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{5x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\,dx} \\ &= z_1 e^{-\frac{x}{2}} \\ &= z_1\left(\mathrm{e}^{-\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-x}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\mathrm{e}^{5x}}{5}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-3x}\right) + c_2 \left(\mathrm{e}^{-3x} \left(\frac{\mathrm{e}^{5x}}{5}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' - 6y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-3x} + \frac{c_2 \mathrm{e}^{2x}}{5}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^{-3x}$$
$$y_2 = \frac{e^{2x}}{5}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-3x} & \frac{e^{2x}}{5} \\ \frac{d}{dx}\left(e^{-3x}\right) & \frac{d}{dx}\left(\frac{e^{2x}}{5}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-3x} & \frac{e^{2x}}{5} \\ -3\,e^{-3x} & \frac{2\,e^{2x}}{5} \end{vmatrix}$$

Therefore

$$W = \left(e^{-3x}\right)\left(\frac{2\,e^{2x}}{5}\right) - \left(\frac{e^{2x}}{5}\right)\left(-3\,e^{-3x}\right)$$

Which simplifies to

$$W = e^{-3x} e^{2x}$$

Which simplifies to

$$W = e^{-x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{e^{2x}(10\,e^{2x}-18\,e^{3x}-6x-11)}{5}}{e^{-x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{(10\,e^{2x} - 18\,e^{3x} - 6x - 11)\,e^{3x}}{5}dx$$

Hence

$$u_1 = \frac{3\,e^{3x}}{5} - \frac{2\,e^{5x}}{5} + \frac{3\,e^{6x}}{5} + \frac{2x\,e^{3x}}{5}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{-3x}(10\,e^{2x} - 18\,e^{3x} - 6x - 11)}{e^{-x}}\,dx$$

Which simplifies to

$$u_2 = \int \left(10\,e^{2x} - 18\,e^{3x} - 6x - 11\right) e^{-2x} dx$$

Hence

$$u_2 = 10x + 7\,e^{-2x} + 3x\,e^{-2x} - 18\,e^{x}$$

Which simplifies to

$$u_1 = \frac{(3+2x)\,e^{3x}}{5} - \frac{2\,e^{5x}}{5} + \frac{3\,e^{6x}}{5}$$
$$u_2 = \left(-18\,e^{3x} + 10\,e^{2x}x + 3x + 7\right) e^{-2x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{(3+2x)\,e^{3x}}{5} - \frac{2\,e^{5x}}{5} + \frac{3\,e^{6x}}{5}\right) e^{-3x} + \frac{(-18\,e^{3x} + 10\,e^{2x}x + 3x + 7)\,e^{-2x}e^{2x}}{5}$$

Which simplifies to

$$y_p(x) = 2 - \frac{2\,e^{2x}}{5} - 3\,e^{3x} + x + 2\,e^{2x}x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-3x} + \frac{c_2 e^{2x}}{5}\right) + \left(2 - \frac{2\,e^{2x}}{5} - 3\,e^{3x} + x + 2\,e^{2x}x\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-3x} + \frac{c_2 e^{2x}}{5} + 2 - \frac{2\,e^{2x}}{5} - 3\,e^{3x} + x + 2\,e^{2x}x \tag{1}$$

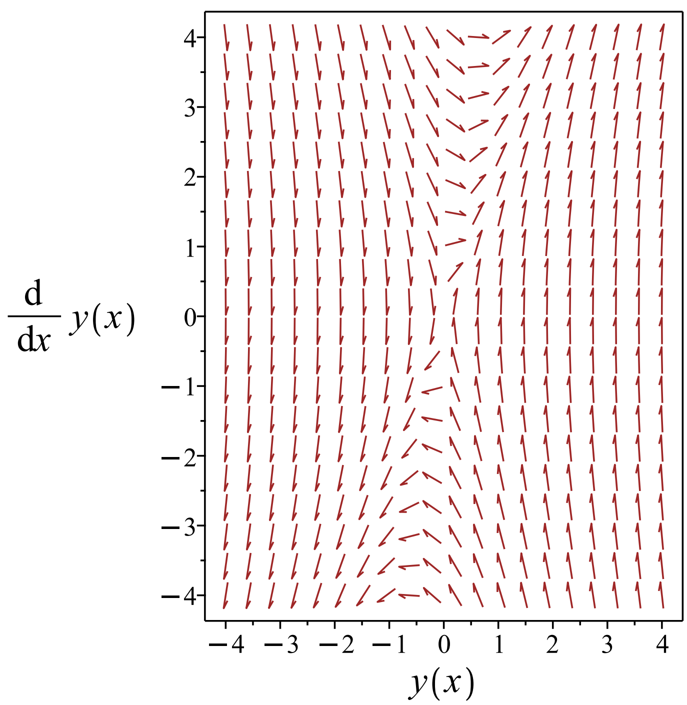

Figure 433: Slope field plot

Verification of solutions

$$y = c_1 e^{-3x} + \frac{c_2 e^{2x}}{5} + 2 - \frac{2\,e^{2x}}{5} - 3\,e^{3x} + x + 2\,e^{2x}x$$

Verified OK.

11.13.3 Maple step by step solution

Let's solve

$y'' + y' - 6y = 10\,e^{2x} - 18\,e^{3x} - 6x - 11$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + r - 6 = 0$

- Factor the characteristic polynomial

  $(r+3)(r-2) = 0$

- Roots of the characteristic polynomial

  $r = (-3, 2)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-3x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-3x} + c_2 e^{2x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 10\,e^{2x} - 18\,e^{3x} - 6x -\right.$

  ◦ Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-3x} & e^{2x} \\ -3\,e^{-3x} & 2\,e^{2x} \end{bmatrix}$

  ◦ Compute Wronskian

    $W(y_1(x), y_2(x)) = 5\,e^{-x}$

  ◦ Substitute functions into equation for $y_p(x)$

$$y_p(x) = \frac{\left(e^{5x}\left(\int \left(10\,e^{2x}-18\,e^{3x}-6x-11\right)e^{-2x}dx\right)-\left(\int \left(10\,e^{2x}-18\,e^{3x}-6x-11\right)e^{3x}dx\right)\right)e^{-3x}}{5}$$

- Compute integrals

$$y_p(x) = 2 - \frac{2\,e^{2x}}{5} - 3\,e^{3x} + x + 2\,e^{2x}x$$

- Substitute particular solution into general solution to ODE

$$y = c_1 e^{-3x} + c_2 e^{2x} + 2 - \frac{2\,e^{2x}}{5} - 3\,e^{3x} + x + 2\,e^{2x}x$$

$$\boxed{y'' + y' - 2y = 6\,\mathrm{e}^{-2x} + 3\,\mathrm{e}^{x} - 4x^2}$$

11.14.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = -2, f(x) = (-4x^2\mathrm{e}^{2x} + 3\,\mathrm{e}^{3x} + 6)\,\mathrm{e}^{-2x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' - 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 1, C = -2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + \lambda e^{\lambda x} - 2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + \lambda - 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 1, C = -2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-1}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{1^2 - (4)(1)(-2)} \\ &= -\frac{1}{2} \pm \frac{3}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{1}{2} + \frac{3}{2} \\ \lambda_2 &= -\frac{1}{2} - \frac{3}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 \\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(1)x} + c_2 e^{(-2)x}\end{aligned}$$

Or

$$y = e^{x} c_1 + c_2 e^{-2x}$$

Therefore the homogeneous solution y_h is

$$y_h = e^{x} c_1 + c_2 e^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\left(-4x^2 e^{2x} + 3\,e^{3x} + 6\right) e^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}, \{e^{-2x}\}, \{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x, e^{-2x}\}$$

Since e^x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^x\}, \{e^{-2x}\}, \{1, x, x^2\}]$$

Since e^{-2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^x\}, \{x\,e^{-2x}\}, \{1, x, x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^x + A_2 x\,e^{-2x} + A_3 + A_4 x + A_5 x^2$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_1 e^x - 3A_2 e^{-2x} + 2A_5 + A_4 + 2A_5 x - 2A_3 - 2A_4 x - 2A_5 x^2 = \left(-4x^2 e^{2x} + 3\,e^{3x} + 6\right) e^{-2x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = -2, A_3 = 3, A_4 = 2, A_5 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x\,e^x - 2x\,e^{-2x} + 3 + 2x + 2x^2$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p \\ &= \left(e^x c_1 + c_2 e^{-2x}\right) + \left(x\,e^x - 2x\,e^{-2x} + 3 + 2x + 2x^2\right)\end{aligned}$$

Summary
The solution(s) found are the following

$$y = e^x c_1 + c_2 e^{-2x} + x\,e^x - 2x\,e^{-2x} + 3 + 2x + 2x^2 \tag{1}$$

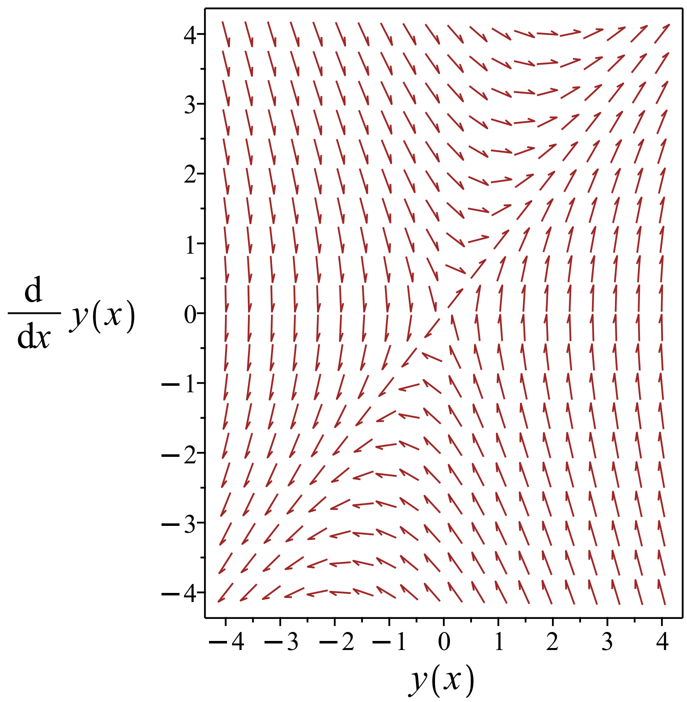

Figure 434: Slope field plot

Verification of solutions

$$y = e^x c_1 + c_2 e^{-2x} + x\,e^x - 2x\,e^{-2x} + 3 + 2x + 2x^2$$

Verified OK.

11.14.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 1 \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 367: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - 0\\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\,dx}\end{aligned}$$

$$
\begin{aligned}
&= z_1 e^{-\frac{x}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-x}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\mathrm{e}^{3x}}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-2x}\right) + c_2 \left(\mathrm{e}^{-2x} \left(\frac{\mathrm{e}^{3x}}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + y' - 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-2x} + \frac{c_2 \mathrm{e}^{x}}{3}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \mathrm{e}^{-2x}$$
$$y_2 = \frac{\mathrm{e}^{x}}{3}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-2x} & \frac{\mathrm{e}^{x}}{3} \\ \frac{d}{dx}(\mathrm{e}^{-2x}) & \frac{d}{dx}\left(\frac{\mathrm{e}^{x}}{3}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{-2x} & \frac{\mathrm{e}^{x}}{3} \\ -2\,\mathrm{e}^{-2x} & \frac{\mathrm{e}^{x}}{3} \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{-2x}\right)\left(\frac{\mathrm{e}^{x}}{3}\right) - \left(\frac{\mathrm{e}^{x}}{3}\right)\left(-2\,\mathrm{e}^{-2x}\right)$$

Which simplifies to

$$W = \mathrm{e}^{-2x}\mathrm{e}^{x}$$

Which simplifies to

$$W = \mathrm{e}^{-x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\mathrm{e}^{x}\left(-4x^2\mathrm{e}^{2x}+3\,\mathrm{e}^{3x}+6\right)\mathrm{e}^{-2x}}{3}}{\mathrm{e}^{-x}}\,dx$$

Which simplifies to

$$u_1 = -\int \left(-\frac{4x^2\mathrm{e}^{2x}}{3}+\mathrm{e}^{3x}+2\right)dx$$

Hence

$$u_1 = -2x+\frac{2x^2\mathrm{e}^{2x}}{3}-\frac{2\,\mathrm{e}^{2x}x}{3}+\frac{\mathrm{e}^{2x}}{3}-\frac{\mathrm{e}^{3x}}{3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\mathrm{e}^{-4x}\left(-4x^2\mathrm{e}^{2x}+3\,\mathrm{e}^{3x}+6\right)}{\mathrm{e}^{-x}}\,dx$$

Which simplifies to

$$u_2 = \int \mathrm{e}^{-3x}\left(-4x^2\mathrm{e}^{2x}+3\,\mathrm{e}^{3x}+6\right)dx$$

Hence

$$u_2 = 3x-2\,\mathrm{e}^{-3x}+4x^2\mathrm{e}^{-x}+8x\,\mathrm{e}^{-x}+8\,\mathrm{e}^{-x}$$

Which simplifies to

$$u_1 = \frac{\left(2x^2-2x+1\right)\mathrm{e}^{2x}}{3}-2x-\frac{\mathrm{e}^{3x}}{3}$$

$$u_2 = \left(4x^2+8x+8\right)\mathrm{e}^{-x}+3x-2\,\mathrm{e}^{-3x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{\left(2x^2-2x+1\right)\mathrm{e}^{2x}}{3}-2x-\frac{\mathrm{e}^{3x}}{3}\right)\mathrm{e}^{-2x}+\frac{\left(\left(4x^2+8x+8\right)\mathrm{e}^{-x}+3x-2\,\mathrm{e}^{-3x}\right)\mathrm{e}^{x}}{3}$$

Which simplifies to

$$y_p(x) = e^{-2x}\left(\left(2x^2+2x+3\right)e^{2x}+x\,e^{3x}-2x-\frac{e^{3x}}{3}-\frac{2}{3}\right)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-2x}+\frac{c_2 e^{x}}{3}\right)+\left(e^{-2x}\left(\left(2x^2+2x+3\right)e^{2x}+x\,e^{3x}-2x-\frac{e^{3x}}{3}-\frac{2}{3}\right)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-2x}+\frac{c_2 e^{x}}{3}+e^{-2x}\left(\left(2x^2+2x+3\right)e^{2x}+x\,e^{3x}-2x-\frac{e^{3x}}{3}-\frac{2}{3}\right) \tag{1}$$

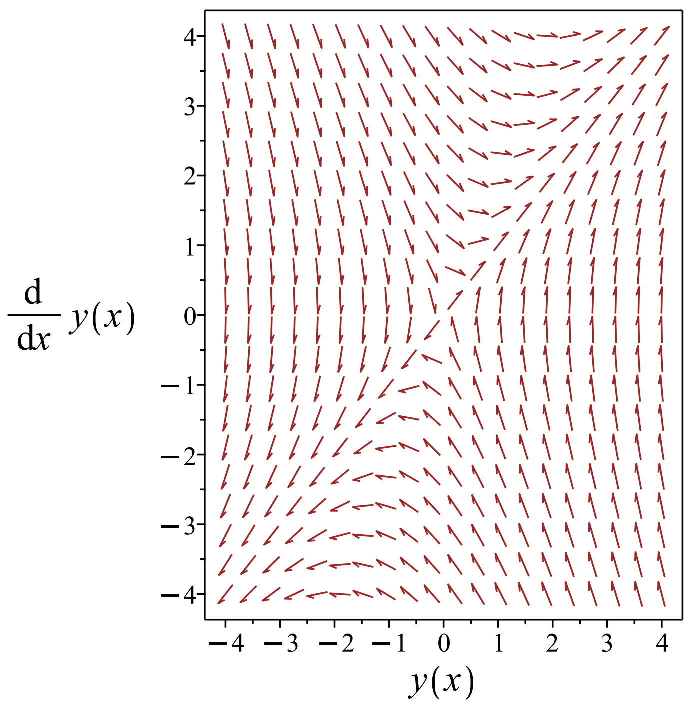

Figure 435: Slope field plot

Verification of solutions

$$y = c_1 e^{-2x}+\frac{c_2 e^{x}}{3}+e^{-2x}\left(\left(2x^2+2x+3\right)e^{2x}+x\,e^{3x}-2x-\frac{e^{3x}}{3}-\frac{2}{3}\right)$$

Verified OK.

11.14.3 Maple step by step solution

Let's solve

$y'' + y' - 2y = (-4x^2 e^{2x} + 3\,e^{3x} + 6)\,e^{-2x}$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -4\,e^{2x} e^{-2x} x^2 + 3\,e^{3x} e^{-2x} - y' + 2y + 6\,e^{-2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + y' - 2y = -(4x^2 e^{2x} - 3\,e^{3x} - 6)\,e^{-2x}$

- Characteristic polynomial of homogeneous ODE

  $r^2 + r - 2 = 0$

- Factor the characteristic polynomial

  $(r+2)(r-1) = 0$

- Roots of the characteristic polynomial

  $r = (-2, 1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-2x} + c_2 e^{x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = -(4x^2 e^{2x} - 3\,e^{3x} - 6)\,e\right.$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-2x} & e^{x} \\ -2\,e^{-2x} & e^{x} \end{bmatrix}$

- Compute Wronskian

  $$W(y_1(x), y_2(x)) = 3\,e^{-x}$$

- Substitute functions into equation for $y_p(x)$

  $$y_p(x) = -\frac{\left(e^{3x}\left(\int e^{-3x}\left(4x^2 e^{2x} - 3\,e^{3x} - 6\right) dx\right) + \int \left(-4x^2 e^{2x} + 3\,e^{3x} + 6\right) dx\right) e^{-2x}}{3}$$

- Compute integrals

  $$y_p(x) = e^{-2x}\left(\left(2x^2 + 2x + 3\right) e^{2x} + x\,e^{3x} - 2x - \frac{e^{3x}}{3} - \frac{2}{3}\right)$$

- Substitute particular solution into general solution to ODE

  $$y = c_1 e^{-2x} + c_2 e^{x} + e^{-2x}\left(\left(2x^2 + 2x + 3\right) e^{2x} + x\,e^{3x} - 2x - \frac{e^{3x}}{3} - \frac{2}{3}\right)$$

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''' - 3y'' + 4y = 4\,e^{x} - 18\,e^{-x}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 3y'' + 4y = 0$$

The characteristic equation is

$$\lambda^3 - 3\lambda^2 + 4 = 0$$

The roots of the above equation are

$$\lambda_1 = -1$$
$$\lambda_2 = 2$$
$$\lambda_3 = 2$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 e^{2x} + x\, e^{2x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = e^{2x}$$
$$y_3 = e^{2x} x$$

Now the particular solution to the given ODE is found

$$y''' - 3y'' + 4y = 4\, e^{x} - 18\, e^{-x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4\, e^{x} - 18\, e^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{x}\}, \{e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{2x} x, e^{-x}, e^{2x}\}$$

Since e^{-x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{x}\}, \{x\, e^{-x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^{x} + A_2 x\, e^{-x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{x} + 9A_2 e^{-x} = 4\, e^{x} - 18\, e^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2, A_2 = -2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2\,\mathrm{e}^{x} - 2x\,\mathrm{e}^{-x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{2x} + x\,\mathrm{e}^{2x} c_3\right) + \left(2\,\mathrm{e}^{x} - 2x\,\mathrm{e}^{-x}\right) \end{aligned}$$

Which simplifies to

$$y = (c_3 x + c_2)\,\mathrm{e}^{2x} + c_1 \mathrm{e}^{-x} + 2\,\mathrm{e}^{x} - 2x\,\mathrm{e}^{-x}$$

Summary
The solution(s) found are the following

$$y = (c_3 x + c_2)\,\mathrm{e}^{2x} + c_1 \mathrm{e}^{-x} + 2\,\mathrm{e}^{x} - 2x\,\mathrm{e}^{-x} \tag{1}$$

Verification of solutions

$$y = (c_3 x + c_2)\,\mathrm{e}^{2x} + c_1 \mathrm{e}^{-x} + 2\,\mathrm{e}^{x} - 2x\,\mathrm{e}^{-x}$$

Verified OK.

11.15.1 Maple step by step solution

Let's solve

$y''' - 3y'' + 4y = 4\,\mathrm{e}^{x} - 18\,\mathrm{e}^{-x}$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

$y_2(x) = y'$

- Define new variable $y_3(x)$

  $y_3(x) = y''$

- Isolate for $y_3'(x)$ using original ODE

  $y_3'(x) = 4\,\mathrm{e}^{x} - 18\,\mathrm{e}^{-x} + 3y_3(x) - 4y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x)\,, y_3(x) = y_2'(x)\,, y_3'(x) = 4\,\mathrm{e}^{x} - 18\,\mathrm{e}^{-x} + 3y_3(x) - 4y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -4 & 0 & 3 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 4\,\mathrm{e}^{x} - 18\,\mathrm{e}^{-x} \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 4\,\mathrm{e}^{x} - 18\,\mathrm{e}^{-x} \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -4 & 0 & 3 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \left[\begin{array}{c}1 \\ -1 \\ 1\end{array}\right]\right], \left[2, \left[\begin{array}{c}\frac{1}{4} \\ \frac{1}{2} \\ 1\end{array}\right]\right], \left[2, \left[\begin{array}{c}0 \\ 0 \\ 0\end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c}1 \\ -1 \\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \mathrm{e}^{-x} \cdot \left[\begin{array}{c}1 \\ -1 \\ 1\end{array}\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[2, \left[\begin{array}{c}\frac{1}{4} \\ \frac{1}{2} \\ 1\end{array}\right]\right]$$

- First solution from eigenvalue 2

$$\overrightarrow{y}_2(x) = \mathrm{e}^{2x} \cdot \left[\begin{array}{c}\frac{1}{4} \\ \frac{1}{2} \\ 1\end{array}\right]$$

- Form of the 2nd homogeneous solution where $\overrightarrow{p}$ is to be solved for, $\lambda = 2$ is the eigenvalue, an

$$\overrightarrow{y}_3(x) = \mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Note that the x multiplying $\overrightarrow{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\overrightarrow{y}_3(x)$ into the homogeneous system

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda x}\overrightarrow{v} = \left(\mathrm{e}^{\lambda x} A\right) \cdot \left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Use the fact that $\overrightarrow{v}$ is an eigenvector of A

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda x}\overrightarrow{v} = \mathrm{e}^{\lambda x}\left(\lambda x\overrightarrow{v} + A \cdot \overrightarrow{p}\right)$$

- Simplify equation

$\lambda\vec{p} + \vec{v} = A \cdot \vec{p}$

- Make use of the identity matrix I

  $(\lambda \cdot I) \cdot \vec{p} + \vec{v} = A \cdot \vec{p}$

- Condition $\vec{p}$ must meet for $\vec{y}_3(x)$ to be a solution to the homogeneous system

  $(A - \lambda \cdot I) \cdot \vec{p} = \vec{v}$

- Choose $\vec{p}$ to use in the second solution to the homogeneous system from eigenvalue 2

  $$\left(\begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -4 & 0 & 3 \end{bmatrix} - 2 \cdot \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) \cdot \vec{p} = \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

- Choice of $\vec{p}$

  $$\vec{p} = \begin{bmatrix} -\frac{1}{8} \\ 0 \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue 2

  $$\vec{y}_3(x) = \mathrm{e}^{2x} \cdot \left(x \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix} + \begin{bmatrix} -\frac{1}{8} \\ 0 \\ 0 \end{bmatrix}\right)$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

  $\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

  $$\phi(x) = \begin{bmatrix} \mathrm{e}^{-x} & \frac{\mathrm{e}^{2x}}{4} & \mathrm{e}^{2x}\left(\frac{x}{4} - \frac{1}{8}\right) \\ -\mathrm{e}^{-x} & \frac{\mathrm{e}^{2x}}{2} & \frac{\mathrm{e}^{2x}x}{2} \\ \mathrm{e}^{-x} & \mathrm{e}^{2x} & \mathrm{e}^{2x}x \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} e^{-x} & \frac{e^{2x}}{4} & e^{2x}\left(\frac{x}{4}-\frac{1}{8}\right) \\ -e^{-x} & \frac{e^{2x}}{2} & \frac{e^{2x}x}{2} \\ e^{-x} & e^{2x} & e^{2x}x \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & \frac{1}{4} & -\frac{1}{8} \\ -1 & \frac{1}{2} & 0 \\ 1 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} (-2x+1)e^{2x} & -\frac{2e^{-x}}{3}+\frac{2e^{2x}}{3}-e^{2x}x & \frac{e^{-x}}{3}-\frac{e^{2x}}{3}+e^{2x}x \\ -4e^{2x}x & \frac{2e^{-x}}{3}+\frac{e^{2x}}{3}-2e^{2x}x & -\frac{e^{-x}}{3}+\frac{e^{2x}}{3}+2e^{2x}x \\ -8e^{2x}x & -\frac{2e^{-x}}{3}+\frac{2e^{2x}}{3}-4e^{2x}x & \frac{e^{-x}}{3}+\frac{2e^{2x}}{3}+4e^{2x}x \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$
- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$
- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$
- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$
- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$
- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \begin{bmatrix} \frac{(-18x-14)e^{-x}}{3} + \frac{(-6x-4)e^{2x}}{3} + 6e^x \\ \frac{(18x-4)e^{-x}}{3} + \frac{(-12x-14)e^{2x}}{3} + 6e^x \\ \frac{(-18x-14)e^{-x}}{3} + \frac{(-24x-28)e^{2x}}{3} + 14e^x \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \begin{bmatrix} \frac{(-18x-14)e^{-x}}{3} + \frac{(-6x-4)e^{2x}}{3} + 6e^x \\ \frac{(18x-4)e^{-x}}{3} + \frac{(-12x-14)e^{2x}}{3} + 6e^x \\ \frac{(-18x-14)e^{-x}}{3} + \frac{(-24x-28)e^{2x}}{3} + 14e^x \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = \frac{(-32+6(-8+c_3)x+6c_2-3c_3)e^{2x}}{24} + \frac{(-14-18x+3c_1)e^{-x}}{3} + 6e^x$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.3. The method of undetermined coefficients. Exercises page 151
Problem number: 16.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''' - 2y'' - y' + 2y = 9\,\mathrm{e}^{2x} - 8\,\mathrm{e}^{3x}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 2y'' - y' + 2y = 0$$

The characteristic equation is

$$\lambda^3 - 2\lambda^2 - \lambda + 2 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 2$$
$$\lambda_3 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 e^{x} + e^{2x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = e^{x}$$
$$y_3 = e^{2x}$$

Now the particular solution to the given ODE is found

$$y''' - 2y'' - y' + 2y = 9\,e^{2x} - 8\,e^{3x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$9\,e^{2x} - 8\,e^{3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x}\}, \{e^{3x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{-x}, e^{2x}\}$$

Since e^{2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{2x} x\}, \{e^{3x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^{2x} x + A_2 e^{3x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_1 e^{2x} + 8A_2 e^{3x} = 9\,e^{2x} - 8\,e^{3x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 3, A_2 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3\,e^{2x}x - e^{3x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2 e^{x} + e^{2x} c_3\right) + \left(3\,e^{2x}x - e^{3x}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 e^{x} + e^{2x} c_3 + 3\,e^{2x}x - e^{3x} \tag{1}$$

Verification of solutions

$$y = c_1 e^{-x} + c_2 e^{x} + e^{2x} c_3 + 3\,e^{2x}x - e^{3x}$$

Verified OK.

11.16.1 Maple step by step solution

Let's solve

$y''' - 2y'' - y' + 2y = 9\,e^{2x} - 8\,e^{3x}$

- Highest derivative means the order of the ODE is 3

  y'''

☐ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

  ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$

- Isolate for $y_3'(x)$ using original ODE

  $y_3'(x) = 9\,e^{2x} - 8\,e^{3x} + 2y_3(x) + y_2(x) - 2y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 9\,e^{2x} - 8\,e^{3x} + 2y_3(x) + y_2(x) - 2y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -2 & 1 & 2 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 9\,e^{2x} - 8\,e^{3x} \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 9\,e^{2x} - 8\,e^{3x} \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -2 & 1 & 2 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = e^{-x} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = e^{2x} \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3 + \vec{y}_p(x)$$

☐ Fundamental matrix

- ○ Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x)=\begin{bmatrix} e^{-x} & e^{x} & \frac{e^{2x}}{4} \\ -e^{-x} & e^{x} & \frac{e^{2x}}{2} \\ e^{-x} & e^{x} & e^{2x} \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0)=I$ where I is t
  $\Phi(x)=\phi(x)\cdot\frac{1}{\phi(0)}$
- Substitute the value of $\phi(x)$ and $\phi(0)$
  $$\Phi(x)=\begin{bmatrix} e^{-x} & e^{x} & \frac{e^{2x}}{4} \\ -e^{-x} & e^{x} & \frac{e^{2x}}{2} \\ e^{-x} & e^{x} & e^{2x} \end{bmatrix}\cdot\frac{1}{\begin{bmatrix} 1 & 1 & \frac{1}{4} \\ -1 & 1 & \frac{1}{2} \\ 1 & 1 & 1 \end{bmatrix}}$$
- Evaluate and simplify to get the fundamental matrix
  $$\Phi(x)=\begin{bmatrix} \frac{e^{-x}}{3}+e^{x}-\frac{e^{2x}}{3} & -\frac{e^{-x}}{2}+\frac{e^{x}}{2} & \frac{e^{-x}}{6}-\frac{e^{x}}{2}+\frac{e^{2x}}{3} \\ -\frac{e^{-x}}{3}+e^{x}-\frac{2e^{2x}}{3} & \frac{e^{-x}}{2}+\frac{e^{x}}{2} & -\frac{e^{-x}}{6}-\frac{e^{x}}{2}+\frac{2e^{2x}}{3} \\ \frac{e^{-x}}{3}+e^{x}-\frac{4e^{2x}}{3} & -\frac{e^{-x}}{2}+\frac{e^{x}}{2} & \frac{e^{-x}}{6}-\frac{e^{x}}{2}+\frac{4e^{2x}}{3} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$
  $\vec{y}_p(x)=\Phi(x)\cdot\vec{v}(x)$
- Take the derivative of the particular solution
  $\vec{y}'_p(x)=\Phi'(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}'(x)$
- Substitute particular solution and its derivative into the system of ODEs
  $\Phi'(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}'(x)=A\cdot\Phi(x)\cdot\vec{v}(x)+\vec{f}(x)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der
  $A\cdot\Phi(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}'(x)=A\cdot\Phi(x)\cdot\vec{v}(x)+\vec{f}(x)$
- Cancel like terms
  $\Phi(x)\cdot\vec{v}'(x)=\vec{f}(x)$
- Multiply by the inverse of the fundamental matrix
  $\vec{v}'(x)=\frac{1}{\Phi(x)}\cdot\vec{f}(x)$

- Integrate to solve for $\overrightarrow{v}(x)$

  $\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$

- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\overrightarrow{y}_p(x) = \left[\begin{array}{c} -\frac{4\,e^{2x}}{3}+3\,e^{2x}x-\frac{e^{-x}}{6}+\frac{5\,e^{x}}{2}-e^{3x} \\ \frac{e^{2x}}{3}+6\,e^{2x}x+\frac{e^{-x}}{6}+\frac{5\,e^{x}}{2}-3\,e^{3x} \\ \frac{20\,e^{2x}}{3}+12\,e^{2x}x-\frac{e^{-x}}{6}+\frac{5\,e^{x}}{2}-9\,e^{3x} \end{array}\right]$$

- Plug particular solution back into general solution

$$\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2 + c_3\overrightarrow{y}_3 + \left[\begin{array}{c} -\frac{4\,e^{2x}}{3}+3\,e^{2x}x-\frac{e^{-x}}{6}+\frac{5\,e^{x}}{2}-e^{3x} \\ \frac{e^{2x}}{3}+6\,e^{2x}x+\frac{e^{-x}}{6}+\frac{5\,e^{x}}{2}-3\,e^{3x} \\ \frac{20\,e^{2x}}{3}+12\,e^{2x}x-\frac{e^{-x}}{6}+\frac{5\,e^{x}}{2}-9\,e^{3x} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = \frac{(36x+3c_3-16)\,e^{2x}}{12} + \frac{(-1+6c_1)\,e^{-x}}{6} - e^{3x} + \frac{(5+2c_2)\,e^{x}}{2}$$

Problem number: 17.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' + y' = 2x^2 + 4\sin(x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + y' = 0$$

The characteristic equation is

$$\lambda^3 + \lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = i$$
$$\lambda_3 = -i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + e^{ix} c_2 + e^{-ix} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= 1 \\ y_2 &= e^{ix} \\ y_3 &= e^{-ix} \end{aligned}$$

Now the particular solution to the given ODE is found

$$y''' + y' = 2x^2 + 4\sin(x)$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)} \, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} 1 & e^{ix} & e^{-ix} \\ 0 & i e^{ix} & -i e^{-ix} \\ 0 & -e^{ix} & -e^{-ix} \end{bmatrix}$$

$$|W| = -2i e^{ix} e^{-ix}$$

The determinant simplifies to

$$|W| = -2i$$

Now we determine W_i for each U_i.

$$\begin{aligned}
W_1(x) &= \det \begin{bmatrix} e^{ix} & e^{-ix} \\ ie^{ix} & -ie^{-ix} \end{bmatrix} \\
&= -2i
\end{aligned}$$

$$\begin{aligned}
W_2(x) &= \det \begin{bmatrix} 1 & e^{-ix} \\ 0 & -ie^{-ix} \end{bmatrix} \\
&= -ie^{-ix}
\end{aligned}$$

$$\begin{aligned}
W_3(x) &= \det \begin{bmatrix} 1 & e^{ix} \\ 0 & ie^{ix} \end{bmatrix} \\
&= ie^{ix}
\end{aligned}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned}
U_1 &= (-1)^{3-1} \int \frac{F(x)W_1(x)}{aW(x)}\, dx \\
&= (-1)^2 \int \frac{(2x^2 + 4\sin(x))(-2i)}{(1)(-2i)}\, dx \\
&= \int \frac{-2i(2x^2 + 4\sin(x))}{-2i}\, dx \\
&= \int \left(2x^2 + 4\sin(x)\right)\, dx \\
&= \frac{2x^3}{3} - 4\cos(x)
\end{aligned}$$

$$\begin{aligned}
U_2 &= (-1)^{3-2} \int \frac{F(x)W_2(x)}{aW(x)}\, dx \\
&= (-1)^1 \int \frac{(2x^2 + 4\sin(x))(-ie^{-ix})}{(1)(-2i)}\, dx \\
&= -\int \frac{-i(2x^2 + 4\sin(x))\, e^{-ix}}{-2i}\, dx \\
&= -\int \left(\left(x^2 + 2\sin(x)\right) e^{-ix}\right)\, dx \\
&= -\left(\int \left(x^2 + 2\sin(x)\right) e^{-ix} dx\right)
\end{aligned}$$

$$
\begin{aligned}
U_3 &= (-1)^{3-3} \int \frac{F(x)W_3(x)}{aW(x)}\, dx \\
&= (-1)^0 \int \frac{(2x^2+4\sin(x))\,(i\mathrm{e}^{ix})}{(1)\,(-2i)}\, dx \\
&= \int \frac{i(2x^2+4\sin(x))\,\mathrm{e}^{ix}}{-2i}\, dx \\
&= \int \left(-(x^2+2\sin(x))\,\mathrm{e}^{ix}\right)\, dx \\
&= \frac{-4i\mathrm{e}^{ix}+(-2-i)\,x\,\mathrm{e}^{ix}+(-4+2i)\,\mathrm{e}^{ix}\tan\left(\frac{x}{2}\right)+ix^2\mathrm{e}^{ix}+(-2+i)\,x\,\mathrm{e}^{ix}\tan\left(\frac{x}{2}\right)^2+ix^2\mathrm{e}^{ix}\tan\left(\frac{x}{2}\right)^2 -}{1+\tan\left(\frac{x}{2}\right)^2} \\
&= \frac{-4i\mathrm{e}^{ix}+(-2-i)\,x\,\mathrm{e}^{ix}+(-4+2i)\,\mathrm{e}^{ix}\tan\left(\frac{x}{2}\right)+ix^2\mathrm{e}^{ix}+(-2+i)\,x\,\mathrm{e}^{ix}\tan\left(\frac{x}{2}\right)^2+ix^2\mathrm{e}^{ix}\tan\left(\frac{x}{2}\right)^2 -}{1+\tan\left(\frac{x}{2}\right)^2}
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1y_1 + U_2y_2 + U_3y_3
$$

Hence

$$
\begin{aligned}
y_p =& \left(\frac{2x^3}{3} - 4\cos(x)\right) \\
&+ \left(-\left(\int (x^2+2\sin(x))\,\mathrm{e}^{-ix}dx\right)\right)(\mathrm{e}^{ix}) \\
&+ \left(\frac{-4i\mathrm{e}^{ix}+(-2-i)\,x\,\mathrm{e}^{ix}+(-4+2i)\,\mathrm{e}^{ix}\tan\left(\frac{x}{2}\right)+ix^2\mathrm{e}^{ix}+(-2+i)\,x\,\mathrm{e}^{ix}\tan\left(\frac{x}{2}\right)^2+ix^2\mathrm{e}^{ix}\tan\left(\frac{x}{2}\right)^2}{1+\tan\left(\frac{x}{2}\right)^2}\right.
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = -2i-\left(\int (x^2+2\sin(x))\,\mathrm{e}^{-ix}dx\right)\mathrm{e}^{ix}+(-ix-2i-4)\cos(x)+(-2+i-x)\sin(x)+ix^2+\frac{2x^3}{3}-2x
$$

Which simplifies to

$$
y_p = -2i-\left(\int (x^2+2\sin(x))\cos(x)\,dx\right)(i\sin(x)+\cos(x))+(-\sin(x)+i\cos(x))\left(\int (x^2+2\sin(x))\right.
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1+\mathrm{e}^{ix}c_2+\mathrm{e}^{-ix}c_3\right) + \left(-2i - \left(\int (x^2+2\sin(x))\cos(x)\,dx\right)(i\sin(x)+\cos(x))\right. \\
&\quad + (-\sin(x)+i\cos(x))\left(\int (x^2+2\sin(x))\sin(x)\,dx\right) + (-ix-2i-4)\cos(x) \\
&\quad \left. + (-2+i-x)\sin(x) + ix^2 + \frac{2x^3}{3} - 2x\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
\begin{aligned}
y = {} & c_1 + \mathrm{e}^{ix} c_2 + \mathrm{e}^{-ix} c_3 - 2i - \left(\int \left(x^2 + 2\sin(x)\right)\cos(x)\, dx\right)\left(i\sin(x) + \cos(x)\right) \\
& + \left(-\sin(x) + i\cos(x)\right)\left(\int \left(x^2 + 2\sin(x)\right)\sin(x)\, dx\right) \\
& + \left(-ix - 2i - 4\right)\cos(x) + \left(-2 + i - x\right)\sin(x) + i x^2 + \frac{2x^3}{3} - 2x
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & c_1 + \mathrm{e}^{ix} c_2 + \mathrm{e}^{-ix} c_3 - 2i - \left(\int \left(x^2 + 2\sin(x)\right)\cos(x)\, dx\right)\left(i\sin(x) + \cos(x)\right) \\
& + \left(-\sin(x) + i\cos(x)\right)\left(\int \left(x^2 + 2\sin(x)\right)\sin(x)\, dx\right) \\
& + \left(-ix - 2i - 4\right)\cos(x) + \left(-2 + i - x\right)\sin(x) + i x^2 + \frac{2x^3}{3} - 2x
\end{aligned}
$$

Verified OK.

11.17.1 Maple step by step solution

Let's solve

$y''' + y' = 2x^2 + 4\sin(x)$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(x)$

    $y_1(x) = y$

  - Define new variable $y_2(x)$

    $y_2(x) = y'$

  - Define new variable $y_3(x)$

    $y_3(x) = y''$

  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = 2x^2 + 4\sin(x) - y_2(x)$

  Convert linear ODE into a system of first order ODEs

$$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 2x^2 + 4\sin(x) - y_2(x)]$$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 2x^2 + 4\sin(x) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 2x^2 + 4\sin(x) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} -1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$\mathrm{e}^{-\mathrm{I}x} \cdot \begin{bmatrix} -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(x) - \mathrm{I}\sin(x)) \cdot \begin{bmatrix} -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\cos(x) + \mathrm{I}\sin(x) \\ \mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ \cos(x) - \mathrm{I}\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_3(x) = \begin{bmatrix} \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \vec{y}_p(x)$

☐ Fundamental matrix

  ○ Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} 1 & -\cos(x) & \sin(x) \\ 0 & \sin(x) & \cos(x) \\ 0 & \cos(x) & -\sin(x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} 1 & -\cos(x) & \sin(x) \\ 0 & \sin(x) & \cos(x) \\ 0 & \cos(x) & -\sin(x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & -1 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} 1 & \sin(x) & 1-\cos(x) \\ 0 & \cos(x) & \sin(x) \\ 0 & -\sin(x) & \cos(x) \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \begin{bmatrix} -2x \sin(x) + 4 \sin(x) + \frac{2x^3}{3} - 4 \cos(x) - 4x + 4 \\ (-2x + 4) \cos(x) + 2x^2 + 2 \sin(x) - 4 \\ (2x - 4) \sin(x) + 4x \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1 \vec{y}_1 + c_2 \vec{y}_2(x) + c_3 \vec{y}_3(x) + \begin{bmatrix} -2x \sin(x) + 4 \sin(x) + \frac{2x^3}{3} - 4 \cos(x) - 4x + 4 \\ (-2x + 4) \cos(x) + 2x^2 + 2 \sin(x) - 4 \\ (2x - 4) \sin(x) + 4x \end{bmatrix}$$

- First component of the vector is the solution to the ODE

  $y = 4 + (-2x + 4 + c_3) \sin(x) + (-4 - c_2) \cos(x) + \frac{2x^3}{3} - 4x + c_1$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.3. The method of undetermined coefficients. Exercises page 151
Problem number: 18.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_y]]
```

$$\boxed{y'''' - 3y''' + 2y'' = 3\,\mathrm{e}^{-x} + 6\,\mathrm{e}^{2x} - 6x}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - 3y''' + 2y'' = 0$$

The characteristic equation is

$$\lambda^4 - 3\lambda^3 + 2\lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = 2$$
$$\lambda_4 = 1$$

Therefore the homogeneous solution is

$$y_h(x) = c_2 x + c_1 + c_3 e^x + e^{2x} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = x$$
$$y_3 = e^x$$
$$y_4 = e^{2x}$$

Now the particular solution to the given ODE is found

$$y'''' - 3y''' + 2y'' = 3\,e^{-x} + 6\,e^{2x} - 6x$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$3\,e^{-x} + 6\,e^{2x} - 6x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-x}\}, \{e^{2x}\}, \{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, e^x, e^{2x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{-x}\}, \{e^{2x}\}, \{x, x^2\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{-x}\}, \{e^{2x}\}, \{x^2, x^3\}]$$

Since e^{2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{-x}\}, \{e^{2x} x\}, \{x^2, x^3\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^{-x} + A_2 e^{2x} x + A_3 x^2 + A_4 x^3$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$6A_1 e^{-x} + 4A_2 e^{2x} - 18A_4 + 4A_3 + 12A_4 x = 3\, e^{-x} + 6\, e^{2x} - 6x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = \frac{3}{2}, A_3 = -\frac{9}{4}, A_4 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{-x}}{2} + \frac{3\, e^{2x} x}{2} - \frac{9x^2}{4} - \frac{x^3}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_2 x + c_1 + c_3 e^{x} + e^{2x} c_4\right) + \left(\frac{e^{-x}}{2} + \frac{3\, e^{2x} x}{2} - \frac{9x^2}{4} - \frac{x^3}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_2 x + c_1 + c_3 e^{x} + e^{2x} c_4 + \frac{e^{-x}}{2} + \frac{3\, e^{2x} x}{2} - \frac{9x^2}{4} - \frac{x^3}{2} \tag{1}$$

Verification of solutions

$$y = c_2 x + c_1 + c_3 e^{x} + e^{2x} c_4 + \frac{e^{-x}}{2} + \frac{3\, e^{2x} x}{2} - \frac{9x^2}{4} - \frac{x^3}{2}$$

Verified OK.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''' - 6y'' + 11y' - 6y = x\,\mathrm{e}^{x} - 4\,\mathrm{e}^{2x} + 6\,\mathrm{e}^{4x}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 6y'' + 11y' - 6y = 0$$

The characteristic equation is

$$\lambda^3 - 6\lambda^2 + 11\lambda - 6 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 2$$
$$\lambda_3 = 3$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + c_2 e^{2x} + c_3 e^{3x}$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^x$$
$$y_2 = e^{2x}$$
$$y_3 = e^{3x}$$

Now the particular solution to the given ODE is found

$$y''' - 6y'' + 11y' - 6y = x\,e^x - 4\,e^{2x} + 6\,e^{4x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x\,e^x - 4\,e^{2x} + 6\,e^{4x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x}\}, \{e^{4x}\}, \{x\,e^x, e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x, e^{2x}, e^{3x}\}$$

Since e^x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{2x}\}, \{e^{4x}\}, \{x\,e^x, x^2 e^x\}]$$

Since e^{2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{2x} x\}, \{e^{4x}\}, \{x\,e^x, x^2 e^x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^{2x} x + A_2 e^{4x} + A_3 x\,e^x + A_4 x^2 e^x$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_4x\,\mathrm{e}^{x} - A_1\mathrm{e}^{2x} + 2A_3\mathrm{e}^{x} - 6A_4\mathrm{e}^{x} + 6A_2\mathrm{e}^{4x} = x\,\mathrm{e}^{x} - 4\,\mathrm{e}^{2x} + 6\,\mathrm{e}^{4x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 4, A_2 = 1, A_3 = \frac{3}{4}, A_4 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 4\,\mathrm{e}^{2x}x + \mathrm{e}^{4x} + \frac{3x\,\mathrm{e}^{x}}{4} + \frac{x^2\mathrm{e}^{x}}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{x}c_1 + c_2\mathrm{e}^{2x} + c_3\mathrm{e}^{3x}\right) + \left(4\,\mathrm{e}^{2x}x + \mathrm{e}^{4x} + \frac{3x\,\mathrm{e}^{x}}{4} + \frac{x^2\mathrm{e}^{x}}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{x}c_1 + c_2\mathrm{e}^{2x} + c_3\mathrm{e}^{3x} + 4\,\mathrm{e}^{2x}x + \mathrm{e}^{4x} + \frac{3x\,\mathrm{e}^{x}}{4} + \frac{x^2\mathrm{e}^{x}}{4} \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{x}c_1 + c_2\mathrm{e}^{2x} + c_3\mathrm{e}^{3x} + 4\,\mathrm{e}^{2x}x + \mathrm{e}^{4x} + \frac{3x\,\mathrm{e}^{x}}{4} + \frac{x^2\mathrm{e}^{x}}{4}$$

Verified OK.

11.19.1 Maple step by step solution

Let's solve

$y''' - 6y'' + 11y' - 6y = x\,\mathrm{e}^{x} - 4\,\mathrm{e}^{2x} + 6\,\mathrm{e}^{4x}$

- Highest derivative means the order of the ODE is 3

  y'''

☐ Convert linear ODE into a system of first order ODEs

- Define new variable $y_1(x)$

  $y_1(x) = y$

- Define new variable $y_2(x)$

  $y_2(x) = y'$

- Define new variable $y_3(x)$

  $y_3(x) = y''$

- Isolate for $y_3'(x)$ using original ODE

  $y_3'(x) = x\,\mathrm{e}^{x} - 4\,\mathrm{e}^{2x} + 6\,\mathrm{e}^{4x} + 6y_3(x) - 11y_2(x) + 6y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = x\,\mathrm{e}^{x} - 4\,\mathrm{e}^{2x} + 6\,\mathrm{e}^{4x} + 6y_3(x) - 11y_2(x) + 6y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 6 & -11 & 6 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ x\,\mathrm{e}^{x} - 4\,\mathrm{e}^{2x} + 6\,\mathrm{e}^{4x} \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ x\,\mathrm{e}^{x} - 4\,\mathrm{e}^{2x} + 6\,\mathrm{e}^{4x} \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 6 & -11 & 6 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \end{array}\right]\right], \left[2, \left[\begin{array}{c} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]\right], \left[3, \left[\begin{array}{c} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = e^{x} \cdot \left[\begin{array}{c} 1 \\ 1 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[2, \left[\begin{array}{c} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{2x} \cdot \left[\begin{array}{c} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[3, \left[\begin{array}{c} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = e^{3x} \cdot \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

  $\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3 + \vec{y}_p(x)$

□ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} e^x & \frac{e^{2x}}{4} & \frac{e^{3x}}{9} \\ e^x & \frac{e^{2x}}{2} & \frac{e^{3x}}{3} \\ e^x & e^{2x} & e^{3x} \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} e^x & \frac{e^{2x}}{4} & \frac{e^{3x}}{9} \\ e^x & \frac{e^{2x}}{2} & \frac{e^{3x}}{3} \\ e^x & e^{2x} & e^{3x} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & \frac{1}{4} & \frac{1}{9} \\ 1 & \frac{1}{2} & \frac{1}{3} \\ 1 & 1 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} 3e^x - 3e^{2x} + e^{3x} & -\frac{5e^x}{2} + 4e^{2x} - \frac{3e^{3x}}{2} & \frac{e^x}{2} - e^{2x} + \frac{e^{3x}}{2} \\ 3e^x - 6e^{2x} + 3e^{3x} & -\frac{5e^x}{2} + 8e^{2x} - \frac{9e^{3x}}{2} & \frac{e^x}{2} - 2e^{2x} + \frac{3e^{3x}}{2} \\ 3e^x - 12e^{2x} + 9e^{3x} & -\frac{5e^x}{2} + 16e^{2x} - \frac{27e^{3x}}{2} & \frac{e^x}{2} - 4e^{2x} + \frac{9e^{3x}}{2} \end{bmatrix}$$

□ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

$\Phi'(x)\cdot \vec{v}(x)+\Phi(x)\cdot \vec{v}'(x)=A\cdot \Phi(x)\cdot \vec{v}(x)+\vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A\cdot \Phi(x)\cdot \vec{v}(x)+\Phi(x)\cdot \vec{v}'(x)=A\cdot \Phi(x)\cdot \vec{v}(x)+\vec{f}(x)$

- Cancel like terms

  $\Phi(x)\cdot \vec{v}'(x)=\vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x)=\frac{1}{\Phi(x)}\cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x)=\int_0^x \frac{1}{\Phi(s)}\cdot \vec{f}(s)\,ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x)=\Phi(x)\cdot \left(\int_0^x \frac{1}{\Phi(s)}\cdot \vec{f}(s)\,ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x)=\left[\begin{array}{c} 2(2x+1)\,\mathrm{e}^{2x}-\frac{39\,\mathrm{e}^{3x}}{8}+\mathrm{e}^{4x}+\frac{(2x^2+6x+15)\mathrm{e}^{x}}{8} \\ 8(1+x)\,\mathrm{e}^{2x}-\frac{117\,\mathrm{e}^{3x}}{8}+4\,\mathrm{e}^{4x}+\frac{(2x^2+10x+21)\mathrm{e}^{x}}{8} \\ 8(3+2x)\,\mathrm{e}^{2x}-\frac{351\,\mathrm{e}^{3x}}{8}+16\,\mathrm{e}^{4x}+\frac{(2x^2+14x+31)\mathrm{e}^{x}}{8} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x)=c_1\vec{y}_1+c_2\vec{y}_2+c_3\vec{y}_3+\left[\begin{array}{c} 2(2x+1)\,\mathrm{e}^{2x}-\frac{39\,\mathrm{e}^{3x}}{8}+\mathrm{e}^{4x}+\frac{(2x^2+6x+15)\mathrm{e}^{x}}{8} \\ 8(1+x)\,\mathrm{e}^{2x}-\frac{117\,\mathrm{e}^{3x}}{8}+4\,\mathrm{e}^{4x}+\frac{(2x^2+10x+21)\mathrm{e}^{x}}{8} \\ 8(3+2x)\,\mathrm{e}^{2x}-\frac{351\,\mathrm{e}^{3x}}{8}+16\,\mathrm{e}^{4x}+\frac{(2x^2+14x+31)\mathrm{e}^{x}}{8} \end{array}\right]$$

- First component of the vector is the solution to the ODE

  $y=\frac{(8+16x+c_2)\mathrm{e}^{2x}}{4}+\frac{(8c_3-351)\mathrm{e}^{3x}}{72}+\mathrm{e}^{4x}+\frac{(2x^2+8c_1+6x+15)\mathrm{e}^{x}}{8}$

Problem number: 20.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''' - 4y'' + 5y' - 2y = 3x^2 \mathrm{e}^x - 7\,\mathrm{e}^x}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 4y'' + 5y' - 2y = 0$$

The characteristic equation is

$$\lambda^3 - 4\lambda^2 + 5\lambda - 2 = 0$$

The roots of the above equation are

$$\lambda_1 = 2$$
$$\lambda_2 = 1$$
$$\lambda_3 = 1$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + c_2 x\, e^x + e^{2x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^x$$
$$y_2 = x\, e^x$$
$$y_3 = e^{2x}$$

Now the particular solution to the given ODE is found

$$y''' - 4y'' + 5y' - 2y = 3x^2 e^x - 7\, e^x$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$3x^2 e^x - 7\, e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\, e^x, x^2 e^x, e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^x, e^x, e^{2x}\}$$

Since e^x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\, e^x, x^2 e^x, x^3 e^x\}]$$

Since $x\, e^x$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 e^x, x^3 e^x, e^x x^4\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 e^x + A_2 x^3 e^x + A_3 e^x x^4$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-6A_2 x\,\mathrm{e}^x - 12A_3\mathrm{e}^x x^2 + 24A_3\mathrm{e}^x x + 6A_2\mathrm{e}^x - 2A_1\mathrm{e}^x = 3x^2\mathrm{e}^x - 7\,\mathrm{e}^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = -1, A_3 = -\frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2\mathrm{e}^x}{2} - x^3\mathrm{e}^x - \frac{\mathrm{e}^x x^4}{4}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(\mathrm{e}^x c_1 + c_2 x\,\mathrm{e}^x + \mathrm{e}^{2x} c_3\right) + \left(\frac{x^2\mathrm{e}^x}{2} - x^3\mathrm{e}^x - \frac{\mathrm{e}^x x^4}{4}\right)
\end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{2x} c_3 + \mathrm{e}^x (c_2 x + c_1) + \frac{x^2\mathrm{e}^x}{2} - x^3\mathrm{e}^x - \frac{\mathrm{e}^x x^4}{4}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{2x} c_3 + \mathrm{e}^x (c_2 x + c_1) + \frac{x^2\mathrm{e}^x}{2} - x^3\mathrm{e}^x - \frac{\mathrm{e}^x x^4}{4} \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{2x} c_3 + \mathrm{e}^x (c_2 x + c_1) + \frac{x^2\mathrm{e}^x}{2} - x^3\mathrm{e}^x - \frac{\mathrm{e}^x x^4}{4}$$

Verified OK.

11.20.1 Maple step by step solution

Let's solve

$y''' - 4y'' + 5y' - 2y = 3x^2 e^x - 7 e^x$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs

  - ○ Define new variable $y_1(x)$

    $y_1(x) = y$

  - ○ Define new variable $y_2(x)$

    $y_2(x) = y'$

  - ○ Define new variable $y_3(x)$

    $y_3(x) = y''$

  - ○ Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = 3x^2 e^x + 4y_3(x) - 5y_2(x) + 2y_1(x) - 7 e^x$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 3x^2 e^x + 4y_3(x) - 5y_2(x) + 2y_1(x) - 7 e^x]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 2 & -5 & 4 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 3x^2 e^x - 7 e^x \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 3x^2 e^x - 7 e^x \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 2 & -5 & 4 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- First solution from eigenvalue 1

$$\vec{y}_1(x) = e^x \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\vec{p}$ is to be solved for, $\lambda = 1$ is the eigenvalue, an

$$\vec{y}_2(x) = e^{\lambda x}\left(x\vec{v} + \vec{p}\right)$$

- Note that the x multiplying $\vec{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\vec{y}_2(x)$ into the homogeneous system

$$\lambda e^{\lambda x}\left(x\vec{v} + \vec{p}\right) + e^{\lambda x}\vec{v} = \left(e^{\lambda x}A\right) \cdot \left(x\vec{v} + \vec{p}\right)$$

- Use the fact that $\vec{v}$ is an eigenvector of A

$$\lambda e^{\lambda x}\left(x\vec{v} + \vec{p}\right) + e^{\lambda x}\vec{v} = e^{\lambda x}\left(\lambda x\vec{v} + A \cdot \vec{p}\right)$$

- Simplify equation

$\lambda\vec{p}+\vec{v}=A\cdot\vec{p}$

- Make use of the identity matrix I

  $(\lambda\cdot I)\cdot\vec{p}+\vec{v}=A\cdot\vec{p}$

- Condition $\vec{p}$ must meet for $\vec{y}_2(x)$ to be a solution to the homogeneous system

  $(A-\lambda\cdot I)\cdot\vec{p}=\vec{v}$

- Choose $\vec{p}$ to use in the second solution to the homogeneous system from eigenvalue 1

$$\left(\begin{bmatrix}0 & 1 & 0\\ 0 & 0 & 1\\ 2 & -5 & 4\end{bmatrix}-1\cdot\begin{bmatrix}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{bmatrix}\right)\cdot\vec{p}=\begin{bmatrix}1\\ 1\\ 1\end{bmatrix}$$

- Choice of $\vec{p}$

$$\vec{p}=\begin{bmatrix}-1\\ 0\\ 0\end{bmatrix}$$

- Second solution from eigenvalue 1

$$\vec{y}_2(x)=\mathrm{e}^{x}\cdot\left(x\cdot\begin{bmatrix}1\\ 1\\ 1\end{bmatrix}+\begin{bmatrix}-1\\ 0\\ 0\end{bmatrix}\right)$$

- Consider eigenpair

$$\left[2,\begin{bmatrix}\frac{1}{4}\\ \frac{1}{2}\\ 1\end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3=\mathrm{e}^{2x}\cdot\begin{bmatrix}\frac{1}{4}\\ \frac{1}{2}\\ 1\end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

  $\vec{y}(x)=c_1\vec{y}_1(x)+c_2\vec{y}_2(x)+c_3\vec{y}_3+\vec{y}_p(x)$

□ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x)=\begin{bmatrix} e^{x} & e^{x}(x-1) & \frac{e^{2x}}{4} \\ e^{x} & x\,e^{x} & \frac{e^{2x}}{2} \\ e^{x} & x\,e^{x} & e^{2x} \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0)=I$ where I is t

$\Phi(x)=\phi(x)\cdot\frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x)=\begin{bmatrix} e^{x} & e^{x}(x-1) & \frac{e^{2x}}{4} \\ e^{x} & x\,e^{x} & \frac{e^{2x}}{2} \\ e^{x} & x\,e^{x} & e^{2x} \end{bmatrix}\cdot\frac{1}{\begin{bmatrix} 1 & -1 & \frac{1}{4} \\ 1 & 0 & \frac{1}{2} \\ 1 & 0 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x)=\begin{bmatrix} -e^{x}(x-1) & -\frac{e^{2x}}{2}+\frac{e^{x}(3x+1)}{2} & \frac{e^{2x}}{2}+\frac{e^{x}(-x-1)}{2} \\ -x\,e^{x} & 2\,e^{x}+\frac{3x\,e^{x}}{2}-e^{2x} & -e^{x}-\frac{x\,e^{x}}{2}+e^{2x} \\ -x\,e^{x} & 2\,e^{x}+\frac{3x\,e^{x}}{2}-2\,e^{2x} & -e^{x}-\frac{x\,e^{x}}{2}+2\,e^{2x} \end{bmatrix}$$

□ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

$\vec{y}_p(x)=\Phi(x)\cdot\vec{v}(x)$

- Take the derivative of the particular solution

$\vec{y}_p'(x)=\Phi'(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

$\Phi'(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}'(x)=A\cdot\Phi(x)\cdot\vec{v}(x)+\vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$A\cdot\Phi(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}'(x)=A\cdot\Phi(x)\cdot\vec{v}(x)+\vec{f}(x)$

- Cancel like terms

$\Phi(x)\cdot\vec{v}'(x)=\vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

$$\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$$

- Integrate to solve for $\vec{v}(x)$

$$\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$$

- Plug $\vec{v}(x)$ into the equation for the particular solution

$$\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \begin{bmatrix} -\frac{e^{2x}}{2} + \frac{(-x^4-4x^3+2x^2+4x+4)e^x}{8} \\ -e^{2x} + \frac{(-x^4-8x^3-10x^2+8x+8)e^x}{8} \\ -2\,e^{2x} + \frac{(-x^4-8x^3-34x^2-40x+16)e^x}{8} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1(x) + c_2\vec{y}_2(x) + c_3\vec{y}_3 + \begin{bmatrix} -\frac{e^{2x}}{2} + \frac{(-x^4-4x^3+2x^2+4x+4)e^x}{8} \\ -e^{2x} + \frac{(-x^4-8x^3-10x^2+8x+8)e^x}{8} \\ -2\,e^{2x} + \frac{(-x^4-8x^3-34x^2-40x+16)e^x}{8} \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = \frac{(2c_3-4)e^{2x}}{8} - \frac{(x^4+4x^3-2x^2+(-8c_2-4)x-8c_1+8c_2-4)e^x}{8}$$

Problem number: 21.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = x \sin (x)}$$

11.21.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = x \sin (x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)}\\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i\\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i\\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x \sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x \sin(x), \cos(x) x, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x \sin(x), \cos(x) x, \cos(x) x^2, \sin(x) x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x \sin(x) + A_2 \cos(x) x + A_3 \cos(x) x^2 + A_4 \sin(x) x^2$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 \cos(x) - 2A_2 \sin(x) - 4A_3 \sin(x) x + 2A_3 \cos(x) + 4A_4 \cos(x) x + 2A_4 \sin(x) = x \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{4}, A_2 = 0, A_3 = -\frac{1}{4}, A_4 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x \sin(x)}{4} - \frac{\cos(x) x^2}{4}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + \left(\frac{x \sin(x)}{4} - \frac{\cos(x) x^2}{4}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(x) + c_2 \sin(x) + \frac{x \sin(x)}{4} - \frac{\cos(x) x^2}{4} \tag{1}
$$

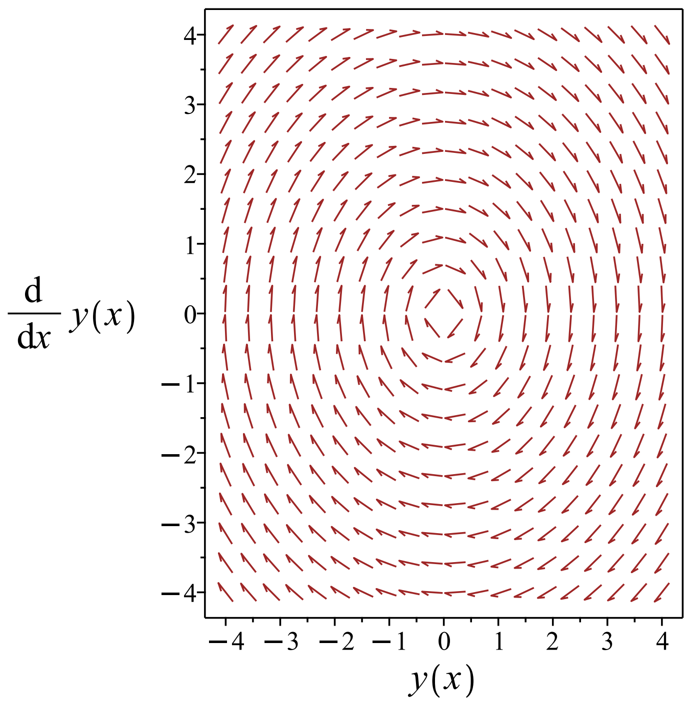

Figure 436: Slope field plot

Verification of solutions

$$
y = c_1 \cos(x) + c_2 \sin(x) + \frac{x \sin(x)}{4} - \frac{\cos(x) x^2}{4}
$$

Verified OK.

11.21.2 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{aligned}
y'' + y &= 0 \qquad (1)\\
Ay'' + By' + Cy &= 0 \qquad (2)
\end{aligned}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1\\
B &= 0 \qquad (3)\\
C &= 1
\end{aligned}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \qquad (5)\\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-1}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -1\\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = -z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 374: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \cos(x)
\end{aligned}
$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\
&= \cos(x)\,(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x\sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\sin(x), \cos(x)x, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\sin(x), \cos(x)x, \cos(x)x^2, \sin(x)x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1x\sin(x) + A_2\cos(x)x + A_3\cos(x)x^2 + A_4\sin(x)x^2$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&2A_1\cos(x) - 2A_2\sin(x) - 4A_3\sin(x)x + 2A_3\cos(x) + 4A_4\cos(x)x + 2A_4\sin(x)\\&= x\sin(x)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{4}, A_2 = 0, A_3 = -\frac{1}{4}, A_4 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x\sin(x)}{4} - \frac{\cos(x)x^2}{4}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\&= (c_1\cos(x) + c_2\sin(x)) + \left(\frac{x\sin(x)}{4} - \frac{\cos(x)x^2}{4}\right)\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{x \sin(x)}{4} - \frac{\cos(x) x^2}{4} \tag{1}$$

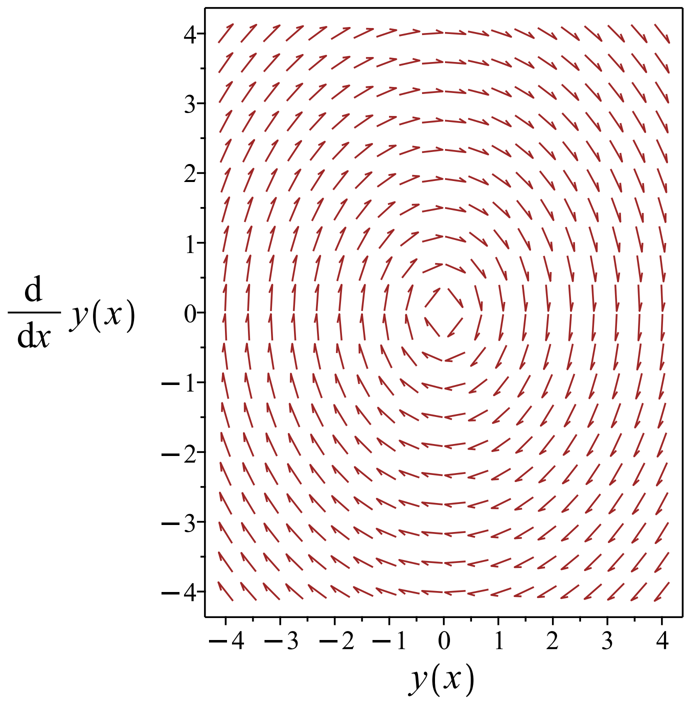

Figure 437: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{x \sin(x)}{4} - \frac{\cos(x) x^2}{4}$$

Verified OK.

11.21.3 Maple step by step solution

Let's solve

$y'' + y = x \sin(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x \sin(x)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$

  ◦ Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$

  ◦ Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\cos(x) \left(\int \sin(x)^2 x dx\right) + \frac{\sin(x)\left(\int \sin(2x) x dx\right)}{2}$

  ◦ Compute integrals

    $y_p(x) = \frac{x(-\cos(x) x + \sin(x))}{4}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + \frac{x(-\cos(x) x + \sin(x))}{4}$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 4y = 12x^2 - 16x\cos(2x)}$$

11.22.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 4, f(x) = 12x^2 - 16x\cos(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(4)}\\ &= \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2i\\ \lambda_2 &= -2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2i\\ \lambda_2 &= -2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(2x) + c_2 \sin(2x))$$

Or

$$y = c_1 \cos(2x) + c_2 \sin(2x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(2x) + c_2 \sin(2x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$12x^2 - 16x \cos(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}, \{x \cos(2x), \sin(2x) x, \cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(2x), \sin(2x)\}$$

Since $\cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{1, x, x^2\}, \{x \cos(2x), x^2 \cos(2x), x^2 \sin(2x), \sin(2x) x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_3x^2 + A_2x + A_1 + A_4x \cos(2x) + A_5x^2 \cos(2x) + A_6x^2 \sin(2x) + A_7 \sin(2x) x$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6, A_7\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&2A_3 - 4A_4 \sin(2x) + 2A_5 \cos(2x) - 8A_5x \sin(2x) + 2A_6 \sin(2x)\\ &+ 8A_6x \cos(2x) + 4A_7 \cos(2x) + 4A_3x^2 + 4A_2x + 4A_1 = 12x^2 - 16x \cos(2x)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{3}{2}, A_2 = 0, A_3 = 3, A_4 = -1, A_5 = 0, A_6 = -2, A_7 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3x^2 - \frac{3}{2} - x\cos(2x) - 2x^2\sin(2x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(2x) + c_2\sin(2x)) + \left(3x^2 - \frac{3}{2} - x\cos(2x) - 2x^2\sin(2x)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\cos(2x) + c_2\sin(2x) + 3x^2 - \frac{3}{2} - x\cos(2x) - 2x^2\sin(2x) \tag{1}$$

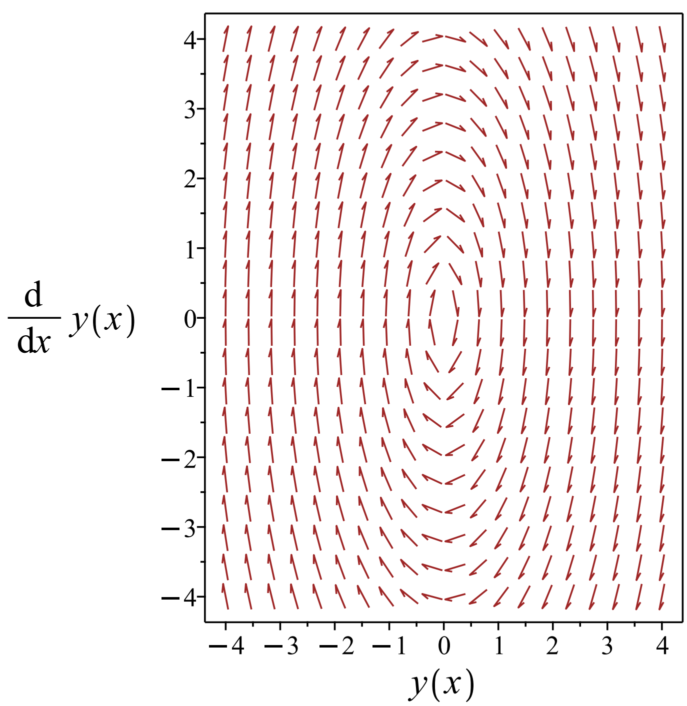

Figure 438: Slope field plot

Verification of solutions

$$y = c_1\cos(2x) + c_2\sin(2x) + 3x^2 - \frac{3}{2} - x\cos(2x) - 2x^2\sin(2x)$$

Verified OK.

11.22.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 376: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \cos(2x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \cos(2x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \cos(2x) \int \frac{1}{\cos(2x)^2}\, dx \\
&= \cos(2x) \left(\frac{\tan(2x)}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(2x)) + c_2\left(\cos(2x)\left(\frac{\tan(2x)}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 4y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$12x^2 - 16x \cos(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}, \{x \cos(2x), \sin(2x)\, x, \cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sin(2x)}{2}, \cos(2x)\right\}$$

Since $\cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{1, x, x^2\}, \{x \cos(2x), x^2 \cos(2x), x^2 \sin(2x), \sin(2x)\, x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_3x^2 + A_2x + A_1 + A_4x \cos(2x) + A_5x^2 \cos(2x) + A_6x^2 \sin(2x) + A_7 \sin(2x)\, x$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6, A_7\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&2A_3 - 4A_4 \sin(2x) + 2A_5 \cos(2x) - 8A_5x \sin(2x) + 2A_6 \sin(2x)\\&+ 8A_6x \cos(2x) + 4A_7 \cos(2x) + 4A_3x^2 + 4A_2x + 4A_1 = 12x^2 - 16x \cos(2x)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{3}{2}, A_2 = 0, A_3 = 3, A_4 = -1, A_5 = 0, A_6 = -2, A_7 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3x^2 - \frac{3}{2} - x\cos(2x) - 2x^2\sin(2x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\cos(2x) + \frac{c_2\sin(2x)}{2}\right) + \left(3x^2 - \frac{3}{2} - x\cos(2x) - 2x^2\sin(2x)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\cos(2x) + \frac{c_2\sin(2x)}{2} + 3x^2 - \frac{3}{2} - x\cos(2x) - 2x^2\sin(2x) \tag{1}$$

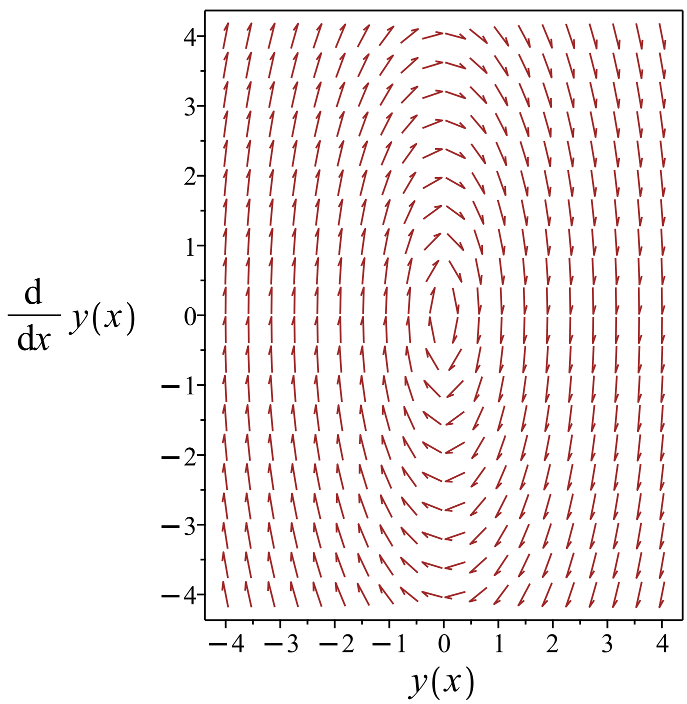

Figure 439: Slope field plot

Verification of solutions

$$y = c_1\cos(2x) + \frac{c_2\sin(2x)}{2} + 3x^2 - \frac{3}{2} - x\cos(2x) - 2x^2\sin(2x)$$

Verified OK.

11.22.3 Maple step by step solution

Let's solve

$y'' + 4y = 12x^2 - 16x\cos(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r = (-2\,\mathrm{I}, 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(2x) + c_2 \sin(2x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 12x^2 - 16x\cos(2x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(2x) & \sin(2x) \\ -2\sin(2x) & 2\cos(2x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2$

  - Substitute functions into equation for $y_p(x)$

$$y_p(x) = 2\cos(2x)\left(\int \sin(2x)\, x(4\cos(2x) - 3x)\, dx\right) - 2\sin(2x)\left(\int \cos(2x)\, x(4\cos(2x) - 3x)\, dx\right)$$

- Compute integrals

$$y_p(x) = -2x^2 \sin(2x) + \frac{\sin(2x)}{2} - x\cos(2x) + 3x^2 - \frac{3}{2}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 \cos(2x) + c_2 \sin(2x) - 2x^2 \sin(2x) + \frac{\sin(2x)}{2} - x\cos(2x) + 3x^2 - \frac{3}{2}$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.3. The method of undetermined coefficients. Exercises page 151
Problem number: 23.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_high_order, _missing_y]]`

$$\boxed{y'''' + 2y''' - 3y'' = 18x^2 + 16x\,e^x + 4\,e^{3x} - 9}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 2y''' - 3y'' = 0$$

The characteristic equation is

$$\lambda^4 + 2\lambda^3 - 3\lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = 1$$
$$\lambda_4 = -3$$

Therefore the homogeneous solution is

$$y_h(x) = c_2x + c_1 + c_3\mathrm{e}^x + \mathrm{e}^{-3x}c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned}
y_1 &= 1 \\
y_2 &= x \\
y_3 &= \mathrm{e}^x \\
y_4 &= \mathrm{e}^{-3x}
\end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' + 2y''' - 3y'' = 18x^2 + 16x\,\mathrm{e}^x + 4\,\mathrm{e}^{3x} - 9$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$18x^2 + 16x\,\mathrm{e}^x + 4\,\mathrm{e}^{3x} - 9$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{3x}\}, \{x\,\mathrm{e}^x, \mathrm{e}^x\}, \{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, \mathrm{e}^x, \mathrm{e}^{-3x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{\mathrm{e}^{3x}\}, \{x\,\mathrm{e}^x, \mathrm{e}^x\}, \{x, x^2, x^3\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{\mathrm{e}^{3x}\}, \{x\,\mathrm{e}^x, \mathrm{e}^x\}, \{x^2, x^3, x^4\}]$$

Since e^x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{\mathrm{e}^{3x}\}, \{x\,\mathrm{e}^x, x^2\mathrm{e}^x\}, \{x^2, x^3, x^4\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^{3x} + A_2 x\, e^{x} + A_3 x^2 e^{x} + A_4 x^2 + A_5 x^3 + A_6 x^4$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&108A_1 e^{3x} + 4A_2 e^{x} + 18A_3 e^{x} + 8A_3 x\, e^{x} + 24A_6 + 12A_5 + 48A_6 x \\ &- 6A_4 - 18A_5 x - 36A_6 x^2 = 18x^2 + 16x\, e^{x} + 4\, e^{3x} - 9\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{27}, A_2 = -9, A_3 = 2, A_4 = -\frac{19}{6}, A_5 = -\frac{4}{3}, A_6 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{3x}}{27} - 9x\, e^{x} + 2x^2 e^{x} - \frac{19x^2}{6} - \frac{4x^3}{3} - \frac{x^4}{2}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p \\ &= \left(c_2 x + c_1 + c_3 e^{x} + e^{-3x} c_4\right) + \left(\frac{e^{3x}}{27} - 9x\, e^{x} + 2x^2 e^{x} - \frac{19x^2}{6} - \frac{4x^3}{3} - \frac{x^4}{2}\right)\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_2 x + c_1 + c_3 e^{x} + e^{-3x} c_4 + \frac{e^{3x}}{27} - 9x\, e^{x} + 2x^2 e^{x} - \frac{19x^2}{6} - \frac{4x^3}{3} - \frac{x^4}{2} \tag{1}$$

Verification of solutions

$$y = c_2 x + c_1 + c_3 e^{x} + e^{-3x} c_4 + \frac{e^{3x}}{27} - 9x\, e^{x} + 2x^2 e^{x} - \frac{19x^2}{6} - \frac{4x^3}{3} - \frac{x^4}{2}$$

Verified OK.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'''' - 5y''' + 7y'' - 5y' + 6y = 5\sin(x) - 12\sin(2x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - 5y''' + 7y'' - 5y' + 6y = 0$$

The characteristic equation is

$$\lambda^4 - 5\lambda^3 + 7\lambda^2 - 5\lambda + 6 = 0$$

The roots of the above equation are

$$\lambda_1 = 2$$
$$\lambda_2 = 3$$
$$\lambda_3 = i$$
$$\lambda_4 = -i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{2x} + e^{3x} c_2 + e^{ix} c_3 + e^{-ix} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{2x}$$
$$y_2 = e^{3x}$$
$$y_3 = e^{ix}$$
$$y_4 = e^{-ix}$$

Now the particular solution to the given ODE is found

$$y'''' - 5y''' + 7y'' - 5y' + 6y = 5\sin(x) - 12\sin(2x)$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)}\, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 & y_4 \\ y_1' & y_2' & y_3' & y_4' \\ y_1'' & y_2'' & y_3'' & y_4'' \\ y_1''' & y_2''' & y_3''' & y_4''' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} e^{2x} & e^{3x} & e^{ix} & e^{-ix} \\ 2\,e^{2x} & 3\,e^{3x} & ie^{ix} & -ie^{-ix} \\ 4\,e^{2x} & 9\,e^{3x} & -e^{ix} & -e^{-ix} \\ 8\,e^{2x} & 27\,e^{3x} & -ie^{ix} & ie^{-ix} \end{bmatrix}$$

$$|W| = -100i e^{2x} e^{3x} e^{ix} e^{-ix}$$

The determinant simplifies to

$$|W| = -100i\mathrm{e}^{5x}$$

Now we determine W_i for each U_i.

$$\begin{aligned} W_1(x) &= \det \begin{bmatrix} \mathrm{e}^{3x} & \mathrm{e}^{ix} & \mathrm{e}^{-ix} \\ 3\,\mathrm{e}^{3x} & i\mathrm{e}^{ix} & -i\mathrm{e}^{-ix} \\ 9\,\mathrm{e}^{3x} & -\mathrm{e}^{ix} & -\mathrm{e}^{-ix} \end{bmatrix} \\ &= -20i\mathrm{e}^{3x} \end{aligned}$$

$$\begin{aligned} W_2(x) &= \det \begin{bmatrix} \mathrm{e}^{2x} & \mathrm{e}^{ix} & \mathrm{e}^{-ix} \\ 2\,\mathrm{e}^{2x} & i\mathrm{e}^{ix} & -i\mathrm{e}^{-ix} \\ 4\,\mathrm{e}^{2x} & -\mathrm{e}^{ix} & -\mathrm{e}^{-ix} \end{bmatrix} \\ &= -10i\mathrm{e}^{2x} \end{aligned}$$

$$\begin{aligned} W_3(x) &= \det \begin{bmatrix} \mathrm{e}^{2x} & \mathrm{e}^{3x} & \mathrm{e}^{-ix} \\ 2\,\mathrm{e}^{2x} & 3\,\mathrm{e}^{3x} & -i\mathrm{e}^{-ix} \\ 4\,\mathrm{e}^{2x} & 9\,\mathrm{e}^{3x} & -\mathrm{e}^{-ix} \end{bmatrix} \\ &= (5+5i)\,\mathrm{e}^{(5-i)x} \end{aligned}$$

$$\begin{aligned} W_4(x) &= \det \begin{bmatrix} \mathrm{e}^{2x} & \mathrm{e}^{3x} & \mathrm{e}^{ix} \\ 2\,\mathrm{e}^{2x} & 3\,\mathrm{e}^{3x} & i\mathrm{e}^{ix} \\ 4\,\mathrm{e}^{2x} & 9\,\mathrm{e}^{3x} & -\mathrm{e}^{ix} \end{bmatrix} \\ &= (5-5i)\,\mathrm{e}^{(5+i)x} \end{aligned}$$

Now we are ready to evaluate each $U_i(x)$.

$$
\begin{aligned}
U_1 &= (-1)^{4-1} \int \frac{F(x)W_1(x)}{aW(x)}\,dx \\
&= (-1)^3 \int \frac{(5\sin(x) - 12\sin(2x))\left(-20i\mathrm{e}^{3x}\right)}{(1)\left(-100i\mathrm{e}^{5x}\right)}\,dx \\
&= -\int \frac{-20i(5\sin(x) - 12\sin(2x))\,\mathrm{e}^{3x}}{-100i\mathrm{e}^{5x}}\,dx \\
&= -\int \left(-\frac{(-5\sin(x) + 12\sin(2x))\,\mathrm{e}^{-2x}}{5}\right)dx \\
&= \frac{3\,\mathrm{e}^{-2x}(-2\sin(2x) - 2\cos(2x))}{10} + \frac{\cos(x)\,\mathrm{e}^{-2x}}{5} + \frac{2\,\mathrm{e}^{-2x}\sin(x)}{5} \\
&= \frac{3\,\mathrm{e}^{-2x}(-2\sin(2x) - 2\cos(2x))}{10} + \frac{\cos(x)\,\mathrm{e}^{-2x}}{5} + \frac{2\,\mathrm{e}^{-2x}\sin(x)}{5}
\end{aligned}
$$

$$
\begin{aligned}
U_2 &= (-1)^{4-2} \int \frac{F(x)W_2(x)}{aW(x)}\,dx \\
&= (-1)^2 \int \frac{(5\sin(x) - 12\sin(2x))\left(-10i\mathrm{e}^{2x}\right)}{(1)\left(-100i\mathrm{e}^{5x}\right)}\,dx \\
&= \int \frac{-10i(5\sin(x) - 12\sin(2x))\,\mathrm{e}^{2x}}{-100i\mathrm{e}^{5x}}\,dx \\
&= \int \left(-\frac{(-5\sin(x) + 12\sin(2x))\,\mathrm{e}^{-3x}}{10}\right)dx \\
&= -\frac{6\,\mathrm{e}^{-3x}(-3\sin(2x) - 2\cos(2x))}{65} - \frac{\mathrm{e}^{-3x}\cos(x)}{20} - \frac{3\,\mathrm{e}^{-3x}\sin(x)}{20} \\
&= -\frac{6\,\mathrm{e}^{-3x}(-3\sin(2x) - 2\cos(2x))}{65} - \frac{\mathrm{e}^{-3x}\cos(x)}{20} - \frac{3\,\mathrm{e}^{-3x}\sin(x)}{20}
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{4-3} \int \frac{F(x)W_3(x)}{aW(x)}\,dx \\
&= (-1)^1 \int \frac{(5\sin(x) - 12\sin(2x))\left((5+5i)\,\mathrm{e}^{(5-i)x}\right)}{(1)\left(-100i\mathrm{e}^{5x}\right)}\,dx \\
&= -\int \frac{(5+5i)\,(5\sin(x) - 12\sin(2x))\,\mathrm{e}^{(5-i)x}}{-100i\mathrm{e}^{5x}}\,dx \\
&= -\int \left(\left(\frac{1}{20} - \frac{i}{20}\right)(-5\sin(x) + 12\sin(2x))\,\mathrm{e}^{-ix}\right)dx \\
&= -\left(\int \left(\frac{1}{20} - \frac{i}{20}\right)(-5\sin(x) + 12\sin(2x))\,\mathrm{e}^{-ix}dx\right)
\end{aligned}
$$

$$
\begin{aligned}
U_4 &= (-1)^{4-4} \int \frac{F(x)W_4(x)}{aW(x)}\,dx \\
&= (-1)^0 \int \frac{(5\sin(x) - 12\sin(2x))\left((5-5i)\,\mathrm{e}^{(5+i)x}\right)}{(1)\left(-100i\mathrm{e}^{5x}\right)}\,dx \\
&= \int \frac{(5-5i)\,(5\sin(x) - 12\sin(2x))\,\mathrm{e}^{(5+i)x}}{-100i\mathrm{e}^{5x}}\,dx \\
&= \int \left(\left(-\frac{1}{20} - \frac{i}{20}\right)(-5\sin(x) + 12\sin(2x))\,\mathrm{e}^{ix}\right)dx \\
&= \int \left(-\frac{1}{20} - \frac{i}{20}\right)(-5\sin(x) + 12\sin(2x))\,\mathrm{e}^{ix}dx
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4
$$

Hence

$$
\begin{aligned}
y_p = &\left(\frac{3\,\mathrm{e}^{-2x}(-2\sin(2x) - 2\cos(2x))}{10} + \frac{\cos(x)\,\mathrm{e}^{-2x}}{5} + \frac{2\,\mathrm{e}^{-2x}\sin(x)}{5}\right)\left(\mathrm{e}^{2x}\right) \\
&+ \left(-\frac{6\,\mathrm{e}^{-3x}(-3\sin(2x) - 2\cos(2x))}{65} - \frac{\mathrm{e}^{-3x}\cos(x)}{20} - \frac{3\,\mathrm{e}^{-3x}\sin(x)}{20}\right)\left(\mathrm{e}^{3x}\right) \\
&+ \left(-\left(\int \left(\frac{1}{20} - \frac{i}{20}\right)(-5\sin(x) + 12\sin(2x))\,\mathrm{e}^{-ix}dx\right)\right)\left(\mathrm{e}^{ix}\right) \\
&+ \left(\int \left(-\frac{1}{20} - \frac{i}{20}\right)(-5\sin(x) + 12\sin(2x))\,\mathrm{e}^{ix}dx\right)\left(\mathrm{e}^{-ix}\right)
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = \left(-\frac{1}{20} + \frac{i}{20}\right)\left(\int (-5\sin(x) + 12\sin(2x))\,\mathrm{e}^{-ix}dx\right)\mathrm{e}^{ix} + \left(-\frac{1}{20} - \frac{i}{20}\right)\left(\int (-5\sin(x) + 12\sin(2x)
$$

Which simplifies to

$$
y_p = \frac{27}{65} + \frac{(\cos(x) - \sin(x))\left(\int (24\cos(x) - 5)\sin(x)^2\,dx\right)}{10} + \frac{(-\cos(x) - \sin(x))\left(\int (24\cos(x) - 5)\sin(x
}{10}
$$

Therefore the general solution is

$$
y = y_h + y_p
$$

$$
\begin{aligned}
&= \left(c_1 e^{2x} + e^{3x} c_2 + e^{ix} c_3 + e^{-ix} c_4\right) \\
&+ \left(\frac{27}{65} + \frac{(\cos(x) - \sin(x)) \left(\int (24\cos(x) - 5)\sin(x)^2 dx\right)}{10}\right. \\
&+ \frac{(-\cos(x) - \sin(x)) \left(\int (24\cos(x) - 5)\sin(x)\cos(x) dx\right)}{10} - \frac{54\cos(x)^2}{65} \\
&\left. + \frac{3(13 - 56\sin(x))\cos(x)}{260} + \frac{\sin(x)}{4}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 e^{2x} + e^{3x} c_2 + e^{ix} c_3 + e^{-ix} c_4 + \frac{27}{65} \\
&+ \frac{(\cos(x) - \sin(x)) \left(\int (24\cos(x) - 5)\sin(x)^2 dx\right)}{10} \\
&+ \frac{(-\cos(x) - \sin(x)) \left(\int (24\cos(x) - 5)\sin(x)\cos(x) dx\right)}{10} \\
&- \frac{54\cos(x)^2}{65} + \frac{3(13 - 56\sin(x))\cos(x)}{260} + \frac{\sin(x)}{4}
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 e^{2x} + e^{3x} c_2 + e^{ix} c_3 + e^{-ix} c_4 + \frac{27}{65} + \frac{(\cos(x) - \sin(x)) \left(\int (24\cos(x) - 5)\sin(x)^2 dx\right)}{10} \\
&+ \frac{(-\cos(x) - \sin(x)) \left(\int (24\cos(x) - 5)\sin(x)\cos(x) dx\right)}{10} \\
&- \frac{54\cos(x)^2}{65} + \frac{3(13 - 56\sin(x))\cos(x)}{260} + \frac{\sin(x)}{4}
\end{aligned}
$$

Verified OK.

11.24.1 Maple step by step solution

Let's solve

$y'''' - 5y''' + 7y'' - 5y' + 6y = 5\sin(x) - 12\sin(2x)$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

$y_1(x) = y$

- Define new variable $y_2(x)$

  $y_2(x) = y'$

- Define new variable $y_3(x)$

  $y_3(x) = y''$

- Define new variable $y_4(x)$

  $y_4(x) = y'''$

- Isolate for $y_4'(x)$ using original ODE

  $y_4'(x) = 5\sin(x) - 12\sin(2x) + 5y_4(x) - 7y_3(x) + 5y_2(x) - 6y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = 5\sin(x) - 12\sin(2x) + 5y_4(x) - 7y_3(x) +$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -6 & 5 & -7 & 5 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ 5\sin(x) - 12\sin(2x) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 5\sin(x) - 12\sin(2x) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -6 & 5 & -7 & 5 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{y}'(x) = A \cdot \overrightarrow{y}(x) + \overrightarrow{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[2, \begin{bmatrix} \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} \frac{1}{27} \\ \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} \mathrm{I} \\ -1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \mathrm{e}^{2x} \cdot \begin{bmatrix} \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[3, \begin{bmatrix} \frac{1}{27} \\ \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{3x} \cdot \begin{bmatrix} \frac{1}{27} \\ \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-\mathrm{I}x} \cdot \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$(\cos(x) - \mathrm{I}\sin(x)) \cdot \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ -\cos(x) + \mathrm{I}\sin(x) \\ \mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ \cos(x) - \mathrm{I}\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \begin{bmatrix} -\sin(x) \\ -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_4(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} \frac{e^{2x}}{8} & \frac{e^{3x}}{27} & -\sin(x) & -\cos(x) \\ \frac{e^{2x}}{4} & \frac{e^{3x}}{9} & -\cos(x) & \sin(x) \\ \frac{e^{2x}}{2} & \frac{e^{3x}}{3} & \sin(x) & \cos(x) \\ e^{2x} & e^{3x} & \cos(x) & -\sin(x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} \frac{e^{2x}}{8} & \frac{e^{3x}}{27} & -\sin(x) & -\cos(x) \\ \frac{e^{2x}}{4} & \frac{e^{3x}}{9} & -\cos(x) & \sin(x) \\ \frac{e^{2x}}{2} & \frac{e^{3x}}{3} & \sin(x) & \cos(x) \\ e^{2x} & e^{3x} & \cos(x) & -\sin(x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} \frac{1}{8} & \frac{1}{27} & 0 & -1 \\ \frac{1}{4} & \frac{1}{9} & -1 & 0 \\ \frac{1}{2} & \frac{1}{3} & 0 & 1 \\ 1 & 1 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} \frac{3e^{2x}}{5} - \frac{e^{3x}}{5} - \frac{3\sin(x)}{5} + \frac{3\cos(x)}{5} & -\frac{e^{2x}}{5} + \frac{e^{3x}}{10} + \frac{11\sin(x)}{10} + \frac{\cos(x)}{10} & \frac{3e^{2x}}{5} - \frac{e^{3x}}{5} - \frac{3\sin(x)}{5} \\ \frac{6e^{2x}}{5} - \frac{3e^{3x}}{5} - \frac{3\cos(x)}{5} - \frac{3\sin(x)}{5} & -\frac{2e^{2x}}{5} + \frac{3e^{3x}}{10} + \frac{11\cos(x)}{10} - \frac{\sin(x)}{10} & \frac{6e^{2x}}{5} - \frac{3e^{3x}}{5} - \frac{3\cos(x}{5} \\ \frac{12e^{2x}}{5} - \frac{9e^{3x}}{5} + \frac{3\sin(x)}{5} - \frac{3\cos(x)}{5} & -\frac{4e^{2x}}{5} + \frac{9e^{3x}}{10} - \frac{11\sin(x)}{10} - \frac{\cos(x)}{10} & \frac{12e^{2x}}{5} - \frac{9e^{3x}}{5} + \frac{3\sin(x}{5} \\ \frac{24e^{2x}}{5} - \frac{27e^{3x}}{5} + \frac{3\cos(x)}{5} + \frac{3\sin(x)}{5} & -\frac{8e^{2x}}{5} + \frac{27e^{3x}}{10} - \frac{11\cos(x)}{10} + \frac{\sin(x)}{10} & \frac{24e^{2x}}{5} - \frac{27e^{3x}}{5} + \frac{3\cos(}{5} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

$\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \left[\begin{array}{c} -\frac{5}{13}+\frac{2\,\mathrm{e}^{2x}}{5}-\frac{7\,\mathrm{e}^{3x}}{52}+\frac{10\cos(x)^2}{13}+\frac{(-65x+40\sin(x)-169)\cos(x)}{260}+\frac{(-6+5x)\sin(x)}{20} \\ -\frac{2}{13}+\frac{4\,\mathrm{e}^{2x}}{5}-\frac{21\,\mathrm{e}^{3x}}{52}+\frac{4\cos(x)^2}{13}+\frac{(65x-400\sin(x)-143)\cos(x)}{260}+\frac{(18+5x)\sin(x)}{20} \\ \frac{20}{13}+\frac{8\,\mathrm{e}^{2x}}{5}-\frac{63\,\mathrm{e}^{3x}}{52}-\frac{40\cos(x)^2}{13}+\frac{(65x-160\sin(x)+299)\cos(x)}{260}+\frac{(16-5x)\sin(x)}{20} \\ \frac{8}{13}+\frac{16\,\mathrm{e}^{2x}}{5}-\frac{189\,\mathrm{e}^{3x}}{52}-\frac{16\cos(x)^2}{13}+\frac{(-65x+1600\sin(x)+273)\cos(x)}{260}+\frac{(-28-5x)\sin(x)}{20} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \left[\begin{array}{c} -\frac{5}{13}+\frac{2\,\mathrm{e}^{2x}}{5}-\frac{7\,\mathrm{e}^{3x}}{52}+\frac{10\cos(x)^2}{13}+\frac{(-65x+40\sin(x)-169}{260} \\ -\frac{2}{13}+\frac{4\,\mathrm{e}^{2x}}{5}-\frac{21\,\mathrm{e}^{3x}}{52}+\frac{4\cos(x)^2}{13}+\frac{(65x-400\sin(x)-143}{260} \\ \frac{20}{13}+\frac{8\,\mathrm{e}^{2x}}{5}-\frac{63\,\mathrm{e}^{3x}}{52}-\frac{40\cos(x)^2}{13}+\frac{(65x-160\sin(x)+299)}{260} \\ \frac{8}{13}+\frac{16\,\mathrm{e}^{2x}}{5}-\frac{189\,\mathrm{e}^{3x}}{52}-\frac{16\cos(x)^2}{13}+\frac{(-65x+1600\sin(x)+27}{260} \end{array}\right.$$

- First component of the vector is the solution to the ODE

$$y = -\frac{5}{13} + \frac{(16+5c_1)\,\mathrm{e}^{2x}}{40} + \frac{(-189+52c_2)\,\mathrm{e}^{3x}}{1404} + \frac{10\cos(x)^2}{13} + \frac{(-169-65x-260c_4+40\sin(x))\cos(x)}{260} + \frac{(-6+5x-20c_3)\sin(x)}{20}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y'' - 4y' + 3y = 9x^2 + 4}$$

With initial conditions

$$[y(0) = 6, y'(0) = 8]$$

11.25.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -4 \\ q(x) &= 3 \\ F &= 9x^2 + 4 \end{aligned}$$

Hence the ode is

$$y'' - 4y' + 3y = 9x^2 + 4$$

The domain of $p(x) = -4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 3$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 9x^2 + 4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

11.25.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 3, f(x) = 9x^2 + 4$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 3y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 3$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 4\lambda e^{\lambda x} + 3 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 3 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 3$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-4^2 - (4)(1)(3)} \\ &= 2 \pm 1\end{aligned}$$

Hence

$$\lambda_1 = 2 + 1$$
$$\lambda_2 = 2 - 1$$

Which simplifies to

$$\lambda_1 = 3$$
$$\lambda_2 = 1$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(3)x} + c_2 e^{(1)x}$$

Or

$$y = c_1 \mathrm{e}^{3x} + c_2 \mathrm{e}^{x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{3x} + c_2 \mathrm{e}^{x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 + 1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x, e^{3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_3x^2 + A_2x + A_1$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_3x^2 + 3A_2x - 8xA_3 + 3A_1 - 4A_2 + 2A_3 = 9x^2 + 4$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 10, A_2 = 8, A_3 = 3]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3x^2 + 8x + 10$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1e^{3x} + c_2e^x) + (3x^2 + 8x + 10) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1e^{3x} + c_2e^x + 3x^2 + 8x + 10 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 6$ and $x = 0$ in the above gives

$$6 = c_1 + c_2 + 10 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 3c_1 e^{3x} + c_2 e^x + 6x + 8$$

substituting $y' = 8$ and $x = 0$ in the above gives

$$8 = 3c_1 + c_2 + 8 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 2$$
$$c_2 = -6$$

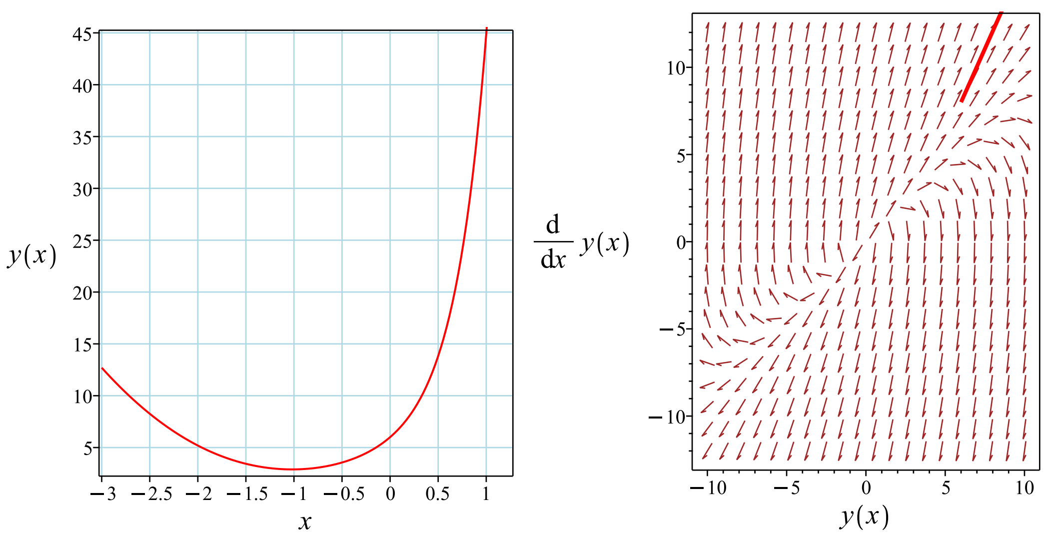
Substituting these values back in above solution results in

$$y = 10 + 3x^2 + 2\,e^{3x} - 6\,e^x + 8x$$

Summary

The solution(s) found are the following

$$y = 10 + 3x^2 + 2\,e^{3x} - 6\,e^x + 8x \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = 10 + 3x^2 + 2\,e^{3x} - 6\,e^x + 8x$$

Verified OK.

11.25.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 379: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-x}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{2x} \\
&= z_1 \left(\mathrm{e}^{2x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{4x}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\frac{\mathrm{e}^{2x}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 (\mathrm{e}^{x}) + c_2 \left(\mathrm{e}^{x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 4y' + 3y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^{x} c_1 + \frac{\mathrm{e}^{3x} c_2}{2}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 + 1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{e^{3x}}{2}, e^x\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_3x^2 + A_2x + A_1$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_3x^2 + 3A_2x - 8xA_3 + 3A_1 - 4A_2 + 2A_3 = 9x^2 + 4$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 10, A_2 = 8, A_3 = 3]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3x^2 + 8x + 10$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^x c_1 + \frac{e^{3x} c_2}{2}\right) + (3x^2 + 8x + 10) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{x} c_1 + \frac{e^{3x} c_2}{2} + 3x^2 + 8x + 10 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 6$ and $x = 0$ in the above gives

$$6 = c_1 + \frac{c_2}{2} + 10 \tag{1A}$$

Taking derivative of the solution gives

$$y' = e^{x} c_1 + \frac{3\,e^{3x} c_2}{2} + 6x + 8$$

substituting $y' = 8$ and $x = 0$ in the above gives

$$8 = c_1 + \frac{3c_2}{2} + 8 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -6$$
$$c_2 = 4$$

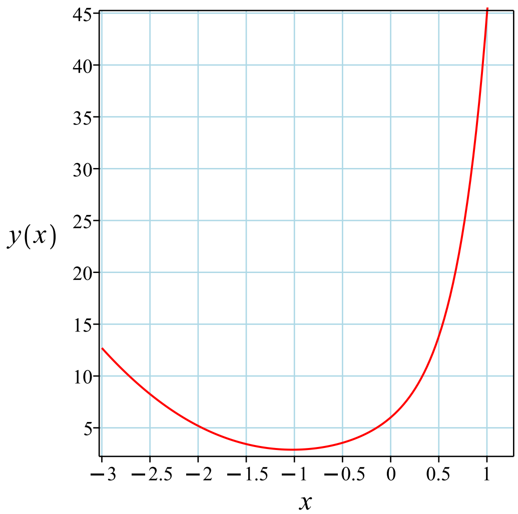
Substituting these values back in above solution results in

$$y = 10 + 3x^2 + 2\,e^{3x} - 6\,e^{x} + 8x$$

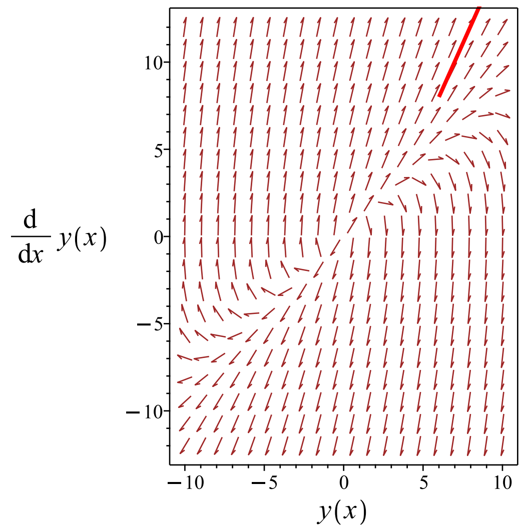
Summary

The solution(s) found are the following

$$y = 10 + 3x^2 + 2\,e^{3x} - 6\,e^{x} + 8x \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = 10 + 3x^2 + 2\,e^{3x} - 6\,e^{x} + 8x$$

Verified OK.

11.25.4 Maple step by step solution

Let's solve

$$\left[y'' - 4y' + 3y = 9x^2 + 4, y(0) = 6, y'\Big|_{\{x=0\}} = 8\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 4r + 3 = 0$

- Factor the characteristic polynomial

  $(r-1)(r-3) = 0$

- Roots of the characteristic polynomial

  $r = (1, 3)$

- 1st solution of the homogeneous ODE

$y_1(x) = \mathrm{e}^{x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \mathrm{e}^{x} c_1 + \mathrm{e}^{3x} c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 9x^2 + 4\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{x} & \mathrm{e}^{3x} \\ \mathrm{e}^{x} & 3\,\mathrm{e}^{3x} \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2\,\mathrm{e}^{4x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\mathrm{e}^{x}\left(\int (9x^2+4)\mathrm{e}^{-x} dx\right)}{2} + \frac{\mathrm{e}^{3x}\left(\int \mathrm{e}^{-3x}(9x^2+4) dx\right)}{2}$

  ◦ Compute integrals

  $y_p(x) = 3x^2 + 8x + 10$

- Substitute particular solution into general solution to ODE

  $y = \mathrm{e}^{x} c_1 + \mathrm{e}^{3x} c_2 + 3x^2 + 8x + 10$

☐ Check validity of solution $y = \mathrm{e}^{x} c_1 + \mathrm{e}^{3x} c_2 + 3x^2 + 8x + 10$

  ◦ Use initial condition $y(0) = 6$

  $6 = c_1 + c_2 + 10$

  ◦ Compute derivative of the solution

  $y' = \mathrm{e}^{x} c_1 + 3\,\mathrm{e}^{3x} c_2 + 6x + 8$

  ◦ Use the initial condition $y'\Big|_{\{x=0\}} = 8$

  $8 = c_1 + 3c_2 + 8$

- Solve for c_1 and c_2

  $\{c_1 = -6, c_2 = 2\}$

- Substitute constant values into general solution and simplify

  $y = 10 + 3x^2 + 2\,e^{3x} - 6\,e^{x} + 8x$

- Solution to the IVP

  $y = 10 + 3x^2 + 2\,e^{3x} - 6\,e^{x} + 8x$

Section: Chapter 4, Section 4.3. The method of undetermined coefficients. Exercises page 151
Problem number: 26.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y'' + 5y' + 4y = 16x + 20\,\mathrm{e}^{x}}$$

With initial conditions

$$[y(0) = 0, y'(0) = 3]$$

11.26.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 5 \\ q(x) &= 4 \\ F &= 16x + 20\,\mathrm{e}^{x} \end{aligned}$$

Hence the ode is

$$y'' + 5y' + 4y = 16x + 20\,\mathrm{e}^{x}$$

The domain of $p(x) = 5$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 16x + 20\,\mathrm{e}^{x}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

11.26.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 5, C = 4, f(x) = 16x + 20\,\mathrm{e}^{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 5y' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 5, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 5\lambda\,\mathrm{e}^{\lambda x} + 4\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 5\lambda + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 5, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-5}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{5^2 - (4)(1)(4)} \\ &= -\frac{5}{2} \pm \frac{3}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{5}{2} + \frac{3}{2} \\ \lambda_2 &= -\frac{5}{2} - \frac{3}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 \\ \lambda_2 &= -4\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(-1)x} + c_2 e^{(-4)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{-4x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{-4x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$16x + 20\,\mathrm{e}^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}, \{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-4x}, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^x + A_2 + A_3 x$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$10A_1 e^x + 5A_3 + 4A_2 + 4A_3 x = 16x + 20\, e^x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2, A_2 = -5, A_3 = 4]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2\, e^x - 5 + 4x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2 e^{-4x}\right) + \left(2\, e^x - 5 + 4x\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{-x} + c_2 e^{-4x} + 2\, e^x - 5 + 4x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + c_2 - 3 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 e^{-x} - 4c_2 e^{-4x} + 2\,e^{x} + 4$$

substituting $y' = 3$ and $x = 0$ in the above gives

$$3 = -c_1 - 4c_2 + 6 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 3$$
$$c_2 = 0$$

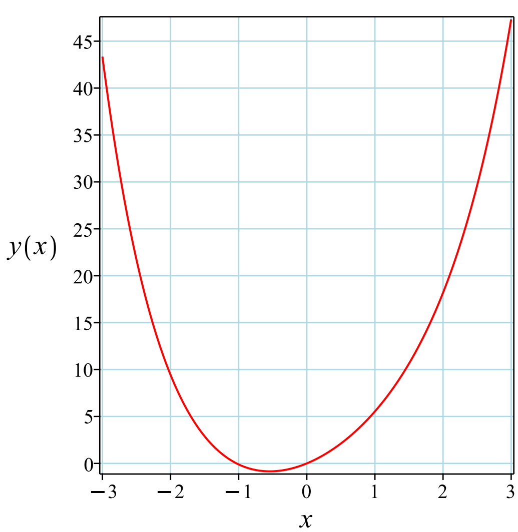
Substituting these values back in above solution results in

$$y = -5 + 2\,e^{x} + 3\,e^{-x} + 4x$$

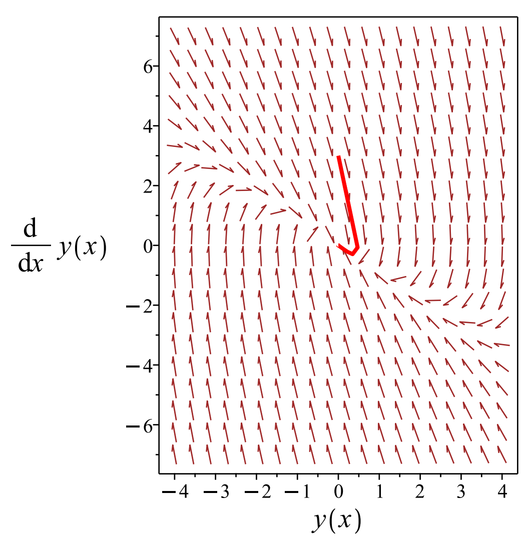
Summary

The solution(s) found are the following

$$y = -5 + 2\,e^{x} + 3\,e^{-x} + 4x \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -5 + 2\,e^{x} + 3\,e^{-x} + 4x$$

Verified OK.

11.26.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 5y' + 4y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 5 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 381: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{5}{1}\,dx} \end{aligned}$$

$$
\begin{aligned}
&= z_1 e^{-\frac{5x}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{5x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-4x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{5}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-5x}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\mathrm{e}^{3x}}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-4x}\right) + c_2 \left(\mathrm{e}^{-4x} \left(\frac{\mathrm{e}^{3x}}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 5y' + 4y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-4x} + \frac{c_2 \mathrm{e}^{-x}}{3}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$16x + 20\,\mathrm{e}^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{x}\}, \{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\mathrm{e}^{-x}}{3}, \mathrm{e}^{-4x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\mathrm{e}^{x} + A_2 + A_3x$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$10A_1\mathrm{e}^{x} + 5A_3 + 4A_2 + 4A_3x = 16x + 20\,\mathrm{e}^{x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2, A_2 = -5, A_3 = 4]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2\,\mathrm{e}^{x} - 5 + 4x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-4x} + \frac{c_2\mathrm{e}^{-x}}{3}\right) + (2\,\mathrm{e}^{x} - 5 + 4x) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{-4x} + \frac{c_2 \mathrm{e}^{-x}}{3} + 2\,\mathrm{e}^{x} - 5 + 4x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + \frac{c_2}{3} - 3 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -4c_1 \mathrm{e}^{-4x} - \frac{c_2 \mathrm{e}^{-x}}{3} + 2\,\mathrm{e}^{x} + 4$$

substituting $y' = 3$ and $x = 0$ in the above gives

$$3 = -4c_1 - \frac{c_2}{3} + 6 \tag{2A}$$

Equations $\{1\mathrm{A}, 2\mathrm{A}\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 9$$

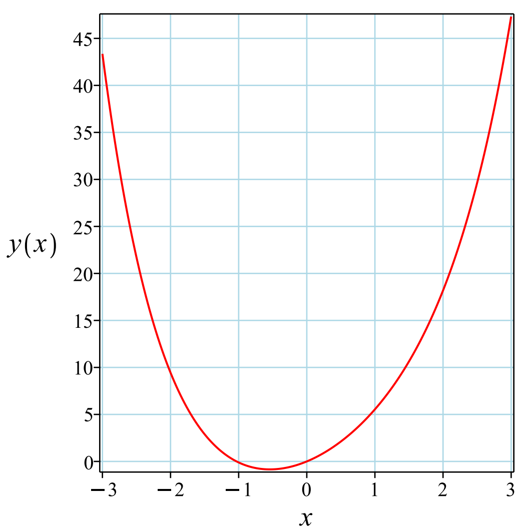
Substituting these values back in above solution results in

$$y = -5 + 2\,\mathrm{e}^{x} + 3\,\mathrm{e}^{-x} + 4x$$

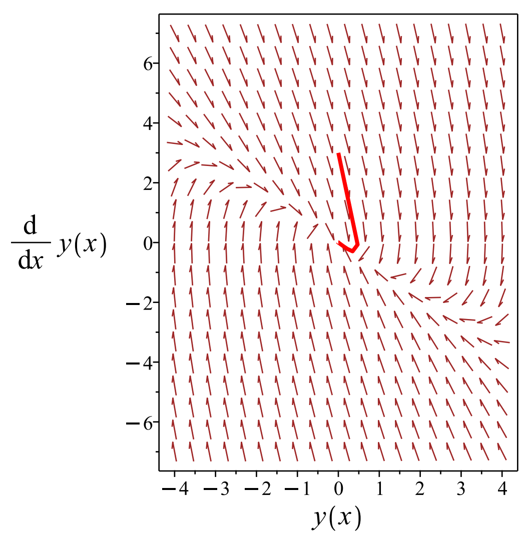
Summary

The solution(s) found are the following

$$y = -5 + 2\,\mathrm{e}^{x} + 3\,\mathrm{e}^{-x} + 4x \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -5 + 2\,e^{x} + 3\,e^{-x} + 4x$$

Verified OK.

11.26.4 Maple step by step solution

Let's solve

$\left[y'' + 5y' + 4y = 16x + 20\,e^{x}, y(0) = 0, y'\Big|_{\{x=0\}} = 3\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 5r + 4 = 0$

- Factor the characteristic polynomial

  $(r+4)(r+1) = 0$

- Roots of the characteristic polynomial

  $r = (-4, -1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-4x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-4x} + c_2 e^{-x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 16x + 20\,e^{x}\right]$

  - Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-4x} & e^{-x} \\ -4\,e^{-4x} & -e^{-x} \end{bmatrix}$$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = 3\,e^{-5x}$

- Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{4\,e^{-4x}\left(\int (4x+5\,e^{x})e^{4x}dx\right)}{3} + \frac{4\,e^{-x}\left(\int (4x+5\,e^{x})e^{x}dx\right)}{3}$

- Compute integrals

  $y_p(x) = 2\,e^{x} - 5 + 4x$

- Substitute particular solution into general solution to ODE

  $y = c_1e^{-4x} + c_2e^{-x} + 2\,e^{x} - 5 + 4x$

☐ Check validity of solution $y = c_1e^{-4x} + c_2e^{-x} + 2e^{x} - 5 + 4x$

- Use initial condition $y(0) = 0$

  $0 = c_1 + c_2 - 3$

- Compute derivative of the solution

  $y' = -4c_1e^{-4x} - c_2e^{-x} + 2\,e^{x} + 4$

- Use the initial condition $y'\Big|_{\{x=0\}} = 3$

  $3 = -4c_1 - c_2 + 6$

- Solve for c_1 and c_2

  $\{c_1 = 0, c_2 = 3\}$

- Substitute constant values into general solution and simplify

  $y = -5 + 2\,e^{x} + 3\,e^{-x} + 4x$

- Solution to the IVP

  $y = -5 + 2\,e^{x} + 3\,e^{-x} + 4x$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 8y' + 15y = 9\,\mathrm{e}^{2x} x}$$

With initial conditions

$$[y(0) = 5, y'(0) = 10]$$

11.27.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -8 \\ q(x) &= 15 \\ F &= 9\,\mathrm{e}^{2x} x \end{aligned}$$

Hence the ode is

$$y'' - 8y' + 15y = 9\,e^{2x}x$$

The domain of $p(x) = -8$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 15$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 9\,e^{2x}x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

11.27.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -8, C = 15, f(x) = 9\,e^{2x}x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 8y' + 15y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -8, C = 15$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 8\lambda\,e^{\lambda x} + 15\,e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 8\lambda + 15 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -8, C = 15$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{8}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-8^2 - (4)(1)(15)} \\
&= 4 \pm 1
\end{aligned}$$

Hence

$$\lambda_1 = 4 + 1$$
$$\lambda_2 = 4 - 1$$

Which simplifies to

$$\lambda_1 = 5$$
$$\lambda_2 = 3$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(5)x} + c_2 e^{(3)x}$$

Or

$$y = c_1 e^{5x} + e^{3x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{5x} + e^{3x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$9 e^{2x} x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x} x, e^{2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{3x}, e^{5x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{2x} x + A_2 e^{2x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_1 e^{2x} x - 4A_1 e^{2x} + 3A_2 e^{2x} = 9\, e^{2x} x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 3, A_2 = 4]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3\, e^{2x} x + 4\, e^{2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{5x} + e^{3x} c_2\right) + \left(3\, e^{2x} x + 4\, e^{2x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{5x} + e^{3x} c_2 + 3\, e^{2x} x + 4\, e^{2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 5$ and $x = 0$ in the above gives

$$5 = c_1 + c_2 + 4 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 5c_1 e^{5x} + 3\, e^{3x} c_2 + 6\, e^{2x} x + 11\, e^{2x}$$

substituting $y' = 10$ and $x = 0$ in the above gives

$$10 = 5c_1 + 3c_2 + 11 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -2$$
$$c_2 = 3$$

Substituting these values back in above solution results in

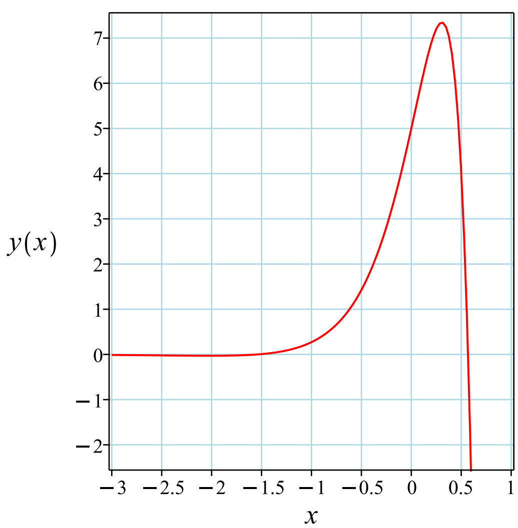
$$y = 3\,\mathrm{e}^{2x}x + 4\,\mathrm{e}^{2x} - 2\,\mathrm{e}^{5x} + 3\,\mathrm{e}^{3x}$$

Which simplifies to

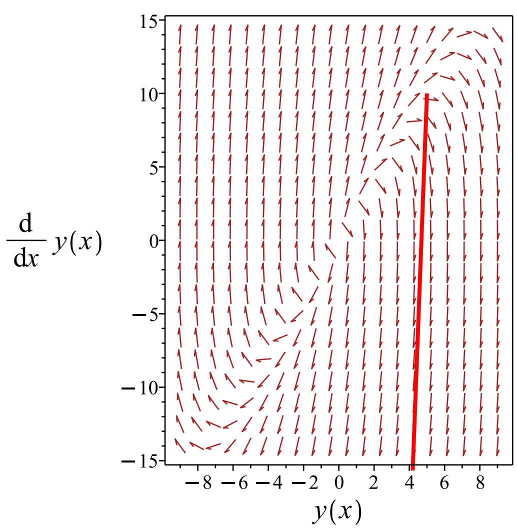
$$y = (4 + 3x)\,\mathrm{e}^{2x} + 3\,\mathrm{e}^{3x} - 2\,\mathrm{e}^{5x}$$

Summary
The solution(s) found are the following

$$y = (4 + 3x)\,\mathrm{e}^{2x} + 3\,\mathrm{e}^{3x} - 2\,\mathrm{e}^{5x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = (4 + 3x)\,\mathrm{e}^{2x} + 3\,\mathrm{e}^{3x} - 2\,\mathrm{e}^{5x}$$

Verified OK.

11.27.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 8y' + 15y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -8 \\ C &= 15 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 383: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - 0\\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{-8}{1}\,dx}\end{aligned}$$

$$
\begin{aligned}
&= z_1 e^{4x} \\
&= z_1\left(\mathrm{e}^{4x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{3x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-8}{1}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{8x}}{\left(y_1\right)^2}\, dx \\
&= y_1\left(\frac{\mathrm{e}^{2x}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{3x}\right) + c_2\left(\mathrm{e}^{3x}\left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 8y' + 15y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{3x} + \frac{c_2 \mathrm{e}^{5x}}{2}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$9\,\mathrm{e}^{2x}x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{2x}x, \mathrm{e}^{2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\mathrm{e}^{5x}}{2}, \mathrm{e}^{3x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\mathrm{e}^{2x}x + A_2\mathrm{e}^{2x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_1\mathrm{e}^{2x}x - 4A_1\mathrm{e}^{2x} + 3A_2\mathrm{e}^{2x} = 9\,\mathrm{e}^{2x}x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 3, A_2 = 4]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3\,\mathrm{e}^{2x}x + 4\,\mathrm{e}^{2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{3x} + \frac{c_2\mathrm{e}^{5x}}{2}\right) + \left(3\,\mathrm{e}^{2x}x + 4\,\mathrm{e}^{2x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{3x} + \frac{c_2 e^{5x}}{2} + 3\,e^{2x} x + 4\,e^{2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 5$ and $x = 0$ in the above gives

$$5 = c_1 + \frac{c_2}{2} + 4 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 3c_1 e^{3x} + \frac{5c_2 e^{5x}}{2} + 6\,e^{2x} x + 11\,e^{2x}$$

substituting $y' = 10$ and $x = 0$ in the above gives

$$10 = 3c_1 + \frac{5c_2}{2} + 11 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 3 \\ c_2 &= -4 \end{aligned}$$

Substituting these values back in above solution results in

$$y = 3\,e^{2x} x + 4\,e^{2x} - 2\,e^{5x} + 3\,e^{3x}$$

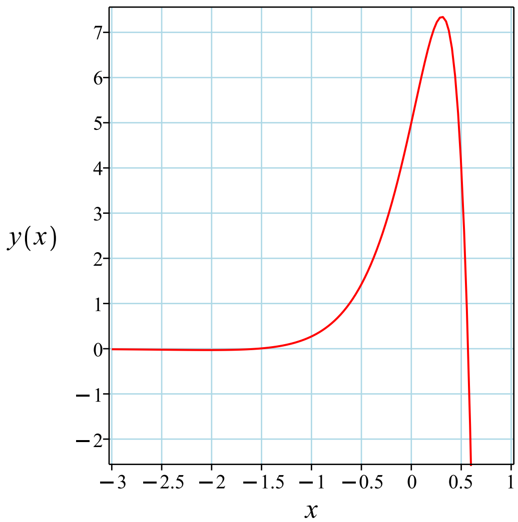
Which simplifies to

$$y = (4 + 3x)\,e^{2x} + 3\,e^{3x} - 2\,e^{5x}$$

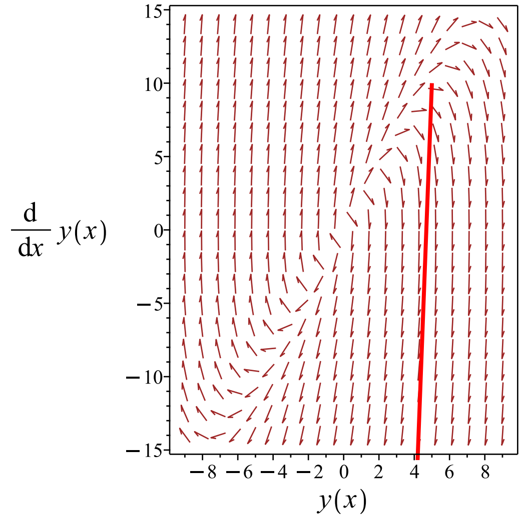
Summary

The solution(s) found are the following

$$y = (4 + 3x)\,e^{2x} + 3\,e^{3x} - 2\,e^{5x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = (4 + 3x)\, e^{2x} + 3\, e^{3x} - 2\, e^{5x}$$

Verified OK.

11.27.4 Maple step by step solution

Let's solve

$$\left[y'' - 8y' + 15y = 9\, e^{2x} x, y(0) = 5, y'\Big|_{\{x=0\}} = 10\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 8r + 15 = 0$

- Factor the characteristic polynomial

  $(r - 3)(r - 5) = 0$

- Roots of the characteristic polynomial

  $r = (3, 5)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{3x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{5x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{3x} + c_2 \mathrm{e}^{5x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 9\,\mathrm{e}^{2x} x\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{3x} & \mathrm{e}^{5x} \\ 3\,\mathrm{e}^{3x} & 5\,\mathrm{e}^{5x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2\,\mathrm{e}^{8x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\frac{9\,\mathrm{e}^{3x}\left(\int x\,\mathrm{e}^{-x}dx\right)}{2} + \frac{9\,\mathrm{e}^{5x}\left(\int x\,\mathrm{e}^{-3x}dx\right)}{2}$

  - Compute integrals

    $y_p(x) = (4 + 3x)\,\mathrm{e}^{2x}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{3x} + c_2 \mathrm{e}^{5x} + (4 + 3x)\,\mathrm{e}^{2x}$

☐ Check validity of solution $y = c_1 \mathrm{e}^{3x} + c_2 \mathrm{e}^{5x} + (4 + 3x)\,\mathrm{e}^{2x}$

  - Use initial condition $y(0) = 5$

    $5 = c_1 + c_2 + 4$

  - Compute derivative of the solution

    $y' = 3c_1 \mathrm{e}^{3x} + 5c_2 \mathrm{e}^{5x} + 3\,\mathrm{e}^{2x} + 2(4 + 3x)\,\mathrm{e}^{2x}$

  - Use the initial condition $y'\Big|_{\{x=0\}} = 10$

    $10 = 3c_1 + 5c_2 + 11$

  - Solve for c_1 and c_2

$\{c_1 = 3, c_2 = -2\}$

- Substitute constant values into general solution and simplify

  $y = (4 + 3x) e^{2x} + 3 e^{3x} - 2 e^{5x}$

- Solution to the IVP

  $y = (4 + 3x) e^{2x} + 3 e^{3x} - 2 e^{5x}$

Problem number: 28.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + 7y' + 10y = 4x\,\mathrm{e}^{-3x}}$$

With initial conditions

$$[y(0) = 0, y'(0) = -1]$$

11.28.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 7 \\ q(x) &= 10 \\ F &= 4x\,\mathrm{e}^{-3x} \end{aligned}$$

Hence the ode is

$$y'' + 7y' + 10y = 4x\,e^{-3x}$$

The domain of $p(x) = 7$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 10$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 4x\,e^{-3x}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

11.28.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 7, C = 10, f(x) = 4x\,e^{-3x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 7y' + 10y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 7, C = 10$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 7\lambda\,e^{\lambda x} + 10\,e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 7\lambda + 10 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 7, C = 10$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{-7}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{7^2 - (4)(1)(10)} \\
&= -\frac{7}{2} \pm \frac{3}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
\lambda_1 &= -\frac{7}{2} + \frac{3}{2} \\
\lambda_2 &= -\frac{7}{2} - \frac{3}{2}
\end{aligned}$$

Which simplifies to

$$\begin{aligned}
\lambda_1 &= -2 \\
\lambda_2 &= -5
\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}
y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\
y &= c_1 e^{(-2)x} + c_2 e^{(-5)x}
\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-5x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-5x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4x\,\mathrm{e}^{-3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,\mathrm{e}^{-3x},\mathrm{e}^{-3x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-5x},\mathrm{e}^{-2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,\mathrm{e}^{-3x} + A_2 \mathrm{e}^{-3x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1\mathrm{e}^{-3x} - 2A_1 x\,\mathrm{e}^{-3x} - 2A_2\mathrm{e}^{-3x} = 4x\,\mathrm{e}^{-3x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2, A_2 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2x\,\mathrm{e}^{-3x} - \mathrm{e}^{-3x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-2x} + c_2\mathrm{e}^{-5x}\right) + \left(-2x\,\mathrm{e}^{-3x} - \mathrm{e}^{-3x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1\mathrm{e}^{-2x} + c_2\mathrm{e}^{-5x} - 2x\,\mathrm{e}^{-3x} - \mathrm{e}^{-3x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + c_2 - 1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -2c_1 e^{-2x} - 5c_2 e^{-5x} + e^{-3x} + 6x\, e^{-3x}$$

substituting $y' = -1$ and $x = 0$ in the above gives

$$-1 = -2c_1 - 5c_2 + 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = -2x\, e^{-3x} - e^{-3x} + e^{-2x}$$

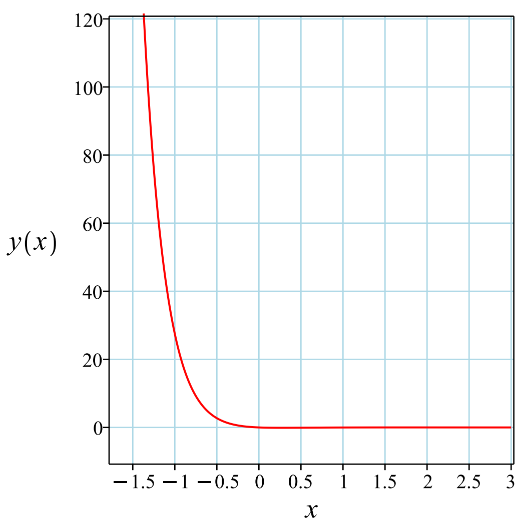
Which simplifies to

$$y = (-2x - 1)\, e^{-3x} + e^{-2x}$$

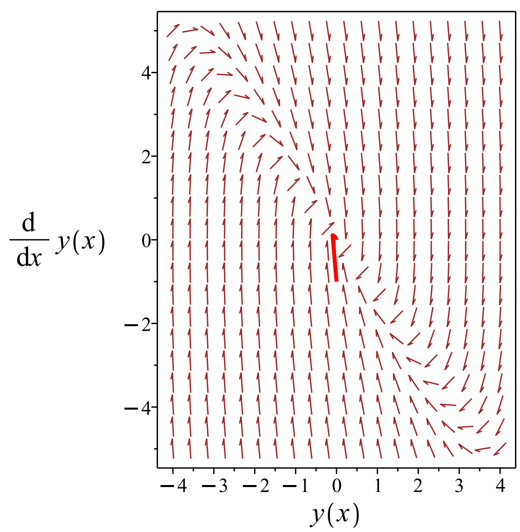
Summary

The solution(s) found are the following

$$y = (-2x - 1)\, e^{-3x} + e^{-2x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = (-2x - 1)\, e^{-3x} + e^{-2x}$$

Verified OK.

11.28.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 7y' + 10y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 7 \\ C &= 10 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 385: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{7}{1}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{-\frac{7x}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{7x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-5x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{7}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-7x}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\mathrm{e}^{3x}}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-5x}\right) + c_2 \left(\mathrm{e}^{-5x} \left(\frac{\mathrm{e}^{3x}}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 7y' + 10y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-5x} + \frac{c_2 \mathrm{e}^{-2x}}{3}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4x\,e^{-3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^{-3x}, e^{-3x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{e^{-2x}}{3}, e^{-5x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,e^{-3x} + A_2 e^{-3x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 e^{-3x} - 2A_1 x\,e^{-3x} - 2A_2 e^{-3x} = 4x\,e^{-3x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2, A_2 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2x\,e^{-3x} - e^{-3x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-5x} + \frac{c_2 e^{-2x}}{3}\right) + \left(-2x\,e^{-3x} - e^{-3x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{-5x} + \frac{c_2 \mathrm{e}^{-2x}}{3} - 2x\,\mathrm{e}^{-3x} - \mathrm{e}^{-3x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + \frac{c_2}{3} - 1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -5c_1 \mathrm{e}^{-5x} - \frac{2c_2 \mathrm{e}^{-2x}}{3} + \mathrm{e}^{-3x} + 6x\,\mathrm{e}^{-3x}$$

substituting $y' = -1$ and $x = 0$ in the above gives

$$-1 = -5c_1 - \frac{2c_2}{3} + 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 3$$

Substituting these values back in above solution results in

$$y = -2x\,\mathrm{e}^{-3x} - \mathrm{e}^{-3x} + \mathrm{e}^{-2x}$$

Which simplifies to

$$y = (-2x - 1)\,\mathrm{e}^{-3x} + \mathrm{e}^{-2x}$$

Summary

The solution(s) found are the following

$$y = (-2x - 1)\,\mathrm{e}^{-3x} + \mathrm{e}^{-2x} \tag{1}$$

(b) Slope field plot

<u>Verification of solutions</u>

$$y = (-2x - 1)\,\mathrm{e}^{-3x} + \mathrm{e}^{-2x}$$

Verified OK.

11.28.4 Maple step by step solution

Let's solve

$$\left[y'' + 7y' + 10y = 4x\,\mathrm{e}^{-3x}, y(0) = 0, y'\Big|_{\{x=0\}} = -1\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 7r + 10 = 0$

- Factor the characteristic polynomial

  $(r + 5)(r + 2) = 0$

- Roots of the characteristic polynomial

  $r = (-5, -2)$

- 1st solution of the homogeneous ODE

$y_1(x) = \mathrm{e}^{-5x}$

- 2nd solution of the homogeneous ODE

$y_2(x) = \mathrm{e}^{-2x}$

- General solution of the ODE

$y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

$y = c_1 \mathrm{e}^{-5x} + c_2 \mathrm{e}^{-2x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

$\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 4x\,\mathrm{e}^{-3x}\right]$

- ○ Wronskian of solutions of the homogeneous equation

$W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-5x} & \mathrm{e}^{-2x} \\ -5\,\mathrm{e}^{-5x} & -2\,\mathrm{e}^{-2x} \end{bmatrix}$

- ○ Compute Wronskian

$W(y_1(x), y_2(x)) = 3\,\mathrm{e}^{-7x}$

- ○ Substitute functions into equation for $y_p(x)$

$y_p(x) = -\frac{4\,\mathrm{e}^{-5x}\left(\int \mathrm{e}^{2x} x dx\right)}{3} + \frac{4\,\mathrm{e}^{-2x}\left(\int x\,\mathrm{e}^{-x} dx\right)}{3}$

- ○ Compute integrals

$y_p(x) = (-2x-1)\,\mathrm{e}^{-3x}$

- Substitute particular solution into general solution to ODE

$y = c_1 \mathrm{e}^{-5x} + c_2 \mathrm{e}^{-2x} + (-2x-1)\,\mathrm{e}^{-3x}$

☐ Check validity of solution $y = c_1 \mathrm{e}^{-5x} + c_2 \mathrm{e}^{-2x} + (-2x-1)\,\mathrm{e}^{-3x}$

- ○ Use initial condition $y(0) = 0$

$0 = c_1 + c_2 - 1$

- ○ Compute derivative of the solution

$y' = -5c_1 \mathrm{e}^{-5x} - 2c_2 \mathrm{e}^{-2x} - 2\,\mathrm{e}^{-3x} - 3(-2x-1)\,\mathrm{e}^{-3x}$

- ○ Use the initial condition $y'\Big|_{\{x=0\}} = -1$

$-1 = -5c_1 - 2c_2 + 1$

- Solve for c_1 and c_2

  $\{c_1 = 0, c_2 = 1\}$
- Substitute constant values into general solution and simplify

  $y = (-2x - 1)\,\mathrm{e}^{-3x} + \mathrm{e}^{-2x}$

- Solution to the IVP

  $y = (-2x - 1)\,\mathrm{e}^{-3x} + \mathrm{e}^{-2x}$

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + 8y' + 16y = 8\,\mathrm{e}^{-2x}}$$

With initial conditions

$$[y(0) = 2, y'(0) = 0]$$

11.29.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 8 \\ q(x) &= 16 \\ F &= 8\,\mathrm{e}^{-2x} \end{aligned}$$

Hence the ode is

$$y'' + 8y' + 16y = 8\,\mathrm{e}^{-2x}$$

The domain of $p(x) = 8$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 16$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 8\,\mathrm{e}^{-2x}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

11.29.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 8, C = 16, f(x) = 8\,\mathrm{e}^{-2x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 8y' + 16y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 8, C = 16$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 8\lambda e^{\lambda x} + 16 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 8\lambda + 16 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 8, C = 16$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-8}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(8)^2 - (4)(1)(16)} \\ &= -4\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 4$. Therefore the solution is

$$y = c_1 e^{-4x} + c_2 e^{-4x} x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{-4x} + c_2 x\, e^{-4x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8\, e^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-4x} x, e^{-4x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{-2x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1 e^{-2x} = 8\,e^{-2x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2\,e^{-2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-4x} + c_2 x\,e^{-4x}\right) + \left(2\,e^{-2x}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-4x}(c_2 x + c_1) + 2\,e^{-2x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{-4x}(c_2 x + c_1) + 2\,e^{-2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = 2 + c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -4\,e^{-4x}(c_2 x + c_1) + c_2 e^{-4x} - 4\,e^{-2x}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -4 - 4c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 4$$

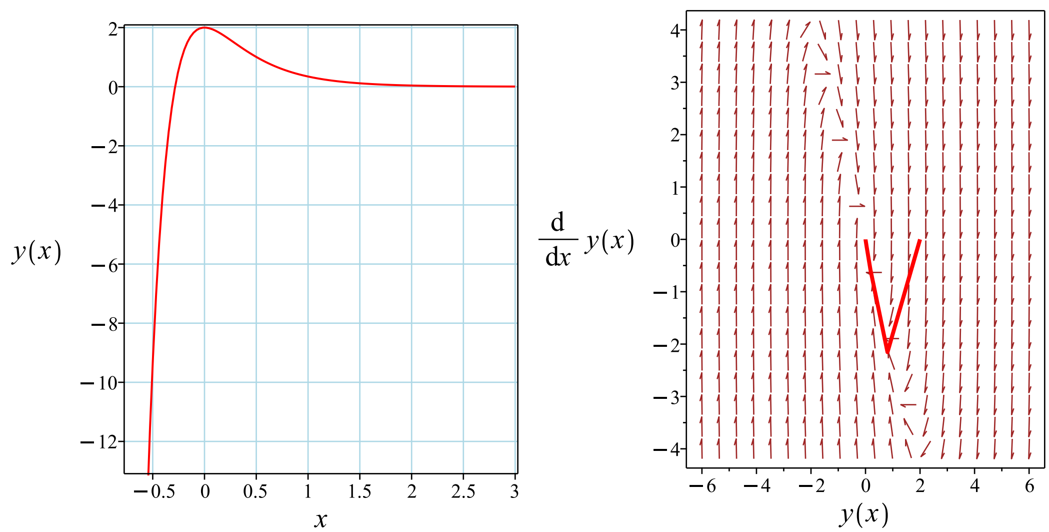
Substituting these values back in above solution results in

$$y = 4\,\mathrm{e}^{-4x}x + 2\,\mathrm{e}^{-2x}$$

Summary

The solution(s) found are the following

$$y = 4\,\mathrm{e}^{-4x}x + 2\,\mathrm{e}^{-2x} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = 4\,\mathrm{e}^{-4x}x + 2\,\mathrm{e}^{-2x}$$

Verified OK.

11.29.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y''+p(x)\,y'+\frac{\left(p(x)^{2}+p'(x)\right)y}{2}=f(x)$$

Where $p(x)=8$. Therefore, there is an integrating factor given by

$$\begin{aligned}M(x)&=e^{\frac{1}{2}\int p\,dx}\\&=e^{\int 8\,dx}\\&=\mathrm{e}^{4x}\end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned}\left(M(x)y\right)''&=8\,\mathrm{e}^{4x}\mathrm{e}^{-2x}\\\left(\mathrm{e}^{4x}y\right)''&=8\,\mathrm{e}^{4x}\mathrm{e}^{-2x}\end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{4x}y\right)'=4\,\mathrm{e}^{2x}+c_1$$

Integrating again gives

$$\left(\mathrm{e}^{4x}y\right)=c_1x+2\,\mathrm{e}^{2x}+c_2$$

Hence the solution is

$$y=\frac{c_1x+2\,\mathrm{e}^{2x}+c_2}{\mathrm{e}^{4x}}$$

Or

$$y=c_1x\,\mathrm{e}^{-4x}+2\,\mathrm{e}^{-2x}+c_2\mathrm{e}^{-4x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y=c_1x\,\mathrm{e}^{-4x}+2\,\mathrm{e}^{-2x}+c_2\mathrm{e}^{-4x}\tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y=2$ and $x=0$ in the above gives

$$2=c_2+2\tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 e^{-4x} - 4c_1 x\, e^{-4x} - 4\, e^{-2x} - 4c_2 e^{-4x}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -4 + c_1 - 4c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 4$$
$$c_2 = 0$$

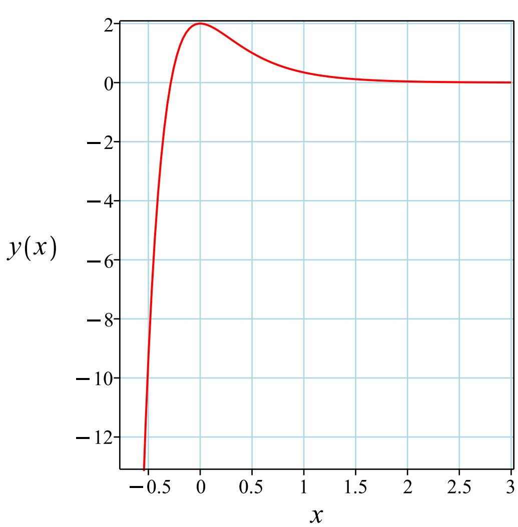
Substituting these values back in above solution results in

$$y = 4\, e^{-4x} x + 2\, e^{-2x}$$

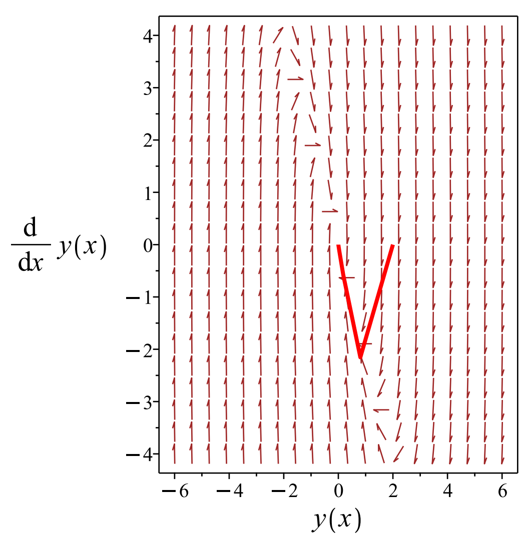
Summary

The solution(s) found are the following

$$y = 4\, e^{-4x} x + 2\, e^{-2x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 4\, e^{-4x} x + 2\, e^{-2x}$$

Verified OK.

11.29.4 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 8y' + 16y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 8 \\ C &= 16 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 387: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{8}{1} \, dx}
\end{aligned}$$

$$
\begin{aligned}
&= z_1 e^{-4x} \\
&= z_1\left(\mathrm{e}^{-4x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-4x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{8}{1}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-8x}}{\left(y_1\right)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-4x}\right) + c_2\left(\mathrm{e}^{-4x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 8y' + 16y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-4x} + c_2 x\,\mathrm{e}^{-4x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8\,\mathrm{e}^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{-2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-4x}x, \mathrm{e}^{-4x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \mathrm{e}^{-2x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1 \mathrm{e}^{-2x} = 8\,\mathrm{e}^{-2x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2\,\mathrm{e}^{-2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-4x} + c_2 x\,\mathrm{e}^{-4x}\right) + \left(2\,\mathrm{e}^{-2x}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{-4x}(c_2 x + c_1) + 2\,\mathrm{e}^{-2x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{-4x}(c_2 x + c_1) + 2\,e^{-2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = 2 + c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -4\,e^{-4x}(c_2 x + c_1) + c_2 e^{-4x} - 4\,e^{-2x}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -4 - 4c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 4$$

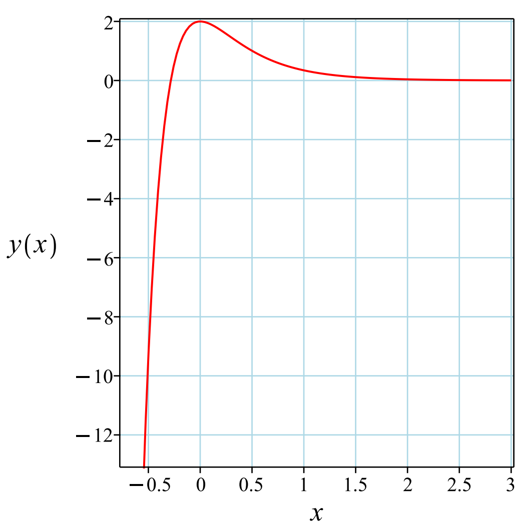
Substituting these values back in above solution results in

$$y = 4\,e^{-4x}x + 2\,e^{-2x}$$

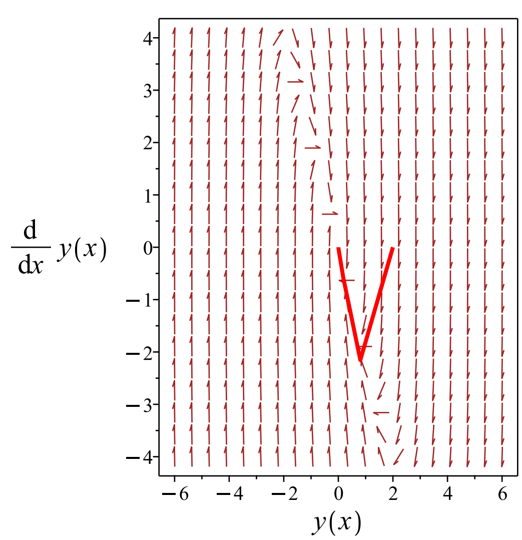
Summary

The solution(s) found are the following

$$y = 4\,e^{-4x}x + 2\,e^{-2x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 4\,\mathrm{e}^{-4x} x + 2\,\mathrm{e}^{-2x}$$

Verified OK.

11.29.5 Maple step by step solution

Let's solve

$\left[y'' + 8y' + 16y = 8\,\mathrm{e}^{-2x}, y(0) = 2, y'\Big|_{\{x=0\}} = 0\right]$

- Highest derivative means the order of the ODE is 2

  y''
- Characteristic polynomial of homogeneous ODE

  $r^2 + 8r + 16 = 0$
- Factor the characteristic polynomial

  $(r+4)^2 = 0$
- Root of the characteristic polynomial

  $r = -4$
- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-4x}$
- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = \mathrm{e}^{-4x} x$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-4x} + c_2 x\,\mathrm{e}^{-4x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 8\,\mathrm{e}^{-2x}\right]$
- ○ Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-4x} & e^{-4x}x \\ -4\,e^{-4x} & -4\,e^{-4x}x + e^{-4x} \end{bmatrix}$$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{-8x}$
- Substitute functions into equation for $y_p(x)$

  $y_p(x) = -8\,e^{-4x}\left(\int e^{2x}x dx - \left(\int e^{2x}dx\right)x\right)$
- Compute integrals

  $y_p(x) = 2\,e^{-2x}$

- Substitute particular solution into general solution to ODE

  $y = c_1e^{-4x} + c_2x\,e^{-4x} + 2\,e^{-2x}$

☐ Check validity of solution $y = c_1e^{-4x} + c_2xe^{-4x} + 2e^{-2x}$

- Use initial condition $y(0) = 2$

  $2 = 2 + c_1$
- Compute derivative of the solution

  $y' = -4c_1e^{-4x} + c_2e^{-4x} - 4c_2x\,e^{-4x} - 4\,e^{-2x}$
- Use the initial condition $y'\Big|_{\{x=0\}} = 0$

  $0 = -4 - 4c_1 + c_2$
- Solve for c_1 and c_2

  $\{c_1 = 0, c_2 = 4\}$
- Substitute constant values into general solution and simplify

  $y = 4\,e^{-4x}x + 2\,e^{-2x}$

- Solution to the IVP

  $y = 4\,e^{-4x}x + 2\,e^{-2x}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + 6y' + 9y = 27\,\mathrm{e}^{-6x}}$$

With initial conditions

$$[y(0) = -2, y'(0) = 0]$$

11.30.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 6 \\ q(x) &= 9 \\ F &= 27\,\mathrm{e}^{-6x} \end{aligned}$$

Hence the ode is

$$y'' + 6y' + 9y = 27\,\mathrm{e}^{-6x}$$

The domain of $p(x) = 6$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 9$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 27\,\mathrm{e}^{-6x}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

11.30.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 6, C = 9, f(x) = 27\,\mathrm{e}^{-6x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 6y' + 9y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 6, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 6\lambda\, e^{\lambda x} + 9\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 6\lambda + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 6, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-6}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{(6)^2 - (4)\,(1)\,(9)}\\ &= -3\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 3$. Therefore the solution is

$$y = c_1 e^{-3x} + c_2 x\, e^{-3x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{-3x} + c_2 x\, e^{-3x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$27\, e^{-6x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-6x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{-3x}, e^{-3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{-6x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$9A_1 e^{-6x} = 27\,e^{-6x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 3]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3\,e^{-6x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-3x} + c_2 x\,e^{-3x}\right) + \left(3\,e^{-6x}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-3x}(c_2 x + c_1) + 3\,e^{-6x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{-3x}(c_2 x + c_1) + 3\,e^{-6x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -2$ and $x = 0$ in the above gives

$$-2 = 3 + c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -3\,e^{-3x}(c_2 x + c_1) + c_2 e^{-3x} - 18\,e^{-6x}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -18 - 3c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -5$$
$$c_2 = 3$$

Substituting these values back in above solution results in

$$y = 3x\,e^{-3x} + 3\,e^{-6x} - 5\,e^{-3x}$$

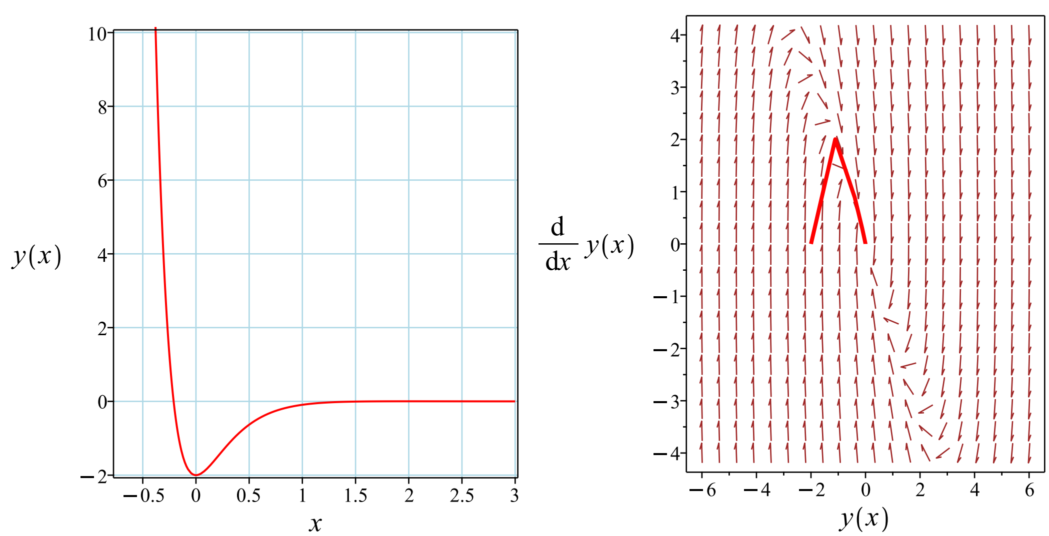
Which simplifies to

$$y = (3x - 5)\,e^{-3x} + 3\,e^{-6x}$$

Summary

The solution(s) found are the following

$$y = (3x - 5)\,e^{-3x} + 3\,e^{-6x} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = (3x - 5)\,e^{-3x} + 3\,e^{-6x}$$

Verified OK.

11.30.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = 6$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int 6\,dx} \\ &= \mathrm{e}^{3x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= 27\,\mathrm{e}^{3x}\mathrm{e}^{-6x} \\ \left(\mathrm{e}^{3x}y\right)'' &= 27\,\mathrm{e}^{3x}\mathrm{e}^{-6x} \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{3x}y\right)' = -9\,\mathrm{e}^{-3x} + c_1$$

Integrating again gives

$$\left(\mathrm{e}^{3x}y\right) = c_1x + 3\,\mathrm{e}^{-3x} + c_2$$

Hence the solution is

$$y = \frac{c_1x + 3\,\mathrm{e}^{-3x} + c_2}{\mathrm{e}^{3x}}$$

Or

$$y = c_1x\,\mathrm{e}^{-3x} + c_2\mathrm{e}^{-3x} + 3\,\mathrm{e}^{-6x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1x\,\mathrm{e}^{-3x} + c_2\mathrm{e}^{-3x} + 3\,\mathrm{e}^{-6x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -2$ and $x = 0$ in the above gives

$$-2 = c_2 + 3 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 \mathrm{e}^{-3x} - 3c_1 x\, \mathrm{e}^{-3x} - 3c_2 \mathrm{e}^{-3x} - 18\, \mathrm{e}^{-6x}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = c_1 - 3c_2 - 18 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 3$$
$$c_2 = -5$$

Substituting these values back in above solution results in

$$y = 3x\, \mathrm{e}^{-3x} + 3\, \mathrm{e}^{-6x} - 5\, \mathrm{e}^{-3x}$$

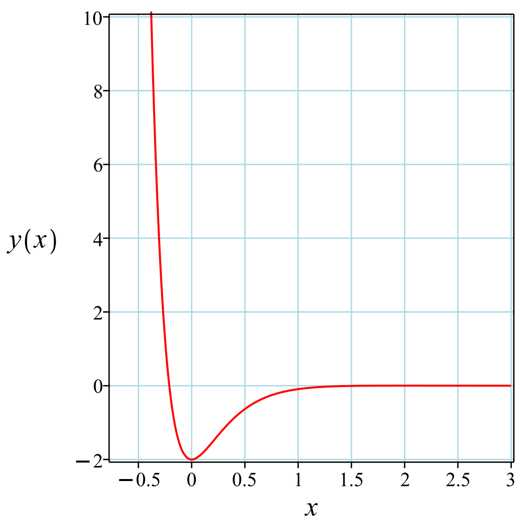
Which simplifies to

$$y = (3x - 5)\, \mathrm{e}^{-3x} + 3\, \mathrm{e}^{-6x}$$

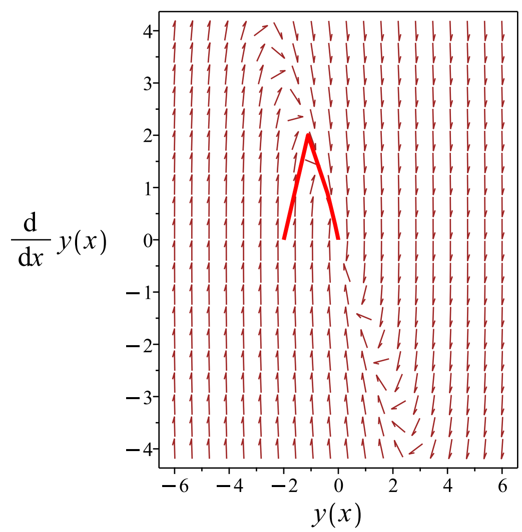
Summary

The solution(s) found are the following

$$y = (3x - 5)\, \mathrm{e}^{-3x} + 3\, \mathrm{e}^{-6x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = (3x - 5)\, \mathrm{e}^{-3x} + 3\, \mathrm{e}^{-6x}$$

Verified OK.

11.30.4 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 6y' + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 6 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 389: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{6}{1}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{-3x} \\
&= z_1\left(\mathrm{e}^{-3x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-3x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{6}{1}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{-6x}}{\left(y_1\right)^2}\, dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-3x}\right) + c_2\left(\mathrm{e}^{-3x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 6y' + 9y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-3x} + c_2 x\, \mathrm{e}^{-3x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$27\,\mathrm{e}^{-6x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{-6x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\,\mathrm{e}^{-3x}, \mathrm{e}^{-3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\mathrm{e}^{-6x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$9A_1\mathrm{e}^{-6x} = 27\,\mathrm{e}^{-6x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 3]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3\,\mathrm{e}^{-6x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-3x} + c_2x\,\mathrm{e}^{-3x}\right) + \left(3\,\mathrm{e}^{-6x}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{-3x}(c_2x + c_1) + 3\,\mathrm{e}^{-6x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{-3x}(c_2 x + c_1) + 3\,e^{-6x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -2$ and $x = 0$ in the above gives

$$-2 = 3 + c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -3\,e^{-3x}(c_2 x + c_1) + c_2 e^{-3x} - 18\,e^{-6x}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -18 - 3c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -5$$
$$c_2 = 3$$

Substituting these values back in above solution results in

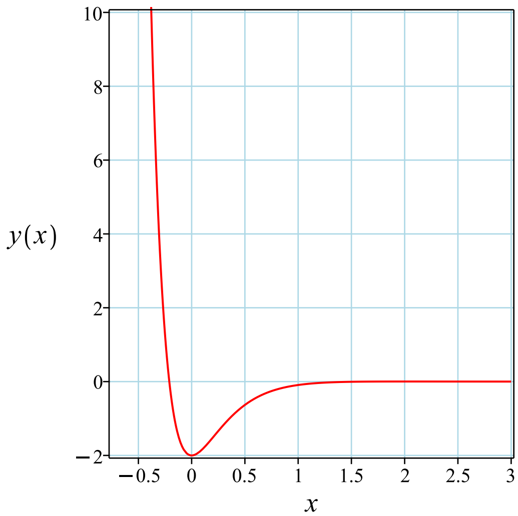
$$y = 3x\,e^{-3x} + 3\,e^{-6x} - 5\,e^{-3x}$$

Which simplifies to

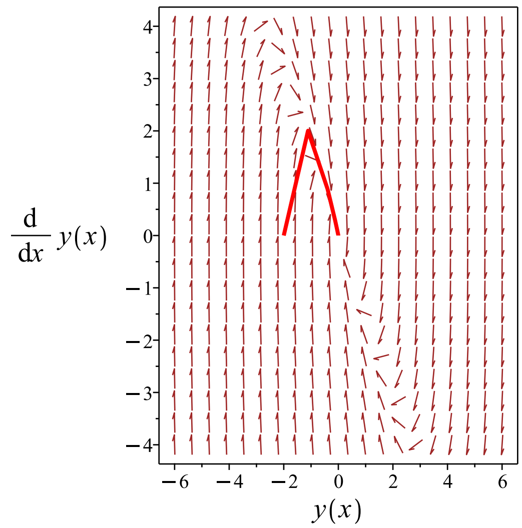
$$y = (3x - 5)\,e^{-3x} + 3\,e^{-6x}$$

Summary
The solution(s) found are the following

$$y = (3x - 5)\,e^{-3x} + 3\,e^{-6x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = (3x - 5)\,\mathrm{e}^{-3x} + 3\,\mathrm{e}^{-6x}$$

Verified OK.

11.30.5 Maple step by step solution

Let's solve

$$\left[y'' + 6y' + 9y = 27\,\mathrm{e}^{-6x}, y(0) = -2, y'\Big|_{\{x=0\}} = 0\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 6r + 9 = 0$

- Factor the characteristic polynomial

  $(r + 3)^2 = 0$

- Root of the characteristic polynomial

  $r = -3$

- 1st solution of the homogeneous ODE

$y_1(x) = \mathrm{e}^{-3x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,\mathrm{e}^{-3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-3x} + c_2 x\,\mathrm{e}^{-3x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 27\,\mathrm{e}^{-6x}\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-3x} & x\,\mathrm{e}^{-3x} \\ -3\,\mathrm{e}^{-3x} & \mathrm{e}^{-3x} - 3x\,\mathrm{e}^{-3x} \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = \mathrm{e}^{-6x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -27\,\mathrm{e}^{-3x}\left(\int x\,\mathrm{e}^{-3x}dx - \left(\int \mathrm{e}^{-3x}dx\right)x\right)$

  ◦ Compute integrals

  $y_p(x) = 3\,\mathrm{e}^{-6x}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-3x} + c_2 x\,\mathrm{e}^{-3x} + 3\,\mathrm{e}^{-6x}$

☐ Check validity of solution $y = c_1 \mathrm{e}^{-3x} + c_2 x \mathrm{e}^{-3x} + 3\mathrm{e}^{-6x}$

  ◦ Use initial condition $y(0) = -2$

  $-2 = 3 + c_1$

  ◦ Compute derivative of the solution

  $y' = -3c_1 \mathrm{e}^{-3x} + c_2 \mathrm{e}^{-3x} - 3c_2 x\,\mathrm{e}^{-3x} - 18\,\mathrm{e}^{-6x}$

  ◦ Use the initial condition $y'\Big|_{\{x=0\}} = 0$

  $0 = -18 - 3c_1 + c_2$

- Solve for c_1 and c_2

  $\{c_1 = -5, c_2 = 3\}$

- Substitute constant values into general solution and simplify

  $y = (3x - 5)\,\mathrm{e}^{-3x} + 3\,\mathrm{e}^{-6x}$

- Solution to the IVP

  $y = (3x - 5)\,\mathrm{e}^{-3x} + 3\,\mathrm{e}^{-6x}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y'' + 4y' + 13y = 18\,\mathrm{e}^{-2x}}$$

With initial conditions

$$[y(0) = 0, y'(0) = 4]$$

11.31.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 4 \\ q(x) &= 13 \\ F &= 18\,\mathrm{e}^{-2x} \end{aligned}$$

Hence the ode is

$$y'' + 4y' + 13y = 18\,\mathrm{e}^{-2x}$$

The domain of $p(x) = 4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 13$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 18\,\mathrm{e}^{-2x}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

11.31.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 4, C = 13, f(x) = 18\,\mathrm{e}^{-2x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 13y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 4, C = 13$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 4\lambda\,\mathrm{e}^{\lambda x} + 13\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4\lambda + 13 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 4, C = 13$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-4}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{4^2 - (4)(1)(13)} \\ &= -2 \pm 3i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -2 + 3i \\ \lambda_2 &= -2 - 3i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -2 + 3i \\ \lambda_2 &= -2 - 3i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -2$ and $\beta = 3$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-2x}(c_1 \cos(3x) + c_2 \sin(3x))$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{-2x}(c_1 \cos(3x) + c_2 \sin(3x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$18\,\mathrm{e}^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-2x} \cos(3x), e^{-2x} \sin(3x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{-2x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$9A_1 e^{-2x} = 18 e^{-2x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2 e^{-2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-2x}(c_1 \cos(3x) + c_2 \sin(3x))\right) + \left(2 e^{-2x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{-2x}(c_1 \cos(3x) + c_2 \sin(3x)) + 2 e^{-2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -2\,\mathrm{e}^{-2x}(c_1 \cos(3x) + c_2 \sin(3x)) + \mathrm{e}^{-2x}(-3c_1 \sin(3x) + 3c_2 \cos(3x)) - 4\,\mathrm{e}^{-2x}$$

substituting $y' = 4$ and $x = 0$ in the above gives

$$4 = -2c_1 + 3c_2 - 4 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -2$$
$$c_2 = \frac{4}{3}$$

Substituting these values back in above solution results in

$$y = \frac{4\,\mathrm{e}^{-2x} \sin(3x)}{3} - 2\,\mathrm{e}^{-2x} \cos(3x) + 2\,\mathrm{e}^{-2x}$$

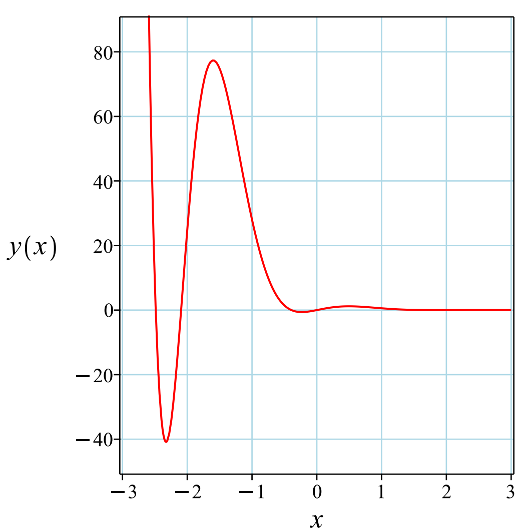
Which simplifies to

$$y = -\frac{2\,\mathrm{e}^{-2x}(-3 - 2\sin(3x) + 3\cos(3x))}{3}$$

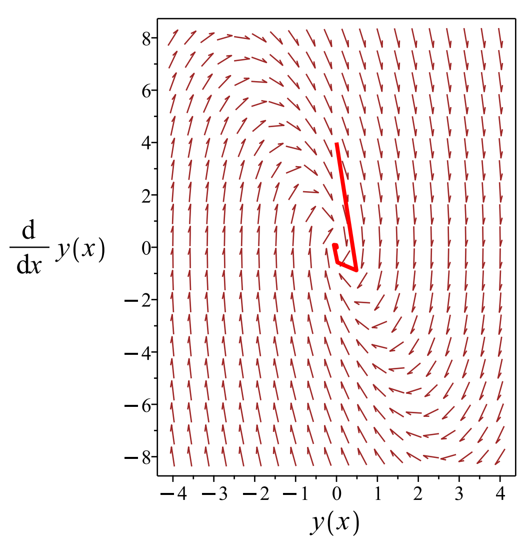
Summary

The solution(s) found are the following

$$y = -\frac{2\,\mathrm{e}^{-2x}(-3 - 2\sin(3x) + 3\cos(3x))}{3} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -\frac{2\,e^{-2x}(-3 - 2\sin(3x) + 3\cos(3x))}{3}$$

Verified OK.

11.31.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y' + 13y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4 \\ C &= 13 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-9}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -9 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -9z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 391: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -9$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(3x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4}{1}\,dx} \\
&= z_1 e^{-2x} \\
&= z_1 \left(\mathrm{e}^{-2x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-2x} \cos(3x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-4x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\tan(3x)}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-2x} \cos(3x)\right) + c_2 \left(\mathrm{e}^{-2x} \cos(3x) \left(\frac{\tan(3x)}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 13y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{-2x} \cos(3x) + \frac{\sin(3x) e^{-2x} c_2}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$18 e^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^{-2x} \cos(3x), \frac{e^{-2x} \sin(3x)}{3}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{-2x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$9A_1 e^{-2x} = 18 e^{-2x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2 e^{-2x}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \mathrm{e}^{-2x} \cos(3x) + \frac{\sin(3x)\,\mathrm{e}^{-2x} c_2}{3}\right) + \left(2\,\mathrm{e}^{-2x}\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{-2x} \cos(3x) + \frac{\sin(3x)\,\mathrm{e}^{-2x} c_2}{3} + 2\,\mathrm{e}^{-2x} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$
0 = c_1 + 2 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -2c_1 \mathrm{e}^{-2x} \cos(3x) - 3c_1 \mathrm{e}^{-2x} \sin(3x) + \cos(3x)\,\mathrm{e}^{-2x} c_2 - \frac{2\sin(3x)\,\mathrm{e}^{-2x} c_2}{3} - 4\,\mathrm{e}^{-2x}
$$

substituting $y' = 4$ and $x = 0$ in the above gives

$$
4 = -2c_1 - 4 + c_2 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= -2 \\
c_2 &= 4
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \frac{4\,\mathrm{e}^{-2x} \sin(3x)}{3} - 2\,\mathrm{e}^{-2x} \cos(3x) + 2\,\mathrm{e}^{-2x}
$$

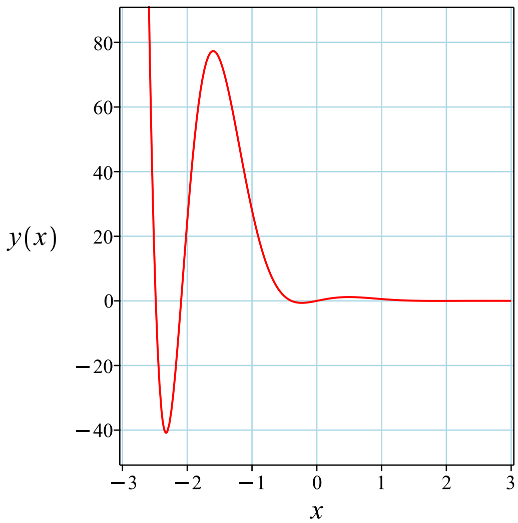
Which simplifies to

$$
y = -\frac{2\,\mathrm{e}^{-2x}(-3 - 2\sin(3x) + 3\cos(3x))}{3}
$$

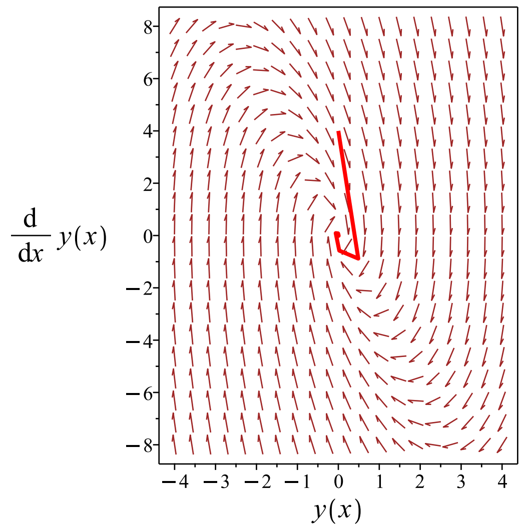
Summary

The solution(s) found are the following

$$
y = -\frac{2\,\mathrm{e}^{-2x}(-3 - 2\sin(3x) + 3\cos(3x))}{3} \tag{1}
$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -\frac{2\,\mathrm{e}^{-2x}(-3-2\sin(3x)+3\cos(3x))}{3}$$

Verified OK.

11.31.4 Maple step by step solution

Let's solve

$$\left[y''+4y'+13y=18\,\mathrm{e}^{-2x}, y(0)=0, y'\Big|_{\{x=0\}}=4\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2+4r+13=0$

- Use quadratic formula to solve for r

  $r=\frac{(-4)\pm(\sqrt{-36})}{2}$

- Roots of the characteristic polynomial

  $r=(-2-3\,\mathrm{I}, -2+3\,\mathrm{I})$

- 1st solution of the homogeneous ODE

$y_1(x) = \mathrm{e}^{-2x} \cos(3x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-2x} \sin(3x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-2x} \cos(3x) + \sin(3x) \mathrm{e}^{-2x} c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 18\,\mathrm{e}^{-2x}\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-2x} \cos(3x) & \mathrm{e}^{-2x} \sin(3x) \\ -2\,\mathrm{e}^{-2x} \cos(3x) - 3\,\mathrm{e}^{-2x} \sin(3x) & -2\,\mathrm{e}^{-2x} \sin(3x) + 3\,\mathrm{e}^{-2x} \cos(3x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 3\,\mathrm{e}^{-4x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -6\,\mathrm{e}^{-2x}\left(\cos(3x)\left(\int \sin(3x)\, dx\right) - \sin(3x)\left(\int \cos(3x)\, dx\right)\right)$

  - Compute integrals

    $y_p(x) = 2\,\mathrm{e}^{-2x}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-2x} \cos(3x) + \sin(3x) \mathrm{e}^{-2x} c_2 + 2\,\mathrm{e}^{-2x}$

□ Check validity of solution $y = c_1 \mathrm{e}^{-2x} \cos(3x) + \sin(3x) \mathrm{e}^{-2x} c_2 + 2\mathrm{e}^{-2x}$

  - Use initial condition $y(0) = 0$

    $0 = c_1 + 2$

  - Compute derivative of the solution

    $y' = -2c_1 \mathrm{e}^{-2x} \cos(3x) - 3c_1 \mathrm{e}^{-2x} \sin(3x) + 3\cos(3x) \mathrm{e}^{-2x} c_2 - 2\sin(3x) \mathrm{e}^{-2x} c_2 - 4\,\mathrm{e}^{-2x}$

  - Use the initial condition $y'\Big|_{\{x=0\}} = 4$

    $4 = -2c_1 + 3c_2 - 4$

- Solve for c_1 and c_2

  $\{c_1 = -2, c_2 = \frac{4}{3}\}$

- Substitute constant values into general solution and simplify

  $y = -\frac{2\,e^{-2x}(-3-2\sin(3x)+3\cos(3x))}{3}$

- Solution to the IVP

  $y = -\frac{2\,e^{-2x}(-3-2\sin(3x)+3\cos(3x))}{3}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y'' - 10y' + 29y = 8\,e^{5x}}$$

With initial conditions

$$[y(0) = 0, y'(0) = 8]$$

11.32.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -10 \\ q(x) &= 29 \\ F &= 8\,e^{5x} \end{aligned}$$

Hence the ode is

$$y'' - 10y' + 29y = 8\,\mathrm{e}^{5x}$$

The domain of $p(x) = -10$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 29$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 8\,\mathrm{e}^{5x}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

11.32.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -10, C = 29, f(x) = 8\,\mathrm{e}^{5x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 10y' + 29y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -10, C = 29$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 10\lambda\,\mathrm{e}^{\lambda x} + 29\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 10\lambda + 29 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -10, C = 29$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{10}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-10^2 - (4)(1)(29)} \\ &= 5 \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 5 + 2i \\ \lambda_2 &= 5 - 2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 5 + 2i \\ \lambda_2 &= 5 - 2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 5$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{5x}(c_1 \cos(2x) + c_2 \sin(2x))$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{5x}(c_1 \cos(2x) + c_2 \sin(2x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8\,\mathrm{e}^{5x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{5x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{5x} \cos(2x), e^{5x} \sin(2x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{5x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1 e^{5x} = 8\,e^{5x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2\,e^{5x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{5x}(c_1 \cos(2x) + c_2 \sin(2x))\right) + \left(2\,e^{5x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{5x}(c_1 \cos(2x) + c_2 \sin(2x)) + 2\,e^{5x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 5\,e^{5x}(c_1 \cos(2x) + c_2 \sin(2x)) + e^{5x}(-2c_1 \sin(2x) + 2c_2 \cos(2x)) + 10\,e^{5x}$$

substituting $y' = 8$ and $x = 0$ in the above gives

$$8 = 5c_1 + 2c_2 + 10 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -2$$
$$c_2 = 4$$

Substituting these values back in above solution results in

$$y = -2\,e^{5x} \cos(2x) + 4\,e^{5x} \sin(2x) + 2\,e^{5x}$$

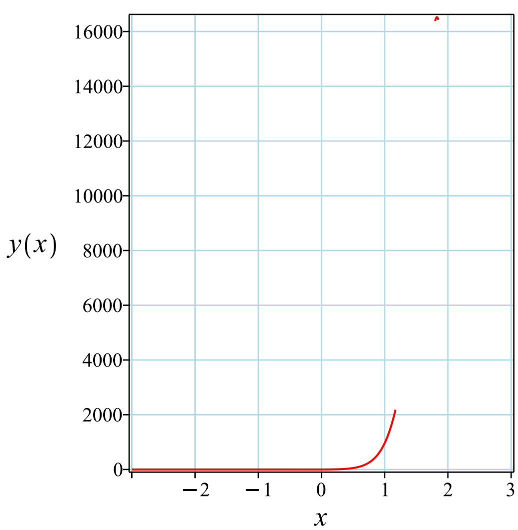
Which simplifies to

$$y = -2\,e^{5x}(-1 + \cos(2x) - 2\sin(2x))$$

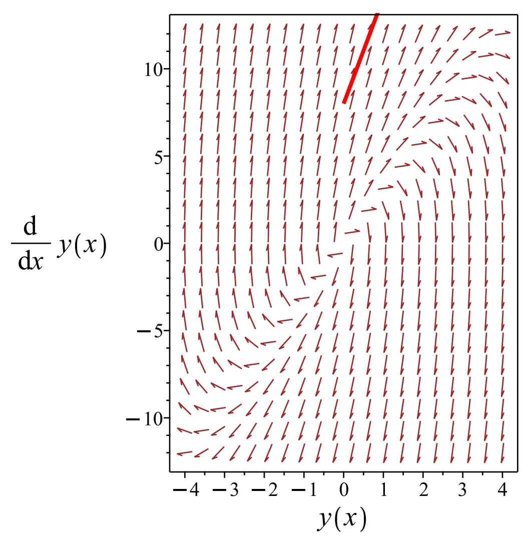
Summary

The solution(s) found are the following

$$y = -2\,e^{5x}(-1 + \cos(2x) - 2\sin(2x)) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -2\,e^{5x}(-1 + \cos(2x) - 2\sin(2x))$$

Verified OK.

11.32.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 10y' + 29y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -10 \\ C &= 29 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 393: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(2x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-10}{1}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{5x} \\
&= z_1 \left(\mathrm{e}^{5x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{5x} \cos(2x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-10}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{10x}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\tan(2x)}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{5x} \cos(2x)\right) + c_2 \left(\mathrm{e}^{5x} \cos(2x) \left(\frac{\tan(2x)}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 10y' + 29y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{5x} \cos(2x) + \frac{\sin(2x)\, \mathrm{e}^{5x} c_2}{2}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8\,\mathrm{e}^{5x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{5x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\mathrm{e}^{5x}\cos(2x), \frac{\mathrm{e}^{5x}\sin(2x)}{2}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\mathrm{e}^{5x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1\mathrm{e}^{5x} = 8\,\mathrm{e}^{5x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2\,\mathrm{e}^{5x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{5x}\cos(2x) + \frac{\sin(2x)\,\mathrm{e}^{5x}c_2}{2}\right) + \left(2\,\mathrm{e}^{5x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{5x} \cos(2x) + \frac{\sin(2x)\,\mathrm{e}^{5x} c_2}{2} + 2\,\mathrm{e}^{5x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 5c_1 \mathrm{e}^{5x} \cos(2x) - 2c_1 \mathrm{e}^{5x} \sin(2x) + \cos(2x)\,\mathrm{e}^{5x} c_2 + \frac{5\sin(2x)\,\mathrm{e}^{5x} c_2}{2} + 10\,\mathrm{e}^{5x}$$

substituting $y' = 8$ and $x = 0$ in the above gives

$$8 = 5c_1 + 10 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -2$$
$$c_2 = 8$$

Substituting these values back in above solution results in

$$y = -2\,\mathrm{e}^{5x} \cos(2x) + 4\,\mathrm{e}^{5x} \sin(2x) + 2\,\mathrm{e}^{5x}$$

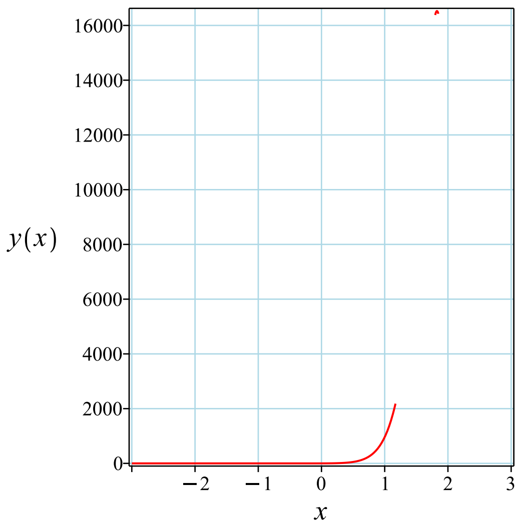
Which simplifies to

$$y = -2\,\mathrm{e}^{5x}(-1 + \cos(2x) - 2\sin(2x))$$

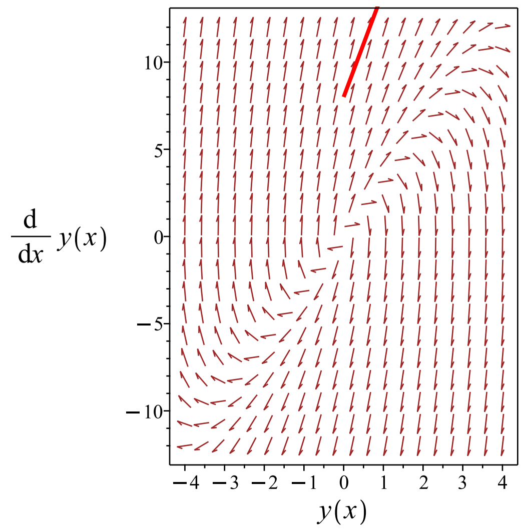
Summary

The solution(s) found are the following

$$y = -2\,\mathrm{e}^{5x}(-1 + \cos(2x) - 2\sin(2x)) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -2\,\mathrm{e}^{5x}(-1 + \cos(2x) - 2\sin(2x))$$

Verified OK.

11.32.4 Maple step by step solution

Let's solve

$$\left[y'' - 10y' + 29y = 8\,\mathrm{e}^{5x}, y(0) = 0, y'\Big|_{\{x=0\}} = 8\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 10r + 29 = 0$

- Use quadratic formula to solve for r

  $r = \frac{10 \pm (\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r = (5 - 2\,\mathrm{I}, 5 + 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

$y_1(x) = e^{5x} \cos(2x)$

- 2nd solution of the homogeneous ODE

$y_2(x) = e^{5x} \sin(2x)$

- General solution of the ODE

$y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

$y = c_1 e^{5x} \cos(2x) + \sin(2x) e^{5x} c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

$\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 8\,e^{5x}\right]$

- ◦ Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{5x}\cos(2x) & e^{5x}\sin(2x) \\ 5\,e^{5x}\cos(2x) - 2\,e^{5x}\sin(2x) & 5\,e^{5x}\sin(2x) + 2\,e^{5x}\cos(2x) \end{bmatrix}$$

- ◦ Compute Wronskian

$W(y_1(x), y_2(x)) = 2\,e^{10x}$

- ◦ Substitute functions into equation for $y_p(x)$

$y_p(x) = -4\,e^{5x}\left(\cos(2x)\left(\int \sin(2x)\,dx\right) - \sin(2x)\left(\int \cos(2x)\,dx\right)\right)$

- ◦ Compute integrals

$y_p(x) = 2\,e^{5x}$

- Substitute particular solution into general solution to ODE

$y = c_1 e^{5x} \cos(2x) + \sin(2x) e^{5x} c_2 + 2\,e^{5x}$

□ Check validity of solution $y = c_1 e^{5x} \cos(2x) + \sin(2x) e^{5x} c_2 + 2e^{5x}$

- ◦ Use initial condition $y(0) = 0$

$0 = c_1 + 2$

- ◦ Compute derivative of the solution

$y' = 5c_1 e^{5x} \cos(2x) - 2c_1 e^{5x} \sin(2x) + 2\cos(2x) e^{5x} c_2 + 5\sin(2x) e^{5x} c_2 + 10\,e^{5x}$

- ◦ Use the initial condition $y'\Big|_{\{x=0\}} = 8$

$8 = 5c_1 + 2c_2 + 10$

- Solve for c_1 and c_2

  $\{c_1 = -2, c_2 = 4\}$

- Substitute constant values into general solution and simplify

  $y = -2\,\mathrm{e}^{5x}(-1 + \cos(2x) - 2\sin(2x))$

- Solution to the IVP

  $y = -2\,\mathrm{e}^{5x}(-1 + \cos(2x) - 2\sin(2x))$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 4y' + 13y = 8 \sin(3x)}$$

With initial conditions

$$[y(0) = 1, y'(0) = 2]$$

11.33.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -4 \\ q(x) &= 13 \\ F &= 8 \sin(3x) \end{aligned}$$

Hence the ode is

$$y'' - 4y' + 13y = 8 \sin (3x)$$

The domain of $p(x) = -4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 13$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 8 \sin (3x)$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

11.33.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 13, f(x) = 8 \sin (3x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 13y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 13$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 4\lambda e^{\lambda x} + 13 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 13 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 13$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-4^2 - (4)\,(1)\,(13)} \\ &= 2 \pm 3i\end{aligned}$$

Hence

$$\lambda_1 = 2 + 3i$$
$$\lambda_2 = 2 - 3i$$

Which simplifies to

$$\lambda_1 = 2 + 3i$$
$$\lambda_2 = 2 - 3i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 2$ and $\beta = 3$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{2x}(c_1 \cos(3x) + c_2 \sin(3x))$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{2x}(c_1 \cos(3x) + c_2 \sin(3x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8 \sin(3x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(3x), \sin(3x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{2x}\cos(3x), e^{2x}\sin(3x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\cos(3x) + A_2\sin(3x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1\cos(3x) + 4A_2\sin(3x) + 12A_1\sin(3x) - 12A_2\cos(3x) = 8\sin(3x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{3}{5}, A_2 = \frac{1}{5}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{3\cos(3x)}{5} + \frac{\sin(3x)}{5}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{2x}(c_1\cos(3x) + c_2\sin(3x))\right) + \left(\frac{3\cos(3x)}{5} + \frac{\sin(3x)}{5}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{2x}(c_1\cos(3x) + c_2\sin(3x)) + \frac{3\cos(3x)}{5} + \frac{\sin(3x)}{5} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 + \frac{3}{5} \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2\,\mathrm{e}^{2x}(c_1 \cos(3x) + c_2 \sin(3x)) + \mathrm{e}^{2x}(-3c_1 \sin(3x) + 3c_2 \cos(3x)) - \frac{9\sin(3x)}{5} + \frac{3\cos(3x)}{5}$$

substituting $y' = 2$ and $x = 0$ in the above gives

$$2 = 2c_1 + \frac{3}{5} + 3c_2 \tag{2A}$$

Equations $\{1\text{A},2\text{A}\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{2}{5}$$
$$c_2 = \frac{1}{5}$$

Substituting these values back in above solution results in

$$y = \frac{2\,\mathrm{e}^{2x}\cos(3x)}{5} + \frac{\mathrm{e}^{2x}\sin(3x)}{5} + \frac{3\cos(3x)}{5} + \frac{\sin(3x)}{5}$$

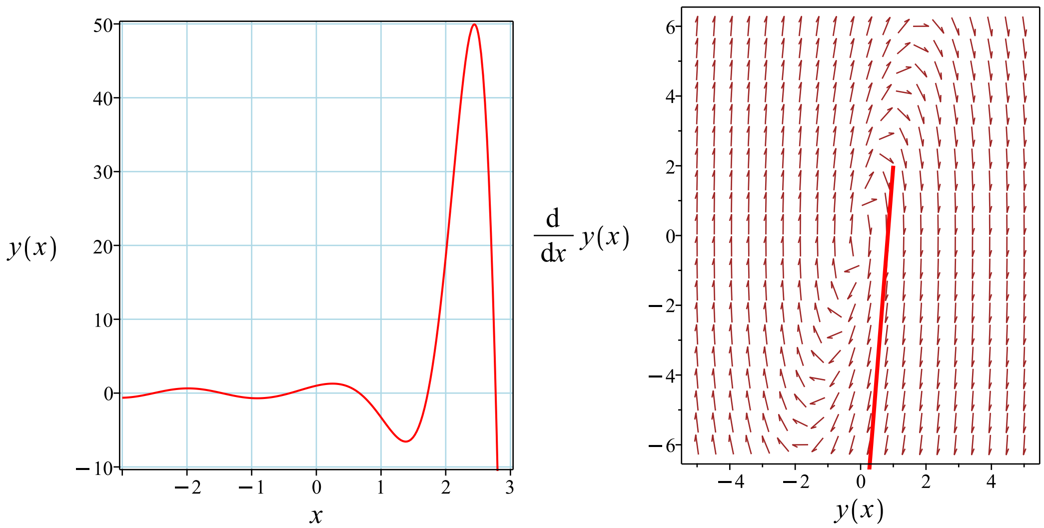
Which simplifies to

$$y = \frac{(2\,\mathrm{e}^{2x} + 3)\cos(3x)}{5} + \frac{\sin(3x)(\mathrm{e}^{2x} + 1)}{5}$$

Summary

The solution(s) found are the following

$$y = \frac{(2\,\mathrm{e}^{2x} + 3)\cos(3x)}{5} + \frac{\sin(3x)(\mathrm{e}^{2x} + 1)}{5} \tag{1}$$



(a) Solution plot (b) Slope field plot

<u>Verification of solutions</u>

$$y = \frac{(2\,e^{2x}+3)\cos(3x)}{5} + \frac{\sin(3x)\,(e^{2x}+1)}{5}$$

Verified OK.

11.33.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 13y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 13 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-9}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = -9$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = -9z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 395: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -9$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(3x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx} \\ &= z_1 e^{2x} \\ &= z_1\left(\mathrm{e}^{2x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2x}\cos(3x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{4x}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\tan(3x)}{3}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(e^{2x}\cos(3x)\right) + c_2\left(e^{2x}\cos(3x)\left(\frac{\tan(3x)}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
y'' - 4y' + 13y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 e^{2x}\cos(3x) + \frac{e^{2x} c_2 \sin(3x)}{3}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
8\sin(3x)
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\cos(3x), \sin(3x)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{e^{2x}\cos(3x), \frac{e^{2x}\sin(3x)}{3}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1\cos(3x) + A_2\sin(3x)
$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1 \cos(3x) + 4A_2 \sin(3x) + 12A_1 \sin(3x) - 12A_2 \cos(3x) = 8 \sin(3x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{3}{5}, A_2 = \frac{1}{5}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{3\cos(3x)}{5} + \frac{\sin(3x)}{5}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{2x} \cos(3x) + \frac{\mathrm{e}^{2x} c_2 \sin(3x)}{3}\right) + \left(\frac{3\cos(3x)}{5} + \frac{\sin(3x)}{5}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{2x} \cos(3x) + \frac{\mathrm{e}^{2x} c_2 \sin(3x)}{3} + \frac{3\cos(3x)}{5} + \frac{\sin(3x)}{5} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 + \frac{3}{5} \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2c_1 \mathrm{e}^{2x} \cos(3x) - 3c_1 \mathrm{e}^{2x} \sin(3x) + \frac{2\,\mathrm{e}^{2x} c_2 \sin(3x)}{3} + \mathrm{e}^{2x} c_2 \cos(3x) - \frac{9\sin(3x)}{5} + \frac{3\cos(3x)}{5}$$

substituting $y' = 2$ and $x = 0$ in the above gives

$$2 = 2c_1 + \frac{3}{5} + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{2}{5}$$
$$c_2 = \frac{3}{5}$$

Substituting these values back in above solution results in

$$y = \frac{2\,e^{2x}\cos(3x)}{5} + \frac{e^{2x}\sin(3x)}{5} + \frac{3\cos(3x)}{5} + \frac{\sin(3x)}{5}$$

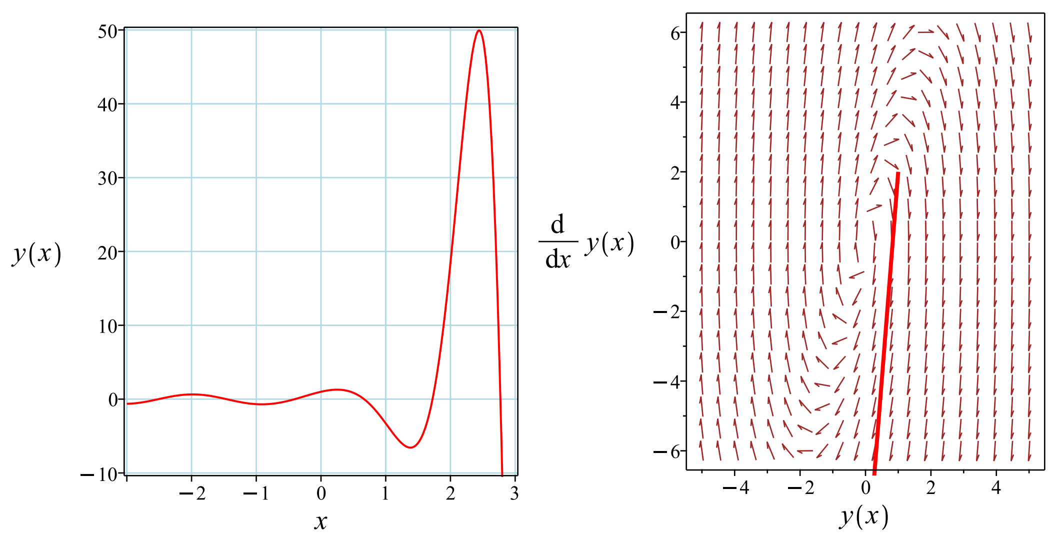
Which simplifies to

$$y = \frac{(2\,e^{2x}+3)\cos(3x)}{5} + \frac{\sin(3x)\,(e^{2x}+1)}{5}$$

Summary

The solution(s) found are the following

$$y = \frac{(2\,e^{2x}+3)\cos(3x)}{5} + \frac{\sin(3x)\,(e^{2x}+1)}{5} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \frac{(2\,e^{2x}+3)\cos(3x)}{5} + \frac{\sin(3x)\,(e^{2x}+1)}{5}$$

Verified OK.

11.33.4 Maple step by step solution

Let's solve

$$\left[y''-4y'+13y=8\sin\left(3x\right), y(0)=1, y'\Big|_{\{x=0\}}=2\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2-4r+13=0$

- Use quadratic formula to solve for r

  $r=\frac{4\pm\left(\sqrt{-36}\right)}{2}$

- Roots of the characteristic polynomial

  $r=\left(2-3\,\mathrm{I}, 2+3\,\mathrm{I}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x)=\mathrm{e}^{2x}\cos\left(3x\right)$

- 2nd solution of the homogeneous ODE

  $y_2(x)=\mathrm{e}^{2x}\sin\left(3x\right)$

- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)+y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y=c_1\mathrm{e}^{2x}\cos\left(3x\right)+\mathrm{e}^{2x}c_2\sin\left(3x\right)+y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x)=-y_1(x)\left(\int\frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right)+y_2(x)\left(\int\frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x)=8\sin\left(3x\right)\right]$

- ◦ Wronskian of solutions of the homogeneous equation

  $W\left(y_1(x), y_2(x)\right)=\left[\begin{array}{cc}\mathrm{e}^{2x}\cos\left(3x\right) & \mathrm{e}^{2x}\sin\left(3x\right)\\ 2\,\mathrm{e}^{2x}\cos\left(3x\right)-3\,\mathrm{e}^{2x}\sin\left(3x\right) & 2\,\mathrm{e}^{2x}\sin\left(3x\right)+3\,\mathrm{e}^{2x}\cos\left(3x\right)\end{array}\right]$

- ◦ Compute Wronskian

  $W\left(y_1(x), y_2(x)\right)=3\,\mathrm{e}^{4x}$

- ◦ Substitute functions into equation for $y_p(x)$

$$y_p(x) = \frac{4\,\mathrm{e}^{2x}\left(-2\cos(3x)\left(\int \mathrm{e}^{-2x}\sin(3x)^2 dx\right)+\sin(3x)\left(\int \sin(6x)\mathrm{e}^{-2x}dx\right)\right)}{3}$$

- ◦ Compute integrals

$$y_p(x) = \frac{3\cos(3x)}{5} + \frac{\sin(3x)}{5}$$

- • Substitute particular solution into general solution to ODE

$$y = c_1\mathrm{e}^{2x}\cos(3x) + \mathrm{e}^{2x}c_2\sin(3x) + \frac{3\cos(3x)}{5} + \frac{\sin(3x)}{5}$$

- □ Check validity of solution $y = c_1\mathrm{e}^{2x}\cos(3x) + \mathrm{e}^{2x}c_2\sin(3x) + \frac{3\cos(3x)}{5} + \frac{\sin(3x)}{5}$
  - ◦ Use initial condition $y(0) = 1$

$$1 = c_1 + \frac{3}{5}$$

  - ◦ Compute derivative of the solution

$$y' = 2c_1\mathrm{e}^{2x}\cos(3x) - 3c_1\mathrm{e}^{2x}\sin(3x) + 2\,\mathrm{e}^{2x}c_2\sin(3x) + 3\,\mathrm{e}^{2x}c_2\cos(3x) - \frac{9\sin(3x)}{5} + \frac{3\cos(3x)}{5}$$

  - ◦ Use the initial condition $y'\Big|_{\{x=0\}} = 2$

$$2 = 2c_1 + \frac{3}{5} + 3c_2$$

  - ◦ Solve for c_1 and c_2

$$\left\{c_1 = \frac{2}{5}, c_2 = \frac{1}{5}\right\}$$

  - ◦ Substitute constant values into general solution and simplify

$$y = \frac{(2\,\mathrm{e}^{2x}+3)\cos(3x)}{5} + \frac{\sin(3x)(\mathrm{e}^{2x}+1)}{5}$$

- • Solution to the IVP

$$y = \frac{(2\,\mathrm{e}^{2x}+3)\cos(3x)}{5} + \frac{\sin(3x)(\mathrm{e}^{2x}+1)}{5}$$

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - y' - 6y = 8\,\mathrm{e}^{2x} - 5\,\mathrm{e}^{3x}}$$

With initial conditions

$$[y(0) = 3, y'(0) = 5]$$

11.34.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned}p(x) &= -1\\ q(x) &= -6\\ F &= 8\,\mathrm{e}^{2x} - 5\,\mathrm{e}^{3x}\end{aligned}$$

Hence the ode is

$$y'' - y' - 6y = 8\,e^{2x} - 5\,e^{3x}$$

The domain of $p(x) = -1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -6$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 8\,e^{2x} - 5\,e^{3x}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

11.34.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -1, C = -6, f(x) = 8\,e^{2x} - 5\,e^{3x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' - 6y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -1, C = -6$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - \lambda\,e^{\lambda x} - 6\,e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \lambda - 6 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -1, C = -6$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{1}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-1^2 - (4)(1)(-6)} \\ &= \frac{1}{2} \pm \frac{5}{2}\end{aligned}$$

Hence

$$\lambda_1 = \frac{1}{2} + \frac{5}{2}$$
$$\lambda_2 = \frac{1}{2} - \frac{5}{2}$$

Which simplifies to

$$\lambda_1 = 3$$
$$\lambda_2 = -2$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(3)x} + c_2 e^{(-2)x}$$

Or

$$y = c_1 \mathrm{e}^{3x} + c_2 \mathrm{e}^{-2x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{3x} + c_2 \mathrm{e}^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8\,\mathrm{e}^{2x} - 5\,\mathrm{e}^{3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x}\}, \{e^{3x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-2x}, e^{3x}\}$$

Since e^{3x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{2x}\}, \{x\,e^{3x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^{2x} + A_2 x\,e^{3x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 e^{2x} + 5A_2 e^{3x} = 8\,e^{2x} - 5\,e^{3x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2, A_2 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2\,e^{2x} - x\,e^{3x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{3x} + c_2 e^{-2x}\right) + \left(-2\,e^{2x} - x\,e^{3x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{3x} + c_2 e^{-2x} - 2\,e^{2x} - x\,e^{3x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$3 = c_1 + c_2 - 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 3c_1 e^{3x} - 2c_2 e^{-2x} - 4\,e^{2x} - e^{3x} - 3x\,e^{3x}$$

substituting $y' = 5$ and $x = 0$ in the above gives

$$5 = 3c_1 - 2c_2 - 5 \tag{2A}$$

Equations $\{1A,2A\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 4$$
$$c_2 = 1$$

Substituting these values back in above solution results in

$$y = -x\,e^{3x} - 2\,e^{2x} + 4\,e^{3x} + e^{-2x}$$

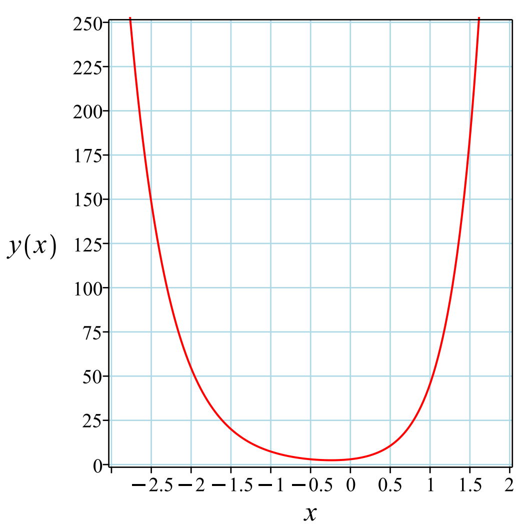
Which simplifies to

$$y = -\left((-4 + x)\,e^{5x} + 2\,e^{4x} - 1\right) e^{-2x}$$

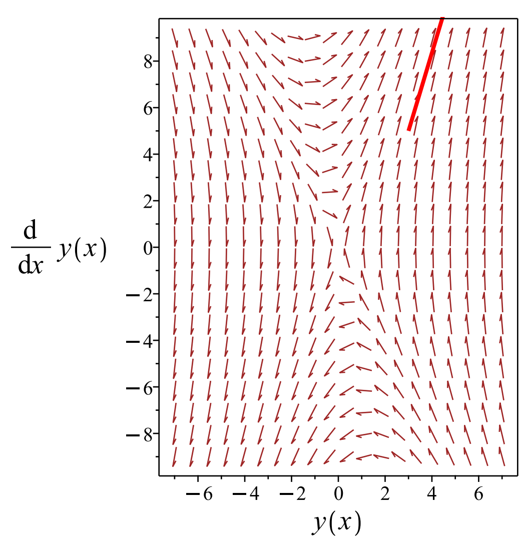
Summary

The solution(s) found are the following

$$y = -\left((-4 + x)\,e^{5x} + 2\,e^{4x} - 1\right) e^{-2x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -\left((-4+x)\,\mathrm{e}^{5x} + 2\,\mathrm{e}^{4x} - 1\right)\mathrm{e}^{-2x}$$

Verified OK.

11.34.3 Solving using Kovacic algorithm

Writing the ode as

$$\begin{align*} y'' - y' - 6y &= 0 \tag{1} \\ Ay'' + By' + Cy &= 0 \tag{2} \end{align*}$$

Comparing (1) and (2) shows that

$$\begin{align*} A &= 1 \\ B &= -1 \tag{3} \\ C &= -6 \end{align*}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{align*} r &= \frac{s}{t} \tag{5} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{align*}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{25}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{align*} s &= 25 \\ t &= 4 \end{align*}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{25z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 397: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{25}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{5x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-1}{1}\,dx} \\
&= z_1 e^{\frac{x}{2}} \\
&= z_1 \left(e^{\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = e^{-2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{e^{5x}}{5}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(e^{-2x}\right) + c_2\left(e^{-2x}\left(\frac{e^{5x}}{5}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' - 6y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{-2x} + \frac{e^{3x} c_2}{5}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^{-2x}$$
$$y_2 = \frac{e^{3x}}{5}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-2x} & \frac{e^{3x}}{5} \\ \frac{d}{dx}\left(e^{-2x}\right) & \frac{d}{dx}\left(\frac{e^{3x}}{5}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-2x} & \frac{e^{3x}}{5} \\ -2\,e^{-2x} & \frac{3\,e^{3x}}{5} \end{vmatrix}$$

Therefore

$$W = \left(e^{-2x}\right)\left(\frac{3\,e^{3x}}{5}\right) - \left(\frac{e^{3x}}{5}\right)\left(-2\,e^{-2x}\right)$$

Which simplifies to

$$W = e^{3x}e^{-2x}$$

Which simplifies to

$$W = e^{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{e^{3x}\left(8\,e^{2x}-5\,e^{3x}\right)}{5}}{e^{x}}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{e^{4x}(5\,e^{x}-8)}{5}dx$$

Hence

$$u_1 = -\frac{2\,e^{4x}}{5} + \frac{e^{5x}}{5}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{-2x}(8\,e^{2x}-5\,e^{3x})}{e^{x}}\,dx$$

Which simplifies to

$$u_2 = \int \left(-5 + 8\,e^{-x}\right)dx$$

Hence

$$u_2 = -5x - 8\,e^{-x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{2\,\mathrm{e}^{4x}}{5} + \frac{\mathrm{e}^{5x}}{5}\right)\mathrm{e}^{-2x} + \frac{(-5x - 8\,\mathrm{e}^{-x})\,\mathrm{e}^{3x}}{5}$$

Which simplifies to

$$y_p(x) = -2\,\mathrm{e}^{2x} + \frac{\mathrm{e}^{3x}}{5} - x\,\mathrm{e}^{3x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-2x} + \frac{\mathrm{e}^{3x}c_2}{5}\right) + \left(-2\,\mathrm{e}^{2x} + \frac{\mathrm{e}^{3x}}{5} - x\,\mathrm{e}^{3x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1\mathrm{e}^{-2x} + \frac{\mathrm{e}^{3x}c_2}{5} - 2\,\mathrm{e}^{2x} + \frac{\mathrm{e}^{3x}}{5} - x\,\mathrm{e}^{3x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$3 = c_1 + \frac{c_2}{5} - \frac{9}{5} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -2c_1\mathrm{e}^{-2x} + \frac{3\,\mathrm{e}^{3x}c_2}{5} - 4\,\mathrm{e}^{2x} - \frac{2\,\mathrm{e}^{3x}}{5} - 3x\,\mathrm{e}^{3x}$$

substituting $y' = 5$ and $x = 0$ in the above gives

$$5 = -2c_1 + \frac{3c_2}{5} - \frac{22}{5} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 1 \\ c_2 &= 19 \end{aligned}$$

Substituting these values back in above solution results in

$$y = -x\,e^{3x} - 2\,e^{2x} + 4\,e^{3x} + e^{-2x}$$

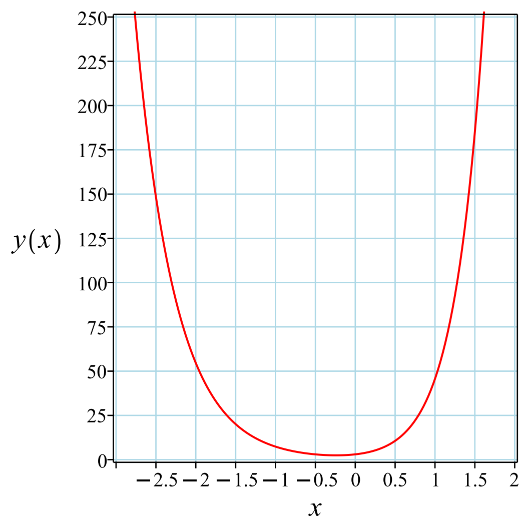
Which simplifies to

$$y = -\left((-4 + x)\,e^{5x} + 2\,e^{4x} - 1\right) e^{-2x}$$

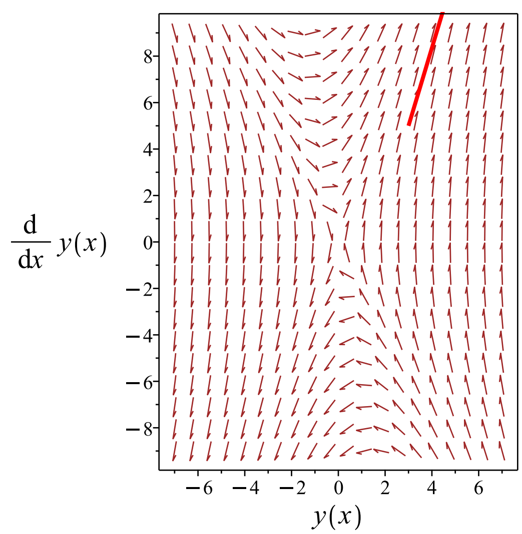
Summary

The solution(s) found are the following

$$y = -\left((-4 + x)\,e^{5x} + 2\,e^{4x} - 1\right) e^{-2x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -\left((-4 + x)\,e^{5x} + 2\,e^{4x} - 1\right) e^{-2x}$$

Verified OK.

11.34.4 Maple step by step solution

Let's solve

$$\left[y''-y'-6y=8\,\mathrm{e}^{2x}-5\,\mathrm{e}^{3x}, y(0)=3, y'\Big|_{\{x=0\}}=5\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2-r-6=0$

- Factor the characteristic polynomial

  $(r+2)(r-3)=0$

- Roots of the characteristic polynomial

  $r=(-2,3)$

- 1st solution of the homogeneous ODE

  $y_1(x)=\mathrm{e}^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x)=\mathrm{e}^{3x}$

- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)+y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y=c_1\mathrm{e}^{-2x}+\mathrm{e}^{3x}c_2+y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x)=-y_1(x)\left(\int\frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right)+y_2(x)\left(\int\frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x)=8\,\mathrm{e}^{2x}-5\,\mathrm{e}^{3x}\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x))=\begin{bmatrix}\mathrm{e}^{-2x} & \mathrm{e}^{3x}\\ -2\,\mathrm{e}^{-2x} & 3\,\mathrm{e}^{3x}\end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x))=5\,\mathrm{e}^{x}$

  - Substitute functions into equation for $y_p(x)$

$$y_p(x) = \frac{\left(\mathrm{e}^{5x}\left(\int \left(-5+8\,\mathrm{e}^{-x}\right)dx\right)+\int \mathrm{e}^{4x}\left(5\,\mathrm{e}^{x}-8\right)dx\right)\mathrm{e}^{-2x}}{5}$$

- ∘ Compute integrals

$$y_p(x) = \frac{\left(-10+\left(-5x+1\right)\mathrm{e}^{x}\right)\mathrm{e}^{2x}}{5}$$

- • Substitute particular solution into general solution to ODE

$$y = c_1\mathrm{e}^{-2x} + \mathrm{e}^{3x}c_2 + \frac{\left(-10+\left(-5x+1\right)\mathrm{e}^{x}\right)\mathrm{e}^{2x}}{5}$$

- □ Check validity of solution $y = c_1\mathrm{e}^{-2x} + \mathrm{e}^{3x}c_2 + \frac{\left(-10+\left(-5x+1\right)\mathrm{e}^{x}\right)\mathrm{e}^{2x}}{5}$
  - ∘ Use initial condition $y(0) = 3$

$$3 = c_1 + c_2 - \frac{9}{5}$$

  - ∘ Compute derivative of the solution

$$y' = -2c_1\mathrm{e}^{-2x} + 3\,\mathrm{e}^{3x}c_2 + \frac{\left(-5\,\mathrm{e}^{x}+\left(-5x+1\right)\mathrm{e}^{x}\right)\mathrm{e}^{2x}}{5} + \frac{2\left(-10+\left(-5x+1\right)\mathrm{e}^{x}\right)\mathrm{e}^{2x}}{5}$$

  - ∘ Use the initial condition $y'\Big|_{\{x=0\}} = 5$

$$5 = -2c_1 + 3c_2 - \frac{22}{5}$$

  - ∘ Solve for c_1 and c_2

$$\left\{c_1 = 1, c_2 = \frac{19}{5}\right\}$$

  - ∘ Substitute constant values into general solution and simplify

$$y = -\left(\left(-4+x\right)\mathrm{e}^{5x} + 2\,\mathrm{e}^{4x} - 1\right)\mathrm{e}^{-2x}$$

- • Solution to the IVP

Problem number: 35.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 2y' + y = 2\,\mathrm{e}^{2x} x + 6\,\mathrm{e}^{x}}$$

With initial conditions

$$[y(0) = 1, y'(0) = 0]$$

11.35.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -2 \\ q(x) &= 1 \\ F &= 2\,\mathrm{e}^{2x}x + 6\,\mathrm{e}^{x} \end{aligned}$$

Hence the ode is

$$y'' - 2y' + y = 2\,\mathrm{e}^{2x}x + 6\,\mathrm{e}^{x}$$

The domain of $p(x) = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 2\,\mathrm{e}^{2x}x + 6\,\mathrm{e}^{x}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

11.35.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 1, f(x) = 2\,\mathrm{e}^{2x}x + 6\,\mathrm{e}^{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-2)^2 - (4)(1)(1)} \\ &= 1\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -1$. Therefore the solution is

$$y = c_1 e^{x} + c_2 x\, e^{x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = e^{x} c_1 + c_2 x\, e^{x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2\, e^{2x} x + 6\, e^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{x}\}, \{e^{2x} x, e^{2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{x}, e^{x}\}$$

Since e^x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^x\}, \{e^{2x}x, e^{2x}\}]$$

Since $x\,e^x$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2e^x\}, \{e^{2x}x, e^{2x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1x^2e^x + A_2e^{2x}x + A_3e^{2x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1e^x + A_2e^{2x}x + 2A_2e^{2x} + A_3e^{2x} = 2\,e^{2x}x + 6\,e^x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 3, A_2 = 2, A_3 = -4]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3x^2e^x + 2\,e^{2x}x - 4\,e^{2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x c_1 + c_2 x\,e^x) + \left(3x^2e^x + 2\,e^{2x}x - 4\,e^{2x}\right) \end{aligned}$$

Which simplifies to

$$y = e^x(c_2x + c_1) + 3x^2e^x + 2\,e^{2x}x - 4\,e^{2x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{x}(c_2 x + c_1) + 3x^2 e^{x} + 2\,e^{2x} x - 4\,e^{2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = -4 + c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = e^{x}(c_2 x + c_1) + c_2 e^{x} + 6x\,e^{x} + 3x^2 e^{x} + 4\,e^{2x} x - 6\,e^{2x}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -6 + c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 5$$
$$c_2 = 1$$

Substituting these values back in above solution results in

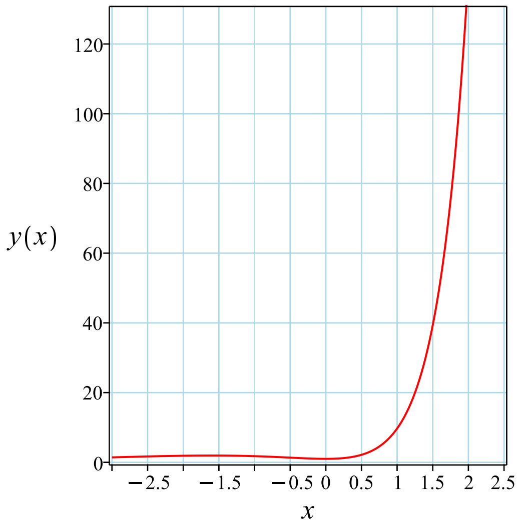
$$y = 3x^2 e^{x} + 2\,e^{2x} x + x\,e^{x} - 4\,e^{2x} + 5\,e^{x}$$

Which simplifies to

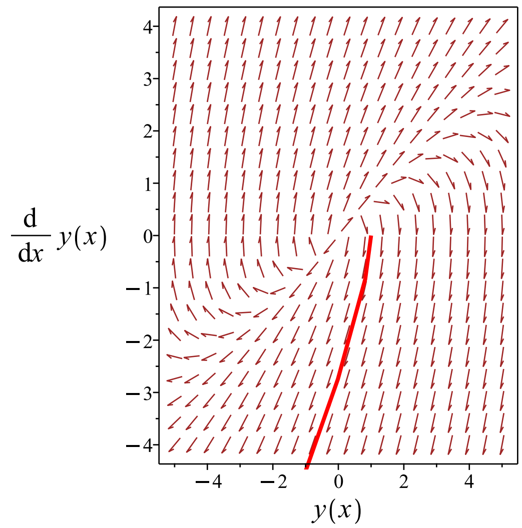
$$y = (2x - 4)\,e^{2x} + e^{x}\left(3x^2 + x + 5\right)$$

Summary
The solution(s) found are the following

$$y = (2x - 4)\,e^{2x} + e^{x}\left(3x^2 + x + 5\right) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = (2x-4)\,\mathrm{e}^{2x} + \mathrm{e}^{x}\left(3x^{2}+x+5\right)$$

Verified OK.

11.35.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^{2}+p'(x)\right)y}{2} = f(x)$$

Where $p(x) = -2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int -2\,dx} \\ &= \mathrm{e}^{-x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= \mathrm{e}^{-x}\left(2\,\mathrm{e}^{2x}x + 6\,\mathrm{e}^{x}\right) \\ \left(\mathrm{e}^{-x}y\right)'' &= \mathrm{e}^{-x}\left(2\,\mathrm{e}^{2x}x + 6\,\mathrm{e}^{x}\right) \end{aligned}$$

Integrating once gives

$$\left(e^{-x}y\right)' = (2x-2)\,e^{x} + 6x + c_1$$

Integrating again gives

$$\left(e^{-x}y\right) = (2x-4)\,e^{x} + 3x^2 + c_1x + c_2$$

Hence the solution is

$$y = \frac{(2x-4)\,e^{x} + 3x^2 + c_1x + c_2}{e^{-x}}$$

Or

$$y = c_1x\,e^{x} + 3x^2e^{x} + 2\,e^{2x}x + c_2e^{x} - 4\,e^{2x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1x\,e^{x} + 3x^2e^{x} + 2\,e^{2x}x + c_2e^{x} - 4\,e^{2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = -4 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = e^{x}c_1 + c_1x\,e^{x} + 6x\,e^{x} + 3x^2e^{x} - 6\,e^{2x} + 4\,e^{2x}x + c_2e^{x}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -6 + c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = 5$$

Substituting these values back in above solution results in

$$y = 3x^2e^{x} + 2\,e^{2x}x + x\,e^{x} - 4\,e^{2x} + 5\,e^{x}$$

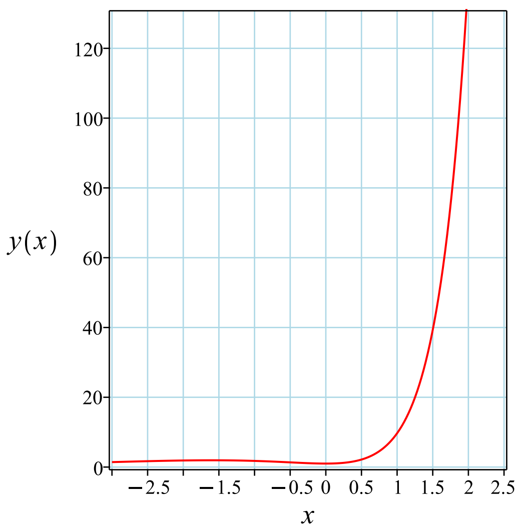
Which simplifies to

$$y = (2x-4)\,e^{2x} + e^{x}\left(3x^2 + x + 5\right)$$

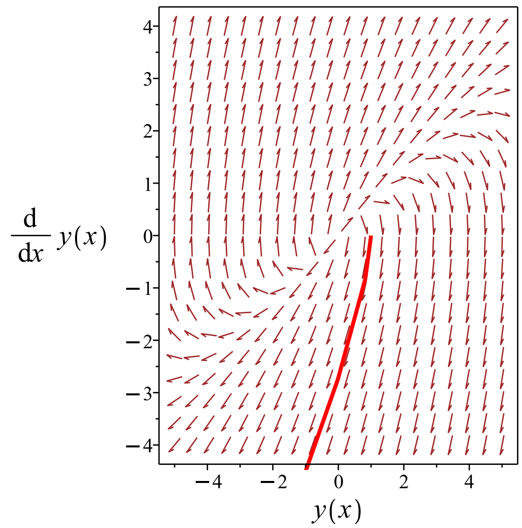
Summary

The solution(s) found are the following

$$y = (2x - 4)\,e^{2x} + e^{x}\left(3x^{2} + x + 5\right) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = (2x - 4)\,e^{2x} + e^{x}\left(3x^{2} + x + 5\right)$$

Verified OK.

11.35.4 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 399: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - -\infty\\ &= \infty\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx}\\ &= z_1 e^{x}\\ &= z_1(\mathrm{e}^{x})\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx\\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx\\ &= y_1(x)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2(\mathrm{e}^x(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^x c_1 + c_2 x\,\mathrm{e}^x
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
2\,\mathrm{e}^{2x} x + 6\,\mathrm{e}^x
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\mathrm{e}^x\}, \{\mathrm{e}^{2x} x, \mathrm{e}^{2x}\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{x\,\mathrm{e}^x, \mathrm{e}^x\}
$$

Since e^x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$
[\{x\,\mathrm{e}^x\}, \{\mathrm{e}^{2x} x, \mathrm{e}^{2x}\}]
$$

Since $x\,\mathrm{e}^x$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$
[\{x^2 \mathrm{e}^x\}, \{\mathrm{e}^{2x} x, \mathrm{e}^{2x}\}]
$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 e^x + A_2 e^{2x} x + A_3 e^{2x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^x + A_2 e^{2x} x + 2A_2 e^{2x} + A_3 e^{2x} = 2\,e^{2x} x + 6\,e^x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 3, A_2 = 2, A_3 = -4]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3x^2 e^x + 2\,e^{2x} x - 4\,e^{2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x c_1 + c_2 x\,e^x) + \left(3x^2 e^x + 2\,e^{2x} x - 4\,e^{2x}\right) \end{aligned}$$

Which simplifies to

$$y = e^x (c_2 x + c_1) + 3x^2 e^x + 2\,e^{2x} x - 4\,e^{2x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^x (c_2 x + c_1) + 3x^2 e^x + 2\,e^{2x} x - 4\,e^{2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = -4 + c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = e^{x}(c_2 x + c_1) + c_2 e^{x} + 6x\,e^{x} + 3x^2 e^{x} + 4\,e^{2x} x - 6\,e^{2x}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -6 + c_1 + c_2 \tag{2A}$$

Equations $\{1\text{A},2\text{A}\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 5$$
$$c_2 = 1$$

Substituting these values back in above solution results in

$$y = 3x^2 e^{x} + 2\,e^{2x} x + x\,e^{x} - 4\,e^{2x} + 5\,e^{x}$$

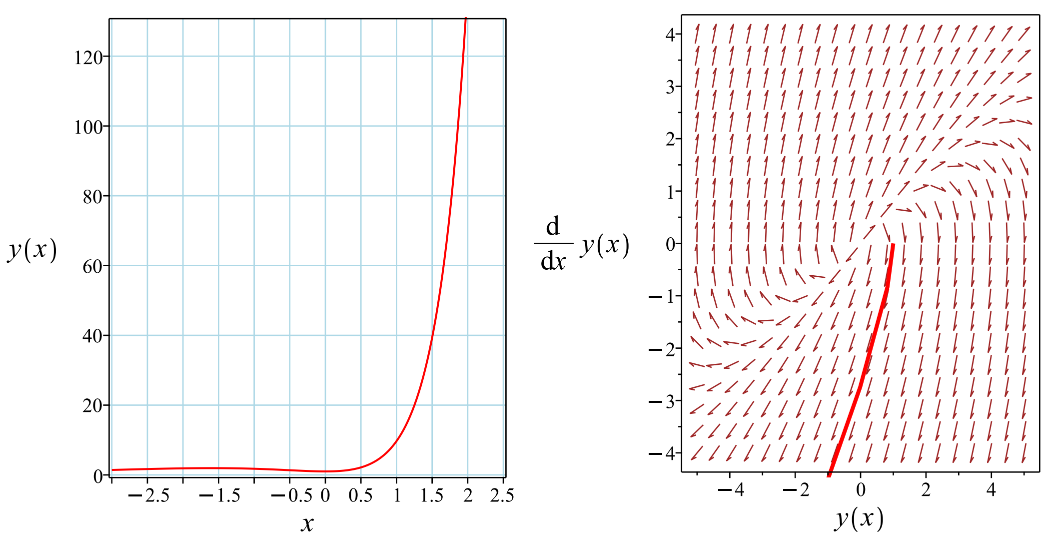
Which simplifies to

$$y = (2x - 4)\,e^{2x} + e^{x}\left(3x^2 + x + 5\right)$$

Summary

The solution(s) found are the following

$$y = (2x - 4)\,e^{2x} + e^{x}\left(3x^2 + x + 5\right) \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = (2x - 4)\,e^{2x} + e^{x}\left(3x^2 + x + 5\right)$$

Verified OK.

11.35.5 Maple step by step solution

Let's solve

$$\left[y'' - 2y' + y = 2\,\mathrm{e}^{2x} x + 6\,\mathrm{e}^{x}, y(0) = 1, y'\Big|_{\{x=0\}} = 0\right]$$

- Highest derivative means the order of the ODE is 2
  y''
- Characteristic polynomial of homogeneous ODE
  $r^2 - 2r + 1 = 0$
- Factor the characteristic polynomial
  $(r-1)^2 = 0$
- Root of the characteristic polynomial
  $r = 1$
- 1st solution of the homogeneous ODE
  $y_1(x) = \mathrm{e}^{x}$
- Repeated root, multiply $y_1(x)$ by x to ensure linear independence
  $y_2(x) = x\,\mathrm{e}^{x}$
- General solution of the ODE
  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE
  $y = \mathrm{e}^{x} c_1 + c_2 x\,\mathrm{e}^{x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function
  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 2\,\mathrm{e}^{2x} x + 6\,\mathrm{e}^{x}\right]$
- ○ Wronskian of solutions of the homogeneous equation
  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{x} & x\,\mathrm{e}^{x} \\ \mathrm{e}^{x} & x\,\mathrm{e}^{x} + \mathrm{e}^{x} \end{bmatrix}$
- ○ Compute Wronskian
  $W(y_1(x), y_2(x)) = \mathrm{e}^{2x}$
- ○ Substitute functions into equation for $y_p(x)$

$y_p(x) = -2\,\mathrm{e}^x\left(\int x(x\,\mathrm{e}^x+3)\,dx - \left(\int (x\,\mathrm{e}^x+3)\,dx\right)x\right)$

- Compute integrals

  $y_p(x) = (2x-4)\left(\mathrm{e}^x\right)^2 + 3x^2\mathrm{e}^x$

- Substitute particular solution into general solution to ODE

  $y = \mathrm{e}^x c_1 + c_2 x\,\mathrm{e}^x + (2x-4)\left(\mathrm{e}^x\right)^2 + 3x^2\mathrm{e}^x$

- ☐ Check validity of solution $y = \mathrm{e}^x c_1 + c_2 x\mathrm{e}^x + (2x-4)\left(\mathrm{e}^x\right)^2 + 3x^2\mathrm{e}^x$
  - Use initial condition $y(0) = 1$

    $1 = -4 + c_1$
  - Compute derivative of the solution

    $y' = \mathrm{e}^x c_1 + c_2\mathrm{e}^x + c_2 x\,\mathrm{e}^x + 2(\mathrm{e}^x)^2 + 2(2x-4)\left(\mathrm{e}^x\right)^2 + 6x\,\mathrm{e}^x + 3x^2\mathrm{e}^x$
  - Use the initial condition $y'\Big|_{\{x=0\}} = 0$

    $0 = -6 + c_1 + c_2$
  - Solve for c_1 and c_2

    $\{c_1 = 5, c_2 = 1\}$
  - Substitute constant values into general solution and simplify

    $y = (2x-4)\,\mathrm{e}^{2x} + \mathrm{e}^x(3x^2+x+5)$

- Solution to the IVP

  $y = (2x-4)\,\mathrm{e}^{2x} + \mathrm{e}^x(3x^2+x+5)$

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' - y = 3x^2 e^x}$$

With initial conditions

$$[y(0) = 1, y'(0) = 2]$$

11.36.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= -1 \\ F &= 3x^2 e^x \end{aligned}$$

Hence the ode is

$$y'' - y = 3x^2 e^x$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 3x^2 e^x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

11.36.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = -1, f(x) = 3x^2 e^x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)} \\ &= \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +1 \\ \lambda_2 &= -1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 \\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(1)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$y = e^x c_1 + c_2 e^{-x}$$

Therefore the homogeneous solution y_h is

$$y_h = e^x c_1 + c_2 e^{-x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$3x^2 e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\, e^x, x^2 e^x, e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{-x}\}$$

Since e^{x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{x}, x^{2}e^{x}, x^{3}e^{x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^{x} + A_2 x^{2} e^{x} + A_3 x^{3} e^{x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{x} + 2A_2 e^{x} + 4A_2 x\,e^{x} + 6A_3 x\,e^{x} + 6A_3 x^{2} e^{x} = 3x^{2} e^{x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{3}{4}, A_2 = -\frac{3}{4}, A_3 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{3x\,e^{x}}{4} - \frac{3x^{2}e^{x}}{4} + \frac{x^{3}e^{x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{x} c_1 + c_2 e^{-x}\right) + \left(\frac{3x\,e^{x}}{4} - \frac{3x^{2}e^{x}}{4} + \frac{x^{3}e^{x}}{2}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{x} c_1 + c_2 e^{-x} + \frac{3x\,e^{x}}{4} - \frac{3x^{2}e^{x}}{4} + \frac{x^{3}e^{x}}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \mathrm{e}^{x} c_1 - c_2 \mathrm{e}^{-x} - \frac{3x\,\mathrm{e}^{x}}{4} + \frac{3\,\mathrm{e}^{x}}{4} + \frac{3x^2 \mathrm{e}^{x}}{4} + \frac{x^3 \mathrm{e}^{x}}{2}$$

substituting $y' = 2$ and $x = 0$ in the above gives

$$2 = c_1 - c_2 + \frac{3}{4} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{9}{8}$$
$$c_2 = -\frac{1}{8}$$

Substituting these values back in above solution results in

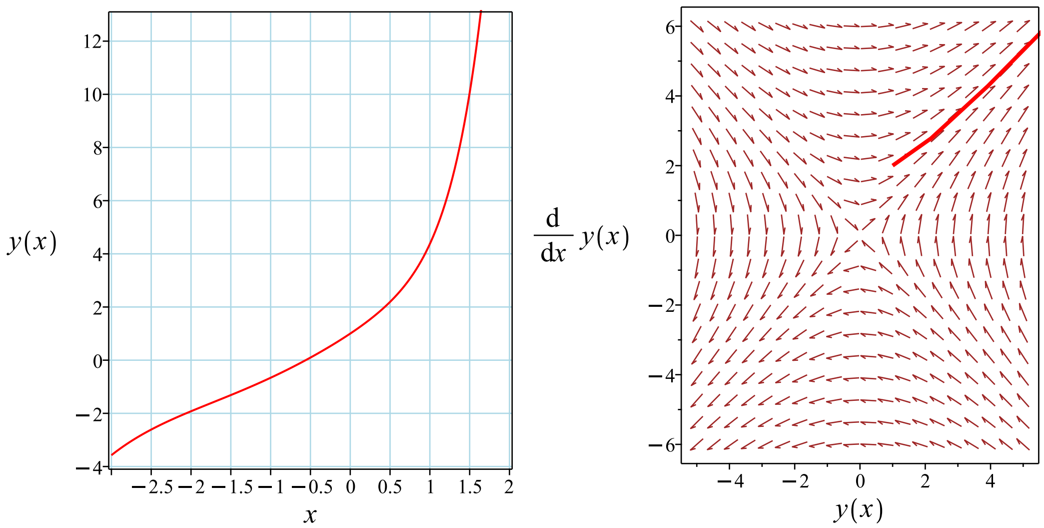
$$y = \frac{9\,\mathrm{e}^{x}}{8} - \frac{\mathrm{e}^{-x}}{8} + \frac{3x\,\mathrm{e}^{x}}{4} - \frac{3x^2 \mathrm{e}^{x}}{4} + \frac{x^3 \mathrm{e}^{x}}{2}$$

Which simplifies to

$$y = -\frac{\mathrm{e}^{-x}}{8} + \frac{(4x^3 - 6x^2 + 6x + 9)\,\mathrm{e}^{x}}{8}$$

<u>Summary</u>
The solution(s) found are the following

$$y = -\frac{\mathrm{e}^{-x}}{8} + \frac{(4x^3 - 6x^2 + 6x + 9)\,\mathrm{e}^{x}}{8} \tag{1}$$



(a) Solution plot (b) Slope field plot

<u>Verification of solutions</u>

$$y = -\frac{e^{-x}}{8} + \frac{(4x^3 - 6x^2 + 6x + 9)\, e^{x}}{8}$$

Verified OK.

11.36.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 1$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 401: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \mathrm{e}^{-x} \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \mathrm{e}^{-x} \int \frac{1}{\mathrm{e}^{-2x}}\,dx \\ &= \mathrm{e}^{-x}\left(\frac{\mathrm{e}^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(e^{-x}\right) + c_2 \left(e^{-x} \left(\frac{e^{2x}}{2}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_2 e^{x}}{2} + c_1 e^{-x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= e^{-x} \\
y_2 &= \frac{e^{x}}{2}
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-x} & \frac{e^x}{2} \\ \frac{d}{dx}\left(e^{-x}\right) & \frac{d}{dx}\left(\frac{e^x}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-x} & \frac{e^x}{2} \\ -e^{-x} & \frac{e^x}{2} \end{vmatrix}$$

Therefore

$$W = \left(e^{-x}\right)\left(\frac{e^x}{2}\right) - \left(\frac{e^x}{2}\right)\left(-e^{-x}\right)$$

Which simplifies to

$$W = e^{-x} e^x$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{3x^2 e^{2x}}{2}}{1} dx$$

Which simplifies to

$$u_1 = -\int \frac{3x^2 e^{2x}}{2} dx$$

Hence

$$u_1 = -\frac{3(2x^2 - 2x + 1) e^{2x}}{8}$$

And Eq. (3) becomes

$$u_2 = \int \frac{3 e^{-x} x^2 e^x}{1} dx$$

Which simplifies to

$$u_2 = \int 3x^2 dx$$

Hence

$$u_2 = x^3$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{3(2x^2 - 2x + 1)\,\mathrm{e}^{2x}\mathrm{e}^{-x}}{8} + \frac{x^3 \mathrm{e}^x}{2}$$

Which simplifies to

$$y_p(x) = \frac{\mathrm{e}^x (4x^3 - 6x^2 + 6x - 3)}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_2 \mathrm{e}^x}{2} + c_1 \mathrm{e}^{-x}\right) + \left(\frac{\mathrm{e}^x (4x^3 - 6x^2 + 6x - 3)}{8}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_2 \mathrm{e}^x}{2} + c_1 \mathrm{e}^{-x} + \frac{\mathrm{e}^x (4x^3 - 6x^2 + 6x - 3)}{8} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = \frac{c_2}{2} + c_1 - \frac{3}{8} \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{c_2 \mathrm{e}^x}{2} - c_1 \mathrm{e}^{-x} + \frac{\mathrm{e}^x (4x^3 - 6x^2 + 6x - 3)}{8} + \frac{(12x^2 - 12x + 6)\,\mathrm{e}^x}{8}$$

substituting $y' = 2$ and $x = 0$ in the above gives

$$2 = \frac{c_2}{2} - c_1 + \frac{3}{8} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -\frac{1}{8}$$
$$c_2 = 3$$

Substituting these values back in above solution results in

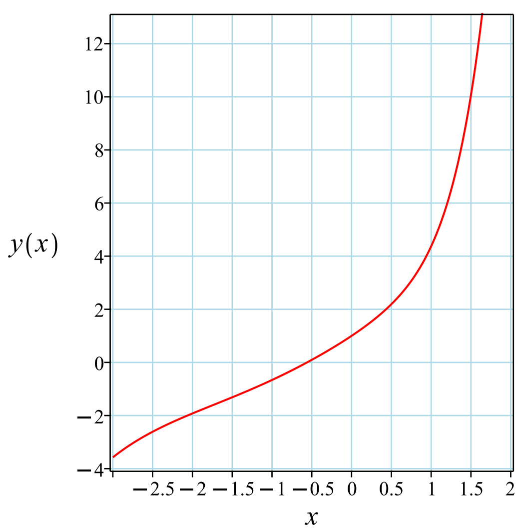
$$y = \frac{9\,\mathrm{e}^{x}}{8} - \frac{\mathrm{e}^{-x}}{8} + \frac{3x\,\mathrm{e}^{x}}{4} - \frac{3x^2\mathrm{e}^{x}}{4} + \frac{x^3\mathrm{e}^{x}}{2}$$

Which simplifies to

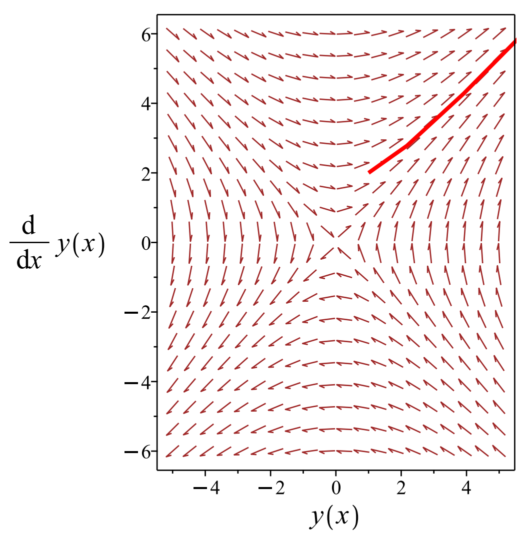
$$y = -\frac{\mathrm{e}^{-x}}{8} + \frac{(4x^3 - 6x^2 + 6x + 9)\,\mathrm{e}^{x}}{8}$$

<u>Summary</u>
The solution(s) found are the following

$$y = -\frac{\mathrm{e}^{-x}}{8} + \frac{(4x^3 - 6x^2 + 6x + 9)\,\mathrm{e}^{x}}{8} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = -\frac{\mathrm{e}^{-x}}{8} + \frac{(4x^3 - 6x^2 + 6x + 9)\,\mathrm{e}^{x}}{8}$$

Verified OK.

11.36.4 Maple step by step solution

Let's solve

$$\left[y'' - y = 3x^2 e^x, y(0) = 1, y'\Big|_{\{x=0\}} = 2\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 1 = 0$

- Factor the characteristic polynomial

  $(r - 1)(r + 1) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-x} + c_2 e^x + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $$\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 3x^2 e^x\right]$$

  ◦ Wronskian of solutions of the homogeneous equation

  $$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x} & e^x \\ -e^{-x} & e^x \end{bmatrix}$$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2$

  ◦ Substitute functions into equation for $y_p(x)$

$y_p(x) = -\frac{3\,\mathrm{e}^{-x}\left(\int x^2 \mathrm{e}^{2x}dx\right)}{2} + \frac{3\,\mathrm{e}^{x}\left(\int x^2 dx\right)}{2}$

- ◦ Compute integrals

  $y_p(x) = \frac{\mathrm{e}^{x}\left(4x^3-6x^2+6x-3\right)}{8}$

- • Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} + \frac{\mathrm{e}^{x}\left(4x^3-6x^2+6x-3\right)}{8}$

- □ Check validity of solution $y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} + \frac{\mathrm{e}^{x}\left(4x^3-6x^2+6x-3\right)}{8}$

  - ◦ Use initial condition $y(0) = 1$

    $1 = c_1 + c_2 - \frac{3}{8}$

  - ◦ Compute derivative of the solution

    $y' = -c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} + \frac{\mathrm{e}^{x}\left(4x^3-6x^2+6x-3\right)}{8} + \frac{\left(12x^2-12x+6\right)\mathrm{e}^{x}}{8}$

  - ◦ Use the initial condition $y'\Big|_{\{x=0\}} = 2$

    $2 = -c_1 + c_2 + \frac{3}{8}$

  - ◦ Solve for c_1 and c_2

    $\left\{c_1 = -\frac{1}{8}, c_2 = \frac{3}{2}\right\}$

  - ◦ Substitute constant values into general solution and simplify

    $y = -\frac{\mathrm{e}^{-x}}{8} + \frac{\left(4x^3-6x^2+6x+9\right)\mathrm{e}^{x}}{8}$

- • Solution to the IVP

  $y = -\frac{\mathrm{e}^{-x}}{8} + \frac{\left(4x^3-6x^2+6x+9\right)\mathrm{e}^{x}}{8}$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = 3x^2 - 4\sin(x)}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1]$$

11.37.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= 1 \\ F &= 3x^2 - 4\sin(x) \end{aligned}$$

Hence the ode is

$$y'' + y = 3x^2 - 4\sin(x)$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 3x^2 - 4\sin(x)$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

11.37.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = 3x^2 - 4\sin(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$3x^2 - 4\sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}, \{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\sin(x), \cos(x)\, x\}, \{1, x, x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x \sin(x) + A_2 \cos(x)\, x + A_3 + A_4 x + A_5 x^2$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 \cos(x) - 2A_2 \sin(x) + 2A_5 + A_3 + A_4 x + A_5 x^2 = 3x^2 - 4\sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 2, A_3 = -6, A_4 = 0, A_5 = 3]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -6 + 2\cos(x)\, x + 3x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + \left(-6 + 2\cos(x)\, x + 3x^2\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(x) + c_2 \sin(x) - 6 + 2\cos(x)\, x + 3x^2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 - 6 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\sin(x) c_1 + c_2 \cos(x) - 2x \sin(x) + 2\cos(x) + 6x$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = c_2 + 2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 6$$
$$c_2 = -1$$

Substituting these values back in above solution results in

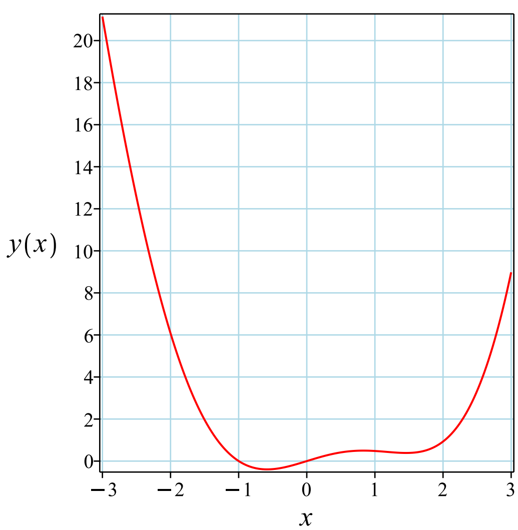
$$y = -6 + 2\cos(x) x + 3x^2 - \sin(x) + 6\cos(x)$$

Which simplifies to

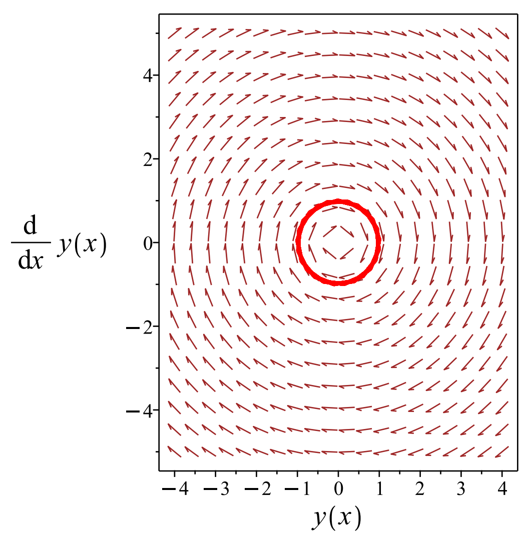
$$y = (2x + 6)\cos(x) + 3x^2 - \sin(x) - 6$$

<u>Summary</u>
The solution(s) found are the following

$$y = (2x + 6)\cos(x) + 3x^2 - \sin(x) - 6 \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = (2x+6)\cos(x) + 3x^2 - \sin(x) - 6$$

Verified OK.

11.37.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 403: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\,dx \\ &= \cos(x)\,(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$3x^2 - 4\sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}, \{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\sin(x), \cos(x)\, x\}, \{1, x, x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x \sin(x) + A_2 \cos(x)\, x + A_3 + A_4 x + A_5 x^2$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 \cos(x) - 2A_2 \sin(x) + 2A_5 + A_3 + A_4 x + A_5 x^2 = 3x^2 - 4\sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 2, A_3 = -6, A_4 = 0, A_5 = 3]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -6 + 2\cos(x)\, x + 3x^2$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + \left(-6 + 2\cos(x)\, x + 3x^2\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \cos(x) + c_2 \sin(x) - 6 + 2\cos(x)\, x + 3x^2 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$
0 = c_1 - 6 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -\sin(x)\, c_1 + c_2 \cos(x) - 2x \sin(x) + 2\cos(x) + 6x
$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$
1 = c_2 + 2 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 6 \\
c_2 &= -1
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = -6 + 2\cos(x)\, x + 3x^2 - \sin(x) + 6\cos(x)
$$

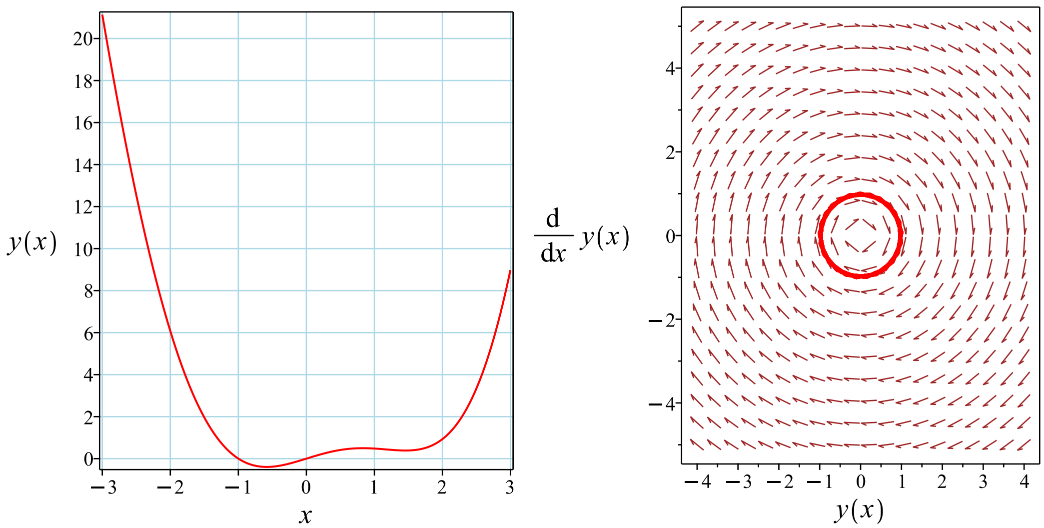
Which simplifies to

$$
y = (2x + 6)\cos(x) + 3x^2 - \sin(x) - 6
$$

Summary

The solution(s) found are the following

$$
y = (2x + 6)\cos(x) + 3x^2 - \sin(x) - 6 \tag{1}
$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = (2x+6)\cos(x) + 3x^2 - \sin(x) - 6$$

Verified OK.

11.37.4 Maple step by step solution

Let's solve

$$\left[y'' + y = 3x^2 - 4\sin(x), y(0) = 0, y'\Big|_{\{x=0\}} = 1\right]$$

- Highest derivative means the order of the ODE is 2
  y''
- Characteristic polynomial of homogeneous ODE
  $r^2 + 1 = 0$
- Use quadratic formula to solve for r
  $r = \frac{0 \pm (\sqrt{-4})}{2}$
- Roots of the characteristic polynomial
  $r = (-\mathrm{I}, \mathrm{I})$
- 1st solution of the homogeneous ODE

$y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 3x^2 - 4\sin(x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = \cos(x)\left(\int \left(4\sin(x)^2 - 3\sin(x)x^2\right)dx\right) - \sin(x)\left(\int \cos(x)\left(-3x^2 + 4\sin(x)\right)dx\right)$

  - Compute integrals

    $y_p(x) = -6 + 2\cos(x)x + 3x^2$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(x) + c_2 \sin(x) - 6 + 2\cos(x)x + 3x^2$

☐ Check validity of solution $y = c_1 \cos(x) + c_2 \sin(x) - 6 + 2\cos(x)x + 3x^2$

  - Use initial condition $y(0) = 0$

    $0 = c_1 - 6$

  - Compute derivative of the solution

    $y' = -\sin(x)c_1 + c_2 \cos(x) - 2x\sin(x) + 2\cos(x) + 6x$

  - Use the initial condition $y'\Big|_{\{x=0\}} = 1$

    $1 = c_2 + 2$

- Solve for c_1 and c_2

  $\{c_1 = 6, c_2 = -1\}$

- Substitute constant values into general solution and simplify

  $y = (2x + 6)\cos(x) + 3x^2 - \sin(x) - 6$

- Solution to the IVP

  $y = (2x + 6)\cos(x) + 3x^2 - \sin(x) - 6$

Problem number: 38.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + 4y = 8\sin(2x)}$$

With initial conditions

$$[y(0) = 6, y'(0) = 8]$$

11.38.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= 4 \\ F &= 8\sin(2x) \end{aligned}$$

Hence the ode is

$$y'' + 4y = 8 \sin(2x)$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 8 \sin(2x)$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

11.38.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 4, f(x) = 8 \sin(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(4)} \\ &= \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2i \\ \lambda_2 &= -2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2i \\ \lambda_2 &= -2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(2x) + c_2 \sin(2x))$$

Or

$$y = c_1 \cos(2x) + c_2 \sin(2x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(2x) + c_2 \sin(2x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8 \sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(2x), \sin(2x)\}$$

Since $\cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\cos(2x), \sin(2x)\,x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\cos(2x) + A_2 \sin(2x)\,x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 \sin(2x) + 4A_2 \cos(2x) = 8\sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2, A_2 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2x\cos(2x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(2x) + c_2 \sin(2x)) + (-2x\cos(2x)) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(2x) + c_2 \sin(2x) - 2x\cos(2x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 6$ and $x = 0$ in the above gives

$$6 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -2c_1 \sin(2x) + 2c_2 \cos(2x) - 2\cos(2x) + 4\sin(2x)\, x$$

substituting $y' = 8$ and $x = 0$ in the above gives

$$8 = -2 + 2c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 6$$
$$c_2 = 5$$

Substituting these values back in above solution results in

$$y = -2x\cos(2x) + 5\sin(2x) + 6\cos(2x)$$

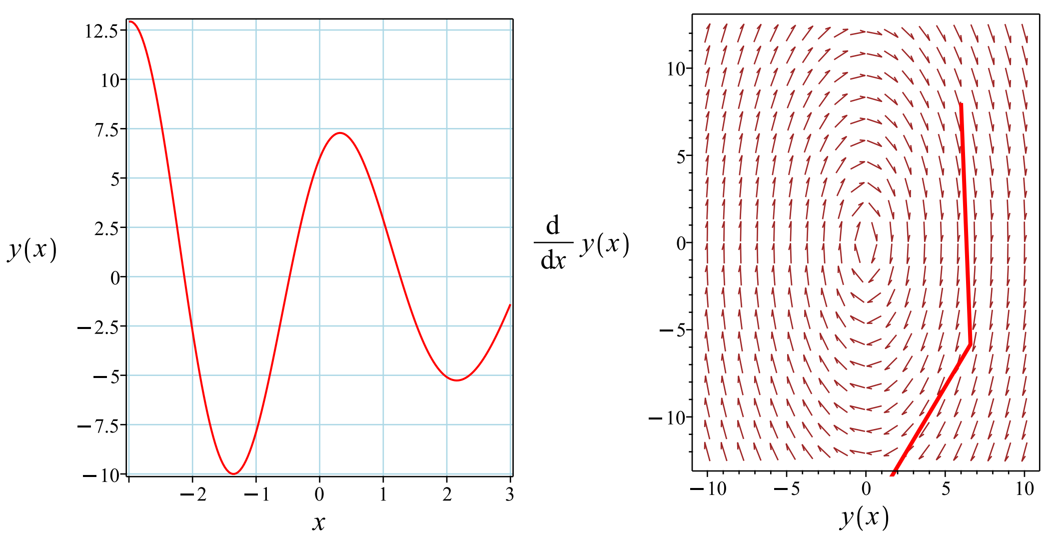
Which simplifies to

$$y = (-2x + 6)\cos(2x) + 5\sin(2x)$$

Summary

The solution(s) found are the following

$$y = (-2x + 6)\cos(2x) + 5\sin(2x) \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = (-2x + 6)\cos(2x) + 5\sin(2x)$$

Verified OK.

11.38.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 405: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(2x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(2x) \int \frac{1}{\cos(2x)^2}\,dx \\ &= \cos(2x) \left(\frac{\tan(2x)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(2x)) + c_2\left(\cos(2x)\left(\frac{\tan(2x)}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8 \sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sin(2x)}{2}, \cos(2x)\right\}$$

Since $\cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x \cos(2x), \sin(2x) x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x \cos(2x) + A_2 \sin(2x) x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 \sin(2x) + 4A_2 \cos(2x) = 8 \sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2, A_2 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2x\cos(2x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\cos(2x) + \frac{c_2\sin(2x)}{2}\right) + (-2x\cos(2x)) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1\cos(2x) + \frac{c_2\sin(2x)}{2} - 2x\cos(2x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 6$ and $x = 0$ in the above gives

$$6 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -2c_1\sin(2x) + c_2\cos(2x) - 2\cos(2x) + 4\sin(2x)\,x$$

substituting $y' = 8$ and $x = 0$ in the above gives

$$8 = c_2 - 2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 6 \\ c_2 &= 10 \end{aligned}$$

Substituting these values back in above solution results in

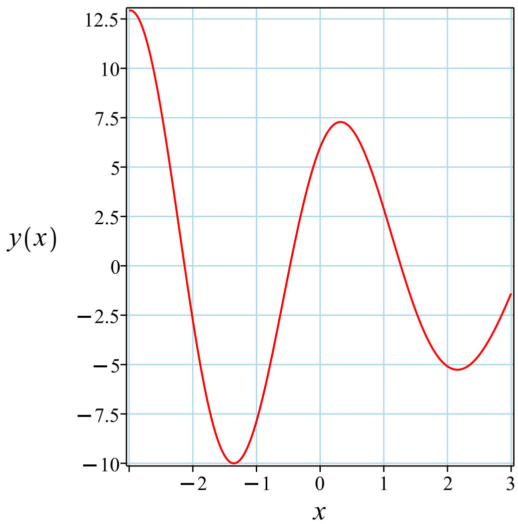
$$y = -2x\cos(2x) + 5\sin(2x) + 6\cos(2x)$$

Which simplifies to

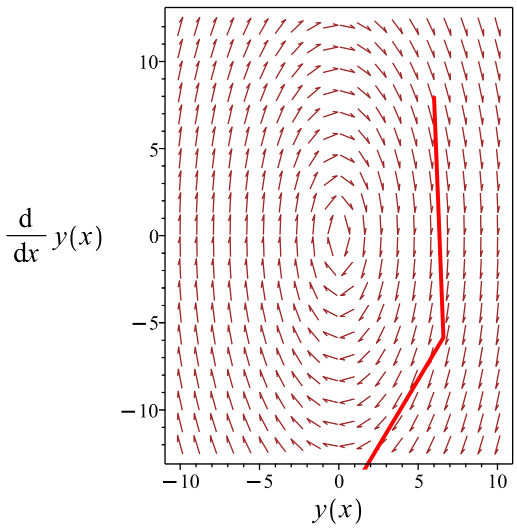
$$y = (-2x + 6)\cos(2x) + 5\sin(2x)$$

Summary
The solution(s) found are the following

$$y = (-2x + 6)\cos(2x) + 5\sin(2x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = (-2x + 6)\cos(2x) + 5\sin(2x)$$

Verified OK.

11.38.4 Maple step by step solution

Let's solve

$$\left[y'' + 4y = 8\sin(2x), y(0) = 6, y'\Big|_{\{x=0\}} = 8\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r = (-2\,\mathrm{I}, 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(2x) + c_2 \sin(2x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 8\sin(2x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(2x) & \sin(2x) \\ -2\sin(2x) & 2\cos(2x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -2\cos(2x)\left(\int (1 - \cos(4x))\, dx\right) + 2\sin(2x)\left(\int \sin(4x)\, dx\right)$

  - Compute integrals

    $y_p(x) = \frac{\sin(2x)}{2} - 2x\cos(2x)$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(2x) + c_2 \sin(2x) + \frac{\sin(2x)}{2} - 2x\cos(2x)$

☐ Check validity of solution $y = c_1 \cos(2x) + c_2 \sin(2x) + \frac{\sin(2x)}{2} - 2x\cos(2x)$

  - Use initial condition $y(0) = 6$

    $6 = c_1$

  - Compute derivative of the solution

    $y' = -2c_1 \sin(2x) + 2c_2 \cos(2x) - \cos(2x) + 4\sin(2x)\, x$

- Use the initial condition $y'\Big|_{\{x=0\}} = 8$

  $8 = -1 + 2c_2$
- Solve for c_1 and c_2

  $\left\{c_1 = 6, c_2 = \frac{9}{2}\right\}$
- Substitute constant values into general solution and simplify

  $y = (-2x + 6)\cos(2x) + 5\sin(2x)$

- Solution to the IVP

  $y = (-2x + 6)\cos(2x) + 5\sin(2x)$

Problem number: 39.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''' - 4y'' + y' + 6y = 3x\,e^{x} + 2\,e^{x} - \sin(x)}$$

With initial conditions

$$\left[y(0) = \frac{33}{40}, y'(0) = 0, y''(0) = 0\right]$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 4y'' + y' + 6y = 0$$

The characteristic equation is

$$\lambda^3 - 4\lambda^2 + \lambda + 6 = 0$$

The roots of the above equation are

$$\lambda_1 = 2$$
$$\lambda_2 = 3$$
$$\lambda_3 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 e^{2x} + c_3 e^{3x}$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = e^{2x}$$
$$y_3 = e^{3x}$$

Now the particular solution to the given ODE is found

$$y''' - 4y'' + y' + 6y = 3x e^x + 2 e^x - \sin(x)$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$3x e^x + 2 e^x - \sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x e^x, e^x\}, \{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-x}, e^{2x}, e^{3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x e^x + A_2 e^x + A_3 \cos(x) + A_4 \sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 e^x + 4A_1 x e^x + 4A_2 e^x + 10A_3 \cos(x) + 10A_4 \sin(x) = 3x e^x + 2 e^x - \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{3}{4}, A_2 = \frac{5}{4}, A_3 = 0, A_4 = -\frac{1}{10}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{3x\,\mathrm{e}^x}{4} + \frac{5\,\mathrm{e}^x}{4} - \frac{\sin(x)}{10}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-x} + c_2\mathrm{e}^{2x} + c_3\mathrm{e}^{3x}\right) + \left(\frac{3x\,\mathrm{e}^x}{4} + \frac{5\,\mathrm{e}^x}{4} - \frac{\sin(x)}{10}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1\mathrm{e}^{-x} + c_2\mathrm{e}^{2x} + c_3\mathrm{e}^{3x} + \frac{3x\,\mathrm{e}^x}{4} + \frac{5\,\mathrm{e}^x}{4} - \frac{\sin(x)}{10} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{33}{40}$ and $x = 0$ in the above gives

$$\frac{33}{40} = c_1 + c_2 + c_3 + \frac{5}{4} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1\mathrm{e}^{-x} + 2c_2\mathrm{e}^{2x} + 3c_3\mathrm{e}^{3x} + \frac{3x\,\mathrm{e}^x}{4} + 2\,\mathrm{e}^x - \frac{\cos(x)}{10}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -c_1 + 2c_2 + 3c_3 + \frac{19}{10} \tag{2A}$$

Taking two derivatives of the solution gives

$$y'' = c_1\mathrm{e}^{-x} + 4c_2\mathrm{e}^{2x} + 9c_3\mathrm{e}^{3x} + \frac{3x\,\mathrm{e}^x}{4} + \frac{11\,\mathrm{e}^x}{4} + \frac{\sin(x)}{10}$$

substituting $y'' = 0$ and $x = 0$ in the above gives

$$0 = c_1 + 4c_2 + 9c_3 + \frac{11}{4} \tag{3A}$$

Equations {1A,2A,3A} are now solved for $\{c_1, c_2, c_3\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= \frac{7}{20} \\
c_2 &= -\frac{31}{40} \\
c_3 &= 0
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \frac{7\,\mathrm{e}^{-x}}{20} - \frac{31\,\mathrm{e}^{2x}}{40} + \frac{3x\,\mathrm{e}^{x}}{4} + \frac{5\,\mathrm{e}^{x}}{4} - \frac{\sin(x)}{10}
$$

Summary

The solution(s) found are the following

$$
y = \frac{7\,\mathrm{e}^{-x}}{20} - \frac{31\,\mathrm{e}^{2x}}{40} + \frac{3x\,\mathrm{e}^{x}}{4} + \frac{5\,\mathrm{e}^{x}}{4} - \frac{\sin(x)}{10} \tag{1}
$$

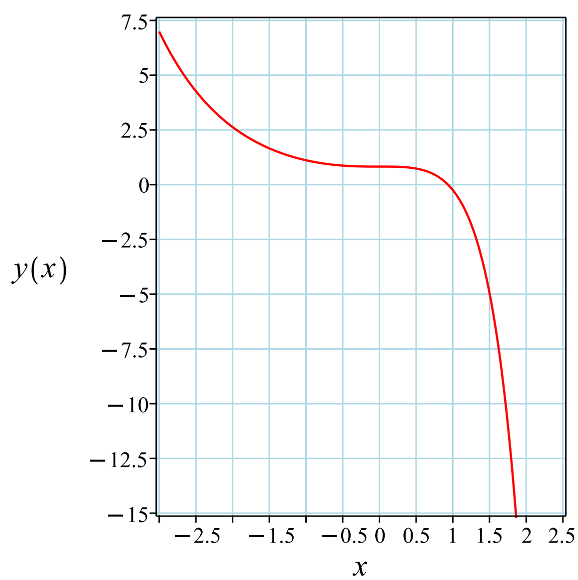

Figure 471: Solution plot

Verification of solutions

$$
y = \frac{7\,\mathrm{e}^{-x}}{20} - \frac{31\,\mathrm{e}^{2x}}{40} + \frac{3x\,\mathrm{e}^{x}}{4} + \frac{5\,\mathrm{e}^{x}}{4} - \frac{\sin(x)}{10}
$$

Verified OK.

11.39.1 Maple step by step solution

Let's solve

$$\left[y''' - 4y'' + y' + 6y = 3x\,\mathrm{e}^{x} + 2\,\mathrm{e}^{x} - \sin(x), y(0) = \frac{33}{40}, y'\Big|_{\{x=0\}} = 0, y''\Big|_{\{x=0\}} = 0\right]$$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = 3x\,\mathrm{e}^{x} + 2\,\mathrm{e}^{x} - \sin(x) + 4y_3(x) - y_2(x) - 6y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 3x\,\mathrm{e}^{x} + 2\,\mathrm{e}^{x} - \sin(x) + 4y_3(x) - y_2(x) - 6y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -6 & -1 & 4 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 3x\,\mathrm{e}^{x} + 2\,\mathrm{e}^{x} - \sin(x) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 3x\,\mathrm{e}^{x} + 2\,\mathrm{e}^{x} - \sin(x) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \left[\begin{array}{ccc} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -6 & -1 & 4 \end{array}\right]$$

- Rewrite the system as

$${\overrightarrow{y}}^{\prime}(x) = A \cdot \overrightarrow{y}(x) + \overrightarrow{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]\right], \left[2, \left[\begin{array}{c} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]\right], \left[3, \left[\begin{array}{c} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_{1} = \mathrm{e}^{-x} \cdot \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[2, \left[\begin{array}{c} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_{2} = \mathrm{e}^{2x} \cdot \left[\begin{array}{c} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[3, \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = \mathrm{e}^{3x} \cdot \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$$\vec{y}(x) = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3 + \vec{y}_p(x)$$

☐ Fundamental matrix

  - Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} \mathrm{e}^{-x} & \frac{\mathrm{e}^{2x}}{4} & \frac{\mathrm{e}^{3x}}{9} \\ -\mathrm{e}^{-x} & \frac{\mathrm{e}^{2x}}{2} & \frac{\mathrm{e}^{3x}}{3} \\ \mathrm{e}^{-x} & \mathrm{e}^{2x} & \mathrm{e}^{3x} \end{bmatrix}$$

  - The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$$

  - Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} \mathrm{e}^{-x} & \frac{\mathrm{e}^{2x}}{4} & \frac{\mathrm{e}^{3x}}{9} \\ -\mathrm{e}^{-x} & \frac{\mathrm{e}^{2x}}{2} & \frac{\mathrm{e}^{3x}}{3} \\ \mathrm{e}^{-x} & \mathrm{e}^{2x} & \mathrm{e}^{3x} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & \frac{1}{4} & \frac{1}{9} \\ -1 & \frac{1}{2} & \frac{1}{3} \\ 1 & 1 & 1 \end{bmatrix}}$$

  - Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} \frac{\mathrm{e}^{-x}}{2} + \mathrm{e}^{2x} - \frac{\mathrm{e}^{3x}}{2} & -\frac{5\,\mathrm{e}^{-x}}{12} + \frac{2\,\mathrm{e}^{2x}}{3} - \frac{\mathrm{e}^{3x}}{4} & \frac{\mathrm{e}^{-x}}{12} - \frac{\mathrm{e}^{2x}}{3} + \frac{\mathrm{e}^{3x}}{4} \\ -\frac{\mathrm{e}^{-x}}{2} + 2\,\mathrm{e}^{2x} - \frac{3\,\mathrm{e}^{3x}}{2} & \frac{5\,\mathrm{e}^{-x}}{12} + \frac{4\,\mathrm{e}^{2x}}{3} - \frac{3\,\mathrm{e}^{3x}}{4} & -\frac{\mathrm{e}^{-x}}{12} - \frac{2\,\mathrm{e}^{2x}}{3} + \frac{3\,\mathrm{e}^{3x}}{4} \\ \frac{\mathrm{e}^{-x}}{2} + 4\,\mathrm{e}^{2x} - \frac{9\,\mathrm{e}^{3x}}{2} & -\frac{5\,\mathrm{e}^{-x}}{12} + \frac{8\,\mathrm{e}^{2x}}{3} - \frac{9\,\mathrm{e}^{3x}}{4} & \frac{\mathrm{e}^{-x}}{12} - \frac{4\,\mathrm{e}^{2x}}{3} + \frac{9\,\mathrm{e}^{3x}}{4} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(x)$ and solve for $\overrightarrow{v}(x)$

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \overrightarrow{v}(x)$

- Take the derivative of the particular solution

  $\overrightarrow{y}'_p(x) = \Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \overrightarrow{v}'(x) = \overrightarrow{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\overrightarrow{v}'(x) = \frac{1}{\Phi(x)} \cdot \overrightarrow{f}(x)$

- Integrate to solve for $\overrightarrow{v}(x)$

  $\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$

- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\overrightarrow{y}_p(x) = \begin{bmatrix} -\frac{e^{-x}}{16} - \frac{8\,e^{2x}}{5} + \frac{33\,e^{3x}}{80} + \frac{(3x+5)e^{x}}{4} - \frac{\sin(x)}{10} \\ \frac{99\,e^{3x}}{80} - \frac{16\,e^{2x}}{5} + \frac{3x\,e^{x}}{4} + 2\,e^{x} - \frac{\cos(x)}{10} + \frac{e^{-x}}{16} \\ -\frac{e^{-x}}{16} - \frac{32\,e^{2x}}{5} + \frac{297\,e^{3x}}{80} + \frac{(3x+11)e^{x}}{4} + \frac{\sin(x)}{10} \end{bmatrix}$$

- Plug particular solution back into general solution

  $$\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2 + c_3\overrightarrow{y}_3 + \begin{bmatrix} -\frac{e^{-x}}{16} - \frac{8\,e^{2x}}{5} + \frac{33\,e^{3x}}{80} + \frac{(3x+5)e^{x}}{4} - \frac{\sin(x)}{10} \\ \frac{99\,e^{3x}}{80} - \frac{16\,e^{2x}}{5} + \frac{3x\,e^{x}}{4} + 2\,e^{x} - \frac{\cos(x)}{10} + \frac{e^{-x}}{16} \\ -\frac{e^{-x}}{16} - \frac{32\,e^{2x}}{5} + \frac{297\,e^{3x}}{80} + \frac{(3x+11)e^{x}}{4} + \frac{\sin(x)}{10} \end{bmatrix}$$

- First component of the vector is the solution to the ODE

  $y = \frac{(720c_1-45)e^{-x}}{720} + \frac{(180c_2-1152)e^{2x}}{720} + \frac{(80c_3+297)e^{3x}}{720} + \frac{(540x+900)e^{x}}{720} - \frac{\sin(x)}{10}$

- Use the initial condition $y(0) = \frac{33}{40}$

$\frac{33}{40} = c_1 + \frac{c_2}{4} + \frac{c_3}{9}$

- Calculate the 1st derivative of the solution

  $y' = -\frac{(720c_1-45)\mathrm{e}^{-x}}{720} + \frac{(180c_2-1152)\mathrm{e}^{2x}}{360} + \frac{(80c_3+297)\mathrm{e}^{3x}}{240} + \frac{3\,\mathrm{e}^{x}}{4} + \frac{(540x+900)\mathrm{e}^{x}}{720} - \frac{\cos(x)}{10}$

- Use the initial condition $y'\Big|_{\{x=0\}} = 0$

  $0 = -c_1 + \frac{c_2}{2} + \frac{c_3}{3}$

- Calculate the 2nd derivative of the solution

  $y'' = \frac{(720c_1-45)\mathrm{e}^{-x}}{720} + \frac{(180c_2-1152)\mathrm{e}^{2x}}{180} + \frac{(80c_3+297)\mathrm{e}^{3x}}{80} + \frac{3\,\mathrm{e}^{x}}{2} + \frac{(540x+900)\mathrm{e}^{x}}{720} + \frac{\sin(x)}{10}$

- Use the initial condition $y''\Big|_{\{x=0\}} = 0$

  $0 = c_1 + c_2 + c_3$

- Solve for the unknown coefficients

  $\left\{c_1 = \frac{33}{80}, c_2 = \frac{33}{10}, c_3 = -\frac{297}{80}\right\}$

- Solution to the IVP

  $y = \frac{7\,\mathrm{e}^{-x}}{20} - \frac{31\,\mathrm{e}^{2x}}{40} + \frac{(3x+5)\mathrm{e}^{x}}{4} - \frac{\sin(x)}{10}$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.3. The method of undetermined coefficients. Exercises page 151
Problem number: 40.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''' - 6y'' + 9y' - 4y = 8x^2 + 3 - 6\,\mathrm{e}^{2x}}$$

With initial conditions

$$[y(0) = 1, y'(0) = 7, y''(0) = 0]$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 6y'' + 9y' - 4y = 0$$

The characteristic equation is

$$\lambda^3 - 6\lambda^2 + 9\lambda - 4 = 0$$

The roots of the above equation are

$$\lambda_1 = 4$$
$$\lambda_2 = 1$$
$$\lambda_3 = 1$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + c_2 x\, e^x + e^{4x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^x$$
$$y_2 = x\, e^x$$
$$y_3 = e^{4x}$$

Now the particular solution to the given ODE is found

$$y''' - 6y'' + 9y' - 4y = 8x^2 + 3 - 6\, e^{2x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8x^2 + 3 - 6\, e^{2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x}\}, \{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^x, e^x, e^{4x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{2x} + A_2 + A_3 x + A_4 x^2$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 e^{2x} - 12A_4 + 9A_3 + 18A_4 x - 4A_2 - 4A_3 x - 4A_4 x^2 = 8x^2 + 3 - 6\, e^{2x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 3, A_2 = -15, A_3 = -9, A_4 = -2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3\,\mathrm{e}^{2x} - 15 - 9x - 2x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{x} c_1 + c_2 x\,\mathrm{e}^{x} + \mathrm{e}^{4x} c_3\right) + \left(3\,\mathrm{e}^{2x} - 15 - 9x - 2x^2\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{4x} c_3 + \mathrm{e}^{x}(c_2 x + c_1) + 3\,\mathrm{e}^{2x} - 15 - 9x - 2x^2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \mathrm{e}^{4x} c_3 + \mathrm{e}^{x}(c_2 x + c_1) + 3\,\mathrm{e}^{2x} - 15 - 9x - 2x^2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = -12 + c_3 + c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 4\,\mathrm{e}^{4x} c_3 + \mathrm{e}^{x}(c_2 x + c_1) + c_2\mathrm{e}^{x} + 6\,\mathrm{e}^{2x} - 9 - 4x$$

substituting $y' = 7$ and $x = 0$ in the above gives

$$7 = -3 + 4c_3 + c_1 + c_2 \tag{2A}$$

Taking two derivatives of the solution gives

$$y'' = 16\,\mathrm{e}^{4x} c_3 + \mathrm{e}^{x}(c_2 x + c_1) + 2c_2\mathrm{e}^{x} + 12\,\mathrm{e}^{2x} - 4$$

substituting $y'' = 0$ and $x = 0$ in the above gives

$$0 = 8 + 16c_3 + c_1 + 2c_2 \tag{3A}$$

Equations {1A,2A,3A} are now solved for $\{c_1, c_2, c_3\}$. Solving for the constants gives

$$c_1 = \frac{44}{3}$$
$$c_2 = 2$$
$$c_3 = -\frac{5}{3}$$

Substituting these values back in above solution results in

$$y = -15 - \frac{5\,\mathrm{e}^{4x}}{3} + 2x\,\mathrm{e}^{x} + \frac{44\,\mathrm{e}^{x}}{3} + 3\,\mathrm{e}^{2x} - 9x - 2x^2$$

Summary
The solution(s) found are the following

$$y = -15 - \frac{5\,\mathrm{e}^{4x}}{3} + 2x\,\mathrm{e}^{x} + \frac{44\,\mathrm{e}^{x}}{3} + 3\,\mathrm{e}^{2x} - 9x - 2x^2 \tag{1}$$

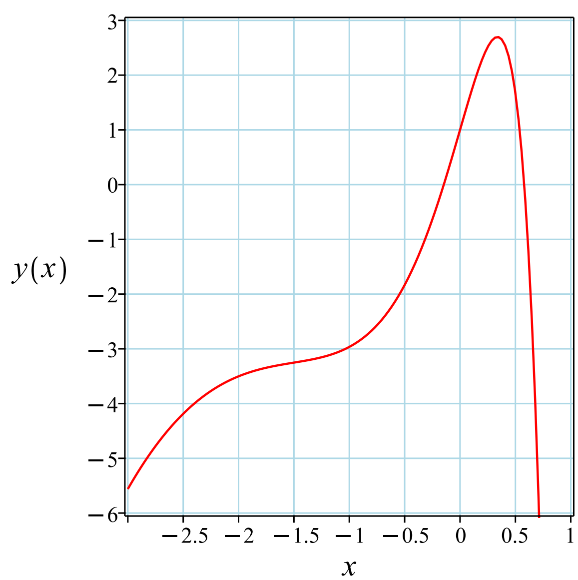

Figure 472: Solution plot

Verification of solutions

$$y = -15 - \frac{5\,\mathrm{e}^{4x}}{3} + 2x\,\mathrm{e}^{x} + \frac{44\,\mathrm{e}^{x}}{3} + 3\,\mathrm{e}^{2x} - 9x - 2x^2$$

Verified OK.

11.40.1 Maple step by step solution

Let's solve

$$\left[y''' - 6y'' + 9y' - 4y = 8x^2 + 3 - 6\,e^{2x}, y(0) = 1, y'\Big|_{\{x=0\}} = 7, y''\Big|_{\{x=0\}} = 0\right]$$

- Highest derivative means the order of the ODE is 3

y'''

- □ Convert linear ODE into a system of first order ODEs
  - ○ Define new variable $y_1(x)$

    $y_1(x) = y$
  - ○ Define new variable $y_2(x)$

    $y_2(x) = y'$
  - ○ Define new variable $y_3(x)$

    $y_3(x) = y''$
  - ○ Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = 8x^2 - 6\,e^{2x} + 6y_3(x) - 9y_2(x) + 4y_1(x) + 3$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 8x^2 - 6\,e^{2x} + 6y_3(x) - 9y_2(x) + 4y_1(x) + 3]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 4 & -9 & 6 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 8x^2 + 3 - 6\,e^{2x} \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 8x^2 + 3 - 6\,e^{2x} \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 4 & -9 & 6 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[4, \begin{bmatrix} \frac{1}{16} \\ \frac{1}{4} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- First solution from eigenvalue 1

$$\vec{y}_1(x) = e^x \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\vec{p}$ is to be solved for, $\lambda = 1$ is the eigenvalue, an

$$\vec{y}_2(x) = e^{\lambda x}\left(x\vec{v} + \vec{p}\right)$$

- Note that the x multiplying $\vec{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\vec{y}_2(x)$ into the homogeneous system

$$\lambda e^{\lambda x}\left(x\vec{v} + \vec{p}\right) + e^{\lambda x}\vec{v} = \left(e^{\lambda x}A\right) \cdot \left(x\vec{v} + \vec{p}\right)$$

- Use the fact that $\vec{v}$ is an eigenvector of A

$$\lambda e^{\lambda x}\left(x\vec{v} + \vec{p}\right) + e^{\lambda x}\vec{v} = e^{\lambda x}\left(\lambda x\vec{v} + A \cdot \vec{p}\right)$$

- Simplify equation

$\lambda \overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$

- Make use of the identity matrix I

$(\lambda \cdot I) \cdot \overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$

- Condition $\overrightarrow{p}$ must meet for $\overrightarrow{y}_2(x)$ to be a solution to the homogeneous system

$(A - \lambda \cdot I) \cdot \overrightarrow{p} = \overrightarrow{v}$

- Choose $\overrightarrow{p}$ to use in the second solution to the homogeneous system from eigenvalue 1

$$\left(\begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 4 & -9 & 6 \end{bmatrix} - 1 \cdot \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) \cdot \overrightarrow{p} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Choice of $\overrightarrow{p}$

$$\overrightarrow{p} = \begin{bmatrix} -1 \\ 0 \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue 1

$$\overrightarrow{y}_2(x) = \mathrm{e}^{x} \cdot \left(x \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \end{bmatrix}\right)$$

- Consider eigenpair

$$\left[4, \begin{bmatrix} \frac{1}{16} \\ \frac{1}{4} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_3 = \mathrm{e}^{4x} \cdot \begin{bmatrix} \frac{1}{16} \\ \frac{1}{4} \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{y}_p($

$\overrightarrow{y}(x) = c_1 \overrightarrow{y}_1(x) + c_2 \overrightarrow{y}_2(x) + c_3 \overrightarrow{y}_3 + \overrightarrow{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} e^{x} & e^{x}(x-1) & \frac{e^{4x}}{16} \\ e^{x} & x\,e^{x} & \frac{e^{4x}}{4} \\ e^{x} & x\,e^{x} & e^{4x} \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} e^{x} & e^{x}(x-1) & \frac{e^{4x}}{16} \\ e^{x} & x\,e^{x} & \frac{e^{4x}}{4} \\ e^{x} & x\,e^{x} & e^{4x} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & -1 & \frac{1}{16} \\ 1 & 0 & \frac{1}{4} \\ 1 & 0 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} -e^{x}(x-1) & -\frac{e^{4x}}{12} + \frac{(15x+1)e^{x}}{12} & \frac{e^{4x}}{12} + \frac{(-3x-1)e^{x}}{12} \\ -x\,e^{x} & \frac{4\,e^{x}}{3} + \frac{5x\,e^{x}}{4} - \frac{e^{4x}}{3} & \frac{e^{4x}}{3} + \frac{(-4-3x)e^{x}}{12} \\ -x\,e^{x} & \frac{4\,e^{x}}{3} + \frac{5x\,e^{x}}{4} - \frac{4\,e^{4x}}{3} & \frac{4\,e^{4x}}{3} + \frac{(-4-3x)e^{x}}{12} \end{bmatrix}$$

□ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

$\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

$\vec{y}'_p(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

$\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

$\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

$\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \begin{bmatrix} -\frac{45}{4} + \frac{9\,e^{2x}}{4} - \frac{e^{4x}}{6} + \frac{5(22-15x)e^{x}}{12} - \frac{3x^2}{2} - \frac{27x}{4} \\ -\frac{27}{4} + \frac{9\,e^{2x}}{2} - \frac{2\,e^{4x}}{3} + \frac{5(7-15x)e^{x}}{12} - 3x \\ -\frac{31}{4} + \frac{15\,e^{2x}}{2} - \frac{8\,e^{4x}}{3} + \frac{5(7-15x)e^{x}}{12} - 2x^2 - 4x \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1(x) + c_2\vec{y}_2(x) + c_3\vec{y}_3 + \begin{bmatrix} -\frac{45}{4} + \frac{9\,e^{2x}}{4} - \frac{e^{4x}}{6} + \frac{5(22-15x)e^{x}}{12} - \frac{3x^2}{2} - \frac{27x}{4} \\ -\frac{27}{4} + \frac{9\,e^{2x}}{2} - \frac{2\,e^{4x}}{3} + \frac{5(7-15x)e^{x}}{12} - 3x \\ -\frac{31}{4} + \frac{15\,e^{2x}}{2} - \frac{8\,e^{4x}}{3} + \frac{5(7-15x)e^{x}}{12} - 2x^2 - 4x \end{bmatrix}$$

- First component of the vector is the solution to the ODE

  $y = \frac{(3c_3-8)e^{4x}}{48} + \frac{9\,e^{2x}}{4} + \frac{((48c_2-300)x+48c_1-48c_2+440)e^{x}}{48} - \frac{3x^2}{2} - \frac{27x}{4} - \frac{45}{4}$

- Use the initial condition $y(0) = 1$

  $1 = \frac{c_3}{16} + c_1 - c_2$

- Calculate the 1st derivative of the solution

  $y' = \frac{(3c_3-8)e^{4x}}{12} + \frac{9\,e^{2x}}{2} + \frac{(48c_2-300)e^{x}}{48} + \frac{((48c_2-300)x+48c_1-48c_2+440)e^{x}}{48} - 3x - \frac{27}{4}$

- Use the initial condition $y'\Big|_{\{x=0\}} = 7$

  $7 = \frac{c_3}{4} + c_1$

- Calculate the 2nd derivative of the solution

  $y'' = \frac{(3c_3-8)e^{4x}}{3} + 9\,e^{2x} + \frac{(48c_2-300)e^{x}}{24} + \frac{((48c_2-300)x+48c_1-48c_2+440)e^{x}}{48} - 3$

- Use the initial condition $y''\Big|_{\{x=0\}} = 0$

  $0 = c_1 + c_2 + c_3$

- Solve for the unknown coefficients

$$\left\{c_1 = \frac{115}{9}, c_2 = \frac{31}{3}, c_3 = -\frac{208}{9}\right\}$$

- Solution to the IVP

$$y = \frac{9\,e^{2x}}{4} - \frac{29\,e^{4x}}{18} + \frac{(147x+418)e^{x}}{36} - \frac{3x^2}{2} - \frac{27x}{4} - \frac{45}{4}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 6y' + 8y = x^3 + x + e^{-2x}}$$

11.41.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -6, C = 8, f(x) = x^3 + x + e^{-2x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 6y' + 8y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -6, C = 8$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 6\lambda\, \mathrm{e}^{\lambda x} + 8\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 6\lambda + 8 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -6, C = 8$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{6}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-6^2 - (4)(1)(8)}\\ &= 3 \pm 1\end{aligned}$$

Hence

$$\lambda_1 = 3 + 1$$
$$\lambda_2 = 3 - 1$$

Which simplifies to

$$\lambda_1 = 4$$
$$\lambda_2 = 2$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(4)x} + c_2 e^{(2)x}$$

Or

$$y = c_1 \mathrm{e}^{4x} + c_2 \mathrm{e}^{2x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{4x} + c_2 \mathrm{e}^{2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^3 + x + e^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-2x}\}, \{1, x, x^2, x^3\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{2x}, e^{4x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{-2x} + A_2 + A_3 x + A_4 x^2 + A_5 x^3$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&24A_1 e^{-2x} + 2A_4 + 6A_5 x - 6A_3 - 12A_4 x - 18A_5 x^2 + 8A_2 + 8A_3 x + 8A_4 x^2 + 8A_5 x^3 \\ &= x^3 + x + e^{-2x}\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{24}, A_2 = \frac{69}{256}, A_3 = \frac{29}{64}, A_4 = \frac{9}{32}, A_5 = \frac{1}{8}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{-2x}}{24} + \frac{69}{256} + \frac{29x}{64} + \frac{9x^2}{32} + \frac{x^3}{8}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p \\ &= \left(c_1 e^{4x} + c_2 e^{2x}\right) + \left(\frac{e^{-2x}}{24} + \frac{69}{256} + \frac{29x}{64} + \frac{9x^2}{32} + \frac{x^3}{8}\right)\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{4x} + c_2 e^{2x} + \frac{e^{-2x}}{24} + \frac{69}{256} + \frac{29x}{64} + \frac{9x^2}{32} + \frac{x^3}{8} \quad (1)$$

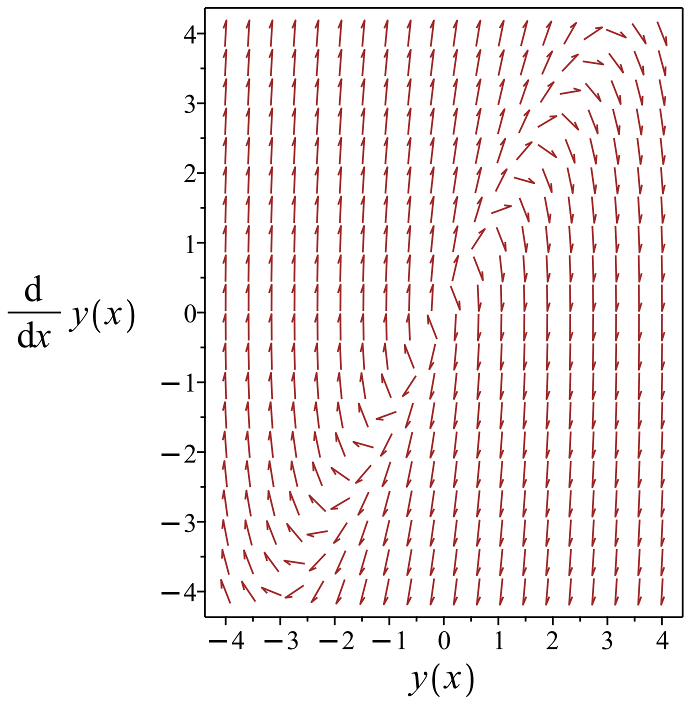

Figure 473: Slope field plot

Verification of solutions

$$y = c_1 e^{4x} + c_2 e^{2x} + \frac{e^{-2x}}{24} + \frac{69}{256} + \frac{29x}{64} + \frac{9x^2}{32} + \frac{x^3}{8}$$

Verified OK.

11.41.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 6y' + 8y = 0 \quad (1)$$
$$Ay'' + By' + Cy = 0 \quad (2)$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -6 \\ C &= 8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 409: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-6}{1}\, dx} \\
&= z_1 e^{3x} \\
&= z_1 \left(\mathrm{e}^{3x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = e^{2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-6}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{6x}}{(y_1)^2}\, dx \\ &= y_1 \left(\frac{e^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(e^{2x}\right) + c_2 \left(e^{2x} \left(\frac{e^{2x}}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 6y' + 8y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{2x} + \frac{c_2 e^{4x}}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^3 + x + e^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-2x}\}, \{1, x, x^2, x^3\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{e^{4x}}{2}, e^{2x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{-2x} + A_2 + A_3 x + A_4 x^2 + A_5 x^3$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&24A_1 e^{-2x} + 2A_4 + 6A_5 x - 6A_3 - 12A_4 x - 18A_5 x^2 + 8A_2 + 8A_3 x + 8A_4 x^2 + 8A_5 x^3 \\ &= x^3 + x + e^{-2x}\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{24}, A_2 = \frac{69}{256}, A_3 = \frac{29}{64}, A_4 = \frac{9}{32}, A_5 = \frac{1}{8}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{-2x}}{24} + \frac{69}{256} + \frac{29x}{64} + \frac{9x^2}{32} + \frac{x^3}{8}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p \\ &= \left(c_1 e^{2x} + \frac{c_2 e^{4x}}{2}\right) + \left(\frac{e^{-2x}}{24} + \frac{69}{256} + \frac{29x}{64} + \frac{9x^2}{32} + \frac{x^3}{8}\right)\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{2x} + \frac{c_2 e^{4x}}{2} + \frac{e^{-2x}}{24} + \frac{69}{256} + \frac{29x}{64} + \frac{9x^2}{32} + \frac{x^3}{8} \tag{1}$$

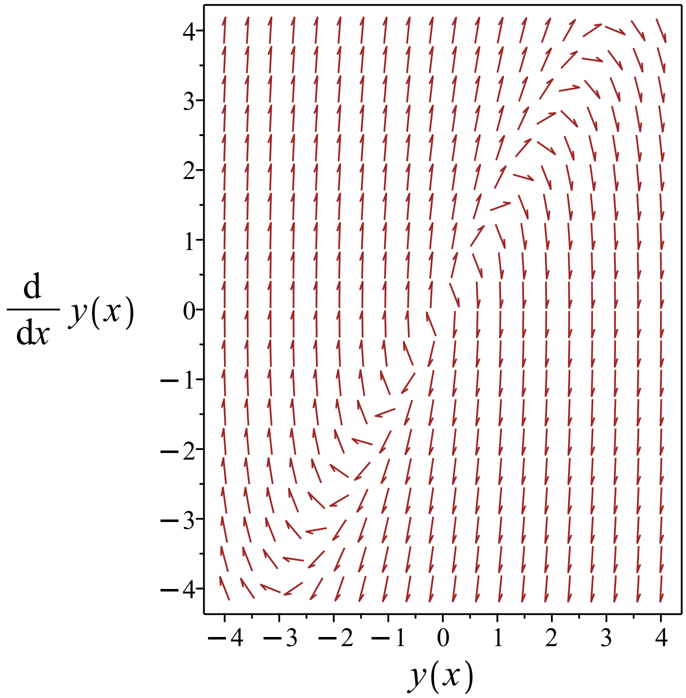

Figure 474: Slope field plot

Verification of solutions

$$y = c_1 e^{2x} + \frac{c_2 e^{4x}}{2} + \frac{e^{-2x}}{24} + \frac{69}{256} + \frac{29x}{64} + \frac{9x^2}{32} + \frac{x^3}{8}$$

Verified OK.

11.41.3 Maple step by step solution

Let's solve

$y'' - 6y' + 8y = x^3 + x + e^{-2x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 - 6r + 8 = 0$

- Factor the characteristic polynomial

  $(r-2)(r-4) = 0$

- Roots of the characteristic polynomial

  $r = (2, 4)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{4x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{2x} + c_2 e^{4x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x^3 + x + e^{-2x}\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{2x} & e^{4x} \\ 2\,e^{2x} & 4\,e^{4x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2\,e^{6x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\frac{e^{2x}\left(\int e^{-2x}(x^3+x+e^{-2x})dx\right)}{2} + \frac{e^{4x}\left(\int e^{-4x}(x^3+x+e^{-2x})dx\right)}{2}$

  - Compute integrals

    $y_p(x) = \frac{e^{-2x}}{24} + \frac{69}{256} + \frac{29x}{64} + \frac{9x^2}{32} + \frac{x^3}{8}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{2x} + c_2 e^{4x} + \frac{e^{-2x}}{24} + \frac{69}{256} + \frac{29x}{64} + \frac{9x^2}{32} + \frac{x^3}{8}$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 9y = e^{3x} + e^{-3x} + e^{3x} \sin(3x)}$$

11.42.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 9, f(x) = e^{3x} + e^{-3x} + e^{3x} \sin(3x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 9y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 9 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(9)} \\ &= \pm 3i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +3i \\ \lambda_2 &= -3i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 3i \\ \lambda_2 &= -3i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 3$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(3x) + c_2 \sin(3x))$$

Or

$$y = c_1 \cos(3x) + c_2 \sin(3x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(3x) + c_2 \sin(3x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{3x} + e^{-3x} + e^{3x} \sin(3x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-3x}\}, \{e^{3x}\}, \{e^{3x} \cos(3x), e^{3x} \sin(3x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(3x), \sin(3x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{-3x} + A_2 e^{3x} + A_3 e^{3x} \cos(3x) + A_4 e^{3x} \sin(3x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&18A_1 e^{-3x} + 18A_2 e^{3x} - 18A_3 e^{3x} \sin(3x) + 18A_4 e^{3x} \cos(3x)\\ &+ 9A_3 e^{3x} \cos(3x) + 9A_4 e^{3x} \sin(3x) = e^{3x} + e^{-3x} + e^{3x} \sin(3x)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{18}, A_2 = \frac{1}{18}, A_3 = -\frac{2}{45}, A_4 = \frac{1}{45}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{-3x}}{18} + \frac{e^{3x}}{18} - \frac{2 e^{3x} \cos(3x)}{45} + \frac{e^{3x} \sin(3x)}{45}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(3x) + c_2 \sin(3x)) + \left(\frac{e^{-3x}}{18} + \frac{e^{3x}}{18} - \frac{2 e^{3x} \cos(3x)}{45} + \frac{e^{3x} \sin(3x)}{45}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(3x) + c_2 \sin(3x) + \frac{e^{-3x}}{18} + \frac{e^{3x}}{18} - \frac{2 e^{3x} \cos(3x)}{45} + \frac{e^{3x} \sin(3x)}{45} \tag{1}
$$

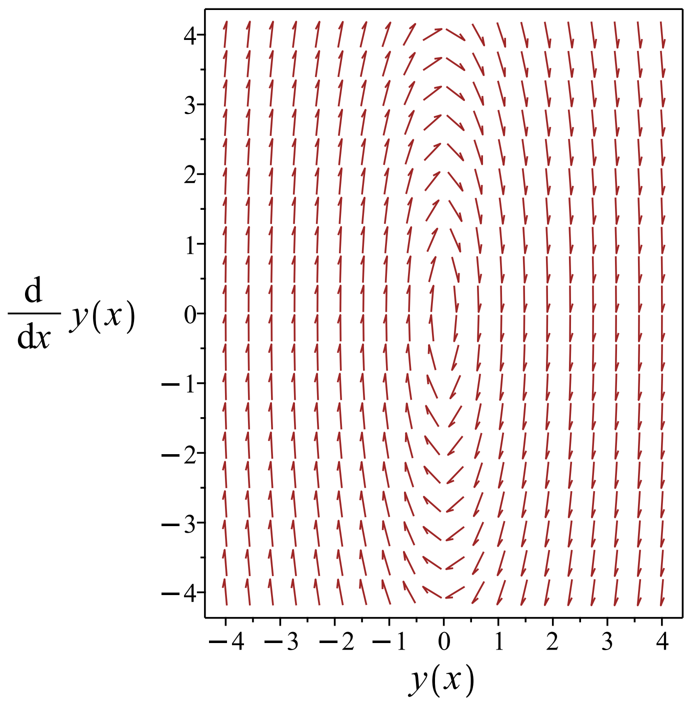

Figure 475: Slope field plot

Verification of solutions

$$
y = c_1 \cos(3x) + c_2 \sin(3x) + \frac{e^{-3x}}{18} + \frac{e^{3x}}{18} - \frac{2 e^{3x} \cos(3x)}{45} + \frac{e^{3x} \sin(3x)}{45}
$$

Verified OK.

11.42.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-9}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -9 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -9z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 411: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -9$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(3x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(3x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(3x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2} \, dx \\ &= \cos(3x) \int \frac{1}{\cos(3x)^2} \, dx \\ &= \cos(3x) \left(\frac{\tan(3x)}{3} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(3x)) + c_2 \left(\cos(3x) \left(\frac{\tan(3x)}{3} \right) \right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 9y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{3x} + e^{-3x} + e^{3x} \sin(3x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-3x}\}, \{e^{3x}\}, \{e^{3x} \cos(3x), e^{3x} \sin(3x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sin(3x)}{3}, \cos(3x)\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{-3x} + A_2 e^{3x} + A_3 e^{3x} \cos(3x) + A_4 e^{3x} \sin(3x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}
&18A_1 e^{-3x} + 18A_2 e^{3x} - 18A_3 e^{3x} \sin(3x) + 18A_4 e^{3x} \cos(3x) \\
&\quad + 9A_3 e^{3x} \cos(3x) + 9A_4 e^{3x} \sin(3x) = e^{3x} + e^{-3x} + e^{3x} \sin(3x)
\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{18}, A_2 = \frac{1}{18}, A_3 = -\frac{2}{45}, A_4 = \frac{1}{45}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{-3x}}{18} + \frac{e^{3x}}{18} - \frac{2 e^{3x} \cos(3x)}{45} + \frac{e^{3x} \sin(3x)}{45}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3}\right) + \left(\frac{e^{-3x}}{18} + \frac{e^{3x}}{18} - \frac{2\,e^{3x} \cos(3x)}{45} + \frac{e^{3x} \sin(3x)}{45}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3} + \frac{e^{-3x}}{18} + \frac{e^{3x}}{18} - \frac{2\,e^{3x} \cos(3x)}{45} + \frac{e^{3x} \sin(3x)}{45} \tag{1}
$$

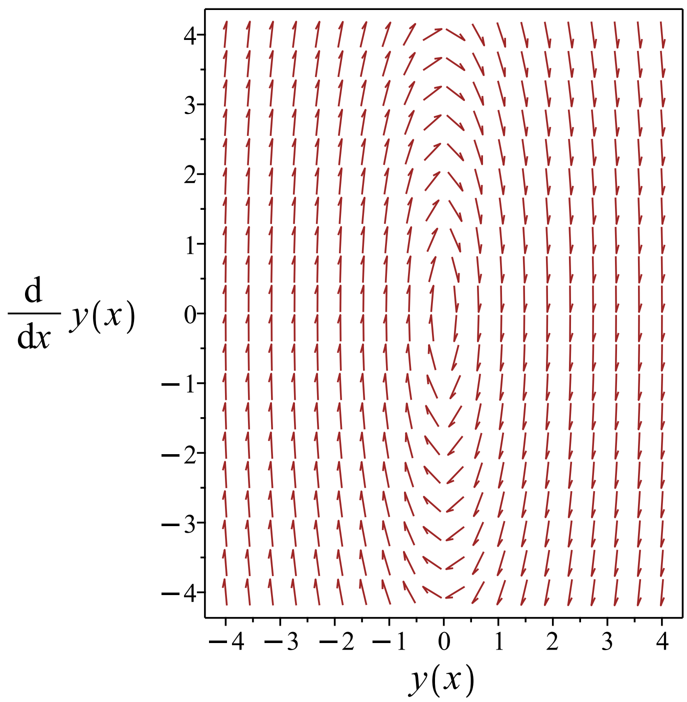

Figure 476: Slope field plot

Verification of solutions

$$
y = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3} + \frac{e^{-3x}}{18} + \frac{e^{3x}}{18} - \frac{2\,e^{3x} \cos(3x)}{45} + \frac{e^{3x} \sin(3x)}{45}
$$

Verified OK.

11.42.3 Maple step by step solution

Let's solve

$y'' + 9y = e^{3x} + e^{-3x} + e^{3x}\sin(3x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 9 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-36})}{2}$

- Roots of the characteristic polynomial

  $r = (-3\,\mathrm{I}, 3\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(3x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(3x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(3x) + c_2 \sin(3x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = e^{3x} + e^{-3x} + e^{3x}\sin(3x\right.$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(3x) & \sin(3x) \\ -3\sin(3x) & 3\cos(3x) \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 3$

- ○ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{\cos(3x)\left(\int \sin(3x)\left(e^{3x}+e^{-3x}+e^{3x}\sin(3x)\right)dx\right)}{3} + \frac{\sin(3x)\left(\int \cos(3x)\left(e^{3x}+e^{-3x}+e^{3x}\sin(3x)\right)dx\right)}{3}$$

- ◦ Compute integrals

$$y_p(x) = \frac{(5-4\cos(3x)+2\sin(3x))e^{3x}}{90} + \frac{e^{-3x}}{18}$$

- Substitute particular solution into general solution to ODE

$$y = \frac{(5-4\cos(3x)+2\sin(3x))e^{3x}}{90} + c_1\cos(3x) + c_2\sin(3x) + \frac{e^{-3x}}{18}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 4y' + 5y = e^{-2x}(\cos(x) + 1)}$$

11.43.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 4, C = 5, f(x) = e^{-2x}(\cos(x) + 1)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 4, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4\lambda\, e^{\lambda x} + 5\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 4, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{4^2 - (4)\,(1)\,(5)}\\ &= -2 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -2 + i\\ \lambda_2 &= -2 - i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -2 + i\\ \lambda_2 &= -2 - i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -2$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-2x}(c_1 \cos(x) + c_2 \sin(x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{-2x}(\cos(x) + 1)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-2x}\}, \{\cos(x) e^{-2x}, e^{-2x} \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x) e^{-2x}, e^{-2x} \sin(x)\}$$

Since $\cos(x) e^{-2x}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{-2x}\}, \{x \cos(x) e^{-2x}, x e^{-2x} \sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^{-2x} + A_2 x \cos(x) e^{-2x} + A_3 x e^{-2x} \sin(x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 e^{-2x} - 2A_2 \sin(x) e^{-2x} + 2A_3 e^{-2x} \cos(x) = e^{-2x}(\cos(x) + 1)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 1, A_2 = 0, A_3 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = e^{-2x} + \frac{x e^{-2x} \sin(x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-2x}(c_1 \cos(x) + c_2 \sin(x))\right) + \left(e^{-2x} + \frac{x e^{-2x} \sin(x)}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + e^{-2x} + \frac{x e^{-2x} \sin(x)}{2} \tag{1}$$

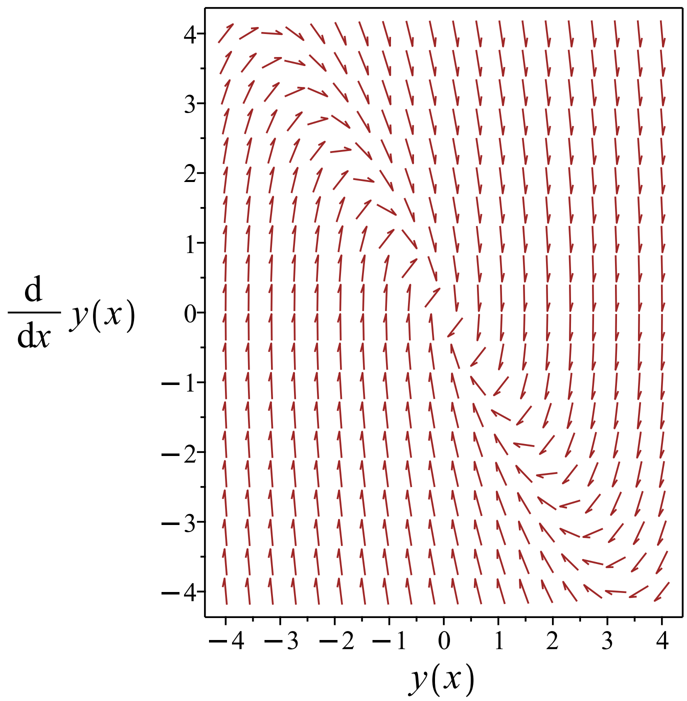

Figure 477: Slope field plot

Verification of solutions

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + e^{-2x} + \frac{x e^{-2x} \sin(x)}{2}$$

Verified OK.

11.43.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 413: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4}{1}\,dx} \\ &= z_1 e^{-2x} \\ &= z_1\left(\mathrm{e}^{-2x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)\, e^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{4}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-4x}}{(y_1)^2}\, dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\cos(x)\, e^{-2x}\right) + c_2\left(\cos(x)\, e^{-2x}(\tan(x))\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 5y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \cos(x)\, e^{-2x} c_1 + c_2 e^{-2x} \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{-2x}(\cos(x) + 1)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-2x}\}, \{\cos(x)\, e^{-2x}, e^{-2x} \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x)\, e^{-2x}, e^{-2x} \sin(x)\}$$

Since $\cos(x)\, e^{-2x}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{-2x}\}, \{x \cos(x)\, e^{-2x}, x\, e^{-2x} \sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^{-2x} + A_2 x \cos(x)\, e^{-2x} + A_3 x\, e^{-2x} \sin(x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 e^{-2x} - 2A_2 \sin(x)\, e^{-2x} + 2A_3 e^{-2x} \cos(x) = e^{-2x}(\cos(x) + 1)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 1, A_2 = 0, A_3 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = e^{-2x} + \frac{x\, e^{-2x} \sin(x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\cos(x)\, e^{-2x} c_1 + c_2 e^{-2x} \sin(x)\right) + \left(e^{-2x} + \frac{x\, e^{-2x} \sin(x)}{2}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + e^{-2x} + \frac{x\,e^{-2x} \sin(x)}{2}$$

Summary
The solution(s) found are the following

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + e^{-2x} + \frac{x\,e^{-2x} \sin(x)}{2} \tag{1}$$

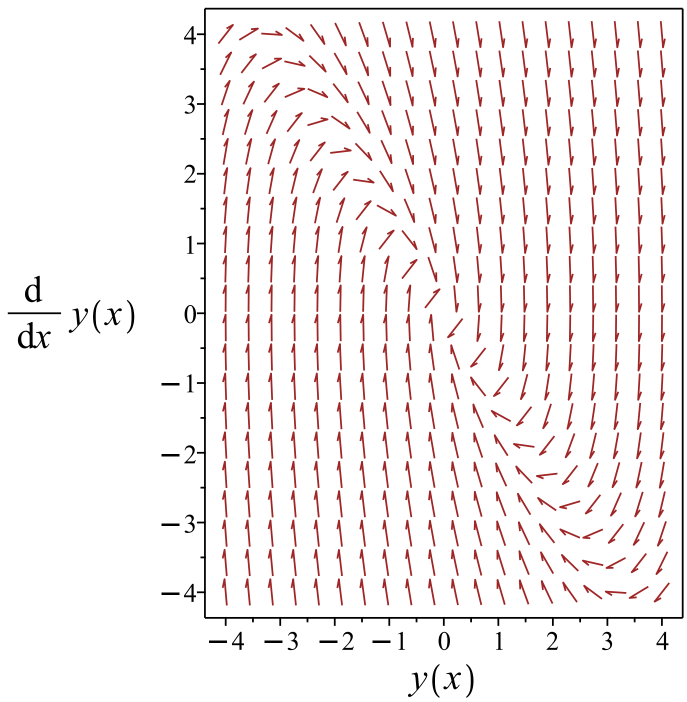

Figure 478: Slope field plot

Verification of solutions

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + e^{-2x} + \frac{x\,e^{-2x} \sin(x)}{2}$$

Verified OK.

11.43.3 Maple step by step solution

Let's solve

$y'' + 4y' + 5y = e^{-2x}(\cos(x) + 1)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4r + 5 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-4)\pm(\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-2 - I, -2 + I)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)\, e^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-2x} \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \cos(x)\, e^{-2x} c_1 + c_2 e^{-2x} \sin(x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = e^{-2x}(\cos(x) + 1)\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x)\, e^{-2x} & e^{-2x} \sin(x) \\ -e^{-2x} \sin(x) - 2\cos(x)\, e^{-2x} & -2\, e^{-2x} \sin(x) + \cos(x)\, e^{-2x} \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{-4x}$

- ○ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\mathrm{e}^{-2x}\left(\cos(x)\left(\int \sin(x)(\cos(x)+1)\,dx\right) - \sin(x)\left(\int \left(\cos(x)^2+\cos(x)\right)dx\right)\right)$$

- Compute integrals

$$y_p(x) = \frac{(x\sin(x)+\cos(x)+2)\,\mathrm{e}^{-2x}}{2}$$

- Substitute particular solution into general solution to ODE

$$y = \cos(x)\,\mathrm{e}^{-2x}c_1 + c_2\mathrm{e}^{-2x}\sin(x) + \frac{(x\sin(x)+\cos(x)+2)\,\mathrm{e}^{-2x}}{2}$$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 6y' + 9y = e^{x}x^{4} + x^{3}e^{2x} + e^{3x}x^{2}}$$

11.44.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -6, C = 9, f(x) = e^{x}x^{2}(e^{2x} + x\,e^{x} + x^{2})$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 6y' + 9y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -6, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 6\lambda\,\mathrm{e}^{\lambda x} + 9\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 6\lambda + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -6, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{6}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-6)^2 - (4)(1)(9)}\\ &= 3\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -3$. Therefore the solution is

$$y = c_1 \mathrm{e}^{3x} + c_2 x\,\mathrm{e}^{3x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{3x} + \mathrm{e}^{3x} c_2 x$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\mathrm{e}^x x^2 \left(\mathrm{e}^{2x} + x\,\mathrm{e}^x + x^2\right)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,\mathrm{e}^{3x}, \mathrm{e}^{3x} x^2, \mathrm{e}^{3x}\}, \{x^2 \mathrm{e}^{2x}, x^3 \mathrm{e}^{2x}, \mathrm{e}^{2x} x, \mathrm{e}^{2x}\}, \{x\,\mathrm{e}^x, x^2 \mathrm{e}^x, x^3 \mathrm{e}^x, \mathrm{e}^x x^4, \mathrm{e}^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\,\mathrm{e}^{3x}, \mathrm{e}^{3x}\}$$

Since e^{3x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,\mathrm{e}^{3x}, x^3\mathrm{e}^{3x}, \mathrm{e}^{3x}x^2\}, \{x^2\mathrm{e}^{2x}, x^3\mathrm{e}^{2x}, \mathrm{e}^{2x}x, \mathrm{e}^{2x}\}, \{x\,\mathrm{e}^{x}, x^2\mathrm{e}^{x}, x^3\mathrm{e}^{x}, \mathrm{e}^{x}x^4, \mathrm{e}^{x}\}]$$

Since $x\,\mathrm{e}^{3x}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^3\mathrm{e}^{3x}, x^4\mathrm{e}^{3x}, \mathrm{e}^{3x}x^2\}, \{x^2\mathrm{e}^{2x}, x^3\mathrm{e}^{2x}, \mathrm{e}^{2x}x, \mathrm{e}^{2x}\}, \{x\,\mathrm{e}^{x}, x^2\mathrm{e}^{x}, x^3\mathrm{e}^{x}, \mathrm{e}^{x}x^4, \mathrm{e}^{x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$\begin{aligned} y_p = {} & A_1x^3\mathrm{e}^{3x} + A_2x^4\mathrm{e}^{3x} + A_3\mathrm{e}^{3x}x^2 + A_4x^2\mathrm{e}^{2x} + A_5x^3\mathrm{e}^{2x} + A_6\mathrm{e}^{2x}x \\ & + A_7\mathrm{e}^{2x} + A_8x\,\mathrm{e}^{x} + A_9x^2\mathrm{e}^{x} + A_{10}x^3\mathrm{e}^{x} + A_{11}\mathrm{e}^{x}x^4 + A_{12}\mathrm{e}^{x} \end{aligned}$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6, A_7, A_8, A_9, A_{10}, A_{11}, A_{12}\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned} & -6A_5x^2\mathrm{e}^{2x} - 8A_9x\,\mathrm{e}^{x} - 12A_{10}x^2\mathrm{e}^{x} - 16A_{11}\mathrm{e}^{x}x^3 + 6A_1x\,\mathrm{e}^{3x} + 12A_2x^2\mathrm{e}^{3x} \\ & + 6A_5x\,\mathrm{e}^{2x} + 6A_{10}x\,\mathrm{e}^{x} + 12A_{11}\mathrm{e}^{x}x^2 - 4A_4x\,\mathrm{e}^{2x} - 2A_6\mathrm{e}^{2x} - 4A_8\mathrm{e}^{x} \\ & + 4A_{11}\mathrm{e}^{x}x^4 + A_4x^2\mathrm{e}^{2x} + A_5x^3\mathrm{e}^{2x} + A_6\mathrm{e}^{2x}x + 4A_8x\,\mathrm{e}^{x} + 4A_9x^2\mathrm{e}^{x} + 4A_{10}x^3\mathrm{e}^{x} \\ & + 4A_{12}\mathrm{e}^{x} + A_7\mathrm{e}^{2x} + 2A_3\mathrm{e}^{3x} + 2A_4\mathrm{e}^{2x} + 2A_9\mathrm{e}^{x} = \mathrm{e}^{x}x^2\left(\mathrm{e}^{2x} + x\,\mathrm{e}^{x} + x^2\right) \end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{12}, A_3 = 0, A_4 = 6, A_5 = 1, A_6 = 18, A_7 = 24, A_8 = 3, A_9 = \frac{9}{4}, A_{10} = 1, A_{11} = \frac{1}{4}, A_{12} = \frac{15}{8}\right.$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^4\mathrm{e}^{3x}}{12} + 6x^2\mathrm{e}^{2x} + x^3\mathrm{e}^{2x} + 18\,\mathrm{e}^{2x}x + 24\,\mathrm{e}^{2x} + 3x\,\mathrm{e}^{x} + \frac{9x^2\mathrm{e}^{x}}{4} + x^3\mathrm{e}^{x} + \frac{\mathrm{e}^{x}x^4}{4} + \frac{15\,\mathrm{e}^{x}}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{3x} + \mathrm{e}^{3x}c_2x\right) \\ &\quad + \left(\frac{x^4\mathrm{e}^{3x}}{12} + 6x^2\mathrm{e}^{2x} + x^3\mathrm{e}^{2x} + 18\,\mathrm{e}^{2x}x + 24\,\mathrm{e}^{2x} + 3x\,\mathrm{e}^{x} + \frac{9x^2\mathrm{e}^{x}}{4} + x^3\mathrm{e}^{x} + \frac{\mathrm{e}^{x}x^4}{4} + \frac{15\,\mathrm{e}^{x}}{8}\right) \end{aligned}$$

Which simplifies to

$$y = e^{3x}(c_2x + c_1) + \frac{x^4 e^{3x}}{12} + 6x^2 e^{2x} + x^3 e^{2x} + 18\, e^{2x} x + 24\, e^{2x} + 3x\, e^x + \frac{9x^2 e^x}{4} + x^3 e^x + \frac{e^x x^4}{4} + \frac{15\, e^x}{8}$$

Summary

The solution(s) found are the following

$$y = e^{3x}(c_2x + c_1) + \frac{x^4 e^{3x}}{12} + 6x^2 e^{2x} + x^3 e^{2x} + 18\, e^{2x} x + 24\, e^{2x} + 3x\, e^x + \frac{9x^2 e^x}{4} + x^3 e^x + \frac{e^x x^4}{4} + \frac{15\, e^x}{8} \tag{1}$$

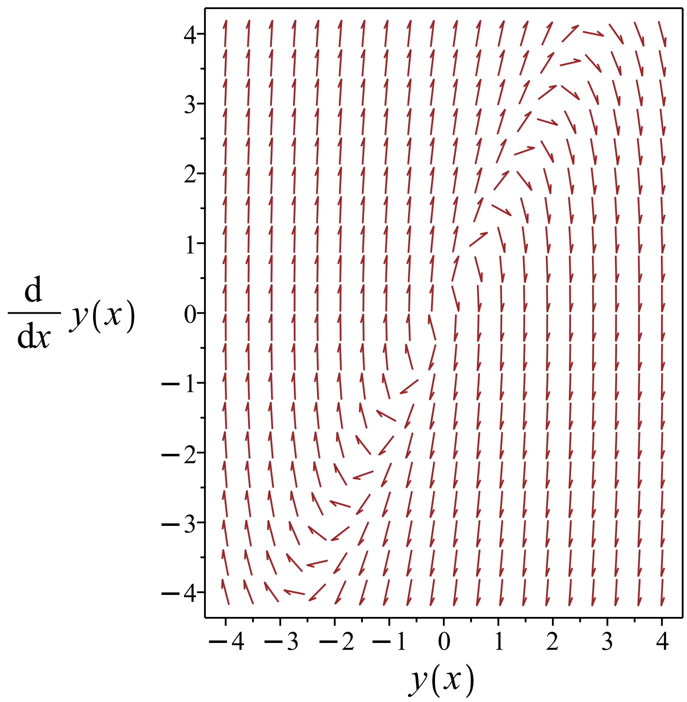

Figure 479: Slope field plot

Verification of solutions

$$y = e^{3x}(c_2x + c_1) + \frac{x^4 e^{3x}}{12} + 6x^2 e^{2x} + x^3 e^{2x} + 18\, e^{2x} x + 24\, e^{2x} + 3x\, e^x + \frac{9x^2 e^x}{4} + x^3 e^x + \frac{e^x x^4}{4} + \frac{15\, e^x}{8}$$

Verified OK.

11.44.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y''+p(x)\,y'+\frac{\left(p(x)^{2}+p'(x)\right)y}{2}=f(x)$$

Where $p(x)=-6$. Therefore, there is an integrating factor given by

$$\begin{aligned}M(x)&=e^{\frac{1}{2}\int p\,dx}\\&=e^{\int -6\,dx}\\&=\mathrm{e}^{-3x}\end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned}(M(x)y)''&=\mathrm{e}^{-3x}\mathrm{e}^{x}x^{2}\left(\mathrm{e}^{2x}+x\,\mathrm{e}^{x}+x^{2}\right)\\\left(\mathrm{e}^{-3x}y\right)''&=\mathrm{e}^{-3x}\mathrm{e}^{x}x^{2}\left(\mathrm{e}^{2x}+x\,\mathrm{e}^{x}+x^{2}\right)\end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{-3x}y\right)'=\frac{\left(-2x^{4}-4x^{3}-6x^{2}-6x-3\right)\mathrm{e}^{-2x}}{4}+\left(-x^{3}-3x^{2}-6x-6\right)\mathrm{e}^{-x}+\frac{x^{3}}{3}+c_1$$

Integrating again gives

$$\left(\mathrm{e}^{-3x}y\right)=\frac{\left(2x^{4}+8x^{3}+18x^{2}+24x+15\right)\mathrm{e}^{-2x}}{8}+\left(x^{3}+6x^{2}+18x+24\right)\mathrm{e}^{-x}+\frac{x^{4}}{12}+c_1x+c_2$$

Hence the solution is

$$y=\frac{\frac{\left(2x^{4}+8x^{3}+18x^{2}+24x+15\right)\mathrm{e}^{-2x}}{8}+\left(x^{3}+6x^{2}+18x+24\right)\mathrm{e}^{-x}+\frac{x^{4}}{12}+c_1x+c_2}{\mathrm{e}^{-3x}}$$

Or

$$\begin{aligned}y=&\frac{x^{4}\mathrm{e}^{3x}}{12}+c_1x\,\mathrm{e}^{3x}+\frac{x^{4}\mathrm{e}^{x}}{4}+x^{3}\mathrm{e}^{2x}+\mathrm{e}^{3x}c_2+x^{3}\mathrm{e}^{x}\\&+6x^{2}\mathrm{e}^{2x}+\frac{9x^{2}\mathrm{e}^{x}}{4}+18\,\mathrm{e}^{2x}x+3x\,\mathrm{e}^{x}+24\,\mathrm{e}^{2x}+\frac{15\,\mathrm{e}^{x}}{8}\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{x^4 e^{3x}}{12} + c_1 x\, e^{3x} + \frac{x^4 e^x}{4} + x^3 e^{2x} + e^{3x} c_2 + x^3 e^x + 6x^2 e^{2x} + \frac{9x^2 e^x}{4} + 18\, e^{2x} x + 3x\, e^x + 24\, e^{2x} + \frac{15\, e^x}{8} \tag{1}$$

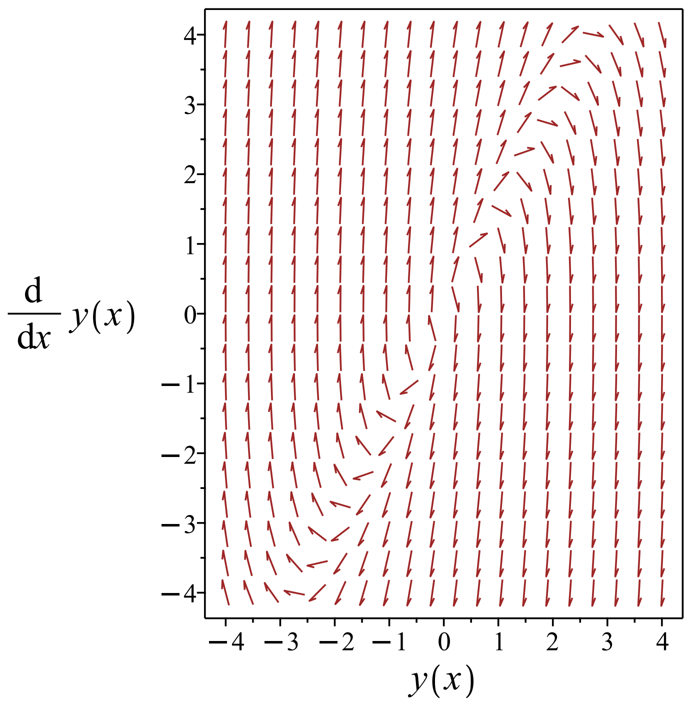

Figure 480: Slope field plot

Verification of solutions

$$y = \frac{x^4 e^{3x}}{12} + c_1 x\, e^{3x} + \frac{x^4 e^x}{4} + x^3 e^{2x} + e^{3x} c_2 + x^3 e^x + 6x^2 e^{2x} + \frac{9x^2 e^x}{4} + 18\, e^{2x} x + 3x\, e^x + 24\, e^{2x} + \frac{15\, e^x}{8}$$

Verified OK.

11.44.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 6y' + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -6 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 415: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-6}{1}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{3x} \\
&= z_1 \left(\mathrm{e}^{3x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{3x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-6}{1}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{6x}}{\left(y_1\right)^2}\, dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{3x}\right) + c_2 \left(\mathrm{e}^{3x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 6y' + 9y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{3x} + \mathrm{e}^{3x} c_2 x
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{x} x^{2} \left(e^{2x} + x\,e^{x} + x^{2}\right)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^{3x}, e^{3x} x^{2}, e^{3x}\}, \{x^{2} e^{2x}, x^{3} e^{2x}, e^{2x} x, e^{2x}\}, \{x\,e^{x}, x^{2} e^{x}, x^{3} e^{x}, x^{4} e^{x}, e^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\,e^{3x}, e^{3x}\}$$

Since e^{3x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{3x}, x^{3} e^{3x}, e^{3x} x^{2}\}, \{x^{2} e^{2x}, x^{3} e^{2x}, e^{2x} x, e^{2x}\}, \{x\,e^{x}, x^{2} e^{x}, x^{3} e^{x}, x^{4} e^{x}, e^{x}\}]$$

Since $x\,e^{3x}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^{3} e^{3x}, x^{4} e^{3x}, e^{3x} x^{2}\}, \{x^{2} e^{2x}, x^{3} e^{2x}, e^{2x} x, e^{2x}\}, \{x\,e^{x}, x^{2} e^{x}, x^{3} e^{x}, x^{4} e^{x}, e^{x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$\begin{aligned} y_p = {} & A_1 x^{3} e^{3x} + A_2 x^{4} e^{3x} + A_3 e^{3x} x^{2} + A_4 x^{2} e^{2x} + A_5 x^{3} e^{2x} + A_6 e^{2x} x \\ & + A_7 e^{2x} + A_8 x\,e^{x} + A_9 x^{2} e^{x} + A_{10} x^{3} e^{x} + A_{11} x^{4} e^{x} + A_{12} e^{x} \end{aligned}$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6, A_7, A_8, A_9, A_{10}, A_{11}, A_{12}\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned} & 2A_3 e^{3x} + 2A_4 e^{2x} + 2A_9 e^{x} - 2A_6 e^{2x} - 4A_8 e^{x} + A_7 e^{2x} + 4A_{12} e^{x} + A_6 e^{2x} x \\ & + 4A_8 x\,e^{x} + 4A_9 x^{2} e^{x} + 4A_{10} x^{3} e^{x} + 4A_{11} x^{4} e^{x} + A_4 x^{2} e^{2x} + A_5 x^{3} e^{2x} \\ & - 6A_5 x^{2} e^{2x} - 8A_9 x\,e^{x} - 12A_{10} x^{2} e^{x} - 16A_{11} x^{3} e^{x} + 6A_1 x\,e^{3x} + 12A_2 x^{2} e^{3x} \\ & + 6A_5 x\,e^{2x} + 6A_{10} x\,e^{x} + 12A_{11} x^{2} e^{x} - 4A_4 x\,e^{2x} = e^{x} x^{2} \left(e^{2x} + x\,e^{x} + x^{2}\right) \end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{12}, A_3 = 0, A_4 = 6, A_5 = 1, A_6 = 18, A_7 = 24, A_8 = 3, A_9 = \frac{9}{4}, A_{10} = 1, A_{11} = \frac{1}{4}, A_{12} = \frac{15}{8}\right.$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^4 e^{3x}}{12} + 6x^2 e^{2x} + x^3 e^{2x} + 18\,e^{2x} x + 24\,e^{2x} + 3x\,e^{x} + \frac{9x^2 e^{x}}{4} + x^3 e^{x} + \frac{x^4 e^{x}}{4} + \frac{15\,e^{x}}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{3x} + e^{3x} c_2 x\right) \\ &\quad + \left(\frac{x^4 e^{3x}}{12} + 6x^2 e^{2x} + x^3 e^{2x} + 18\,e^{2x} x + 24\,e^{2x} + 3x\,e^{x} + \frac{9x^2 e^{x}}{4} + x^3 e^{x} + \frac{x^4 e^{x}}{4} + \frac{15\,e^{x}}{8}\right) \end{aligned}$$

Which simplifies to

$$\begin{aligned} y = {} & e^{3x}(c_2 x + c_1) + \frac{x^4 e^{3x}}{12} + 6x^2 e^{2x} + x^3 e^{2x} + 18\,e^{2x} x \\ & + 24\,e^{2x} + 3x\,e^{x} + \frac{9x^2 e^{x}}{4} + x^3 e^{x} + \frac{x^4 e^{x}}{4} + \frac{15\,e^{x}}{8} \end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & e^{3x}(c_2 x + c_1) + \frac{x^4 e^{3x}}{12} + 6x^2 e^{2x} + x^3 e^{2x} + 18\,e^{2x} x \\ & + 24\,e^{2x} + 3x\,e^{x} + \frac{9x^2 e^{x}}{4} + x^3 e^{x} + \frac{x^4 e^{x}}{4} + \frac{15\,e^{x}}{8} \end{aligned} \tag{1}$$

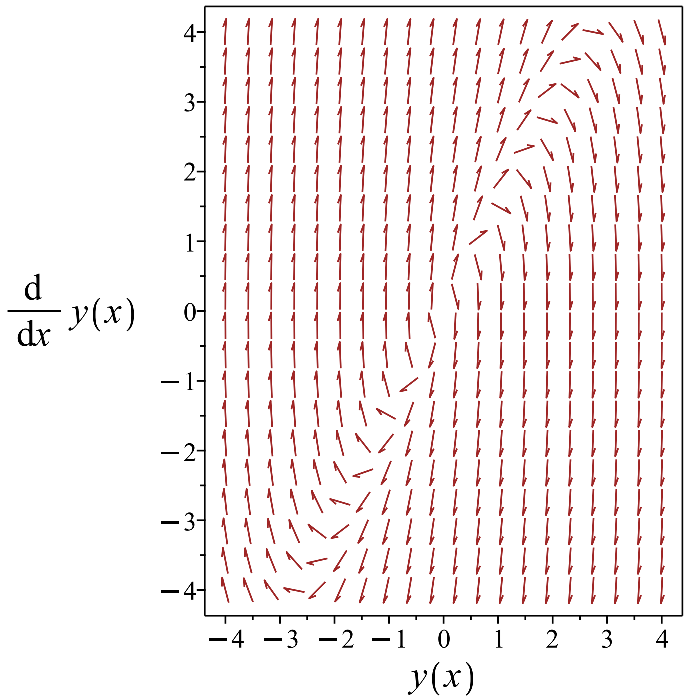

Figure 481: Slope field plot

Verification of solutions

$$y = e^{3x}(c_2x + c_1) + \frac{x^4 e^{3x}}{12} + 6x^2 e^{2x} + x^3 e^{2x} + 18\,e^{2x}x + 24\,e^{2x} + 3x\,e^{x} + \frac{9x^2 e^{x}}{4} + x^3 e^{x} + \frac{x^4 e^{x}}{4} + \frac{15\,e^{x}}{8}$$

Verified OK.

11.44.4 Maple step by step solution

Let's solve

$y'' - 6y' + 9y = e^{x}x^2(e^{2x} + x\,e^{x} + x^2)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 6r + 9 = 0$

- Factor the characteristic polynomial

  $(r-3)^2 = 0$

- Root of the characteristic polynomial

  $r = 3$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{3x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^{3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{3x} + e^{3x} c_2 x + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = e^x x^2 (e^{2x} + x\,e^x + x^2)\right]$

  - Wronskian of solutions of the homogeneous equation

    $$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{3x} & x\,e^{3x} \\ 3\,e^{3x} & e^{3x} + 3x\,e^{3x} \end{bmatrix}$$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = e^{6x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = e^{3x}\left(-\left(\int x^3 e^{-2x}(e^{2x} + x\,e^x + x^2)\,dx\right) + \left(\int x^2 e^{-2x}(e^{2x} + x\,e^x + x^2)\,dx\right) x\right)$

  - Compute integrals

    $y_p(x) = \frac{e^x\left(\frac{45}{2} + e^{2x}x^4 + 12(x^3+6x^2+18x+24)e^x + 3x^4 + 12x^3 + 27x^2 + 36x\right)}{12}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{3x} + e^{3x} c_2 x + \frac{e^x\left(\frac{45}{2} + e^{2x}x^4 + 12(x^3+6x^2+18x+24)e^x + 3x^4 + 12x^3 + 27x^2 + 36x\right)}{12}$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 6y' + 13y = x\,\mathrm{e}^{-3x} \sin(2x) + x^2 \mathrm{e}^{-2x} \sin(3x)}$$

11.45.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 6, C = 13, f(x) = x\,\mathrm{e}^{-2x}(x \sin(3x) + \mathrm{e}^{-x} \sin(2x))$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 6y' + 13y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 6, C = 13$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 6\lambda e^{\lambda x} + 13 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 6\lambda + 13 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 6, C = 13$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-6}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{6^2 - (4)(1)(13)} \\ &= -3 \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -3 + 2i \\ \lambda_2 &= -3 - 2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -3 + 2i \\ \lambda_2 &= -3 - 2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -3$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-3x}(c_1 \cos(2x) + c_2 \sin(2x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-3x}(c_1 \cos(2x) + c_2 \sin(2x))$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^{-3x} \cos(2x)$$
$$y_2 = e^{-3x} \sin(2x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-3x} \cos(2x) & e^{-3x} \sin(2x) \\ \frac{d}{dx}(e^{-3x} \cos(2x)) & \frac{d}{dx}(e^{-3x} \sin(2x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-3x} \cos(2x) & e^{-3x} \sin(2x) \\ -3\,e^{-3x} \cos(2x) - 2\,e^{-3x} \sin(2x) & -3\,e^{-3x} \sin(2x) + 2\,e^{-3x} \cos(2x) \end{vmatrix}$$

Therefore

$$W = \left(e^{-3x}\cos(2x)\right)\left(-3\,e^{-3x}\sin(2x) + 2\,e^{-3x}\cos(2x)\right) - \left(e^{-3x}\sin(2x)\right)\left(-3\,e^{-3x}\cos(2x) - 2\,e^{-3x}\sin(2x)\right)$$

Which simplifies to

$$W = 2\,e^{-6x}\cos(2x)^2 + 2\,e^{-6x}\sin(2x)^2$$

Which simplifies to

$$W = 2\,e^{-6x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{e^{-3x}\sin(2x)\,x\,e^{-2x}(x\sin(3x) + e^{-x}\sin(2x))}{2\,e^{-6x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{x\sin(2x)\left(\sin(3x)\,x\,e^{x} + \sin(2x)\right)}{2}dx$$

Hence

$$\begin{aligned} u_1 = &-\frac{\left(\frac{x^2}{2} - \frac{1}{2}\right)e^{x}\cos(x)}{4} + \frac{\left(-\frac{1}{2}x^2 + x - \frac{1}{2}\right)e^{x}\sin(x)}{4} \\ &+ \frac{\left(\frac{1}{26}x^2 + \frac{12}{169}x - \frac{37}{4394}\right)e^{x}\cos(5x)}{4} - \frac{\left(-\frac{5}{26}x^2 + \frac{5}{169}x + \frac{55}{4394}\right)e^{x}\sin(5x)}{4} \\ &- 2x\left(-\frac{\cos(x)\sin(x)}{2} + \frac{x}{2}\right) + \frac{x^2}{8} - \frac{\sin(x)^2}{2} \\ &+ 2x\left(-\frac{\left(\sin(x)^3 + \frac{3\sin(x)}{2}\right)\cos(x)}{4} + \frac{3x}{8}\right) + \frac{\left(2\cos(x)^2 - 5\right)^2}{32} \end{aligned}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{-3x}\cos(2x)\,x\,e^{-2x}(x\sin(3x) + e^{-x}\sin(2x))}{2\,e^{-6x}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{x \cos(2x) \left(\sin(3x)\, x\, \mathrm{e}^{x} + \sin(2x)\right)}{2} dx$$

Hence

$$\begin{aligned} u_2 = {} & \frac{\left(-\frac{5}{26}x^2 + \frac{5}{169}x + \frac{55}{4394}\right) \mathrm{e}^{x} \cos(5x)}{4} + \frac{\left(\frac{1}{26}x^2 + \frac{12}{169}x - \frac{37}{4394}\right) \mathrm{e}^{x} \sin(5x)}{4} \\ & + \frac{\left(-\frac{1}{2}x^2 + x - \frac{1}{2}\right) \mathrm{e}^{x} \cos(x)}{4} + \frac{\left(\frac{x^2}{2} - \frac{1}{2}\right) \mathrm{e}^{x} \sin(x)}{4} - \frac{x \cos(x)^4}{2} \\ & + \frac{\left(\cos(x)^3 + \frac{3\cos(x)}{2}\right) \sin(x)}{8} - \frac{x}{16} + \frac{\cos(x)^2 x}{2} - \frac{\cos(x)\sin(x)}{4} \end{aligned}$$

Which simplifies to

$$\begin{aligned} u_1 = {} & \frac{\mathrm{e}^{x} \left(x^2 + \frac{24}{13}x - \frac{37}{169}\right) \cos(5x)}{104} + \frac{5\,\mathrm{e}^{x} \left(x^2 - \frac{2}{13}x - \frac{11}{169}\right) \sin(5x)}{104} \\ & - \frac{\left((1+x)\cos(x) + \sin(x)(x-1)\right)(x-1)\,\mathrm{e}^{x}}{8} + \frac{\cos(x)^4}{8} \\ & - \frac{5\cos(x)^2}{8} - \frac{x\left(\sin(x)^2 - \frac{1}{2}\right)\sin(x)\cos(x)}{2} - \frac{x^2}{8} - \frac{\sin(x)^2}{2} + \frac{25}{32} \\ u_2 = {} & -\frac{5\,\mathrm{e}^{x} \left(x^2 - \frac{2}{13}x - \frac{11}{169}\right) \cos(5x)}{104} + \frac{\left(338x^2 + 624x - 74\right) \mathrm{e}^{x} \sin(5x)}{35152} \\ & - \frac{\left((x-1)\cos(x) - \sin(x)(1+x)\right)(x-1)\,\mathrm{e}^{x}}{8} - \frac{x\cos(x)^4}{2} \\ & + \frac{\cos(x)^3 \sin(x)}{8} + \frac{\cos(x)^2 x}{2} - \frac{\cos(x)\sin(x)}{16} - \frac{x}{16} \end{aligned}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{e^x\left(x^2+\frac{24}{13}x-\frac{37}{169}\right)\cos(5x)}{104} + \frac{5\,e^x\left(x^2-\frac{2}{13}x-\frac{11}{169}\right)\sin(5x)}{104} - \frac{((1+x)\cos(x)+\sin(x)(x-1))(x-1)\,e^x}{8} + \frac{\cos(x)^4}{8} - \frac{5\cos(x)^2}{8} - \frac{x\left(\sin(x)^2-\frac{1}{2}\right)\sin(x)\cos(x)}{2} - \frac{x^2}{8} - \frac{\sin(x)^2}{2} + \frac{25}{32}\right)e^{-3x}\cos(2x) + \left(-\frac{5\,e^x\left(x^2-\frac{2}{13}x-\frac{11}{169}\right)\cos(5x)}{104} + \frac{(338x^2+624x-74)\,e^x\sin(5x)}{35152} - \frac{((x-1)\cos(x)-\sin(x)(1+x))(x-1)\,e^x}{8} - \frac{x\cos(x)^4}{2} + \frac{\cos(x)^3\sin(x)}{8} + \frac{\cos(x)^2 x}{2} - \frac{\cos(x)\sin(x)}{16} - \frac{x}{16}\right)e^{-3x}\sin(2x)$$

Which simplifies to

$$y_p(x) = -\frac{6\left(e^x\left(x^2-\frac{2}{13}x-\frac{180}{169}\right)\cos(x)^3 + \left(\frac{2\left(x^2-\frac{41}{13}x+\frac{563}{338}\right)\sin(x)e^x}{3} + \frac{13x^2}{24} - \frac{39}{32}\right)\cos(x)^2 + \left(\left(-\frac{3}{4}x^2+\frac{3}{26}x+\frac{135}{169}\right)e\right.}{13}$$

Therefore the general solution is

$$y = y_h + y_p$$

$$= \left(e^{-3x}(c_1\cos(2x)+c_2\sin(2x))\right) + \left(-\frac{6\left(e^x\left(x^2-\frac{2}{13}x-\frac{180}{169}\right)\cos(x)^3 + \left(\frac{2\left(x^2-\frac{41}{13}x+\frac{563}{338}\right)\sin(x)e^x}{3} + \frac{13x^2}{24} - \frac{39}{32}\right)\cos(x)^2 + \left(\left(-\frac{3}{4}x^2+\frac{3}{26}x+\right.\right.}{13}\right.$$

Summary

The solution(s) found are the following

$$y = e^{-3x}(c_1\cos(2x)+c_2\sin(2x)) - \frac{6\left(e^x\left(x^2-\frac{2}{13}x-\frac{180}{169}\right)\cos(x)^3 + \left(\frac{2\left(x^2-\frac{41}{13}x+\frac{563}{338}\right)\sin(x)e^x}{3} + \frac{13x^2}{24} - \frac{39}{32}\right)\cos(x)^2 + \left(\left(-\frac{3}{4}x^2+\frac{3}{26}x+\frac{135}{169}\right)e\right.}{13} \quad (1)$$

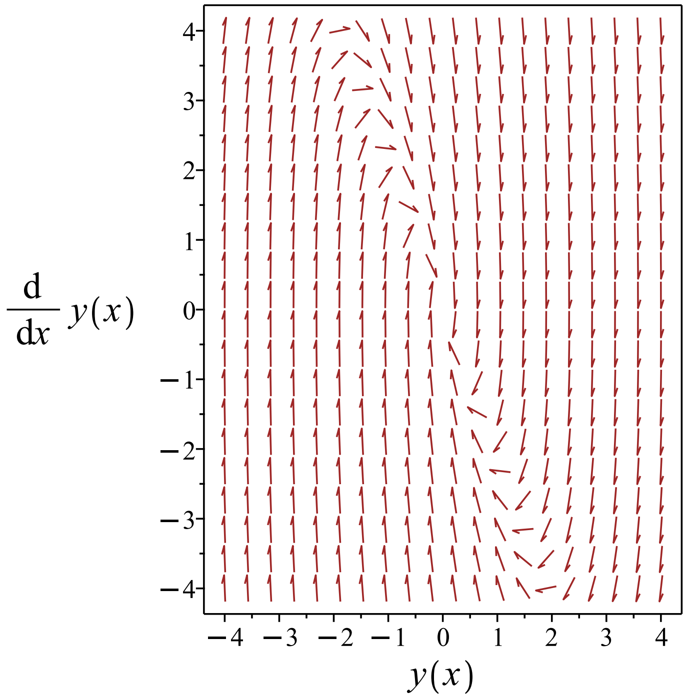

Figure 482: Slope field plot

Verification of solutions

$$y = e^{-3x}(c_1 \cos(2x) + c_2 \sin(2x)) - \frac{6\left(e^x\left(x^2 - \frac{2}{13}x - \frac{180}{169}\right)\cos(x)^3 + \left(\frac{2\left(x^2 - \frac{41}{13}x + \frac{563}{338}\right)\sin(x)e^x}{3} + \frac{13x^2}{24} - \frac{39}{32}\right)\cos(x)^2 + \left(\left(-\frac{3}{4}x^2 + \frac{3}{26}x + \frac{135}{169}\right)e^{x}\right.}{13}$$

Verified OK.

11.45.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 6y' + 13y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 6 \\ C &= 13 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 417: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{6}{1}\,dx} \\ &= z_1 e^{-3x} \\ &= z_1\left(\mathrm{e}^{-3x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x} \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{6}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-6x}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{\tan(2x)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-3x} \cos(2x)\right) + c_2 \left(\mathrm{e}^{-3x} \cos(2x) \left(\frac{\tan(2x)}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 6y' + 13y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-3x} \cos(2x) + \frac{\mathrm{e}^{-3x} \sin(2x)\, c_2}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^{-3x} \cos(2x)$$
$$y_2 = \frac{e^{-3x} \sin(2x)}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-3x} \cos(2x) & \frac{e^{-3x} \sin(2x)}{2} \\ \frac{d}{dx}\left(e^{-3x} \cos(2x)\right) & \frac{d}{dx}\left(\frac{e^{-3x} \sin(2x)}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-3x} \cos(2x) & \frac{e^{-3x} \sin(2x)}{2} \\ -3\,e^{-3x} \cos(2x) - 2\,e^{-3x} \sin(2x) & -\frac{3\,e^{-3x} \sin(2x)}{2} + e^{-3x} \cos(2x) \end{vmatrix}$$

Therefore

$$W = \left(e^{-3x} \cos(2x)\right)\left(-\frac{3\,e^{-3x} \sin(2x)}{2} + e^{-3x} \cos(2x)\right) - \left(\frac{e^{-3x} \sin(2x)}{2}\right)\left(-3\,e^{-3x} \cos(2x) - 2\,e^{-3x} \sin(2x)\right)$$

Which simplifies to

$$W = \mathrm{e}^{-6x} \cos(2x)^2 + \mathrm{e}^{-6x} \sin(2x)^2$$

Which simplifies to

$$W = \mathrm{e}^{-6x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\mathrm{e}^{-3x} \sin(2x) x\, \mathrm{e}^{-2x} (x \sin(3x) + \mathrm{e}^{-x} \sin(2x))}{2}}{\mathrm{e}^{-6x}} \, dx$$

Which simplifies to

$$u_1 = -\int \frac{x \sin(2x) (\sin(3x)\, x\, \mathrm{e}^{x} + \sin(2x))}{2} dx$$

Hence

$$\begin{aligned} u_1 = &-\frac{\left(\frac{x^2}{2} - \frac{1}{2}\right) \mathrm{e}^{x} \cos(x)}{4} + \frac{\left(-\frac{1}{2}x^2 + x - \frac{1}{2}\right) \mathrm{e}^{x} \sin(x)}{4} \\ &+ \frac{\left(\frac{1}{26}x^2 + \frac{12}{169}x - \frac{37}{4394}\right) \mathrm{e}^{x} \cos(5x)}{4} - \frac{\left(-\frac{5}{26}x^2 + \frac{5}{169}x + \frac{55}{4394}\right) \mathrm{e}^{x} \sin(5x)}{4} \\ &- 2x\left(-\frac{\cos(x) \sin(x)}{2} + \frac{x}{2}\right) + \frac{x^2}{8} - \frac{\sin(x)^2}{2} \\ &+ 2x\left(-\frac{\left(\sin(x)^3 + \frac{3\sin(x)}{2}\right) \cos(x)}{4} + \frac{3x}{8}\right) + \frac{\left(2\cos(x)^2 - 5\right)^2}{32} \end{aligned}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\mathrm{e}^{-3x} \cos(2x)\, x\, \mathrm{e}^{-2x} (x \sin(3x) + \mathrm{e}^{-x} \sin(2x))}{\mathrm{e}^{-6x}} \, dx$$

Which simplifies to

$$u_2 = \int x \cos(2x) (\sin(3x)\, x\, \mathrm{e}^{x} + \sin(2x)) \, dx$$

Hence

$$u_2 = \frac{\left(-\frac{5}{26}x^2 + \frac{5}{169}x + \frac{55}{4394}\right) e^x \cos(5x)}{2} + \frac{\left(\frac{1}{26}x^2 + \frac{12}{169}x - \frac{37}{4394}\right) e^x \sin(5x)}{2} + \frac{\left(-\frac{1}{2}x^2 + x - \frac{1}{2}\right) e^x \cos(x)}{2} + \frac{\left(\frac{x^2}{2} - \frac{1}{2}\right) e^x \sin(x)}{2} - x\cos(x)^4 + \frac{\left(\cos(x)^3 + \frac{3\cos(x)}{2}\right)\sin(x)}{4} - \frac{x}{8} + \cos(x)^2 x - \frac{\cos(x)\sin(x)}{2}$$

Which simplifies to

$$u_1 = \frac{e^x\left(x^2 + \frac{24}{13}x - \frac{37}{169}\right)\cos(5x)}{104} + \frac{5\,e^x\left(x^2 - \frac{2}{13}x - \frac{11}{169}\right)\sin(5x)}{104} - \frac{((1+x)\cos(x) + \sin(x)(x-1))(x-1)e^x}{8} + \frac{\cos(x)^4}{8} - \frac{5\cos(x)^2}{8} - \frac{x\left(\sin(x)^2 - \frac{1}{2}\right)\sin(x)\cos(x)}{2} - \frac{x^2}{8} - \frac{\sin(x)^2}{2} + \frac{25}{32}$$

$$u_2 = -\frac{5\,e^x\left(x^2 - \frac{2}{13}x - \frac{11}{169}\right)\cos(5x)}{52} + \frac{(169x^2 + 312x - 37)e^x \sin(5x)}{8788} - \frac{((x-1)\cos(x) - \sin(x)(1+x))(x-1)e^x}{4} - x\cos(x)^4 + \frac{\cos(x)^3\sin(x)}{4} + \cos(x)^2 x - \frac{\cos(x)\sin(x)}{8} - \frac{x}{8}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{e^x\left(x^2 + \frac{24}{13}x - \frac{37}{169}\right)\cos(5x)}{104} + \frac{5\,e^x\left(x^2 - \frac{2}{13}x - \frac{11}{169}\right)\sin(5x)}{104} - \frac{((1+x)\cos(x) + \sin(x)(x-1))(x-1)e^x}{8} + \frac{\cos(x)^4}{8} - \frac{5\cos(x)^2}{8} - \frac{x\left(\sin(x)^2 - \frac{1}{2}\right)\sin(x)\cos(x)}{2} - \frac{x^2}{8} - \frac{\sin(x)^2}{2} + \frac{25}{32}\right) e^{-3x}\cos(2x) + \frac{\left(-\frac{5\,e^x\left(x^2 - \frac{2}{13}x - \frac{11}{169}\right)\cos(5x)}{52} + \frac{(169x^2+312x-37)e^x\sin(5x)}{8788} - \frac{((x-1)\cos(x) - \sin(x)(1+x))(x-1)e^x}{4} - x\cos(x)^4 + \frac{\cos(x)^3 \sin}{4}\right.}{2}$$

Which simplifies to

$$y_p(x) = -\frac{6\left(e^x\left(x^2 - \frac{2}{13}x - \frac{180}{169}\right)\cos(x)^3 + \left(\frac{2\left(x^2 - \frac{41}{13}x + \frac{563}{338}\right)\sin(x)e^x}{3} + \frac{13x^2}{24} - \frac{39}{32}\right)\cos(x)^2 + \left(\left(-\frac{3}{4}x^2 + \frac{3}{26}x + \frac{135}{169}\right)e\right.\right.}{13}$$

Therefore the general solution is

$$y = y_h + y_p$$

$$= \left(c_1 \mathrm{e}^{-3x} \cos(2x) + \frac{\mathrm{e}^{-3x} \sin(2x) c_2}{2}\right)$$

$$+ \left(-\frac{6\left(\mathrm{e}^x \left(x^2 - \frac{2}{13}x - \frac{180}{169}\right) \cos(x)^3 + \left(\frac{2\left(x^2 - \frac{41}{13}x + \frac{563}{338}\right) \sin(x) \mathrm{e}^x}{3} + \frac{13x^2}{24} - \frac{39}{32}\right) \cos(x)^2 + \left(\left(-\frac{3}{4}x^2 + \frac{3}{26}x + \right.\right.\right.}{13}\right.$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-3x} \cos(2x) + \frac{\mathrm{e}^{-3x} \sin(2x) c_2}{2} \tag{1}$$
$$- \frac{6\left(\mathrm{e}^x \left(x^2 - \frac{2}{13}x - \frac{180}{169}\right) \cos(x)^3 + \left(\frac{2\left(x^2 - \frac{41}{13}x + \frac{563}{338}\right) \sin(x) \mathrm{e}^x}{3} + \frac{13x^2}{24} - \frac{39}{32}\right) \cos(x)^2 + \left(\left(-\frac{3}{4}x^2 + \frac{3}{26}x + \frac{135}{169}\right) \mathrm{e}\right.\right.}{13}$$

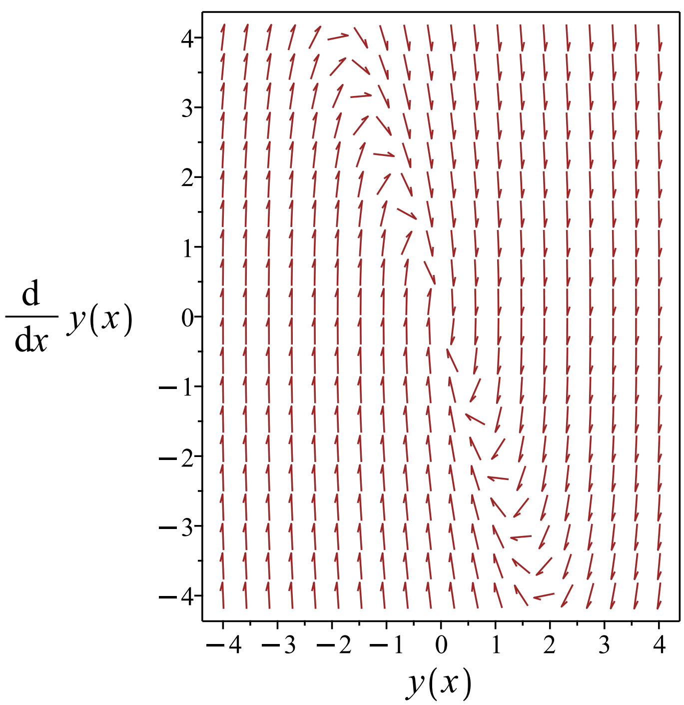

Figure 483: Slope field plot

Verification of solutions

$$y = c_1 \mathrm{e}^{-3x} \cos(2x) + \frac{\mathrm{e}^{-3x} \sin(2x) c_2}{2} - \frac{6\left(\mathrm{e}^{x}\left(x^2 - \frac{2}{13}x - \frac{180}{169}\right)\cos(x)^3 + \left(\frac{2\left(x^2 - \frac{41}{13}x + \frac{563}{338}\right)\sin(x)\mathrm{e}^{x}}{3} + \frac{13x^2}{24} - \frac{39}{32}\right)\cos(x)^2 + \left(\left(-\frac{3}{4}x^2 + \frac{3}{26}x + \frac{135}{169}\right)\mathrm{e}\right.\right.}{13}$$

Verified OK.

11.45.3 Maple step by step solution

Let's solve

$y'' + 6y' + 13y = x\,\mathrm{e}^{-2x}(x \sin(3x) + \mathrm{e}^{-x} \sin(2x))$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 6r + 13 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-6)\pm(\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r = (-3 - 2\,\mathrm{I}, -3 + 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-3x} \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-3x} \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-3x} \cos(2x) + \mathrm{e}^{-3x} \sin(2x) c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = x\,\mathrm{e}^{-2x}(x \sin(3x) + \mathrm{e}^{-x}\right.$

  ◦ Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-3x}\cos(2x) & e^{-3x}\sin(2x) \\ -3e^{-3x}\cos(2x) - 2e^{-3x}\sin(2x) & -3e^{-3x}\sin(2x) + 2e^{-3x}\cos(2x) \end{bmatrix}$$

- Compute Wronskian

  $$W(y_1(x), y_2(x)) = 2e^{-6x}$$

- Substitute functions into equation for $y_p(x)$

  $$y_p(x) = -\frac{e^{-3x}\left(\cos(2x)\left(\int x\sin(2x)(\sin(3x)x\,e^{x}+\sin(2x))dx\right)-\sin(2x)\left(\int x\cos(2x)(\sin(3x)x\,e^{x}+\sin(2x))dx\right)\right)}{2}$$

- Compute integrals

  $$y_p(x) = -\frac{6\left(e^{x}\left(x^2-\frac{2}{13}x-\frac{180}{169}\right)\cos(x)^3+\left(\frac{2\left(x^2-\frac{41}{13}x+\frac{563}{338}\right)\sin(x)e^{x}}{3}+\frac{13x^2}{24}-\frac{39}{32}\right)\cos(x)^2+\left(\left(-\frac{3}{4}x^2+\frac{3}{26}x+\frac{135}{169}\right)e^{x}-\frac{13x\sin(x)}{48}\right)\text{co}}{13}$$

- Substitute particular solution into general solution to ODE

  $$y = c_1e^{-3x}\cos(2x) + e^{-3x}\sin(2x)c_2 - \frac{6\left(e^{x}\left(x^2-\frac{2}{13}x-\frac{180}{169}\right)\cos(x)^3+\left(\frac{2\left(x^2-\frac{41}{13}x+\frac{563}{338}\right)\sin(x)e^{x}}{3}+\frac{13x^2}{24}-\frac{39}{32}\right)\cos(x)^2}{}$$

Problem number: 46.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' - 3y'' + 2y' = x^2 e^x + 3\,e^{2x} x + 5x^2}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 3y'' + 2y' = 0$$

The characteristic equation is

$$\lambda^3 - 3\lambda^2 + 2\lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 2$$
$$\lambda_3 = 1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + c_2 e^x + e^{2x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = e^x$$
$$y_3 = e^{2x}$$

Now the particular solution to the given ODE is found

$$y''' - 3y'' + 2y' = x^2 e^x + 3\,e^{2x} x + 5x^2$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 e^x + 3\,e^{2x} x + 5x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x} x, e^{2x}\}, \{1, x, x^2\}, \{x\,e^x, x^2 e^x, e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^x, e^{2x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{2x} x, e^{2x}\}, \{x, x^2, x^3\}, \{x\,e^x, x^2 e^x, e^x\}]$$

Since e^x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{2x} x, e^{2x}\}, \{x, x^2, x^3\}, \{x\,e^x, x^2 e^x, x^3 e^x\}]$$

Since e^{2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 e^{2x}, e^{2x} x\}, \{x, x^2, x^3\}, \{x\,e^x, x^2 e^x, x^3 e^x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 e^{2x} + A_2 e^{2x} x + A_3 x + A_4 x^2 + A_5 x^3 + A_6 x\,e^x + A_7 x^2 e^x + A_8 x^3 e^x$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6, A_7, A_8\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1x\,e^{2x} - 2A_7x\,e^{x} - 3A_8x^2e^{x} + 2A_3 - 6A_4 + 6A_5 - 18A_5x + 4A_4x \\ + 6A_5x^2 + 6A_8e^{x} + 6A_1e^{2x} + 2A_2e^{2x} - A_6e^{x} = x^2e^{x} + 3\,e^{2x}x + 5x^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{3}{4}, A_2 = -\frac{9}{4}, A_3 = \frac{35}{4}, A_4 = \frac{15}{4}, A_5 = \frac{5}{6}, A_6 = -2, A_7 = 0, A_8 = -\frac{1}{3}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{3x^2e^{2x}}{4} - \frac{9\,e^{2x}x}{4} + \frac{35x}{4} + \frac{15x^2}{4} + \frac{5x^3}{6} - 2x\,e^{x} - \frac{x^3e^{x}}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + c_2e^{x} + e^{2x}c_3\right) + \left(\frac{3x^2e^{2x}}{4} - \frac{9\,e^{2x}x}{4} + \frac{35x}{4} + \frac{15x^2}{4} + \frac{5x^3}{6} - 2x\,e^{x} - \frac{x^3e^{x}}{3}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + c_2e^{x} + e^{2x}c_3 + \frac{3x^2e^{2x}}{4} - \frac{9\,e^{2x}x}{4} + \frac{35x}{4} + \frac{15x^2}{4} + \frac{5x^3}{6} - 2x\,e^{x} - \frac{x^3e^{x}}{3} \quad (1)$$

Verification of solutions

$$y = c_1 + c_2e^{x} + e^{2x}c_3 + \frac{3x^2e^{2x}}{4} - \frac{9\,e^{2x}x}{4} + \frac{35x}{4} + \frac{15x^2}{4} + \frac{5x^3}{6} - 2x\,e^{x} - \frac{x^3e^{x}}{3}$$

Verified OK.

11.46.1 Maple step by step solution

Let's solve

$y''' - 3y'' + 2y' = x^2 e^x + 3\,e^{2x} x + 5x^2$

- Highest derivative means the order of the ODE is 3

  y'''

- ☐ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = x^2 e^x + 3\,e^{2x} x + 5x^2 + 3y_3(x) - 2y_2(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x)\,, y_3(x) = y_2'(x)\,, y_3'(x) = x^2 e^x + 3\,e^{2x} x + 5x^2 + 3y_3(x) - 2y_2(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -2 & 3 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ x^2 e^x + 3\,e^{2x} x + 5x^2 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ x^2 e^x + 3\,e^{2x} x + 5x^2 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -2 & 3 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{y}'(x) = A \cdot \overrightarrow{y}(x) + \overrightarrow{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_2 = \mathrm{e}^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = e^{2x} \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$$\vec{y}(x) = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3 + \vec{y}_p(x)$$

☐ Fundamental matrix

  - Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} 1 & e^{x} & \frac{e^{2x}}{4} \\ 0 & e^{x} & \frac{e^{2x}}{2} \\ 0 & e^{x} & e^{2x} \end{bmatrix}$$

  - The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$$

  - Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} 1 & e^{x} & \frac{e^{2x}}{4} \\ 0 & e^{x} & \frac{e^{2x}}{2} \\ 0 & e^{x} & e^{2x} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & 1 & \frac{1}{4} \\ 0 & 1 & \frac{1}{2} \\ 0 & 1 & 1 \end{bmatrix}}$$

  - Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} 1 & -\frac{3}{2} + 2\,e^{x} - \frac{e^{2x}}{2} & \frac{1}{2} - e^{x} + \frac{e^{2x}}{2} \\ 0 & 2\,e^{x} - e^{2x} & -e^{x} + e^{2x} \\ 0 & 2\,e^{x} - 2\,e^{2x} & -e^{x} + 2\,e^{2x} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

  - Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

$\overrightarrow{y}_p(x) = \Phi(x) \cdot \overrightarrow{v}(x)$

- Take the derivative of the particular solution

  $\overrightarrow{y}_p^{\prime}(x) = \Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}^{\prime}(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}^{\prime}(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}^{\prime}(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \overrightarrow{v}^{\prime}(x) = \overrightarrow{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\overrightarrow{v}^{\prime}(x) = \frac{1}{\Phi(x)} \cdot \overrightarrow{f}(x)$

- Integrate to solve for $\overrightarrow{v}(x)$

  $\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$

- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\overrightarrow{y}_p(x) = \left[\begin{array}{c} \frac{35}{4}+\frac{(3x^2-9x+17)\mathrm{e}^{2x}}{4}+\frac{(-x^3-6x-39)\mathrm{e}^{x}}{3}+\frac{5x^3}{6}+\frac{15x^2}{4}+\frac{35x}{4} \\ \frac{35}{4}+\frac{(6x^2-12x+25)\mathrm{e}^{2x}}{4}+\frac{(-x^3-3x^2-6x-45)\mathrm{e}^{x}}{3}+\frac{5x^2}{2}+\frac{15x}{2} \\ \frac{15}{2}+\frac{(6x^2-6x+19)\mathrm{e}^{2x}}{2}+\frac{(-x^3-6x^2-12x-51)\mathrm{e}^{x}}{3}+5x \end{array}\right]$$

- Plug particular solution back into general solution

  $$\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2 + c_3\overrightarrow{y}_3 + \left[\begin{array}{c} \frac{35}{4}+\frac{(3x^2-9x+17)\mathrm{e}^{2x}}{4}+\frac{(-x^3-6x-39)\mathrm{e}^{x}}{3}+\frac{5x^3}{6}+\frac{15x^2}{4}+\frac{35x}{4} \\ \frac{35}{4}+\frac{(6x^2-12x+25)\mathrm{e}^{2x}}{4}+\frac{(-x^3-3x^2-6x-45)\mathrm{e}^{x}}{3}+\frac{5x^2}{2}+\frac{15x}{2} \\ \frac{15}{2}+\frac{(6x^2-6x+19)\mathrm{e}^{2x}}{2}+\frac{(-x^3-6x^2-12x-51)\mathrm{e}^{x}}{3}+5x \end{array}\right]$$

- First component of the vector is the solution to the ODE

  $y = \frac{35}{4} + \frac{(3x^2+c_3-9x+17)\mathrm{e}^{2x}}{4} + \frac{(-x^3+3c_2-6x-39)\mathrm{e}^{x}}{3} + \frac{5x^3}{6} + \frac{15x^2}{4} + \frac{35x}{4} + c_1$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.3. The method of undetermined coefficients. Exercises page 151
Problem number: 47.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_3rd_order, _linear, _nonhomogeneous]]`

$$\boxed{y''' - 6y'' + 12y' - 8y = e^{2x}x + e^{3x}x^2}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 6y'' + 12y' - 8y = 0$$

The characteristic equation is

$$\lambda^3 - 6\lambda^2 + 12\lambda - 8 = 0$$

The roots of the above equation are

$$\lambda_1 = 2$$
$$\lambda_2 = 2$$
$$\lambda_3 = 2$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{2x} + c_2 e^{2x} x + x^2 e^{2x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned}
y_1 &= e^{2x} \\
y_2 &= e^{2x} x \\
y_3 &= x^2 e^{2x}
\end{aligned}$$

Now the particular solution to the given ODE is found

$$y''' - 6y'' + 12y' - 8y = e^{2x} x + e^{3x} x^2$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{2x} x + e^{3x} x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x} x, e^{2x}\}, \{x\, e^{3x}, e^{3x} x^2, e^{3x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x^2 e^{2x}, e^{2x} x, e^{2x}\}$$

Since e^{2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 e^{2x}, e^{2x} x\}, \{x\, e^{3x}, e^{3x} x^2, e^{3x}\}]$$

Since $e^{2x} x$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 e^{2x}, x^3 e^{2x}\}, \{x\, e^{3x}, e^{3x} x^2, e^{3x}\}]$$

Since $x^2 e^{2x}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^3 e^{2x}, e^{2x} x^4\}, \{x\, e^{3x}, e^{3x} x^2, e^{3x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^3 e^{2x} + A_2 e^{2x} x^4 + A_3 x\, e^{3x} + A_4 e^{3x} x^2 + A_5 e^{3x}$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&6A_4 e^{3x} x + 24A_2 e^{2x} x + A_3 x\,e^{3x} + A_4 e^{3x} x^2 + A_5 e^{3x} + 3A_3 e^{3x} + 6A_4 e^{3x} + 6A_1 e^{2x}\\ &= e^{2x} x + e^{3x} x^2\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{24}, A_3 = -6, A_4 = 1, A_5 = 12\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{2x} x^4}{24} - 6x\,e^{3x} + e^{3x} x^2 + 12\,e^{3x}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\ &= \left(c_1 e^{2x} + c_2 e^{2x} x + x^2 e^{2x} c_3\right) + \left(\frac{e^{2x} x^4}{24} - 6x\,e^{3x} + e^{3x} x^2 + 12\,e^{3x}\right)\end{aligned}$$

Which simplifies to

$$y = e^{2x}\left(c_3 x^2 + c_2 x + c_1\right) + \frac{e^{2x} x^4}{24} - 6x\,e^{3x} + e^{3x} x^2 + 12\,e^{3x}$$

Summary

The solution(s) found are the following

$$y = e^{2x}\left(c_3 x^2 + c_2 x + c_1\right) + \frac{e^{2x} x^4}{24} - 6x\,e^{3x} + e^{3x} x^2 + 12\,e^{3x} \tag{1}$$

Verification of solutions

$$y = e^{2x}\left(c_3 x^2 + c_2 x + c_1\right) + \frac{e^{2x} x^4}{24} - 6x\,e^{3x} + e^{3x} x^2 + 12\,e^{3x}$$

Verified OK.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _linear, _nonhomogeneous]]
```

$$y'''' + 3y''' + 4y'' + 3y' + y = x^2 e^{-x} + 3\,e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 3y''' + 4y'' + 3y' + y = 0$$

The characteristic equation is

$$\lambda^4 + 3\lambda^3 + 4\lambda^2 + 3\lambda + 1 = 0$$

The roots of the above equation are

$$\begin{aligned}
\lambda_1 &= -\frac{1}{2}-\frac{i\sqrt{3}}{2} \\
\lambda_2 &= -\frac{1}{2}+\frac{i\sqrt{3}}{2} \\
\lambda_3 &= -1 \\
\lambda_4 &= -1
\end{aligned}$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 \mathrm{e}^{-x} + x\,\mathrm{e}^{-x} c_2 + \mathrm{e}^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_3 + \mathrm{e}^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned}
y_1 &= \mathrm{e}^{-x} \\
y_2 &= x\,\mathrm{e}^{-x} \\
y_3 &= \mathrm{e}^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} \\
y_4 &= \mathrm{e}^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x}
\end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' + 3y''' + 4y'' + 3y' + y = x^2 \mathrm{e}^{-x} + 3\,\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)}\, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 & y_4 \\ y_1' & y_2' & y_3' & y_4' \\ y_1'' & y_2'' & y_3'' & y_4'' \\ y_1''' & y_2''' & y_3''' & y_4''' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} e^{-x} & x\,e^{-x} & e^{-\frac{(1+i\sqrt{3})x}{2}} & e^{\frac{(i\sqrt{3}-1)x}{2}} \\ -e^{-x} & e^{-x}(1-x) & -\frac{(1+i\sqrt{3})e^{-\frac{(1+i\sqrt{3})x}{2}}}{2} & \frac{(i\sqrt{3}-1)e^{\frac{(i\sqrt{3}-1)x}{2}}}{2} \\ e^{-x} & e^{-x}(x-2) & \frac{(1+i\sqrt{3})^2 e^{-\frac{(1+i\sqrt{3})x}{2}}}{4} & \frac{(i\sqrt{3}-1)^2 e^{\frac{(i\sqrt{3}-1)x}{2}}}{4} \\ -e^{-x} & e^{-x}(-x+3) & e^{-\frac{(1+i\sqrt{3})x}{2}} & e^{\frac{(i\sqrt{3}-1)x}{2}} \end{bmatrix}$$

$$|W| = ie^{-2x}\sqrt{3}\,e^{\frac{(i\sqrt{3}-1)x}{2}}\,e^{-\frac{(1+i\sqrt{3})x}{2}}$$

The determinant simplifies to

$$|W| = i\sqrt{3}\,e^{-3x}$$

Now we determine W_i for each U_i.

$$\begin{aligned} W_1(x) &= \det\begin{bmatrix} x\,e^{-x} & e^{-\frac{(1+i\sqrt{3})x}{2}} & e^{\frac{(i\sqrt{3}-1)x}{2}} \\ e^{-x}(1-x) & -\frac{(1+i\sqrt{3})e^{-\frac{(1+i\sqrt{3})x}{2}}}{2} & \frac{(i\sqrt{3}-1)e^{\frac{(i\sqrt{3}-1)x}{2}}}{2} \\ e^{-x}(x-2) & \frac{(1+i\sqrt{3})^2 e^{-\frac{(1+i\sqrt{3})x}{2}}}{4} & \frac{(i\sqrt{3}-1)^2 e^{\frac{(i\sqrt{3}-1)x}{2}}}{4} \end{bmatrix} \\ &= i\sqrt{3}\,e^{-2x}(x-1) \end{aligned}$$

$$\begin{aligned} W_2(x) &= \det\begin{bmatrix} e^{-x} & e^{-\frac{(1+i\sqrt{3})x}{2}} & e^{\frac{(i\sqrt{3}-1)x}{2}} \\ -e^{-x} & -\frac{(1+i\sqrt{3})e^{-\frac{(1+i\sqrt{3})x}{2}}}{2} & \frac{(i\sqrt{3}-1)e^{\frac{(i\sqrt{3}-1)x}{2}}}{2} \\ e^{-x} & \frac{(1+i\sqrt{3})^2 e^{-\frac{(1+i\sqrt{3})x}{2}}}{4} & \frac{(i\sqrt{3}-1)^2 e^{\frac{(i\sqrt{3}-1)x}{2}}}{4} \end{bmatrix} \\ &= i\sqrt{3}\,e^{-2x} \end{aligned}$$

$$W_3(x) = \det \begin{bmatrix} e^{-x} & x\,e^{-x} & e^{\frac{\left(i\sqrt{3}-1\right)x}{2}} \\ -e^{-x} & e^{-x}(1-x) & \frac{\left(i\sqrt{3}-1\right)e^{\frac{\left(i\sqrt{3}-1\right)x}{2}}}{2} \\ e^{-x} & e^{-x}(x-2) & \frac{\left(i\sqrt{3}-1\right)^2 e^{\frac{\left(i\sqrt{3}-1\right)x}{2}}}{4} \end{bmatrix}$$

$$= \frac{e^{\frac{x\left(i\sqrt{3}-5\right)}{2}}\left(i\sqrt{3}-1\right)}{2}$$

$$W_4(x) = \det \begin{bmatrix} e^{-x} & x\,e^{-x} & e^{-\frac{\left(1+i\sqrt{3}\right)x}{2}} \\ -e^{-x} & e^{-x}(1-x) & -\frac{\left(1+i\sqrt{3}\right)e^{-\frac{\left(1+i\sqrt{3}\right)x}{2}}}{2} \\ e^{-x} & e^{-x}(x-2) & \frac{\left(1+i\sqrt{3}\right)^2 e^{-\frac{\left(1+i\sqrt{3}\right)x}{2}}}{4} \end{bmatrix}$$

$$= -\frac{e^{-\frac{x\left(i\sqrt{3}+5\right)}{2}}\left(1+i\sqrt{3}\right)}{2}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned}
U_1 &= (-1)^{4-1} \int \frac{F(x)W_1(x)}{aW(x)}\,dx \\
&= (-1)^3 \int \frac{\left(x^2 e^{-x} + 3\,e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)\right)\left(i\sqrt{3}\,e^{-2x}(x-1)\right)}{(1)\left(i\sqrt{3}\,e^{-3x}\right)}\,dx \\
&= -\int \frac{i\left(x^2 e^{-x} + 3\,e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)\right)\sqrt{3}\,e^{-2x}(x-1)}{i\sqrt{3}\,e^{-3x}}\,dx \\
&= -\int \left((x-1)\left(3\,e^{\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) + x^2\right)\right)dx \\
&= -3\left(\frac{x}{2}+\frac{1}{2}\right)e^{\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) + 3\left(-\frac{\sqrt{3}\,x}{2}+\frac{\sqrt{3}}{2}\right)e^{\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right) - \frac{x^4}{4} + \frac{3\,e^{\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{3\sqrt{3}\,e^{\ldots}}{\ldots} \\
&= -3\left(\frac{x}{2}+\frac{1}{2}\right)e^{\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) + 3\left(-\frac{\sqrt{3}\,x}{2}+\frac{\sqrt{3}}{2}\right)e^{\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right) - \frac{x^4}{4} + \frac{3\,e^{\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{3\sqrt{3}\,e^{\ldots}}{\ldots}
\end{aligned}$$

$$U_2 = (-1)^{4-2} \int \frac{F(x)W_2(x)}{aW(x)}\,dx$$

$$= (-1)^2 \int \frac{\left(x^2 e^{-x} + 3\,e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)\right)\left(i\sqrt{3}\,e^{-2x}\right)}{(1)\left(i\sqrt{3}\,e^{-3x}\right)}\,dx$$

$$= \int \frac{i\left(x^2 e^{-x} + 3\,e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)\right)\sqrt{3}\,e^{-2x}}{i\sqrt{3}\,e^{-3x}}\,dx$$

$$= \int \left(3\,e^{\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) + x^2\right)dx$$

$$= \frac{x^3}{3} + \frac{3\,e^{\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{3\sqrt{3}\,e^{\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2}$$

$$U_3 = (-1)^{4-3} \int \frac{F(x)W_3(x)}{aW(x)}\,dx$$

$$= (-1)^1 \int \frac{\left(x^2 e^{-x} + 3\,e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)\right)\left(\frac{e^{\frac{x\left(i\sqrt{3}-5\right)}{2}}\left(i\sqrt{3}-1\right)}{2}\right)}{(1)\left(i\sqrt{3}\,e^{-3x}\right)}\,dx$$

$$= -\int \frac{\frac{\left(x^2 e^{-x}+3\,e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)\right)e^{\frac{x\left(i\sqrt{3}-5\right)}{2}}\left(i\sqrt{3}-1\right)}{2}}{i\sqrt{3}\,e^{-3x}}\,dx$$

$$= -\int \left(\frac{\sqrt{3}\,e^{\frac{i\sqrt{3}\,x}{2}}\left(\sqrt{3}+i\right)\left(e^{-\frac{x}{2}}x^2 + 3\cos\left(\frac{\sqrt{3}\,x}{2}\right)\right)}{6}\right)dx$$

$$= -\frac{3x}{4} - \frac{i\sqrt{3}\,x}{4} + \frac{ie^{i\sqrt{3}\,x}\sqrt{3}}{4} - \frac{e^{i\sqrt{3}\,x}}{4} + \frac{\left(i\sqrt{3}\,x + i\sqrt{3} + x^2 + x - 1\right)\left(1 + i\sqrt{3}\right)\sqrt{3}\left(\sqrt{3}+i\right)e^{\frac{\left(i\sqrt{3}-1\right)x}{2}}}{12}$$

$$= -\frac{3x}{4} - \frac{i\sqrt{3}\,x}{4} + \frac{ie^{i\sqrt{3}\,x}\sqrt{3}}{4} - \frac{e^{i\sqrt{3}\,x}}{4} + \frac{\left(i\sqrt{3}\,x + i\sqrt{3} + x^2 + x - 1\right)\left(1 + i\sqrt{3}\right)\sqrt{3}\left(\sqrt{3}+i\right)e^{\frac{\left(i\sqrt{3}-1\right)x}{2}}}{12}$$

$$U_4 = (-1)^{4-4} \int \frac{F(x) W_4(x)}{a W(x)}\, dx$$

$$= (-1)^0 \int \frac{\left(x^2 \mathrm{e}^{-x} + 3\,\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)\right) \left(-\frac{\mathrm{e}^{-\frac{x\left(i\sqrt{3}+5\right)}{2}} \left(1+i\sqrt{3}\right)}{2}\right)}{(1)\left(i\sqrt{3}\,\mathrm{e}^{-3x}\right)}\, dx$$

$$= \int \frac{-\frac{\left(x^2 \mathrm{e}^{-x}+3\,\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)\right) \mathrm{e}^{-\frac{x\left(i\sqrt{3}+5\right)}{2}} \left(1+i\sqrt{3}\right)}{2}}{i\sqrt{3}\,\mathrm{e}^{-3x}}\, dx$$

$$= \int \left(-\frac{\sqrt{3}\,\mathrm{e}^{-\frac{i\sqrt{3}\,x}{2}} \left(-i+\sqrt{3}\right) \left(\mathrm{e}^{-\frac{x}{2}} x^2 + 3\cos\left(\frac{\sqrt{3}\,x}{2}\right)\right)}{6}\right) dx$$

$$= -\frac{\left(-i\sqrt{3}\,x - i\sqrt{3} + x^2 + x - 1\right)\left(i\sqrt{3}-1\right)\sqrt{3}\left(-i+\sqrt{3}\right)\mathrm{e}^{-\frac{\left(1+i\sqrt{3}\right)x}{2}}}{12} - \frac{3x}{4} + \frac{i\sqrt{3}\,x}{4} - \frac{i\mathrm{e}^{-i\sqrt{3}\,x}\sqrt{3}}{4} -$$

$$= -\frac{\left(-i\sqrt{3}\,x - i\sqrt{3} + x^2 + x - 1\right)\left(i\sqrt{3}-1\right)\sqrt{3}\left(-i+\sqrt{3}\right)\mathrm{e}^{-\frac{\left(1+i\sqrt{3}\right)x}{2}}}{12} - \frac{3x}{4} + \frac{i\sqrt{3}\,x}{4} - \frac{i\mathrm{e}^{-i\sqrt{3}\,x}\sqrt{3}}{4} -$$

Now that all the U_i functions have been determined, the particular solution is found from

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4$$

Hence

$$y_p = \left(-3\left(\frac{x}{2}+\frac{1}{2}\right)\mathrm{e}^{\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) + 3\left(-\frac{\sqrt{3}\,x}{2}+\frac{\sqrt{3}}{2}\right)\mathrm{e}^{\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right) - \frac{x^4}{4} + \frac{3\,\mathrm{e}^{\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{3\sqrt{3}}{}\right.$$

$$+ \left(\frac{x^3}{3} + \frac{3\,\mathrm{e}^{\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{3\sqrt{3}\,\mathrm{e}^{\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2}\right)\left(x\,\mathrm{e}^{-x}\right)$$

$$+ \left(-\frac{3x}{4} - \frac{i\sqrt{3}\,x}{4} + \frac{i\mathrm{e}^{i\sqrt{3}\,x}\sqrt{3}}{4} - \frac{\mathrm{e}^{i\sqrt{3}\,x}}{4} + \frac{\left(i\sqrt{3}\,x + i\sqrt{3} + x^2 + x - 1\right)\left(1+i\sqrt{3}\right)\sqrt{3}\left(\sqrt{3}+i\right)\mathrm{e}^{\frac{\left(i\sqrt{3}-1\right)x}{2}}}{12}\right.$$

$$+ \left(-\frac{\left(-i\sqrt{3}\,x - i\sqrt{3} + x^2 + x - 1\right)\left(i\sqrt{3}-1\right)\sqrt{3}\left(-i+\sqrt{3}\right)\mathrm{e}^{-\frac{\left(1+i\sqrt{3}\right)x}{2}}}{12} - \frac{3x}{4} + \frac{i\sqrt{3}\,x}{4} - \frac{i\mathrm{e}^{-i\sqrt{3}\,x}\sqrt{3}}{4}\right.$$

Therefore the particular solution is

$$y_p = \frac{(-3x-1)\,\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} - \frac{\sqrt{3}\,\mathrm{e}^{-\frac{x}{2}}(-5+x) \sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{\mathrm{e}^{-x}\left(x^4+4x^3-24x-24\right)}{12}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \mathrm{e}^{-x} + x\,\mathrm{e}^{-x} c_2 + \mathrm{e}^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_3 + \mathrm{e}^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_4\right) + \left(\frac{(-3x-1)\,\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2}\right. \\
&\quad \left. - \frac{\sqrt{3}\,\mathrm{e}^{-\frac{x}{2}}(-5+x)\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{\mathrm{e}^{-x}(x^4+4x^3-24x-24)}{12}\right)
\end{aligned}
$$

Which simplifies to

$$
\begin{aligned}
y &= \mathrm{e}^{-\frac{\left(1+i\sqrt{3}\right)x}{2}} c_3 + \mathrm{e}^{\frac{\left(i\sqrt{3}-1\right)x}{2}} c_4 + \mathrm{e}^{-x}(c_2 x + c_1) + \frac{(-3x-1)\,\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} \\
&\quad - \frac{\sqrt{3}\,\mathrm{e}^{-\frac{x}{2}}(-5+x)\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{\mathrm{e}^{-x}(x^4+4x^3-24x-24)}{12}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= \mathrm{e}^{-\frac{\left(1+i\sqrt{3}\right)x}{2}} c_3 + \mathrm{e}^{\frac{\left(i\sqrt{3}-1\right)x}{2}} c_4 + \mathrm{e}^{-x}(c_2 x + c_1) + \frac{(-3x-1)\,\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} \\
&\quad - \frac{\sqrt{3}\,\mathrm{e}^{-\frac{x}{2}}(-5+x)\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{\mathrm{e}^{-x}(x^4+4x^3-24x-24)}{12}
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= \mathrm{e}^{-\frac{\left(1+i\sqrt{3}\right)x}{2}} c_3 + \mathrm{e}^{\frac{\left(i\sqrt{3}-1\right)x}{2}} c_4 + \mathrm{e}^{-x}(c_2 x + c_1) + \frac{(-3x-1)\,\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} \\
&\quad - \frac{\sqrt{3}\,\mathrm{e}^{-\frac{x}{2}}(-5+x)\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{\mathrm{e}^{-x}(x^4+4x^3-24x-24)}{12}
\end{aligned}
$$

Verified OK.

11.48.1 Maple step by step solution

Let's solve

$y'''' + 3y''' + 4y'' + 3y' + y = x^2 e^{-x} + 3\,e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)$

- Highest derivative means the order of the ODE is 4

  y''''

□ Convert linear ODE into a system of first order ODEs

  ○ Define new variable $y_1(x)$

  $y_1(x) = y$

  ○ Define new variable $y_2(x)$

  $y_2(x) = y'$

  ○ Define new variable $y_3(x)$

  $y_3(x) = y''$

  ○ Define new variable $y_4(x)$

  $y_4(x) = y'''$

  ○ Isolate for $y_4'(x)$ using original ODE

  $y_4'(x) = x^2 e^{-x} + 3\,e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) - 4y_3(x) - 3y_2(x) - y_1(x) - 3y_4(x)$

  Convert linear ODE into a system of first order ODEs

  $\left[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = x^2 e^{-x} + 3\,e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) - 4y_3(x) - 3y_2(\right.$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\overrightarrow{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & -3 & -4 & -3 \end{bmatrix} \cdot \overrightarrow{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ x^2 \mathrm{e}^{-x} + 3\,\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) \end{bmatrix}$$

- Define the forcing function

$$\overrightarrow{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 0 \\ x^2 \mathrm{e}^{-x} + 3\,\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & -3 & -4 & -3 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{y}'(x) = A \cdot \overrightarrow{y}(x) + \overrightarrow{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[-1, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[-\frac{1}{2} - \frac{\mathrm{I}\sqrt{3}}{2}, \begin{bmatrix} \frac{1}{\left(-\frac{1}{2} - \frac{\mathrm{I}\sqrt{3}}{2}\right)^3} \\ \frac{1}{\left(-\frac{1}{2} - \frac{\mathrm{I}\sqrt{3}}{2}\right)^2} \\ \frac{1}{-\frac{1}{2} - \frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{bmatrix}\right], \left[-\frac{1}{2} + \frac{\mathrm{I}\sqrt{3}}{2}, \begin{bmatrix} \frac{1}{\left(-\frac{1}{2} + \frac{\mathrm{I}\sqrt{3}}{2}\right)^3} \\ \frac{1}{\left(-\frac{1}{2} + \frac{\mathrm{I}\sqrt{3}}{2}\right)^2} \\ \frac{1}{-\frac{1}{2} + \frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[-1, \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]\right]$$

- First solution from eigenvalue -1

$$\overrightarrow{y}_1(x) = \mathrm{e}^{-x} \cdot \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]$$

- Form of the 2nd homogeneous solution where $\overrightarrow{p}$ is to be solved for, $\lambda = -1$ is the eigenvalue, a

$$\overrightarrow{y}_2(x) = \mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Note that the x multiplying $\overrightarrow{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\overrightarrow{y}_2(x)$ into the homogeneous system

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda x}\overrightarrow{v} = \left(\mathrm{e}^{\lambda x} A\right) \cdot \left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Use the fact that $\overrightarrow{v}$ is an eigenvector of A

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda x}\overrightarrow{v} = \mathrm{e}^{\lambda x}\left(\lambda x\overrightarrow{v} + A \cdot \overrightarrow{p}\right)$$

- Simplify equation

$$\lambda\overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$$

- Make use of the identity matrix I

$$(\lambda \cdot I) \cdot \overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$$

- Condition $\overrightarrow{p}$ must meet for $\overrightarrow{y}_2(x)$ to be a solution to the homogeneous system

$$(A - \lambda \cdot I) \cdot \overrightarrow{p} = \overrightarrow{v}$$

- Choose $\overrightarrow{p}$ to use in the second solution to the homogeneous system from eigenvalue -1

$$\left(\left[\begin{array}{cccc} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & -3 & -4 & -3 \end{array}\right] - (-1) \cdot \left[\begin{array}{cccc} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{array}\right]\right) \cdot \overrightarrow{p} = \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]$$

- Choice of $\overrightarrow{p}$

$$\vec{p} = \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue -1

$$\vec{y}_2(x) = \mathrm{e}^{-x} \cdot \left(x \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right)$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\frac{1}{2} - \frac{\mathrm{I}\sqrt{3}}{2}, \begin{bmatrix} \frac{1}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^3} \\ \frac{1}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^2} \\ \frac{1}{-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$\mathrm{e}^{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)x} \cdot \begin{bmatrix} \frac{1}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^3} \\ \frac{1}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^2} \\ \frac{1}{-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$\mathrm{e}^{-\frac{x}{2}} \cdot \left(\cos\left(\frac{\sqrt{3}\,x}{2}\right) - \mathrm{I}\sin\left(\frac{\sqrt{3}\,x}{2}\right)\right) \cdot \begin{bmatrix} \frac{1}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^3} \\ \frac{1}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^2} \\ \frac{1}{-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{bmatrix}$$

- Simplify expression

$$e^{-\frac{x}{2}}\cdot\left[\begin{array}{c}\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)-\mathrm{I}\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^{3}}\\ \frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)-\mathrm{I}\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^{2}}\\ \frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)-\mathrm{I}\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}}\\ \cos\left(\frac{\sqrt{3}\,x}{2}\right)-\mathrm{I}\sin\left(\frac{\sqrt{3}\,x}{2}\right)\end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_{3}(x)=e^{-\frac{x}{2}}\cdot\left[\begin{array}{c}\cos\left(\frac{\sqrt{3}\,x}{2}\right)\\ -\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2}-\frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2}\\ \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2}-\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2}\\ \cos\left(\frac{\sqrt{3}\,x}{2}\right)\end{array}\right],\vec{y}_{4}(x)=e^{-\frac{x}{2}}\cdot\left[\begin{array}{c}-\sin\left(\frac{\sqrt{3}\,x}{2}\right)\\ -\frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2}+\frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2}\\ \frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2}+\frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2}\\ -\sin\left(\frac{\sqrt{3}\,x}{2}\right)\end{array}\right]\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x)=c_1\vec{y}_1(x)+c_2\vec{y}_2(x)+c_3\vec{y}_3(x)+c_4\vec{y}_4(x)+\vec{y}_p(x)$

☐ Fundamental matrix

  - Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x)=\left[\begin{array}{cccc}-e^{-x} & e^{-x}(-x-1) & e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right) & -e^{-\frac{x}{2}}\sin\left(\frac{\sqrt{3}\,x}{2}\right)\\ e^{-x} & x\,e^{-x} & e^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2}-\frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2}\right) & e^{-\frac{x}{2}}\left(-\frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2}+\frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2}\right)\\ -e^{-x} & -x\,e^{-x} & e^{-\frac{x}{2}}\left(\frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2}-\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2}\right) & e^{-\frac{x}{2}}\left(\frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2}+\frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2}\right)\\ e^{-x} & x\,e^{-x} & e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right) & -e^{-\frac{x}{2}}\sin\left(\frac{\sqrt{3}\,x}{2}\right)\end{array}\right.$$

  - The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0)=I$ where I is t

$\Phi(x)=\phi(x)\cdot\frac{1}{\phi(0)}$

  - Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} -e^{-x} & e^{-x}(-x-1) & e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right) & -e^{-\frac{x}{2}}\sin\left(\frac{\sqrt{3}\,x}{2}\right) \\ e^{-x} & x\,e^{-x} & e^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} - \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2}\right) & e^{-\frac{x}{2}}\left(-\frac{\sqrt{3}\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2}\right) \\ -e^{-x} & -x\,e^{-x} & e^{-\frac{x}{2}}\left(\frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2} - \frac{\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2}\right) & e^{-\frac{x}{2}}\left(\frac{\sqrt{3}\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2}\right) \\ e^{-x} & x\,e^{-x} & e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right) & -e^{-\frac{x}{2}}\sin\left(\frac{\sqrt{3}\,x}{2}\right) \end{bmatrix}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} (1+x)\,e^{-x} & -\frac{e^{-\frac{x}{2}}\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{3} + 2x\,e^{-x} - e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right) + e^{-x} & -e^{-\frac{x}{2}}\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3} + \\ -x\,e^{-x} & \frac{2\,e^{-\frac{x}{2}}\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{3} - 2x\,e^{-x} + e^{-x} & -e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right) + e^{-} \\ x\,e^{-x} & e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right) - \frac{e^{-\frac{x}{2}}\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{3} + e^{-x}(2x-1) & 2\,e^{-\frac{x}{2}}\cos\Big(\\ -x\,e^{-x} & e^{-x} - 2x\,e^{-x} - e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right) - \frac{e^{-\frac{x}{2}}\sin\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{3} & e^{-x} - 2x\,e^{-x} - e^{-\frac{x}{2}}\,\mathrm{c} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$
- Take the derivative of the particular solution

  $\vec{y}'_p(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$
- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$
- Integrate to solve for $\vec{v}(x)$

$\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\,ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\,ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \left[\begin{array}{c} -\sqrt{3}\,e^{-\frac{x}{2}}\left(x-\frac{17}{6}\right)\sin\left(\frac{\sqrt{3}\,x}{2}\right)-\frac{3\,e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2}+\frac{e^{-x}(x^4-12x^2-42x+18)}{12} \\ \frac{(-3x+10)e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2}+\frac{\sqrt{3}\,e^{-\frac{x}{2}}\left(x-\frac{10}{3}\right)\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2}-\frac{e^{-x}(x^4-4x^3-12x^2-18x+60)}{12} \\ \frac{(3x-10)e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2}+\frac{\left(x+\frac{2}{3}\right)\sqrt{3}\,e^{-\frac{x}{2}}\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2}+\frac{e^{-x}(x^4-4x^3+6x+60)}{12} \\ -\sqrt{3}\,e^{-\frac{x}{2}}\left(x-\frac{4}{3}\right)\sin\left(\frac{\sqrt{3}\,x}{2}\right)+3\,e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right)-\frac{e^{-x}(x^4-4x^3+12x^2+6x+36)}{12} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1(x)+c_2\vec{y}_2(x)+c_3\vec{y}_3(x)+c_4\vec{y}_4(x)+\left[\begin{array}{c} -\sqrt{3}\,e^{-\frac{x}{2}}\left(x-\frac{17}{6}\right)\sin\left(\frac{\sqrt{3}\,x}{2}\right)-\frac{3\,e^{-\frac{x}{2}}\cos\left(\right.}{2} \\ \frac{(-3x+10)e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2}+\frac{\sqrt{3}\,e^{-\frac{x}{2}}\left(x-\frac{10}{3}\right)\sin\left(\frac{\sqrt{3}\,x}{2}\right.}{2} \\ \frac{(3x-10)e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2}+\frac{\left(x+\frac{2}{3}\right)\sqrt{3}\,e^{-\frac{x}{2}}\sin\left(\right.}{2} \\ -\sqrt{3}\,e^{-\frac{x}{2}}\left(x-\frac{4}{3}\right)\sin\left(\frac{\sqrt{3}\,x}{2}\right)+3\,e^{-\frac{x}{2}}\cos\left(\right. \end{array}\right.$$

- First component of the vector is the solution to the ODE

$$y = -\left(\left(x-\frac{17}{6}\right)\sqrt{3}+c_4\right)e^{-\frac{x}{2}}\sin\left(\frac{\sqrt{3}\,x}{2}\right)+\frac{(12c_3-18)e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right)}{12}+\frac{(x^4-12x^2+(-12c_2-42)x-12c_1-12c_2+18}{12}$$

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'''' - 16y = x^2 \sin(2x) + e^{2x}x^4}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - 16y = 0$$

The characteristic equation is

$$\lambda^4 - 16 = 0$$

The roots of the above equation are

$$\lambda_1 = 2$$
$$\lambda_2 = -2$$
$$\lambda_3 = 2i$$
$$\lambda_4 = -2i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-2x} + c_2 e^{2x} + e^{2ix} c_3 + e^{-2ix} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= e^{-2x} \\ y_2 &= e^{2x} \\ y_3 &= e^{2ix} \\ y_4 &= e^{-2ix} \end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' - 16y = x^2 \sin(2x) + e^{2x} x^4$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)} \, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 & y_4 \\ y_1' & y_2' & y_3' & y_4' \\ y_1'' & y_2'' & y_3'' & y_4'' \\ y_1''' & y_2''' & y_3''' & y_4''' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} e^{-2x} & e^{2x} & e^{2ix} & e^{-2ix} \\ -2 e^{-2x} & 2 e^{2x} & 2i e^{2ix} & -2i e^{-2ix} \\ 4 e^{-2x} & 4 e^{2x} & -4 e^{2ix} & -4 e^{-2ix} \\ -8 e^{-2x} & 8 e^{2x} & -8i e^{2ix} & 8i e^{-2ix} \end{bmatrix}$$

$$|W| = -1024i e^{-2x} e^{2x} e^{2ix} e^{-2ix}$$

The determinant simplifies to

$$|W| = -1024i$$

Now we determine W_i for each U_i.

$$\begin{aligned} W_1(x) &= \det \begin{bmatrix} e^{2x} & e^{2ix} & e^{-2ix} \\ 2\,e^{2x} & 2ie^{2ix} & -2ie^{-2ix} \\ 4\,e^{2x} & -4\,e^{2ix} & -4\,e^{-2ix} \end{bmatrix} \\ &= -32ie^{2x} \end{aligned}$$

$$\begin{aligned} W_2(x) &= \det \begin{bmatrix} e^{-2x} & e^{2ix} & e^{-2ix} \\ -2\,e^{-2x} & 2ie^{2ix} & -2ie^{-2ix} \\ 4\,e^{-2x} & -4\,e^{2ix} & -4\,e^{-2ix} \end{bmatrix} \\ &= -32ie^{-2x} \end{aligned}$$

$$\begin{aligned} W_3(x) &= \det \begin{bmatrix} e^{-2x} & e^{2x} & e^{-2ix} \\ -2\,e^{-2x} & 2\,e^{2x} & -2ie^{-2ix} \\ 4\,e^{-2x} & 4\,e^{2x} & -4\,e^{-2ix} \end{bmatrix} \\ &= -32\,e^{-2ix} \end{aligned}$$

$$\begin{aligned} W_4(x) &= \det \begin{bmatrix} e^{-2x} & e^{2x} & e^{2ix} \\ -2\,e^{-2x} & 2\,e^{2x} & 2ie^{2ix} \\ 4\,e^{-2x} & 4\,e^{2x} & -4\,e^{2ix} \end{bmatrix} \\ &= -32\,e^{2ix} \end{aligned}$$

Now we are ready to evaluate each $U_i(x)$.

$$
\begin{aligned}
U_1 &= (-1)^{4-1} \int \frac{F(x)W_1(x)}{aW(x)}\, dx \\
&= (-1)^3 \int \frac{\left(x^2 \sin(2x) + \mathrm{e}^{2x} x^4\right)\left(-32i\mathrm{e}^{2x}\right)}{(1)\,(-1024i)}\, dx \\
&= -\int \frac{-32i(x^2 \sin(2x) + \mathrm{e}^{2x} x^4)\, \mathrm{e}^{2x}}{-1024i}\, dx \\
&= -\int \left(\frac{x^2(x^2\mathrm{e}^{2x} + \sin(2x))\, \mathrm{e}^{2x}}{32}\right) dx \\
&= -\frac{x^4\mathrm{e}^{4x}}{128} + \frac{x^3\mathrm{e}^{4x}}{128} - \frac{3x^2\mathrm{e}^{4x}}{512} + \frac{3x\,\mathrm{e}^{4x}}{1024} - \frac{3\,\mathrm{e}^{4x}}{4096} - \frac{\left(-2x^2 + 2x - \frac{1}{2}\right)\mathrm{e}^{2x}\cos(2x)}{256} - \frac{\left(2x^2 - \frac{1}{2}\right)\mathrm{e}^{2x}\sin(2x)}{256} \\
&= -\frac{x^4\mathrm{e}^{4x}}{128} + \frac{x^3\mathrm{e}^{4x}}{128} - \frac{3x^2\mathrm{e}^{4x}}{512} + \frac{3x\,\mathrm{e}^{4x}}{1024} - \frac{3\,\mathrm{e}^{4x}}{4096} - \frac{\left(-2x^2 + 2x - \frac{1}{2}\right)\mathrm{e}^{2x}\cos(2x)}{256} - \frac{\left(2x^2 - \frac{1}{2}\right)\mathrm{e}^{2x}\sin(2x)}{256}
\end{aligned}
$$

$$
\begin{aligned}
U_2 &= (-1)^{4-2} \int \frac{F(x)W_2(x)}{aW(x)}\, dx \\
&= (-1)^2 \int \frac{\left(x^2 \sin(2x) + \mathrm{e}^{2x} x^4\right)\left(-32i\mathrm{e}^{-2x}\right)}{(1)\,(-1024i)}\, dx \\
&= \int \frac{-32i(x^2 \sin(2x) + \mathrm{e}^{2x} x^4)\, \mathrm{e}^{-2x}}{-1024i}\, dx \\
&= \int \left(\frac{x^2(x^2 + \mathrm{e}^{-2x}\sin(2x))}{32}\right) dx \\
&= \frac{x^5}{160} + \frac{\left(-\frac{1}{4}x^2 - \frac{1}{4}x - \frac{1}{16}\right)\mathrm{e}^{-2x}\cos(2x)}{32} + \frac{\left(-\frac{x^2}{4} + \frac{1}{16}\right)\mathrm{e}^{-2x}\sin(2x)}{32} \\
&= \frac{x^5}{160} + \frac{\left(-\frac{1}{4}x^2 - \frac{1}{4}x - \frac{1}{16}\right)\mathrm{e}^{-2x}\cos(2x)}{32} + \frac{\left(-\frac{x^2}{4} + \frac{1}{16}\right)\mathrm{e}^{-2x}\sin(2x)}{32}
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{4-3} \int \frac{F(x)W_3(x)}{aW(x)}\, dx \\
&= (-1)^1 \int \frac{\left(x^2 \sin\left(2x\right) + \mathrm{e}^{2x} x^4\right)\left(-32\,\mathrm{e}^{-2ix}\right)}{(1)\left(-1024i\right)}\, dx \\
&= -\int \frac{-32(x^2 \sin\left(2x\right) + \mathrm{e}^{2x} x^4)\,\mathrm{e}^{-2ix}}{-1024i}\, dx \\
&= -\int \left(-\frac{ix^2(x^2 \mathrm{e}^{2x} + \sin\left(2x\right))\,\mathrm{e}^{-2ix}}{32}\right) dx \\
&= \left(-\frac{1}{1024} + \frac{i}{1024}\right)\left(8x^4 - 8ix^3 - 8x^3 + 12ix^2 - 6ix + 6x - 3\right)\mathrm{e}^{(2-2i)x} + \frac{x^3}{192} - \frac{i(8x^2 - 4ix - 1)\,\mathrm{e}^{-4}}{2048} \\
&= \left(-\frac{1}{1024} + \frac{i}{1024}\right)\left(8x^4 - 8ix^3 - 8x^3 + 12ix^2 - 6ix + 6x - 3\right)\mathrm{e}^{(2-2i)x} + \frac{x^3}{192} - \frac{i(8x^2 - 4ix - 1)\,\mathrm{e}^{-4}}{2048}
\end{aligned}
$$

$$
\begin{aligned}
U_4 &= (-1)^{4-4} \int \frac{F(x)W_4(x)}{aW(x)}\, dx \\
&= (-1)^0 \int \frac{\left(x^2 \sin\left(2x\right) + \mathrm{e}^{2x} x^4\right)\left(-32\,\mathrm{e}^{2ix}\right)}{(1)\left(-1024i\right)}\, dx \\
&= \int \frac{-32(x^2 \sin\left(2x\right) + \mathrm{e}^{2x} x^4)\,\mathrm{e}^{2ix}}{-1024i}\, dx \\
&= \int \left(-\frac{ix^2(x^2 \mathrm{e}^{2x} + \sin\left(2x\right))\,\mathrm{e}^{2ix}}{32}\right) dx \\
&= \frac{x^3}{192} - \frac{i\left(\frac{1}{64} - \frac{1}{16}ix - \frac{1}{8}x^2\right)\mathrm{e}^{4ix}}{32} + \left(-\frac{1}{1024} - \frac{i}{1024}\right)\left(8x^4 + 8ix^3 - 8x^3 - 12ix^2 + 6ix + 6x - 3\right)\mathrm{e}^{(2+} \\
&= \frac{x^3}{192} - \frac{i\left(\frac{1}{64} - \frac{1}{16}ix - \frac{1}{8}x^2\right)\mathrm{e}^{4ix}}{32} + \left(-\frac{1}{1024} - \frac{i}{1024}\right)\left(8x^4 + 8ix^3 - 8x^3 - 12ix^2 + 6ix + 6x - 3\right)\mathrm{e}^{(2+}
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4
$$

Hence

$$y_p = \left(-\frac{x^4 e^{4x}}{128} + \frac{x^3 e^{4x}}{128} - \frac{3x^2 e^{4x}}{512} + \frac{3x\, e^{4x}}{1024} - \frac{3\, e^{4x}}{4096} - \frac{\left(-2x^2 + 2x - \frac{1}{2}\right) e^{2x} \cos(2x)}{256} - \frac{\left(2x^2 - \frac{1}{2}\right) e^{2x} \sin(2x)}{256}\right.$$
$$+ \left(\frac{x^5}{160} + \frac{\left(-\frac{1}{4}x^2 - \frac{1}{4}x - \frac{1}{16}\right) e^{-2x} \cos(2x)}{32} + \frac{\left(-\frac{x^2}{4} + \frac{1}{16}\right) e^{-2x} \sin(2x)}{32}\right) \left(e^{2x}\right)$$
$$+ \left(\left(-\frac{1}{1024} + \frac{i}{1024}\right) \left(8x^4 - 8ix^3 - 8x^3 + 12ix^2 - 6ix + 6x - 3\right) e^{(2-2i)x} + \frac{x^3}{192} - \frac{i(8x^2 - 4ix - 1)\, e^{-}}{2048}\right.$$
$$+ \left(\frac{x^3}{192} - \frac{i\left(\frac{1}{64} - \frac{1}{16}ix - \frac{1}{8}x^2\right) e^{4ix}}{32} + \left(-\frac{1}{1024} - \frac{i}{1024}\right) \left(8x^4 + 8ix^3 - 8x^3 - 12ix^2 + 6ix + 6x - 3\right) e^{(2}\right.$$

Therefore the particular solution is

$$y_p = \frac{(128x^5 - 480x^4 + 800x^3 - 600x^2 + 60x + 105)\, e^{2x}}{20480} + \frac{(8x^3 - 15x)\cos(2x)}{768} + \frac{(-24x^2 + 5)\sin(2x)}{1024}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-2x} + c_2 e^{2x} + e^{2ix} c_3 + e^{-2ix} c_4\right) \\ &\quad + \left(\frac{(128x^5 - 480x^4 + 800x^3 - 600x^2 + 60x + 105)\, e^{2x}}{20480} + \frac{(8x^3 - 15x)\cos(2x)}{768} \right. \\ &\quad \left. + \frac{(-24x^2 + 5)\sin(2x)}{1024}\right) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$\begin{aligned} y = {} & c_1 e^{-2x} + c_2 e^{2x} + e^{2ix} c_3 + e^{-2ix} c_4 \\ & + \frac{(128x^5 - 480x^4 + 800x^3 - 600x^2 + 60x + 105)\, e^{2x}}{20480} \\ & + \frac{(8x^3 - 15x)\cos(2x)}{768} + \frac{(-24x^2 + 5)\sin(2x)}{1024} \end{aligned} \tag{1}$$

<u>Verification of solutions</u>

$$y = c_1 e^{-2x} + c_2 e^{2x} + e^{2ix} c_3 + e^{-2ix} c_4 + \frac{(128x^5 - 480x^4 + 800x^3 - 600x^2 + 60x + 105)\, e^{2x}}{20480} + \frac{(8x^3 - 15x)\cos(2x)}{768} + \frac{(-24x^2 + 5)\sin(2x)}{1024}$$

Verified OK.

11.49.1 Maple step by step solution

Let's solve

$y'''' - 16y = x^2 \sin(2x) + e^{2x}x^4$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Define new variable $y_4(x)$

    $y_4(x) = y'''$
  - Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = e^{2x}x^4 + x^2 \sin(2x) + 16y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = e^{2x}x^4 + x^2 \sin(2x) + 16y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 16 & 0 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ x^2 \sin(2x) + e^{2x}x^4 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 0 \\ x^2 \sin(2x) + e^{2x} x^4 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 16 & 0 & 0 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2, \begin{bmatrix} -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}\right], \left[2, \begin{bmatrix} \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right], \left[-2\,\mathrm{I}, \begin{bmatrix} -\frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right], \left[2\,\mathrm{I}, \begin{bmatrix} \frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ -\frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-2, \begin{bmatrix} -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = e^{-2x} \cdot \begin{bmatrix} -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[2, \left[\begin{array}{c} \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_2 = e^{2x} \cdot \left[\begin{array}{c} \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-2\,\mathrm{I}, \left[\begin{array}{c} -\frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$e^{-2\,\mathrm{I}x} \cdot \left[\begin{array}{c} -\frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(2x) - \mathrm{I}\sin(2x)) \cdot \left[\begin{array}{c} -\frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{array}\right]$$

- Simplify expression

$$\begin{bmatrix} -\frac{I}{8}(\cos(2x) - I\sin(2x)) \\ -\frac{\cos(2x)}{4} + \frac{I\sin(2x)}{4} \\ \frac{I}{2}(\cos(2x) - I\sin(2x)) \\ \cos(2x) - I\sin(2x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \begin{bmatrix} -\frac{\sin(2x)}{8} \\ -\frac{\cos(2x)}{4} \\ \frac{\sin(2x)}{2} \\ \cos(2x) \end{bmatrix}, \vec{y}_4(x) = \begin{bmatrix} -\frac{\cos(2x)}{8} \\ \frac{\sin(2x)}{4} \\ \frac{\cos(2x)}{2} \\ -\sin(2x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} -\frac{e^{-2x}}{8} & \frac{e^{2x}}{8} & -\frac{\sin(2x)}{8} & -\frac{\cos(2x)}{8} \\ \frac{e^{-2x}}{4} & \frac{e^{2x}}{4} & -\frac{\cos(2x)}{4} & \frac{\sin(2x)}{4} \\ -\frac{e^{-2x}}{2} & \frac{e^{2x}}{2} & \frac{\sin(2x)}{2} & \frac{\cos(2x)}{2} \\ e^{-2x} & e^{2x} & \cos(2x) & -\sin(2x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} -\frac{e^{-2x}}{8} & \frac{e^{2x}}{8} & -\frac{\sin(2x)}{8} & -\frac{\cos(2x)}{8} \\ \frac{e^{-2x}}{4} & \frac{e^{2x}}{4} & -\frac{\cos(2x)}{4} & \frac{\sin(2x)}{4} \\ -\frac{e^{-2x}}{2} & \frac{e^{2x}}{2} & \frac{\sin(2x)}{2} & \frac{\cos(2x)}{2} \\ e^{-2x} & e^{2x} & \cos(2x) & -\sin(2x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -\frac{1}{8} & \frac{1}{8} & 0 & -\frac{1}{8} \\ \frac{1}{4} & \frac{1}{4} & -\frac{1}{4} & 0 \\ -\frac{1}{2} & \frac{1}{2} & 0 & \frac{1}{2} \\ 1 & 1 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} \frac{e^{-2x}}{4} + \frac{e^{2x}}{4} + \frac{\cos(2x)}{2} & -\frac{e^{-2x}}{8} + \frac{e^{2x}}{8} + \frac{\sin(2x)}{4} & \frac{e^{-2x}}{16} + \frac{e^{2x}}{16} - \frac{\cos(2x)}{8} & -\frac{e^{-2x}}{32} + \\ -\frac{e^{-2x}}{2} + \frac{e^{2x}}{2} - \sin(2x) & \frac{e^{-2x}}{4} + \frac{e^{2x}}{4} + \frac{\cos(2x)}{2} & -\frac{e^{-2x}}{8} + \frac{e^{2x}}{8} + \frac{\sin(2x)}{4} & \frac{e^{-2x}}{16} + \\ e^{-2x} + e^{2x} - 2\cos(2x) & -\frac{e^{-2x}}{2} + \frac{e^{2x}}{2} - \sin(2x) & \frac{e^{-2x}}{4} + \frac{e^{2x}}{4} + \frac{\cos(2x)}{2} & -\frac{e^{-2x}}{8} + \\ -2e^{-2x} + 2e^{2x} + 4\sin(2x) & e^{-2x} + e^{2x} - 2\cos(2x) & -\frac{e^{-2x}}{2} + \frac{e^{2x}}{2} - \sin(2x) & \frac{e^{-2x}}{4} + \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}'_p(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \begin{bmatrix} \frac{3}{512} + \frac{(128x^5 - 480x^4 + 800x^3 - 600x^2 + 60x + 145) e^{2x}}{20480} - \frac{5 e^{-2x}}{4096} + \frac{(16x^3 - 30x - 9)\cos(x)^2}{768} - \frac{3x^2 \cos(x)\sin(\ldots}{64} \\ \frac{5}{256} + \frac{(128x^5 - 160x^4 - 160x^3 + 600x^2 - 540x + 175) e^{2x}}{10240} + \frac{5 e^{-2x}}{2048} + \frac{(-4x^2 - 5)\cos(x)^2}{128} + \frac{(-16x^3 - 6x + 9)\sin\ldots}{384} \\ -\frac{3}{128} + \frac{(128x^5 + 160x^4 - 480x^3 + 360x^2 + 60x - 95) e^{2x}}{5120} - \frac{5 e^{-2x}}{1024} + \frac{(-16x^3 - 18x + 9)\cos(x)^2}{192} + \frac{(-x^2 + 1)\sin(x)\ldots}{16} \\ -\frac{1}{64} + \frac{(128x^5 + 480x^4 - 160x^3 - 360x^2 + 420x - 65) e^{2x}}{2560} + \frac{5 e^{-2x}}{512} + \frac{(-12x^2 + 1)\cos(x)^2}{32} + \frac{(16x^3 + 6x - 9)\sin\ldots}{96} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3(x) + c_4 \vec{y}_4(x) + \left[\begin{array}{c} \frac{3}{512} + \frac{(128x^5-480x^4+800x^3-600x^2+60x+145)\,\mathrm{e}^{2x}}{20480} - \frac{5\,\mathrm{e}^{-2}}{4096} \\ \frac{5}{256} + \frac{(128x^5-160x^4-160x^3+600x^2-540x+175)\,\mathrm{e}^{2x}}{10240} + \frac{5\,\mathrm{e}^{-}}{204} \\ -\frac{3}{128} + \frac{(128x^5+160x^4-480x^3+360x^2+60x-95)\,\mathrm{e}^{2x}}{5120} - \frac{5\,\mathrm{e}^{-2x}}{1024} \\ -\frac{1}{64} + \frac{(128x^5+480x^4-160x^3-360x^2+420x-65)\,\mathrm{e}^{2x}}{2560} + \frac{5\,\mathrm{e}^{-}}{512} \end{array}\right.$$

- First component of the vector is the solution to the ODE

$$y = \frac{3}{512} + \frac{(128x^5-480x^4+800x^3-600x^2+2560c_2+60x+145)\,\mathrm{e}^{2x}}{20480} + \frac{(-5-512c_1)\,\mathrm{e}^{-2x}}{4096} + \frac{(16x^3-192c_4-30x-9)\cos(x)^2}{768} - \frac{3\,\mathrm{s}}{}$$

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_high_order, _missing_y]]`

$$\boxed{y^{(6)} + 2y^{(5)} + 5y'''' = x^3 + x^2 \mathrm{e}^{-x} + \mathrm{e}^{-x} \sin(2x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y^{(6)} + 2y^{(5)} + 5y'''' = 0$$

The characteristic equation is

$$\lambda^6 + 2\lambda^5 + 5\lambda^4 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$
$$\lambda_4 = 0$$
$$\lambda_5 = -1 + 2i$$
$$\lambda_6 = -1 - 2i$$

Therefore the homogeneous solution is

$$y_h(x) = x^3 c_4 + c_3 x^2 + c_2 x + c_1 + e^{(-1-2i)x} c_5 + e^{(-1+2i)x} c_6$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= 1 \\ y_2 &= x \\ y_3 &= x^2 \\ y_4 &= x^3 \\ y_5 &= e^{(-1-2i)x} \\ y_6 &= e^{(-1+2i)x} \end{aligned}$$

Now the particular solution to the given ODE is found

$$y^{(6)} + 2y^{(5)} + 5y'''' = x^3 + x^2 e^{-x} + e^{-x} \sin(2x)$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4 + U_5 y_5 + U_6 y_6$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)} \, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 & y_4 & y_5 & y_6 \\ y_1' & y_2' & y_3' & y_4' & y_5' & y_6' \\ y_1'' & y_2'' & y_3'' & y_4'' & y_5'' & y_6'' \\ y_1''' & y_2''' & y_3''' & y_4''' & y_5''' & y_6''' \\ y_1'''' & y_2'''' & y_3'''' & y_4'''' & y_5'''' & y_6'''' \\ y_1''''' & y_2''''' & y_3''''' & y_4''''' & y_5''''' & y_6''''' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} 1 & x & x^2 & x^3 & e^{(-1-2i)x} & e^{(-1+2i)x} \\ 0 & 1 & 2x & 3x^2 & (-1-2i)\,e^{(-1-2i)x} & (-1+2i)\,e^{(-1+2i)x} \\ 0 & 0 & 2 & 6x & (-3+4i)\,e^{(-1-2i)x} & (-3-4i)\,e^{(-1+2i)x} \\ 0 & 0 & 0 & 6 & (11+2i)\,e^{(-1-2i)x} & (11-2i)\,e^{(-1+2i)x} \\ 0 & 0 & 0 & 0 & (-7-24i)\,e^{(-1-2i)x} & (-7+24i)\,e^{(-1+2i)x} \\ 0 & 0 & 0 & 0 & (-41+38i)\,e^{(-1-2i)x} & (-41-38i)\,e^{(-1+2i)x} \end{bmatrix}$$

$$|W| = 30000i e^{(-1-2i)x} e^{(-1+2i)x}$$

The determinant simplifies to

$$|W| = 30000i e^{-2x}$$

Now we determine W_i for each U_i.

$$W_1(x) = \det \begin{bmatrix} x & x^2 & x^3 & e^{(-1-2i)x} & e^{(-1+2i)x} \\ 1 & 2x & 3x^2 & (-1-2i)\,e^{(-1-2i)x} & (-1+2i)\,e^{(-1+2i)x} \\ 0 & 2 & 6x & (-3+4i)\,e^{(-1-2i)x} & (-3-4i)\,e^{(-1+2i)x} \\ 0 & 0 & 6 & (11+2i)\,e^{(-1-2i)x} & (11-2i)\,e^{(-1+2i)x} \\ 0 & 0 & 0 & (-7-24i)\,e^{(-1-2i)x} & (-7+24i)\,e^{(-1+2i)x} \end{bmatrix}$$

$$= 8i e^{-2x}\left(125x^3 + 150x^2 - 30x - 72\right)$$

$$W_2(x) = \det \begin{bmatrix} 1 & x^2 & x^3 & e^{(-1-2i)x} & e^{(-1+2i)x} \\ 0 & 2x & 3x^2 & (-1-2i)\,e^{(-1-2i)x} & (-1+2i)\,e^{(-1+2i)x} \\ 0 & 2 & 6x & (-3+4i)\,e^{(-1-2i)x} & (-3-4i)\,e^{(-1+2i)x} \\ 0 & 0 & 6 & (11+2i)\,e^{(-1-2i)x} & (11-2i)\,e^{(-1+2i)x} \\ 0 & 0 & 0 & (-7-24i)\,e^{(-1-2i)x} & (-7+24i)\,e^{(-1+2i)x} \end{bmatrix}$$

$$= 120i e^{-2x}\left(25x^2 + 20x - 2\right)$$

$$W_3(x) = \det \begin{bmatrix} 1 & x & x^3 & e^{(-1-2i)x} & e^{(-1+2i)x} \\ 0 & 1 & 3x^2 & (-1-2i)\,e^{(-1-2i)x} & (-1+2i)\,e^{(-1+2i)x} \\ 0 & 0 & 6x & (-3+4i)\,e^{(-1-2i)x} & (-3-4i)\,e^{(-1+2i)x} \\ 0 & 0 & 6 & (11+2i)\,e^{(-1-2i)x} & (11-2i)\,e^{(-1+2i)x} \\ 0 & 0 & 0 & (-7-24i)\,e^{(-1-2i)x} & (-7+24i)\,e^{(-1+2i)x} \end{bmatrix}$$
$$= 600ie^{-2x}(2+5x)$$

$$W_4(x) = \det \begin{bmatrix} 1 & x & x^2 & e^{(-1-2i)x} & e^{(-1+2i)x} \\ 0 & 1 & 2x & (-1-2i)\,e^{(-1-2i)x} & (-1+2i)\,e^{(-1+2i)x} \\ 0 & 0 & 2 & (-3+4i)\,e^{(-1-2i)x} & (-3-4i)\,e^{(-1+2i)x} \\ 0 & 0 & 0 & (11+2i)\,e^{(-1-2i)x} & (11-2i)\,e^{(-1+2i)x} \\ 0 & 0 & 0 & (-7-24i)\,e^{(-1-2i)x} & (-7+24i)\,e^{(-1+2i)x} \end{bmatrix}$$
$$= 1000ie^{-2x}$$

$$W_5(x) = \det \begin{bmatrix} 1 & x & x^2 & x^3 & e^{(-1+2i)x} \\ 0 & 1 & 2x & 3x^2 & (-1+2i)\,e^{(-1+2i)x} \\ 0 & 0 & 2 & 6x & (-3-4i)\,e^{(-1+2i)x} \\ 0 & 0 & 0 & 6 & (11-2i)\,e^{(-1+2i)x} \\ 0 & 0 & 0 & 0 & (-7+24i)\,e^{(-1+2i)x} \end{bmatrix}$$
$$= (-84+288i)\,e^{(-1+2i)x}$$

$$W_6(x) = \det \begin{bmatrix} 1 & x & x^2 & x^3 & e^{(-1-2i)x} \\ 0 & 1 & 2x & 3x^2 & (-1-2i)\,e^{(-1-2i)x} \\ 0 & 0 & 2 & 6x & (-3+4i)\,e^{(-1-2i)x} \\ 0 & 0 & 0 & 6 & (11+2i)\,e^{(-1-2i)x} \\ 0 & 0 & 0 & 0 & (-7-24i)\,e^{(-1-2i)x} \end{bmatrix}$$
$$= (-84-288i)\,e^{(-1-2i)x}$$

Now we are ready to evaluate each $U_i(x)$.

$$
\begin{aligned}
U_1 &= (-1)^{6-1} \int \frac{F(x)W_1(x)}{aW(x)}\,dx \\
&= (-1)^5 \int \frac{\left(x^3 + x^2\mathrm{e}^{-x} + \mathrm{e}^{-x}\sin(2x)\right)\left(8i\mathrm{e}^{-2x}(125x^3 + 150x^2 - 30x - 72)\right)}{(1)\left(30000i\mathrm{e}^{-2x}\right)}\,dx \\
&= -\int \frac{8i(x^3 + x^2\mathrm{e}^{-x} + \mathrm{e}^{-x}\sin(2x))\,\mathrm{e}^{-2x}(125x^3 + 150x^2 - 30x - 72)}{30000i\mathrm{e}^{-2x}}\,dx \\
&= -\int \left(\frac{(x^3 + x^2\mathrm{e}^{-x} + \mathrm{e}^{-x}\sin(2x))\,(125x^3 + 150x^2 - 30x - 72)}{3750}\right)dx \\
&= \frac{3x^4}{625} + \frac{12\,\mathrm{e}^{-x}(-\sin(2x) - 2\cos(2x))}{3125} + \frac{3046\,\mathrm{e}^{-x}}{625} + \frac{31x^4\mathrm{e}^{-x}}{150} + \frac{307x^3\mathrm{e}^{-x}}{375} + \frac{x^5}{625} + \frac{3046x\,\mathrm{e}^{-x}}{625} - \frac{x^6}{150}
\end{aligned}
$$

$$
\begin{aligned}
U_2 &= (-1)^{6-2} \int \frac{F(x)W_2(x)}{aW(x)}\,dx \\
&= (-1)^4 \int \frac{\left(x^3 + x^2\mathrm{e}^{-x} + \mathrm{e}^{-x}\sin(2x)\right)\left(120i\mathrm{e}^{-2x}(25x^2 + 20x - 2)\right)}{(1)\left(30000i\mathrm{e}^{-2x}\right)}\,dx \\
&= \int \frac{120i(x^3 + x^2\mathrm{e}^{-x} + \mathrm{e}^{-x}\sin(2x))\,\mathrm{e}^{-2x}(25x^2 + 20x - 2)}{30000i\mathrm{e}^{-2x}}\,dx \\
&= \int \left(\frac{(x^3 + x^2\mathrm{e}^{-x} + \mathrm{e}^{-x}\sin(2x))\,(25x^2 + 20x - 2)}{250}\right)dx \\

\end{aligned}
$$

$$
\begin{aligned}
U_5 &= (-1)^{6-5} \int \frac{F(x)W_5(x)}{aW(x)}\,dx \\
&= (-1)^1 \int \frac{\left(x^3 + x^2\mathrm{e}^{-x} + \mathrm{e}^{-x}\sin(2x)\right)\left((-84+288i)\,\mathrm{e}^{(-1+2i)x}\right)}{(1)\left(30000i\mathrm{e}^{-2x}\right)}\,dx \\
&= -\int \frac{(-84+288i)\left(x^3 + x^2\mathrm{e}^{-x} + \mathrm{e}^{-x}\sin(2x)\right)\mathrm{e}^{(-1+2i)x}}{30000i\mathrm{e}^{-2x}}\,dx \\
&= -\int \left(\left(\frac{6}{625} + \frac{7i}{2500}\right)\left(\left(x^2 + \sin(2x)\right)\mathrm{e}^{-x} + x^3\right)\mathrm{e}^{(1+2i)x}\right)\,dx \\
&= \left(-\frac{6}{625} - \frac{7i}{2500}\right)\left(\left(-\frac{7}{625} + \frac{24i}{625}\right)\left((-11-2i)\,\mathrm{e}^{(1+2i)x}x^3 + (9-12i)\,\mathrm{e}^{(1+2i)x}x^2 + (6+12i)\,x\,\mathrm{e}^{(1+2i)}\right.\right. \\
&= \left(-\frac{6}{625} - \frac{7i}{2500}\right)\left(\left(-\frac{7}{625} + \frac{24i}{625}\right)\left((-11-2i)\,\mathrm{e}^{(1+2i)x}x^3 + (9-12i)\,\mathrm{e}^{(1+2i)x}x^2 + (6+12i)\,x\,\mathrm{e}^{(1+2i)}\right.\right.
\end{aligned}
$$

$$
\begin{aligned}
U_6 &= (-1)^{6-6} \int \frac{F(x) W_6(x)}{a W(x)}\, dx \\
&= (-1)^0 \int \frac{\left(x^3 + x^2 \mathrm{e}^{-x} + \mathrm{e}^{-x} \sin(2x)\right)\left((-84 - 288i)\, \mathrm{e}^{(-1-2i)x}\right)}{(1)\left(30000 i \mathrm{e}^{-2x}\right)}\, dx \\
&= \int \frac{(-84 - 288i)\left(x^3 + x^2 \mathrm{e}^{-x} + \mathrm{e}^{-x} \sin(2x)\right) \mathrm{e}^{(-1-2i)x}}{30000 i \mathrm{e}^{-2x}}\, dx \\
&= \int \left(\left(-\frac{6}{625} + \frac{7i}{2500}\right)\left(\left(x^2 + \sin(2x)\right) \mathrm{e}^{-x} + x^3\right) \mathrm{e}^{(1-2i)x}\right)\, dx \\
&= \left(-\frac{6}{625} + \frac{7i}{2500}\right)\left(\left(-\frac{7}{625} - \frac{24i}{625}\right)\left((-11 + 2i)\, \mathrm{e}^{(1-2i)x} x^3 + (9 + 12i)\, \mathrm{e}^{(1-2i)x} x^2 + (6 - 12i)\, x\, \mathrm{e}^{(1-2i)} \right.\right. \\
&= \left(-\frac{6}{625} + \frac{7i}{2500}\right)\left(\left(-\frac{7}{625} - \frac{24i}{625}\right)\left((-11 + 2i)\, \mathrm{e}^{(1-2i)x} x^3 + (9 + 12i)\, \mathrm{e}^{(1-2i)x} x^2 + (6 - 12i)\, x\, \mathrm{e}^{(1-2i)} \right.\right.
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4 + U_5 y_5 + U_6 y_6
$$

Hence

$$
\begin{aligned}
y_p = &\left(\frac{3x^4}{625} + \frac{12\, \mathrm{e}^{-x}(-\sin(2x) - 2\cos(2x))}{3125} + \frac{3046\, \mathrm{e}^{-x}}{625} + \frac{31 x^4 \mathrm{e}^{-x}}{150} + \frac{307 x^3 \mathrm{e}^{-x}}{375} + \frac{x^5}{625} + \frac{3046 x\, \mathrm{e}^{-x}}{625} - \frac{x}{1} \right. \\
&+ \left(\frac{x^6}{60} + \frac{2x^5}{125} - \frac{x^4}{500} - \frac{x^4 \mathrm{e}^{-x}}{10} - \frac{12 x^3 \mathrm{e}^{-x}}{25} - \frac{179 x^2 \mathrm{e}^{-x}}{125} - \frac{358 x\, \mathrm{e}^{-x}}{125} - \frac{358\, \mathrm{e}^{-x}}{125} + \frac{\left(-\frac{2}{5}x^2 - \frac{8}{25}x + \frac{4}{125}\right) \mathrm{e}^{-}}{10} \right. \\
&+ \left(-\frac{x^4}{100} - \frac{x^5}{50} + \frac{17 x^2 \mathrm{e}^{-x}}{50} + \frac{17 x\, \mathrm{e}^{-x}}{25} + \frac{17\, \mathrm{e}^{-x}}{25} + \frac{x^3 \mathrm{e}^{-x}}{10} - \frac{\mathrm{e}^{-x}(-\sin(2x) - 2\cos(2x))}{125} - \frac{\left(-\frac{2x}{5} - \frac{4}{25}\right)}{1} \right. \\
&+ \left(\frac{x^4}{120} - \frac{x^2 \mathrm{e}^{-x}}{30} - \frac{x\, \mathrm{e}^{-x}}{15} - \frac{\mathrm{e}^{-x}}{15} + \frac{\mathrm{e}^{-x}(-\sin(2x) - 2\cos(2x))}{150}\right)\left(x^3\right) \\
&+ \left(\left(-\frac{6}{625} - \frac{7i}{2500}\right)\left(\left(-\frac{7}{625} + \frac{24i}{625}\right)\left((-11 - 2i)\, \mathrm{e}^{(1+2i)x} x^3 + (9 - 12i)\, \mathrm{e}^{(1+2i)x} x^2 + (6 + 12i)\, x\, \mathrm{e}^{(1+2} \right.\right.\right. \\
&+ \left(\left(-\frac{6}{625} + \frac{7i}{2500}\right)\left(\left(-\frac{7}{625} - \frac{24i}{625}\right)\left((-11 + 2i)\, \mathrm{e}^{(1-2i)x} x^3 + (9 + 12i)\, \mathrm{e}^{(1-2i)x} x^2 + (6 - 12i)\, x\, \mathrm{e}^{(1-2} \right.\right.\right.
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = -\frac{1008}{390625} + \frac{(-448 - 339i + (70 - 240i)\, x)\, \mathrm{e}^{(-1-2i)x}}{50000} + \frac{(-448 + 339i + (70 + 240i)\, x)\, \mathrm{e}^{(-1+2i)x}}{50000} + \frac{(2x^2 -}{}
$$

Which simplifies to

$$
y_p = \frac{((183750x - 1176000)\cos(2x) + (-630000x - 889875)\sin(2x) + 16406250x^2 + 131250000x + 3199}{65625000}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(x^3 c_4 + c_3 x^2 + c_2 x + c_1 + \mathrm{e}^{(-1-2i)x} c_5 + \mathrm{e}^{(-1+2i)x} c_6\right) \\
&\quad + \left(\frac{((183750x - 1176000)\cos(2x) + (-630000x - 889875)\sin(2x) + 16406250x^2 + 131250000x + 31}{65625000}\right. \\
&\quad \left. + \frac{x^7}{4200} - \frac{x^6}{1500} - \frac{x^5}{2500} + \frac{3x^4}{625} - \frac{19x^3}{3125} - \frac{66x^2}{15625} + \frac{834x}{78125} - \frac{1008}{390625}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= x^3 c_4 + c_3 x^2 + c_2 x + c_1 + \mathrm{e}^{(-1-2i)x} c_5 + \mathrm{e}^{(-1+2i)x} c_6 \\
&\quad + \frac{((183750x - 1176000)\cos(2x) + (-630000x - 889875)\sin(2x) + 16406250x^2 + 131250000x + 3199}{65625000} \\
&\quad + \frac{x^7}{4200} - \frac{x^6}{1500} - \frac{x^5}{2500} + \frac{3x^4}{625} - \frac{19x^3}{3125} - \frac{66x^2}{15625} + \frac{834x}{78125} - \frac{1008}{390625}
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= x^3 c_4 + c_3 x^2 + c_2 x + c_1 + \mathrm{e}^{(-1-2i)x} c_5 + \mathrm{e}^{(-1+2i)x} c_6 \\
&\quad + \frac{((183750x - 1176000)\cos(2x) + (-630000x - 889875)\sin(2x) + 16406250x^2 + 131250000x + 3199}{65625000} \\
&\quad + \frac{x^7}{4200} - \frac{x^6}{1500} - \frac{x^5}{2500} + \frac{3x^4}{625} - \frac{19x^3}{3125} - \frac{66x^2}{15625} + \frac{834x}{78125} - \frac{1008}{390625}
\end{aligned}
$$

Verified OK.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'''' + 2y'' + y = \cos(x)\, x^2}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 2y'' + y = 0$$

The characteristic equation is

$$\lambda^4 + 2\lambda^2 + 1 = 0$$

The roots of the above equation are

$$\lambda_1 = i$$
$$\lambda_2 = -i$$
$$\lambda_3 = i$$
$$\lambda_4 = -i$$

Therefore the homogeneous solution is

$$y_h(x) = e^{ix} c_1 + x\,e^{ix} c_2 + e^{-ix} c_3 + x\,e^{-ix} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= e^{ix} \\ y_2 &= x\,e^{ix} \\ y_3 &= e^{-ix} \\ y_4 &= x\,e^{-ix} \end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' + 2y'' + y = \cos(x)\,x^2$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)}\,dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 & y_4 \\ y_1' & y_2' & y_3' & y_4' \\ y_1'' & y_2'' & y_3'' & y_4'' \\ y_1''' & y_2''' & y_3''' & y_4''' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} e^{ix} & x\,e^{ix} & e^{-ix} & x\,e^{-ix} \\ i e^{ix} & e^{ix}(ix+1) & -i e^{-ix} & e^{-ix}(-ix+1) \\ -e^{ix} & e^{ix}(2i-x) & -e^{-ix} & e^{-ix}(-2i-x) \\ -i e^{ix} & -e^{ix}(ix+3) & i e^{-ix} & e^{-ix}(ix-3) \end{bmatrix}$$

$$|W| = 16\,e^{2ix} e^{-2ix}$$

The determinant simplifies to

$$|W| = 16$$

Now we determine W_i for each U_i.

$$\begin{aligned} W_1(x) &= \det \begin{bmatrix} x\,e^{ix} & e^{-ix} & x\,e^{-ix} \\ e^{ix}(ix+1) & -ie^{-ix} & e^{-ix}(-ix+1) \\ e^{ix}(2i-x) & -e^{-ix} & e^{-ix}(-2i-x) \end{bmatrix} \\ &= -4\,e^{-ix}(x-i) \end{aligned}$$

$$\begin{aligned} W_2(x) &= \det \begin{bmatrix} e^{ix} & e^{-ix} & x\,e^{-ix} \\ ie^{ix} & -ie^{-ix} & e^{-ix}(-ix+1) \\ -e^{ix} & -e^{-ix} & e^{-ix}(-2i-x) \end{bmatrix} \\ &= -4\,e^{-ix} \end{aligned}$$

$$\begin{aligned} W_3(x) &= \det \begin{bmatrix} e^{ix} & x\,e^{ix} & x\,e^{-ix} \\ ie^{ix} & e^{ix}(ix+1) & e^{-ix}(-ix+1) \\ -e^{ix} & e^{ix}(2i-x) & e^{-ix}(-2i-x) \end{bmatrix} \\ &= -4\,e^{ix}(x+i) \end{aligned}$$

$$\begin{aligned} W_4(x) &= \det \begin{bmatrix} e^{ix} & x\,e^{ix} & e^{-ix} \\ ie^{ix} & e^{ix}(ix+1) & -ie^{-ix} \\ -e^{ix} & e^{ix}(2i-x) & -e^{-ix} \end{bmatrix} \\ &= -4\,e^{ix} \end{aligned}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned} U_1 &= (-1)^{4-1} \int \frac{F(x)W_1(x)}{aW(x)}\,dx \\ &= (-1)^3 \int \frac{(\cos(x)\,x^2)\,(-4\,e^{-ix}(x-i))}{(1)\,(16)}\,dx \\ &= -\int \frac{-4\cos(x)\,x^2 e^{-ix}(x-i)}{16}\,dx \\ &= -\int \left(-\frac{\cos(x)\,x^2 e^{-ix}(x-i)}{4}\right)dx \\ &= -\left(\int -\frac{\cos(x)\,x^2 e^{-ix}(x-i)}{4}dx\right) \end{aligned}$$

$$
\begin{aligned}
U_2 &= (-1)^{4-2} \int \frac{F(x) W_2(x)}{a W(x)} \, dx \\
&= (-1)^2 \int \frac{(\cos(x) x^2)(-4\,\mathrm{e}^{-ix})}{(1)(16)} \, dx \\
&= \int \frac{-4\cos(x) x^2 \mathrm{e}^{-ix}}{16} \, dx \\
&= \int \left(-\frac{\cos(x) x^2 \mathrm{e}^{-ix}}{4}\right) dx \\
&= \int -\frac{\cos(x) x^2 \mathrm{e}^{-ix}}{4} dx
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{4-3} \int \frac{F(x) W_3(x)}{a W(x)} \, dx \\
&= (-1)^1 \int \frac{(\cos(x) x^2)(-4\,\mathrm{e}^{ix}(x+i))}{(1)(16)} \, dx \\
&= -\int \frac{-4\cos(x) x^2 \mathrm{e}^{ix}(x+i)}{16} \, dx \\
&= -\int \left(-\frac{\cos(x) x^2 \mathrm{e}^{ix}(x+i)}{4}\right) dx \\
&= \frac{x^4}{32} + \frac{i x^3}{24} - \frac{i(4x^3 + 10 i x^2 - 10x - 5i)\,\mathrm{e}^{2ix}}{64}
\end{aligned}
$$

$$
\begin{aligned}
U_4 &= (-1)^{4-4} \int \frac{F(x) W_4(x)}{a W(x)} \, dx \\
&= (-1)^0 \int \frac{(\cos(x) x^2)(-4\,\mathrm{e}^{ix})}{(1)(16)} \, dx \\
&= \int \frac{-4\cos(x) x^2 \mathrm{e}^{ix}}{16} \, dx \\
&= \int \left(-\frac{\cos(x) x^2 \mathrm{e}^{ix}}{4}\right) dx \\
&= -\frac{x^3}{24} + \frac{i(2x^2 + 2ix - 1)\,\mathrm{e}^{2ix}}{32}
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4
$$

Hence

$$
\begin{aligned}
y_p = {} & \left(-\left(\int -\frac{\cos(x)\, x^2 \mathrm{e}^{-ix} (x-i)}{4} dx\right)\right) \left(\mathrm{e}^{ix}\right) \\
& + \left(\int -\frac{\cos(x)\, x^2 \mathrm{e}^{-ix}}{4} dx\right) \left(x\, \mathrm{e}^{ix}\right) \\
& + \left(\frac{x^4}{32} + \frac{i x^3}{24} - \frac{i(4x^3 + 10 i x^2 - 10x - 5i)\, \mathrm{e}^{2ix}}{64}\right) \left(\mathrm{e}^{-ix}\right) \\
& + \left(-\frac{x^3}{24} + \frac{i(2x^2 + 2ix - 1)\, \mathrm{e}^{2ix}}{32}\right) \left(x\, \mathrm{e}^{-ix}\right)
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = \frac{\cos(x)\left(-4x^4 + 36x^2 + 6ix - 45\right)}{192} - \frac{5\sin(x)\left(-\frac{16}{15}x^3 + i + \frac{18}{5}x\right)}{64}
$$

Which simplifies to

$$
y_p = \frac{\cos(x)\left(-4x^4 + 36x^2 + 6ix - 45\right)}{192} - \frac{5\sin(x)\left(-\frac{16}{15}x^3 + i + \frac{18}{5}x\right)}{64}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\mathrm{e}^{ix} c_1 + x\, \mathrm{e}^{ix} c_2 + \mathrm{e}^{-ix} c_3 + x\, \mathrm{e}^{-ix} c_4\right) \\
&\quad + \left(\frac{\cos(x)\left(-4x^4 + 36x^2 + 6ix - 45\right)}{192} - \frac{5\sin(x)\left(-\frac{16}{15}x^3 + i + \frac{18}{5}x\right)}{64}\right)
\end{aligned}
$$

Which simplifies to

$$
\begin{aligned}
y = {} & (c_4 x + c_3)\, \mathrm{e}^{-ix} + (c_2 x + c_1)\, \mathrm{e}^{ix} \\
& + \frac{\cos(x)\left(-4x^4 + 36x^2 + 6ix - 45\right)}{192} - \frac{5\sin(x)\left(-\frac{16}{15}x^3 + i + \frac{18}{5}x\right)}{64}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & (c_4 x + c_3)\, \mathrm{e}^{-ix} + (c_2 x + c_1)\, \mathrm{e}^{ix} \\
& + \frac{\cos(x)\left(-4x^4 + 36x^2 + 6ix - 45\right)}{192} - \frac{5\sin(x)\left(-\frac{16}{15}x^3 + i + \frac{18}{5}x\right)}{64}
\end{aligned} \tag{1}
$$

Verification of solutions

$$y = (c_4x + c_3)\,\mathrm{e}^{-ix} + (c_2x + c_1)\,\mathrm{e}^{ix} + \frac{\cos(x)\left(-4x^4 + 36x^2 + 6ix - 45\right)}{192} - \frac{5\sin(x)\left(-\frac{16}{15}x^3 + i + \frac{18}{5}x\right)}{64}$$

Verified OK.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _linear, _nonhomogeneous]]
```

$$y'''' + 16y = x\,\mathrm{e}^{\sqrt{2}\,x} \sin\left(\sqrt{2}\,x\right) + \mathrm{e}^{-\sqrt{2}\,x} \cos\left(\sqrt{2}\,x\right)$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 16y = 0$$

The characteristic equation is

$$\lambda^4 + 16 = 0$$

The roots of the above equation are

$$\lambda_1 = \sqrt{2} + i\sqrt{2}$$
$$\lambda_2 = -\sqrt{2} + i\sqrt{2}$$
$$\lambda_3 = -\sqrt{2} - i\sqrt{2}$$
$$\lambda_4 = \sqrt{2} - i\sqrt{2}$$

Therefore the homogeneous solution is

$$y_h(x) = e^{\left(\sqrt{2}-i\sqrt{2}\right)x} c_1 + e^{\left(-\sqrt{2}+i\sqrt{2}\right)x} c_2 + e^{\left(-\sqrt{2}-i\sqrt{2}\right)x} c_3 + e^{\left(\sqrt{2}+i\sqrt{2}\right)x} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{\left(\sqrt{2}-i\sqrt{2}\right)x}$$

$$y_2 = e^{\left(-\sqrt{2}+i\sqrt{2}\right)x}$$

$$y_3 = e^{\left(-\sqrt{2}-i\sqrt{2}\right)x}$$

$$y_4 = e^{\left(\sqrt{2}+i\sqrt{2}\right)x}$$

Now the particular solution to the given ODE is found

$$y'''' + 16y = x\,e^{\sqrt{2}\,x} \sin\left(\sqrt{2}\,x\right) + e^{-\sqrt{2}\,x} \cos\left(\sqrt{2}\,x\right)$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)}\, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 & y_4 \\ y_1' & y_2' & y_3' & y_4' \\ y_1'' & y_2'' & y_3'' & y_4'' \\ y_1''' & y_2''' & y_3''' & y_4''' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \left[\begin{array}{cccc} e^{(1-i)\sqrt{2}\,x} & e^{(-1+i)\sqrt{2}\,x} & e^{(-1-i)\sqrt{2}\,x} & e^{(1+i)\sqrt{2}\,x} \\ (1-i)\sqrt{2}\,e^{(1-i)\sqrt{2}\,x} & (-1+i)\sqrt{2}\,e^{(-1+i)\sqrt{2}\,x} & (-1-i)\sqrt{2}\,e^{(-1-i)\sqrt{2}\,x} & (1+i)\sqrt{2}\,e^{(1+i)\sqrt{2}\,x} \\ -4i e^{(1-i)\sqrt{2}\,x} & -4i e^{(-1+i)\sqrt{2}\,x} & 4i e^{(-1-i)\sqrt{2}\,x} & 4i e^{(1+i)\sqrt{2}\,x} \\ (-4-4i)\sqrt{2}\,e^{(1-i)\sqrt{2}\,x} & (4+4i)\sqrt{2}\,e^{(-1+i)\sqrt{2}\,x} & (4-4i)\sqrt{2}\,e^{(-1-i)\sqrt{2}\,x} & (-4+4i)\sqrt{2}\,e^{(1+i)\sqrt{2}\,x} \end{array}\right]$$

$$|W| = 1024\,e^{(1-i)\sqrt{2}\,x} e^{(-1+i)\sqrt{2}\,x} e^{(-1-i)\sqrt{2}\,x} e^{(1+i)\sqrt{2}\,x}$$

The determinant simplifies to

$$|W| = 1024$$

Now we determine W_i for each U_i.

$$\begin{aligned} W_1(x) &= \det\left[\begin{array}{ccc} e^{(-1+i)\sqrt{2}\,x} & e^{(-1-i)\sqrt{2}\,x} & e^{(1+i)\sqrt{2}\,x} \\ (-1+i)\sqrt{2}\,e^{(-1+i)\sqrt{2}\,x} & (-1-i)\sqrt{2}\,e^{(-1-i)\sqrt{2}\,x} & (1+i)\sqrt{2}\,e^{(1+i)\sqrt{2}\,x} \\ -4i e^{(-1+i)\sqrt{2}\,x} & 4i e^{(-1-i)\sqrt{2}\,x} & 4i e^{(1+i)\sqrt{2}\,x} \end{array}\right] \\ &= (16-16i)\sqrt{2}\,e^{(-1+i)\sqrt{2}\,x} \end{aligned}$$

$$\begin{aligned} W_2(x) &= \det\left[\begin{array}{ccc} e^{(1-i)\sqrt{2}\,x} & e^{(-1-i)\sqrt{2}\,x} & e^{(1+i)\sqrt{2}\,x} \\ (1-i)\sqrt{2}\,e^{(1-i)\sqrt{2}\,x} & (-1-i)\sqrt{2}\,e^{(-1-i)\sqrt{2}\,x} & (1+i)\sqrt{2}\,e^{(1+i)\sqrt{2}\,x} \\ -4i e^{(1-i)\sqrt{2}\,x} & 4i e^{(-1-i)\sqrt{2}\,x} & 4i e^{(1+i)\sqrt{2}\,x} \end{array}\right] \\ &= (16-16i)\sqrt{2}\,e^{(1-i)\sqrt{2}\,x} \end{aligned}$$

$$\begin{aligned} W_3(x) &= \det\left[\begin{array}{ccc} e^{(1-i)\sqrt{2}\,x} & e^{(-1+i)\sqrt{2}\,x} & e^{(1+i)\sqrt{2}\,x} \\ (1-i)\sqrt{2}\,e^{(1-i)\sqrt{2}\,x} & (-1+i)\sqrt{2}\,e^{(-1+i)\sqrt{2}\,x} & (1+i)\sqrt{2}\,e^{(1+i)\sqrt{2}\,x} \\ -4i e^{(1-i)\sqrt{2}\,x} & -4i e^{(-1+i)\sqrt{2}\,x} & 4i e^{(1+i)\sqrt{2}\,x} \end{array}\right] \\ &= (-16-16i)\sqrt{2}\,e^{(1+i)\sqrt{2}\,x} \end{aligned}$$

$$\begin{aligned} W_4(x) &= \det\left[\begin{array}{ccc} e^{(1-i)\sqrt{2}\,x} & e^{(-1+i)\sqrt{2}\,x} & e^{(-1-i)\sqrt{2}\,x} \\ (1-i)\sqrt{2}\,e^{(1-i)\sqrt{2}\,x} & (-1+i)\sqrt{2}\,e^{(-1+i)\sqrt{2}\,x} & (-1-i)\sqrt{2}\,e^{(-1-i)\sqrt{2}\,x} \\ -4i e^{(1-i)\sqrt{2}\,x} & -4i e^{(-1+i)\sqrt{2}\,x} & 4i e^{(-1-i)\sqrt{2}\,x} \end{array}\right] \\ &= (-16-16i)\sqrt{2}\,e^{(-1-i)\sqrt{2}\,x} \end{aligned}$$

Now we are ready to evaluate each $U_i(x)$.

$$
\begin{aligned}
U_1 &= (-1)^{4-1} \int \frac{F(x)W_1(x)}{aW(x)}\,dx \\
&= (-1)^3 \int \frac{\left(x\,\mathrm{e}^{\sqrt{2}\,x}\sin\left(\sqrt{2}\,x\right) + \mathrm{e}^{-\sqrt{2}\,x}\cos\left(\sqrt{2}\,x\right)\right)\left((16-16i)\,\sqrt{2}\,\mathrm{e}^{(-1+i)\sqrt{2}\,x}\right)}{(1)\,(1024)}\,dx \\
&= -\int \frac{(16-16i)\left(x\,\mathrm{e}^{\sqrt{2}\,x}\sin\left(\sqrt{2}\,x\right) + \mathrm{e}^{-\sqrt{2}\,x}\cos\left(\sqrt{2}\,x\right)\right)\sqrt{2}\,\mathrm{e}^{(-1+i)\sqrt{2}\,x}}{1024}\,dx \\
&= -\int \left(\left(\frac{1}{64}-\frac{i}{64}\right)\sqrt{2}\,\mathrm{e}^{(-2+i)\sqrt{2}\,x}\left(x\,\mathrm{e}^{2\sqrt{2}\,x}\sin\left(\sqrt{2}\,x\right) + \cos\left(\sqrt{2}\,x\right)\right)\right)dx \\
&= -\left(\int \left(\frac{1}{64}-\frac{i}{64}\right)\sqrt{2}\,\mathrm{e}^{(-2+i)\sqrt{2}\,x}\left(x\,\mathrm{e}^{2\sqrt{2}\,x}\sin\left(\sqrt{2}\,x\right) + \cos\left(\sqrt{2}\,x\right)\right)dx\right)
\end{aligned}
$$

$$
\begin{aligned}
U_2 &= (-1)^{4-2} \int \frac{F(x)W_2(x)}{aW(x)}\,dx \\
&= (-1)^2 \int \frac{\left(x\,\mathrm{e}^{\sqrt{2}\,x}\sin\left(\sqrt{2}\,x\right) + \mathrm{e}^{-\sqrt{2}\,x}\cos\left(\sqrt{2}\,x\right)\right)\left((16-16i)\,\sqrt{2}\,\mathrm{e}^{(1-i)\sqrt{2}\,x}\right)}{(1)\,(1024)}\,dx \\
&= \int \frac{(16-16i)\left(x\,\mathrm{e}^{\sqrt{2}\,x}\sin\left(\sqrt{2}\,x\right) + \mathrm{e}^{-\sqrt{2}\,x}\cos\left(\sqrt{2}\,x\right)\right)\sqrt{2}\,\mathrm{e}^{(1-i)\sqrt{2}\,x}}{1024}\,dx \\
&= \int \left(\left(\frac{1}{64}-\frac{i}{64}\right)\sqrt{2}\,\mathrm{e}^{-i\sqrt{2}\,x}\left(x\,\mathrm{e}^{2\sqrt{2}\,x}\sin\left(\sqrt{2}\,x\right) + \cos\left(\sqrt{2}\,x\right)\right)\right)dx \\
&= \int \left(\frac{1}{64}-\frac{i}{64}\right)\sqrt{2}\,\mathrm{e}^{-i\sqrt{2}\,x}\left(x\,\mathrm{e}^{2\sqrt{2}\,x}\sin\left(\sqrt{2}\,x\right) + \cos\left(\sqrt{2}\,x\right)\right)dx
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{4-3} \int \frac{F(x)W_3(x)}{aW(x)}\,dx \\
&= (-1)^1 \int \frac{\left(x\,\mathrm{e}^{\sqrt{2}\,x}\sin\left(\sqrt{2}\,x\right) + \mathrm{e}^{-\sqrt{2}\,x}\cos\left(\sqrt{2}\,x\right)\right)\left((-16-16i)\,\sqrt{2}\,\mathrm{e}^{(1+i)\sqrt{2}\,x}\right)}{(1)\,(1024)}\,dx \\
&= -\int \frac{(-16-16i)\left(x\,\mathrm{e}^{\sqrt{2}\,x}\sin\left(\sqrt{2}\,x\right) + \mathrm{e}^{-\sqrt{2}\,x}\cos\left(\sqrt{2}\,x\right)\right)\sqrt{2}\,\mathrm{e}^{(1+i)\sqrt{2}\,x}}{1024}\,dx \\
&= -\int \left(\left(-\frac{1}{64}-\frac{i}{64}\right)\sqrt{2}\,\mathrm{e}^{i\sqrt{2}\,x}\left(x\,\mathrm{e}^{2\sqrt{2}\,x}\sin\left(\sqrt{2}\,x\right) + \cos\left(\sqrt{2}\,x\right)\right)\right)dx \\
&= \frac{\sqrt{2}\,x}{128} + \frac{i\sqrt{2}\,x}{128} + \frac{\mathrm{e}^{2i\sqrt{2}\,x}}{256} - \frac{i\mathrm{e}^{2i\sqrt{2}\,x}}{256} + \left(-\frac{1}{8192}-\frac{i}{8192}\right)\sqrt{2}\left(\sqrt{2}+i\sqrt{2}\right)\left(i\sqrt{2}\,\mathrm{e}^{2i\sqrt{2}\,x} - \sqrt{2}\,\mathrm{e}^{2i\sqrt{2}\,x} + \right. \\
&= \frac{\sqrt{2}\,x}{128} + \frac{i\sqrt{2}\,x}{128} + \frac{\mathrm{e}^{2i\sqrt{2}\,x}}{256} - \frac{i\mathrm{e}^{2i\sqrt{2}\,x}}{256} + \left(-\frac{1}{8192}-\frac{i}{8192}\right)\sqrt{2}\left(\sqrt{2}+i\sqrt{2}\right)\left(i\sqrt{2}\,\mathrm{e}^{2i\sqrt{2}\,x} - \sqrt{2}\,\mathrm{e}^{2i\sqrt{2}\,x} + \right.
\end{aligned}
$$

$$
\begin{aligned}
U_4 &= (-1)^{4-4} \int \frac{F(x)W_4(x)}{aW(x)}\,dx \\
&= (-1)^{0} \int \frac{\left(x\,\mathrm{e}^{\sqrt{2}\,x} \sin\left(\sqrt{2}\,x\right) + \mathrm{e}^{-\sqrt{2}\,x} \cos\left(\sqrt{2}\,x\right)\right)\left(\left(-16-16i\right)\sqrt{2}\,\mathrm{e}^{(-1-i)\sqrt{2}\,x}\right)}{(1)\,(1024)}\,dx \\
&= \int \frac{\left(-16-16i\right)\left(x\,\mathrm{e}^{\sqrt{2}\,x} \sin\left(\sqrt{2}\,x\right) + \mathrm{e}^{-\sqrt{2}\,x} \cos\left(\sqrt{2}\,x\right)\right)\sqrt{2}\,\mathrm{e}^{(-1-i)\sqrt{2}\,x}}{1024}\,dx \\
&= \int \left(\left(-\frac{1}{64}-\frac{i}{64}\right)\sqrt{2}\,\mathrm{e}^{(-2-i)\sqrt{2}\,x}\left(x\,\mathrm{e}^{2\sqrt{2}\,x} \sin\left(\sqrt{2}\,x\right) + \cos\left(\sqrt{2}\,x\right)\right)\right) dx \\
&= \int \left(-\frac{1}{64}-\frac{i}{64}\right)\sqrt{2}\,\mathrm{e}^{(-2-i)\sqrt{2}\,x}\left(x\,\mathrm{e}^{2\sqrt{2}\,x} \sin\left(\sqrt{2}\,x\right) + \cos\left(\sqrt{2}\,x\right)\right) dx
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4
$$

Hence

$$
\begin{aligned}
y_p = {} & \left(-\left(\int \left(\frac{1}{64}-\frac{i}{64}\right)\sqrt{2}\,\mathrm{e}^{(-2+i)\sqrt{2}\,x}\left(x\,\mathrm{e}^{2\sqrt{2}\,x} \sin\left(\sqrt{2}\,x\right) + \cos\left(\sqrt{2}\,x\right)\right) dx\right)\right)\left(\mathrm{e}^{\left(\sqrt{2}-i\sqrt{2}\right)x}\right) \\
& + \left(\int \left(\frac{1}{64}-\frac{i}{64}\right)\sqrt{2}\,\mathrm{e}^{-i\sqrt{2}\,x}\left(x\,\mathrm{e}^{2\sqrt{2}\,x} \sin\left(\sqrt{2}\,x\right) + \cos\left(\sqrt{2}\,x\right)\right) dx\right)\left(\mathrm{e}^{\left(-\sqrt{2}+i\sqrt{2}\right)x}\right) \\
& + \left(\frac{\sqrt{2}\,x}{128} + \frac{i\sqrt{2}\,x}{128} + \frac{\mathrm{e}^{2i\sqrt{2}\,x}}{256} - \frac{i\mathrm{e}^{2i\sqrt{2}\,x}}{256} + \left(-\frac{1}{8192}-\frac{i}{8192}\right)\sqrt{2}\left(\sqrt{2}+i\sqrt{2}\right)\left(i\sqrt{2}\,\mathrm{e}^{2i\sqrt{2}\,x} - \sqrt{2}\,\mathrm{e}^{2i\sqrt{2}\,x} \right.\right. \\
& + \left(\int \left(-\frac{1}{64}-\frac{i}{64}\right)\sqrt{2}\,\mathrm{e}^{(-2-i)\sqrt{2}\,x}\left(x\,\mathrm{e}^{2\sqrt{2}\,x} \sin\left(\sqrt{2}\,x\right) + \cos\left(\sqrt{2}\,x\right)\right) dx\right)\left(\mathrm{e}^{\left(\sqrt{2}+i\sqrt{2}\right)x}\right)
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = \frac{\mathrm{e}^{-\sqrt{2}\,x}\left(\left(4\sqrt{2}\,x-1+i\right)\sin\left(\sqrt{2}\,x\right) + \cos\left(\sqrt{2}\,x\right)\left(4\sqrt{2}\,x+7+i\right)\right)}{256} - \frac{\left(\left(\sqrt{2}\,x^2-3x+\frac{7\sqrt{2}}{8}\right)\sin\left(\sqrt{2}\,x\right)\right.}{12}
$$

Which simplifies to

$$
y_p = \frac{\mathrm{e}^{-\sqrt{2}\,x}\left(\left(4\sqrt{2}\,x-1+i\right)\sin\left(\sqrt{2}\,x\right) + \cos\left(\sqrt{2}\,x\right)\left(4\sqrt{2}\,x+7+i\right)\right)}{256} - \frac{\left(\left(\sqrt{2}\,x^2-3x+\frac{7\sqrt{2}}{8}\right)\sin\left(\sqrt{2}\,x\right)\right.}{12}
$$

Therefore the general solution is

$$
y = y_h + y_p
$$

$$= \left(e^{\left(\sqrt{2}-i\sqrt{2}\right)x} c_1 + e^{\left(-\sqrt{2}+i\sqrt{2}\right)x} c_2 + e^{\left(-\sqrt{2}-i\sqrt{2}\right)x} c_3 + e^{\left(\sqrt{2}+i\sqrt{2}\right)x} c_4\right) + \left(\frac{e^{-\sqrt{2}\,x}\left(\left(4\sqrt{2}\,x-1+i\right)\sin\left(\sqrt{2}\,x\right)+\cos\left(\sqrt{2}\,x\right)\left(4\sqrt{2}\,x+7+i\right)\right)}{256} - \frac{\left(\left(\sqrt{2}\,x^2-3x+\frac{7\sqrt{2}}{8}\right)\sin\left(\sqrt{2}\,x\right)+\cos\left(\sqrt{2}\,x\right)\sqrt{2}\left(x^2-\frac{3}{8}\right)\right)e^{\sqrt{2}\,x}}{128}\right)$$

Which simplifies to

$$y = e^{(1-i)\sqrt{2}\,x} c_1 + e^{(-1+i)\sqrt{2}\,x} c_2 + e^{(-1-i)\sqrt{2}\,x} c_3 + e^{(1+i)\sqrt{2}\,x} c_4 + \frac{e^{-\sqrt{2}\,x}\left(\left(4\sqrt{2}\,x-1+i\right)\sin\left(\sqrt{2}\,x\right)+\cos\left(\sqrt{2}\,x\right)\left(4\sqrt{2}\,x+7+i\right)\right)}{256} - \frac{\left(\left(\sqrt{2}\,x^2-3x+\frac{7\sqrt{2}}{8}\right)\sin\left(\sqrt{2}\,x\right)+\cos\left(\sqrt{2}\,x\right)\sqrt{2}\left(x^2-\frac{3}{8}\right)\right)e^{\sqrt{2}\,x}}{128}$$

Summary

The solution(s) found are the following

$$y = e^{(1-i)\sqrt{2}\,x} c_1 + e^{(-1+i)\sqrt{2}\,x} c_2 + e^{(-1-i)\sqrt{2}\,x} c_3 + e^{(1+i)\sqrt{2}\,x} c_4 + \frac{e^{-\sqrt{2}\,x}\left(\left(4\sqrt{2}\,x-1+i\right)\sin\left(\sqrt{2}\,x\right)+\cos\left(\sqrt{2}\,x\right)\left(4\sqrt{2}\,x+7+i\right)\right)}{256} - \frac{\left(\left(\sqrt{2}\,x^2-3x+\frac{7\sqrt{2}}{8}\right)\sin\left(\sqrt{2}\,x\right)+\cos\left(\sqrt{2}\,x\right)\sqrt{2}\left(x^2-\frac{3}{8}\right)\right)e^{\sqrt{2}\,x}}{128} \tag{1}$$

Verification of solutions

$$y = e^{(1-i)\sqrt{2}\,x} c_1 + e^{(-1+i)\sqrt{2}\,x} c_2 + e^{(-1-i)\sqrt{2}\,x} c_3 + e^{(1+i)\sqrt{2}\,x} c_4 + \frac{e^{-\sqrt{2}\,x}\left(\left(4\sqrt{2}\,x-1+i\right)\sin\left(\sqrt{2}\,x\right)+\cos\left(\sqrt{2}\,x\right)\left(4\sqrt{2}\,x+7+i\right)\right)}{256} - \frac{\left(\left(\sqrt{2}\,x^2-3x+\frac{7\sqrt{2}}{8}\right)\sin\left(\sqrt{2}\,x\right)+\cos\left(\sqrt{2}\,x\right)\sqrt{2}\left(x^2-\frac{3}{8}\right)\right)e^{\sqrt{2}\,x}}{128}$$

Verified OK.

11.52.1 Maple step by step solution

Let's solve

$y'''' + 16y = x\,e^{\sqrt{2}\,x} \sin\left(\sqrt{2}\,x\right) + e^{-\sqrt{2}\,x} \cos\left(\sqrt{2}\,x\right)$

- Highest derivative means the order of the ODE is 4

  y''''

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

  $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

  $y_2(x) = y'$

  ◦ Define new variable $y_3(x)$

  $y_3(x) = y''$

  ◦ Define new variable $y_4(x)$

  $y_4(x) = y'''$

  ◦ Isolate for $y_4'(x)$ using original ODE

  $y_4'(x) = x\,e^{\sqrt{2}\,x} \sin\left(\sqrt{2}\,x\right) + e^{-\sqrt{2}\,x} \cos\left(\sqrt{2}\,x\right) - 16y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $\left[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = x\,e^{\sqrt{2}\,x} \sin\left(\sqrt{2}\,x\right) + e^{-\sqrt{2}\,x} \cos\left(\sqrt{2}\,x\right) - 1\right.$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -16 & 0 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ x\,e^{\sqrt{2}\,x} \sin\left(\sqrt{2}\,x\right) + e^{-\sqrt{2}\,x} \cos\left(\sqrt{2}\,x\right) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \left[\begin{array}{c} 0 \\ 0 \\ 0 \\ x\,\mathrm{e}^{\sqrt{2}\,x} \sin\left(\sqrt{2}\,x\right)+\mathrm{e}^{-\sqrt{2}\,x} \cos\left(\sqrt{2}\,x\right) \end{array}\right]$$

- Define the coefficient matrix

$$A = \left[\begin{array}{cccc} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -16 & 0 & 0 & 0 \end{array}\right]$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-\sqrt{2}-\mathrm{I}\sqrt{2}, \left[\begin{array}{c} \frac{1}{\left(-\sqrt{2}-\mathrm{I}\sqrt{2}\right)^{3}} \\ \frac{1}{\left(-\sqrt{2}-\mathrm{I}\sqrt{2}\right)^{2}} \\ \frac{1}{-\sqrt{2}-\mathrm{I}\sqrt{2}} \\ 1 \end{array}\right]\right], \left[-\sqrt{2}+\mathrm{I}\sqrt{2}, \left[\begin{array}{c} \frac{1}{\left(-\sqrt{2}+\mathrm{I}\sqrt{2}\right)^{3}} \\ \frac{1}{\left(-\sqrt{2}+\mathrm{I}\sqrt{2}\right)^{2}} \\ \frac{1}{-\sqrt{2}+\mathrm{I}\sqrt{2}} \\ 1 \end{array}\right]\right], \left[\sqrt{2}-\mathrm{I}\sqrt{2}, \left[\begin{array}{c} \frac{1}{\left(\sqrt{2}-\mathrm{I}\sqrt{2}\right)^{3}} \\ \frac{1}{\left(\sqrt{2}-\mathrm{I}\sqrt{2}\right)^{2}} \\ \frac{1}{\sqrt{2}-\mathrm{I}\sqrt{2}} \\ 1 \end{array}\right.\right.$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\sqrt{2}-\mathrm{I}\sqrt{2}, \left[\begin{array}{c} \frac{1}{\left(-\sqrt{2}-\mathrm{I}\sqrt{2}\right)^{3}} \\ \frac{1}{\left(-\sqrt{2}-\mathrm{I}\sqrt{2}\right)^{2}} \\ \frac{1}{-\sqrt{2}-\mathrm{I}\sqrt{2}} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$e^{\left(-\sqrt{2}-I\sqrt{2}\right)x} \cdot \begin{bmatrix} \frac{1}{\left(-\sqrt{2}-I\sqrt{2}\right)^3} \\ \frac{1}{\left(-\sqrt{2}-I\sqrt{2}\right)^2} \\ \frac{1}{-\sqrt{2}-I\sqrt{2}} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$e^{-\sqrt{2}\,x} \cdot \left(\cos\left(\sqrt{2}\,x\right) - I\sin\left(\sqrt{2}\,x\right)\right) \cdot \begin{bmatrix} \frac{1}{\left(-\sqrt{2}-I\sqrt{2}\right)^3} \\ \frac{1}{\left(-\sqrt{2}-I\sqrt{2}\right)^2} \\ \frac{1}{-\sqrt{2}-I\sqrt{2}} \\ 1 \end{bmatrix}$$

- Simplify expression

$$e^{-\sqrt{2}\,x} \cdot \begin{bmatrix} \frac{\cos\left(\sqrt{2}\,x\right)-I\sin\left(\sqrt{2}\,x\right)}{\left(-\sqrt{2}-I\sqrt{2}\right)^3} \\ \frac{\cos\left(\sqrt{2}\,x\right)-I\sin\left(\sqrt{2}\,x\right)}{\left(-\sqrt{2}-I\sqrt{2}\right)^2} \\ \frac{\cos\left(\sqrt{2}\,x\right)-I\sin\left(\sqrt{2}\,x\right)}{-\sqrt{2}-I\sqrt{2}} \\ \cos\left(\sqrt{2}\,x\right) - I\sin\left(\sqrt{2}\,x\right) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_1(x) = e^{-\sqrt{2}\,x} \cdot \begin{bmatrix} \frac{\cos\left(\sqrt{2}\,x\right)\sqrt{2}}{16} + \frac{\sin\left(\sqrt{2}\,x\right)\sqrt{2}}{16} \\ -\frac{\sin\left(\sqrt{2}\,x\right)}{4} \\ -\frac{\cos\left(\sqrt{2}\,x\right)\sqrt{2}}{4} + \frac{\sin\left(\sqrt{2}\,x\right)\sqrt{2}}{4} \\ \cos\left(\sqrt{2}\,x\right) \end{bmatrix}, \vec{y}_2(x) = e^{-\sqrt{2}\,x} \cdot \begin{bmatrix} \frac{\cos\left(\sqrt{2}\,x\right)\sqrt{2}}{16} - \frac{\sin\left(\sqrt{2}\,x\right)\sqrt{2}}{16} \\ -\frac{\cos\left(\sqrt{2}\,x\right)}{4} \\ \frac{\cos\left(\sqrt{2}\,x\right)\sqrt{2}}{4} + \frac{\sin\left(\sqrt{2}\,x\right)\sqrt{2}}{4} \\ -\sin\left(\sqrt{2}\,x\right) \end{bmatrix}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[\sqrt{2}-\mathrm{I}\sqrt{2}, \left[\begin{array}{c} \frac{1}{\left(\sqrt{2}-\mathrm{I}\sqrt{2}\right)^{3}} \\ \frac{1}{\left(\sqrt{2}-\mathrm{I}\sqrt{2}\right)^{2}} \\ \frac{1}{\sqrt{2}-\mathrm{I}\sqrt{2}} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$e^{\left(\sqrt{2}-\mathrm{I}\sqrt{2}\right)x} \cdot \left[\begin{array}{c} \frac{1}{\left(\sqrt{2}-\mathrm{I}\sqrt{2}\right)^{3}} \\ \frac{1}{\left(\sqrt{2}-\mathrm{I}\sqrt{2}\right)^{2}} \\ \frac{1}{\sqrt{2}-\mathrm{I}\sqrt{2}} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$e^{\sqrt{2}\,x} \cdot \left(\cos\left(\sqrt{2}\,x\right)-\mathrm{I}\sin\left(\sqrt{2}\,x\right)\right) \cdot \left[\begin{array}{c} \frac{1}{\left(\sqrt{2}-\mathrm{I}\sqrt{2}\right)^{3}} \\ \frac{1}{\left(\sqrt{2}-\mathrm{I}\sqrt{2}\right)^{2}} \\ \frac{1}{\sqrt{2}-\mathrm{I}\sqrt{2}} \\ 1 \end{array}\right]$$

- Simplify expression

$$e^{\sqrt{2}\,x} \cdot \left[\begin{array}{c} \frac{\cos\left(\sqrt{2}\,x\right)-\mathrm{I}\sin\left(\sqrt{2}\,x\right)}{\left(\sqrt{2}-\mathrm{I}\sqrt{2}\right)^{3}} \\ \frac{\cos\left(\sqrt{2}\,x\right)-\mathrm{I}\sin\left(\sqrt{2}\,x\right)}{\left(\sqrt{2}-\mathrm{I}\sqrt{2}\right)^{2}} \\ \frac{\cos\left(\sqrt{2}\,x\right)-\mathrm{I}\sin\left(\sqrt{2}\,x\right)}{\sqrt{2}-\mathrm{I}\sqrt{2}} \\ \cos\left(\sqrt{2}\,x\right)-\mathrm{I}\sin\left(\sqrt{2}\,x\right) \end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = e^{\sqrt{2}\,x}\cdot\left[\begin{array}{c} -\frac{\cos(\sqrt{2}\,x)\sqrt{2}}{16}+\frac{\sin(\sqrt{2}\,x)\sqrt{2}}{16} \\ \frac{\sin(\sqrt{2}\,x)}{4} \\ \frac{\cos(\sqrt{2}\,x)\sqrt{2}}{4}+\frac{\sin(\sqrt{2}\,x)\sqrt{2}}{4} \\ \cos(\sqrt{2}\,x) \end{array}\right], \vec{y}_4(x) = e^{\sqrt{2}\,x}\cdot\left[\begin{array}{c} \frac{\cos(\sqrt{2}\,x)\sqrt{2}}{16}+\frac{\sin(\sqrt{2}\,x)\sqrt{2}}{16} \\ \frac{\cos(\sqrt{2}\,x)}{4} \\ \frac{\cos(\sqrt{2}\,x)\sqrt{2}}{4}-\frac{\sin(\sqrt{2}\,x)\sqrt{2}}{4} \\ -\sin(\sqrt{2}\,x) \end{array}\right]\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

  $\vec{y}(x) = c_1\vec{y}_1(x) + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \left[\begin{array}{ccc} e^{-\sqrt{2}\,x}\left(\frac{\cos(\sqrt{2}\,x)\sqrt{2}}{16}+\frac{\sin(\sqrt{2}\,x)\sqrt{2}}{16}\right) & e^{-\sqrt{2}\,x}\left(\frac{\cos(\sqrt{2}\,x)\sqrt{2}}{16}-\frac{\sin(\sqrt{2}\,x)\sqrt{2}}{16}\right) & e^{\sqrt{2}\,x}\left(-\frac{\cos(\sqrt{}}{1}\right. \\ -\frac{e^{-\sqrt{2}\,x}\sin(\sqrt{2}\,x)}{4} & -\frac{e^{-\sqrt{2}\,x}\cos(\sqrt{2}\,x)}{4} & \frac{e^{\sqrt{2}}}{} \\ e^{-\sqrt{2}\,x}\left(-\frac{\cos(\sqrt{2}\,x)\sqrt{2}}{4}+\frac{\sin(\sqrt{2}\,x)\sqrt{2}}{4}\right) & e^{-\sqrt{2}\,x}\left(\frac{\cos(\sqrt{2}\,x)\sqrt{2}}{4}+\frac{\sin(\sqrt{2}\,x)\sqrt{2}}{4}\right) & e^{\sqrt{2}\,x}\left(\frac{\cos(\sqrt{2}}{4}\right. \\ e^{-\sqrt{2}\,x}\cos(\sqrt{2}\,x) & -e^{-\sqrt{2}\,x}\sin(\sqrt{2}\,x) & e^{\sqrt{2}\,x} \end{array}\right.$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x)\cdot\frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \left[\begin{array}{ccc} e^{-\sqrt{2}\,x}\left(\frac{\cos(\sqrt{2}\,x)\sqrt{2}}{16}+\frac{\sin(\sqrt{2}\,x)\sqrt{2}}{16}\right) & e^{-\sqrt{2}\,x}\left(\frac{\cos(\sqrt{2}\,x)\sqrt{2}}{16}-\frac{\sin(\sqrt{2}\,x)\sqrt{2}}{16}\right) & e^{\sqrt{2}\,x}\left(-\frac{\cos(\sqrt{}}{1}\right. \\ -\frac{e^{-\sqrt{2}\,x}\sin(\sqrt{2}\,x)}{4} & -\frac{e^{-\sqrt{2}\,x}\cos(\sqrt{2}\,x)}{4} & \frac{e^{\sqrt{}}}{} \\ e^{-\sqrt{2}\,x}\left(-\frac{\cos(\sqrt{2}\,x)\sqrt{2}}{4}+\frac{\sin(\sqrt{2}\,x)\sqrt{2}}{4}\right) & e^{-\sqrt{2}\,x}\left(\frac{\cos(\sqrt{2}\,x)\sqrt{2}}{4}+\frac{\sin(\sqrt{2}\,x)\sqrt{2}}{4}\right) & e^{\sqrt{2}\,x}\left(\frac{\cos(\sqrt{2}}{4}\right. \\ e^{-\sqrt{2}\,x}\cos(\sqrt{2}\,x) & -e^{-\sqrt{2}\,x}\sin(\sqrt{2}\,x) & e^{\sqrt{2}\,x} \end{array}\right.$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} \frac{\cos(\sqrt{2}\,x)\left(e^{-\sqrt{2}\,x}+e^{\sqrt{2}\,x}\right)}{2} & \frac{\sqrt{2}\left(e^{-}\right.}{} \\ \frac{\left(\left(-\cos(\sqrt{2}\,x)-\sin(\sqrt{2}\,x)\right)e^{-\sqrt{2}\,x}+e^{\sqrt{2}\,x}\left(-\sin(\sqrt{2}\,x)+\cos(\sqrt{2}\,x)\right)\right)\sqrt{2}}{2} & \\ -2\sin\left(\sqrt{2}\,x\right)\left(-e^{-\sqrt{2}\,x}+e^{\sqrt{2}\,x}\right) & \frac{\left(\left(-\cos\right.\right.}{} \\ -2\sqrt{2}\left(e^{-\sqrt{2}\,x}\left(-\cos\left(\sqrt{2}\,x\right)+\sin\left(\sqrt{2}\,x\right)\right)+e^{\sqrt{2}\,x}\left(\cos\left(\sqrt{2}\,x\right)+\sin\left(\sqrt{2}\,x\right)\right)\right) & \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$
- Take the derivative of the particular solution

  $\vec{y}'_p(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$
- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$
- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$
- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$
- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \left[\begin{array}{c} \frac{\left(\left(8+(16x+1)\sqrt{2}\right)\sin\left(\sqrt{2}\,x\right)+16\cos\left(\sqrt{2}\,x\right)\left(1+\left(x-\frac{3}{16}\right)\sqrt{2}\right)\right)\mathrm{e}^{-\sqrt{2}\,x}}{1024} - \frac{\left(\left(\sqrt{2}\,x^2-3x+\frac{7\sqrt{2}}{8}-1\right)\sin\left(\sqrt{2}\,x\right)+\cos\cdots}{128} \\ -\frac{\mathrm{e}^{-\sqrt{2}\,x}\left(\left(\left(\frac{1}{4}+\frac{(1-x)\sqrt{2}}{4}+x^2\right)\cos\left(\sqrt{2}\,x\right)-\frac{\left(\frac{1}{2}+(x+3)\sqrt{2}\right)\sin\left(\sqrt{2}\,x\right)}{4}\right)\mathrm{e}^{2\sqrt{2}\,x}+\frac{\left(-\sqrt{2}-1\right)\cos\left(\sqrt{2}\,x\right)}{4}+2\left(x+\cdots\right.\right.}{32} \\ \frac{\left(\left(-8+(-16x-1)\sqrt{2}\right)\cos\left(\sqrt{2}\,x\right)+16\sin\left(\sqrt{2}\,x\right)\left(-1+\left(x-\frac{3}{16}\right)\sqrt{2}\right)\right)\mathrm{e}^{-\sqrt{2}\,x}}{256} - \frac{\left(\left(\sqrt{2}\,x^2+x-\frac{\sqrt{2}}{8}-1\right)\cos\left(\sqrt{2}\,x\right)-\left(\cdots\right.\right.}{32} \\ \frac{\left(\left(16x-6\sqrt{2}-1\right)\cos\left(\sqrt{2}\,x\right)+\left(10\sqrt{2}+2\right)\sin\left(\sqrt{2}\,x\right)\right)\mathrm{e}^{-\sqrt{2}\,x}}{64} + \frac{\mathrm{e}^{\sqrt{2}\,x}\left(\left(\frac{1}{8}+\left(-\frac{3x}{4}+\frac{3}{4}\right)\sqrt{2}\right)\cos\left(\sqrt{2}\,x\right)+\left(\left(\frac{3x}{4}+\cdots\right.\right.\right.}{8} \end{array}\right.$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1(x) + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \left[\begin{array}{c} \frac{\left(\left(8+(16x+1)\sqrt{2}\right)\sin\left(\sqrt{2}\,x\right)+16\cos\left(\sqrt{2}\,x\right)\left(1+\left(x-\frac{3}{16}\right)\cdots\right.\right.}{1024} \\ -\frac{\mathrm{e}^{-\sqrt{2}\,x}\left(\left(\left(\frac{1}{4}+\frac{(1-x)\sqrt{2}}{4}+x^2\right)\cos\left(\sqrt{2}\,x\right)-\cdots\right.\right.}{\cdots} \\ \frac{\left(\left(-8+(-16x-1)\sqrt{2}\right)\cos\left(\sqrt{2}\,x\right)+16\sin\left(\sqrt{2}\,x\right)\left(-1+(x-\cdots\right.\right.}{256} \\ \frac{\left(\left(16x-6\sqrt{2}-1\right)\cos\left(\sqrt{2}\,x\right)+\left(10\sqrt{2}+2\right)\sin\left(\sqrt{2}\,x\right)\right)\cdots}{64} \end{array}\right.$$

- First component of the vector is the solution to the ODE

$$y = \frac{\left(\left(8+(16x+64c_1-64c_2+1)\sqrt{2}\right)\sin\left(\sqrt{2}\,x\right)+16\left(1+\left(x+4c_1+4c_2-\frac{3}{16}\right)\sqrt{2}\right)\cos\left(\sqrt{2}\,x\right)\right)\mathrm{e}^{-\sqrt{2}\,x}}{1024} - \frac{\mathrm{e}^{\sqrt{2}\,x}\left(\left(\left(x^2-8c_3-8c_4+\frac{7}{8}\right)\sqrt{\cdots}\right.\right.}{\cdots}$$

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_high_order, _linear, _nonhomogeneous]]`

$$\boxed{y'''' + 3y'' - 4y = \cos(x)^2 - \cosh(x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 3y'' - 4y = 0$$

The characteristic equation is

$$\lambda^4 + 3\lambda^2 - 4 = 0$$

The roots of the above equation are

$$\lambda_1 = 2i$$
$$\lambda_2 = -2i$$
$$\lambda_3 = 1$$
$$\lambda_4 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} + \mathrm{e}^{2ix} c_3 + \mathrm{e}^{-2ix} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= \mathrm{e}^{-x} \\ y_2 &= \mathrm{e}^{x} \\ y_3 &= \mathrm{e}^{2ix} \\ y_4 &= \mathrm{e}^{-2ix} \end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' + 3y'' - 4y = \cos(x)^2 - \cosh(x)$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)} \, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 & y_4 \\ y_1' & y_2' & y_3' & y_4' \\ y_1'' & y_2'' & y_3'' & y_4'' \\ y_1''' & y_2''' & y_3''' & y_4''' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} \mathrm{e}^{-x} & \mathrm{e}^{x} & \mathrm{e}^{2ix} & \mathrm{e}^{-2ix} \\ -\mathrm{e}^{-x} & \mathrm{e}^{x} & 2i\mathrm{e}^{2ix} & -2i\mathrm{e}^{-2ix} \\ \mathrm{e}^{-x} & \mathrm{e}^{x} & -4\,\mathrm{e}^{2ix} & -4\,\mathrm{e}^{-2ix} \\ -\mathrm{e}^{-x} & \mathrm{e}^{x} & -8i\mathrm{e}^{2ix} & 8i\mathrm{e}^{-2ix} \end{bmatrix}$$

$$|W| = -200i\mathrm{e}^{-x}\mathrm{e}^{x}\mathrm{e}^{2ix}\mathrm{e}^{-2ix}$$

The determinant simplifies to

$$|W| = -200i$$

Now we determine W_i for each U_i.

$$W_1(x) = \det \begin{bmatrix} e^x & e^{2ix} & e^{-2ix} \\ e^x & 2ie^{2ix} & -2ie^{-2ix} \\ e^x & -4\,e^{2ix} & -4\,e^{-2ix} \end{bmatrix}$$
$$= -20ie^x$$

$$W_2(x) = \det \begin{bmatrix} e^{-x} & e^{2ix} & e^{-2ix} \\ -e^{-x} & 2ie^{2ix} & -2ie^{-2ix} \\ e^{-x} & -4\,e^{2ix} & -4\,e^{-2ix} \end{bmatrix}$$
$$= -20ie^{-x}$$

$$W_3(x) = \det \begin{bmatrix} e^{-x} & e^x & e^{-2ix} \\ -e^{-x} & e^x & -2ie^{-2ix} \\ e^{-x} & e^x & -4\,e^{-2ix} \end{bmatrix}$$
$$= -10\,e^{-2ix}$$

$$W_4(x) = \det \begin{bmatrix} e^{-x} & e^x & e^{2ix} \\ -e^{-x} & e^x & 2ie^{2ix} \\ e^{-x} & e^x & -4\,e^{2ix} \end{bmatrix}$$
$$= -10\,e^{2ix}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned} U_1 &= (-1)^{4-1} \int \frac{F(x) W_1(x)}{a W(x)}\, dx \\ &= (-1)^3 \int \frac{\left(\cos(x)^2 - \cosh(x)\right)\left(-20ie^x\right)}{(1)\,(-200i)}\, dx \\ &= -\int \frac{-20i\left(\cos(x)^2 - \cosh(x)\right) e^x}{-200i}\, dx \\ &= -\int \left(\frac{\left(\cos(x)^2 - \cosh(x)\right) e^x}{10}\right) dx \\ &= \frac{x}{20} - \frac{\left(\cos(x) + 2\sin(x)\right) e^x \cos(x)}{50} - \frac{e^x}{25} + \frac{e^{2x}}{40} \end{aligned}$$

$$
\begin{aligned}
U_2 &= (-1)^{4-2} \int \frac{F(x) W_2(x)}{a W(x)}\, dx \\
&= (-1)^2 \int \frac{\left(\cos(x)^2 - \cosh(x)\right)\left(-20 i\,\mathrm{e}^{-x}\right)}{(1)\,(-200 i)}\, dx \\
&= \int \frac{-20 i \left(\cos(x)^2 - \cosh(x)\right) \mathrm{e}^{-x}}{-200 i}\, dx \\
&= \int \left(\frac{\left(\cos(x)^2 - \cosh(x)\right) \mathrm{e}^{-x}}{10}\right) dx \\
&= \frac{\left(-\cos(x) + 2\sin(x)\right) \mathrm{e}^{-x} \cos(x)}{50} - \frac{\mathrm{e}^{-x}}{25} - \frac{x}{20} + \frac{\mathrm{e}^{-2x}}{40}
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{4-3} \int \frac{F(x) W_3(x)}{a W(x)}\, dx \\
&= (-1)^1 \int \frac{\left(\cos(x)^2 - \cosh(x)\right)\left(-10\,\mathrm{e}^{-2ix}\right)}{(1)\,(-200 i)}\, dx \\
&= -\int \frac{-10 \left(\cos(x)^2 - \cosh(x)\right) \mathrm{e}^{-2ix}}{-200 i}\, dx \\
&= -\int \left(-\frac{i \left(\cos(x)^2 - \cosh(x)\right) \mathrm{e}^{-2ix}}{20}\right) dx \\
&= \frac{i\mathrm{e}^{(-1-2i)x}}{200} - \frac{\mathrm{e}^{-2ix}}{80} + \frac{\mathrm{e}^{(1-2i)x}}{100} + \frac{\mathrm{e}^{(-1-2i)x}}{100} - \frac{i\mathrm{e}^{(1-2i)x}}{200} + \frac{ix}{80} - \frac{\mathrm{e}^{-4ix}}{320}
\end{aligned}
$$

$$
\begin{aligned}
U_4 &= (-1)^{4-4} \int \frac{F(x) W_4(x)}{a W(x)}\, dx \\
&= (-1)^0 \int \frac{\left(\cos(x)^2 - \cosh(x)\right)\left(-10\,\mathrm{e}^{2ix}\right)}{(1)\,(-200 i)}\, dx \\
&= \int \frac{-10 \left(\cos(x)^2 - \cosh(x)\right) \mathrm{e}^{2ix}}{-200 i}\, dx \\
&= \int \left(-\frac{i \left(\cos(x)^2 - \cosh(x)\right) \mathrm{e}^{2ix}}{20}\right) dx \\
&= \int -\frac{i \left(\cos(x)^2 - \cosh(x)\right) \mathrm{e}^{2ix}}{20} dx
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4
$$

Hence

$$
\begin{aligned}
y_p = &\left(\frac{x}{20}-\frac{(\cos(x)+2\sin(x))\,\mathrm{e}^{x}\cos(x)}{50}-\frac{\mathrm{e}^{x}}{25}+\frac{\mathrm{e}^{2x}}{40}\right)\left(\mathrm{e}^{-x}\right)\\
&+\left(\frac{(-\cos(x)+2\sin(x))\,\mathrm{e}^{-x}\cos(x)}{50}-\frac{\mathrm{e}^{-x}}{25}-\frac{x}{20}+\frac{\mathrm{e}^{-2x}}{40}\right)\left(\mathrm{e}^{x}\right)\\
&+\left(\frac{i\,\mathrm{e}^{(-1-2i)x}}{200}-\frac{\mathrm{e}^{-2ix}}{80}+\frac{\mathrm{e}^{(1-2i)x}}{100}+\frac{\mathrm{e}^{(-1-2i)x}}{100}-\frac{i\,\mathrm{e}^{(1-2i)x}}{200}+\frac{ix}{80}-\frac{\mathrm{e}^{-4ix}}{320}\right)\left(\mathrm{e}^{2ix}\right)\\
&+\left(\int -\frac{i\left(\cos(x)^{2}-\cosh(x)\right)\mathrm{e}^{2ix}}{20}dx\right)\left(\mathrm{e}^{-2ix}\right)
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = -\frac{1}{8}+\frac{(9+10x)\,\mathrm{e}^{-x}}{200}-\frac{\sin(2x)\,(8x+i)}{320}-\frac{37\cos(2x)}{1600}+\frac{(9-10x)\,\mathrm{e}^{x}}{200}
$$

Which simplifies to

$$
y_p = -\frac{1}{8}+\frac{(9+10x)\,\mathrm{e}^{-x}}{200}-\frac{\sin(2x)\,(8x+i)}{320}-\frac{37\cos(2x)}{1600}+\frac{(9-10x)\,\mathrm{e}^{x}}{200}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p\\
&= \left(c_1\mathrm{e}^{-x}+c_2\mathrm{e}^{x}+\mathrm{e}^{2ix}c_3+\mathrm{e}^{-2ix}c_4\right)\\
&\quad+\left(-\frac{1}{8}+\frac{(9+10x)\,\mathrm{e}^{-x}}{200}-\frac{\sin(2x)\,(8x+i)}{320}-\frac{37\cos(2x)}{1600}+\frac{(9-10x)\,\mathrm{e}^{x}}{200}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & c_1\mathrm{e}^{-x}+c_2\mathrm{e}^{x}+\mathrm{e}^{2ix}c_3+\mathrm{e}^{-2ix}c_4-\frac{1}{8}+\frac{(9+10x)\,\mathrm{e}^{-x}}{200}\\
&-\frac{\sin(2x)\,(8x+i)}{320}-\frac{37\cos(2x)}{1600}+\frac{(9-10x)\,\mathrm{e}^{x}}{200}
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & c_1\mathrm{e}^{-x}+c_2\mathrm{e}^{x}+\mathrm{e}^{2ix}c_3+\mathrm{e}^{-2ix}c_4-\frac{1}{8}+\frac{(9+10x)\,\mathrm{e}^{-x}}{200}\\
&-\frac{\sin(2x)\,(8x+i)}{320}-\frac{37\cos(2x)}{1600}+\frac{(9-10x)\,\mathrm{e}^{x}}{200}
\end{aligned}
$$

Verified OK.

11.53.1 Maple step by step solution

Let's solve

$y'''' + 3y'' - 4y = \cos(x)^2 - \cosh(x)$

- Highest derivative means the order of the ODE is 4

  y''''

☐ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(x)$

    $y_1(x) = y$

  - Define new variable $y_2(x)$

    $y_2(x) = y'$

  - Define new variable $y_3(x)$

    $y_3(x) = y''$

  - Define new variable $y_4(x)$

    $y_4(x) = y'''$

  - Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = \cos(x)^2 - \cosh(x) - 3y_3(x) + 4y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = \cos(x)^2 - \cosh(x) - 3y_3(x) + 4y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 4 & 0 & -3 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ \cos(x)^2 - \cosh(x) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \left[\begin{array}{c} 0 \\ 0 \\ 0 \\ \cos(x)^2 - \cosh(x) \end{array}\right]$$

- Define the coefficient matrix

$$A = \left[\begin{array}{cccc} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 4 & 0 & -3 & 0 \end{array}\right]$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]\right], \left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array}\right]\right], \left[-2\,\mathrm{I}, \left[\begin{array}{c} -\frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{array}\right]\right], \left[2\,\mathrm{I}, \left[\begin{array}{c} \frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ -\frac{\mathrm{I}}{2} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{-x} \cdot \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c}1 \\ 1 \\ 1 \\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \mathrm{e}^{x} \cdot \left[\begin{array}{c}1 \\ 1 \\ 1 \\ 1\end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-2\,\mathrm{I}, \left[\begin{array}{c}-\frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1\end{array}\right]\right]$$

- Solution from eigenpair

$$\mathrm{e}^{-2\,\mathrm{I}x} \cdot \left[\begin{array}{c}-\frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1\end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$\left(\cos\left(2x\right) - \mathrm{I}\sin\left(2x\right)\right) \cdot \left[\begin{array}{c}-\frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1\end{array}\right]$$

- Simplify expression

$$\begin{bmatrix} -\frac{I}{8}(\cos(2x) - I\sin(2x)) \\ -\frac{\cos(2x)}{4} + \frac{I\sin(2x)}{4} \\ \frac{I}{2}(\cos(2x) - I\sin(2x)) \\ \cos(2x) - I\sin(2x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \begin{bmatrix} -\frac{\sin(2x)}{8} \\ -\frac{\cos(2x)}{4} \\ \frac{\sin(2x)}{2} \\ \cos(2x) \end{bmatrix}, \vec{y}_4(x) = \begin{bmatrix} -\frac{\cos(2x)}{8} \\ \frac{\sin(2x)}{4} \\ \frac{\cos(2x)}{2} \\ -\sin(2x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} -e^{-x} & e^{x} & -\frac{\sin(2x)}{8} & -\frac{\cos(2x)}{8} \\ e^{-x} & e^{x} & -\frac{\cos(2x)}{4} & \frac{\sin(2x)}{4} \\ -e^{-x} & e^{x} & \frac{\sin(2x)}{2} & \frac{\cos(2x)}{2} \\ e^{-x} & e^{x} & \cos(2x) & -\sin(2x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} -e^{-x} & e^{x} & -\frac{\sin(2x)}{8} & -\frac{\cos(2x)}{8} \\ e^{-x} & e^{x} & -\frac{\cos(2x)}{4} & \frac{\sin(2x)}{4} \\ -e^{-x} & e^{x} & \frac{\sin(2x)}{2} & \frac{\cos(2x)}{2} \\ e^{-x} & e^{x} & \cos(2x) & -\sin(2x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -1 & 1 & 0 & -\frac{1}{8} \\ 1 & 1 & -\frac{1}{4} & 0 \\ -1 & 1 & 0 & \frac{1}{2} \\ 1 & 1 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \left[\begin{array}{cccc} \frac{2\,\mathrm{e}^{-x}}{5}+\frac{2\,\mathrm{e}^{x}}{5}+\frac{\cos(2x)}{5} & -\frac{2\,\mathrm{e}^{-x}}{5}+\frac{2\,\mathrm{e}^{x}}{5}+\frac{\sin(2x)}{10} & \frac{\mathrm{e}^{-x}}{10}+\frac{\mathrm{e}^{x}}{10}-\frac{\cos(2x)}{5} & -\frac{\mathrm{e}^{-x}}{10}+\frac{\mathrm{e}^{x}}{10}-\mathrm{si} \\ -\frac{2\,\mathrm{e}^{-x}}{5}+\frac{2\,\mathrm{e}^{x}}{5}-\frac{2\sin(2x)}{5} & \frac{2\,\mathrm{e}^{-x}}{5}+\frac{2\,\mathrm{e}^{x}}{5}+\frac{\cos(2x)}{5} & -\frac{\mathrm{e}^{-x}}{10}+\frac{\mathrm{e}^{x}}{10}+\frac{2\sin(2x)}{5} & \frac{\mathrm{e}^{-x}}{10}+\frac{\mathrm{e}^{x}}{10}-\mathrm{cos} \\ \frac{2\,\mathrm{e}^{-x}}{5}+\frac{2\,\mathrm{e}^{x}}{5}-\frac{4\cos(2x)}{5} & -\frac{2\,\mathrm{e}^{-x}}{5}+\frac{2\,\mathrm{e}^{x}}{5}-\frac{2\sin(2x)}{5} & \frac{\mathrm{e}^{-x}}{10}+\frac{\mathrm{e}^{x}}{10}+\frac{4\cos(2x)}{5} & -\frac{\mathrm{e}^{-x}}{10}+\frac{\mathrm{e}^{x}}{10}+2\,\mathrm{s} \\ -\frac{2\,\mathrm{e}^{-x}}{5}+\frac{2\,\mathrm{e}^{x}}{5}+\frac{8\sin(2x)}{5} & \frac{2\,\mathrm{e}^{-x}}{5}+\frac{2\,\mathrm{e}^{x}}{5}-\frac{4\cos(2x)}{5} & -\frac{\mathrm{e}^{-x}}{10}+\frac{\mathrm{e}^{x}}{10}-\frac{8\sin(2x)}{5} & \frac{\mathrm{e}^{-x}}{10}+\frac{\mathrm{e}^{x}}{10}+4\,\mathrm{co} \end{array}\right.$$

- ☐ Find a particular solution of the system of ODEs using variation of parameters
  - Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(x)$ and solve for $\overrightarrow{v}(x)$

    $\overrightarrow{y}_p(x) = \Phi(x) \cdot \overrightarrow{v}(x)$
  - Take the derivative of the particular solution

    $\overrightarrow{y}_p'(x) = \Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x)$
  - Substitute particular solution and its derivative into the system of ODEs

    $\Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$
  - The fundamental matrix has columns that are solutions to the homogeneous system so its der

    $A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$
  - Cancel like terms

    $\Phi(x) \cdot \overrightarrow{v}'(x) = \overrightarrow{f}(x)$
  - Multiply by the inverse of the fundamental matrix

    $\overrightarrow{v}'(x) = \frac{1}{\Phi(x)} \cdot \overrightarrow{f}(x)$
  - Integrate to solve for $\overrightarrow{v}(x)$

    $\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\,ds$
  - Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

    $\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\,ds\right)$
  - Plug in the fundamental matrix and the forcing function and compute

$$\overrightarrow{y}_p(x) = \left[\begin{array}{c} \frac{(5x+8)\mathrm{e}^{-x}}{100}-\frac{7\cos(x)^2}{100}-\frac{\sin(x)\cos(x)x}{20}-\frac{9}{100}+\frac{(-5x+8)\mathrm{e}^{x}}{100} \\ \frac{(-5x-3)\mathrm{e}^{-x}}{100}-\frac{\cos(x)^2 x}{10}+\frac{9\cos(x)\sin(x)}{100}+\frac{(-5x+3)\mathrm{e}^{x}}{100}+\frac{x}{20} \\ \frac{(5x-2)\mathrm{e}^{-x}}{100}+\frac{2\cos(x)^2}{25}+\frac{\sin(x)\cos(x)x}{5}-\frac{1}{25}+\frac{(-5x-2)\mathrm{e}^{x}}{100} \\ \frac{(-5x+7)\mathrm{e}^{-x}}{100}+\frac{x\cos(2x)}{5}+\frac{\sin(2x)}{50}+\frac{(-5x-7)\mathrm{e}^{x}}{100} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3(x) + c_4 \vec{y}_4(x) + \begin{bmatrix} \frac{(5x+8)e^{-x}}{100} - \frac{7\cos(x)^2}{100} - \frac{\sin(x)\cos(x)x}{20} - \frac{9}{100} + \frac{(-5x+8)e^{x}}{100} \\ \frac{(-5x-3)e^{-x}}{100} - \frac{\cos(x)^2 x}{10} + \frac{9\cos(x)\sin(x)}{100} + \frac{(-5x+3)e^{x}}{100} + \frac{x}{20} \\ \frac{(5x-2)e^{-x}}{100} + \frac{2\cos(x)^2}{25} + \frac{\sin(x)\cos(x)x}{5} - \frac{1}{25} + \frac{(-5x-2)e^{x}}{100} \\ \frac{(-5x+7)e^{-x}}{100} + \frac{x\cos(2x)}{5} + \frac{\sin(2x)}{50} + \frac{(-5x-7)e^{x}}{100} \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = -\frac{9}{100} + \frac{(8+5x-100c_1)e^{-x}}{100} + \frac{(-7-25c_4)\cos(x)^2}{100} - \frac{\sin(x)(x+5c_3)\cos(x)}{20} + \frac{(8-5x+100c_2)e^{x}}{100} + \frac{c_4}{8}$$

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'''' + 10y'' + 9y = \sin(x)\sin(2x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 10y'' + 9y = 0$$

The characteristic equation is

$$\lambda^4 + 10\lambda^2 + 9 = 0$$

The roots of the above equation are

$$\lambda_1 = 3i$$
$$\lambda_2 = -3i$$
$$\lambda_3 = i$$
$$\lambda_4 = -i$$

Therefore the homogeneous solution is

$$y_h(x) = e^{ix}c_1 + e^{3ix}c_2 + e^{-ix}c_3 + e^{-3ix}c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{ix}$$

$$y_2 = e^{3ix}$$

$$y_3 = e^{-ix}$$

$$y_4 = e^{-3ix}$$

Now the particular solution to the given ODE is found

$$y'''' + 10y'' + 9y = \sin(x)\sin(2x)$$

Let the particular solution be

$$y_p = U_1y_1 + U_2y_2 + U_3y_3 + U_4y_4$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x)W_i(x)}{aW(x)}\,dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 & y_4 \\ y_1' & y_2' & y_3' & y_4' \\ y_1'' & y_2'' & y_3'' & y_4'' \\ y_1''' & y_2''' & y_3''' & y_4''' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} e^{ix} & e^{3ix} & e^{-ix} & e^{-3ix} \\ ie^{ix} & 3ie^{3ix} & -ie^{-ix} & -3ie^{-3ix} \\ -e^{ix} & -9\,e^{3ix} & -e^{-ix} & -9\,e^{-3ix} \\ -ie^{ix} & -27ie^{3ix} & ie^{-ix} & 27ie^{-3ix} \end{bmatrix}$$

$$|W| = 768\,e^{ix}e^{3ix}e^{-ix}e^{-3ix}$$

The determinant simplifies to

$$|W| = 768$$

Now we determine W_i for each U_i.

$$W_1(x) = \det \begin{bmatrix} e^{3ix} & e^{-ix} & e^{-3ix} \\ 3ie^{3ix} & -ie^{-ix} & -3ie^{-3ix} \\ -9\,e^{3ix} & -e^{-ix} & -9\,e^{-3ix} \end{bmatrix}$$
$$= 48ie^{-ix}$$

$$W_2(x) = \det \begin{bmatrix} e^{ix} & e^{-ix} & e^{-3ix} \\ ie^{ix} & -ie^{-ix} & -3ie^{-3ix} \\ -e^{ix} & -e^{-ix} & -9\,e^{-3ix} \end{bmatrix}$$
$$= 16ie^{-3ix}$$

$$W_3(x) = \det \begin{bmatrix} e^{ix} & e^{3ix} & e^{-3ix} \\ ie^{ix} & 3ie^{3ix} & -3ie^{-3ix} \\ -e^{ix} & -9\,e^{3ix} & -9\,e^{-3ix} \end{bmatrix}$$
$$= -48ie^{ix}$$

$$W_4(x) = \det \begin{bmatrix} e^{ix} & e^{3ix} & e^{-ix} \\ ie^{ix} & 3ie^{3ix} & -ie^{-ix} \\ -e^{ix} & -9\,e^{3ix} & -e^{-ix} \end{bmatrix}$$
$$= -16ie^{3ix}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned} U_1 &= (-1)^{4-1} \int \frac{F(x)W_1(x)}{aW(x)}\,dx \\ &= (-1)^3 \int \frac{(\sin(x)\sin(2x))\,(48ie^{-ix})}{(1)\,(768)}\,dx \\ &= -\int \frac{48i\sin(x)\sin(2x)\,e^{-ix}}{768}\,dx \\ &= -\int \left(\frac{i\sin(x)\sin(2x)\,e^{-ix}}{16}\right)\,dx \\ &= -\left(\int \frac{i\sin(x)\sin(2x)\,e^{-ix}}{16}dx\right) \end{aligned}$$

$$\begin{aligned}
U_2 &= (-1)^{4-2} \int \frac{F(x) W_2(x)}{a W(x)} \, dx \\
&= (-1)^2 \int \frac{(\sin(x)\sin(2x))\left(16i \mathrm{e}^{-3ix}\right)}{(1)(768)} \, dx \\
&= \int \frac{16i \sin(x) \sin(2x) \mathrm{e}^{-3ix}}{768} \, dx \\
&= \int \left(\frac{i \sin(x) \sin(2x) \mathrm{e}^{-3ix}}{48}\right) dx \\
&= \int \frac{i \sin(x) \sin(2x) \mathrm{e}^{-3ix}}{48} dx
\end{aligned}$$

$$\begin{aligned}
U_3 &= (-1)^{4-3} \int \frac{F(x) W_3(x)}{a W(x)} \, dx \\
&= (-1)^1 \int \frac{(\sin(x)\sin(2x))\left(-48i \mathrm{e}^{ix}\right)}{(1)(768)} \, dx \\
&= -\int \frac{-48i \sin(x) \sin(2x) \mathrm{e}^{ix}}{768} \, dx \\
&= -\int \left(-\frac{i \sin(x) \sin(2x) \mathrm{e}^{ix}}{16}\right) dx \\
&= -\left(\int -\frac{i \sin(x) \sin(2x) \mathrm{e}^{ix}}{16} dx\right)
\end{aligned}$$

$$\begin{aligned}
U_4 &= (-1)^{4-4} \int \frac{F(x) W_4(x)}{a W(x)} \, dx \\
&= (-1)^0 \int \frac{(\sin(x)\sin(2x))\left(-16i \mathrm{e}^{3ix}\right)}{(1)(768)} \, dx \\
&= \int \frac{-16i \sin(x) \sin(2x) \mathrm{e}^{3ix}}{768} \, dx \\
&= \int \left(-\frac{i \sin(x) \sin(2x) \mathrm{e}^{3ix}}{48}\right) dx \\
&= \int -\frac{i \sin(x) \sin(2x) \mathrm{e}^{3ix}}{48} dx
\end{aligned}$$

Now that all the U_i functions have been determined, the particular solution is found from

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4$$

Hence

$$
\begin{aligned}
y_p = {} & \left(-\left(\int \frac{i \sin(x) \sin(2x)\, e^{-ix}}{16} dx\right)\right) \left(e^{ix}\right) \\
& + \left(\int \frac{i \sin(x) \sin(2x)\, e^{-3ix}}{48} dx\right) \left(e^{3ix}\right) \\
& + \left(-\left(\int -\frac{i \sin(x) \sin(2x)\, e^{ix}}{16} dx\right)\right) \left(e^{-ix}\right) \\
& + \left(\int -\frac{i \sin(x) \sin(2x)\, e^{3ix}}{48} dx\right) \left(e^{-3ix}\right)
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = \frac{i\left(\left(\int \sin(x) \sin(2x)\, e^{-3ix} dx\right) e^{3ix} - 3\left(\int \sin(x) \sin(2x)\, e^{-ix} dx\right) e^{ix} + 3\left(\int \sin(x) \sin(2x)\, e^{ix} dx\right) e^{-ix} -}{48}
$$

Which simplifies to

$$
y_p = \frac{\left(\int \sin(x) \sin(2x) \sin(3x)\, dx\right) \cos(3x)}{24} - \frac{\left(\int \sin(x) \sin(2x) \cos(3x)\, dx\right) \sin(3x)}{24} - \frac{\left(\int \sin(x)^2 \sin(2x)\, d\right.}{8}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(e^{ix} c_1 + e^{3ix} c_2 + e^{-ix} c_3 + e^{-3ix} c_4\right) \\
&\quad + \left(\frac{\left(\int \sin(x) \sin(2x) \sin(3x)\, dx\right) \cos(3x)}{24} - \frac{\left(\int \sin(x) \sin(2x) \cos(3x)\, dx\right) \sin(3x)}{24}\right. \\
&\quad \left. - \frac{\left(\int \sin(x)^2 \sin(2x)\, dx\right) \cos(x)}{8} + \frac{\left(\int (1 - \cos(4x))\, dx\right) \sin(x)}{32}\right)
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
\begin{aligned}
y = {} & e^{ix} c_1 + e^{3ix} c_2 + e^{-ix} c_3 + e^{-3ix} c_4 + \frac{\left(\int \sin(x) \sin(2x) \sin(3x)\, dx\right) \cos(3x)}{24} \\
& - \frac{\left(\int \sin(x) \sin(2x) \cos(3x)\, dx\right) \sin(3x)}{24} \\
& - \frac{\left(\int \sin(x)^2 \sin(2x)\, dx\right) \cos(x)}{8} + \frac{\left(\int (1 - \cos(4x))\, dx\right) \sin(x)}{32}
\end{aligned} \tag{1}
$$

Verification of solutions

$$y = e^{ix}c_1 + e^{3ix}c_2 + e^{-ix}c_3 + e^{-3ix}c_4 + \frac{\left(\int \sin(x)\sin(2x)\sin(3x)\,dx\right)\cos(3x)}{24} - \frac{\left(\int \sin(x)\sin(2x)\cos(3x)\,dx\right)\sin(3x)}{24} - \frac{\left(\int \sin(x)^2\sin(2x)\,dx\right)\cos(x)}{8} + \frac{\left(\int (1-\cos(4x))\,dx\right)\sin(x)}{32}$$

Verified OK.

11.54.1 Maple step by step solution

Let's solve

$y'''' + 10y'' + 9y = \sin(x)\sin(2x)$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs
  - ◦ Define new variable $y_1(x)$

    $y_1(x) = y$
  - ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$
  - ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$
  - ◦ Define new variable $y_4(x)$

    $y_4(x) = y'''$
  - ◦ Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = \sin(x)\sin(2x) - 10y_3(x) - 9y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = \sin(x)\sin(2x) - 10y_3(x) - 9y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -9 & 0 & -10 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ \sin(x)\sin(2x) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 0 \\ \sin(x)\sin(2x) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -9 & 0 & -10 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-3\,\mathrm{I}, \begin{bmatrix} -\frac{\mathrm{I}}{27} \\ -\frac{1}{9} \\ \frac{\mathrm{I}}{3} \\ 1 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} \mathrm{I} \\ -1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right], \left[3\,\mathrm{I}, \begin{bmatrix} \frac{\mathrm{I}}{27} \\ -\frac{1}{9} \\ -\frac{\mathrm{I}}{3} \\ 1 \end{bmatrix}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-3\,\mathrm{I}, \left[\begin{array}{c} -\frac{\mathrm{I}}{27} \\ -\frac{1}{9} \\ \frac{\mathrm{I}}{3} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$e^{-3\,\mathrm{I}x} \cdot \left[\begin{array}{c} -\frac{\mathrm{I}}{27} \\ -\frac{1}{9} \\ \frac{\mathrm{I}}{3} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of sin and cos

$$(\cos(3x) - \mathrm{I}\sin(3x)) \cdot \left[\begin{array}{c} -\frac{\mathrm{I}}{27} \\ -\frac{1}{9} \\ \frac{\mathrm{I}}{3} \\ 1 \end{array}\right]$$

- Simplify expression

$$\left[\begin{array}{c} -\frac{\mathrm{I}}{27}(\cos(3x) - \mathrm{I}\sin(3x)) \\ -\frac{\cos(3x)}{9} + \frac{\mathrm{I}\sin(3x)}{9} \\ \frac{\mathrm{I}}{3}(\cos(3x) - \mathrm{I}\sin(3x)) \\ \cos(3x) - \mathrm{I}\sin(3x) \end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_1(x) = \left[\begin{array}{c} -\frac{\sin(3x)}{27} \\ -\frac{\cos(3x)}{9} \\ \frac{\sin(3x)}{3} \\ \cos(3x) \end{array}\right], \vec{y}_2(x) = \left[\begin{array}{c} -\frac{\cos(3x)}{27} \\ \frac{\sin(3x)}{9} \\ \frac{\cos(3x)}{3} \\ -\sin(3x) \end{array}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$\mathrm{e}^{-\mathrm{I}x} \cdot \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(x) - \mathrm{I}\sin(x)) \cdot \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ -\cos(x) + \mathrm{I}\sin(x) \\ \mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ \cos(x) - \mathrm{I}\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \begin{bmatrix} -\sin(x) \\ -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_4(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1(x) + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x)=\begin{bmatrix} -\frac{\sin(3x)}{27} & -\frac{\cos(3x)}{27} & -\sin(x) & -\cos(x) \\ -\frac{\cos(3x)}{9} & \frac{\sin(3x)}{9} & -\cos(x) & \sin(x) \\ \frac{\sin(3x)}{3} & \frac{\cos(3x)}{3} & \sin(x) & \cos(x) \\ \cos(3x) & -\sin(3x) & \cos(x) & -\sin(x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0)=I$ where I is t

  $\Phi(x)=\phi(x)\cdot\frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x)=\begin{bmatrix} -\frac{\sin(3x)}{27} & -\frac{\cos(3x)}{27} & -\sin(x) & -\cos(x) \\ -\frac{\cos(3x)}{9} & \frac{\sin(3x)}{9} & -\cos(x) & \sin(x) \\ \frac{\sin(3x)}{3} & \frac{\cos(3x)}{3} & \sin(x) & \cos(x) \\ \cos(3x) & -\sin(3x) & \cos(x) & -\sin(x) \end{bmatrix}\cdot\frac{1}{\begin{bmatrix} 0 & -\frac{1}{27} & 0 & -1 \\ -\frac{1}{9} & 0 & -1 & 0 \\ 0 & \frac{1}{3} & 0 & 1 \\ 1 & 0 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x)=\begin{bmatrix} -\frac{\cos(x)^3}{2}+\frac{3\cos(x)}{2} & -\frac{\sin(3x)}{24}+\frac{9\sin(x)}{8} & \frac{\sin(x)^2\cos(x)}{2} & \frac{\sin(x)^3}{6} \\ -\frac{3\sin(x)^3}{2} & -\frac{\cos(x)^3}{2}+\frac{3\cos(x)}{2} & \frac{3\sin(3x)}{8}-\frac{\sin(x)}{8} & \frac{\sin(x)^2\cos(x)}{2} \\ -\frac{9\sin(x)^2\cos(x)}{2} & -\frac{3\sin(x)^3}{2} & \frac{9\cos(x)^3}{2}-\frac{7\cos(x)}{2} & \frac{3\sin(3x)}{8}-\frac{\sin(x)}{8} \\ -\frac{27\sin(3x)}{8}+\frac{9\sin(x)}{8} & -\frac{9\sin(x)^2\cos(x)}{2} & -\frac{27\sin(3x)}{8}+\frac{\sin(x)}{8} & \frac{9\cos(x)^3}{2}-\frac{7\cos(x)}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x)=\Phi(x)\cdot\vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}'_p(x)=\Phi'(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}'(x)=A\cdot\Phi(x)\cdot\vec{v}(x)+\vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A\cdot\Phi(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}'(x)=A\cdot\Phi(x)\cdot\vec{v}(x)+\vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \overrightarrow{v}'(x) = \overrightarrow{f}(x)$
- Multiply by the inverse of the fundamental matrix

  $\overrightarrow{v}'(x) = \frac{1}{\Phi(x)} \cdot \overrightarrow{f}(x)$
- Integrate to solve for $\overrightarrow{v}(x)$

  $\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$
- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$
- Plug in the fundamental matrix and the forcing function and compute

$$\overrightarrow{y}_p(x) = \left[\begin{array}{c} \frac{\sin(x)\left(2\cos(x)^2 x-3\cos(x)\sin(x)+x\right)}{48} \\ -\frac{7\cos(x)^2\sin(x)}{48}+\frac{\sin(x)}{12}+\frac{\cos(x)^3 x}{8}-\frac{\cos(x) x}{16} \\ -\frac{3\cos(x)^2\sin(x) x}{8}+\frac{5\sin(x)^2\cos(x)}{16}+\frac{x\sin(x)}{16} \\ \frac{9\cos(x)^2\sin(x)}{16}-\frac{\sin(x)}{4}-\frac{9\cos(x)^3 x}{8}+\frac{13\cos(x) x}{16} \end{array}\right]$$

- Plug particular solution back into general solution

$$\overrightarrow{y}(x) = c_1\overrightarrow{y}_1(x)+c_2\overrightarrow{y}_2(x)+c_3\overrightarrow{y}_3(x)+c_4\overrightarrow{y}_4(x)+\left[\begin{array}{c} \frac{\sin(x)\left(2\cos(x)^2 x-3\cos(x)\sin(x)+x\right)}{48} \\ -\frac{7\cos(x)^2\sin(x)}{48}+\frac{\sin(x)}{12}+\frac{\cos(x)^3 x}{8}-\frac{\cos(x) x}{16} \\ -\frac{3\cos(x)^2\sin(x) x}{8}+\frac{5\sin(x)^2\cos(x)}{16}+\frac{x\sin(x)}{16} \\ \frac{9\cos(x)^2\sin(x)}{16}-\frac{\sin(x)}{4}-\frac{9\cos(x)^3 x}{8}+\frac{13\cos(x) x}{16} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = -\frac{c_2\cos(3x)}{27}-\frac{c_1\sin(3x)}{27}-\frac{\sin(x)^2\cos(x)}{16}+\frac{\left(2\cos(x)^2 x+x-48c_3\right)\sin(x)}{48}-c_4\cos(x)$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = \cot(x)}$$

12.1.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = \cot(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\cot(x)}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \cos(x)\,dx$$

Hence

$$u_1 = -\sin(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\cot(x)}{1}\,dx$$

Which simplifies to

$$u_2 = \int \cos(x)\cot(x)\,dx$$

Hence

$$u_2 = \cos(x) + \ln(\csc(x) - \cot(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\cos(x)\sin(x) + (\cos(x) + \ln(\csc(x) - \cot(x)))\sin(x)$$

Which simplifies to

$$y_p(x) = \sin(x)\ln(\csc(x) - \cot(x))$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + (\sin(x) \ln(\csc(x) - \cot(x)))
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 \cos(x) + c_2 \sin(x) + \sin(x) \ln(\csc(x) - \cot(x)) \tag{1}
$$

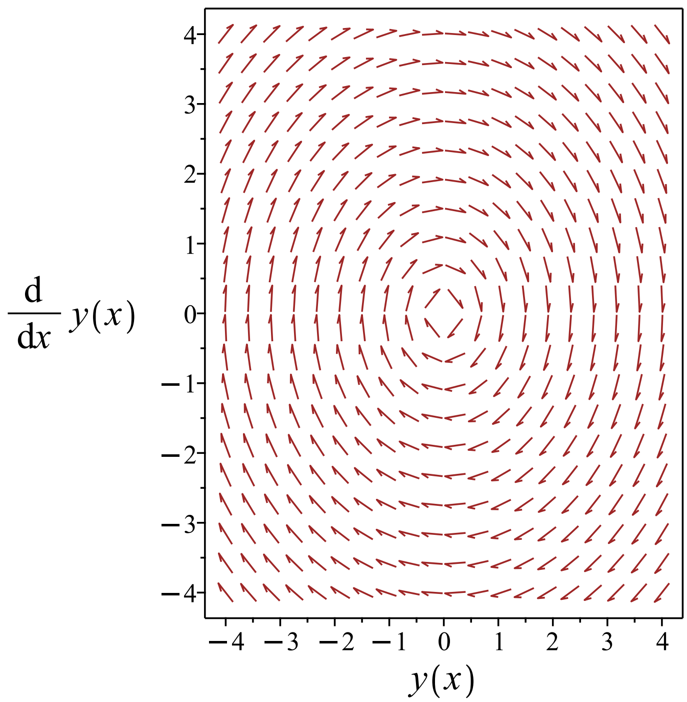

Figure 484: Slope field plot

Verification of solutions

$$
y = c_1 \cos(x) + c_2 \sin(x) + \sin(x) \ln(\csc(x) - \cot(x))
$$

Verified OK.

12.1.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 425: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}
y_1 &= z_1 \\
&= \cos(x)
\end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\
&= \cos(x) \int \frac{1}{\cos(x)^2}\,dx \\
&= \cos(x)\,(\tan(x))
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x)))
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$

$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\cot(x)}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \cos(x)\,dx$$

Hence

$$u_1 = -\sin(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\cot(x)}{1}\,dx$$

Which simplifies to

$$u_2 = \int \cos(x)\cot(x)\,dx$$

Hence

$$u_2 = \cos(x) + \ln(\csc(x) - \cot(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\cos(x)\sin(x) + (\cos(x) + \ln(\csc(x) - \cot(x)))\sin(x)$$

Which simplifies to

$$y_p(x) = \sin(x)\ln(\csc(x) - \cot(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + (\sin(x)\ln(\csc(x) - \cot(x))) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) + \sin(x) \ln(\csc(x) - \cot(x)) \tag{1}$$

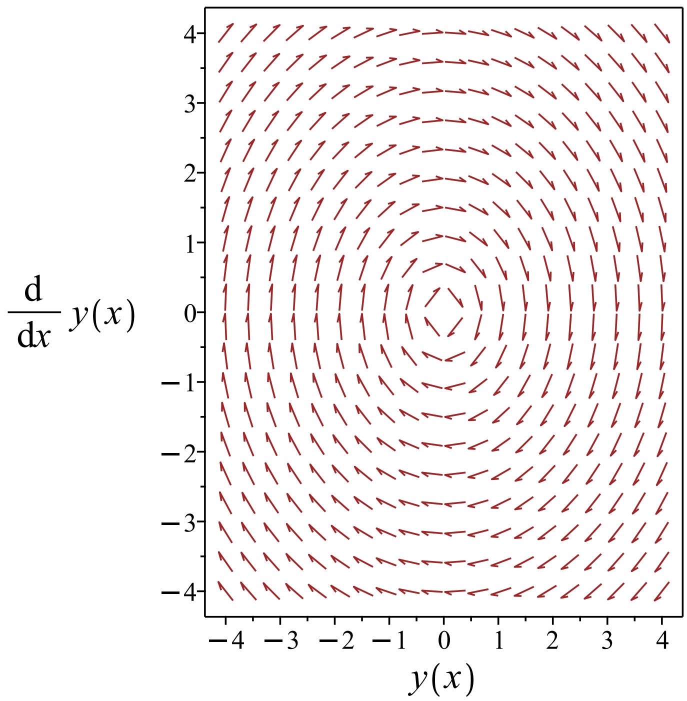

Figure 485: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + \sin(x) \ln(\csc(x) - \cot(x))$$

Verified OK.

12.1.3 Maple step by step solution

Let's solve

$y'' + y = \cot(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$
- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$
- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$
- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \cot(x)\right]$
  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$
  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$
  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\cos(x) \left(\int \cos(x)\, dx\right) + \sin(x) \left(\int \cos(x) \cot(x)\, dx\right)$
  - Compute integrals

    $y_p(x) = \sin(x) \ln(\csc(x) - \cot(x))$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + \sin(x) \ln(\csc(x) - \cot(x))$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + y = \tan(x)^2}$$

12.2.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = \tan(x)^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)}\\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i\\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i\\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\tan(x)^2}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \sin(x)\tan(x)^2\,dx$$

Hence

$$u_1 = -\frac{\sin(x)^4}{\cos(x)} - \left(2 + \sin(x)^2\right)\cos(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\tan(x)^2}{1}\,dx$$

Which simplifies to

$$u_2 = \int \sin(x)\tan(x)\,dx$$

Hence

$$u_2 = -\sin(x) + \ln(\sec(x) + \tan(x))$$

Which simplifies to

$$u_1 = -\cos(x) - \sec(x)$$
$$u_2 = -\sin(x) + \ln(\sec(x) + \tan(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (-\cos(x) - \sec(x))\cos(x) + (-\sin(x) + \ln(\sec(x) + \tan(x)))\sin(x)$$

Which simplifies to

$$y_p(x) = -2 + \sin(x)\ln(\sec(x) + \tan(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + (-2 + \sin(x)\ln(\sec(x) + \tan(x))) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) - 2 + \sin(x)\ln(\sec(x) + \tan(x)) \tag{1}$$

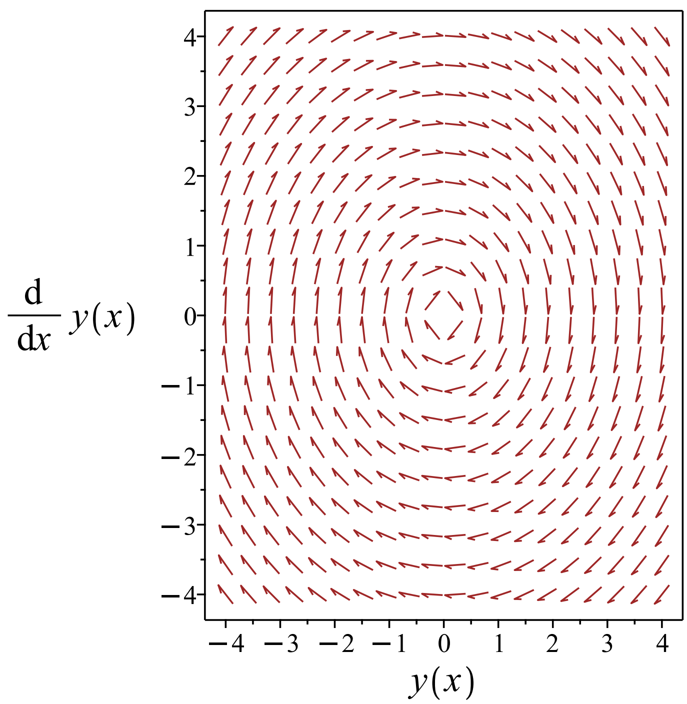

Figure 486: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) - 2 + \sin(x)\ln(\sec(x) + \tan(x))$$

Verified OK.

12.2.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 427: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\,dx \\ &= \cos(x)(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x)(\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\tan(x)^2}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \sin(x)\tan(x)^2\,dx$$

Hence

$$u_1 = -\frac{\sin(x)^4}{\cos(x)} - \left(2+\sin(x)^2\right)\cos(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\tan(x)^2}{1}\,dx$$

Which simplifies to

$$u_2 = \int \sin(x)\tan(x)\,dx$$

Hence

$$u_2 = -\sin(x) + \ln(\sec(x)+\tan(x))$$

Which simplifies to

$$u_1 = -\cos(x) - \sec(x)$$
$$u_2 = -\sin(x) + \ln(\sec(x)+\tan(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (-\cos(x)-\sec(x))\cos(x) + (-\sin(x)+\ln(\sec(x)+\tan(x)))\sin(x)$$

Which simplifies to

$$y_p(x) = -2 + \sin(x)\ln(\sec(x)+\tan(x))$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + (-2 + \sin(x) \ln(\sec(x) + \tan(x)))
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(x) + c_2 \sin(x) - 2 + \sin(x) \ln(\sec(x) + \tan(x)) \tag{1}
$$

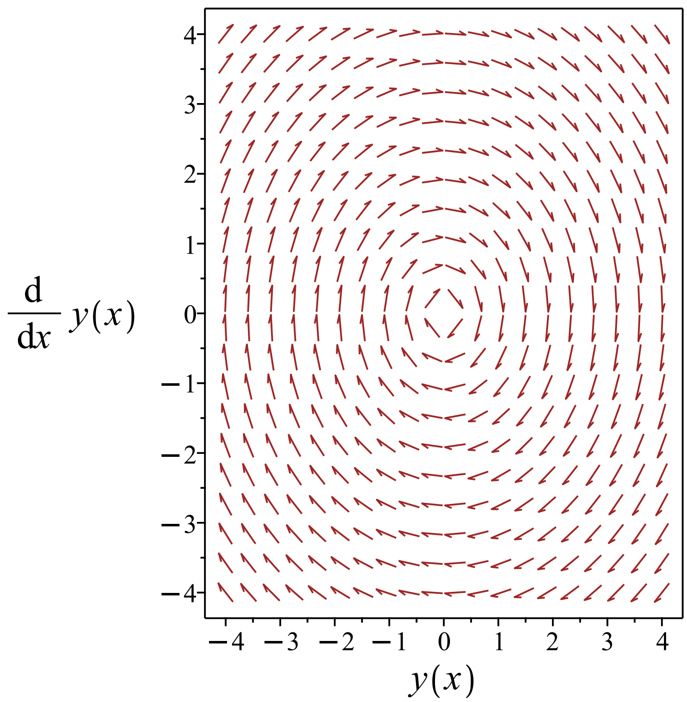

Figure 487: Slope field plot

Verification of solutions

$$
y = c_1 \cos(x) + c_2 \sin(x) - 2 + \sin(x) \ln(\sec(x) + \tan(x))
$$

Verified OK.

12.2.3 Maple step by step solution

Let's solve

$y'' + y = \tan(x)^2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \tan(x)^2\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 1$

- ○ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\cos(x)\left(\int \sin(x)\tan(x)^2\,dx\right) + \sin(x)\left(\int \sin(x)\tan(x)\,dx\right)$$

- Compute integrals

  $$y_p(x) = -2 + \sin(x)\ln(\sec(x) + \tan(x))$$

- Substitute particular solution into general solution to ODE

  $$y = c_1\cos(x) + c_2\sin(x) - 2 + \sin(x)\ln(\sec(x) + \tan(x))$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + y = \sec(x)}$$

12.3.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = \sec(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)}\\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i\\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i\\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\sec(x)}{1} dx$$

Which simplifies to

$$u_1 = -\int \tan(x)\, dx$$

Hence

$$u_1 = \ln(\cos(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\sec(x)}{1} dx$$

Which simplifies to

$$u_2 = \int 1 dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln(\cos(x))\cos(x) + x\sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + (\ln(\cos(x))\cos(x) + x\sin(x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) + \ln(\cos(x)) \cos(x) + x \sin(x) \tag{1}$$

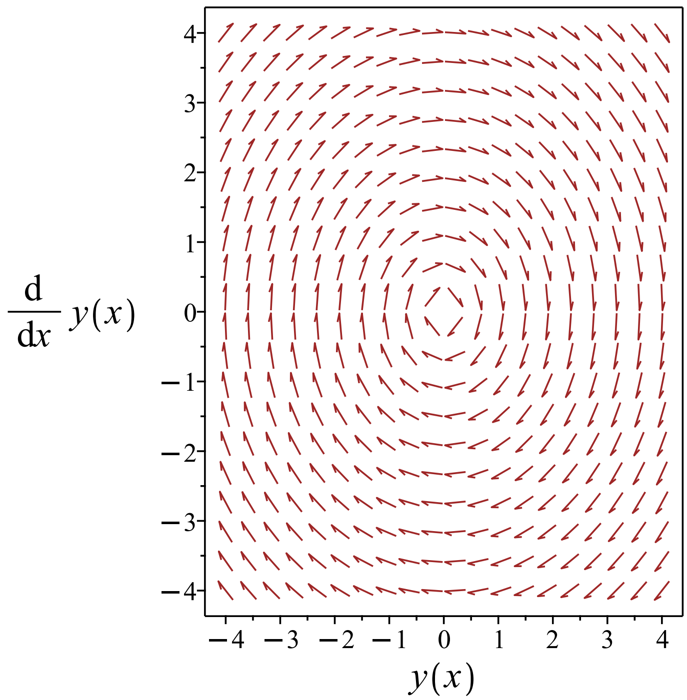

Figure 488: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + \ln(\cos(x)) \cos(x) + x \sin(x)$$

Verified OK.

12.3.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 429: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\
&= \cos(x)\,(\tan(x))
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x)))
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\sec(x)}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \tan(x)\,dx$$

Hence

$$u_1 = \ln(\cos(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\sec(x)}{1}\,dx$$

Which simplifies to

$$u_2 = \int 1 dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln(\cos(x))\cos(x) + x\sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + (\ln(\cos(x))\cos(x) + x\sin(x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\cos(x) + c_2\sin(x) + \ln(\cos(x))\cos(x) + x\sin(x) \tag{1}$$

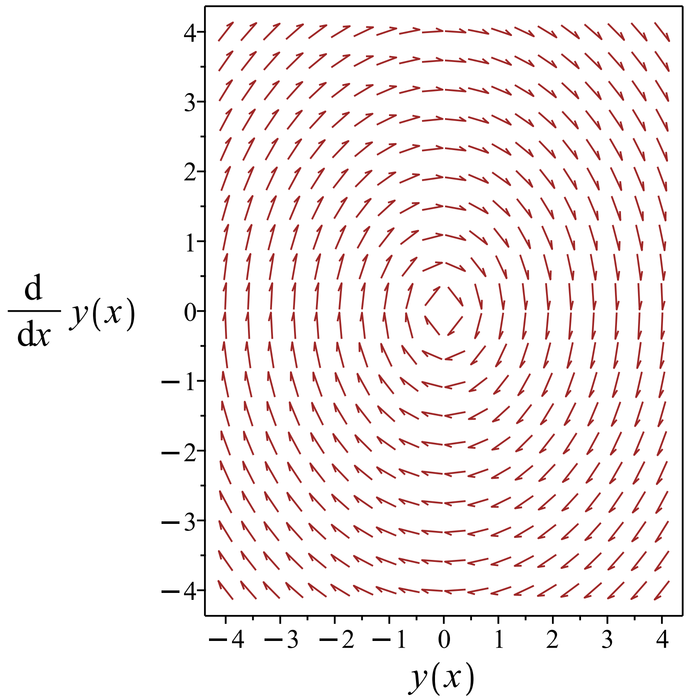

Figure 489: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + \ln(\cos(x)) \cos(x) + x \sin(x)$$

Verified OK.

12.3.3 Maple step by step solution

Let's solve

$y'' + y = \sec(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

$r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ∘ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \sec(x)\right]$

  ∘ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$

  ∘ Compute Wronskian

  $W(y_1(x), y_2(x)) = 1$

  ∘ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\cos(x)\left(\int \tan(x)\, dx\right) + \sin(x)\left(\int 1 dx\right)$

  ∘ Compute integrals

  $y_p(x) = \ln(\cos(x)) \cos(x) + x \sin(x)$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + \ln(\cos(x)) \cos(x) + x \sin(x)$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + y = \sec(x)^3}$$

12.4.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = \sec(x)^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\sec(x)^3}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \tan(x)\sec(x)^2\,dx$$

Hence

$$u_1 = -\frac{\sec(x)^2}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\sec(x)^3}{1}\,dx$$

Which simplifies to

$$u_2 = \int \sec(x)^2\,dx$$

Hence

$$u_2 = \tan(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\sec(x)^2\cos(x)}{2} + \sin(x)\tan(x)$$

Which simplifies to

$$y_p(x) = -\cos(x) + \frac{\sec(x)}{2}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + \left(-\cos(x) + \frac{\sec(x)}{2}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(x) + c_2 \sin(x) - \cos(x) + \frac{\sec(x)}{2} \tag{1}
$$

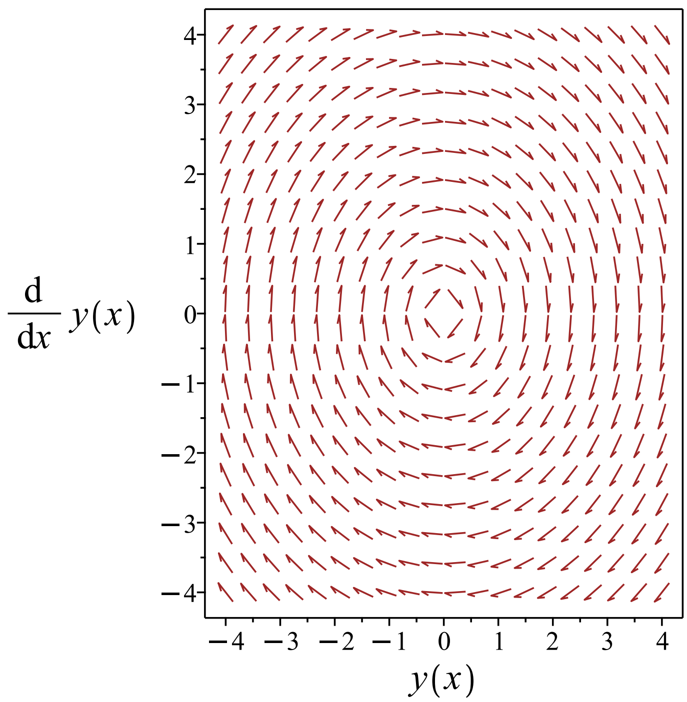

Figure 490: Slope field plot

Verification of solutions

$$
y = c_1 \cos(x) + c_2 \sin(x) - \cos(x) + \frac{\sec(x)}{2}
$$

Verified OK.

12.4.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 431: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2} \, dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2} \, dx \\ &= \cos(x) (\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x) (\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\sec(x)^3}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \tan(x)\sec(x)^2\,dx$$

Hence

$$u_1 = -\frac{\sec(x)^2}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\sec(x)^3}{1}\,dx$$

Which simplifies to

$$u_2 = \int \sec(x)^2\,dx$$

Hence

$$u_2 = \tan(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\sec(x)^2\cos(x)}{2} + \sin(x)\tan(x)$$

Which simplifies to

$$y_p(x) = -\cos(x) + \frac{\sec(x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + \left(-\cos(x) + \frac{\sec(x)}{2}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) - \cos(x) + \frac{\sec(x)}{2} \tag{1}$$

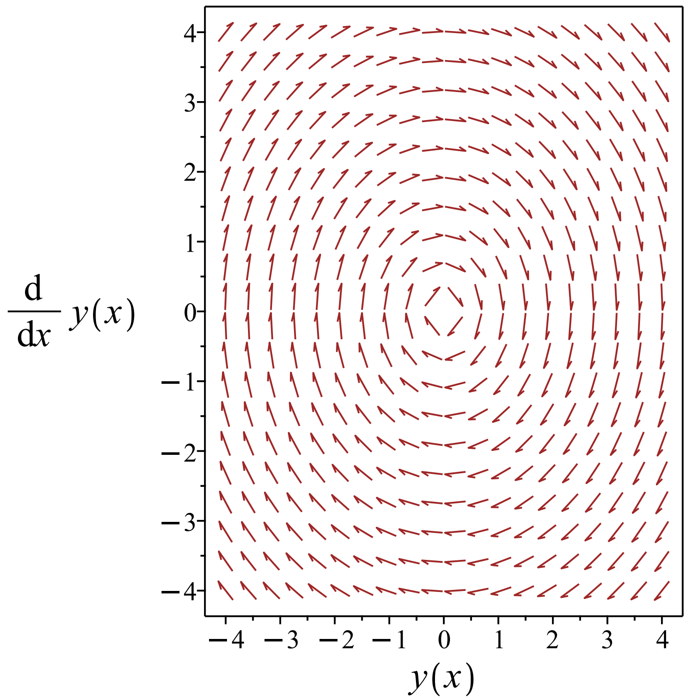

Figure 491: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) - \cos(x) + \frac{\sec(x)}{2}$$

Verified OK.

12.4.3 Maple step by step solution

Let's solve

$y'' + y = \sec(x)^3$

- Highest derivative means the order of the ODE is 2

y''

- Characteristic polynomial of homogeneous ODE

$r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \sec(x)^3\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\cos(x) \left(\int \tan(x) \sec(x)^2 dx\right) + \sin(x) \left(\int \sec(x)^2 dx\right)$

  - Compute integrals

    $y_p(x) = -\cos(x) + \frac{\sec(x)}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(x) + c_2 \sin(x) - \cos(x) + \frac{\sec(x)}{2}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + 4y = \sec(x)^2}$$

12.5.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 4, f(x) = \sec(x)^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 4\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(4)} \\ &= \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2i \\ \lambda_2 &= -2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2i \\ \lambda_2 &= -2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(2x) + c_2 \sin(2x))$$

Or

$$y = c_1 \cos(2x) + c_2 \sin(2x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(2x) + c_2 \sin(2x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(2x)$$
$$y_2 = \sin(2x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(2x) & \sin(2x) \\ \frac{d}{dx}(\cos(2x)) & \frac{d}{dx}(\sin(2x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(2x) & \sin(2x) \\ -2\sin(2x) & 2\cos(2x) \end{vmatrix}$$

Therefore

$$W = (\cos(2x))(2\cos(2x)) - (\sin(2x))(-2\sin(2x))$$

Which simplifies to

$$W = 2\cos(2x)^2 + 2\sin(2x)^2$$

Which simplifies to

$$W = 2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(2x)\sec(x)^2}{2} dx$$

Which simplifies to

$$u_1 = -\int \tan(x)\, dx$$

Hence

$$u_1 = \ln(\cos(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(2x)\sec(x)^2}{2} dx$$

Which simplifies to

$$u_2 = \int \frac{\cos(2x)\sec(x)^2}{2} dx$$

Hence

$$u_2 = x - \frac{\tan(x)}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln(\cos(x))\cos(2x) + \left(x - \frac{\tan(x)}{2}\right)\sin(2x)$$

Which simplifies to

$$y_p(x) = \ln(\cos(x))\left(2\cos(x)^2 - 1\right) + 2\sin(x)\cos(x)x - \sin(x)^2$$

Therefore the general solution is

$$y = y_h + y_p$$
$$= (c_1 \cos(2x) + c_2 \sin(2x)) + \left(\ln(\cos(x))\left(2\cos(x)^2 - 1\right) + 2\sin(x)\cos(x)\,x - \sin(x)^2\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(2x) + c_2 \sin(2x) + \ln(\cos(x))\left(2\cos(x)^2 - 1\right) + 2\sin(x)\cos(x)\,x - \sin(x)^2 \tag{1}$$

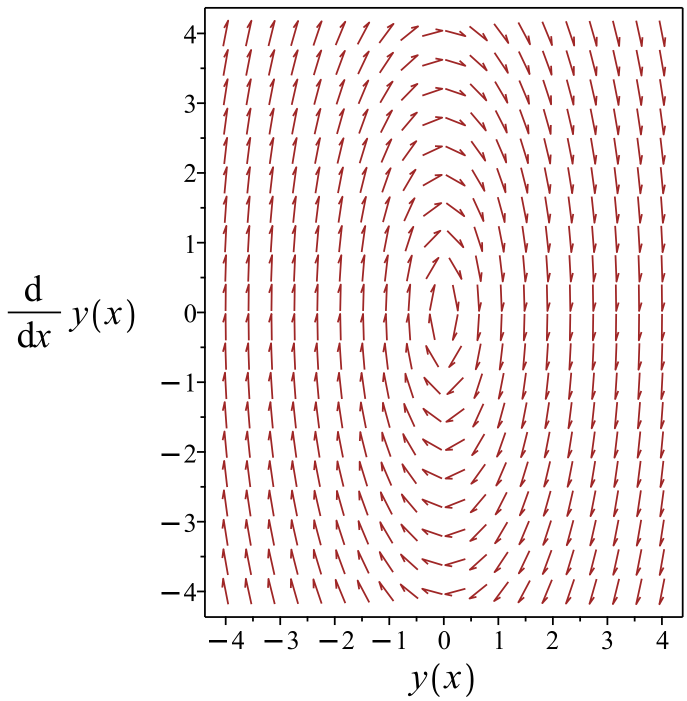

Figure 492: Slope field plot

Verification of solutions

$$y = c_1 \cos(2x) + c_2 \sin(2x) + \ln(\cos(x))\left(2\cos(x)^2 - 1\right) + 2\sin(x)\cos(x)\,x - \sin(x)^2$$

Verified OK.

12.5.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 433: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(2x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2} \, dx \\ &= \cos(2x) \int \frac{1}{\cos(2x)^2} \, dx \\ &= \cos(2x) \left(\frac{\tan(2x)}{2} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(2x)) + c_2 \left(\cos(2x) \left(\frac{\tan(2x)}{2} \right) \right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(2x)$$
$$y_2 = \frac{\sin(2x)}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(2x) & \frac{\sin(2x)}{2} \\ \frac{d}{dx}(\cos(2x)) & \frac{d}{dx}\left(\frac{\sin(2x)}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(2x) & \frac{\sin(2x)}{2} \\ -2\sin(2x) & \cos(2x) \end{vmatrix}$$

Therefore

$$W = (\cos(2x))(\cos(2x)) - \left(\frac{\sin(2x)}{2}\right)(-2\sin(2x))$$

Which simplifies to

$$W = \sin(2x)^2 + \cos(2x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sin(2x)\sec(x)^2}{2}}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \tan(x)\,dx$$

Hence

$$u_1 = \ln(\cos(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(2x)\sec(x)^2}{1}\,dx$$

Which simplifies to

$$u_2 = \int \cos(2x)\sec(x)^2\,dx$$

Hence

$$u_2 = 2x - \tan(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln(\cos(x))\cos(2x) + \frac{(2x - \tan(x))\sin(2x)}{2}$$

Which simplifies to

$$y_p(x) = \ln(\cos(x))\left(2\cos(x)^2 - 1\right) + 2\sin(x)\cos(x)\,x - \sin(x)^2$$

Therefore the general solution is

$y = y_h + y_p$

$$= \left(c_1\cos(2x) + \frac{c_2\sin(2x)}{2}\right) + \left(\ln(\cos(x))\left(2\cos(x)^2 - 1\right) + 2\sin(x)\cos(x)\,x - \sin(x)^2\right)$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1\cos(2x) + \frac{c_2\sin(2x)}{2} + \ln(\cos(x))\left(2\cos(x)^2 - 1\right) + 2\sin(x)\cos(x)\,x - \sin(x)^2 \tag{1}$$

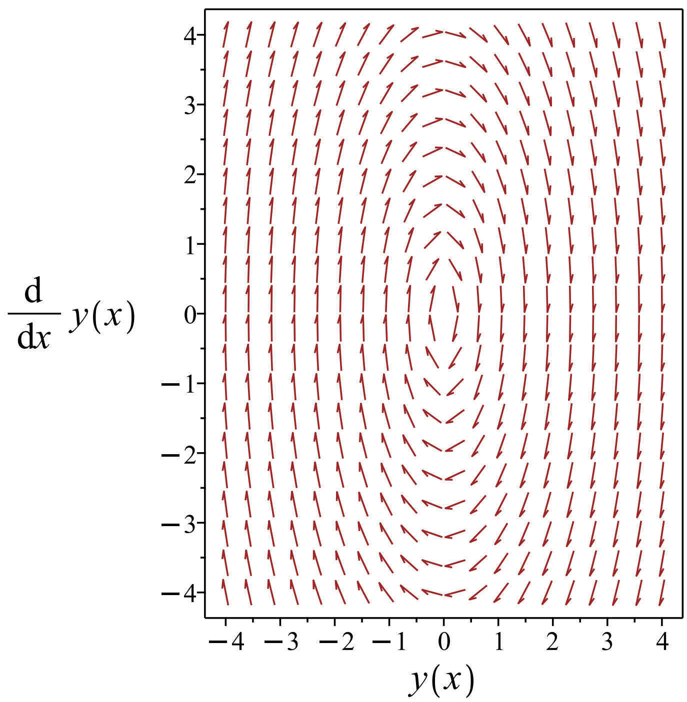

Figure 493: Slope field plot

<u>Verification of solutions</u>

$$y = c_1\cos(2x) + \frac{c_2\sin(2x)}{2} + \ln(\cos(x))\left(2\cos(x)^2 - 1\right) + 2\sin(x)\cos(x)\,x - \sin(x)^2$$

Verified OK.

12.5.3 Maple step by step solution

Let's solve

$y'' + 4y = \sec(x)^2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r = (-2\,\mathrm{I}, 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(2x) + c_2 \sin(2x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \sec(x)^2\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(2x) & \sin(2x) \\ -2\sin(2x) & 2\cos(2x) \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2$

  ◦ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\cos(2x)\left(\int \tan(x)\,dx\right) + \frac{\sin(2x)\left(\int \cos(2x)\sec(x)^2 dx\right)}{2}$$

- Compute integrals

$$y_p(x) = \ln(\cos(x))\left(2\cos(x)^2 - 1\right) + 2\sin(x)\cos(x)\,x - \sin(x)^2$$

- Substitute particular solution into general solution to ODE

$$y = c_1\cos(2x) + c_2\sin(2x) + \ln(\cos(x))\left(2\cos(x)^2 - 1\right) + 2\sin(x)\cos(x)\,x - \sin(x)^2$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + y = \sec(x)\tan(x)}$$

12.6.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = \sec(x)\tan(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)}\\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i\\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i\\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\tan(x)\sec(x)}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \tan(x)^2\,dx$$

Hence

$$u_1 = -\tan(x) + x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\sec(x)\tan(x)}{1}\,dx$$

Which simplifies to

$$u_2 = \int \tan(x)\,dx$$

Hence

$$u_2 = -\ln(\cos(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (-\tan(x) + x)\cos(x) - \ln(\cos(x))\sin(x)$$

Which simplifies to

$$y_p(x) = -\ln(\cos(x))\sin(x) - \sin(x) + \cos(x)\,x$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + (-\ln(\cos(x)) \sin(x) - \sin(x) + \cos(x)\, x)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) - \ln(\cos(x)) \sin(x) - \sin(x) + \cos(x)\, x \tag{1}$$

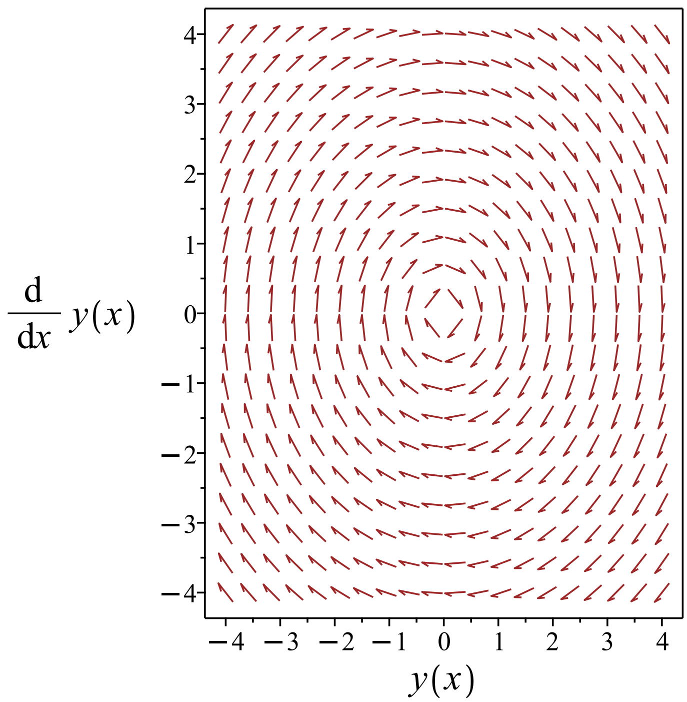

Figure 494: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) - \ln(\cos(x)) \sin(x) - \sin(x) + \cos(x)\, x$$

Verified OK.

12.6.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 435: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\ &= \cos(x)(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x)(\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\tan(x)\sec(x)}{1} dx$$

Which simplifies to

$$u_1 = -\int \tan(x)^2 dx$$

Hence

$$u_1 = -\tan(x) + x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\sec(x)\tan(x)}{1} dx$$

Which simplifies to

$$u_2 = \int \tan(x) dx$$

Hence

$$u_2 = -\ln(\cos(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (-\tan(x) + x)\cos(x) - \ln(\cos(x))\sin(x)$$

Which simplifies to

$$y_p(x) = -\ln(\cos(x))\sin(x) - \sin(x) + \cos(x)x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + (-\ln(\cos(x))\sin(x) - \sin(x) + \cos(x)x) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) - \ln(\cos(x)) \sin(x) - \sin(x) + \cos(x) x \tag{1}$$

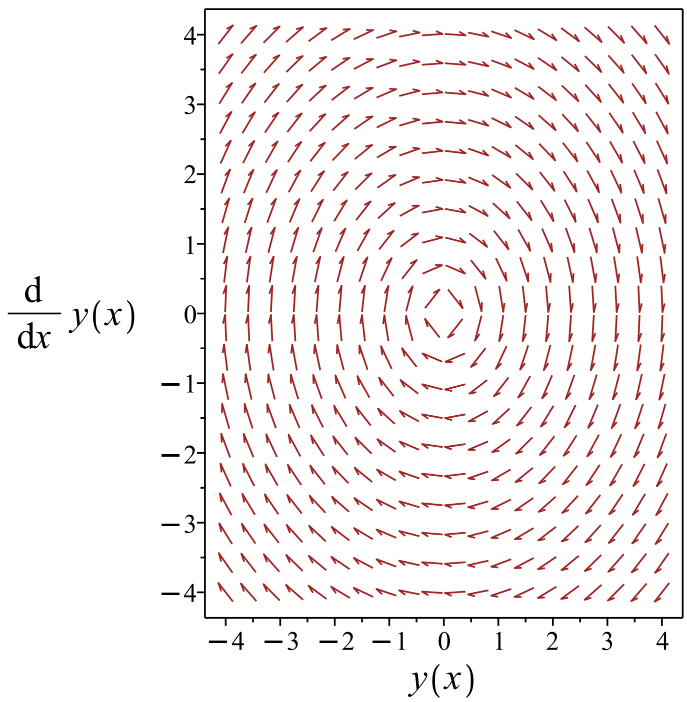

Figure 495: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) - \ln(\cos(x)) \sin(x) - \sin(x) + \cos(x) x$$

Verified OK.

12.6.3 Maple step by step solution

Let's solve

$y'' + y = \sec(x) \tan(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$
- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$
- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$
- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \sec(x)\tan(x)\right]$
  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$
  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$
  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\cos(x)\left(\int \tan(x)^2 dx\right) + \sin(x)\left(\int \tan(x) dx\right)$
  - Compute integrals

    $y_p(x) = -\ln(\cos(x))\sin(x) - \sin(x) + \cos(x)x$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(x) + c_2 \sin(x) - \ln(\cos(x))\sin(x) - \sin(x) + \cos(x)x$

Problem number: 7.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y''+4y'+5y = \mathrm{e}^{-2x} \sec(x)}$$

12.7.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 4, C = 5, f(x) = \mathrm{e}^{-2x} \sec(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y''+4y'+5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 4, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4\lambda\, e^{\lambda x} + 5\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 4, C = 5$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{-4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{4^2 - (4)\,(1)\,(5)} \\
&= -2 \pm i
\end{aligned}$$

Hence

$$\begin{aligned}
\lambda_1 &= -2 + i \\
\lambda_2 &= -2 - i
\end{aligned}$$

Which simplifies to

$$\begin{aligned}
\lambda_1 &= -2 + i \\
\lambda_2 &= -2 - i
\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -2$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-2x}(c_1 \cos(x) + c_2 \sin(x))$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)\,\mathrm{e}^{-2x}$$
$$y_2 = \mathrm{e}^{-2x}\sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x)\,\mathrm{e}^{-2x} & \mathrm{e}^{-2x}\sin(x) \\ \frac{d}{dx}\left(\cos(x)\,\mathrm{e}^{-2x}\right) & \frac{d}{dx}\left(\mathrm{e}^{-2x}\sin(x)\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x)\,\mathrm{e}^{-2x} & \mathrm{e}^{-2x}\sin(x) \\ -\mathrm{e}^{-2x}\sin(x) - 2\cos(x)\,\mathrm{e}^{-2x} & -2\,\mathrm{e}^{-2x}\sin(x) + \cos(x)\,\mathrm{e}^{-2x} \end{vmatrix}$$

Therefore

$$W = \left(\cos(x)\,\mathrm{e}^{-2x}\right)\left(-2\,\mathrm{e}^{-2x}\sin(x) + \cos(x)\,\mathrm{e}^{-2x}\right) - \left(\mathrm{e}^{-2x}\sin(x)\right)\left(-\mathrm{e}^{-2x}\sin(x) - 2\cos(x)\,\mathrm{e}^{-2x}\right)$$

Which simplifies to

$$W = \mathrm{e}^{-4x}\cos(x)^2 + \mathrm{e}^{-4x}\sin(x)^2$$

Which simplifies to

$$W = e^{-4x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{e^{-4x} \sin(x) \sec(x)}{e^{-4x}} dx$$

Which simplifies to

$$u_1 = -\int \tan(x)\, dx$$

Hence

$$u_1 = \ln(\cos(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x) e^{-4x} \sec(x)}{e^{-4x}} dx$$

Which simplifies to

$$u_2 = \int 1 dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln(\cos(x)) \cos(x) e^{-2x} + x e^{-2x} \sin(x)$$

Which simplifies to

$$y_p(x) = e^{-2x}(\ln(\cos(x)) \cos(x) + x \sin(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-2x}(c_1 \cos(x) + c_2 \sin(x))\right) + \left(e^{-2x}(\ln(\cos(x)) \cos(x) + x \sin(x))\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + e^{-2x}(\ln(\cos(x)) \cos(x) + x \sin(x)) \tag{1}$$

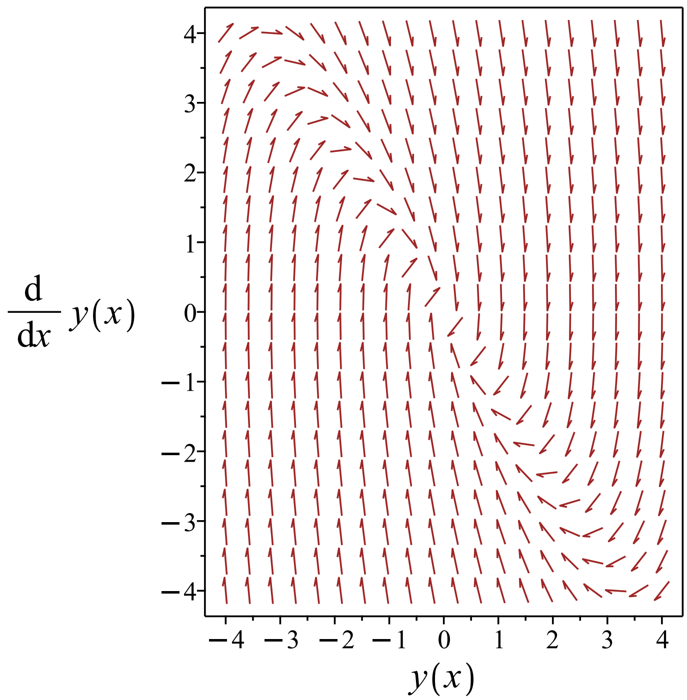

Figure 496: Slope field plot

Verification of solutions

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + e^{-2x}(\ln(\cos(x)) \cos(x) + x \sin(x))$$

Verified OK.

12.7.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 437: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4}{1}\,dx} \\ &= z_1 e^{-2x} \\ &= z_1\left(\mathrm{e}^{-2x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)\,e^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{4}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-4x}}{(y_1)^2}\,dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\cos(x)\,e^{-2x}\right) + c_2\left(\cos(x)\,e^{-2x}(\tan(x))\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 5y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = e^{-2x}\cos(x)\,c_1 + c_2 e^{-2x}\sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)\,\mathrm{e}^{-2x}$$
$$y_2 = \mathrm{e}^{-2x}\sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x)\,\mathrm{e}^{-2x} & \mathrm{e}^{-2x}\sin(x) \\ \frac{d}{dx}\left(\cos(x)\,\mathrm{e}^{-2x}\right) & \frac{d}{dx}\left(\mathrm{e}^{-2x}\sin(x)\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x)\,\mathrm{e}^{-2x} & \mathrm{e}^{-2x}\sin(x) \\ -\mathrm{e}^{-2x}\sin(x) - 2\cos(x)\,\mathrm{e}^{-2x} & -2\,\mathrm{e}^{-2x}\sin(x) + \cos(x)\,\mathrm{e}^{-2x} \end{vmatrix}$$

Therefore

$$W = \left(\cos(x)\,\mathrm{e}^{-2x}\right)\left(-2\,\mathrm{e}^{-2x}\sin(x) + \cos(x)\,\mathrm{e}^{-2x}\right) - \left(\mathrm{e}^{-2x}\sin(x)\right)\left(-\mathrm{e}^{-2x}\sin(x) - 2\cos(x)\,\mathrm{e}^{-2x}\right)$$

Which simplifies to

$$W = \mathrm{e}^{-4x}\cos(x)^2 + \mathrm{e}^{-4x}\sin(x)^2$$

Which simplifies to

$$W = \mathrm{e}^{-4x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\mathrm{e}^{-4x} \sin(x) \sec(x)}{\mathrm{e}^{-4x}} \, dx$$

Which simplifies to

$$u_1 = -\int \tan(x) \, dx$$

Hence

$$u_1 = \ln(\cos(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x) \mathrm{e}^{-4x} \sec(x)}{\mathrm{e}^{-4x}} \, dx$$

Which simplifies to

$$u_2 = \int 1 dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln(\cos(x)) \cos(x) \mathrm{e}^{-2x} + x \, \mathrm{e}^{-2x} \sin(x)$$

Which simplifies to

$$y_p(x) = \mathrm{e}^{-2x} (\ln(\cos(x)) \cos(x) + x \sin(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{-2x} \cos(x) c_1 + c_2 \mathrm{e}^{-2x} \sin(x)\right) + \left(\mathrm{e}^{-2x} (\ln(\cos(x)) \cos(x) + x \sin(x))\right) \end{aligned}$$

Which simplifies to

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + e^{-2x}(\ln(\cos(x))\cos(x) + x\sin(x))$$

Summary

The solution(s) found are the following

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + e^{-2x}(\ln(\cos(x))\cos(x) + x\sin(x)) \tag{1}$$

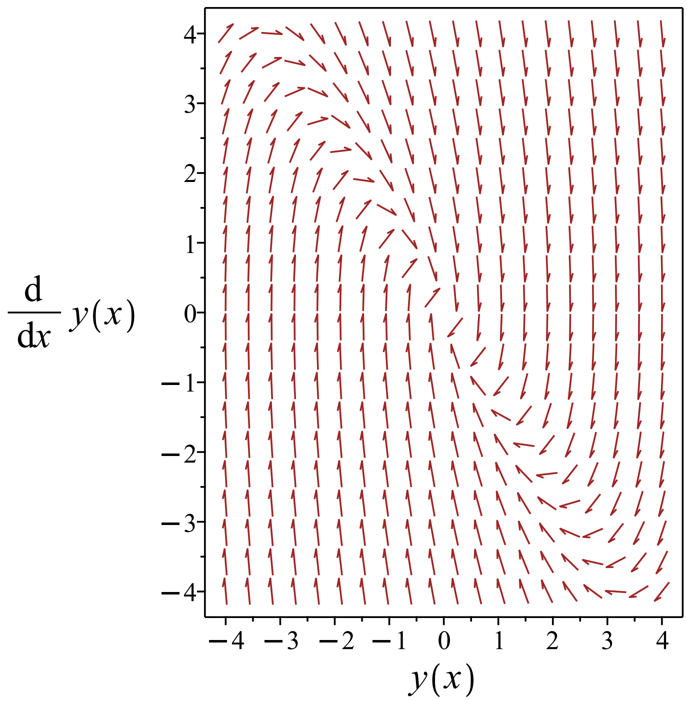

Figure 497: Slope field plot

Verification of solutions

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + e^{-2x}(\ln(\cos(x))\cos(x) + x\sin(x))$$

Verified OK.

12.7.3 Maple step by step solution

Let's solve

$y'' + 4y' + 5y = e^{-2x} \sec(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4r + 5 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-4) \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-2 - I, -2 + I)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x) e^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-2x} \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{-2x} \cos(x) c_1 + c_2 e^{-2x} \sin(x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = e^{-2x} \sec(x)\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) e^{-2x} & e^{-2x} \sin(x) \\ -e^{-2x} \sin(x) - 2\cos(x) e^{-2x} & -2 e^{-2x} \sin(x) + \cos(x) e^{-2x} \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{-4x}$

- ○ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -e^{-2x}\left(\cos(x)\left(\int \tan(x)\,dx\right) - \sin(x)\left(\int 1dx\right)\right)$$

- Compute integrals

$$y_p(x) = e^{-2x}(\ln(\cos(x))\cos(x) + x\sin(x))$$

- Substitute particular solution into general solution to ODE

$$y = e^{-2x}\cos(x)\,c_1 + c_2e^{-2x}\sin(x) + e^{-2x}(\ln(\cos(x))\cos(x) + x\sin(x))$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' - 2y' + 5y = e^{x} \tan(2x)}$$

12.8.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 5, f(x) = e^{x} \tan(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 2\lambda\,\mathrm{e}^{\lambda x} + 5\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-2^2 - (4)\,(1)\,(5)}\\ &= 1 \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 1 + 2i\\ \lambda_2 &= 1 - 2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 + 2i\\ \lambda_2 &= 1 - 2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 1$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{x}(c_1 \cos(2x) + c_2 \sin(2x))$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{x}(c_1 \cos(2x) + c_2 \sin(2x))$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^x \cos(2x)$$
$$y_2 = e^x \sin(2x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x \cos(2x) & e^x \sin(2x) \\ \frac{d}{dx}(e^x \cos(2x)) & \frac{d}{dx}(e^x \sin(2x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^x \cos(2x) & e^x \sin(2x) \\ e^x \cos(2x) - 2 e^x \sin(2x) & e^x \sin(2x) + 2 e^x \cos(2x) \end{vmatrix}$$

Therefore

$$W = (e^x \cos(2x))(e^x \sin(2x) + 2 e^x \cos(2x)) - (e^x \sin(2x))(e^x \cos(2x) - 2 e^x \sin(2x))$$

Which simplifies to

$$W = 2 e^{2x} \sin(2x)^2 + 2 e^{2x} \cos(2x)^2$$

Which simplifies to

$$W = 2\,\mathrm{e}^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\mathrm{e}^{2x} \sin(2x) \tan(2x)}{2\,\mathrm{e}^{2x}}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(2x) \tan(2x)}{2} dx$$

Hence

$$u_1 = \frac{\sin(2x)}{4} - \frac{\ln(\sec(2x) + \tan(2x))}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\mathrm{e}^{2x} \cos(2x) \tan(2x)}{2\,\mathrm{e}^{2x}}\, dx$$

Which simplifies to

$$u_2 = \int \frac{\sin(2x)}{2} dx$$

Hence

$$u_2 = -\frac{\cos(2x)}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{\sin(2x)}{4} - \frac{\ln(\sec(2x) + \tan(2x))}{4}\right) \mathrm{e}^{x} \cos(2x) - \frac{\cos(2x)\,\mathrm{e}^{x} \sin(2x)}{4}$$

Which simplifies to

$$y_p(x) = -\frac{\mathrm{e}^{x} \cos(2x) \ln(\sec(2x) + \tan(2x))}{4}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (e^x(c_1 \cos(2x) + c_2 \sin(2x))) + \left(-\frac{e^x \cos(2x) \ln(\sec(2x) + \tan(2x))}{4}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = e^x(c_1 \cos(2x) + c_2 \sin(2x)) - \frac{e^x \cos(2x) \ln(\sec(2x) + \tan(2x))}{4} \tag{1}
$$

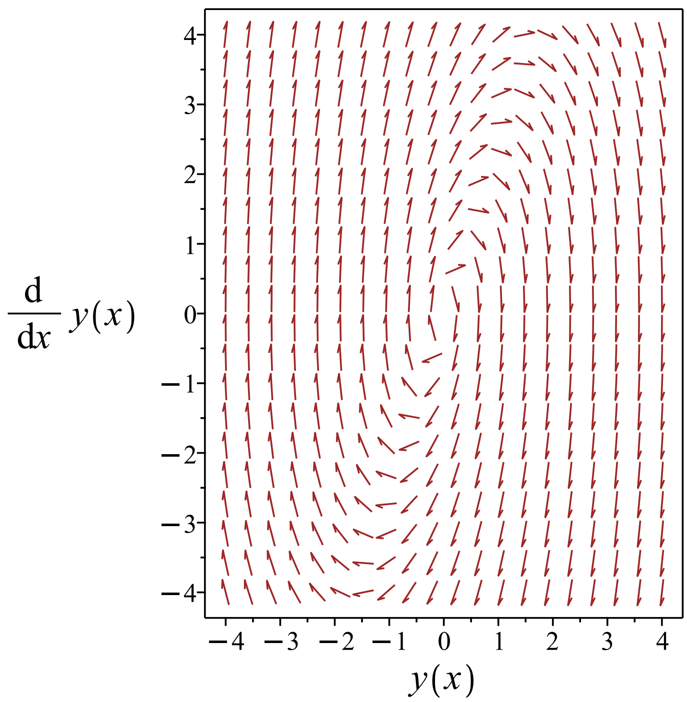

Figure 498: Slope field plot

Verification of solutions

$$
y = e^x(c_1 \cos(2x) + c_2 \sin(2x)) - \frac{e^x \cos(2x) \ln(\sec(2x) + \tan(2x))}{4}
$$

Verified OK.

12.8.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 439: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(2x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^x \\
&= z_1(\mathrm{e}^x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^x \cos(2x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\tan(2x)}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x \cos(2x)) + c_2\left(\mathrm{e}^x \cos(2x)\left(\frac{\tan(2x)}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' + 5y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^x \cos(2x)\, c_1 + \frac{\mathrm{e}^x \sin(2x)\, c_2}{2}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \mathrm{e}^x \cos(2x) \\ y_2 &= \frac{\mathrm{e}^x \sin(2x)}{2} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^x \cos(2x) & \frac{\mathrm{e}^x \sin(2x)}{2} \\ \frac{d}{dx}\left(\mathrm{e}^x \cos(2x)\right) & \frac{d}{dx}\left(\frac{\mathrm{e}^x \sin(2x)}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^x \cos(2x) & \frac{\mathrm{e}^x \sin(2x)}{2} \\ \mathrm{e}^x \cos(2x) - 2\,\mathrm{e}^x \sin(2x) & \frac{\mathrm{e}^x \sin(2x)}{2} + \mathrm{e}^x \cos(2x) \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^x \cos(2x)\right)\left(\frac{\mathrm{e}^x \sin(2x)}{2} + \mathrm{e}^x \cos(2x)\right) - \left(\frac{\mathrm{e}^x \sin(2x)}{2}\right)\left(\mathrm{e}^x \cos(2x) - 2\,\mathrm{e}^x \sin(2x)\right)$$

Which simplifies to

$$W = e^{2x} \sin(2x)^2 + e^{2x} \cos(2x)^2$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{e^{2x} \sin(2x) \tan(2x)}{2}}{e^{2x}} dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(2x) \tan(2x)}{2} dx$$

Hence

$$u_1 = \frac{\sin(2x)}{4} - \frac{\ln(\sec(2x) + \tan(2x))}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{2x} \cos(2x) \tan(2x)}{e^{2x}} dx$$

Which simplifies to

$$u_2 = \int \sin(2x)\, dx$$

Hence

$$u_2 = -\frac{\cos(2x)}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{\sin(2x)}{4} - \frac{\ln(\sec(2x) + \tan(2x))}{4}\right) e^x \cos(2x) - \frac{\cos(2x) e^x \sin(2x)}{4}$$

Which simplifies to

$$y_p(x) = -\frac{e^x \cos(2x) \ln(\sec(2x) + \tan(2x))}{4}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(e^x \cos(2x) c_1 + \frac{e^x \sin(2x) c_2}{2}\right) + \left(-\frac{e^x \cos(2x) \ln(\sec(2x) + \tan(2x))}{4}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = e^x \cos(2x) c_1 + \frac{e^x \sin(2x) c_2}{2} - \frac{e^x \cos(2x) \ln(\sec(2x) + \tan(2x))}{4} \tag{1}
$$

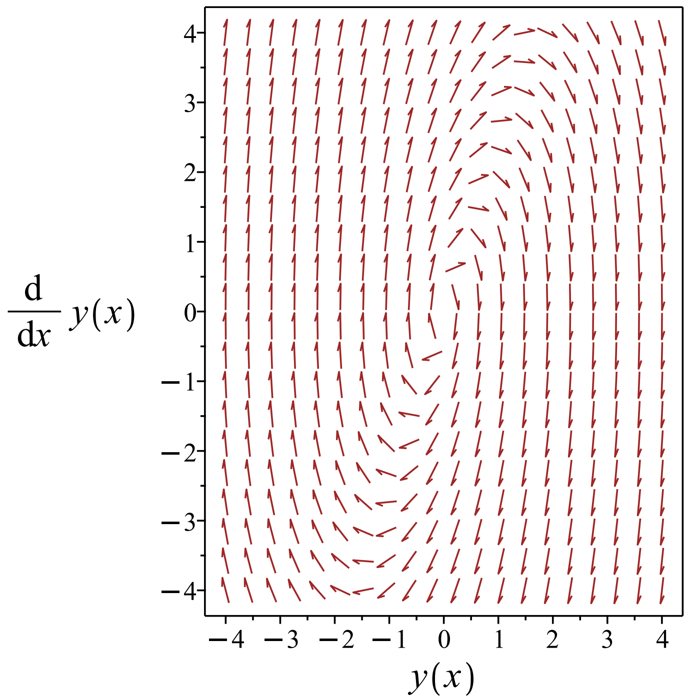

Figure 499: Slope field plot

Verification of solutions

$$
y = e^x \cos(2x) c_1 + \frac{e^x \sin(2x) c_2}{2} - \frac{e^x \cos(2x) \ln(\sec(2x) + \tan(2x))}{4}
$$

Verified OK.

12.8.3 Maple step by step solution

Let's solve

$y'' - 2y' + 5y = e^{x} \tan(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 5 = 0$

- Use quadratic formula to solve for r

  $r = \frac{2 \pm (\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r = (1 - 2\,\mathrm{I}, 1 + 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{x} \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{x} \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{x} \cos(2x)\, c_1 + e^{x} \sin(2x)\, c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = e^{x} \tan(2x)\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{x} \cos(2x) & e^{x} \sin(2x) \\ e^{x} \cos(2x) - 2 e^{x} \sin(2x) & e^{x} \sin(2x) + 2 e^{x} \cos(2x) \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2 e^{2x}$

- ○ Substitute functions into equation for $y_p(x)$

$$y_p(x) = \frac{e^x \left(-\cos(2x) \left(\int \sin(2x) \tan(2x) dx\right) + \sin(2x) \left(\int \sin(2x) dx\right)\right)}{2}$$

- ∘ Compute integrals

$$y_p(x) = -\frac{e^x \cos(2x) \ln(\sec(2x) + \tan(2x))}{4}$$

- Substitute particular solution into general solution to ODE

$$y = e^x \sin(2x) c_2 - \frac{e^x \cos(2x) \ln(\sec(2x) + \tan(2x))}{4} + e^x \cos(2x) c_1$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''+6y'+9y=\frac{\mathrm{e}^{-3x}}{x^3}}$$

12.9.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=1, B=6, C=9, f(x)=\frac{\mathrm{e}^{-3x}}{x^3}$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+6y'+9y=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 6, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 6\lambda \, e^{\lambda x} + 9 \, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 6\lambda + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 6, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-6}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(6)^2 - (4)(1)(9)} \\ &= -3\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 3$. Therefore the solution is

$$y = c_1 e^{-3x} + c_2 x \, e^{-3x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{-3x} + c_2 x \, e^{-3x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}y_1 &= e^{-3x} \\ y_2 &= x \, e^{-3x}\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-3x} & x\,\mathrm{e}^{-3x} \\ \frac{d}{dx}(\mathrm{e}^{-3x}) & \frac{d}{dx}(x\,\mathrm{e}^{-3x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{-3x} & x\,\mathrm{e}^{-3x} \\ -3\,\mathrm{e}^{-3x} & \mathrm{e}^{-3x} - 3x\,\mathrm{e}^{-3x} \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{-3x}\right)\left(\mathrm{e}^{-3x} - 3x\,\mathrm{e}^{-3x}\right) - \left(x\,\mathrm{e}^{-3x}\right)\left(-3\,\mathrm{e}^{-3x}\right)$$

Which simplifies to

$$W = \mathrm{e}^{-6x}$$

Which simplifies to

$$W = \mathrm{e}^{-6x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\mathrm{e}^{-6x}}{x^2}}{\mathrm{e}^{-6x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{1}{x^2}dx$$

Hence

$$u_1 = \frac{1}{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{e^{-6x}}{x^3}}{e^{-6x}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x^3}dx$$

Hence

$$u_2 = -\frac{1}{2x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{e^{-3x}}{2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-3x} + c_2 x\, e^{-3x}\right) + \left(\frac{e^{-3x}}{2x}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-3x}(c_2 x + c_1) + \frac{e^{-3x}}{2x}$$

Summary

The solution(s) found are the following

$$y = e^{-3x}(c_2 x + c_1) + \frac{e^{-3x}}{2x} \tag{1}$$

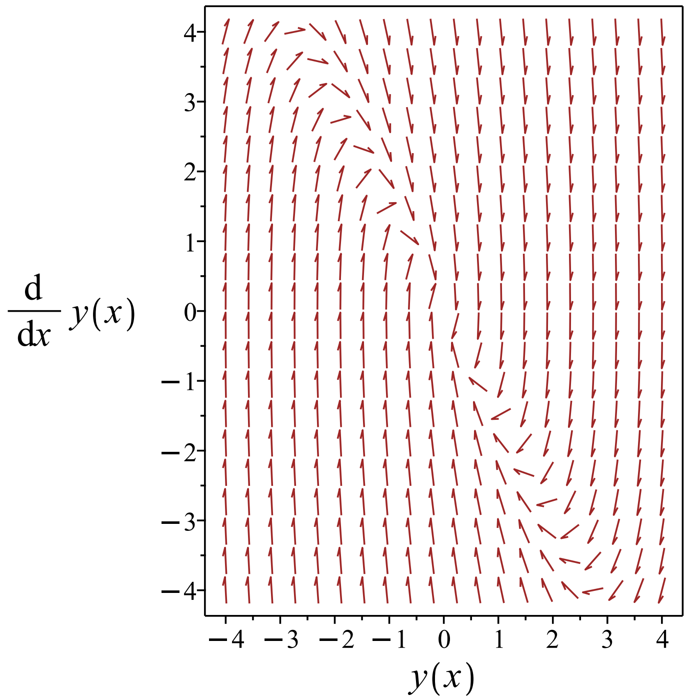

Figure 500: Slope field plot

Verification of solutions

$$y = e^{-3x}(c_2x + c_1) + \frac{e^{-3x}}{2x}$$

Verified OK.

12.9.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)$$

Where $p(x) = 6$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int 6\,dx} \\ &= e^{3x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= \frac{e^{3x} e^{-3x}}{x^3} \\
(e^{3x} y)'' &= \frac{e^{3x} e^{-3x}}{x^3}
\end{aligned}
$$

Integrating once gives

$$
(e^{3x} y)' = -\frac{1}{2x^2} + c_1
$$

Integrating again gives

$$
(e^{3x} y) = c_1 x + \frac{1}{2x} + c_2
$$

Hence the solution is

$$
y = \frac{c_1 x + \frac{1}{2x} + c_2}{e^{3x}}
$$

Or

$$
y = c_1 x \, e^{-3x} + c_2 e^{-3x} + \frac{e^{-3x}}{2x}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x \, e^{-3x} + c_2 e^{-3x} + \frac{e^{-3x}}{2x} \tag{1}
$$

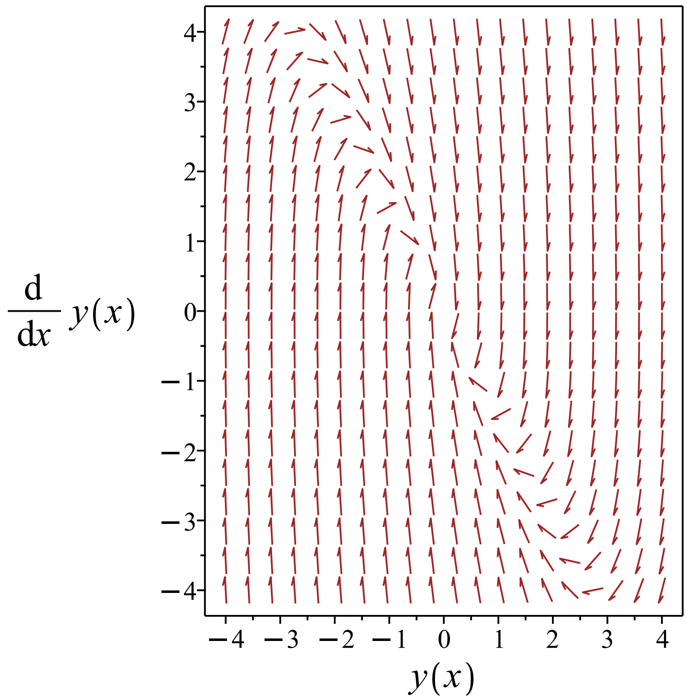

Figure 501: Slope field plot

Verification of solutions

$$y = c_1 x \,\mathrm{e}^{-3x} + c_2 \mathrm{e}^{-3x} + \frac{\mathrm{e}^{-3x}}{2x}$$

Verified OK.

12.9.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 6y' + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 6 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 441: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{6}{1}\,dx} \\
&= z_1 e^{-3x} \\
&= z_1 \left(\mathrm{e}^{-3x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{6}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-6x}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-3x}\right) + c_2\left(\mathrm{e}^{-3x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
y'' + 6y' + 9y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-3x} + c_2 x\,\mathrm{e}^{-3x}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \mathrm{e}^{-3x} \\
y_2 &= x\,\mathrm{e}^{-3x}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-3x} & x\,e^{-3x} \\ \frac{d}{dx}\left(e^{-3x}\right) & \frac{d}{dx}\left(x\,e^{-3x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-3x} & x\,e^{-3x} \\ -3\,e^{-3x} & e^{-3x} - 3x\,e^{-3x} \end{vmatrix}$$

Therefore

$$W = \left(e^{-3x}\right)\left(e^{-3x} - 3x\,e^{-3x}\right) - \left(x\,e^{-3x}\right)\left(-3\,e^{-3x}\right)$$

Which simplifies to

$$W = e^{-6x}$$

Which simplifies to

$$W = e^{-6x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{e^{-6x}}{x^2}}{e^{-6x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{1}{x^2}dx$$

Hence

$$u_1 = \frac{1}{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{e^{-6x}}{x^3}}{e^{-6x}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x^3} dx$$

Hence

$$u_2 = -\frac{1}{2x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{e^{-3x}}{2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-3x} + c_2 x\, e^{-3x}\right) + \left(\frac{e^{-3x}}{2x}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-3x}(c_2 x + c_1) + \frac{e^{-3x}}{2x}$$

Summary

The solution(s) found are the following

$$y = e^{-3x}(c_2 x + c_1) + \frac{e^{-3x}}{2x} \tag{1}$$

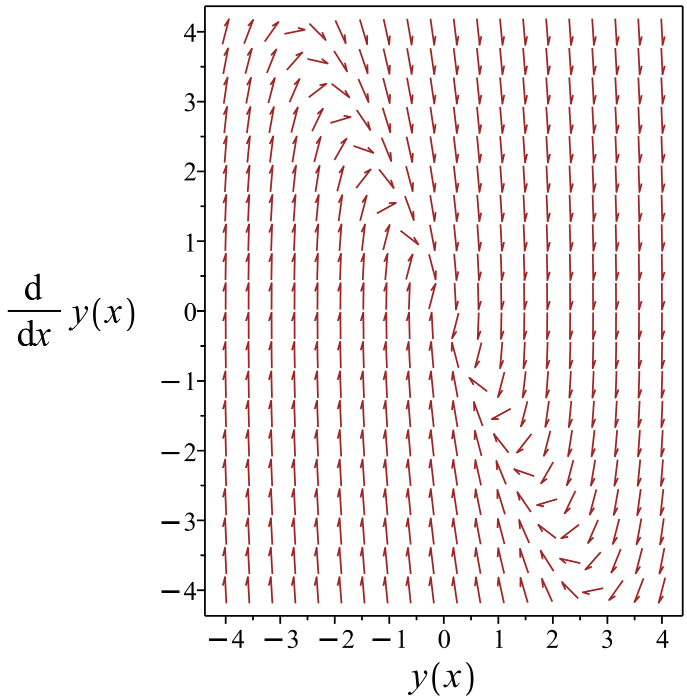

Figure 502: Slope field plot

Verification of solutions

$$y = e^{-3x}(c_2 x + c_1) + \frac{e^{-3x}}{2x}$$

Verified OK.

12.9.4 Maple step by step solution

Let's solve

$y'' + 6y' + 9y = \frac{e^{-3x}}{x^3}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 6r + 9 = 0$

- Factor the characteristic polynomial

  $(r+3)^2 = 0$

- Root of the characteristic polynomial

$r = -3$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-3x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,\mathrm{e}^{-3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-3x} + c_2 x\,\mathrm{e}^{-3x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 2y' + y = x\,\mathrm{e}^{x} \ln(x)}$$

12.10.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 1, f(x) = x\,\mathrm{e}^{x} \ln(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-2)^2 - (4)(1)(1)} \\ &= 1\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -1$. Therefore the solution is

$$y = c_1 e^x + c_2 x\, e^x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = e^x c_1 + c_2 x\, e^x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}y_1 &= e^x \\ y_2 &= x\, e^x\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x & x\,e^x \\ \frac{d}{dx}(e^x) & \frac{d}{dx}(x\,e^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^x & x\,e^x \\ e^x & x\,e^x + e^x \end{vmatrix}$$

Therefore

$$W = (e^x)(x\,e^x + e^x) - (x\,e^x)(e^x)$$

Which simplifies to

$$W = e^{2x}$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^2 e^{2x} \ln(x)}{e^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int x^2 \ln(x)\,dx$$

Hence

$$u_1 = -\frac{x^3 \ln(x)}{3} + \frac{x^3}{9}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{2x} x \ln(x)}{e^{2x}} dx$$

Which simplifies to

$$u_2 = \int x \ln(x) dx$$

Hence

$$u_2 = \frac{x^2 \ln(x)}{2} - \frac{x^2}{4}$$

Which simplifies to

$$u_1 = -\frac{x^3 (3 \ln(x) - 1)}{9}$$

$$u_2 = \frac{x^2 (-1 + 2 \ln(x))}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^3 (3 \ln(x) - 1) e^x}{9} + \frac{x^3 (-1 + 2 \ln(x)) e^x}{4}$$

Which simplifies to

$$y_p(x) = \frac{x^3 e^x (-5 + 6 \ln(x))}{36}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x c_1 + c_2 x e^x) + \left(\frac{x^3 e^x (-5 + 6 \ln(x))}{36}\right) \end{aligned}$$

Which simplifies to

$$y = e^x (c_2 x + c_1) + \frac{x^3 e^x (-5 + 6 \ln(x))}{36}$$

Summary

The solution(s) found are the following

$$y = e^{x}(c_2x + c_1) + \frac{x^3e^x(-5 + 6\ln(x))}{36} \tag{1}$$

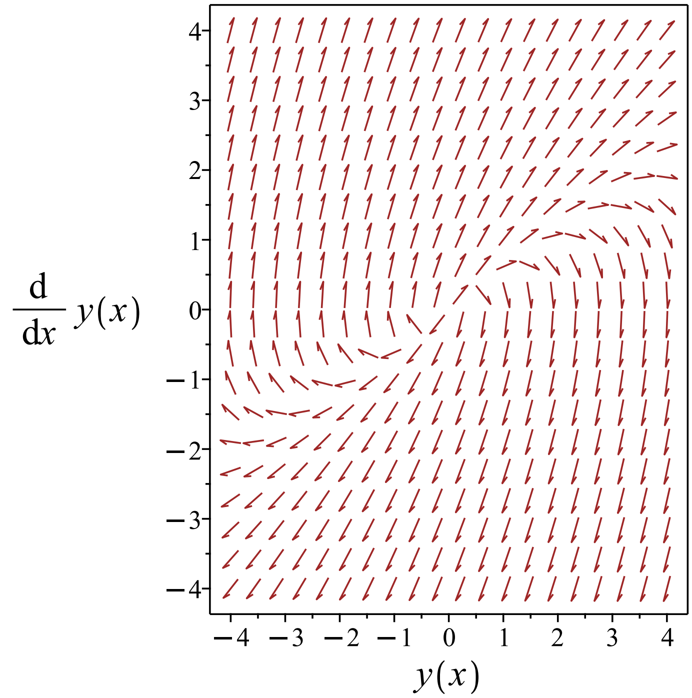

Figure 503: Slope field plot

Verification of solutions

$$y = e^{x}(c_2x + c_1) + \frac{x^3e^x(-5 + 6\ln(x))}{36}$$

Verified OK.

12.10.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{(p(x)^2 + p'(x))\,y}{2} = f(x)$$

Where $p(x) = -2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int -2\, dx} \\ &= \mathrm{e}^{-x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= \mathrm{e}^{-x} x\, \mathrm{e}^{x} \ln(x) \\ \left(\mathrm{e}^{-x} y\right)'' &= \mathrm{e}^{-x} x\, \mathrm{e}^{x} \ln(x) \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{-x} y\right)' = \frac{x^2(-1 + 2\ln(x))}{4} + c_1$$

Integrating again gives

$$\left(\mathrm{e}^{-x} y\right) = -\frac{5x^3}{36} + \frac{x^3 \ln(x)}{6} + c_1 x + c_2$$

Hence the solution is

$$y = \frac{-\frac{5x^3}{36} + \frac{x^3 \ln(x)}{6} + c_1 x + c_2}{\mathrm{e}^{-x}}$$

Or

$$y = \frac{x^3 \mathrm{e}^{x} \ln(x)}{6} - \frac{5x^3 \mathrm{e}^{x}}{36} + c_1 x\, \mathrm{e}^{x} + c_2 \mathrm{e}^{x}$$

Summary

The solution(s) found are the following

$$y = \frac{x^3 \mathrm{e}^{x} \ln(x)}{6} - \frac{5x^3 \mathrm{e}^{x}}{36} + c_1 x\, \mathrm{e}^{x} + c_2 \mathrm{e}^{x} \tag{1}$$

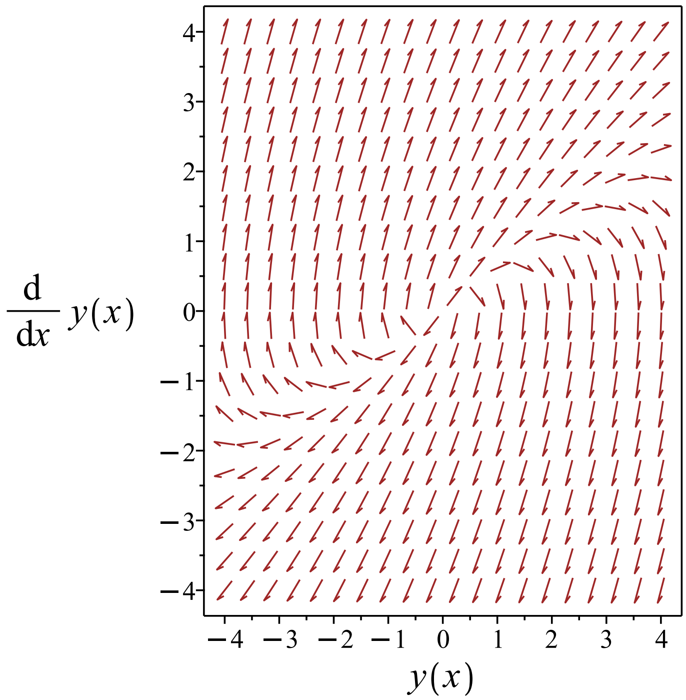

Figure 504: Slope field plot

Verification of solutions

$$y = \frac{x^3 e^x \ln(x)}{6} - \frac{5x^3 e^x}{36} + c_1 x \, e^x + c_2 e^x$$

Verified OK.

12.10.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 443: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\
&= z_1 e^{x} \\
&= z_1(\mathrm{e}^{x})
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2(\mathrm{e}^x(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^x c_1 + c_2 x\,\mathrm{e}^x
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \mathrm{e}^x \\
y_2 &= x\,\mathrm{e}^x
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x & x\,e^x \\ \frac{d}{dx}(e^x) & \frac{d}{dx}(x\,e^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^x & x\,e^x \\ e^x & x\,e^x + e^x \end{vmatrix}$$

Therefore

$$W = (e^x)(x\,e^x + e^x) - (x\,e^x)(e^x)$$

Which simplifies to

$$W = e^{2x}$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^2 e^{2x} \ln(x)}{e^{2x}}\, dx$$

Which simplifies to

$$u_1 = -\int x^2 \ln(x)\, dx$$

Hence

$$u_1 = -\frac{x^3 \ln(x)}{3} + \frac{x^3}{9}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{2x} x \ln(x)}{e^{2x}}\, dx$$

Which simplifies to

$$u_2 = \int x \ln(x)\, dx$$

Hence

$$u_2 = \frac{x^2 \ln(x)}{2} - \frac{x^2}{4}$$

Which simplifies to

$$u_1 = -\frac{x^3(3\ln(x) - 1)}{9}$$
$$u_2 = \frac{x^2(-1 + 2\ln(x))}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^3(3\ln(x) - 1)\,\mathrm{e}^x}{9} + \frac{x^3(-1 + 2\ln(x))\,\mathrm{e}^x}{4}$$

Which simplifies to

$$y_p(x) = \frac{x^3 \mathrm{e}^x(-5 + 6\ln(x))}{36}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (\mathrm{e}^x c_1 + c_2 x\,\mathrm{e}^x) + \left(\frac{x^3 \mathrm{e}^x(-5 + 6\ln(x))}{36}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^x(c_2 x + c_1) + \frac{x^3 \mathrm{e}^x(-5 + 6\ln(x))}{36}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^x(c_2 x + c_1) + \frac{x^3 \mathrm{e}^x(-5 + 6\ln(x))}{36} \tag{1}$$

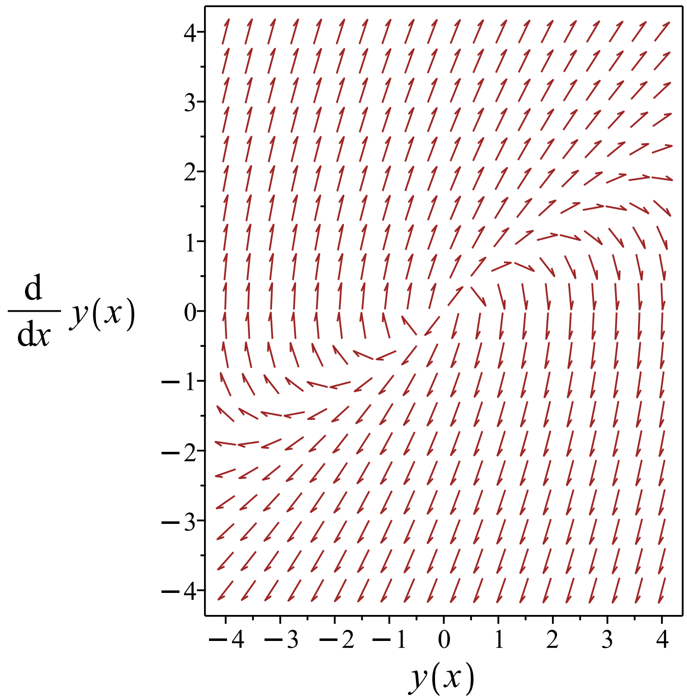

Figure 505: Slope field plot

Verification of solutions

$$y = e^{x}(c_2 x + c_1) + \frac{x^3 e^{x}(-5 + 6\ln(x))}{36}$$

Verified OK.

12.10.4 Maple step by step solution

Let's solve

$y'' - 2y' + y = x\,e^{x} \ln(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 1 = 0$

- Factor the characteristic polynomial

  $(r-1)^2 = 0$

- Root of the characteristic polynomial

$r = 1$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^x$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^x c_1 + c_2 x\,e^x + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))}dx\right), f(x) = x\,e^x \ln(x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^x & x\,e^x \\ e^x & x\,e^x + e^x \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = e^{2x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = e^x\left(-\left(\int x^2 \ln(x)\,dx\right) + \left(\int x \ln(x)\,dx\right) x\right)$

  - Compute integrals

    $y_p(x) = \frac{x^3 e^x (-5 + 6\ln(x))}{36}$

- Substitute particular solution into general solution to ODE

  $y = e^x c_1 + c_2 x\,e^x + \frac{x^3 e^x (-5 + 6\ln(x))}{36}$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = \sec(x)\csc(x)}$$

12.11.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = \sec(x)\csc(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A=1, B=0, C=1$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A=1, B=0, C=1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\sec(x)\csc(x)}{1} dx$$

Which simplifies to

$$u_1 = -\int \sec(x)\, dx$$

Hence

$$u_1 = -\ln(\sec(x) + \tan(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\sec(x)\csc(x)}{1} dx$$

Which simplifies to

$$u_2 = \int \csc(x)\, dx$$

Hence

$$u_2 = -\ln(\csc(x) + \cot(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\ln(\sec(x) + \tan(x))\cos(x) - \ln(\csc(x) + \cot(x))\sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + (-\ln(\sec(x) + \tan(x))\cos(x) - \ln(\csc(x) + \cot(x))\sin(x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) - \ln(\sec(x) + \tan(x)) \cos(x) - \ln(\csc(x) + \cot(x)) \sin(x) \tag{1}$$

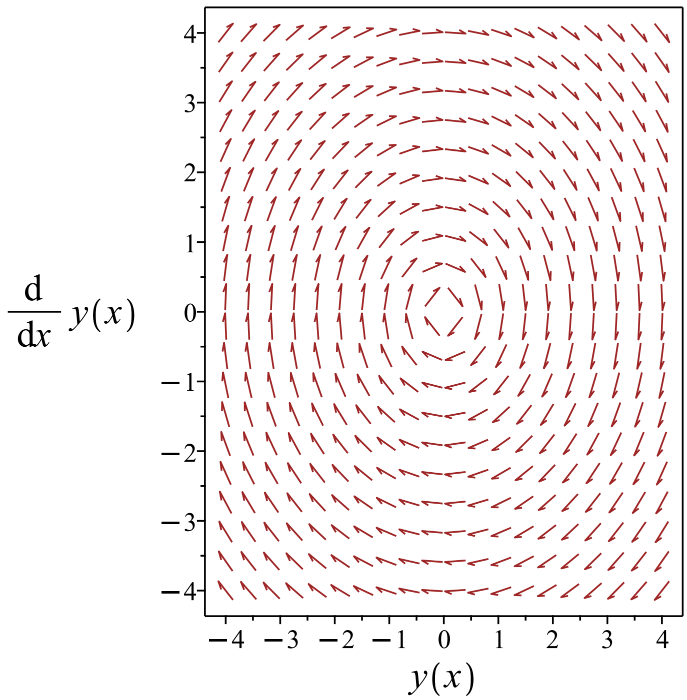

Figure 506: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) - \ln(\sec(x) + \tan(x)) \cos(x) - \ln(\csc(x) + \cot(x)) \sin(x)$$

Verified OK.

12.11.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 445: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\ &= \cos(x)\,(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\sec(x)\csc(x)}{1} dx$$

Which simplifies to

$$u_1 = -\int \sec(x) dx$$

Hence

$$u_1 = -\ln(\sec(x) + \tan(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\sec(x)\csc(x)}{1} dx$$

Which simplifies to

$$u_2 = \int \csc(x) dx$$

Hence

$$u_2 = -\ln(\csc(x) + \cot(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\ln(\sec(x) + \tan(x))\cos(x) - \ln(\csc(x) + \cot(x))\sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + (-\ln(\sec(x) + \tan(x))\cos(x) - \ln(\csc(x) + \cot(x))\sin(x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\cos(x) + c_2\sin(x) - \ln(\sec(x) + \tan(x))\cos(x) - \ln(\csc(x) + \cot(x))\sin(x) \tag{1}$$

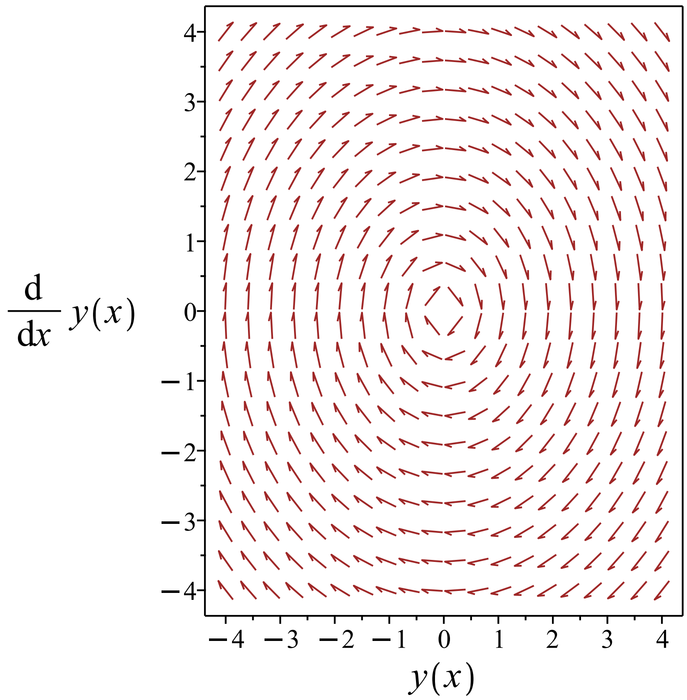

Figure 507: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) - \ln(\sec(x) + \tan(x))\cos(x) - \ln(\csc(x) + \cot(x))\sin(x)$$

Verified OK.

12.11.3 Maple step by step solution

Let's solve

$y'' + y = \sec(x)\csc(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

$r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \sec(x)\csc(x)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $$W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 1$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\cos(x)\left(\int \sec(x)\,dx\right) + \sin(x)\left(\int \csc(x)\,dx\right)$

  ◦ Compute integrals

  $y_p(x) = -\ln(\sec(x) + \tan(x))\cos(x) - \ln(\csc(x) + \cot(x))\sin(x)$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(x) + c_2 \sin(x) - \ln(\sec(x) + \tan(x))\cos(x) - \ln(\csc(x) + \cot(x))\sin(x)$

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + y = \tan(x)^3}$$

12.12.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = \tan(x)^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\tan(x)^3}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \sin(x)\tan(x)^3\,dx$$

Hence

$$u_1 = -\frac{\sin(x)^5}{2\cos(x)^2} - \frac{\sin(x)^3}{2} - \frac{3\sin(x)}{2} + \frac{3\ln(\sec(x)+\tan(x))}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\tan(x)^3}{1}\,dx$$

Which simplifies to

$$u_2 = \int \sin(x)\tan(x)^2\,dx$$

Hence

$$u_2 = \frac{\sin(x)^4}{\cos(x)} + \left(2+\sin(x)^2\right)\cos(x)$$

Which simplifies to

$$\begin{aligned}
u_1 &= -\sin(x) + \frac{3\ln(\sec(x)+\tan(x))}{2} - \frac{\sec(x)\tan(x)}{2} \\
u_2 &= \cos(x) + \sec(x)
\end{aligned}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\sin(x) + \frac{3\ln(\sec(x)+\tan(x))}{2} - \frac{\sec(x)\tan(x)}{2}\right)\cos(x) + (\cos(x)+\sec(x))\sin(x)$$

Which simplifies to

$$y_p(x) = \frac{3\ln(\sec(x)+\tan(x))\cos(x)}{2} + \frac{\tan(x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + \left(\frac{3\ln(\sec(x)+\tan(x))\cos(x)}{2} + \frac{\tan(x)}{2}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1\cos(x) + c_2\sin(x) + \frac{3\ln(\sec(x)+\tan(x))\cos(x)}{2} + \frac{\tan(x)}{2} \tag{1}$$

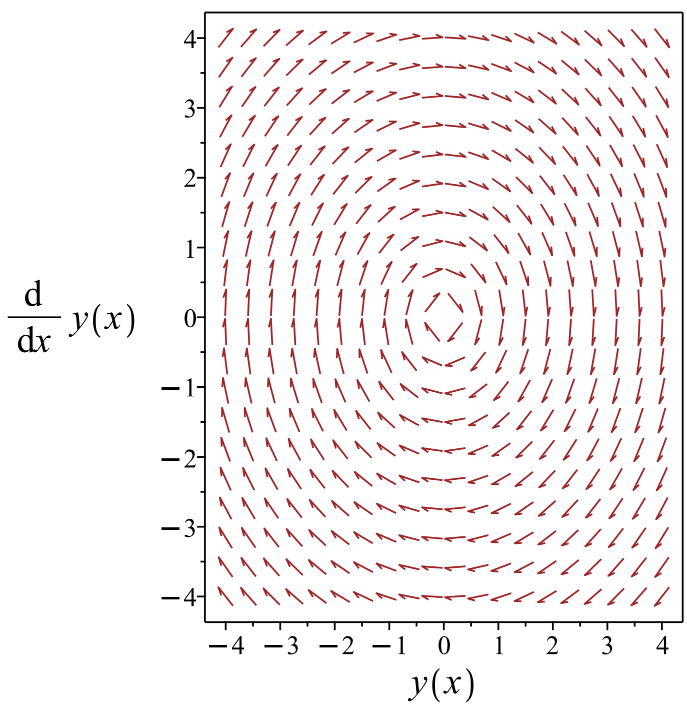

Figure 508: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{3\ln(\sec(x) + \tan(x))\cos(x)}{2} + \frac{\tan(x)}{2}$$

Verified OK.

12.12.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 447: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\,dx \\ &= \cos(x)\,(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\tan(x)^3}{1}\, dx$$

Which simplifies to

$$u_1 = -\int \sin(x)\tan(x)^3\, dx$$

Hence

$$u_1 = -\frac{\sin(x)^5}{2\cos(x)^2} - \frac{\sin(x)^3}{2} - \frac{3\sin(x)}{2} + \frac{3\ln(\sec(x)+\tan(x))}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\tan(x)^3}{1}\, dx$$

Which simplifies to

$$u_2 = \int \sin(x)\tan(x)^2\, dx$$

Hence

$$u_2 = \frac{\sin(x)^4}{\cos(x)} + \left(2+\sin(x)^2\right)\cos(x)$$

Which simplifies to

$$u_1 = -\sin(x) + \frac{3\ln(\sec(x)+\tan(x))}{2} - \frac{\sec(x)\tan(x)}{2}$$

$$u_2 = \cos(x) + \sec(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\sin(x) + \frac{3\ln(\sec(x)+\tan(x))}{2} - \frac{\sec(x)\tan(x)}{2}\right)\cos(x) + (\cos(x)+\sec(x))\sin(x)$$

Which simplifies to

$$y_p(x) = \frac{3\ln(\sec(x)+\tan(x))\cos(x)}{2} + \frac{\tan(x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + \left(\frac{3\ln(\sec(x)+\tan(x))\cos(x)}{2} + \frac{\tan(x)}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\cos(x) + c_2\sin(x) + \frac{3\ln(\sec(x)+\tan(x))\cos(x)}{2} + \frac{\tan(x)}{2} \tag{1}$$

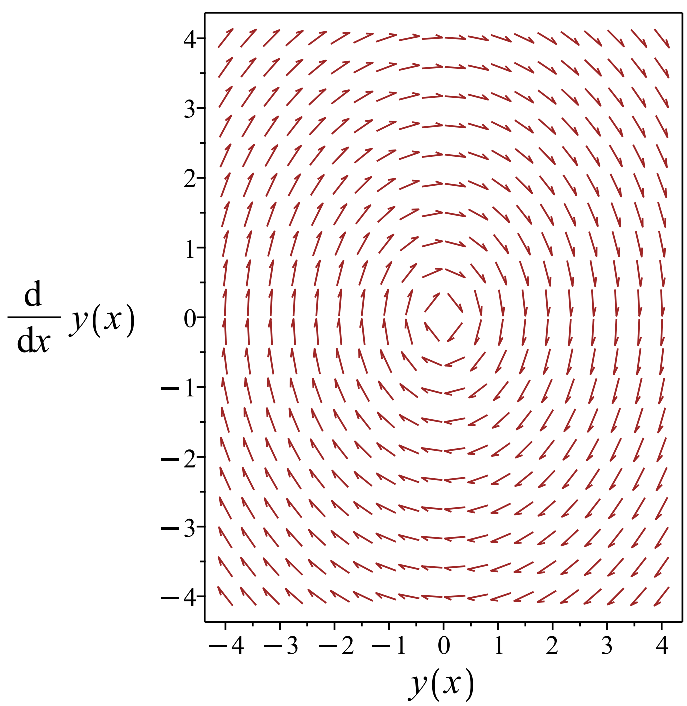

Figure 509: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{3 \ln(\sec(x) + \tan(x)) \cos(x)}{2} + \frac{\tan(x)}{2}$$

Verified OK.

12.13.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 3, C = 2, f(x) = \frac{1}{e^{x}+1}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 3y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 3, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 3\lambda\, \mathrm{e}^{\lambda x} + 2\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 3\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 3, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-3}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{3^2 - (4)\,(1)\,(2)} \\ &= -\frac{3}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{3}{2} + \frac{1}{2} \\ \lambda_2 &= -\frac{3}{2} - \frac{1}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 \\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(-1)x} + c_2 e^{(-2)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{-2x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{-2x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \mathrm{e}^{-x}$$
$$y_2 = \mathrm{e}^{-2x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-x} & \mathrm{e}^{-2x} \\ \frac{d}{dx}(\mathrm{e}^{-x}) & \frac{d}{dx}(\mathrm{e}^{-2x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{-x} & \mathrm{e}^{-2x} \\ -\mathrm{e}^{-x} & -2\,\mathrm{e}^{-2x} \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{-x}\right)\left(-2\,\mathrm{e}^{-2x}\right) - \left(\mathrm{e}^{-2x}\right)\left(-\mathrm{e}^{-x}\right)$$

Which simplifies to

$$W = -\mathrm{e}^{-x}\mathrm{e}^{-2x}$$

Which simplifies to

$$W = -\mathrm{e}^{-3x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\mathrm{e}^{-2x}}{\mathrm{e}^x+1}}{-\mathrm{e}^{-3x}} dx$$

Which simplifies to

$$u_1 = -\int -\frac{\mathrm{e}^x}{\mathrm{e}^x + 1} dx$$

Hence

$$u_1 = \ln\left(\mathrm{e}^x + 1\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\mathrm{e}^{-x}}{\mathrm{e}^x+1}}{-\mathrm{e}^{-3x}} dx$$

Which simplifies to

$$u_2 = \int -\frac{\mathrm{e}^{2x}}{\mathrm{e}^x + 1} dx$$

Hence

$$u_2 = -\mathrm{e}^x + \ln\left(\mathrm{e}^x + 1\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln\left(\mathrm{e}^x + 1\right)\mathrm{e}^{-x} + \left(-\mathrm{e}^x + \ln\left(\mathrm{e}^x + 1\right)\right)\mathrm{e}^{-2x}$$

Which simplifies to

$$y_p(x) = \left(\mathrm{e}^{-2x} + \mathrm{e}^{-x}\right)\ln\left(\mathrm{e}^x + 1\right) - \mathrm{e}^{-x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-x} + c_2\mathrm{e}^{-2x}\right) + \left(\left(\mathrm{e}^{-2x} + \mathrm{e}^{-x}\right)\ln\left(\mathrm{e}^x + 1\right) - \mathrm{e}^{-x}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 e^{-2x} + \left(e^{-2x} + e^{-x}\right) \ln\left(e^x + 1\right) - e^{-x} \tag{1}$$

Verification of solutions

$$y = c_1 e^{-x} + c_2 e^{-2x} + \left(e^{-2x} + e^{-x}\right) \ln\left(e^x + 1\right) - e^{-x}$$

Verified OK.

12.13.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 3y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 3 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 449: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3}{1}\,dx} \\
&= z_1 e^{-\frac{3x}{2}} \\
&= z_1\left(\mathrm{e}^{-\frac{3x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-3x}}{(y_1)^2}\,dx \\
&= y_1(\mathrm{e}^{x})
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-2x}\right) + c_2\left(\mathrm{e}^{-2x}(\mathrm{e}^{x})\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+3y'+2y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h=c_1\mathrm{e}^{-2x}+c_2\mathrm{e}^{-x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x)=u_1y_1+u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1=\mathrm{e}^{-2x}$$
$$y_2=\mathrm{e}^{-x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1=-\int\frac{y_2f(x)}{aW(x)} \tag{2}$$

$$u_2=\int\frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W=\begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W=\begin{vmatrix} \mathrm{e}^{-2x} & \mathrm{e}^{-x} \\ \frac{d}{dx}(\mathrm{e}^{-2x}) & \frac{d}{dx}(\mathrm{e}^{-x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-2x} & e^{-x} \\ -2\,e^{-2x} & -e^{-x} \end{vmatrix}$$

Therefore

$$W = \left(e^{-2x}\right)\left(-e^{-x}\right) - \left(e^{-x}\right)\left(-2\,e^{-2x}\right)$$

Which simplifies to

$$W = e^{-x}e^{-2x}$$

Which simplifies to

$$W = e^{-3x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{e^{-x}}{e^x+1}}{e^{-3x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{e^{2x}}{e^x + 1}dx$$

Hence

$$u_1 = -e^x + \ln\left(e^x + 1\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{e^{-2x}}{e^x+1}}{e^{-3x}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{e^x}{e^x + 1}dx$$

Hence

$$u_2 = \ln\left(e^x + 1\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln\left(e^x + 1\right)e^{-x} + \left(-e^x + \ln\left(e^x + 1\right)\right)e^{-2x}$$

Which simplifies to

$$y_p(x) = \left(\mathrm{e}^{-2x} + \mathrm{e}^{-x}\right) \ln \left(\mathrm{e}^{x} + 1\right) - \mathrm{e}^{-x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x}\right) + \left(\left(\mathrm{e}^{-2x} + \mathrm{e}^{-x}\right) \ln \left(\mathrm{e}^{x} + 1\right) - \mathrm{e}^{-x}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x} + \left(\mathrm{e}^{-2x} + \mathrm{e}^{-x}\right) \ln \left(\mathrm{e}^{x} + 1\right) - \mathrm{e}^{-x} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x} + \left(\mathrm{e}^{-2x} + \mathrm{e}^{-x}\right) \ln \left(\mathrm{e}^{x} + 1\right) - \mathrm{e}^{-x}$$

Verified OK.

12.13.3 Maple step by step solution

Let's solve

$y'' + 3y' + 2y = \frac{1}{\mathrm{e}^{x}+1}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 3r + 2 = 0$

- Factor the characteristic polynomial

  $(r + 2)(r + 1) = 0$

- Roots of the characteristic polynomial

  $r = (-2, -1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-x}$

- General solution of the ODE

$$y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$$

- Substitute in solutions of the homogeneous ODE

$$y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x} + y_p(x)$$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

$$\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \frac{1}{\mathrm{e}^x + 1}\right]$$

  - Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-2x} & \mathrm{e}^{-x} \\ -2\,\mathrm{e}^{-2x} & -\mathrm{e}^{-x} \end{bmatrix}$$

  - Compute Wronskian

$$W(y_1(x), y_2(x)) = \mathrm{e}^{-3x}$$

  - Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\mathrm{e}^{-2x}\left(\int \frac{\mathrm{e}^{2x}}{\mathrm{e}^x + 1} dx\right) + \mathrm{e}^{-x}\left(\int \frac{\mathrm{e}^x}{\mathrm{e}^x + 1} dx\right)$$

  - Compute integrals

$$y_p(x) = \left(\mathrm{e}^{-2x} + \mathrm{e}^{-x}\right) \ln\left(\mathrm{e}^x + 1\right) - \mathrm{e}^{-x}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x} + \left(\mathrm{e}^{-2x} + \mathrm{e}^{-x}\right) \ln\left(\mathrm{e}^x + 1\right) - \mathrm{e}^{-x}$$

$$y'' + 3y' + 2y = \frac{1}{e^{2x} + 1}$$

12.14.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 3, C = 2, f(x) = \frac{1}{e^{2x}+1}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 3y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 3, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 3\lambda\, e^{\lambda x} + 2\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 3\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 3, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-3}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{3^2 - (4)\,(1)\,(2)}\\ &= -\frac{3}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{3}{2} + \frac{1}{2}\\ \lambda_2 &= -\frac{3}{2} - \frac{1}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1\\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(-1)x} + c_2 e^{(-2)x}\end{aligned}$$

Or

$$y = c_1 e^{-x} + c_2 e^{-2x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{-x} + c_2 e^{-2x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \mathrm{e}^{-x}$$
$$y_2 = \mathrm{e}^{-2x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-x} & \mathrm{e}^{-2x} \\ \frac{d}{dx}\left(\mathrm{e}^{-x}\right) & \frac{d}{dx}\left(\mathrm{e}^{-2x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{-x} & \mathrm{e}^{-2x} \\ -\mathrm{e}^{-x} & -2\,\mathrm{e}^{-2x} \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{-x}\right)\left(-2\,\mathrm{e}^{-2x}\right) - \left(\mathrm{e}^{-2x}\right)\left(-\mathrm{e}^{-x}\right)$$

Which simplifies to

$$W = -\mathrm{e}^{-x}\mathrm{e}^{-2x}$$

Which simplifies to

$$W = -\mathrm{e}^{-3x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\mathrm{e}^{-2x}}{\mathrm{e}^{2x}+1}}{-\mathrm{e}^{-3x}}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{\mathrm{e}^{x}}{\mathrm{e}^{2x}+1}dx$$

Hence

$$u_1 = \arctan\left(\mathrm{e}^{x}\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\mathrm{e}^{-x}}{\mathrm{e}^{2x}+1}}{-\mathrm{e}^{-3x}}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{\mathrm{e}^{2x}}{\mathrm{e}^{2x}+1}dx$$

Hence

$$u_2 = -\frac{\ln\left(\mathrm{e}^{2x}+1\right)}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \arctan\left(\mathrm{e}^{x}\right)\mathrm{e}^{-x} - \frac{\ln\left(\mathrm{e}^{2x}+1\right)\mathrm{e}^{-2x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-x} + c_2\mathrm{e}^{-2x}\right) + \left(\arctan\left(\mathrm{e}^{x}\right)\mathrm{e}^{-x} - \frac{\ln\left(\mathrm{e}^{2x}+1\right)\mathrm{e}^{-2x}}{2}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$
y = c_1 e^{-x} + c_2 e^{-2x} + \arctan\left(e^{x}\right) e^{-x} - \frac{\ln\left(e^{2x}+1\right) e^{-2x}}{2} \tag{1}
$$

Verification of solutions

$$
y = c_1 e^{-x} + c_2 e^{-2x} + \arctan\left(e^{x}\right) e^{-x} - \frac{\ln\left(e^{2x}+1\right) e^{-2x}}{2}
$$

Verified OK.

12.14.2 Solving using Kovacic algorithm

Writing the ode as

$$
y'' + 3y' + 2y = 0 \tag{1}
$$

$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 3 \\
C &= 2
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\,dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{1}{4} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 1 \\
t &= 4
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \frac{z(x)}{4} \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 451: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3}{1}\,dx} \\
&= z_1 e^{-\frac{3x}{2}} \\
&= z_1\left(\mathrm{e}^{-\frac{3x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-3x}}{(y_1)^2}\,dx \\
&= y_1(\mathrm{e}^{x})
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-2x}\right) + c_2\left(\mathrm{e}^{-2x}(\mathrm{e}^{x})\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 3y' + 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{-2x} + c_2 e^{-x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^{-2x}$$
$$y_2 = e^{-x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-2x} & e^{-x} \\ \frac{d}{dx}(e^{-2x}) & \frac{d}{dx}(e^{-x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-2x} & e^{-x} \\ -2\,e^{-2x} & -e^{-x} \end{vmatrix}$$

Therefore

$$W = \left(e^{-2x}\right)\left(-e^{-x}\right) - \left(e^{-x}\right)\left(-2\,e^{-2x}\right)$$

Which simplifies to

$$W = e^{-x}e^{-2x}$$

Which simplifies to

$$W = e^{-3x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{e^{-x}}{e^{2x}+1}}{e^{-3x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{e^{2x}}{e^{2x}+1}dx$$

Hence

$$u_1 = -\frac{\ln\left(e^{2x}+1\right)}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{e^{-2x}}{e^{2x}+1}}{e^{-3x}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{e^{x}}{e^{2x}+1}dx$$

Hence

$$u_2 = \arctan\left(e^{x}\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \arctan(e^x) e^{-x} - \frac{\ln(e^{2x}+1) e^{-2x}}{2}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p \\ &= (c_1 e^{-2x} + c_2 e^{-x}) + \left(\arctan(e^x) e^{-x} - \frac{\ln(e^{2x}+1) e^{-2x}}{2}\right)\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-2x} + c_2 e^{-x} + \arctan(e^x) e^{-x} - \frac{\ln(e^{2x}+1) e^{-2x}}{2} \tag{1}$$

Verification of solutions

$$y = c_1 e^{-2x} + c_2 e^{-x} + \arctan(e^x) e^{-x} - \frac{\ln(e^{2x}+1) e^{-2x}}{2}$$

Verified OK.

12.14.3 Maple step by step solution

Let's solve

$y'' + 3y' + 2y = \frac{1}{e^{2x}+1}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 3r + 2 = 0$

- Factor the characteristic polynomial

  $(r+2)(r+1) = 0$

- Roots of the characteristic polynomial

  $r = (-2, -1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x} + y_p(x)$

- ☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \frac{1}{\mathrm{e}^{2x}+1}\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-2x} & \mathrm{e}^{-x} \\ -2\,\mathrm{e}^{-2x} & -\mathrm{e}^{-x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = \mathrm{e}^{-3x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\mathrm{e}^{-2x}\left(\int \frac{\mathrm{e}^{2x}}{\mathrm{e}^{2x}+1}dx\right) + \mathrm{e}^{-x}\left(\int \frac{\mathrm{e}^{x}}{\mathrm{e}^{2x}+1}dx\right)$

  - Compute integrals

    $y_p(x) = \arctan(\mathrm{e}^{x})\,\mathrm{e}^{-x} - \frac{\ln(\mathrm{e}^{2x}+1)\mathrm{e}^{-2x}}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x} + \arctan(\mathrm{e}^{x})\,\mathrm{e}^{-x} - \frac{\ln(\mathrm{e}^{2x}+1)\mathrm{e}^{-2x}}{2}$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = \frac{1}{1 + \sin(x)}}$$

12.15.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = \frac{1}{1+\sin(x)}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)}\\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i\\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i\\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sin(x)}{1+\sin(x)}}{1} dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(x)}{1 + \sin(x)} dx$$

Hence

$$u_1 = -\frac{2}{\tan\left(\frac{x}{2}\right) + 1} - x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\cos(x)}{1+\sin(x)}}{1} dx$$

Which simplifies to

$$u_2 = \int \frac{\cos(x)}{1 + \sin(x)} dx$$

Hence

$$u_2 = \ln(1 + \sin(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{2}{\tan\left(\frac{x}{2}\right) + 1} - x\right) \cos(x) + \ln(1 + \sin(x)) \sin(x)$$

Which simplifies to

$$y_p(x) = \ln(1 + \sin(x)) \sin(x) + (-x - 1) \cos(x) + \sin(x) - 1$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + (\ln(1+\sin(x))\sin(x) + (-x-1)\cos(x) + \sin(x) - 1)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(x) + c_2 \sin(x) + \ln(1+\sin(x))\sin(x) + (-x-1)\cos(x) + \sin(x) - 1 \quad (1)
$$

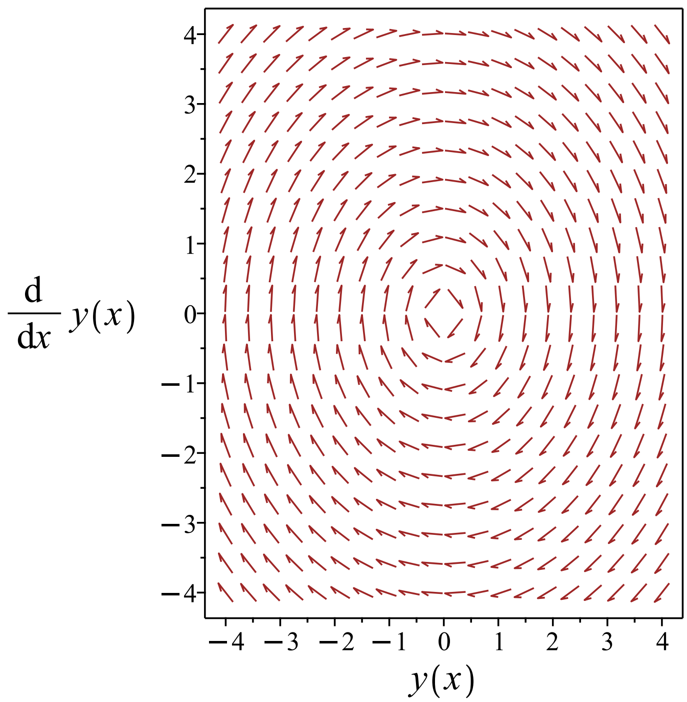

Figure 510: Slope field plot

Verification of solutions

$$
y = c_1 \cos(x) + c_2 \sin(x) + \ln(1+\sin(x))\sin(x) + (-x-1)\cos(x) + \sin(x) - 1
$$

Verified OK.

12.15.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 453: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B=0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \cos(x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \cos(x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Since $B=0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\
&= \cos(x)\,(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
y'' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \cos(x) + c_2 \sin(x)
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sin(x)}{1+\sin(x)}}{1} dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(x)}{1+\sin(x)} dx$$

Hence

$$u_1 = -\frac{2}{\tan\left(\frac{x}{2}\right)+1} - x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\cos(x)}{1+\sin(x)}}{1} dx$$

Which simplifies to

$$u_2 = \int \frac{\cos(x)}{1+\sin(x)} dx$$

Hence

$$u_2 = \ln(1+\sin(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{2}{\tan\left(\frac{x}{2}\right)+1} - x\right)\cos(x) + \ln(1+\sin(x))\sin(x)$$

Which simplifies to

$$y_p(x) = \ln(1+\sin(x))\sin(x) + (-x-1)\cos(x) + \sin(x) - 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + (\ln(1+\sin(x))\sin(x) + (-x-1)\cos(x) + \sin(x) - 1) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) + \ln(1 + \sin(x)) \sin(x) + (-x - 1) \cos(x) + \sin(x) - 1 \quad (1)$$

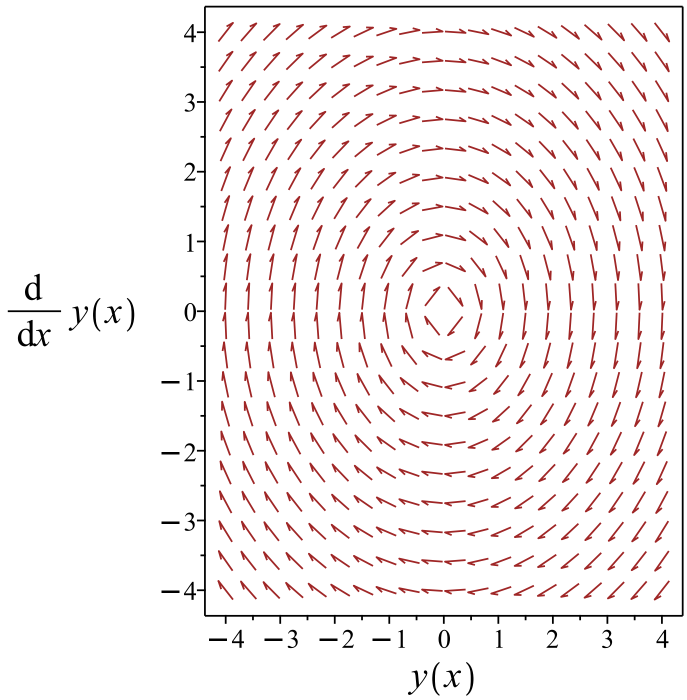

Figure 511: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + \ln(1 + \sin(x)) \sin(x) + (-x - 1) \cos(x) + \sin(x) - 1$$

Verified OK.

12.15.3 Maple step by step solution

Let's solve

$y'' + y = \frac{1}{1+\sin(x)}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$
- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$
- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$
- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \frac{1}{1+\sin(x)}\right]$
  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$
  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$
  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\cos(x) \left(\int \frac{\sin(x)}{1+\sin(x)} dx\right) + \sin(x) \left(\int \frac{\cos(x)}{1+\sin(x)} dx\right)$

Problem number: 16.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 2y' + y = \mathrm{e}^{x} \arcsin(x)}$$

12.16.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 1, f(x) = \mathrm{e}^{x} \arcsin(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-2)^2 - (4)(1)(1)} \\ &= 1\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -1$. Therefore the solution is

$$y = c_1 e^x + c_2 x e^x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = e^x c_1 + c_2 x e^x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}y_1 &= e^x \\ y_2 &= x e^x\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x & x\,e^x \\ \frac{d}{dx}(e^x) & \frac{d}{dx}(x\,e^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^x & x\,e^x \\ e^x & x\,e^x + e^x \end{vmatrix}$$

Therefore

$$W = (e^x)(x\,e^x + e^x) - (x\,e^x)(e^x)$$

Which simplifies to

$$W = e^{2x}$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x\,e^{2x} \arcsin(x)}{e^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int x \arcsin(x)\,dx$$

Hence

$$u_1 = -\frac{x^2 \arcsin(x)}{2} - \frac{\sqrt{-x^2+1}\,x}{4} + \frac{\arcsin(x)}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{2x} \arcsin(x)}{e^{2x}} dx$$

Which simplifies to

$$u_2 = \int \arcsin(x)\, dx$$

Hence

$$u_2 = x \arcsin(x) + \sqrt{-x^2 + 1}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{x^2 \arcsin(x)}{2} - \frac{\sqrt{-x^2+1}\, x}{4} + \frac{\arcsin(x)}{4}\right) e^x + \left(x \arcsin(x) + \sqrt{-x^2+1}\right) x\, e^x$$

Which simplifies to

$$y_p(x) = \frac{e^x \left(2x^2 \arcsin(x) + 3\sqrt{-x^2+1}\, x + \arcsin(x)\right)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x c_1 + c_2 x\, e^x) + \left(\frac{e^x \left(2x^2 \arcsin(x) + 3\sqrt{-x^2+1}\, x + \arcsin(x)\right)}{4}\right) \end{aligned}$$

Which simplifies to

$$y = e^x (c_2 x + c_1) + \frac{e^x \left(2x^2 \arcsin(x) + 3\sqrt{-x^2+1}\, x + \arcsin(x)\right)}{4}$$

Summary

The solution(s) found are the following

$$y = e^x (c_2 x + c_1) + \frac{e^x \left(2x^2 \arcsin(x) + 3\sqrt{-x^2+1}\, x + \arcsin(x)\right)}{4} \tag{1}$$

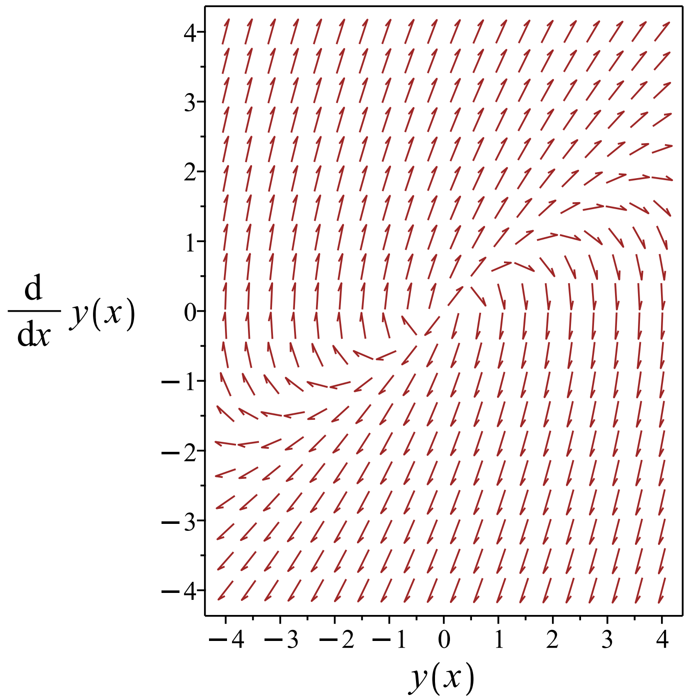

Figure 512: Slope field plot

Verification of solutions

$$y = e^{x}(c_2 x + c_1) + \frac{e^{x}\left(2x^2 \arcsin(x) + 3\sqrt{-x^2+1}\, x + \arcsin(x)\right)}{4}$$

Verified OK.

12.16.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int -2\, dx} \\ &= e^{-x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$(M(x)y)'' = e^{-x}e^{x} \arcsin(x)$$
$$(e^{-x}y)'' = e^{-x}e^{x} \arcsin(x)$$

Integrating once gives

$$(e^{-x}y)' = x \arcsin(x) + \sqrt{-x^2+1} + c_1$$

Integrating again gives

$$(e^{-x}y) = c_1 x + \frac{3\sqrt{-x^2+1}\,x}{4} + \frac{\arcsin(x)}{4} + \frac{x^2 \arcsin(x)}{2} + c_2$$

Hence the solution is

$$y = \frac{c_1 x + \frac{3\sqrt{-x^2+1}\,x}{4} + \frac{\arcsin(x)}{4} + \frac{x^2 \arcsin(x)}{2} + c_2}{e^{-x}}$$

Or

$$y = \frac{x^2 \arcsin(x)\, e^{x}}{2} + c_1 x\, e^{x} + c_2 e^{x} + \frac{3\sqrt{-x^2+1}\,x\, e^{x}}{4} + \frac{\arcsin(x)\, e^{x}}{4}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2 \arcsin(x)\, e^{x}}{2} + c_1 x\, e^{x} + c_2 e^{x} + \frac{3\sqrt{-x^2+1}\,x\, e^{x}}{4} + \frac{\arcsin(x)\, e^{x}}{4} \tag{1}$$

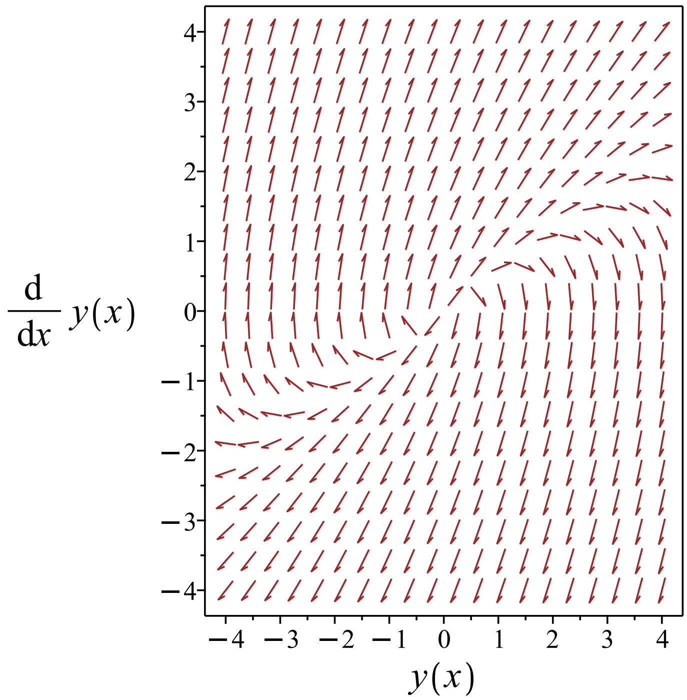

Figure 513: Slope field plot

Verification of solutions

$$y = \frac{x^2 \arcsin(x)\, e^x}{2} + c_1 x\, e^x + c_2 e^x + \frac{3\sqrt{-x^2+1}\, x\, e^x}{4} + \frac{\arcsin(x)\, e^x}{4}$$

Verified OK.

12.16.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 455: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\ &= z_1 e^{x} \\ &= z_1 (\mathrm{e}^{x}) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned}y &= c_1y_1 + c_2y_2\\ &= c_1(\mathrm{e}^x) + c_2(\mathrm{e}^x(x))\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \mathrm{e}^x c_1 + c_2 x\,\mathrm{e}^x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}y_1 &= \mathrm{e}^x\\ y_2 &= x\,\mathrm{e}^x\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{x} & x\,e^{x} \\ \frac{d}{dx}\left(e^{x}\right) & \frac{d}{dx}\left(x\,e^{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{x} & x\,e^{x} \\ e^{x} & x\,e^{x}+e^{x} \end{vmatrix}$$

Therefore

$$W = \left(e^{x}\right)\left(x\,e^{x}+e^{x}\right) - \left(x\,e^{x}\right)\left(e^{x}\right)$$

Which simplifies to

$$W = e^{2x}$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x\,e^{2x} \arcsin(x)}{e^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int x \arcsin(x)\,dx$$

Hence

$$u_1 = -\frac{x^2 \arcsin(x)}{2} - \frac{\sqrt{-x^2+1}\,x}{4} + \frac{\arcsin(x)}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{2x} \arcsin(x)}{e^{2x}}\,dx$$

Which simplifies to

$$u_2 = \int \arcsin(x)\, dx$$

Hence

$$u_2 = x \arcsin(x) + \sqrt{-x^2+1}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{x^2 \arcsin(x)}{2} - \frac{\sqrt{-x^2+1}\, x}{4} + \frac{\arcsin(x)}{4}\right) e^x + \left(x \arcsin(x) + \sqrt{-x^2+1}\right) x\, e^x$$

Which simplifies to

$$y_p(x) = \frac{e^x \left(2x^2 \arcsin(x) + 3\sqrt{-x^2+1}\, x + \arcsin(x)\right)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x c_1 + c_2 x\, e^x) + \left(\frac{e^x \left(2x^2 \arcsin(x) + 3\sqrt{-x^2+1}\, x + \arcsin(x)\right)}{4}\right) \end{aligned}$$

Which simplifies to

$$y = e^x (c_2 x + c_1) + \frac{e^x \left(2x^2 \arcsin(x) + 3\sqrt{-x^2+1}\, x + \arcsin(x)\right)}{4}$$

Summary

The solution(s) found are the following

$$y = e^x (c_2 x + c_1) + \frac{e^x \left(2x^2 \arcsin(x) + 3\sqrt{-x^2+1}\, x + \arcsin(x)\right)}{4} \tag{1}$$

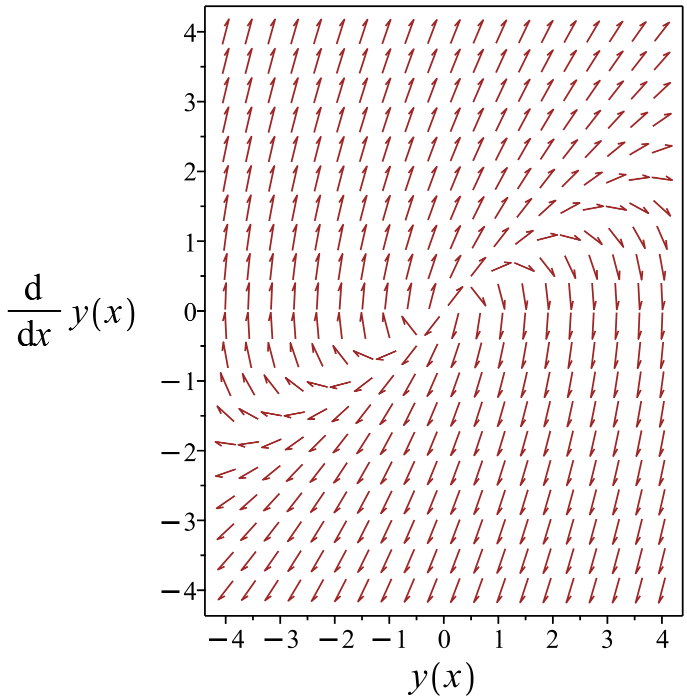

Figure 514: Slope field plot

Verification of solutions

$$y = e^x (c_2 x + c_1) + \frac{e^x \left(2x^2 \arcsin(x) + 3\sqrt{-x^2+1}\, x + \arcsin(x)\right)}{4}$$

Verified OK.

12.16.4 Maple step by step solution

Let's solve

$y'' - 2y' + y = \arcsin(x)\, e^x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 1 = 0$

- Factor the characteristic polynomial

  $(r-1)^2 = 0$

- Root of the characteristic polynomial

$r = 1$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^x$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^x c_1 + c_2 x\,e^x + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \arcsin(x)\,e^x\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^x & x\,e^x \\ e^x & x\,e^x + e^x \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{2x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = e^x\left(-\left(\int x\arcsin(x)\,dx\right) + \left(\int \arcsin(x)\,dx\right)x\right)$

  ◦ Compute integrals

  $y_p(x) = \frac{e^x\left(2x^2\arcsin(x) + 3\sqrt{-x^2+1}\,x + \arcsin(x)\right)}{4}$

- Substitute particular solution into general solution to ODE

  $y = e^x c_1 + c_2 x\,e^x + \frac{e^x\left(2x^2\arcsin(x) + 3\sqrt{-x^2+1}\,x + \arcsin(x)\right)}{4}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 3y' + 2y = \frac{e^{-x}}{x}}$$

12.17.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 3, C = 2, f(x) = \frac{e^{-x}}{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 3y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 3, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 3\lambda\,\mathrm{e}^{\lambda x} + 2\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 3\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 3, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-3}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{3^2 - (4)\,(1)\,(2)}\\ &= -\frac{3}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{3}{2} + \frac{1}{2}\\ \lambda_2 &= -\frac{3}{2} - \frac{1}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1\\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(-1)x} + c_2 e^{(-2)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{-2x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{-2x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \mathrm{e}^{-x}$$
$$y_2 = \mathrm{e}^{-2x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-x} & \mathrm{e}^{-2x} \\ \frac{d}{dx}\left(\mathrm{e}^{-x}\right) & \frac{d}{dx}\left(\mathrm{e}^{-2x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{-x} & \mathrm{e}^{-2x} \\ -\mathrm{e}^{-x} & -2\,\mathrm{e}^{-2x} \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{-x}\right)\left(-2\,\mathrm{e}^{-2x}\right) - \left(\mathrm{e}^{-2x}\right)\left(-\mathrm{e}^{-x}\right)$$

Which simplifies to

$$W = -\mathrm{e}^{-x}\mathrm{e}^{-2x}$$

Which simplifies to

$$W = -e^{-3x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{e^{-2x}e^{-x}}{x}}{-e^{-3x}}\, dx$$

Which simplifies to

$$u_1 = -\int -\frac{1}{x} dx$$

Hence

$$u_1 = \ln(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{e^{-2x}}{x}}{-e^{-3x}}\, dx$$

Which simplifies to

$$u_2 = \int -\frac{e^{x}}{x} dx$$

Hence

$$u_2 = \text{expIntegral}_1(-x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln(x)\, e^{-x} + \text{expIntegral}_1(-x)\, e^{-2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2 e^{-2x}\right) + \left(\ln(x)\, e^{-x} + \text{expIntegral}_1(-x)\, e^{-2x}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 e^{-2x} + \ln(x)\, e^{-x} + \text{expIntegral}_1(-x)\, e^{-2x} \tag{1}$$

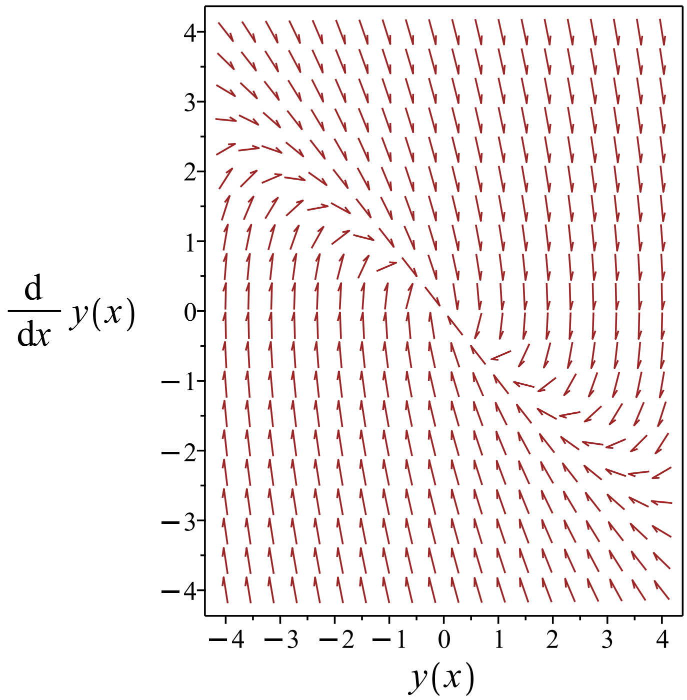

Figure 515: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + c_2 e^{-2x} + \ln(x) e^{-x} + \text{expIntegral}_1(-x) e^{-2x}$$

Verified OK.

12.17.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 3y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 3 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 457: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{3}{1}\,dx} \\ &= z_1 e^{-\frac{3x}{2}} \\ &= z_1 \left(\mathrm{e}^{-\frac{3x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{3}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-3x}}{(y_1)^2}\,dx \\ &= y_1(\mathrm{e}^{x}) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-2x}\right) + c_2 \left(\mathrm{e}^{-2x} (\mathrm{e}^{x})\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 3y' + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \mathrm{e}^{-2x} \\
y_2 &= \mathrm{e}^{-x}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-2x} & \mathrm{e}^{-x} \\ \frac{d}{dx}\left(\mathrm{e}^{-2x}\right) & \frac{d}{dx}\left(\mathrm{e}^{-x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{-2x} & \mathrm{e}^{-x} \\ -2\,\mathrm{e}^{-2x} & -\mathrm{e}^{-x} \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{-2x}\right)\left(-\mathrm{e}^{-x}\right) - \left(\mathrm{e}^{-x}\right)\left(-2\,\mathrm{e}^{-2x}\right)$$

Which simplifies to

$$W = \mathrm{e}^{-x}\mathrm{e}^{-2x}$$

Which simplifies to

$$W = \mathrm{e}^{-3x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\mathrm{e}^{-2x}}{x}}{\mathrm{e}^{-3x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\mathrm{e}^{x}}{x}dx$$

Hence

$$u_1 = \mathrm{expIntegral}_1\left(-x\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\mathrm{e}^{-2x}\mathrm{e}^{-x}}{x}}{\mathrm{e}^{-3x}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x}dx$$

Hence

$$u_2 = \ln(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln(x)\,\mathrm{e}^{-x} + \mathrm{expIntegral}_1(-x)\,\mathrm{e}^{-2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x}\right) + \left(\ln(x)\,\mathrm{e}^{-x} + \mathrm{expIntegral}_1(-x)\,\mathrm{e}^{-2x}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x} + \ln(x)\,\mathrm{e}^{-x} + \mathrm{expIntegral}_1(-x)\,\mathrm{e}^{-2x} \tag{1}$$

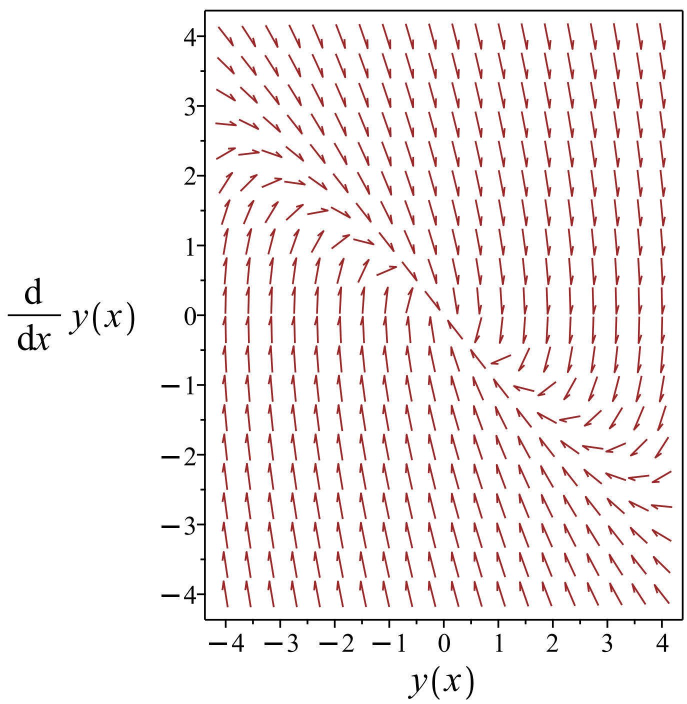

Figure 516: Slope field plot

Verification of solutions

$$y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x} + \ln(x)\,\mathrm{e}^{-x} + \mathrm{expIntegral}_1(-x)\,\mathrm{e}^{-2x}$$

Verified OK.

12.17.3 Maple step by step solution

Let's solve

$y'' + 3y' + 2y = \frac{e^{-x}}{x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 3r + 2 = 0$

- Factor the characteristic polynomial

  $(r + 2)(r + 1) = 0$

- Roots of the characteristic polynomial

  $r = (-2, -1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-2x} + c_2 e^{-x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ∘ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \frac{e^{-x}}{x}\right]$

- ∘ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-2x} & e^{-x} \\ -2\,e^{-2x} & -e^{-x} \end{bmatrix}$

- ∘ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{-3x}$

- ∘ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -e^{-2x}\left(\int \frac{e^{x}}{x} dx\right) + e^{-x}\left(\int \frac{1}{x} dx\right)$

- Compute integrals

  $$y_p(x) = \ln(x)\,\mathrm{e}^{-x} + \mathrm{Ei}_1(-x)\,\mathrm{e}^{-2x}$$

- Substitute particular solution into general solution to ODE

  $$y = c_1\mathrm{e}^{-2x} + c_2\mathrm{e}^{-x} + \ln(x)\,\mathrm{e}^{-x} + \mathrm{Ei}_1(-x)\,\mathrm{e}^{-2x}$$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 2y' + y = x \ln(x)}$$

12.18.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 1, f(x) = x \ln(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-2)^2 - (4)(1)(1)} \\ &= 1\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -1$. Therefore the solution is

$$y = c_1 e^x + c_2 x e^x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = e^x c_1 + c_2 x e^x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}y_1 &= e^x \\ y_2 &= x e^x\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x & x\,e^x \\ \frac{d}{dx}(e^x) & \frac{d}{dx}(x\,e^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^x & x\,e^x \\ e^x & x\,e^x + e^x \end{vmatrix}$$

Therefore

$$W = (e^x)(x\,e^x + e^x) - (x\,e^x)(e^x)$$

Which simplifies to

$$W = e^{2x}$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^2 e^x \ln(x)}{e^{2x}}\, dx$$

Which simplifies to

$$u_1 = -\int x^2 \ln(x)\, e^{-x} dx$$

Hence

$$u_1 = -\left(-x^2 - 2x - 2\right) e^{-x} \ln(x) + 2\, \text{expIntegral}_1(x) + x\, e^{-x} + 3\, e^{-x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x\,\mathrm{e}^{x} \ln \left(x \right)}{\mathrm{e}^{2 x}}d x$$

Which simplifies to

$$u_2 = \int x \ln \left(x \right) \mathrm{e}^{-x}d x$$

Hence

$$u_2 = \left(-x -1\right) \mathrm{e}^{-x} \ln \left(x \right)-\operatorname{expIntegral}_{1}\left(x \right)-\mathrm{e}^{-x}$$

Which simplifies to

$$\begin{aligned} u_1 &= \left(\left(x^{2}+2 x +2\right) \ln \left(x \right)+x +3\right) \mathrm{e}^{-x}+2 \operatorname{expIntegral}_{1}\left(x \right)\\ u_2 &= \left(-1+\ln \left(x \right) \left(-x -1\right)\right) \mathrm{e}^{-x}-\operatorname{expIntegral}_{1}\left(x \right) \end{aligned}$$

Therefore the particular solution, from equation (1) is

$$\begin{aligned} y_p(x) &= \left(\left(\left(x^{2}+2 x +2\right) \ln \left(x \right)+x +3\right) \mathrm{e}^{-x}+2 \operatorname{expIntegral}_{1}\left(x \right)\right) \mathrm{e}^{x}\\ &\quad + \left(\left(-1+\ln \left(x \right) \left(-x -1\right)\right) \mathrm{e}^{-x}-\operatorname{expIntegral}_{1}\left(x \right)\right) x\,\mathrm{e}^{x} \end{aligned}$$

Which simplifies to

$$y_p(x) = -\mathrm{e}^{x} \left(x -2\right) \operatorname{expIntegral}_{1}\left(x \right)+3+\left(x +2\right) \ln \left(x \right)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{x} c_{1} +c_{2} x\,\mathrm{e}^{x}\right) + \left(-\mathrm{e}^{x} \left(x -2\right) \operatorname{expIntegral}_{1}\left(x \right)+3+\left(x +2\right) \ln \left(x \right)\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{x} \left(c_{2} x +c_{1} \right)-\mathrm{e}^{x} \left(x -2\right) \operatorname{expIntegral}_{1}\left(x \right)+3+\left(x +2\right) \ln \left(x \right)$$

<u>Summary</u>
The solution(s) found are the following

$$y = \mathrm{e}^{x} \left(c_{2} x +c_{1} \right)-\mathrm{e}^{x} \left(x -2\right) \operatorname{expIntegral}_{1}\left(x \right)+3+\left(x +2\right) \ln \left(x \right) \tag{1}$$

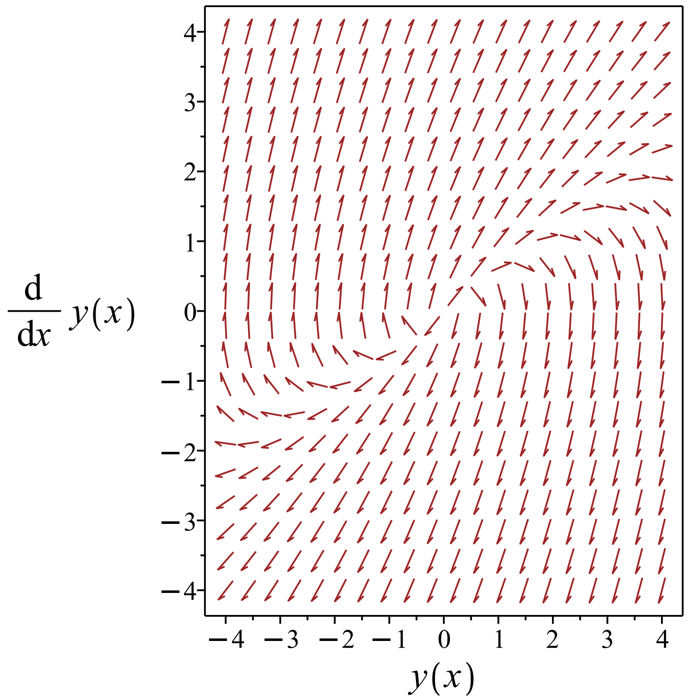

Figure 517: Slope field plot

Verification of solutions

$$y = e^x(c_2x + c_1) - e^x(x - 2)\,\text{expIntegral}_1(x) + 3 + (x + 2)\ln(x)$$

Verified OK.

12.18.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{(p(x)^2 + p'(x))\,y}{2} = f(x)$$

Where $p(x) = -2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int -2\,dx} \\ &= e^{-x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$(M(x)y)'' = x\ln(x)\,e^{-x}$$
$$\left(e^{-x}y\right)'' = x\ln(x)\,e^{-x}$$

Integrating once gives

$$\left(e^{-x}y\right)' = (-1+\ln(x)(-x-1))\,e^{-x} - \operatorname{expIntegral}_1(x) + c_1$$

Integrating again gives

$$\left(e^{-x}y\right) = (3+(x+2)\ln(x))\,e^{-x} + (-x+2)\operatorname{expIntegral}_1(x) + c_1 x + c_2$$

Hence the solution is

$$y = \frac{(3+(x+2)\ln(x))\,e^{-x} + (-x+2)\operatorname{expIntegral}_1(x) + c_1 x + c_2}{e^{-x}}$$

Or

$$y = c_1 x\,e^{x} - x\operatorname{expIntegral}_1(x)\,e^{x} + c_2 e^{x} + x\ln(x) + 2\operatorname{expIntegral}_1(x)\,e^{x} + 2\ln(x) + 3$$

Summary

The solution(s) found are the following

$$y = c_1 x\,e^{x} - x\operatorname{expIntegral}_1(x)\,e^{x} + c_2 e^{x} + x\ln(x) + 2\operatorname{expIntegral}_1(x)\,e^{x} + 2\ln(x) + 3 \tag{1}$$

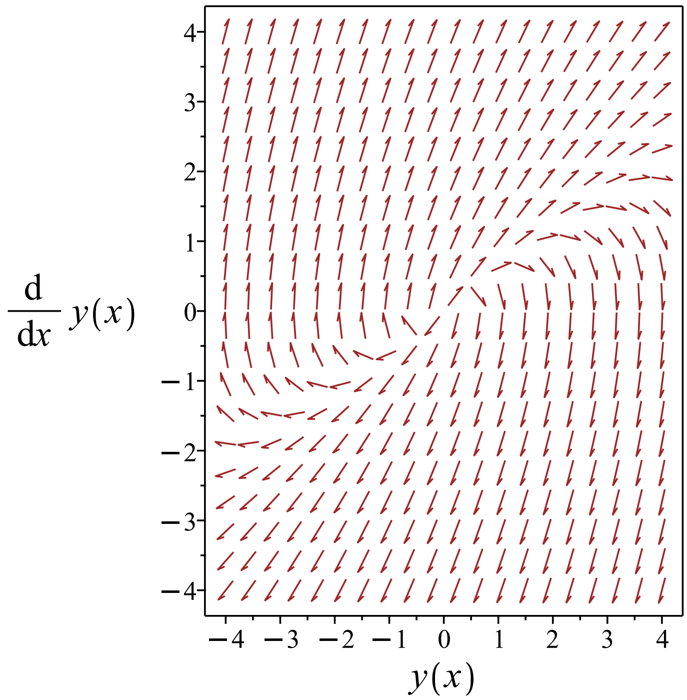

Figure 518: Slope field plot

Verification of solutions

$$y = c_1 x \, e^x - x \, \text{expIntegral}_1(x) \, e^x + c_2 e^x + x \ln(x) + 2 \, \text{expIntegral}_1(x) \, e^x + 2 \ln(x) + 3$$

Verified OK.

12.18.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 459: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\ &= z_1 e^{x} \\ &= z_1(\mathrm{e}^{x}) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^{x}) + c_2(\mathrm{e}^{x}(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^{x} c_1 + c_2 x\,\mathrm{e}^{x}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \mathrm{e}^{x} \\
y_2 &= x\,\mathrm{e}^{x}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x & x\,e^x \\ \frac{d}{dx}(e^x) & \frac{d}{dx}(x\,e^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^x & x\,e^x \\ e^x & x\,e^x + e^x \end{vmatrix}$$

Therefore

$$W = (e^x)(x\,e^x + e^x) - (x\,e^x)(e^x)$$

Which simplifies to

$$W = e^{2x}$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^2 e^x \ln(x)}{e^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int x^2 \ln(x)\,e^{-x} dx$$

Hence

$$u_1 = -\left(-x^2 - 2x - 2\right) e^{-x} \ln(x) + 2\ \mathrm{expIntegral}_1(x) + x\,e^{-x} + 3\,e^{-x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x\,e^x \ln(x)}{e^{2x}}\,dx$$

Which simplifies to

$$u_2 = \int x \ln(x)\,e^{-x} dx$$

Hence

$$u_2 = (-x-1)\,\mathrm{e}^{-x} \ln(x) - \mathrm{expIntegral}_1(x) - \mathrm{e}^{-x}$$

Which simplifies to

$$\begin{aligned}
u_1 &= \left(\left(x^2+2x+2\right)\ln(x)+x+3\right)\mathrm{e}^{-x} + 2\ \mathrm{expIntegral}_1(x)\\
u_2 &= (-1+\ln(x)(-x-1))\,\mathrm{e}^{-x} - \mathrm{expIntegral}_1(x)
\end{aligned}$$

Therefore the particular solution, from equation (1) is

$$\begin{aligned}
y_p(x) = {}&\left(\left(\left(x^2+2x+2\right)\ln(x)+x+3\right)\mathrm{e}^{-x} + 2\ \mathrm{expIntegral}_1(x)\right)\mathrm{e}^{x}\\
&+ \left((-1+\ln(x)(-x-1))\,\mathrm{e}^{-x} - \mathrm{expIntegral}_1(x)\right) x\,\mathrm{e}^{x}
\end{aligned}$$

Which simplifies to

$$y_p(x) = -\mathrm{e}^{x}(x-2)\,\mathrm{expIntegral}_1(x) + 3 + (x+2)\ln(x)$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p\\
&= \left(\mathrm{e}^{x} c_1 + c_2 x\,\mathrm{e}^{x}\right) + \left(-\mathrm{e}^{x}(x-2)\,\mathrm{expIntegral}_1(x) + 3 + (x+2)\ln(x)\right)
\end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{x}(c_2 x + c_1) - \mathrm{e}^{x}(x-2)\,\mathrm{expIntegral}_1(x) + 3 + (x+2)\ln(x)$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{x}(c_2 x + c_1) - \mathrm{e}^{x}(x-2)\,\mathrm{expIntegral}_1(x) + 3 + (x+2)\ln(x) \tag{1}$$

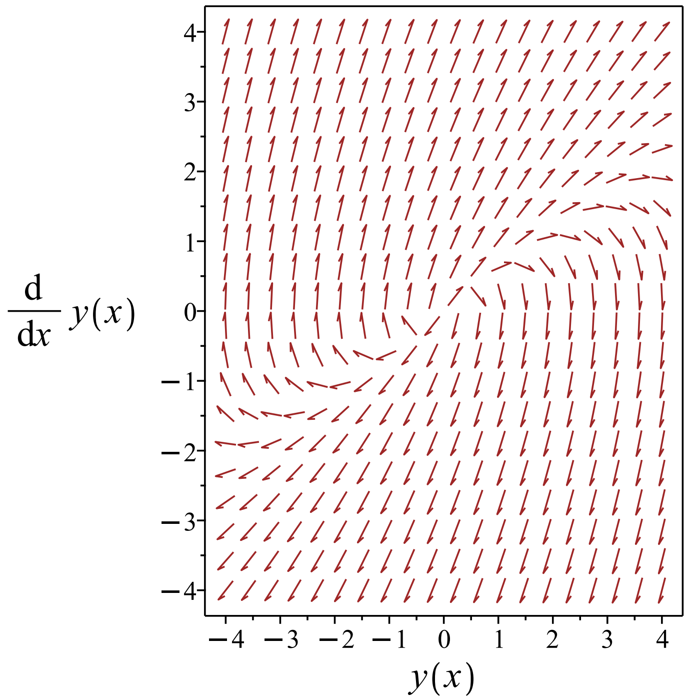

Figure 519: Slope field plot

Verification of solutions

$$y = e^x(c_2x + c_1) - e^x(x - 2)\,\text{expIntegral}_1(x) + 3 + (x + 2)\ln(x)$$

Verified OK.

12.18.4 Maple step by step solution

Let's solve

$y'' - 2y' + y = x\ln(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 1 = 0$

- Factor the characteristic polynomial

  $(r - 1)^2 = 0$

- Root of the characteristic polynomial

$r = 1$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,\mathrm{e}^{x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \mathrm{e}^{x} c_1 + c_2 x\,\mathrm{e}^{x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = x\ln(x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{x} & x\,\mathrm{e}^{x} \\ \mathrm{e}^{x} & x\,\mathrm{e}^{x} + \mathrm{e}^{x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = \mathrm{e}^{2x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = \mathrm{e}^{x}\left(-\left(\int x^2 \ln(x)\,\mathrm{e}^{-x} dx\right) + \left(\int x \ln(x)\,\mathrm{e}^{-x} dx\right) x\right)$

  - Compute integrals

    $y_p(x) = -\mathrm{e}^{x}(x-2)\,\mathrm{Ei}_1(x) + 3 + (x+2)\ln(x)$

- Substitute particular solution into general solution to ODE

  $y = \mathrm{e}^{x} c_1 + c_2 x\,\mathrm{e}^{x} - \mathrm{e}^{x}(x-2)\,\mathrm{Ei}_1(x) + 3 + (x+2)\ln(x)$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{x^2y'' - 6y'x + 10y = 3x^4 + 6x^3}$$

12.19.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -6x, C = 10, f(x) = 3x^4 + 6x^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 6y'x + 10y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 6xrx^{r-1} + 10x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 6r\,x^r + 10x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 6r + 10 = 0$$

Or

$$r^2 - 7r + 10 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = 2$$
$$r_2 = 5$$

Since the roots are real and distinct, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_2 x^5 + c_1 x^2$$

Next, we find the particular solution to the ODE

$$x^2 y'' - 6y'x + 10y = 3x^4 + 6x^3$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2$$
$$y_2 = x^5$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & x^5 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(x^5) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & x^5 \\ 2x & 5x^4 \end{vmatrix}$$

Therefore

$$W = (x^2)(5x^4) - (x^5)(2x)$$

Which simplifies to

$$W = 3x^6$$

Which simplifies to

$$W = 3x^6$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^5(3x^4 + 6x^3)}{3x^8}\, dx$$

Which simplifies to

$$u_1 = -\int (x+2)\, dx$$

Hence

$$u_1 = -\frac{1}{2}x^2 - 2x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2(3x^4 + 6x^3)}{3x^8}\, dx$$

Which simplifies to

$$u_2 = \int \frac{x+2}{x^3} dx$$

Hence

$$u_2 = -\frac{1}{x^2} - \frac{1}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{1}{2}x^2 - 2x\right) x^2 + \left(-\frac{1}{x^2} - \frac{1}{x}\right) x^5$$

Which simplifies to

$$y_p(x) = -\frac{3x^3(x+2)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= -\frac{3}{2}x^4 - 3x^3 + c_2x^5 + c_1x^2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = -\frac{3}{2}x^4 - 3x^3 + c_2x^5 + c_1x^2 \tag{1}$$

Verification of solutions

$$y = -\frac{3}{2}x^4 - 3x^3 + c_2x^5 + c_1x^2$$

Verified OK.

12.19.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 6y'x + 10y = 0$$

In normal form the ode

$$x^2y'' - 6y'x + 10y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{6}{x} \\ q(x) &= \frac{10}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$
\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\
&= \int \mathrm{e}^{-\left(\int -\frac{6}{x} dx\right)} dx \\
&= \int e^{6\ln(x)} \, dx \\
&= \int x^6 dx \\
&= \frac{x^7}{7} \qquad (6)
\end{aligned}
$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{10}{x^2}}{x^{12}} \\
&= \frac{10}{x^{14}} \qquad (7)
\end{aligned}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{10y(\tau)}{x^{14}} &= 0
\end{aligned}
$$

But in terms of τ

$$
\frac{10}{x^{14}} = \frac{10}{49\tau^2}
$$

Hence the above ode becomes

$$
\frac{d^2}{d\tau^2}y(\tau) + \frac{10y(\tau)}{49\tau^2} = 0
$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$
49\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 10y(\tau) = 0
$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$
49\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 10\tau^r = 0
$$

Simplifying gives

$$49r(r-1)\,\tau^r + 0\,\tau^r + 10\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$49r(r-1) + 0 + 10 = 0$$

Or

$$49r^2 - 49r + 10 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{2}{7}$$
$$r_2 = \frac{5}{7}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{\frac{2}{7}} + c_2\tau^{\frac{5}{7}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 7^{\frac{5}{7}} (x^7)^{\frac{2}{7}}}{7} + \frac{c_2 7^{\frac{2}{7}} (x^7)^{\frac{5}{7}}}{7}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 7^{\frac{5}{7}} (x^7)^{\frac{2}{7}}}{7} + \frac{c_2 7^{\frac{2}{7}} (x^7)^{\frac{5}{7}}}{7}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = (x^7)^{\frac{2}{7}}$$
$$y_2 = (x^7)^{\frac{5}{7}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^7)^{\frac{2}{7}} & (x^7)^{\frac{5}{7}} \\ \frac{d}{dx}\left((x^7)^{\frac{2}{7}}\right) & \frac{d}{dx}\left((x^7)^{\frac{5}{7}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^7)^{\frac{2}{7}} & (x^7)^{\frac{5}{7}} \\ \frac{2x^6}{(x^7)^{\frac{5}{7}}} & \frac{5x^6}{(x^7)^{\frac{2}{7}}} \end{vmatrix}$$

Therefore

$$W = \left((x^7)^{\frac{2}{7}}\right)\left(\frac{5x^6}{(x^7)^{\frac{2}{7}}}\right) - \left((x^7)^{\frac{5}{7}}\right)\left(\frac{2x^6}{(x^7)^{\frac{5}{7}}}\right)$$

Which simplifies to

$$W = 3x^6$$

Which simplifies to

$$W = 3x^6$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^7)^{\frac{5}{7}}(3x^4 + 6x^3)}{3x^8}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^7)^{\frac{5}{7}}(x + 2)}{x^5} dx$$

Hence

$$u_1 = -\frac{(x + 4)(x^7)^{\frac{5}{7}}}{2x^4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^7)^{\frac{2}{7}}(3x^4 + 6x^3)}{3x^8}\, dx$$

Which simplifies to

$$u_2 = \int \frac{(x^7)^{\frac{2}{7}}(x + 2)}{x^5} dx$$

Hence

$$u_2 = -\frac{(1 + x)(x^7)^{\frac{2}{7}}}{x^4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^3(x + 4)}{2} - (1 + x)\, x^3$$

Which simplifies to

$$y_p(x) = -\frac{3}{2}x^4 - 3x^3$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 7^{\frac{5}{7}}(x^7)^{\frac{2}{7}}}{7} + \frac{c_2 7^{\frac{2}{7}}(x^7)^{\frac{5}{7}}}{7}\right) + \left(-\frac{3}{2}x^4 - 3x^3\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 7^{\frac{5}{7}} (x^7)^{\frac{2}{7}}}{7} + \frac{c_2 7^{\frac{2}{7}} (x^7)^{\frac{5}{7}}}{7} - \frac{3x^4}{2} - 3x^3 \tag{1}$$

Verification of solutions

$$y = \frac{c_1 7^{\frac{5}{7}} (x^7)^{\frac{2}{7}}}{7} + \frac{c_2 7^{\frac{2}{7}} (x^7)^{\frac{5}{7}}}{7} - \frac{3x^4}{2} - 3x^3$$

Verified OK.

12.19.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -6x, C = 10, f(x) = 3x^4 + 6x^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 6y'x + 10y = 0$$

In normal form the ode

$$x^2y'' - 6y'x + 10y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = -\frac{6}{x}$$
$$q(x) = \frac{10}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}\tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{10}\,\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{\sqrt{10}}{c\sqrt{\frac{1}{x^2}}\,x^3}\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{\sqrt{10}}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{6}{x}\frac{\sqrt{10}\,\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{10}\,\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= -\frac{7c\sqrt{10}}{10}\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) - \frac{7c\sqrt{10}\,\left(\frac{d}{d\tau}y(\tau)\right)}{10} + c^2 y(\tau) &= 0\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = \mathrm{e}^{\frac{7\sqrt{10}\,c\tau}{20}}\left(c_1\cosh\left(\frac{3\sqrt{10}\,c\tau}{20}\right) + ic_2\sinh\left(\frac{3\sqrt{10}\,c\tau}{20}\right)\right)$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\, dx \\
&= \frac{\int \sqrt{10}\, \sqrt{\frac{1}{x^2}} dx}{c} \\
&= \frac{\sqrt{10}\, \sqrt{\frac{1}{x^2}}\, x \ln{(x)}}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = x^{\frac{7}{2}} \left(c_1 \cosh\left(\frac{3\ln{(x)}}{2}\right) + i c_2 \sinh\left(\frac{3\ln{(x)}}{2}\right)\right)
$$

Now the particular solution to this ODE is found

$$
x^2 y'' - 6y'x + 10y = 3x^4 + 6x^3
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \left(x^7\right)^{\frac{2}{7}} \\
y_2 &= \left(x^7\right)^{\frac{5}{7}}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^7)^{\frac{2}{7}} & (x^7)^{\frac{5}{7}} \\ \frac{d}{dx}\left((x^7)^{\frac{2}{7}}\right) & \frac{d}{dx}\left((x^7)^{\frac{5}{7}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^7)^{\frac{2}{7}} & (x^7)^{\frac{5}{7}} \\ \frac{2x^6}{(x^7)^{\frac{5}{7}}} & \frac{5x^6}{(x^7)^{\frac{2}{7}}} \end{vmatrix}$$

Therefore

$$W = \left((x^7)^{\frac{2}{7}}\right)\left(\frac{5x^6}{(x^7)^{\frac{2}{7}}}\right) - \left((x^7)^{\frac{5}{7}}\right)\left(\frac{2x^6}{(x^7)^{\frac{5}{7}}}\right)$$

Which simplifies to

$$W = 3x^6$$

Which simplifies to

$$W = 3x^6$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^7)^{\frac{5}{7}} (3x^4 + 6x^3)}{3x^8}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^7)^{\frac{5}{7}} (x + 2)}{x^5} dx$$

Hence

$$u_1 = -\frac{(x + 4)(x^7)^{\frac{5}{7}}}{2x^4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^7)^{\frac{2}{7}} (3x^4 + 6x^3)}{3x^8}\, dx$$

Which simplifies to

$$u_2 = \int \frac{(x^7)^{\frac{2}{7}} (x+2)}{x^5} dx$$

Hence

$$u_2 = -\frac{(1+x)(x^7)^{\frac{2}{7}}}{x^4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^3(x+4)}{2} - (1+x)\,x^3$$

Which simplifies to

$$y_p(x) = -\frac{3}{2}x^4 - 3x^3$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(x^{\frac{7}{2}}\left(c_1 \cosh\left(\frac{3\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{3\ln(x)}{2}\right)\right)\right) + \left(-\frac{3}{2}x^4 - 3x^3\right) \\
&= -\frac{3x^4}{2} - 3x^3 + x^{\frac{7}{2}}\left(c_1 \cosh\left(\frac{3\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{3\ln(x)}{2}\right)\right)
\end{aligned}$$

Which simplifies to

$$y = i \sinh\left(\frac{3\ln(x)}{2}\right) x^{\frac{7}{2}} c_2 + \cosh\left(\frac{3\ln(x)}{2}\right) x^{\frac{7}{2}} c_1 - \frac{3x^4}{2} - 3x^3$$

Summary

The solution(s) found are the following

$$y = i \sinh\left(\frac{3\ln(x)}{2}\right) x^{\frac{7}{2}} c_2 + \cosh\left(\frac{3\ln(x)}{2}\right) x^{\frac{7}{2}} c_1 - \frac{3x^4}{2} - 3x^3 \tag{1}$$

Verification of solutions

$$y = i \sinh\left(\frac{3\ln(x)}{2}\right) x^{\frac{7}{2}} c_2 + \cosh\left(\frac{3\ln(x)}{2}\right) x^{\frac{7}{2}} c_1 - \frac{3x^4}{2} - 3x^3$$

Verified OK.

12.19.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -6x, C = 10, f(x) = 3x^4 + 6x^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 6y'x + 10y = 0$$

In normal form the ode

$$x^2y'' - 6y'x + 10y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{6}{x} \\ q(x) &= \frac{10}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{6n}{x^2} + \frac{10}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 5 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{4v'(x)}{x} &= 0 \\ v''(x) + \frac{4v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{4u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{4u}{x} \end{aligned}$$

Where $f(x) = -\frac{4}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{4}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{4}{x}\,dx \\ \ln(u) &= -4\ln(x) + c_1 \\ u &= \mathrm{e}^{-4\ln(x)+c_1} \\ &= \frac{c_1}{x^4} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= -\frac{c_1}{3x^3} + c_2 \end{aligned}$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(-\frac{c_1}{3x^3} + c_2\right) x^5 \\
&= c_2 x^5 - \frac{1}{3} c_1 x^2
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
x^2 y'' - 6y'x + 10y = 3x^4 + 6x^3
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x^2 \\
y_2 &= x^5
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix} x^2 & x^5 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(x^5) \end{vmatrix}
$$

Which gives

$$W = \begin{vmatrix} x^2 & x^5 \\ 2x & 5x^4 \end{vmatrix}$$

Therefore

$$W = \left(x^2\right)\left(5x^4\right) - \left(x^5\right)(2x)$$

Which simplifies to

$$W = 3x^6$$

Which simplifies to

$$W = 3x^6$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^5(3x^4 + 6x^3)}{3x^8}\,dx$$

Which simplifies to

$$u_1 = -\int (x+2)\,dx$$

Hence

$$u_1 = -\frac{1}{2}x^2 - 2x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2(3x^4 + 6x^3)}{3x^8}\,dx$$

Which simplifies to

$$u_2 = \int \frac{x+2}{x^3}dx$$

Hence

$$u_2 = -\frac{1}{x^2} - \frac{1}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{1}{2}x^2 - 2x\right)x^2 + \left(-\frac{1}{x^2} - \frac{1}{x}\right)x^5$$

Which simplifies to

$$y_p(x) = -\frac{3x^3(x+2)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(-\frac{c_1}{3x^3} + c_2\right)x^5\right) + \left(-\frac{3x^3(x+2)}{2}\right) \\ &= -\frac{3x^3(x+2)}{2} + \left(-\frac{c_1}{3x^3} + c_2\right)x^5 \end{aligned}$$

Which simplifies to

$$y = -\frac{x^2(-6c_2x^3 + 9x^2 + 2c_1 + 18x)}{6}$$

Summary

The solution(s) found are the following

$$y = -\frac{x^2(-6c_2x^3 + 9x^2 + 2c_1 + 18x)}{6} \tag{1}$$

Verification of solutions

$$y = -\frac{x^2(-6c_2x^3 + 9x^2 + 2c_1 + 18x)}{6}$$

Verified OK.

12.19.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 6y'x + 10y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -6x \\ C &= 10 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 2 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 461: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 2 - 0\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{2}{x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = 2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{2}{x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = -1$ then

$$
\begin{aligned}
d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= -1 - (-1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{x} + (-)(0) \\
&= -\frac{1}{x} \\
&= -\frac{1}{x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{x}\right)(0) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x}\right)^2 - \left(\frac{2}{x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int -\frac{1}{x} dx} \\
&= \frac{1}{x}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-6x}{x^2}\,dx} \\
&= z_1 e^{3\ln(x)} \\
&= z_1\left(x^3\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^2
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-6x}{x^2}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{6\ln(x)}}{\left(y_1\right)^2}\,dx \\
&= y_1\left(\frac{x^3}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^2\right) + c_2\left(x^2\left(\frac{x^3}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' - 6y'x + 10y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 x^2 + \frac{1}{3} c_2 x^5$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2$$
$$y_2 = \frac{x^5}{3}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & \frac{x^5}{3} \\ \frac{d}{dx}(x^2) & \frac{d}{dx}\left(\frac{x^5}{3}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & \frac{x^5}{3} \\ 2x & \frac{5x^4}{3} \end{vmatrix}$$

Therefore

$$W = (x^2)\left(\frac{5x^4}{3}\right) - \left(\frac{x^5}{3}\right)(2x)$$

Which simplifies to

$$W = x^6$$

Which simplifies to

$$W = x^6$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x^5(3x^4+6x^3)}{3}}{x^8}\, dx$$

Which simplifies to

$$u_1 = -\int (x+2)\, dx$$

Hence

$$u_1 = -\frac{1}{2}x^2 - 2x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2(3x^4+6x^3)}{x^8}\, dx$$

Which simplifies to

$$u_2 = \int \frac{3x+6}{x^3} dx$$

Hence

$$u_2 = -\frac{3}{x^2} - \frac{3}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{1}{2}x^2 - 2x\right)x^2 + \frac{\left(-\frac{3}{x^2} - \frac{3}{x}\right)x^5}{3}$$

Which simplifies to

$$y_p(x) = -\frac{3x^3(x+2)}{2}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1x^2 + \frac{1}{3}c_2x^5\right) + \left(-\frac{3x^3(x+2)}{2}\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1x^2 + \frac{c_2x^5}{3} - \frac{3x^3(x+2)}{2} \tag{1}$$

Verification of solutions

$$y = c_1x^2 + \frac{c_2x^5}{3} - \frac{3x^3(x+2)}{2}$$

Verified OK.

```

$$\boxed{(1+x)^2 y'' - 2(1+x) y' + 2y = 1}$$

12.20.1 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x) y' + \frac{(p(x)^2 + p'(x)) y}{2} = f(x)$$

Where $p(x) = -\frac{2}{1+x}$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int -\frac{2}{1+x}\,dx} \\ &= \frac{1}{1+x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= \frac{1}{(1+x)^3} \\ \left(\frac{y}{1+x}\right)'' &= \frac{1}{(1+x)^3} \end{aligned}$$

Integrating once gives

$$\left(\frac{y}{1+x}\right)' = -\frac{1}{2(1+x)^2} + c_1$$

Integrating again gives

$$\left(\frac{y}{1+x}\right) = c_1 x + \frac{1}{2+2x} + c_2$$

Hence the solution is

$$y = \frac{c_1 x + \frac{1}{2+2x} + c_2}{\frac{1}{1+x}}$$

Or

$$y = (x^2 + x) c_1 + (x+1) c_2 + \frac{x}{2x+2} + \frac{1}{2x+2}$$

Summary

The solution(s) found are the following

$$y = (x^2 + x) c_1 + (x+1) c_2 + \frac{x}{2x+2} + \frac{1}{2x+2} \tag{1}$$

Verification of solutions

$$y = (x^2 + x) c_1 + (x+1) c_2 + \frac{x}{2x+2} + \frac{1}{2x+2}$$

Verified OK.

12.20.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$(x+1)^2 y'' + (-2x-2) y' + 2y = 0$$

In normal form the ode

$$(x+1)^2 y'' + (-2x-2) y' + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x) y' + q(x) y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{2}{x+1} \\ q(x) &= \frac{2}{(x+1)^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}\tau &= \int e^{-\left(\int p(x)dx\right)}dx \\ &= \int e^{-\left(\int -\frac{2}{x+1}dx\right)}dx \\ &= \int e^{2\ln(x+1)}\,dx \\ &= \int (x+1)^2\,dx \\ &= \frac{(x+1)^3}{3}\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{2}{(x+1)^2}}{(x+1)^4} \\ &= \frac{2}{(x+1)^6}\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{(x+1)^6} = 0$$

But in terms of τ

$$\frac{2}{(x+1)^6} = \frac{2}{9\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{9\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$9\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 2y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$9\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 2\tau^r = 0$$

Simplifying gives

$$9r(r-1)\,\tau^r + 0\,\tau^r + 2\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$9r(r-1) + 0 + 2 = 0$$

Or

$$9r^2 - 9r + 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{3}$$
$$r_2 = \frac{2}{3}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{\frac{1}{3}} + c_2\tau^{\frac{2}{3}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 3^{\frac{2}{3}}\left((x+1)^3\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}}\left((x+1)^3\right)^{\frac{2}{3}}}{3}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 3^{\frac{2}{3}}\left((x+1)^3\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}}\left((x+1)^3\right)^{\frac{2}{3}}}{3}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(x^3 + 3x^2 + 3x + 1\right)^{\frac{1}{3}}$$

$$y_2 = \left(x^3 + 3x^2 + 3x + 1\right)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(x^3 + 3x^2 + 3x + 1\right)^{\frac{1}{3}} & \left(x^3 + 3x^2 + 3x + 1\right)^{\frac{2}{3}} \\ \frac{d}{dx}\left(\left(x^3 + 3x^2 + 3x + 1\right)^{\frac{1}{3}}\right) & \frac{d}{dx}\left(\left(x^3 + 3x^2 + 3x + 1\right)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(x^3 + 3x^2 + 3x + 1\right)^{\frac{1}{3}} & \left(x^3 + 3x^2 + 3x + 1\right)^{\frac{2}{3}} \\ \frac{3x^2+6x+3}{3(x^3+3x^2+3x+1)^{\frac{2}{3}}} & \frac{2x^2+4x+2}{(x^3+3x^2+3x+1)^{\frac{1}{3}}} \end{vmatrix}$$

Therefore

$$W = \left(\left(x^3 + 3x^2 + 3x + 1\right)^{\frac{1}{3}}\right)\left(\frac{2x^2 + 4x + 2}{\left(x^3 + 3x^2 + 3x + 1\right)^{\frac{1}{3}}}\right) - \left(\left(x^3 + 3x^2 + 3x + 1\right)^{\frac{2}{3}}\right)\left(\frac{3x^2 + 6x + 3}{3\left(x^3 + 3x^2 + 3x + 1\right)^{\frac{2}{3}}}\right)$$

Which simplifies to

$$W = x^2 + 2x + 1$$

Which simplifies to

$$W = (x + 1)^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^3+3x^2+3x+1)^{\frac{2}{3}}}{(x+1)^4}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\left((x+1)^3\right)^{\frac{2}{3}}}{(x+1)^4} dx$$

Hence

$$u_1 = \frac{\left((x+1)^3\right)^{\frac{2}{3}}}{(x+1)^3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^3+3x^2+3x+1)^{\frac{1}{3}}}{(x+1)^4}\, dx$$

Which simplifies to

$$u_2 = \int \frac{\left((x+1)^3\right)^{\frac{1}{3}}}{(x+1)^4} dx$$

Hence

$$u_2 = -\frac{\left((x+1)^3\right)^{\frac{1}{3}}}{2\,(x+1)^3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\left((x+1)^3\right)^{\frac{2}{3}} (x^3+3x^2+3x+1)^{\frac{1}{3}}}{(x+1)^3} - \frac{\left((x+1)^3\right)^{\frac{1}{3}} (x^3+3x^2+3x+1)^{\frac{2}{3}}}{2\,(x+1)^3}$$

Which simplifies to

$$y_p(x) = \frac{1}{2}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\frac{c_1 3^{\frac{2}{3}} \left((x+1)^3\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} \left((x+1)^3\right)^{\frac{2}{3}}}{3}\right) + \left(\frac{1}{2}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1 3^{\frac{2}{3}} \left((x+1)^3\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} \left((x+1)^3\right)^{\frac{2}{3}}}{3} + \frac{1}{2} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1 3^{\frac{2}{3}} \left((x+1)^3\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} \left((x+1)^3\right)^{\frac{2}{3}}}{3} + \frac{1}{2}
$$

Verified OK.

12.20.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$
Ay''(x) + By'(x) + Cy(x) = f(x)
$$

Where $A = (x+1)^2, B = -2x - 2, C = 2, f(x) = 1$. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$
(x+1)^2 y'' + (-2x-2) y' + 2y = 0
$$

In normal form the ode

$$
(x+1)^2 y'' + (-2x-2) y' + 2y = 0 \tag{1}
$$

Becomes

$$
y'' + p(x) y' + q(x) y = 0 \tag{2}
$$

Where

$$p(x) = -\frac{2}{x+1}$$
$$q(x) = \frac{2}{(x+1)^2}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$
$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}\tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{2}\,\sqrt{\frac{1}{(x+1)^2}}}{c} \\ \tau'' &= -\frac{\sqrt{2}}{c\sqrt{\frac{1}{(x+1)^2}}\,(x+1)^3}\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{\sqrt{2}}{c\sqrt{\frac{1}{(x+1)^2}}(x+1)^3} - \frac{2}{x+1}\frac{\sqrt{2}\sqrt{\frac{1}{(x+1)^2}}}{c}}{\left(\frac{\sqrt{2}\sqrt{\frac{1}{(x+1)^2}}}{c}\right)^2} \\ &= -\frac{3c\sqrt{2}}{2}\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) - \frac{3c\sqrt{2}\left(\frac{d}{d\tau}y(\tau)\right)}{2} + c^2 y(\tau) &= 0\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = e^{\frac{3\sqrt{2}\, c\tau}{4}} \left(c_1 \cosh\left(\frac{\sqrt{2}\, c\tau}{4}\right) + i c_2 \sinh\left(\frac{\sqrt{2}\, c\tau}{4}\right)\right)$$

Now from (6)

$$\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\, dx \\
&= \frac{\int \sqrt{2}\sqrt{\frac{1}{(x+1)^2}}dx}{c} \\
&= \frac{\sqrt{2}\sqrt{\frac{1}{(x+1)^2}}\,(x+1)\ln(x+1)}{c}
\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = (x+1)^{\frac{3}{2}} \left(c_1 \cosh\left(\frac{\ln(x+1)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x+1)}{2}\right)\right)$$

Now the particular solution to this ODE is found

$$(x+1)^2 y'' + (-2x-2)\, y' + 2y = 1$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(x^3 + 3x^2 + 3x + 1\right)^{\frac{1}{3}}$$

$$y_2 = \left(x^3 + 3x^2 + 3x + 1\right)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^3+3x^2+3x+1)^{\frac{1}{3}} & (x^3+3x^2+3x+1)^{\frac{2}{3}} \\ \frac{d}{dx}\left((x^3+3x^2+3x+1)^{\frac{1}{3}}\right) & \frac{d}{dx}\left((x^3+3x^2+3x+1)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^3+3x^2+3x+1)^{\frac{1}{3}} & (x^3+3x^2+3x+1)^{\frac{2}{3}} \\ \frac{3x^2+6x+3}{3(x^3+3x^2+3x+1)^{\frac{2}{3}}} & \frac{2x^2+4x+2}{(x^3+3x^2+3x+1)^{\frac{1}{3}}} \end{vmatrix}$$

Therefore

$$W = \left((x^3+3x^2+3x+1)^{\frac{1}{3}}\right)\left(\frac{2x^2+4x+2}{(x^3+3x^2+3x+1)^{\frac{1}{3}}}\right) - \left((x^3+3x^2+3x+1)^{\frac{2}{3}}\right)\left(\frac{3x^2+6x+3}{3(x^3+3x^2+3x+1)^{\frac{2}{3}}}\right)$$

Which simplifies to

$$W = x^2+2x+1$$

Which simplifies to

$$W = (x+1)^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^3+3x^2+3x+1)^{\frac{2}{3}}}{(x+1)^4}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\left((x+1)^3\right)^{\frac{2}{3}}}{(x+1)^4}dx$$

Hence

$$u_1 = \frac{\left((x+1)^3\right)^{\frac{2}{3}}}{(x+1)^3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^3 + 3x^2 + 3x + 1)^{\frac{1}{3}}}{(x+1)^4}\, dx$$

Which simplifies to

$$u_2 = \int \frac{\left((x+1)^3\right)^{\frac{1}{3}}}{(x+1)^4} dx$$

Hence

$$u_2 = -\frac{\left((x+1)^3\right)^{\frac{1}{3}}}{2\,(x+1)^3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\left((x+1)^3\right)^{\frac{2}{3}} (x^3 + 3x^2 + 3x + 1)^{\frac{1}{3}}}{(x+1)^3} - \frac{\left((x+1)^3\right)^{\frac{1}{3}} (x^3 + 3x^2 + 3x + 1)^{\frac{2}{3}}}{2\,(x+1)^3}$$

Which simplifies to

$$y_p(x) = \frac{1}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left((x+1)^{\frac{3}{2}} \left(c_1 \cosh\left(\frac{\ln(x+1)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x+1)}{2}\right)\right)\right) + \left(\frac{1}{2}\right) \\ &= \frac{1}{2} + (x+1)^{\frac{3}{2}} \left(c_1 \cosh\left(\frac{\ln(x+1)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x+1)}{2}\right)\right) \end{aligned}$$

Which simplifies to

$$y = \frac{1}{2} + (x+1)^{\frac{3}{2}} \left(c_1 \cosh\left(\frac{\ln(x+1)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x+1)}{2}\right)\right)$$

Summary

The solution(s) found are the following

$$y = \frac{1}{2} + (x+1)^{\frac{3}{2}} \left(c_1 \cosh\left(\frac{\ln(x+1)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x+1)}{2}\right)\right) \tag{1}$$

Verification of solutions

$$y = \frac{1}{2} + (x+1)^{\frac{3}{2}} \left(c_1 \cosh\left(\frac{\ln(x+1)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x+1)}{2}\right)\right)$$

Verified OK.

12.20.4 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + \left(2AB' + B^2\right) v' + (AB'' + BB' + CB)\, v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right) v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned} A &= (x+1)^2 \\ B &= -2x - 2 \\ C &= 2 \\ F &= 1 \end{aligned}$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= \left((x+1)^2\right)(0) + (-2x-2)(-2) + (2)(-2x-2) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
-2(x+1)^3 v'' + (0) v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
-2(x+1)^3 u'(x) = 0
$$

Which is now solved for u. Integrating both sides gives

$$
\begin{aligned}
u(x) &= \int 0 \, \mathrm{d}x \\
&= c_1
\end{aligned}
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= c_1
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int c_1 \, \mathrm{d}x \\
&= c_1 x + c_2
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= Bv \\
&= (-2x-2)(c_1 x + c_2) \\
&= -2(x+1)(c_1 x + c_2)
\end{aligned}
$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = -2x - 2$$
$$y_2 = -2x^2 - 2x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} -2x - 2 & -2x^2 - 2x \\ \frac{d}{dx}(-2x - 2) & \frac{d}{dx}(-2x^2 - 2x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} -2x - 2 & -2x^2 - 2x \\ -2 & -4x - 2 \end{vmatrix}$$

Therefore

$$W = (-2x - 2)(-4x - 2) - (-2x^2 - 2x)(-2)$$

Which simplifies to

$$W = 4x^2 + 8x + 4$$

Which simplifies to

$$W = 4(x + 1)^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-2x^2 - 2x}{4(x + 1)^4} dx$$

Which simplifies to

$$u_1 = -\int -\frac{x}{2\left(x+1\right)^3} dx$$

Hence

$$u_1 = -\frac{1}{2\left(x+1\right)} + \frac{1}{4\left(x+1\right)^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{-2x-2}{4\left(x+1\right)^4}\, dx$$

Which simplifies to

$$u_2 = \int -\frac{1}{2\left(x+1\right)^3} dx$$

Hence

$$u_2 = \frac{1}{4\left(x+1\right)^2}$$

Which simplifies to

$$u_1 = \frac{-2x-1}{4\left(x+1\right)^2}$$
$$u_2 = \frac{1}{4\left(x+1\right)^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\left(-2x-1\right)\left(-2x-2\right)}{4\left(x+1\right)^2} + \frac{-2x^2-2x}{4\left(x+1\right)^2}$$

Which simplifies to

$$y_p(x) = \frac{1}{2}$$

Hence the complete solution is

$$\begin{aligned}
y(x) &= y_h + y_p \\
&= (-2(x+1)\,(c_1x + c_2)) + \left(\frac{1}{2}\right) \\
&= \frac{1}{2} - 2c_1x^2 + 2(-c_1 - c_2)\,x - 2c_2
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{2} - 2c_1x^2 + 2(-c_1 - c_2)\,x - 2c_2 \tag{1}$$

Verification of solutions

$$y = \frac{1}{2} - 2c_1x^2 + 2(-c_1 - c_2)\,x - 2c_2$$

Verified OK.

12.20.5 Solving using Kovacic algorithm

Writing the ode as

$$(x+1)^2\,y'' + (-2x-2)\,y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}
A &= (x+1)^2 \\
B &= -2x - 2 \\
C &= 2
\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 462: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x-2}{(x+1)^2}\,dx} \\ &= z_1 e^{\ln(x+1)} \\ &= z_1(x+1) \end{aligned}$$

Which simplifies to

$$y_1 = x + 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2x-2}{(x+1)^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2\ln(x+1)}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(x+1) + c_2(x + 1(x)) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$(x+1)^2 y'' + (-2x-2)\, y' + 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1(x+1) + c_2 x(x+1)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x+1$$
$$y_2 = x(x+1)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x+1 & x(x+1) \\ \frac{d}{dx}(x+1) & \frac{d}{dx}(x(x+1)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x+1 & x(x+1) \\ 1 & 2x+1 \end{vmatrix}$$

Therefore

$$W = (x+1)(2x+1) - (x(x+1))(1)$$

Which simplifies to

$$W = x^2 + 2x + 1$$

Which simplifies to

$$W = (x+1)^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x(x+1)}{(x+1)^4}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{x}{(x+1)^3}dx$$

Hence

$$u_1 = \frac{1}{x+1} - \frac{1}{2(x+1)^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x+1}{(x+1)^4}\,dx$$

Which simplifies to

$$u_2 = \int \frac{1}{(x+1)^3}dx$$

Hence

$$u_2 = -\frac{1}{2(x+1)^2}$$

Which simplifies to

$$u_1 = \frac{2x+1}{2\left(x+1\right)^2}$$
$$u_2 = -\frac{1}{2\left(x+1\right)^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{2x+1}{2x+2} - \frac{x}{2\left(x+1\right)}$$

Which simplifies to

$$y_p(x) = \frac{1}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1(x+1) + c_2x(x+1)) + \left(\frac{1}{2}\right) \end{aligned}$$

Which simplifies to

$$y = \left(x+1\right)\left(c_2x + c_1\right) + \frac{1}{2}$$

Summary

The solution(s) found are the following

$$y = \left(x+1\right)\left(c_2x + c_1\right) + \frac{1}{2} \tag{1}$$

Verification of solutions

$$y = \left(x+1\right)\left(c_2x + c_1\right) + \frac{1}{2}$$

Verified OK.

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{(x^2+2x)\,y''-2(x+1)\,y'+2y=(x+2)^2}$$

12.21.1 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=x^2+2x, B=-2x-2, C=2, f(x)=(x+2)^2$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. Solving for y_h from

$$(x^2+2x)\,y''+(-2x-2)\,y'+2y=0$$

In normal form the ode

$$\left(x^2+2x\right)y''+\left(-2x-2\right)y'+2y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned}p(x)&=\frac{-2x-2}{x\left(x+2\right)}\\ q(x)&=\frac{2}{x\left(x+2\right)}\end{aligned}$$

Applying change of variables on the depndent variable $y=v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x)+\left(\frac{2n}{x}+p\right)v'(x)+\left(\frac{n(n-1)}{x^2}+\frac{np}{x}+q\right)v(x)=0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2}+\frac{np}{x}+q=0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}+\frac{n(-2x-2)}{x^2\left(x+2\right)}+\frac{2}{x\left(x+2\right)}=0 \tag{5}$$

Solving (5) for n gives

$$n=2 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned}v''(x)+\left(\frac{4}{x}+\frac{-2x-2}{x\left(x+2\right)}\right)v'(x)&=0\\ v''(x)+\frac{\left(2x+6\right)v'(x)}{x\left(x+2\right)}&=0\end{aligned} \tag{7}$$

Using the substitution

$$u(x)=v'(x)$$

Then (7) becomes

$$u'(x)+\frac{(2x+6)\,u(x)}{x\,(x+2)}=0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u)\\
&= f(x)g(u)\\
&= -\frac{2u(x+3)}{x\,(x+2)}
\end{aligned}$$

Where $f(x)=-\frac{2(x+3)}{x(x+2)}$ and $g(u)=u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= -\frac{2(x+3)}{x\,(x+2)}\,dx\\
\int\frac{1}{u}\,du &= \int-\frac{2(x+3)}{x\,(x+2)}\,dx\\
\ln(u) &= -3\ln(x)+\ln(x+2)+c_1\\
u &= \mathrm{e}^{-3\ln(x)+\ln(x+2)+c_1}\\
&= c_1\mathrm{e}^{-3\ln(x)+\ln(x+2)}
\end{aligned}$$

Which simplifies to

$$u(x)=c_1\left(\frac{1}{x^2}+\frac{2}{x^3}\right)$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x)\\
v(x) &= \int u(x)\,dx+c_2\\
&= c_1\left(-\frac{1}{x^2}-\frac{1}{x}\right)+c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\,x^n\\
&= \left(c_1\left(-\frac{1}{x^2}-\frac{1}{x}\right)+c_2\right)x^2\\
&= (-x-1)\,c_1+c_2x^2
\end{aligned}$$

Now the particular solution to this ODE is found

$$\left(x^2+2x\right) y''+(-2x-2)\, y'+2y=(x+2)^2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x)=u_1y_1+u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= x^2 \\ y_2 &= -x-1 \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1=-\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2=\int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W=\begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W=\begin{vmatrix} x^2 & -x-1 \\ \frac{d}{dx}\left(x^2\right) & \frac{d}{dx}(-x-1) \end{vmatrix}$$

Which gives

$$W=\begin{vmatrix} x^2 & -x-1 \\ 2x & -1 \end{vmatrix}$$

Therefore

$$W=\left(x^2\right)(-1)-(-x-1)\,(2x)$$

Which simplifies to

$$W = x^2 + 2x$$

Which simplifies to

$$W = x^2 + 2x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(-x-1)(x+2)^2}{(x^2+2x)^2}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{-x-1}{x^2} dx$$

Hence

$$u_1 = -\frac{1}{x} + \ln(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2(x+2)^2}{(x^2+2x)^2}\,dx$$

Which simplifies to

$$u_2 = \int 1 dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{1}{x} + \ln(x)\right) x^2 + (-x-1)\,x$$

Which simplifies to

$$y_p(x) = x(x\ln(x) - x - 2)$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\left(c_1\left(-\frac{1}{x^2} - \frac{1}{x}\right) + c_2\right) x^2\right) + (x(x\ln(x) - x - 2)) \\
&= x(x\ln(x) - x - 2) + \left(c_1\left(-\frac{1}{x^2} - \frac{1}{x}\right) + c_2\right) x^2
\end{aligned}
$$

Which simplifies to

$$
y = x^2\ln(x) + c_2x^2 - c_1x - x^2 - c_1 - 2x
$$

Summary

The solution(s) found are the following

$$
y = x^2\ln(x) + c_2x^2 - c_1x - x^2 - c_1 - 2x \tag{1}
$$

Verification of solutions

$$
y = x^2\ln(x) + c_2x^2 - c_1x - x^2 - c_1 - 2x
$$

Verified OK.

12.21.2 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$
Ay'' + By' + Cy = F(x)
$$

This method reduces the order ode the ODE by one by applying the transformation

$$
y = Bv
$$

This results in

$$
\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}
$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + \left(2AB' + B^2\right)v' + (AB'' + BB' + CB)v &= 0
\end{aligned} \tag{1}
$$

If the term $AB''+BB'+CB$ is zero, then this method works and can be used to solve

$$ABv''+\left(2AB'+B^2\right)v'=0$$

By Using $u=v'$ which reduces the order of the above ode to one. The new ode is

$$ABu'+\left(2AB'+B^2\right)u=0$$

The above ode is first order ode which is solved for u. Now a new ode $v'=u$ is solved for v as first order ode. Then the final solution is obtain from $y=Bv$.

This method works only if the term $AB''+BB'+CB$ is zero. The given ODE shows that

$$\begin{aligned}
A &= x^2+2x\\
B &= -2x-2\\
C &= 2\\
F &= (x+2)^2
\end{aligned}$$

The above shows that for this ode

$$\begin{aligned}
AB''+BB'+CB &= \left(x^2+2x\right)(0)+(-2x-2)(-2)+(2)(-2x-2)\\
&= 0
\end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$-2x(x+2)(x+1)v''+(4)v'=0$$

Now by applying $v'=u$ the above becomes

$$\left(-2x^3-6x^2-4x\right)u'(x)+4u(x)=0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u)\\
&= f(x)g(u)\\
&= \frac{2u}{x\left(x^2+3x+2\right)}
\end{aligned}$$

Where $f(x)=\frac{2}{x(x^2+3x+2)}$ and $g(u)=u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= \frac{2}{x\left(x^2+3x+2\right)}\,dx\\
\int\frac{1}{u}\,du &= \int\frac{2}{x\left(x^2+3x+2\right)}\,dx\\
\ln(u) &= -2\ln(x+1)+\ln(x)+\ln(x+2)+c_1\\
u &= \mathrm{e}^{-2\ln(x+1)+\ln(x)+\ln(x+2)+c_1}\\
&= c_1\mathrm{e}^{-2\ln(x+1)+\ln(x)+\ln(x+2)}
\end{aligned}$$

Which simplifies to

$$u(x) = c_1 \left(\frac{x^2}{(x+1)^2} + \frac{2x}{(x+1)^2} \right)$$

The ode for v now becomes

$$\begin{aligned} v' &= u \\ &= c_1 \left(\frac{x^2}{(x+1)^2} + \frac{2x}{(x+1)^2} \right) \end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned} v(x) &= \int \frac{c_1 x(x+2)}{(x+1)^2} \, \mathrm{d}x \\ &= c_1 \left(x + \frac{1}{x+1} \right) + c_2 \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= Bv \\ &= (-2x-2) \left(c_1 \left(x + \frac{1}{x+1} \right) + c_2 \right) \\ &= \left(-2x^2 - 2x - 2 \right) c_1 - 2(x+1) \, c_2 \end{aligned}$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= -2x - 2 \\ y_2 &= -2x^2 - 2x - 2 \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} -2x-2 & -2x^2-2x-2 \\ \frac{d}{dx}(-2x-2) & \frac{d}{dx}(-2x^2-2x-2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} -2x-2 & -2x^2-2x-2 \\ -2 & -4x-2 \end{vmatrix}$$

Therefore

$$W = (-2x-2)(-4x-2) - \left(-2x^2-2x-2\right)(-2)$$

Which simplifies to

$$W = 4x^2 + 8x$$

Which simplifies to

$$W = 4x^2 + 8x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(-2x^2-2x-2\right)(x+2)^2}{(x^2+2x)(4x^2+8x)}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{-x^2-x-1}{2x^2}dx$$

Hence

$$u_1 = \frac{x}{2} - \frac{1}{2x} + \frac{\ln(x)}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(-2x-2)(x+2)^2}{(x^2+2x)(4x^2+8x)}\,dx$$

Which simplifies to

$$u_2 = \int \frac{-x-1}{2x^2} dx$$

Hence

$$u_2 = \frac{1}{2x} - \frac{\ln(x)}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{x}{2} - \frac{1}{2x} + \frac{\ln(x)}{2}\right)(-2x-2) + \left(\frac{1}{2x} - \frac{\ln(x)}{2}\right)(-2x^2-2x-2)$$

Which simplifies to

$$y_p(x) = x(x\ln(x) - x - 2)$$

Hence the complete solution is

$$\begin{aligned} y(x) &= y_h + y_p \\ &= \left(\left(-2x^2-2x-2\right)c_1 - 2(x+1)\,c_2\right) + \left(x(x\ln(x) - x - 2)\right) \\ &= x^2\ln(x) + (-2c_1-1)\,x^2 + (-2c_1-2c_2-2)\,x - 2c_1 - 2c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = x^2\ln(x) + (-2c_1-1)\,x^2 + (-2c_1-2c_2-2)\,x - 2c_1 - 2c_2 \tag{1}$$

Verification of solutions

$$y = x^2\ln(x) + (-2c_1-1)\,x^2 + (-2c_1-2c_2-2)\,x - 2c_1 - 2c_2$$

Verified OK.

12.21.3 Solving using Kovacic algorithm

Writing the ode as

$$\left(x^2+2x\right)y'' + (-2x-2)\,y' + 2y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x^2 + 2x \\
B &= -2x - 2 \\
C &= 2
\end{aligned}
\tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
\tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{3}{\left(x^2 + 2x\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 3 \\
t &= \left(x^2 + 2x\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{3}{\left(x^2 + 2x\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 463: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 + 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4x^2} + \frac{3}{4(x+2)^2} + \frac{3}{4(x+2)} - \frac{3}{4x}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(x+2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{3}{(x^2 + 2x)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-2	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$\begin{aligned} d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right) \\ &= 1 - (1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2(x+2)} + \frac{3}{2x} + (-)(0) \\ &= -\frac{1}{2(x+2)} + \frac{3}{2x} \\ &= \frac{x+3}{x(x+2)} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{1}{2(x+2)} + \frac{3}{2x}\right)(0) + \left(\left(\frac{1}{2(x+2)^2} - \frac{3}{2x^2}\right) + \left(-\frac{1}{2(x+2)} + \frac{3}{2x}\right)^2 - \left(\frac{3}{(x^2+2x)^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(-\frac{1}{2(x+2)} + \frac{3}{2x}\right) dx} \\ &= \frac{x^{\frac{3}{2}}}{\sqrt{x+2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-2x-2}{x^2+2x} \, dx} \\
&= z_1 e^{\frac{\ln(x(x+2))}{2}} \\
&= z_1 \left(\sqrt{x\,(x+2)}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^{\frac{3}{2}} \sqrt{x\,(x+2)}}{\sqrt{x+2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x-2}{x^2+2x} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{\ln(x(x+2))}}{(y_1)^2} \, dx \\
&= y_1 \left(\frac{-x-1}{x^2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^{\frac{3}{2}} \sqrt{x\,(x+2)}}{\sqrt{x+2}}\right) + c_2 \left(\frac{x^{\frac{3}{2}} \sqrt{x\,(x+2)}}{\sqrt{x+2}} \left(\frac{-x-1}{x^2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$\left(x^2+2x\right) y''+(-2x-2)\, y'+2y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_1 x^{\frac{3}{2}} \sqrt{x\,(x+2)}}{\sqrt{x+2}} + \frac{c_2 \sqrt{x\,(x+2)}\,(-x-1)}{\sqrt{x}\,\sqrt{x+2}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{x^{\frac{3}{2}} \sqrt{x\,(x+2)}}{\sqrt{x+2}}$$

$$y_2 = \frac{\sqrt{x\,(x+2)}\,(-x-1)}{\sqrt{x}\,\sqrt{x+2}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{x^{\frac{3}{2}} \sqrt{x(x+2)}}{\sqrt{x+2}} & \frac{\sqrt{x(x+2)}\,(-x-1)}{\sqrt{x}\,\sqrt{x+2}} \\ \frac{d}{dx}\left(\frac{x^{\frac{3}{2}} \sqrt{x(x+2)}}{\sqrt{x+2}}\right) & \frac{d}{dx}\left(\frac{\sqrt{x(x+2)}\,(-x-1)}{\sqrt{x}\,\sqrt{x+2}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{x^{\frac{3}{2}}\sqrt{x(x+2)}}{\sqrt{x+2}} & \frac{\sqrt{x(x+2)}\,(-x-1)}{\sqrt{x}\,\sqrt{x+2}} \\ \frac{3\sqrt{x}\,\sqrt{x(x+2)}}{2\sqrt{x+2}} - \frac{x^{\frac{3}{2}}\sqrt{x(x+2)}}{2(x+2)^{\frac{3}{2}}} + \frac{x^{\frac{3}{2}}(2x+2)}{2\sqrt{x+2}\,\sqrt{x(x+2)}} & -\frac{\sqrt{x(x+2)}\,(-x-1)}{2x^{\frac{3}{2}}\sqrt{x+2}} - \frac{\sqrt{x(x+2)}\,(-x-1)}{2\sqrt{x}\,(x+2)^{\frac{3}{2}}} + \frac{(-x-1)(2x+2)}{2\sqrt{x}\,\sqrt{x+2}\,\sqrt{x(x+2)}} - \frac{\sqrt{x(x+2)}}{\sqrt{x}\,\sqrt{x+2}} \end{vmatrix}$$

Therefore

$$W = \left(\frac{x^{\frac{3}{2}}\sqrt{x\,(x+2)}}{\sqrt{x+2}}\right)\left(-\frac{\sqrt{x\,(x+2)}\,(-x-1)}{2x^{\frac{3}{2}}\sqrt{x+2}} - \frac{\sqrt{x\,(x+2)}\,(-x-1)}{2\sqrt{x}\,(x+2)^{\frac{3}{2}}} + \frac{(-x-1)\,(2x+2)}{2\sqrt{x}\,\sqrt{x+2}\,\sqrt{x\,(x+2)}} - \frac{\sqrt{x\,(x+2)}}{\sqrt{x}\,\sqrt{x+2}}\right) - \left(\frac{\sqrt{x\,(x+2)}\,(-x-1)}{\sqrt{x}\,\sqrt{x+2}}\right)\left(\frac{3\sqrt{x}\,\sqrt{x\,(x+2)}}{2\sqrt{x+2}} - \frac{x^{\frac{3}{2}}\sqrt{x\,(x+2)}}{2\,(x+2)^{\frac{3}{2}}} + \frac{x^{\frac{3}{2}}(2x+2)}{2\sqrt{x+2}\,\sqrt{x\,(x+2)}}\right)$$

Which simplifies to

$$W = x(x+2)$$

Which simplifies to

$$W = x(x+2)$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{(x+2)^{\frac{3}{2}}\sqrt{x(x+2)}\,(-x-1)}{\sqrt{x}}}{(x^2+2x)\,x\,(x+2)}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{(-x-1)\sqrt{x\,(x+2)}}{\sqrt{x+2}\,x^{\frac{5}{2}}}dx$$

Hence

$$u_1 = \frac{\sqrt{x\,(x+2)}\,(x\ln(x)-1)}{\sqrt{x+2}\,x^{\frac{3}{2}}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^{\frac{3}{2}}(x+2)^{\frac{3}{2}}\sqrt{x(x+2)}}{(x^2+2x)\,x\,(x+2)}dx$$

Which simplifies to

$$u_2 = \int \frac{\sqrt{x(x+2)}}{\sqrt{x}\,\sqrt{x+2}}dx$$

Hence

$$u_2 = \frac{\sqrt{x}\,\sqrt{x(x+2)}}{\sqrt{x+2}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x(x\ln(x)-1) + (-x-1)\,x$$

Which simplifies to

$$y_p(x) = x(x\ln(x)-x-2)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 x^{\frac{3}{2}}\sqrt{x(x+2)}}{\sqrt{x+2}} + \frac{c_2\sqrt{x(x+2)}\,(-x-1)}{\sqrt{x}\,\sqrt{x+2}}\right) + (x(x\ln(x)-x-2)) \end{aligned}$$

Which simplifies to

$$y = \frac{\sqrt{x(x+2)}\,((-x-1)\,c_2 + c_1x^2)}{\sqrt{x+2}\,\sqrt{x}} + x(x\ln(x)-x-2)$$

Summary
The solution(s) found are the following

$$y = \frac{\sqrt{x(x+2)}\,((-x-1)\,c_2 + c_1x^2)}{\sqrt{x+2}\,\sqrt{x}} + x(x\ln(x)-x-2) \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{x (x+2)}\, ((-x-1)\, c_2 + c_1 x^2)}{\sqrt{x+2}\, \sqrt{x}} + x(x \ln (x) - x - 2)$$

Verified OK.

$$\boxed{x^2y'' - x(x+2)\,y' + (x+2)\,y = x^3}$$

12.22.1 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + \left(-x^2 - 2x\right) y' + (x+2)\,y = 0$$

In normal form the given ode is written as

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = \frac{-x^2 - 2x}{x^2}$$
$$q(x) = \frac{x + 2}{x^2}$$

Calculating the Liouville ode invariant Q given by

$$\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{x+2}{x^2} - \frac{\left(\frac{-x^2-2x}{x^2}\right)'}{2} - \frac{\left(\frac{-x^2-2x}{x^2}\right)^2}{4} \\
&= \frac{x+2}{x^2} - \frac{\left(\frac{-2x-2}{x^2} - \frac{2(-x^2-2x)}{x^3}\right)}{2} - \frac{\left(\frac{(-x^2-2x)^2}{x^4}\right)}{4} \\
&= \frac{x+2}{x^2} - \left(\frac{-2x-2}{2x^2} - \frac{-x^2-2x}{x^3}\right) - \frac{(-x^2-2x)^2}{4x^4} \\
&= -\frac{1}{4}
\end{aligned}$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y = v(x)\, z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{\frac{-x^2-2x}{x^2}}{2}} \\
&= \mathrm{e}^{\frac{x}{2}} x
\end{aligned} \tag{5}$$

Hence (3) becomes

$$y = v(x)\, \mathrm{e}^{\frac{x}{2}} x \tag{4}$$

Applying this change of variable to the original ode results in

$$\mathrm{e}^{\frac{x}{2}} (4v''(x) - v(x)) = 4$$

Which is now solved for $v(x)$ Simplyfing the ode gives

$$v''(x) - \frac{v(x)}{4} = \mathrm{e}^{-\frac{x}{2}}$$

This is second order non-homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = f(x)$$

Where $A = 1, B = 0, C = -\frac{1}{4}, f(x) = e^{-\frac{x}{2}}$. Let the solution be

$$v(x) = v_h + v_p$$

Where v_h is the solution to the homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = 0$, and v_p is a particular solution to the non-homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = f(x)$. v_h is the solution to

$$v''(x) - \frac{v(x)}{4} = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = 0$$

Where in the above $A = 1, B = 0, C = -\frac{1}{4}$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - \frac{e^{\lambda x}}{4} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \frac{1}{4} = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -\frac{1}{4}$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)\left(-\frac{1}{4}\right)} \\
&= \pm\frac{1}{2}
\end{aligned}$$

Hence

$$\lambda_1 = +\frac{1}{2}$$

$$\lambda_2 = -\frac{1}{2}$$

Which simplifies to

$$\lambda_1 = \frac{1}{2}$$
$$\lambda_2 = -\frac{1}{2}$$

Since roots are real and distinct, then the solution is

$$v(x) = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$v(x) = c_1 e^{\left(\frac{1}{2}\right)x} + c_2 e^{\left(-\frac{1}{2}\right)x}$$

Or

$$v(x) = c_1 \mathrm{e}^{\frac{x}{2}} + c_2 \mathrm{e}^{-\frac{x}{2}}$$

Therefore the homogeneous solution v_h is

$$v_h = c_1 \mathrm{e}^{\frac{x}{2}} + c_2 \mathrm{e}^{-\frac{x}{2}}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\mathrm{e}^{-\frac{x}{2}}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$\left[\left\{\mathrm{e}^{-\frac{x}{2}}\right\}\right]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\mathrm{e}^{-\frac{x}{2}}, \mathrm{e}^{\frac{x}{2}}\right\}$$

Since $\mathrm{e}^{-\frac{x}{2}}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$\left[\left\{x\,\mathrm{e}^{-\frac{x}{2}}\right\}\right]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$v_p = A_1 x\,\mathrm{e}^{-\frac{x}{2}}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution v_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 e^{-\frac{x}{2}} = e^{-\frac{x}{2}}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1]$$

Substituting the above back in the above trial solution v_p, gives the particular solution

$$v_p = -x\, e^{-\frac{x}{2}}$$

Therefore the general solution is

$$\begin{aligned} v &= v_h + v_p \\ &= \left(c_1 e^{\frac{x}{2}} + c_2 e^{-\frac{x}{2}}\right) + \left(-x\, e^{-\frac{x}{2}}\right) \end{aligned}$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= \left(c_1 e^{\frac{x}{2}} + c_2 e^{-\frac{x}{2}} - x\, e^{-\frac{x}{2}}\right) (z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = e^{\frac{x}{2}} x$$

Hence (7) becomes

$$y = \left(c_1 e^{\frac{x}{2}} + c_2 e^{-\frac{x}{2}} - x\, e^{-\frac{x}{2}}\right) e^{\frac{x}{2}} x$$

Therefore the homogeneous solution y_h is

$$y_h = \left(c_1 e^{\frac{x}{2}} + c_2 e^{-\frac{x}{2}} - x\, e^{-\frac{x}{2}}\right) e^{\frac{x}{2}} x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x\,e^x$$
$$y_2 = e^{-\frac{x}{2}} e^{\frac{x}{2}} x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x\,e^x & e^{-\frac{x}{2}} e^{\frac{x}{2}} x \\ \frac{d}{dx}(x\,e^x) & \frac{d}{dx}\left(e^{-\frac{x}{2}} e^{\frac{x}{2}} x\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x\,e^x & e^{-\frac{x}{2}} e^{\frac{x}{2}} x \\ x\,e^x + e^x & e^{-\frac{x}{2}} e^{\frac{x}{2}} \end{vmatrix}$$

Therefore

$$W = (x\,e^x)\left(e^{-\frac{x}{2}} e^{\frac{x}{2}}\right) - \left(e^{-\frac{x}{2}} e^{\frac{x}{2}} x\right)(x\,e^x + e^x)$$

Which simplifies to

$$W = -e^{\frac{3x}{2}} e^{-\frac{x}{2}} x^2$$

Which simplifies to

$$W = -x^2 e^x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{e^{-\frac{x}{2}} e^{\frac{x}{2}} x^4}{-x^4 e^x}\, dx$$

Which simplifies to

$$u_1 = -\int -\mathrm{e}^{-x} dx$$

Hence

$$u_1 = -\mathrm{e}^{-x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^4 \mathrm{e}^x}{-x^4 \mathrm{e}^x} dx$$

Which simplifies to

$$u_2 = \int (-1)\, dx$$

Hence

$$u_2 = -x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\mathrm{e}^{-x} \mathrm{e}^x x - x^2 \mathrm{e}^{-\frac{x}{2}} \mathrm{e}^{\frac{x}{2}}$$

Which simplifies to

$$y_p(x) = -x^2 - x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(c_1 \mathrm{e}^{\frac{x}{2}} + c_2 \mathrm{e}^{-\frac{x}{2}} - x\, \mathrm{e}^{-\frac{x}{2}}\right) \mathrm{e}^{\frac{x}{2}} x\right) + \left(-x^2 - x\right) \end{aligned}$$

Which simplifies to

$$y = x(\mathrm{e}^x c_1 + c_2 - x) - x^2 - x$$

Summary

The solution(s) found are the following

$$y = x(\mathrm{e}^x c_1 + c_2 - x) - x^2 - x \tag{1}$$

Verification of solutions

$$y = x(\mathrm{e}^x c_1 + c_2 - x) - x^2 - x$$

Verified OK.

12.22.2 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -x^2 - 2x, C = x + 2, f(x) = x^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + (-x^2 - 2x)\, y' + (x + 2)\, y = 0$$

In normal form the ode

$$x^2y'' + (-x^2 - 2x)\, y' + (x + 2)\, y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{-x - 2}{x} \\ q(x) &= \frac{x + 2}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n(-x-2)}{x^2} + \frac{x+2}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{2}{x} + \frac{-x-2}{x}\right) v'(x) &= 0 \\ v''(x) - v'(x) &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) - u(x) = 0 \tag{8}$$

The above is now solved for $u(x)$. Integrating both sides gives

$$\begin{aligned} \int \frac{1}{u} du &= x + c_1 \\ \ln(u) &= x + c_1 \\ u &= e^{x+c_1} \\ u &= e^x c_1 \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= e^x c_1 + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\, x^n \\ &= (e^x c_1 + c_2)\, x \\ &= (e^x c_1 + c_2)\, x \end{aligned}$$

Now the particular solution to this ODE is found

$$x^2y'' + (-x^2 - 2x)\, y' + (x + 2)\, y = x^3$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = x\,\mathrm{e}^x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & x\,\mathrm{e}^x \\ \frac{d}{dx}(x) & \frac{d}{dx}(x\,\mathrm{e}^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & x\,\mathrm{e}^x \\ 1 & x\,\mathrm{e}^x + \mathrm{e}^x \end{vmatrix}$$

Therefore

$$W = (x)\,(x\,\mathrm{e}^x + \mathrm{e}^x) - (x\,\mathrm{e}^x)\,(1)$$

Which simplifies to

$$W = x^2 e^x$$

Which simplifies to

$$W = x^2 e^x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^4 e^x}{x^4 e^x}\, dx$$

Which simplifies to

$$u_1 = -\int 1 dx$$

Hence

$$u_1 = -x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^4}{x^4 e^x}\, dx$$

Which simplifies to

$$u_2 = \int e^{-x} dx$$

Hence

$$u_2 = -e^{-x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -x^2 - e^{-x} e^x x$$

Which simplifies to

$$y_p(x) = -x^2 - x$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= ((e^x c_1 + c_2)\, x) + (-x^2 - x) \\
&= -x^2 - x + (e^x c_1 + c_2)\, x
\end{aligned}
$$

Which simplifies to

$$y = x(e^x c_1 + c_2 - x - 1)$$

Summary

The solution(s) found are the following

$$y = x(e^x c_1 + c_2 - x - 1) \tag{1}$$

Verification of solutions

$$y = x(e^x c_1 + c_2 - x - 1)$$

Verified OK.

12.22.3 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' + (-x^2 - 2x)\, y' + (x + 2)\, y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x^2 \\
B &= -x^2 - 2x \\
C &= x + 2
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{1}{4} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 1 \\
t &= 4
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \frac{z(x)}{4} \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 464: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x^2-2x}{x^2}\,dx} \\ &= z_1 e^{\frac{x}{2}+\ln(x)} \\ &= z_1\left(\mathrm{e}^{\frac{x}{2}}x\right) \end{aligned}$$

Which simplifies to

$$y_1 = x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2-2x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{x+2\ln(x)}}{(y_1)^2}\,dx \\ &= y_1(\mathrm{e}^x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x) + c_2(x(e^x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2 y'' + \left(-x^2 - 2x\right) y' + (x + 2) y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 x + c_2 x \, e^x
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x \\
y_2 &= x \, e^x
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & x\,\mathrm{e}^{x} \\ \frac{d}{dx}(x) & \frac{d}{dx}(x\,\mathrm{e}^{x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & x\,\mathrm{e}^{x} \\ 1 & x\,\mathrm{e}^{x} + \mathrm{e}^{x} \end{vmatrix}$$

Therefore

$$W = (x)\left(x\,\mathrm{e}^{x} + \mathrm{e}^{x}\right) - \left(x\,\mathrm{e}^{x}\right)(1)$$

Which simplifies to

$$W = x^{2}\mathrm{e}^{x}$$

Which simplifies to

$$W = x^{2}\mathrm{e}^{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^{4}\mathrm{e}^{x}}{x^{4}\mathrm{e}^{x}}\,dx$$

Which simplifies to

$$u_1 = -\int 1 dx$$

Hence

$$u_1 = -x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^{4}}{x^{4}\mathrm{e}^{x}}\,dx$$

Which simplifies to

$$u_2 = \int \mathrm{e}^{-x} dx$$

Hence

$$u_2 = -e^{-x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -x^2 - e^{-x} e^x x$$

Which simplifies to

$$y_p(x) = -x^2 - x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 x + c_2 x\, e^x) + \left(-x^2 - x\right) \end{aligned}$$

Which simplifies to

$$y = x(c_1 + c_2 e^x) - x^2 - x$$

Summary

The solution(s) found are the following

$$y = x(c_1 + c_2 e^x) - x^2 - x \tag{1}$$

Verification of solutions

$$y = x(c_1 + c_2 e^x) - x^2 - x$$

Verified OK.

$$\boxed{x(x-2)\,y''-\left(x^2-2\right)y'+2y(x-1)=3x^2(x-2)^2\,\mathrm{e}^x}$$

12.23.1 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=x^2-2x, B=-x^2+2, C=2x-2, f(x)=3x^2(x-2)^2\,\mathrm{e}^x$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. Solving for y_h from

$$\left(x^2-2x\right)y''+\left(-x^2+2\right)y'+(2x-2)\,y=0$$

In normal form the ode

$$\left(x^{2}-2x\right) y''+\left(-x^{2}+2\right) y'+\left(2x-2\right) y = 0 \tag{1}$$

Becomes

$$y''+p(x) y'+q(x) y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{-x^{2}+2}{x \left(x-2\right)}\\ q(x) &= \frac{2x-2}{x \left(x-2\right)} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x) x^{n}$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x)+\left(\frac{2n}{x}+p\right) v'(x)+\left(\frac{n(n-1)}{x^{2}}+\frac{np}{x}+q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^{2}}+\frac{np}{x}+q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^{2}}+\frac{n(-x^{2}+2)}{x^{2} \left(x-2\right)}+\frac{2x-2}{x \left(x-2\right)} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 2 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x)+\left(\frac{4}{x}+\frac{-x^{2}+2}{x \left(x-2\right)}\right) v'(x) &= 0\\ v''(x)+\frac{\left(-x^{2}+4x-6\right) v'(x)}{x \left(x-2\right)} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x)+\frac{\left(-x^{2}+4x-6\right)u(x)}{x\left(x-2\right)}=0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u)\\
&= f(x)g(u)\\
&= \frac{u(x^{2}-4x+6)}{x\left(x-2\right)}
\end{aligned}$$

Where $f(x)=\frac{x^{2}-4x+6}{x(x-2)}$ and $g(u)=u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= \frac{x^{2}-4x+6}{x\left(x-2\right)}\,dx\\
\int \frac{1}{u}\,du &= \int \frac{x^{2}-4x+6}{x\left(x-2\right)}\,dx\\
\ln\left(u\right) &= x+\ln\left(x-2\right)-3\ln\left(x\right)+c_{1}\\
u &= \mathrm{e}^{x+\ln(x-2)-3\ln(x)+c_{1}}\\
&= c_{1}\mathrm{e}^{x+\ln(x-2)-3\ln(x)}
\end{aligned}$$

Which simplifies to

$$u(x)=c_{1}\left(\frac{\mathrm{e}^{x}}{x^{2}}-\frac{2\,\mathrm{e}^{x}}{x^{3}}\right)$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x)\\
v(x) &= \int u(x)\,dx+c_{2}\\
&= \frac{\mathrm{e}^{x}c_{1}}{x^{2}}+c_{2}
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\,x^{n}\\
&= \left(\frac{\mathrm{e}^{x}c_{1}}{x^{2}}+c_{2}\right)x^{2}\\
&= c_{2}x^{2}+\mathrm{e}^{x}c_{1}
\end{aligned}$$

Now the particular solution to this ODE is found

$$\left(x^2-2x\right) y''+\left(-x^2+2\right) y'+\left(2x-2\right) y = 3x^2(x-2)^2 \, \mathrm{e}^x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2$$
$$y_2 = \mathrm{e}^x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & \mathrm{e}^x \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(\mathrm{e}^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & \mathrm{e}^x \\ 2x & \mathrm{e}^x \end{vmatrix}$$

Therefore

$$W = \left(x^2\right)\left(\mathrm{e}^x\right) - \left(\mathrm{e}^x\right)\left(2x\right)$$

Which simplifies to

$$W = x^2 e^x - 2x\, e^x$$

Which simplifies to

$$W = e^x (x-2)\, x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{3\, e^{2x} (x-2)^2\, x^2}{(x^2 - 2x)\, e^x\, (x-2)\, x}\, dx$$

Which simplifies to

$$u_1 = -\int 3\, e^x dx$$

Hence

$$u_1 = -3\, e^x$$

And Eq. (3) becomes

$$u_2 = \int \frac{3x^4 (x-2)^2\, e^x}{(x^2 - 2x)\, e^x\, (x-2)\, x}\, dx$$

Which simplifies to

$$u_2 = \int 3x^2 dx$$

Hence

$$u_2 = x^3$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -3x^2 e^x + x^3 e^x$$

Which simplifies to

$$y_p(x) = e^x x^2 (x-3)$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\left(\frac{e^x c_1}{x^2} + c_2\right) x^2\right) + \left(e^x x^2 (x-3)\right) \\
&= e^x x^2 (x-3) + \left(\frac{e^x c_1}{x^2} + c_2\right) x^2
\end{aligned}
$$

Which simplifies to

$$y = \left(x^3 - 3x^2 + c_1\right) e^x + c_2 x^2$$

Summary

The solution(s) found are the following

$$y = \left(x^3 - 3x^2 + c_1\right) e^x + c_2 x^2 \tag{1}$$

Verification of solutions

$$y = \left(x^3 - 3x^2 + c_1\right) e^x + c_2 x^2$$

Verified OK.

12.23.2 Solving using Kovacic algorithm

Writing the ode as

$$\left(x^2 - 2x\right) y'' + \left(-x^2 + 2\right) y' + (2x - 2) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x^2 - 2x \\
B &= -x^2 + 2 \\
C &= 2x - 2
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4\left(x^2 - 2x\right)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= x^4 - 8x^3 + 24x^2 - 24x + 12 \\
t &= 4\left(x^2 - 2x\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4\left(x^2 - 2x\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 465: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 4 - 4\\ &= 0\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 - 2x)^2$. There is a pole at $x = 2$ of order 2. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4x^2} - \frac{1}{4(x-2)} + \frac{3}{4(x-2)^2} - \frac{3}{4x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

For the pole at $x = 2$ let b be the coefficient of $\frac{1}{(x-2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}
$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$
\sqrt{r} \approx \frac{1}{2} - \frac{1}{x} + \frac{2}{x^3} + \frac{11}{x^4} + \frac{42}{x^5} + \frac{132}{x^6} + \frac{348}{x^7} + \frac{711}{x^8} + \dots \tag{9}
$$

Comparing Eq. (9) with Eq. (8) shows that

$$
a = \frac{1}{2}
$$

From Eq. (9) the sum up to $v = 0$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{2}
\end{aligned} \tag{10}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}
$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$
r = Q + \frac{R}{t}
$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4x^4 - 16x^3 + 16x^2} \\
&= Q + \frac{R}{4x^4 - 16x^3 + 16x^2} \\
&= \left(\frac{1}{4}\right) + \left(\frac{-4x^3 + 20x^2 - 24x + 12}{4x^4 - 16x^3 + 16x^2}\right) \\
&= \frac{1}{4} + \frac{-4x^3 + 20x^2 - 24x + 12}{4x^4 - 16x^3 + 16x^2}
\end{aligned}
$$

Since the degree of t is 4, then we see that the coefficient of the term x^3 in the remainder R is -4. Dividing this by leading coefficient in t which is 4 gives -1. Now b can be found.

$$
\begin{aligned}
b &= (-1) - (0) \\
&= -1
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-1}{\frac{1}{2}} - 0\right) &= -1 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-1}{\frac{1}{2}} - 0\right) &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4\left(x^2 - 2x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
2	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	$\frac{1}{2}$	-1	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_{\infty}^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_{\infty}^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_{\infty}^{+} = -1$ then

$$\begin{aligned} d &= \alpha_{\infty}^{+} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{-}\right) \\ &= -1 - (-1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2} \right) + (+)[\sqrt{r}]_{\infty} \\ &= -\frac{1}{2x} - \frac{1}{2\,(x-2)} + \left(\frac{1}{2}\right) \\ &= -\frac{1}{2x} - \frac{1}{2\,(x-2)} + \frac{1}{2} \\ &= -\frac{1}{2x} - \frac{1}{2x-4} + \frac{1}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2x} - \frac{1}{2\,(x-2)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2x^2} + \frac{1}{2\,(x-2)^2}\right) + \left(-\frac{1}{2x} - \frac{1}{2\,(x-2)} + \frac{1}{2}\right)^2 - \left(\frac{x^4 - 8x^3 +}{4(}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2x} - \frac{1}{2(x-2)} + \frac{1}{2}\right) dx} \\
&= \frac{\mathrm{e}^{\frac{x}{2}}}{\sqrt{x}\,\sqrt{x-2}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x^2+2}{x^2-2x} \, dx} \\
&= z_1 e^{\frac{x}{2} + \frac{\ln(x-2)}{2} + \frac{\ln(x)}{2}} \\
&= z_1 \left(\sqrt{x}\,\sqrt{x-2}\,\mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\mathrm{e}^x \sqrt{x}\,\sqrt{x-2}}{\sqrt{x\,(x-2)}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+2}{x^2-2x} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{x+\ln(x-2)+\ln(x)}}{(y_1)^2} \, dx \\
&= y_1 \left(-x^2 \mathrm{e}^{-x}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\mathrm{e}^x \sqrt{x}\,\sqrt{x-2}}{\sqrt{x\,(x-2)}}\right) + c_2 \left(\frac{\mathrm{e}^x \sqrt{x}\,\sqrt{x-2}}{\sqrt{x\,(x-2)}} \left(-x^2 \mathrm{e}^{-x}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$\left(x^2 - 2x\right) y'' + \left(-x^2 + 2\right) y' + (2x - 2) y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_1 e^x \sqrt{x}\, \sqrt{x-2}}{\sqrt{x\,(x-2)}} - \frac{c_2 x^{\frac{5}{2}} \sqrt{x-2}}{\sqrt{x\,(x-2)}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{e^x \sqrt{x}\, \sqrt{x-2}}{\sqrt{x\,(x-2)}}$$

$$y_2 = -\frac{x^{\frac{5}{2}} \sqrt{x-2}}{\sqrt{x\,(x-2)}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{e^x \sqrt{x}\,\sqrt{x-2}}{\sqrt{x(x-2)}} & -\frac{x^{\frac{5}{2}}\sqrt{x-2}}{\sqrt{x(x-2)}} \\ \frac{d}{dx}\left(\frac{e^x \sqrt{x}\,\sqrt{x-2}}{\sqrt{x(x-2)}}\right) & \frac{d}{dx}\left(-\frac{x^{\frac{5}{2}}\sqrt{x-2}}{\sqrt{x(x-2)}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{e^x \sqrt{x}\,\sqrt{x-2}}{\sqrt{x(x-2)}} & -\frac{x^{\frac{5}{2}}\sqrt{x-2}}{\sqrt{x(x-2)}} \\ \frac{e^x \sqrt{x}\,\sqrt{x-2}}{\sqrt{x(x-2)}} - \frac{e^x \sqrt{x}\,\sqrt{x-2}\,(2x-2)}{2(x(x-2))^{\frac{3}{2}}} + \frac{e^x \sqrt{x-2}}{2\sqrt{x(x-2)}\,\sqrt{x}} + \frac{e^x \sqrt{x}}{2\sqrt{x(x-2)}\,\sqrt{x-2}} & -\frac{5x^{\frac{3}{2}}\sqrt{x-2}}{2\sqrt{x(x-2)}} - \frac{x^{\frac{5}{2}}}{2\sqrt{x-2}\,\sqrt{x(x-2)}} + \frac{x^{\frac{5}{2}}\sqrt{x-2}\,(2x-}{2(x(x-2))^{\frac{3}{2}}} \end{vmatrix}$$

Therefore

$$W = \left(\frac{e^x \sqrt{x}\,\sqrt{x-2}}{\sqrt{x\,(x-2)}}\right)\left(-\frac{5x^{\frac{3}{2}}\sqrt{x-2}}{2\sqrt{x\,(x-2)}} - \frac{x^{\frac{5}{2}}}{2\sqrt{x-2}\,\sqrt{x\,(x-2)}} + \frac{x^{\frac{5}{2}}\sqrt{x-2}\,(2x-2)}{2\,(x\,(x-2))^{\frac{3}{2}}}\right) - \left(-\frac{x^{\frac{5}{2}}\sqrt{x-2}}{\sqrt{x\,(x-2)}}\right)\left(\frac{e^x \sqrt{x}\,\sqrt{x-2}}{\sqrt{x\,(x-2)}} - \frac{e^x \sqrt{x}\,\sqrt{x-2}\,(2x-2)}{2\,(x\,(x-2))^{\frac{3}{2}}} + \frac{e^x \sqrt{x-2}}{2\sqrt{x\,(x-2)}\,\sqrt{x}} + \frac{e^x \sqrt{x}}{2\sqrt{x\,(x-2)}\,\sqrt{x-2}}\right)$$

Which simplifies to

$$W = e^x (x-2)\,x$$

Which simplifies to

$$W = e^x (x-2)\,x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{3x^{\frac{9}{2}}(x-2)^{\frac{5}{2}} e^x}{\sqrt{x(x-2)}}}{(x^2-2x)\,e^x\,(x-2)\,x}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{3x^{\frac{5}{2}}\sqrt{x-2}}{\sqrt{x\,(x-2)}}dx$$

Hence

$$u_1 = \frac{x^{\frac{7}{2}}\sqrt{x-2}}{\sqrt{x\,(x-2)}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{3\,\mathrm{e}^{2x}x^{\frac{5}{2}}(x-2)^{\frac{5}{2}}}{\sqrt{x(x-2)}}}{(x^2-2x)\,\mathrm{e}^x\,(x-2)\,x}\,dx$$

Which simplifies to

$$u_2 = \int \frac{3\,\mathrm{e}^x\sqrt{x}\,\sqrt{x-2}}{\sqrt{x\,(x-2)}}dx$$

Hence

$$u_2 = \frac{3\,\mathrm{e}^x\sqrt{x}\,\sqrt{x-2}}{\sqrt{x\,(x-2)}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -3x^2\mathrm{e}^x + x^3\mathrm{e}^x$$

Which simplifies to

$$y_p(x) = \mathrm{e}^x x^2(x-3)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1\mathrm{e}^x\sqrt{x}\,\sqrt{x-2}}{\sqrt{x\,(x-2)}} - \frac{c_2x^{\frac{5}{2}}\sqrt{x-2}}{\sqrt{x\,(x-2)}}\right) + \left(\mathrm{e}^x x^2(x-3)\right) \end{aligned}$$

Which simplifies to

$$y = \frac{\sqrt{x}\,\sqrt{x-2}\,(-c_2x^2+\mathrm{e}^x c_1)}{\sqrt{x\,(x-2)}} + \mathrm{e}^x x^2(x-3)$$

Summary
The solution(s) found are the following

$$y = \frac{\sqrt{x}\,\sqrt{x-2}\,(-c_2x^2 + \mathrm{e}^x c_1)}{\sqrt{x\,(x-2)}} + \mathrm{e}^x x^2(x-3) \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{x}\,\sqrt{x-2}\,(-c_2x^2 + \mathrm{e}^x c_1)}{\sqrt{x\,(x-2)}} + \mathrm{e}^x x^2(x-3)$$

Verified OK.

$$\boxed{(2x+1)(x+1)y''+2y'x-2y=(2x+1)^2}$$

12.24.1 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=2x^2+3x+1, B=2x, C=-2, f(x)=4\left(x+\frac{1}{2}\right)^2$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. Solving for y_h from

$$y''(2x^2+3x+1)+2y'x-2y=0$$

In normal form the ode

$$y''(2x^2+3x+1)+2y'x-2y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{2x}{2x^2+3x+1} \\ q(x) &= -\frac{2}{2x^2+3x+1} \end{aligned}$$

Applying change of variables on the depndent variable $y=v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x)+\left(\frac{2n}{x}+p\right)v'(x)+\left(\frac{n(n-1)}{x^2}+\frac{np}{x}+q\right)v(x)=0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2}+\frac{np}{x}+q=0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}+\frac{2n}{2x^2+3x+1}-\frac{2}{2x^2+3x+1}=0 \tag{5}$$

Solving (5) for n gives

$$n=1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x)+\left(\frac{2}{x}+\frac{2x}{2x^2+3x+1}\right)v'(x) &= 0 \\ v''(x)+\left(\frac{2}{x}+\frac{2x}{2x^2+3x+1}\right)v'(x) &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \left(\frac{2}{x} + \frac{2x}{2x^2 + 3x + 1}\right) u(x) = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x, u) \\
&= f(x)g(u) \\
&= -\frac{2u(3x^2 + 3x + 1)}{x\,(2x^2 + 3x + 1)}
\end{aligned}$$

Where $f(x) = -\frac{2(3x^2+3x+1)}{x(2x^2+3x+1)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\, du &= -\frac{2(3x^2 + 3x + 1)}{x\,(2x^2 + 3x + 1)}\, dx \\
\int \frac{1}{u}\, du &= \int -\frac{2(3x^2 + 3x + 1)}{x\,(2x^2 + 3x + 1)}\, dx \\
\ln(u) &= -2\ln(x + 1) - 2\ln(x) + \ln(2x + 1) + c_1 \\
u &= \mathrm{e}^{-2\ln(x+1) - 2\ln(x) + \ln(2x+1) + c_1} \\
&= c_1 \mathrm{e}^{-2\ln(x+1) - 2\ln(x) + \ln(2x+1)}
\end{aligned}$$

Which simplifies to

$$u(x) = c_1 \left(\frac{2}{(x + 1)^2\, x} + \frac{1}{(x + 1)^2\, x^2}\right)$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= c_1 \left(\frac{1}{x + 1} - \frac{1}{x}\right) + c_2
\end{aligned}$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(c_1 \left(\frac{1}{x+1} - \frac{1}{x}\right) + c_2\right) x \\
&= \frac{(x^2+x)\, c_2 - c_1}{x+1}
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
y''(2x^2+3x+1) + 2y'x - 2y = 4\left(x + \frac{1}{2}\right)^2
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x \\
y_2 &= \frac{x}{x+1} - 1
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix} x & \frac{x}{x+1} - 1 \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(\frac{x}{x+1} - 1\right) \end{vmatrix}
$$

Which gives

$$W = \begin{vmatrix} x & \frac{x}{x+1} - 1 \\ 1 & \frac{1}{x+1} - \frac{x}{(x+1)^2} \end{vmatrix}$$

Therefore

$$W = (x)\left(\frac{1}{x+1} - \frac{x}{(x+1)^2}\right) - \left(\frac{x}{x+1} - 1\right)(1)$$

Which simplifies to

$$W = \frac{2x+1}{(x+1)^2}$$

Which simplifies to

$$W = \frac{2x+1}{(x+1)^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4\left(\frac{x}{x+1} - 1\right)\left(x + \frac{1}{2}\right)^2}{\frac{(2x^2+3x+1)(2x+1)}{(x+1)^2}}\, dx$$

Which simplifies to

$$u_1 = -\int (-1)\, dx$$

Hence

$$u_1 = x$$

And Eq. (3) becomes

$$u_2 = \int \frac{4x\left(x + \frac{1}{2}\right)^2}{\frac{(2x^2+3x+1)(2x+1)}{(x+1)^2}}\, dx$$

Which simplifies to

$$u_2 = \int x(x+1)\, dx$$

Hence

$$u_2 = \frac{1}{3}x^3 + \frac{1}{2}x^2$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x^2 + \left(\frac{1}{3}x^3 + \frac{1}{2}x^2\right)\left(\frac{x}{x+1} - 1\right)$$

Which simplifies to

$$y_p(x) = \frac{x^2(4x+3)}{6x+6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(c_1\left(\frac{1}{x+1} - \frac{1}{x}\right) + c_2\right)x\right) + \left(\frac{x^2(4x+3)}{6x+6}\right) \\ &= \frac{x^2(4x+3)}{6x+6} + \left(c_1\left(\frac{1}{x+1} - \frac{1}{x}\right) + c_2\right)x \end{aligned}$$

Which simplifies to

$$y = \frac{4x^3 + (6c_2+3)\,x^2 + 6c_2x - 6c_1}{6x+6}$$

Summary

The solution(s) found are the following

$$y = \frac{4x^3 + (6c_2+3)\,x^2 + 6c_2x - 6c_1}{6x+6} \tag{1}$$

Verification of solutions

$$y = \frac{4x^3 + (6c_2+3)\,x^2 + 6c_2x - 6c_1}{6x+6}$$

Verified OK.

12.24.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(y''\left(2x^2+3x+1\right)+2y'x-2y\right)dx = \int 4\left(x+\frac{1}{2}\right)^2 dx$$

$$\left(-2x-3\right)y+\left(2x^2+3x+1\right)y' = \frac{4\left(x+\frac{1}{2}\right)^3}{3}+c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y = q(x)$$

Where here

$$p(x) = -\frac{3+2x}{2x^2+3x+1}$$
$$q(x) = \frac{8x^3+12x^2+6c_1+6x+1}{12x^2+18x+6}$$

Hence the ode is

$$y'-\frac{\left(3+2x\right)y}{2x^2+3x+1} = \frac{8x^3+12x^2+6c_1+6x+1}{12x^2+18x+6}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{3+2x}{2x^2+3x+1}dx}$$
$$= e^{\ln(x+1)-2\ln(2x+1)}$$

Which simplifies to

$$\mu = \frac{x+1}{\left(2x+1\right)^2}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{8x^3+12x^2+6c_1+6x+1}{12x^2+18x+6}\right)$$
$$\frac{d}{dx}\left(\frac{\left(x+1\right)y}{\left(2x+1\right)^2}\right) = \left(\frac{x+1}{\left(2x+1\right)^2}\right)\left(\frac{8x^3+12x^2+6c_1+6x+1}{12x^2+18x+6}\right)$$
$$d\left(\frac{\left(x+1\right)y}{\left(2x+1\right)^2}\right) = \left(\frac{8x^3+12x^2+6c_1+6x+1}{6\left(2x+1\right)^3}\right)dx$$

Integrating gives

$$
\begin{aligned}
\frac{(x+1)\,y}{(2x+1)^2} &= \int \frac{8x^3+12x^2+6c_1+6x+1}{6\,(2x+1)^3}\,\mathrm{d}x \\
\frac{(x+1)\,y}{(2x+1)^2} &= \frac{x}{6}-\frac{c_1}{4\,(2x+1)^2}+c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{x+1}{(2x+1)^2}$ results in

$$
y = \frac{(2x+1)^2\left(\frac{x}{6}-\frac{c_1}{4(2x+1)^2}\right)}{x+1}+\frac{c_2(2x+1)^2}{x+1}
$$

which simplifies to

$$
y = \frac{8x^3+(48c_2+8)\,x^2+(48c_2+2)\,x-3c_1+12c_2}{12x+12}
$$

Summary
The solution(s) found are the following

$$
y = \frac{8x^3+(48c_2+8)\,x^2+(48c_2+2)\,x-3c_1+12c_2}{12x+12} \tag{1}
$$

Verification of solutions

$$
y = \frac{8x^3+(48c_2+8)\,x^2+(48c_2+2)\,x-3c_1+12c_2}{12x+12}
$$

Verified OK.

12.24.3 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$
Ay''+By'+Cy=F(x)
$$

This method reduces the order ode the ODE by one by applying the transformation

$$
y = Bv
$$

This results in

$$
\begin{aligned}
y' &= B'v+v'B \\
y'' &= B''v+B'v'+v''B+v'B' \\
&= v''B+2v'+B'+B''v
\end{aligned}
$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + \left(2AB' + B^2\right) v' + \left(AB'' + BB' + CB\right) v &= 0 \qquad (1)
\end{aligned}
$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$
ABv'' + \left(2AB' + B^2\right) v' = 0
$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$
ABu' + \left(2AB' + B^2\right) u = 0
$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= 2x^2 + 3x + 1 \\
B &= 2x \\
C &= -2 \\
F &= 4\left(x + \frac{1}{2}\right)^2
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= \left(2x^2 + 3x + 1\right)(0) + (2x)(2) + (-2)(2x) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
4x^3 + 6x^2 + 2xv'' + \left(12x^2 + 12x + 4\right) v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
\left(4x^3 + 6x^2 + 2x\right) u'(x) + 12u(x)\left(x^2 + x + \frac{1}{3}\right) = 0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x, u) \\
&= f(x)g(u) \\
&= -\frac{2u(3x^2 + 3x + 1)}{x\left(2x^2 + 3x + 1\right)}
\end{aligned}
$$

Where $f(x) = -\frac{2(3x^2+3x+1)}{x(2x^2+3x+1)}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= -\frac{2(3x^2+3x+1)}{x\left(2x^2+3x+1\right)}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{2(3x^2+3x+1)}{x\left(2x^2+3x+1\right)}\,dx \\
\ln\left(u\right) &= -2\ln\left(x+1\right) - 2\ln\left(x\right) + \ln\left(2x+1\right) + c_1 \\
u &= \mathrm{e}^{-2\ln(x+1)-2\ln(x)+\ln(2x+1)+c_1} \\
&= c_1\mathrm{e}^{-2\ln(x+1)-2\ln(x)+\ln(2x+1)}
\end{aligned}
$$

Which simplifies to

$$
u(x) = c_1\left(\frac{2}{\left(x+1\right)^2 x} + \frac{1}{\left(x+1\right)^2 x^2}\right)
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= c_1\left(\frac{2}{\left(x+1\right)^2 x} + \frac{1}{\left(x+1\right)^2 x^2}\right)
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int \frac{c_1(2x+1)}{x^2\left(x+1\right)^2}\,\mathrm{d}x \\
&= c_1\left(\frac{1}{x+1} - \frac{1}{x}\right) + c_2
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= Bv \\
&= (2x)\left(c_1\left(\frac{1}{x+1} - \frac{1}{x}\right) + c_2\right) \\
&= \frac{2c_2x^2 + 2c_2x - 2c_1}{x+1}
\end{aligned}
$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1y_1 + u_2y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x+1}$$

$$y_2 = \frac{2x^2}{x+1} + \frac{2x}{x+1}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x+1} & \frac{2x^2}{x+1} + \frac{2x}{x+1} \\ \frac{d}{dx}\left(\frac{1}{x+1}\right) & \frac{d}{dx}\left(\frac{2x^2}{x+1} + \frac{2x}{x+1}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x+1} & \frac{2x^2}{x+1} + \frac{2x}{x+1} \\ -\frac{1}{(x+1)^2} & -\frac{2x^2}{(x+1)^2} + \frac{4x}{x+1} + \frac{2}{x+1} - \frac{2x}{(x+1)^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x+1}\right)\left(-\frac{2x^2}{(x+1)^2} + \frac{4x}{x+1} + \frac{2}{x+1} - \frac{2x}{(x+1)^2}\right) - \left(\frac{2x^2}{x+1} + \frac{2x}{x+1}\right)\left(-\frac{1}{(x+1)^2}\right)$$

Which simplifies to

$$W = \frac{4x+2}{(x+1)^2}$$

Which simplifies to

$$W = \frac{4x+2}{(x+1)^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4\left(\frac{2x^2}{x+1} + \frac{2x}{x+1}\right)\left(x+\frac{1}{2}\right)^2}{\frac{(2x^2+3x+1)(4x+2)}{(x+1)^2}} \, dx$$

Which simplifies to

$$u_1 = -\int x(x+1) \, dx$$

Hence

$$u_1 = -\frac{1}{3}x^3 - \frac{1}{2}x^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{4\left(x+\frac{1}{2}\right)^2}{x+1}}{\frac{(2x^2+3x+1)(4x+2)}{(x+1)^2}} \, dx$$

Which simplifies to

$$u_2 = \int \frac{1}{2} dx$$

Hence

$$u_2 = \frac{x}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{-\frac{1}{3}x^3 - \frac{1}{2}x^2}{x+1} + \frac{x\left(\frac{2x^2}{x+1} + \frac{2x}{x+1}\right)}{2}$$

Which simplifies to

$$y_p(x) = \frac{x^2(4x+3)}{6x+6}$$

Hence the complete solution is

$$\begin{aligned}
y(x) &= y_h + y_p \\
&= \left(\frac{2c_2x^2 + 2c_2x - 2c_1}{x+1}\right) + \left(\frac{x^2(4x+3)}{6x+6}\right) \\
&= \frac{4x^3 + (12c_2+3)\,x^2 + 12c_2x - 12c_1}{6x+6}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{4x^3 + (12c_2+3)\,x^2 + 12c_2x - 12c_1}{6x+6} \tag{1}$$

Verification of solutions

$$y = \frac{4x^3 + (12c_2+3)\,x^2 + 12c_2x - 12c_1}{6x+6}$$

Verified OK.

12.24.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y''(2x^2+3x+1) + 2y'x - 2y = 4\left(x+\frac{1}{2}\right)^2$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(y''(2x^2+3x+1) + 2y'x - 2y\right) dx = \int 4\left(x+\frac{1}{2}\right)^2 dx$$

$$(-2x-3)\,y + (2x^2+3x+1)\,y' = \frac{4\left(x+\frac{1}{2}\right)^3}{3} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}
p(x) &= -\frac{3+2x}{2x^2+3x+1} \\
q(x) &= \frac{8x^3 + 12x^2 + 6c_1 + 6x + 1}{12x^2 + 18x + 6}
\end{aligned}$$

Hence the ode is

$$y' - \frac{(3+2x)\,y}{2x^2+3x+1} = \frac{8x^3+12x^2+6c_1+6x+1}{12x^2+18x+6}$$

The integrating factor μ is

$$\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{3+2x}{2x^2+3x+1}dx} \\
&= \mathrm{e}^{\ln(x+1)-2\ln(2x+1)}
\end{aligned}$$

Which simplifies to

$$\mu = \frac{x+1}{(2x+1)^2}$$

The ode becomes

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{8x^3+12x^2+6c_1+6x+1}{12x^2+18x+6}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{(x+1)\,y}{(2x+1)^2}\right) &= \left(\frac{x+1}{(2x+1)^2}\right)\left(\frac{8x^3+12x^2+6c_1+6x+1}{12x^2+18x+6}\right) \\
\mathrm{d}\left(\frac{(x+1)\,y}{(2x+1)^2}\right) &= \left(\frac{8x^3+12x^2+6c_1+6x+1}{6\,(2x+1)^3}\right)\mathrm{d}x
\end{aligned}$$

Integrating gives

$$\begin{aligned}
\frac{(x+1)\,y}{(2x+1)^2} &= \int \frac{8x^3+12x^2+6c_1+6x+1}{6\,(2x+1)^3}\,\mathrm{d}x \\
\frac{(x+1)\,y}{(2x+1)^2} &= \frac{x}{6} - \frac{c_1}{4\,(2x+1)^2} + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{x+1}{(2x+1)^2}$ results in

$$y = \frac{(2x+1)^2\left(\frac{x}{6} - \frac{c_1}{4(2x+1)^2}\right)}{x+1} + \frac{c_2(2x+1)^2}{x+1}$$

which simplifies to

$$y = \frac{8x^3+(48c_2+8)\,x^2+(48c_2+2)\,x-3c_1+12c_2}{12x+12}$$

Summary

The solution(s) found are the following

$$y = \frac{8x^3+(48c_2+8)\,x^2+(48c_2+2)\,x-3c_1+12c_2}{12x+12} \tag{1}$$

Verification of solutions

$$y = \frac{8x^3 + (48c_2 + 8)\,x^2 + (48c_2 + 2)\,x - 3c_1 + 12c_2}{12x + 12}$$

Verified OK.

12.24.5 Solving using Kovacic algorithm

Writing the ode as

$$y''(2x^2 + 3x + 1) + 2y'x - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2 + 3x + 1 \\ B &= 2x \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{(2x + 1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= (2x + 1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{(2x+1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 466: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x+1)^2$. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4\left(x+\frac{1}{2}\right)^2}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3}{(2x+1)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{(2x+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$-\frac{1}{2}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2\left(x+\frac{1}{2}\right)} + (-)\left(0\right) \\ &= -\frac{1}{2\left(x+\frac{1}{2}\right)} \\ &= -\frac{1}{2x+1} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{1}{2\left(x+\frac{1}{2}\right)}\right)(0) + \left(\left(\frac{1}{2\left(x+\frac{1}{2}\right)^2}\right) + \left(-\frac{1}{2\left(x+\frac{1}{2}\right)}\right)^2 - \left(\frac{3}{\left(2x+1\right)^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int -\frac{1}{2\left(x+\frac{1}{2}\right)} dx} \\
&= \frac{1}{\sqrt{2x+1}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{2x}{2x^2+3x+1} \, dx} \\
&= z_1 e^{-\ln(x+1)+\frac{\ln(2x+1)}{2}} \\
&= z_1 \left(\frac{\sqrt{2x+1}}{x+1}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x+1}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x}{2x^2+3x+1} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-2\ln(x+1)+\ln(2x+1)}}{(y_1)^2} \, dx \\
&= y_1 (x(x+1))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x+1}\right) + c_2 \left(\frac{1}{x+1} (x(x+1))\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y''\left(2x^2 + 3x + 1\right) + 2y'x - 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_1}{x+1} + c_2 x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x+1}$$
$$y_2 = x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x+1} & x \\ \frac{d}{dx}\left(\frac{1}{x+1}\right) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x+1} & x \\ -\frac{1}{(x+1)^2} & 1 \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x+1}\right)(1) - (x)\left(-\frac{1}{(x+1)^2}\right)$$

Which simplifies to

$$W = \frac{2x+1}{(x+1)^2}$$

Which simplifies to

$$W = \frac{2x+1}{(x+1)^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4x\left(x+\frac{1}{2}\right)^2}{\frac{(2x^2+3x+1)(2x+1)}{(x+1)^2}}\,dx$$

Which simplifies to

$$u_1 = -\int x(x+1)\,dx$$

Hence

$$u_1 = -\frac{1}{3}x^3 - \frac{1}{2}x^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{4\left(x+\frac{1}{2}\right)^2}{x+1}}{\frac{(2x^2+3x+1)(2x+1)}{(x+1)^2}}\,dx$$

Which simplifies to

$$u_2 = \int 1dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{-\frac{1}{3}x^3 - \frac{1}{2}x^2}{x+1} + x^2$$

Which simplifies to

$$y_p(x) = \frac{x^2(4x+3)}{6x+6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x+1} + c_2 x\right) + \left(\frac{x^2(4x+3)}{6x+6}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x+1} + c_2 x + \frac{x^2(4x+3)}{6x+6} \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x+1} + c_2 x + \frac{x^2(4x+3)}{6x+6}$$

Verified OK.

12.24.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}
p(x) &= 2x^2 + 3x + 1 \\
q(x) &= 2x \\
r(x) &= -2 \\
s(x) &= 4\left(x + \frac{1}{2}\right)^2
\end{aligned}$$

Hence

$$\begin{aligned}
p''(x) &= 4 \\
q'(x) &= 2
\end{aligned}$$

Therefore (1) becomes

$$4 - (2) + (-2) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$(-2x - 3)\, y + \left(2x^2 + 3x + 1\right) y' = \int 4\left(x + \frac{1}{2}\right)^2 dx$$

We now have a first order ode to solve which is

$$(-2x - 3)\, y + \left(2x^2 + 3x + 1\right) y' = \frac{4\left(x + \frac{1}{2}\right)^3}{3} + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}
p(x) &= -\frac{3 + 2x}{2x^2 + 3x + 1} \\
q(x) &= \frac{8x^3 + 12x^2 + 6c_1 + 6x + 1}{12x^2 + 18x + 6}
\end{aligned}$$

Hence the ode is

$$y' - \frac{(3+2x)\, y}{2x^2+3x+1} = \frac{8x^3+12x^2+6c_1+6x+1}{12x^2+18x+6}$$

The integrating factor μ is

$$\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{3+2x}{2x^2+3x+1}dx} \\
&= \mathrm{e}^{\ln(x+1)-2\ln(2x+1)}
\end{aligned}$$

Which simplifies to

$$\mu = \frac{x+1}{(2x+1)^2}$$

The ode becomes

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{8x^3+12x^2+6c_1+6x+1}{12x^2+18x+6}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{(x+1)\, y}{(2x+1)^2}\right) &= \left(\frac{x+1}{(2x+1)^2}\right)\left(\frac{8x^3+12x^2+6c_1+6x+1}{12x^2+18x+6}\right) \\
\mathrm{d}\left(\frac{(x+1)\, y}{(2x+1)^2}\right) &= \left(\frac{8x^3+12x^2+6c_1+6x+1}{6\,(2x+1)^3}\right)\, \mathrm{d}x
\end{aligned}$$

Integrating gives

$$\begin{aligned}
\frac{(x+1)\, y}{(2x+1)^2} &= \int \frac{8x^3+12x^2+6c_1+6x+1}{6\,(2x+1)^3}\, \mathrm{d}x \\
\frac{(x+1)\, y}{(2x+1)^2} &= \frac{x}{6} - \frac{c_1}{4\,(2x+1)^2} + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{x+1}{(2x+1)^2}$ results in

$$y = \frac{(2x+1)^2 \left(\frac{x}{6} - \frac{c_1}{4(2x+1)^2}\right)}{x+1} + \frac{c_2(2x+1)^2}{x+1}$$

which simplifies to

$$y = \frac{8x^3+(48c_2+8)\, x^2+(48c_2+2)\, x-3c_1+12c_2}{12x+12}$$

Summary

The solution(s) found are the following

$$y = \frac{8x^3+(48c_2+8)\, x^2+(48c_2+2)\, x-3c_1+12c_2}{12x+12} \tag{1}$$

Verification of solutions

$$y = \frac{8x^3 + (48c_2 + 8)\, x^2 + (48c_2 + 2)\, x - 3c_1 + 12c_2}{12x + 12}$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_y_method_1"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{\sin(x)^2 y'' - 2\sin(x)\cos(x) y' + \left(\cos(x)^2 + 1\right) y = \sin(x)^3}$$

12.25.1 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$\sin(x)^2 y'' - y'\sin(2x) + \left(\cos(x)^2 + 1\right) y = 0$$

In normal form the given ode is written as

$$y'' + p(x) y' + q(x) y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= -\frac{\sin(2x)}{\sin(x)^2} \\
q(x) &= \frac{\cos(x)^2+1}{\sin(x)^2}
\end{aligned}
$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{\cos(x)^2+1}{\sin(x)^2} - \frac{\left(-\frac{\sin(2x)}{\sin(x)^2}\right)'}{2} - \frac{\left(-\frac{\sin(2x)}{\sin(x)^2}\right)^2}{4} \\
&= \frac{\cos(x)^2+1}{\sin(x)^2} - \frac{\left(\frac{2\sin(2x)\cos(x)}{\sin(x)^3} - \frac{2\cos(2x)}{\sin(x)^2}\right)}{2} - \frac{\left(\frac{\sin(2x)^2}{\sin(x)^4}\right)}{4} \\
&= \frac{\cos(x)^2+1}{\sin(x)^2} - \left(\frac{\sin(2x)\cos(x)}{\sin(x)^3} - \frac{\cos(2x)}{\sin(x)^2}\right) - \frac{\sin(2x)^2}{4\sin(x)^4} \\
&= 0
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\, z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{-\frac{\sin(2x)}{\sin(x)^2}}{2}} \\
&= \sin(x)
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\sin(x) \tag{4}
$$

Applying this change of variable to the original ode results in

$$
v''(x) = 1
$$

Which is now solved for $v(x)$ The ODE can be written as

$$
v''(x) = 1
$$

Integrating once gives

$$v'(x) = x + c_1$$

Integrating again gives

$$v(x) = \frac{x^2}{2} + c_1 x + c_2$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= \left(\frac{1}{2}x^2 + c_1 x + c_2\right) (z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = \sin(x)$$

Hence (7) becomes

$$y = \left(\frac{1}{2}x^2 + c_1 x + c_2\right) \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = \left(\frac{1}{2}x^2 + c_1 x + c_2\right) \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \sin(x) \\ y_2 &= x \sin(x) \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sin(x) & x\sin(x) \\ \frac{d}{dx}(\sin(x)) & \frac{d}{dx}(x\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sin(x) & x\sin(x) \\ \cos(x) & \sin(x) + \cos(x)\,x \end{vmatrix}$$

Therefore

$$W = (\sin(x))(\sin(x) + \cos(x)\,x) - (x\sin(x))(\cos(x))$$

Which simplifies to

$$W = \sin(x)^2$$

Which simplifies to

$$W = \sin(x)^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x\sin(x)^4}{\sin(x)^4}\,dx$$

Which simplifies to

$$u_1 = -\int x dx$$

Hence

$$u_1 = -\frac{x^2}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sin(x)^4}{\sin(x)^4}\,dx$$

Which simplifies to

$$u_2 = \int 1dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\sin(x)\,x^2}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(\frac{1}{2}x^2 + c_1x + c_2\right)\sin(x)\right) + \left(\frac{\sin(x)\,x^2}{2}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \left(\frac{1}{2}x^2 + c_1x + c_2\right)\sin(x) + \frac{\sin(x)\,x^2}{2} \tag{1}$$

Verification of solutions

$$y = \left(\frac{1}{2}x^2 + c_1x + c_2\right)\sin(x) + \frac{\sin(x)\,x^2}{2}$$

Verified OK.

Problem number: 26.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''' - 3y'' - y' + 3y = x^2 e^x}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 3y'' - y' + 3y = 0$$

The characteristic equation is

$$\lambda^3 - 3\lambda^2 - \lambda + 3 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 3$$
$$\lambda_3 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 e^{x} + c_3 e^{3x}$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = e^{x}$$
$$y_3 = e^{3x}$$

Now the particular solution to the given ODE is found

$$y''' - 3y'' - y' + 3y = x^2 e^{x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 e^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x e^{x}, x^2 e^{x}, e^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{-x}, e^{3x}\}$$

Since e^{x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x e^{x}, x^2 e^{x}, x^3 e^{x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x e^{x} + A_2 x^2 e^{x} + A_3 x^3 e^{x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-8A_2 x e^{x} - 12A_3 x^2 e^{x} - 4A_1 e^{x} + 6A_3 e^{x} = x^2 e^{x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{8}, A_2 = 0, A_3 = -\frac{1}{12}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\,e^x}{8} - \frac{x^3 e^x}{12}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2 e^x + c_3 e^{3x}\right) + \left(-\frac{x\,e^x}{8} - \frac{x^3 e^x}{12}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 e^x + c_3 e^{3x} - \frac{x\,e^x}{8} - \frac{x^3 e^x}{12} \tag{1}$$

Verification of solutions

$$y = c_1 e^{-x} + c_2 e^x + c_3 e^{3x} - \frac{x\,e^x}{8} - \frac{x^3 e^x}{12}$$

Verified OK.

12.26.1 Maple step by step solution

Let's solve

$y''' - 3y'' - y' + 3y = x^2 e^x$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$

  - Define new variable $y_2(x)$

    $y_2(x) = y'$

- Define new variable $y_3(x)$

  $y_3(x) = y''$

- Isolate for $y_3'(x)$ using original ODE

  $y_3'(x) = x^2 e^x + 3y_3(x) + y_2(x) - 3y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = x^2 e^x + 3y_3(x) + y_2(x) - 3y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -3 & 1 & 3 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ x^2 e^x \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ x^2 e^x \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -3 & 1 & 3 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \left[\begin{array}{c}1 \\ -1 \\ 1\end{array}\right]\right], \left[1, \left[\begin{array}{c}1 \\ 1 \\ 1\end{array}\right]\right], \left[3, \left[\begin{array}{c}\frac{1}{9} \\ \frac{1}{3} \\ 1\end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c}1 \\ -1 \\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \mathrm{e}^{-x} \cdot \left[\begin{array}{c}1 \\ -1 \\ 1\end{array}\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c}1 \\ 1 \\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_2 = \mathrm{e}^{x} \cdot \left[\begin{array}{c}1 \\ 1 \\ 1\end{array}\right]$$

- Consider eigenpair

$$\left[3, \left[\begin{array}{c}\frac{1}{9} \\ \frac{1}{3} \\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_3 = \mathrm{e}^{3x} \cdot \left[\begin{array}{c}\frac{1}{9} \\ \frac{1}{3} \\ 1\end{array}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{y}_p($

  $\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2 + c_3\overrightarrow{y}_3 + \overrightarrow{y}_p(x)$

□ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

  $$\phi(x) = \begin{bmatrix} e^{-x} & e^{x} & \frac{e^{3x}}{9} \\ -e^{-x} & e^{x} & \frac{e^{3x}}{3} \\ e^{-x} & e^{x} & e^{3x} \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

  $$\Phi(x) = \begin{bmatrix} e^{-x} & e^{x} & \frac{e^{3x}}{9} \\ -e^{-x} & e^{x} & \frac{e^{3x}}{3} \\ e^{-x} & e^{x} & e^{3x} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & 1 & \frac{1}{9} \\ -1 & 1 & \frac{1}{3} \\ 1 & 1 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

  $$\Phi(x) = \begin{bmatrix} \frac{3e^{-x}}{8} + \frac{3e^{x}}{4} - \frac{e^{3x}}{8} & -\frac{e^{-x}}{2} + \frac{e^{x}}{2} & \frac{e^{-x}}{8} - \frac{e^{x}}{4} + \frac{e^{3x}}{8} \\ -\frac{3e^{-x}}{8} + \frac{3e^{x}}{4} - \frac{3e^{3x}}{8} & \frac{e^{-x}}{2} + \frac{e^{x}}{2} & -\frac{e^{-x}}{8} - \frac{e^{x}}{4} + \frac{3e^{3x}}{8} \\ \frac{3e^{-x}}{8} + \frac{3e^{x}}{4} - \frac{9e^{3x}}{8} & -\frac{e^{-x}}{2} + \frac{e^{x}}{2} & \frac{e^{-x}}{8} - \frac{e^{x}}{4} + \frac{9e^{3x}}{8} \end{bmatrix}$$

□ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(x)$ and solve for $\overrightarrow{v}(x)$

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \overrightarrow{v}(x)$

- Take the derivative of the particular solution

  $\overrightarrow{y}_p'(x) = \Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

- Cancel like terms

  $\Phi(x)\cdot\vec{v}'(x)=\vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x)=\frac{1}{\Phi(x)}\cdot\vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x)=\int_0^x\frac{1}{\Phi(s)}\cdot\vec{f}(s)\,ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x)=\Phi(x)\cdot\left(\int_0^x\frac{1}{\Phi(s)}\cdot\vec{f}(s)\,ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x)=\left[\begin{array}{c}-\frac{e^{-x}}{32}+\frac{e^{3x}}{32}+\frac{(-2x^3-3x)e^x}{24}\\ \frac{e^{-x}}{32}+\frac{3e^{3x}}{32}+\frac{(-2x^3-6x^2-3x-3)e^x}{24}\\ -\frac{e^{-x}}{32}+\frac{9e^{3x}}{32}+\frac{(-2x^3-12x^2-15x-6)e^x}{24}\end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x)=c_1\vec{y}_1+c_2\vec{y}_2+c_3\vec{y}_3+\left[\begin{array}{c}-\frac{e^{-x}}{32}+\frac{e^{3x}}{32}+\frac{(-2x^3-3x)e^x}{24}\\ \frac{e^{-x}}{32}+\frac{3e^{3x}}{32}+\frac{(-2x^3-6x^2-3x-3)e^x}{24}\\ -\frac{e^{-x}}{32}+\frac{9e^{3x}}{32}+\frac{(-2x^3-12x^2-15x-6)e^x}{24}\end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y=\frac{(-1+32c_1)e^{-x}}{32}+\frac{(32c_3+9)e^{3x}}{288}-\frac{e^x\left(x^3+\frac{3}{2}x-12c_2\right)}{12}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^2y'' - 3y'x + 3y = 0}$$

13.1.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 3xrx^{r-1} + 3x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 3r\,x^r + 3x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 3r + 3 = 0$$

Or

$$r^2 - 4r + 3 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = 1$$
$$r_2 = 3$$

Since the roots are real and distinct, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_2 x^3 + c_1 x$$

Summary
The solution(s) found are the following

$$y = c_2 x^3 + c_1 x \tag{1}$$

Verification of solutions

$$y = c_2 x^3 + c_1 x$$

Verified OK.

13.1.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2y'' - 3y'x + 3y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{3}{x} \\ q(x) &= \frac{3}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\ &= \int \mathrm{e}^{-\left(\int -\frac{3}{x}dx\right)}dx \\ &= \int e^{3\ln(x)}\,dx \\ &= \int x^3dx \\ &= \frac{x^4}{4} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned} q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{3}{x^2}}{x^6} \\ &= \frac{3}{x^8} \end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned} \frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + \frac{3y(\tau)}{x^8} &= 0 \end{aligned}$$

But in terms of τ

$$\frac{3}{x^8} = \frac{3}{16\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{3y(\tau)}{16\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$16\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 3y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$16\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 3\tau^r = 0$$

Simplifying gives

$$16r(r-1)\tau^r + 0\,\tau^r + 3\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$16r(r-1) + 0 + 3 = 0$$

Or

$$16r^2 - 16r + 3 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$
\begin{aligned}
r_1 &= \frac{1}{4} \\
r_2 &= \frac{3}{4}
\end{aligned}
$$

Since the roots are real and distinct, then the general solution is

$$
y(\tau) = c_1 y_1 + c_2 y_2
$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$
y(\tau) = c_1 \tau^{\frac{1}{4}} + c_2 \tau^{\frac{3}{4}}
$$

The above solution is now transformed back to y using (6) which results in

$$
y = \frac{\sqrt{2}\,(x^4)^{\frac{1}{4}} \left(c_2 \sqrt{x^4} + 2c_1\right)}{4}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = \frac{\sqrt{2}\,(x^4)^{\frac{1}{4}} \left(c_2 \sqrt{x^4} + 2c_1\right)}{4} \tag{1}
$$

<u>Verification of solutions</u>

$$
y = \frac{\sqrt{2}\,(x^4)^{\frac{1}{4}} \left(c_2 \sqrt{x^4} + 2c_1\right)}{4}
$$

Verified OK.

13.1.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$
x^2 y'' - 3y'x + 3y = 0 \tag{1}
$$

Becomes

$$
y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= -\frac{3}{x} \\
q(x) &= \frac{3}{x^2}
\end{aligned}
$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'\,(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'\,(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}\tau' &= \frac{1}{c}\sqrt{q}\\ &= \frac{\sqrt{3}\,\sqrt{\frac{1}{x^2}}}{c}\\ \tau'' &= -\frac{\sqrt{3}}{c\sqrt{\frac{1}{x^2}}\,x^3}\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'\,(x)^2}\\ &= \frac{-\frac{\sqrt{3}}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{3}{x}\frac{\sqrt{3}\,\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{3}\,\sqrt{\frac{1}{x^2}}}{c}\right)^2}\\ &= -\frac{4c\sqrt{3}}{3}\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0\\ \frac{d^2}{d\tau^2}y(\tau) - \frac{4c\sqrt{3}\,\left(\frac{d}{d\tau}y(\tau)\right)}{3} + c^2 y(\tau) &= 0\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = e^{\frac{2\sqrt{3}\,c\tau}{3}}\left(c_1\cosh\left(\frac{\sqrt{3}\,c\tau}{3}\right) + ic_2\sinh\left(\frac{\sqrt{3}\,c\tau}{3}\right)\right)$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\, dx \\
&= \frac{\int \sqrt{3}\,\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{3}\,\sqrt{\frac{1}{x^2}}\, x\ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = \frac{x((ic_2 + c_1)\, x^2 - ic_2 + c_1)}{2}
$$

Summary

The solution(s) found are the following

$$
y = \frac{x((ic_2 + c_1)\, x^2 - ic_2 + c_1)}{2} \tag{1}
$$

Verification of solutions

$$
y = \frac{x((ic_2 + c_1)\, x^2 - ic_2 + c_1)}{2}
$$

Verified OK.

13.1.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$
x^2y'' - 3y'x + 3y = 0 \tag{1}
$$

Becomes

$$
y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= -\frac{3}{x} \\
q(x) &= \frac{3}{x^2}
\end{aligned}
$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$
v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}
$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{3n}{x^2} + \frac{3}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 3 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{3v'(x)}{x} &= 0 \\ v''(x) + \frac{3v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{3u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{3u}{x} \end{aligned}$$

Where $f(x) = -\frac{3}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u} \, du &= -\frac{3}{x} \, dx \\ \int \frac{1}{u} \, du &= \int -\frac{3}{x} \, dx \\ \ln(u) &= -3\ln(x) + c_1 \\ u &= e^{-3\ln(x)+c_1} \\ &= \frac{c_1}{x^3} \end{aligned}$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= -\frac{c_1}{2x^2} + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(-\frac{c_1}{2x^2} + c_2\right) x^3 \\
&= c_2 x^3 - \frac{1}{2} c_1 x
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = \left(-\frac{c_1}{2x^2} + c_2\right) x^3 \tag{1}$$

Verification of solutions

$$y = \left(-\frac{c_1}{2x^2} + c_2\right) x^3$$

Verified OK.

13.1.5 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$
\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}
$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B+2v'B'+B''v)+B(B'v+v'B)+CBv &= 0\\
ABv''+\left(2AB'+B^2\right)v'+\left(AB''+BB'+CB\right)v &= 0 \qquad (1)
\end{aligned}
$$

If the term $AB''+BB'+CB$ is zero, then this method works and can be used to solve

$$
ABv''+\left(2AB'+B^2\right)v'=0
$$

By Using $u=v'$ which reduces the order of the above ode to one. The new ode is

$$
ABu'+\left(2AB'+B^2\right)u=0
$$

The above ode is first order ode which is solved for u. Now a new ode $v'=u$ is solved for v as first order ode. Then the final solution is obtain from $y=Bv$.

This method works only if the term $AB''+BB'+CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= x^2\\
B &= -3x\\
C &= 3\\
F &= 0
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB''+BB'+CB &= \left(x^2\right)(0)+(-3x)(-3)+(3)(-3x)\\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
-3x^3v''+\left(3x^2\right)v'=0
$$

Now by applying $v'=u$ the above becomes

$$
-3x^2(u'(x)\,x-u(x))=0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x,u)\\
&= f(x)g(u)\\
&= \frac{u}{x}
\end{aligned}
$$

Where $f(x) = \frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= \frac{1}{x}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{1}{x}\,dx \\
\ln(u) &= \ln(x) + c_1 \\
u &= \mathrm{e}^{\ln(x)+c_1} \\
&= c_1 x
\end{aligned}
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= c_1 x
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int c_1 x \, \mathrm{d}x \\
&= \frac{c_1 x^2}{2} + c_2
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y(x) &= Bv \\
&= (-3x)\left(\frac{c_1 x^2}{2} + c_2\right) \\
&= -\frac{3x(c_1 x^2 + 2c_2)}{2}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = -\frac{3x(c_1 x^2 + 2c_2)}{2} \tag{1}
$$

Verification of solutions

$$
y = -\frac{3x(c_1 x^2 + 2c_2)}{2}
$$

Verified OK.

13.1.6 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 3y'x + 3y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -3x \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 468: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{3}{4x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{3}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{2x} + (-)(0) \\
&= -\frac{1}{2x} \\
&= -\frac{1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(-\frac{1}{2x}\right)^2 - \left(\frac{3}{4x^2}\right) \right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int -\frac{1}{2x} dx} \\
&= \frac{1}{\sqrt{x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3x}{x^2}\,dx} \\
&= z_1 e^{\frac{3\ln(x)}{2}} \\
&= z_1\left(x^{\frac{3}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{3\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{x^2}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x) + c_2\left(x\left(\frac{x^2}{2}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x + \frac{1}{2} c_2 x^3 \tag{1}
$$

Verification of solutions

$$
y = c_1 x + \frac{1}{2} c_2 x^3
$$

Verified OK.

13.1.7 Maple step by step solution

Let's solve

$y''x^2 - 3y'x + 3y = 0$

- Highest derivative means the order of the ODE is 2

y''

- Isolate 2nd derivative

$y'' = \frac{3y'}{x} - \frac{3y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' - \frac{3y'}{x} + \frac{3y}{x^2} = 0$

- Multiply by denominators of the ODE

$y''x^2 - 3y'x + 3y = 0$

- Make a change of variables

$t = \ln(x)$

□ Substitute the change of variables back into the ODE

 ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

 $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

 ◦ Compute derivative

 $y' = \frac{\frac{d}{dt}y(t)}{x}$

 ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

 $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$

 ◦ Compute derivative

 $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

Substitute the change of variables back into the ODE

$\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) x^2 - 3\frac{d}{dt}y(t) + 3y(t) = 0$

- Simplify

$\frac{d^2}{dt^2}y(t) - 4\frac{d}{dt}y(t) + 3y(t) = 0$

- Characteristic polynomial of ODE

$r^2 - 4r + 3 = 0$

- Factor the characteristic polynomial

  $(r-1)(r-3)=0$
- Roots of the characteristic polynomial

  $r=(1,3)$
- 1st solution of the ODE

  $y_1(t)=\mathrm{e}^t$
- 2nd solution of the ODE

  $y_2(t)=\mathrm{e}^{3t}$
- General solution of the ODE

  $y(t)=c_1y_1(t)+c_2y_2(t)$
- Substitute in solutions

  $y(t)=c_1\mathrm{e}^t+c_2\mathrm{e}^{3t}$
- Change variables back using $t=\ln(x)$

  $y=c_2x^3+c_1x$
- Simplify

  $y=x(c_2x^2+c_1)$

$$\boxed{x^2y'' + y'x - 4y = 0}$$

13.2.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + xrx^{r-1} - 4x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + r\,x^r - 4x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1)+r-4=0$$

Or

$$r^2-4=0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1=-2$$
$$r_2=2$$

Since the roots are real and distinct, then the general solution is

$$y=c_1y_1+c_2y_2$$

Where $y_1=x^{r_1}$ and $y_2=x^{r_2}$. Hence

$$y=\frac{c_1}{x^2}+c_2x^2$$

Summary

The solution(s) found are the following

$$y=\frac{c_1}{x^2}+c_2x^2 \tag{1}$$

Verification of solutions

$$y=\frac{c_1}{x^2}+c_2x^2$$

Verified OK.

13.2.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2y''+y'x-4y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$p(x)=\frac{1}{x}$$
$$q(x)=-\frac{4}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int \frac{1}{x}dx\right)}dx \\
&= \int e^{-\ln(x)}\,dx \\
&= \int \frac{1}{x}dx \\
&= \ln(x)
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{-\frac{4}{x^2}}{\frac{1}{x^2}} \\
&= -4
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - 4y(\tau) &= 0
\end{aligned}$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = -4$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda\tau} - 4\, e^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 - 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-4)} \\ &= \pm 2\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2 \\ \lambda_2 &= -2\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2 \\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y(\tau) &= c_1 e^{\lambda_1 \tau} + c_2 e^{\lambda_2 \tau} \\ y(\tau) &= c_1 e^{(2)\tau} + c_2 e^{(-2)\tau}\end{aligned}$$

Or

$$y(\tau) = c_1 e^{2\tau} + c_2 e^{-2\tau}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 x^4 + c_2}{x^2}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 x^4 + c_2}{x^2} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x^4 + c_2}{x^2}$$

Verified OK.

13.2.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2 y'' + y'x - 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= -\frac{4}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}
\tau' &= \frac{1}{c}\sqrt{q} \\
&= \frac{2\sqrt{-\frac{1}{x^2}}}{c} \\
\tau'' &= \frac{2}{c\sqrt{-\frac{1}{x^2}}\, x^3}
\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{\frac{2}{c\sqrt{-\frac{1}{x^2}}\, x^3} + \frac{1}{x}\frac{2\sqrt{-\frac{1}{x^2}}}{c}}{\left(\frac{2\sqrt{-\frac{1}{x^2}}}{c}\right)^2} \\
&= 0
\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2} y(\tau) + c^2 y(\tau) &= 0
\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\, dx \\
&= \frac{\int 2\sqrt{-\frac{1}{x^2}} dx}{c} \\
&= \frac{2\sqrt{-\frac{1}{x^2}}\, x \ln(x)}{c}
\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = c_1 \cosh(2\ln(x)) + i c_2 \sinh(2\ln(x))$$

Summary
The solution(s) found are the following

$$y = c_1 \cosh\left(2\ln\left(x\right)\right) + ic_2 \sinh\left(2\ln\left(x\right)\right) \tag{1}$$

Verification of solutions

$$y = c_1 \cosh\left(2\ln\left(x\right)\right) + ic_2 \sinh\left(2\ln\left(x\right)\right)$$

Verified OK.

13.2.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2y'' + y'x - 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= -\frac{4}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right)v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right)v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n}{x^2} - \frac{4}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 2 \tag{6}$$

Substituting this value in (3) gives

$$
\begin{aligned}
v''(x) + \frac{5v'(x)}{x} &= 0 \\
v''(x) + \frac{5v'(x)}{x} &= 0 \qquad (7)
\end{aligned}
$$

Using the substitution

$$
u(x) = v'(x)
$$

Then (7) becomes

$$
u'(x) + \frac{5u(x)}{x} = 0 \qquad (8)
$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x, u) \\
&= f(x)g(u) \\
&= -\frac{5u}{x}
\end{aligned}
$$

Where $f(x) = -\frac{5}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\, du &= -\frac{5}{x}\, dx \\
\int \frac{1}{u}\, du &= \int -\frac{5}{x}\, dx \\
\ln(u) &= -5\ln(x) + c_1 \\
u &= e^{-5\ln(x)+c_1} \\
&= \frac{c_1}{x^5}
\end{aligned}
$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= -\frac{c_1}{4x^4} + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(-\frac{c_1}{4x^4} + c_2\right) x^2 \\
&= \frac{4c_2x^4 - c_1}{4x^2}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \left(-\frac{c_1}{4x^4} + c_2\right) x^2 \tag{1}
$$

Verification of solutions

$$
y = \left(-\frac{c_1}{4x^4} + c_2\right) x^2
$$

Verified OK.

13.2.5 Solving using Kovacic algorithm

Writing the ode as

$$
x^2y'' + y'x - 4y = 0 \tag{1}
$$

$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x^2 \\
B &= x \\
C &= -4
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{15}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 15 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{15}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 470: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{15}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{15}{4x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = \frac{15}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{15}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = -\frac{3}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= -\frac{3}{2} - \left(-\frac{3}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{3}{2x} + (-)\,(0) \\
&= -\frac{3}{2x} \\
&= -\frac{3}{2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{3}{2x}\right)(0) + \left(\left(\frac{3}{2x^2}\right) + \left(-\frac{3}{2x}\right)^2 - \left(\frac{15}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega \, dx} \\ &= \mathrm{e}^{\int -\frac{3}{2x} dx} \\ &= \frac{1}{x^{\frac{3}{2}}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{x}{x^2} \, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{x^4}{4}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned}y &= c_1y_1 + c_2y_2 \\ &= c_1\left(\frac{1}{x^2}\right) + c_2\left(\frac{1}{x^2}\left(\frac{x^4}{4}\right)\right)\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x^2} + \frac{c_2x^2}{4} \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x^2} + \frac{c_2x^2}{4}$$

Verified OK.

13.2.6 Maple step by step solution

Let's solve

$y''x^2 + y'x - 4y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y'}{x} + \frac{4y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} - \frac{4y}{x^2} = 0$

- Multiply by denominators of the ODE

  $y''x^2 + y'x - 4y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

- Compute derivative

  $y' = \frac{\frac{d}{dt}y(t)}{x}$
- Calculate the 2nd derivative of y with respect to x , using the chain rule

  $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$
- Compute derivative

  $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) x^2 + \frac{d}{dt}y(t) - 4y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) - 4y(t) = 0$
- Characteristic polynomial of ODE

  $r^2 - 4 = 0$
- Factor the characteristic polynomial

  $(r-2)(r+2) = 0$
- Roots of the characteristic polynomial

  $r = (-2, 2)$
- 1st solution of the ODE

  $y_1(t) = \mathrm{e}^{-2t}$
- 2nd solution of the ODE

  $y_2(t) = \mathrm{e}^{2t}$
- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$
- Substitute in solutions

  $y(t) = c_1 \mathrm{e}^{-2t} + c_2 \mathrm{e}^{2t}$
- Change variables back using $t = \ln(x)$

  $y = \frac{c_1}{x^2} + c_2 x^2$
- Simplify

  $y = \frac{c_1}{x^2} + c_2 x^2$

$$\boxed{4x^2y'' - 4y'x + 3y = 0}$$

13.3.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$4x^2(r(r-1))x^{r-2} - 4xrx^{r-1} + 3x^r = 0$$

Simplifying gives

$$4r(r-1)\,x^r - 4r\,x^r + 3x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$4r(r-1) - 4r + 3 = 0$$

Or

$$4r^2 - 8r + 3 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2}$$
$$r_2 = \frac{3}{2}$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_1\sqrt{x} + c_2x^{\frac{3}{2}}$$

Summary
The solution(s) found are the following

$$y = c_1\sqrt{x} + c_2x^{\frac{3}{2}} \tag{1}$$

Verification of solutions

$$y = c_1\sqrt{x} + c_2x^{\frac{3}{2}}$$

Verified OK.

13.3.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -\frac{1}{x}$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2} \int p\, dx} \\ &= e^{\int -\frac{1}{x}\, dx} \\ &= \frac{1}{\sqrt{x}} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= 0 \\ \left(\frac{y}{\sqrt{x}}\right)'' &= 0 \end{aligned}$$

Integrating once gives

$$\left(\frac{y}{\sqrt{x}}\right)' = c_1$$

Integrating again gives

$$\left(\frac{y}{\sqrt{x}}\right) = c_1 x + c_2$$

Hence the solution is

$$y = \frac{c_1 x + c_2}{\frac{1}{\sqrt{x}}}$$

Or

$$y = c_1 x^{\frac{3}{2}} + c_2 \sqrt{x}$$

Summary

The solution(s) found are the following

$$y = c_1 x^{\frac{3}{2}} + c_2 \sqrt{x} \tag{1}$$

Verification of solutions

$$y = c_1 x^{\frac{3}{2}} + c_2 \sqrt{x}$$

Verified OK.

13.3.3 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$4x^2y'' - 4y'x + 3y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= \frac{3}{4x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\ &= \int \mathrm{e}^{-\left(\int -\frac{1}{x}dx\right)}dx \\ &= \int e^{\ln(x)}\, dx \\ &= \int x dx \\ &= \frac{x^2}{2} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{3}{4x^2}}{x^2} \\
&= \frac{3}{4x^4}
\end{aligned}
\tag{7}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{3y(\tau)}{4x^4} &= 0
\end{aligned}
$$

But in terms of τ

$$
\frac{3}{4x^4} = \frac{3}{16\tau^2}
$$

Hence the above ode becomes

$$
\frac{d^2}{d\tau^2}y(\tau) + \frac{3y(\tau)}{16\tau^2} = 0
$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$
16\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 3y(\tau) = 0
$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$
16\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 3\tau^r = 0
$$

Simplifying gives

$$
16r(r-1)\,\tau^r + 0\,\tau^r + 3\tau^r = 0
$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$
16r(r-1) + 0 + 3 = 0
$$

Or

$$
16r^2 - 16r + 3 = 0 \tag{1}
$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$
\begin{aligned}
r_1 &= \frac{1}{4} \\
r_2 &= \frac{3}{4}
\end{aligned}
$$

Since the roots are real and distinct, then the general solution is

$$
y(\tau) = c_1 y_1 + c_2 y_2
$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$
y(\tau) = c_1 \tau^{\frac{1}{4}} + c_2 \tau^{\frac{3}{4}}
$$

The above solution is now transformed back to y using (6) which results in

$$
y = \frac{c_1 2^{\frac{3}{4}} (x^2)^{\frac{1}{4}}}{2} + \frac{c_2 2^{\frac{1}{4}} (x^2)^{\frac{3}{4}}}{2}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1 2^{\frac{3}{4}} (x^2)^{\frac{1}{4}}}{2} + \frac{c_2 2^{\frac{1}{4}} (x^2)^{\frac{3}{4}}}{2} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1 2^{\frac{3}{4}} (x^2)^{\frac{1}{4}}}{2} + \frac{c_2 2^{\frac{1}{4}} (x^2)^{\frac{3}{4}}}{2}
$$

Verified OK.

13.3.4 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$
4x^2 y'' - 4y'x + 3y = 0 \tag{1}
$$

Becomes

$$
y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= \frac{3}{4x^2}
\end{aligned}
$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}\tau' &= \frac{1}{c}\sqrt{q}\\ &= \frac{\sqrt{3}\sqrt{\frac{1}{x^2}}}{2c}\\ \tau'' &= -\frac{\sqrt{3}}{2c\sqrt{\frac{1}{x^2}}\,x^3}\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2}\\ &= \frac{-\frac{\sqrt{3}}{2c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{1}{x}\frac{\sqrt{3}\sqrt{\frac{1}{x^2}}}{2c}}{\left(\frac{\sqrt{3}\sqrt{\frac{1}{x^2}}}{2c}\right)^2}\\ &= -\frac{4c\sqrt{3}}{3}\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0\\ \frac{d^2}{d\tau^2}y(\tau) - \frac{4c\sqrt{3}\left(\frac{d}{d\tau}y(\tau)\right)}{3} + c^2 y(\tau) &= 0\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = \mathrm{e}^{\frac{2\sqrt{3}\,c\tau}{3}}\left(c_1\cosh\left(\frac{\sqrt{3}\,c\tau}{3}\right) + ic_2\sinh\left(\frac{\sqrt{3}\,c\tau}{3}\right)\right)$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\, dx \\
&= \frac{\int \frac{\sqrt{3}\,\sqrt{\frac{1}{x^2}}}{2}dx}{c} \\
&= \frac{\sqrt{3}\,\sqrt{\frac{1}{x^2}}\, x \ln(x)}{2c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = x\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)
$$

Summary

The solution(s) found are the following

$$
y = x\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x)}{2}\right)\right) \tag{1}
$$

Verification of solutions

$$
y = x\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)
$$

Verified OK.

13.3.5 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$
y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= \frac{3}{4x^2}
\end{aligned}
$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{3}{4x^2} - \frac{\left(-\frac{1}{x}\right)'}{2} - \frac{\left(-\frac{1}{x}\right)^2}{4} \\
&= \frac{3}{4x^2} - \frac{\left(\frac{1}{x^2}\right)}{2} - \frac{\left(\frac{1}{x^2}\right)}{4} \\
&= \frac{3}{4x^2} - \left(\frac{1}{2x^2}\right) - \frac{1}{4x^2} \\
&= 0
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\, z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{-\frac{1}{x}}{2}} \\
&= \sqrt{x}
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\, \sqrt{x} \tag{4}
$$

Applying this change of variable to the original ode results in

$$
4x^{\frac{5}{2}} v''(x) = 0
$$

Which is now solved for $v(x)$ Integrating twice gives the solution

$$
v(x) = c_1 x + c_2
$$

Now that $v(x)$ is known, then

$$
\begin{aligned}
y &= v(x)\, z(x) \\
&= (c_1 x + c_2)\, (z(x))
\end{aligned} \tag{7}
$$

But from (5)

$$
z(x) = \sqrt{x}
$$

Hence (7) becomes

$$y = (c_1 x + c_2) \sqrt{x}$$

Summary

The solution(s) found are the following

$$y = (c_1 x + c_2) \sqrt{x} \tag{1}$$

Verification of solutions

$$y = (c_1 x + c_2) \sqrt{x}$$

Verified OK.

13.3.6 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$4x^2 y'' - 4y' x + 3y = 0 \tag{1}$$

Becomes

$$y'' + p(x) y' + q(x) y = 0 \tag{2}$$

Where

$$p(x) = -\frac{1}{x}$$
$$q(x) = \frac{3}{4x^2}$$

Applying change of variables on the depndent variable $y = v(x) x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{n}{x^2} + \frac{3}{4x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = \frac{3}{2} \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{2v'(x)}{x} &= 0 \\ v''(x) + \frac{2v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{2u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{2u}{x} \end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{2}{x}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{2}{x}\, dx \\ \ln(u) &= -2\ln(x) + c_1 \\ u &= \mathrm{e}^{-2\ln(x) + c_1} \\ &= \frac{c_1}{x^2} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= -\frac{c_1}{x} + c_2 \end{aligned}$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(-\frac{c_1}{x} + c_2\right) x^{\frac{3}{2}} \\
&= (c_2 x - c_1)\sqrt{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \left(-\frac{c_1}{x} + c_2\right) x^{\frac{3}{2}} \tag{1}
$$

Verification of solutions

$$
y = \left(-\frac{c_1}{x} + c_2\right) x^{\frac{3}{2}}
$$

Verified OK.

13.3.7 Solving using Kovacic algorithm

Writing the ode as

$$
4x^2 y'' - 4y'x + 3y = 0 \tag{1}
$$
$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 4x^2 \\
B &= -4x \\
C &= 3
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 472: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x}{4x^2}\,dx} \\
&= z_1 e^{\frac{\ln(x)}{2}} \\
&= z_1\left(\sqrt{x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{4x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\sqrt{x}\right) + c_2\left(\sqrt{x}(x)\right)
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1\sqrt{x} + c_2x^{\frac{3}{2}} \tag{1}$$

Verification of solutions

$$y = c_1\sqrt{x} + c_2x^{\frac{3}{2}}$$

Verified OK.

13.3.8 Maple step by step solution

Let's solve

$4y''x^2 - 4y'x + 3y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{y'}{x} - \frac{3y}{4x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{y'}{x} + \frac{3y}{4x^2} = 0$

- Multiply by denominators of the ODE

  $4y''x^2 - 4y'x + 3y = 0$

- Make a change of variables

  $t = \ln(x)$

☐ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right)t'(x)$

  ◦ Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  ◦ Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

Substitute the change of variables back into the ODE

$$4\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2}-\frac{\frac{d}{dt}y(t)}{x^2}\right)x^2-4\frac{d}{dt}y(t)+3y(t)=0$$

- Simplify

$$4\frac{d^2}{dt^2}y(t)-8\frac{d}{dt}y(t)+3y(t)=0$$

- Isolate 2nd derivative

$$\frac{d^2}{dt^2}y(t)=2\frac{d}{dt}y(t)-\frac{3y(t)}{4}$$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$$\frac{d^2}{dt^2}y(t)-2\frac{d}{dt}y(t)+\frac{3y(t)}{4}=0$$

- Characteristic polynomial of ODE

$$r^2-2r+\frac{3}{4}=0$$

- Factor the characteristic polynomial

$$\frac{(2r-1)(2r-3)}{4}=0$$

- Roots of the characteristic polynomial

$$r=\left(\frac{1}{2},\frac{3}{2}\right)$$

- 1st solution of the ODE

$$y_1(t)=\mathrm{e}^{\frac{t}{2}}$$

- 2nd solution of the ODE

$$y_2(t)=\mathrm{e}^{\frac{3t}{2}}$$

- General solution of the ODE

$$y(t)=c_1y_1(t)+c_2y_2(t)$$

- Substitute in solutions

$$y(t)=c_1\mathrm{e}^{\frac{t}{2}}+c_2\mathrm{e}^{\frac{3t}{2}}$$

- Change variables back using $t=\ln(x)$

$$y=c_1\sqrt{x}+c_2x^{\frac{3}{2}}$$

- Simplify

$$y=\sqrt{x}\,(c_2x+c_1)$$

$$\boxed{x^2y'' - 3y'x + 4y = 0}$$

13.4.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 3xrx^{r-1} + 4x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 3r\,x^r + 4x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 3r + 4 = 0$$

Or

$$r^2 - 4r + 4 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = 2$$
$$r_2 = 2$$

Since the roots are equal, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^r$ and $y_2 = x^r \ln(x)$. Hence

$$y = c_1 x^2 + c_2 x^2 \ln(x)$$

Summary
The solution(s) found are the following

$$y = c_1 x^2 + c_2 x^2 \ln(x) \tag{1}$$

Verification of solutions

$$y = c_1 x^2 + c_2 x^2 \ln(x)$$

Verified OK.

13.4.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2 y'' - 3y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = -\frac{3}{x}$$
$$q(x) = \frac{4}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\ &= \int \mathrm{e}^{-\left(\int -\frac{3}{x}dx\right)}dx \\ &= \int e^{3\ln(x)}\,dx \\ &= \int x^3 dx \\ &= \frac{x^4}{4}\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{4}{x^2}}{x^6} \\ &= \frac{4}{x^8}\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + \frac{4y(\tau)}{x^8} &= 0\end{aligned}$$

But in terms of τ

$$\frac{4}{x^8} = \frac{1}{4\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{4\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$4\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0$$

Simplifying gives

$$4r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$4r(r-1) + 0 + 1 = 0$$

Or

$$4r^2 - 4r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2}$$
$$r_2 = \frac{1}{2}$$

Since the roots are equal, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^r$ and $y_2 = \tau^r \ln(\tau)$. Hence

$$y(\tau) = c_1\sqrt{\tau} + c_2\sqrt{\tau}\,\ln(\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{(c_2\ln(x^4) - 2c_2\ln(2) + c_1)\sqrt{x^4}}{2}$$

Summary
The solution(s) found are the following

$$y = \frac{(c_2 \ln(x^4) - 2c_2 \ln(2) + c_1)\sqrt{x^4}}{2} \tag{1}$$

Verification of solutions

$$y = \frac{(c_2 \ln(x^4) - 2c_2 \ln(2) + c_1)\sqrt{x^4}}{2}$$

Verified OK.

13.4.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2 y'' - 3y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = -\frac{3}{x}$$
$$q(x) = \frac{4}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1\left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{2\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{2}{c\sqrt{\frac{1}{x^2}}\, x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'\,(x)^2} \\
&= \frac{-\frac{2}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{3}{x}\,\frac{2\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{2\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= -2c
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - 2c\left(\frac{d}{d\tau}y(\tau)\right) + c^2 y(\tau) &= 0
\end{aligned} \tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = \mathrm{e}^{c\tau} c_1
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int 2\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{2\sqrt{\frac{1}{x^2}}\,x\ln{(x)}}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = c_1 x^2
$$

Summary

The solution(s) found are the following

$$
y = c_1 x^2 \tag{1}
$$

Verification of solutions

$$
y = c_1 x^2
$$

Verified OK.

13.4.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2y'' - 3y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{3}{x} \\ q(x) &= \frac{4}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{3n}{x^2} + \frac{4}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 2 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{v'(x)}{x} &= 0 \\ v''(x) + \frac{v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{u}{x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{1}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{1}{x}\,dx \\ \ln(u) &= -\ln(x) + c_1 \\ u &= e^{-\ln(x)+c_1} \\ &= \frac{c_1}{x} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= c_1 \ln(x) + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\,x^n \\ &= (c_1 \ln(x) + c_2)\,x^2 \\ &= (c_1 \ln(x) + c_2)\,x^2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = (c_1 \ln(x) + c_2)\,x^2 \tag{1}$$

Verification of solutions

$$y = (c_1 \ln(x) + c_2)\,x^2$$

Verified OK.

13.4.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 3y'x + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -3x \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 474: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = -\frac{1}{4x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{1}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_{\infty}^{-} - (\alpha_{c_1}^{-}) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\ &= \frac{1}{2x} + (-)\,(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3x}{x^2}\,dx} \\
&= z_1 e^{\frac{3\ln(x)}{2}} \\
&= z_1\left(x^{\frac{3}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^2
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{3\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^2\right) + c_2\left(x^2(\ln(x))\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x^2 + c_2 x^2 \ln(x) \tag{1}
$$

Verification of solutions

$$
y = c_1 x^2 + c_2 x^2 \ln(x)
$$

Verified OK.

13.4.6 Maple step by step solution

Let's solve

$y''x^2 - 3y'x + 4y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{3y'}{x} - \frac{4y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{3y'}{x} + \frac{4y}{x^2} = 0$

- Multiply by denominators of the ODE

  $y''x^2 - 3y'x + 4y = 0$

- Make a change of variables

  $t = \ln(x)$

☐ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right)t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right)x^2 - 3\frac{d}{dt}y(t) + 4y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) - 4\frac{d}{dt}y(t) + 4y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 - 4r + 4 = 0$

- Factor the characteristic polynomial

  $(r-2)^2 = 0$
- Root of the characteristic polynomial

  $r = 2$
- 1st solution of the ODE

  $y_1(t) = \mathrm{e}^{2t}$
- Repeated root, multiply $y_1(t)$ by t to ensure linear independence

  $y_2(t) = t\,\mathrm{e}^{2t}$
- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$
- Substitute in solutions

  $y(t) = c_1 \mathrm{e}^{2t} + c_2 t\,\mathrm{e}^{2t}$
- Change variables back using $t = \ln(x)$

  $y = c_1 x^2 + c_2 x^2 \ln(x)$
- Simplify

  $y = x^2(c_1 + \ln(x)\, c_2)$

$$\boxed{x^2y'' + y'x + 4y = 0}$$

13.5.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + xrx^{r-1} + 4x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + r\,x^r + 4x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1)+r+4=0$$

Or

$$r^2+4=0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -2i$$
$$r_2 = 2i$$

The roots are complex conjugate of each others. Let the roots be

$$r_1 = \alpha + i\beta$$
$$r_2 = \alpha - i\beta$$

Where in this case $\alpha = 0$ and $\beta = -2$. Hence the solution becomes

$$\begin{aligned}
y &= c_1 x^{r_1} + c_2 x^{r_2} \\
&= c_1 x^{\alpha+i\beta} + c_2 x^{\alpha-i\beta} \\
&= x^{\alpha}\left(c_1 x^{i\beta} + c_2 x^{-i\beta}\right) \\
&= x^{\alpha}\left(c_1 e^{\ln(x^{i\beta})} + c_2 e^{\ln(x^{-i\beta})}\right) \\
&= x^{\alpha}\left(c_1 e^{i(\beta \ln x)} + c_2 e^{-i(\beta \ln x)}\right)
\end{aligned}$$

Using the values for $\alpha = 0, \beta = -2$, the above becomes

$$y = x^0\left(c_1 e^{-2i\ln(x)} + c_2 e^{2i\ln(x)}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x)) \tag{1}$$

Verification of solutions

$$y = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

Verified OK.

13.5.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2y'' + y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= \frac{4}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int e^{-\left(\int p(x)dx\right)}dx \\ &= \int e^{-\left(\int \frac{1}{x}dx\right)}dx \\ &= \int e^{-\ln(x)}\,dx \\ &= \int \frac{1}{x}dx \\ &= \ln(x) \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{4}{x^2}}{\frac{1}{x^2}} \\
&= 4
\end{aligned} \tag{7}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + 4y(\tau) &= 0
\end{aligned}
$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$
Ay''(\tau) + By'(\tau) + Cy(\tau) = 0
$$

Where in the above $A = 1, B = 0, C = 4$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$
\lambda^2 \mathrm{e}^{\lambda\tau} + 4\,\mathrm{e}^{\lambda\tau} = 0 \tag{1}
$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$
\lambda^2 + 4 = 0 \tag{2}
$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$
\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}
$$

Substituting $A = 1, B = 0, C = 4$ into the above gives

$$
\begin{aligned}
\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(4)} \\
&= \pm 2i
\end{aligned}
$$

Hence

$$
\begin{aligned}
\lambda_1 &= +2i \\
\lambda_2 &= -2i
\end{aligned}
$$

Which simplifies to

$$\lambda_1 = 2i$$
$$\lambda_2 = -2i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y(\tau) = e^{\alpha\tau}(c_1 \cos(\beta\tau) + c_2 \sin(\beta\tau))$$

Which becomes

$$y(\tau) = e^0(c_1 \cos(2\tau) + c_2 \sin(2\tau))$$

Or

$$y(\tau) = c_1 \cos(2\tau) + c_2 \sin(2\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

Summary
The solution(s) found are the following

$$y = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x)) \tag{1}$$

Verification of solutions

$$y = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

Verified OK.

13.5.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2y'' + y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{4}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$
$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}\tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{2\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{2}{c\sqrt{\frac{1}{x^2}}\,x^3}\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{2}{c\sqrt{\frac{1}{x^2}}\,x^3} + \frac{1}{x}\frac{2\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{2\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= 0\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$\begin{aligned}\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int 2\sqrt{\frac{1}{x^2}}dx}{c} \\ &= \frac{2\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x)) \tag{1}$$

Verification of solutions

$$y = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

Verified OK.

13.5.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2y'' + y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned}p(x) &= \frac{1}{x} \\ q(x) &= \frac{4}{x^2}\end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n}{x^2} + \frac{4}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 2i \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{4i}{x} + \frac{1}{x}\right) v'(x) &= 0 \\ v''(x) + \frac{(1+4i)\,v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(1+4i)\,u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{(-1-4i)\,u}{x} \end{aligned}$$

Where $f(x) = \frac{-1-4i}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= \frac{-1-4i}{x}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{-1-4i}{x}\,dx \\
\ln(u) &= (-1-4i)\ln(x) + c_1 \\
u &= \mathrm{e}^{(-1-4i)\ln(x)+c_1} \\
&= c_1 \mathrm{e}^{(-1-4i)\ln(x)}
\end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1 x^{-4i}}{x}$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= \frac{i c_1 x^{-4i}}{4} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\,x^n \\
&= \left(\frac{i c_1 x^{-4i}}{4} + c_2\right) x^{2i} \\
&= x^{2i} c_2 + \frac{i x^{-2i} c_1}{4}
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = \left(\frac{i c_1 x^{-4i}}{4} + c_2\right) x^{2i} \tag{1}$$

Verification of solutions

$$y = \left(\frac{i c_1 x^{-4i}}{4} + c_2\right) x^{2i}$$

Verified OK.

13.5.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + y'x + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-17}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -17 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{17}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 476: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{17}{4x^2}
$$

For the pole at $x=0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{17}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2}+\sqrt{1+4b} = \frac{1}{2}+2i \\
\alpha_c^- &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{2}-2i
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = -\frac{17}{4x^2}
$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{17}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b} = \frac{1}{2}+2i \\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{2}-2i
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{17}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}+2i$	$\frac{1}{2}-2i$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}+2i$	$\frac{1}{2}-2i$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = \frac{1}{2} - 2i$ then

$$
\begin{aligned}
d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= \frac{1}{2} - 2i - \left(\frac{1}{2} - 2i\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{\frac{1}{2} - 2i}{x} + (-)(0) \\
&= \frac{\frac{1}{2} - 2i}{x} \\
&= \frac{\frac{1}{2} - 2i}{x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{\frac{1}{2} - 2i}{x}\right)(0) + \left(\left(\frac{-\frac{1}{2} + 2i}{x^2}\right) + \left(\frac{\frac{1}{2} - 2i}{x}\right)^2 - \left(-\frac{17}{4x^2}\right) \right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \frac{\frac{1}{2} - 2i}{x} dx} \\
&= x^{\frac{1}{2} - 2i}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2}\,dx} \\
&= z_1 e^{-\frac{\ln(x)}{2}} \\
&= z_1 \left(\frac{1}{\sqrt{x}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{-2i}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{i x^{4i}}{4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{-2i}\right) + c_2 \left(x^{-2i} \left(-\frac{i x^{4i}}{4}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = x^{-2i} c_1 - \frac{i c_2 x^{2i}}{4} \tag{1}
$$

Verification of solutions

$$
y = x^{-2i} c_1 - \frac{i c_2 x^{2i}}{4}
$$

Verified OK.

13.5.6 Maple step by step solution

Let's solve

$y''x^2 + y'x + 4y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y'}{x} - \frac{4y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + \frac{4y}{x^2} = 0$

- Multiply by denominators of the ODE

  $y''x^2 + y'x + 4y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right)t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right)x^2 + \frac{d}{dt}y(t) + 4y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) + 4y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 + 4 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r = (-2\,\mathrm{I}, 2\,\mathrm{I})$

- 1st solution of the ODE

  $y_1(t) = \cos(2t)$

- 2nd solution of the ODE

  $y_2(t) = \sin(2t)$

- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$

- Substitute in solutions

  $y(t) = c_1 \cos(2t) + c_2 \sin(2t)$

- Change variables back using $t = \ln(x)$

  $y = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^2y'' - 3y'x + 13y = 0}$$

13.6.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 3xrx^{r-1} + 13x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 3r\,x^r + 13x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 3r + 13 = 0$$

Or

$$r^2 - 4r + 13 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= 2 - 3i \\ r_2 &= 2 + 3i \end{aligned}$$

The roots are complex conjugate of each others. Let the roots be

$$\begin{aligned} r_1 &= \alpha + i\beta \\ r_2 &= \alpha - i\beta \end{aligned}$$

Where in this case $\alpha = 2$ and $\beta = -3$. Hence the solution becomes

$$\begin{aligned} y &= c_1 x^{r_1} + c_2 x^{r_2} \\ &= c_1 x^{\alpha + i\beta} + c_2 x^{\alpha - i\beta} \\ &= x^{\alpha}\left(c_1 x^{i\beta} + c_2 x^{-i\beta}\right) \\ &= x^{\alpha}\left(c_1 e^{\ln\left(x^{i\beta}\right)} + c_2 e^{\ln\left(x^{-i\beta}\right)}\right) \\ &= x^{\alpha}\left(c_1 e^{i(\beta \ln x)} + c_2 e^{-i(\beta \ln x)}\right) \end{aligned}$$

Using the values for $\alpha = 2, \beta = -3$, the above becomes

$$y = x^2\left(c_1 e^{-3i \ln(x)} + c_2 e^{3i \ln(x)}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y = x^2(c_1 \cos(3\ln(x)) + c_2 \sin(3\ln(x)))$$

Summary

The solution(s) found are the following

$$y = x^2(c_1 \cos(3\ln(x)) + c_2 \sin(3\ln(x))) \tag{1}$$

Verification of solutions

$$y = x^2(c_1 \cos(3\ln(x)) + c_2 \sin(3\ln(x)))$$

Verified OK.

13.6.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2y'' - 3y'x + 13y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{3}{x} \\ q(x) &= \frac{13}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'\,(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'\,(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}\,dx \\ &= \int \mathrm{e}^{-\left(\int -\frac{3}{x}dx\right)}\,dx \\ &= \int e^{3\ln(x)}\,dx \\ &= \int x^3 dx \\ &= \frac{x^4}{4} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{13}{x^2}}{x^6} \\
&= \frac{13}{x^8}
\end{aligned} \tag{7}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{13y(\tau)}{x^8} &= 0
\end{aligned}
$$

But in terms of τ

$$
\frac{13}{x^8} = \frac{13}{16\tau^2}
$$

Hence the above ode becomes

$$
\frac{d^2}{d\tau^2}y(\tau) + \frac{13y(\tau)}{16\tau^2} = 0
$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$
16\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 13y(\tau) = 0
$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$
16\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 13\tau^r = 0
$$

Simplifying gives

$$
16r(r-1)\,\tau^r + 0\,\tau^r + 13\tau^r = 0
$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$
16r(r-1) + 0 + 13 = 0
$$

Or

$$
16r^2 - 16r + 13 = 0 \tag{1}
$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2} - \frac{3i}{4}$$
$$r_2 = \frac{1}{2} + \frac{3i}{4}$$

The roots are complex conjugate of each others. Let the roots be

$$r_1 = \alpha + i\beta$$
$$r_2 = \alpha - i\beta$$

Where in this case $\alpha = \frac{1}{2}$ and $\beta = -\frac{3}{4}$. Hence the solution becomes

$$\begin{aligned}
y(\tau) &= c_1 \tau^{r_1} + c_2 \tau^{r_2} \\
&= c_1 \tau^{\alpha + i\beta} + c_2 \tau^{\alpha - i\beta} \\
&= \tau^{\alpha} \left(c_1 \tau^{i\beta} + c_2 \tau^{-i\beta}\right) \\
&= \tau^{\alpha} \left(c_1 e^{\ln\left(\tau^{i\beta}\right)} + c_2 e^{\ln\left(\tau^{-i\beta}\right)}\right) \\
&= \tau^{\alpha} \left(c_1 e^{i(\beta \ln \tau)} + c_2 e^{-i(\beta \ln \tau)}\right)
\end{aligned}$$

Using the values for $\alpha = \frac{1}{2}, \beta = -\frac{3}{4}$, the above becomes

$$y(\tau) = \tau^{\frac{1}{2}} \left(c_1 e^{-\frac{3i \ln(\tau)}{4}} + c_2 e^{\frac{3i \ln(\tau)}{4}}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y(\tau) = \sqrt{\tau}\left(c_1 \cos\left(\frac{3\ln(\tau)}{4}\right) + c_2 \sin\left(\frac{3\ln(\tau)}{4}\right)\right)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\left(c_1 \cos\left(-\frac{3\ln(2)}{2} + 3\ln(x)\right) + c_2 \sin\left(-\frac{3\ln(2)}{2} + 3\ln(x)\right)\right) x^2}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(c_1 \cos\left(-\frac{3\ln(2)}{2} + 3\ln(x)\right) + c_2 \sin\left(-\frac{3\ln(2)}{2} + 3\ln(x)\right)\right) x^2}{2} \tag{1}$$

Verification of solutions

$$y = \frac{\left(c_1 \cos\left(-\frac{3\ln(2)}{2} + 3\ln(x)\right) + c_2 \sin\left(-\frac{3\ln(2)}{2} + 3\ln(x)\right)\right) x^2}{2}$$

Verified OK.

13.6.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2 y'' - 3y'x + 13y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{3}{x} \\ q(x) &= \frac{13}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1\left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{13}\,\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{\sqrt{13}}{c\sqrt{\frac{1}{x^2}}\, x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{\sqrt{13}}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{3}{x}\frac{\sqrt{13}\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{13}\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= -\frac{4c\sqrt{13}}{13}
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - \frac{4c\sqrt{13}\,\left(\frac{d}{d\tau}y(\tau)\right)}{13} + c^2 y(\tau) &= 0 \qquad (7)
\end{aligned}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = \mathrm{e}^{\frac{2\sqrt{13}\,c\tau}{13}}\left(c_1\cos\left(\frac{3\sqrt{13}\,c\tau}{13}\right) + c_2\sin\left(\frac{3\sqrt{13}\,c\tau}{13}\right)\right)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{13}\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{13}\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = x^2(c_1\cos(3\ln(x)) + c_2\sin(3\ln(x)))
$$

Summary

The solution(s) found are the following

$$
y = x^2(c_1\cos(3\ln(x)) + c_2\sin(3\ln(x))) \qquad (1)
$$

Verification of solutions

$$
y = x^2(c_1\cos(3\ln(x)) + c_2\sin(3\ln(x)))
$$

Verified OK.

13.6.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2y'' - 3y'x + 13y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{3}{x} \\ q(x) &= \frac{13}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{3n}{x^2} + \frac{13}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 2 + 3i \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{4+6i}{x} - \frac{3}{x}\right) v'(x) &= 0 \\ v''(x) + \frac{(1+6i)\, v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(1+6i)\, u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= \frac{(-1-6i)\, u}{x}
\end{aligned}$$

Where $f(x) = \frac{-1-6i}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\, du &= \frac{-1-6i}{x}\, dx \\
\int \frac{1}{u}\, du &= \int \frac{-1-6i}{x}\, dx \\
\ln(u) &= (-1-6i)\ln(x) + c_1 \\
u &= \mathrm{e}^{(-1-6i)\ln(x)+c_1} \\
&= c_1 \mathrm{e}^{(-1-6i)\ln(x)}
\end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1 x^{-6i}}{x}$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= \frac{i c_1 x^{-6i}}{6} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\, x^n \\
&= \left(\frac{i c_1 x^{-6i}}{6} + c_2\right) x^{2+3i} \\
&= c_2 x^{2+3i} + \frac{i c_1 x^{2-3i}}{6}
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = \left(\frac{i c_1 x^{-6i}}{6}+c_2\right) x^{2+3i} \tag{1}$$

Verification of solutions

$$y = \left(\frac{i c_1 x^{-6i}}{6}+c_2\right) x^{2+3i}$$

Verified OK.

13.6.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' - 3y'x + 13y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -3x \\ C &= 13 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-37}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -37$$
$$t = 4x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{37}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 478: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{37}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{37}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + 3i \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - 3i
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{37}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{37}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + 3i \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - 3i
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{37}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2} + 3i$	$\frac{1}{2} - 3i$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}+3i$	$\frac{1}{2}-3i$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{1}{2} - 3i$ then

$$\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= \frac{1}{2} - 3i - \left(\frac{1}{2} - 3i\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{\frac{1}{2}-3i}{x} + (-)\,(0) \\
&= \frac{\frac{1}{2}-3i}{x} \\
&= \frac{\frac{1}{2}-3i}{x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{\frac{1}{2}-3i}{x}\right)(0)+\left(\left(\frac{-\frac{1}{2}+3i}{x^2}\right)+\left(\frac{\frac{1}{2}-3i}{x}\right)^2-\left(-\frac{37}{4x^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x)&=pe^{\int \omega\,dx}\\
&=e^{\int \frac{\frac{1}{2}-3i}{x}dx}\\
&=x^{\frac{1}{2}-3i}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1&=z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\
&=z_1e^{-\int \frac{1}{2}\frac{-3x}{x^2}\,dx}\\
&=z_1e^{\frac{3\ln(x)}{2}}\\
&=z_1\left(x^{\frac{3}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=x^{2-3i}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2&=y_1\int \frac{e^{\int -\frac{-3x}{x^2}\,dx}}{(y_1)^2}\,dx\\
&=y_1\int \frac{e^{3\ln(x)}}{(y_1)^2}\,dx\\
&=y_1\left(-\frac{ix^{6i}}{6}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(x^{2-3i}\right) + c_2 \left(x^{2-3i} \left(-\frac{i x^{6i}}{6}\right)\right)\end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 x^{2-3i} - \frac{i c_2 x^{2+3i}}{6} \tag{1}$$

<u>Verification of solutions</u>

$$y = c_1 x^{2-3i} - \frac{i c_2 x^{2+3i}}{6}$$

Verified OK.

13.6.6 Maple step by step solution

Let's solve

$y''x^2 - 3y'x + 13y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{3y'}{x} - \frac{13y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{3y'}{x} + \frac{13y}{x^2} = 0$

- Multiply by denominators of the ODE

  $y''x^2 - 3y'x + 13y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt} y(t)\right) t'(x)$

- Compute derivative

  $y' = \frac{\frac{d}{dt}y(t)}{x}$

- Calculate the 2nd derivative of y with respect to x , using the chain rule

  $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$

- Compute derivative

  $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) x^2 - 3\frac{d}{dt}y(t) + 13y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) - 4\frac{d}{dt}y(t) + 13y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 - 4r + 13 = 0$

- Use quadratic formula to solve for r

  $r = \frac{4 \pm (\sqrt{-36})}{2}$

- Roots of the characteristic polynomial

  $r = (2 - 3\,\mathrm{I}, 2 + 3\,\mathrm{I})$

- 1st solution of the ODE

  $y_1(t) = \mathrm{e}^{2t} \cos(3t)$

- 2nd solution of the ODE

  $y_2(t) = \mathrm{e}^{2t} \sin(3t)$

- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$

- Substitute in solutions

  $y(t) = c_1 \mathrm{e}^{2t} \cos(3t) + c_2 \mathrm{e}^{2t} \sin(3t)$

- Change variables back using $t = \ln(x)$

  $y = c_1 x^2 \cos(3\ln(x)) + c_2 x^2 \sin(3\ln(x))$

- Simplify

  $y = x^2 (c_1 \cos(3\ln(x)) + c_2 \sin(3\ln(x)))$

$$\boxed{3x^2y'' - 4y'x + 2y = 0}$$

13.7.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$3x^2(r(r-1))x^{r-2} - 4xrx^{r-1} + 2x^r = 0$$

Simplifying gives

$$3r(r-1)\,x^r - 4r\,x^r + 2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$3r(r-1) - 4r + 2 = 0$$

Or

$$3r^2 - 7r + 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = 2$$
$$r_2 = \frac{1}{3}$$

Since the roots are real and distinct, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_1 x^2 + c_2 x^{\frac{1}{3}}$$

Summary

The solution(s) found are the following

$$y = c_1 x^2 + c_2 x^{\frac{1}{3}} \tag{1}$$

Verification of solutions

$$y = c_1 x^2 + c_2 x^{\frac{1}{3}}$$

Verified OK.

13.7.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$3x^2 y'' - 4y'x + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = -\frac{4}{3x}$$
$$q(x) = \frac{2}{3x^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int -\frac{4}{3x}dx\right)}dx \\
&= \int e^{\frac{4\ln(x)}{3}}\,dx \\
&= \int x^{\frac{4}{3}}dx \\
&= \frac{3x^{\frac{7}{3}}}{7}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{2}{3x^2}}{x^{\frac{8}{3}}} \\
&= \frac{2}{3x^{\frac{14}{3}}}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{3x^{\frac{14}{3}}} &= 0
\end{aligned}$$

But in terms of τ

$$\frac{2}{3x^{\frac{14}{3}}} = \frac{6}{49\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{6y(\tau)}{49\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$49\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 6y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$49\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 6\tau^r = 0$$

Simplifying gives

$$49r(r-1)\,\tau^r + 0\,\tau^r + 6\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$49r(r-1) + 0 + 6 = 0$$

Or

$$49r^2 - 49r + 6 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{7}$$
$$r_2 = \frac{6}{7}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{\frac{1}{7}} + c_2\tau^{\frac{6}{7}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 3^{\frac{1}{7}} 7^{\frac{6}{7}} \left(x^{\frac{7}{3}}\right)^{\frac{1}{7}}}{7} + \frac{c_2 3^{\frac{6}{7}} 7^{\frac{1}{7}} \left(x^{\frac{7}{3}}\right)^{\frac{6}{7}}}{7}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 3^{\frac{1}{7}} 7^{\frac{6}{7}} \left(x^{\frac{7}{3}}\right)^{\frac{1}{7}}}{7} + \frac{c_2 3^{\frac{6}{7}} 7^{\frac{1}{7}} \left(x^{\frac{7}{3}}\right)^{\frac{6}{7}}}{7} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 3^{\frac{1}{7}} 7^{\frac{6}{7}} \left(x^{\frac{7}{3}}\right)^{\frac{1}{7}}}{7} + \frac{c_2 3^{\frac{6}{7}} 7^{\frac{1}{7}} \left(x^{\frac{7}{3}}\right)^{\frac{6}{7}}}{7}$$

Verified OK.

13.7.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$3x^2 y'' - 4y'x + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{3x} \\ q(x) &= \frac{2}{3x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{3c} \\ \tau'' &= -\frac{\sqrt{6}}{3c\sqrt{\frac{1}{x^2}}\,x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{\sqrt{6}}{3c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{4}{3x}\frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{3c}}{\left(\frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{3c}\right)^2} \\ &= -\frac{7c\sqrt{6}}{6} \end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned} y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) - \frac{7c\sqrt{6}\left(\frac{d}{d\tau}y(\tau)\right)}{6} + c^2 y(\tau) &= 0 \end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = \mathrm{e}^{\frac{7\sqrt{6}\,c\tau}{12}}\left(c_1\cosh\left(\frac{5\sqrt{6}\,c\tau}{12}\right) + ic_2\sinh\left(\frac{5\sqrt{6}\,c\tau}{12}\right)\right)$$

Now from (6)

$$\begin{aligned} \tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int \frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{3}dx}{c} \\ &= \frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}\,x\ln(x)}{3c} \end{aligned}$$

Substituting the above into the solution obtained gives

$$y = x^{\frac{7}{6}} \left(c_1 \cosh\left(\frac{5\ln(x)}{6}\right) + ic_2 \sinh\left(\frac{5\ln(x)}{6}\right)\right)$$

Summary

The solution(s) found are the following

$$y = x^{\frac{7}{6}} \left(c_1 \cosh\left(\frac{5\ln(x)}{6}\right) + ic_2 \sinh\left(\frac{5\ln(x)}{6}\right)\right) \tag{1}$$

Verification of solutions

$$y = x^{\frac{7}{6}} \left(c_1 \cosh\left(\frac{5\ln(x)}{6}\right) + ic_2 \sinh\left(\frac{5\ln(x)}{6}\right)\right)$$

Verified OK.

13.7.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$3x^2y'' - 4y'x + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = -\frac{4}{3x}$$
$$q(x) = \frac{2}{3x^2}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right)v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right)v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{4n}{3x^2} + \frac{2}{3x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 2 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{8v'(x)}{3x} &= 0 \\ v''(x) + \frac{8v'(x)}{3x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{8u(x)}{3x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{8u}{3x} \end{aligned}$$

Where $f(x) = -\frac{8}{3x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{8}{3x}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{8}{3x}\, dx \\ \ln(u) &= -\frac{8\ln(x)}{3} + c_1 \\ u &= \mathrm{e}^{-\frac{8\ln(x)}{3} + c_1} \\ &= \frac{c_1}{x^{\frac{8}{3}}} \end{aligned}$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= -\frac{3c_1}{5x^{\frac{5}{3}}} + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(-\frac{3c_1}{5x^{\frac{5}{3}}} + c_2\right) x^2 \\
&= c_2 x^2 - \frac{3x^{\frac{1}{3}} c_1}{5}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \left(-\frac{3c_1}{5x^{\frac{5}{3}}} + c_2\right) x^2 \tag{1}
$$

Verification of solutions

$$
y = \left(-\frac{3c_1}{5x^{\frac{5}{3}}} + c_2\right) x^2
$$

Verified OK.

13.7.5 Solving using Kovacic algorithm

Writing the ode as

$$
3x^2 y'' - 4y'x + 2y = 0 \tag{1}
$$

$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 3x^2 \\
B &= -4x \\
C &= 2
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{9x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4 \\ t &= 9x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4}{9x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 480: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 9x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{4}{9x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition

of r given above. Therefore $b = \frac{4}{9}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{4}{3} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{3}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{4}{9x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{4}{9}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{4}{3} \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{3}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4}{9x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{4}{3}$	$-\frac{1}{3}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{4}{3}$	$-\frac{1}{3}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_\infty^- = -\frac{1}{3}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= -\frac{1}{3} - \left(-\frac{1}{3}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{3x} + (-)(0) \\
&= -\frac{1}{3x} \\
&= -\frac{1}{3x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{3x}\right)(0) + \left(\left(\frac{1}{3x^2}\right) + \left(-\frac{1}{3x}\right)^2 - \left(\frac{4}{9x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int -\frac{1}{3x} dx} \\
&= \frac{1}{x^{\frac{1}{3}}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x}{3x^2}\,dx} \\
&= z_1 e^{\frac{2\ln(x)}{3}} \\
&= z_1 \left(x^{\frac{2}{3}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{\frac{1}{3}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{3x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{4\ln(x)}{3}}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{3x^{\frac{5}{3}}}{5}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^{\frac{1}{3}}\right) + c_2\left(x^{\frac{1}{3}}\left(\frac{3x^{\frac{5}{3}}}{5}\right)\right)
\end{aligned}
$$

<u>Summary</u>
The solution(s) found are the following

$$
y = x^{\frac{1}{3}} c_1 + \frac{3c_2 x^2}{5} \tag{1}
$$

Verification of solutions

$$y = x^{\frac{1}{3}} c_1 + \frac{3 c_2 x^2}{5}$$

Verified OK.

13.7.6 Maple step by step solution

Let's solve

$3y'' x^2 - 4y' x + 2y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{4y'}{3x} - \frac{2y}{3x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{4y'}{3x} + \frac{2y}{3x^2} = 0$

- Multiply by denominators of the ODE

  $3y'' x^2 - 4y' x + 2y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt} y(t)\right) t'(x)$

  ◦ Compute derivative

    $y' = \frac{\frac{d}{dt} y(t)}{x}$

  ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2} y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt} y(t)\right)$

  ◦ Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2} y(t)}{x^2} - \frac{\frac{d}{dt} y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $3\left(\frac{\frac{d^2}{dt^2} y(t)}{x^2} - \frac{\frac{d}{dt} y(t)}{x^2}\right) x^2 - 4 \frac{d}{dt} y(t) + 2y(t) = 0$

- Simplify

  $3\frac{d^2}{dt^2}y(t) - 7\frac{d}{dt}y(t) + 2y(t) = 0$
- Isolate 2nd derivative

  $\frac{d^2}{dt^2}y(t) = \frac{7\frac{d}{dt}y(t)}{3} - \frac{2y(t)}{3}$
- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dt^2}y(t) - \frac{7\frac{d}{dt}y(t)}{3} + \frac{2y(t)}{3} = 0$
- Characteristic polynomial of ODE

  $r^2 - \frac{7}{3}r + \frac{2}{3} = 0$
- Factor the characteristic polynomial

  $\frac{(3r-1)(r-2)}{3} = 0$
- Roots of the characteristic polynomial

  $r = \left(2, \frac{1}{3}\right)$
- 1st solution of the ODE

  $y_1(t) = e^{2t}$
- 2nd solution of the ODE

  $y_2(t) = e^{\frac{t}{3}}$
- General solution of the ODE

  $y(t) = c_1y_1(t) + c_2y_2(t)$
- Substitute in solutions

  $y(t) = c_1e^{2t} + c_2e^{\frac{t}{3}}$
- Change variables back using $t = \ln(x)$

  $y = c_1x^2 + c_2x^{\frac{1}{3}}$

$$\boxed{x^2y'' + y'x + 9y = 0}$$

13.8.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + xrx^{r-1} + 9x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + r\,x^r + 9x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + r + 9 = 0$$

Or

$$r^2 + 9 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= -3i \\ r_2 &= 3i \end{aligned}$$

The roots are complex conjugate of each others. Let the roots be

$$\begin{aligned} r_1 &= \alpha + i\beta \\ r_2 &= \alpha - i\beta \end{aligned}$$

Where in this case $\alpha = 0$ and $\beta = -3$. Hence the solution becomes

$$\begin{aligned} y &= c_1 x^{r_1} + c_2 x^{r_2} \\ &= c_1 x^{\alpha+i\beta} + c_2 x^{\alpha-i\beta} \\ &= x^{\alpha}\left(c_1 x^{i\beta} + c_2 x^{-i\beta}\right) \\ &= x^{\alpha}\left(c_1 e^{\ln\left(x^{i\beta}\right)} + c_2 e^{\ln\left(x^{-i\beta}\right)}\right) \\ &= x^{\alpha}\left(c_1 e^{i(\beta \ln x)} + c_2 e^{-i(\beta \ln x)}\right) \end{aligned}$$

Using the values for $\alpha = 0, \beta = -3$, the above becomes

$$y = x^0\left(c_1 e^{-3i\ln(x)} + c_2 e^{3i\ln(x)}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y = c_1 \cos\left(3\ln\left(x\right)\right) + c_2 \sin\left(3\ln\left(x\right)\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \cos\left(3\ln\left(x\right)\right) + c_2 \sin\left(3\ln\left(x\right)\right) \tag{1}$$

Verification of solutions

$$y = c_1 \cos\left(3\ln\left(x\right)\right) + c_2 \sin\left(3\ln\left(x\right)\right)$$

Verified OK.

13.8.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2 y'' + y'x + 9y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= \frac{9}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\ &= \int \mathrm{e}^{-\left(\int \frac{1}{x}dx\right)} dx \\ &= \int e^{-\ln(x)}\, dx \\ &= \int \frac{1}{x} dx \\ &= \ln(x) \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned} q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{9}{x^2}}{\frac{1}{x^2}} \\ &= 9 \end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned} \frac{d^2}{d\tau^2} y(\tau) + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2} y(\tau) + 9y(\tau) &= 0 \end{aligned}$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = 9$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda\tau} + 9\, e^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 9$ into the above gives

$$\begin{aligned} \lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(9)} \\ &= \pm 3i \end{aligned}$$

Hence

$$\begin{aligned} \lambda_1 &= +3i \\ \lambda_2 &= -3i \end{aligned}$$

Which simplifies to

$$\lambda_1 = 3i$$
$$\lambda_2 = -3i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 3$. Therefore the final solution, when using Euler relation, can be written as

$$y(\tau) = e^{\alpha\tau}(c_1 \cos(\beta\tau) + c_2 \sin(\beta\tau))$$

Which becomes

$$y(\tau) = e^0(c_1 \cos(3\tau) + c_2 \sin(3\tau))$$

Or

$$y(\tau) = c_1 \cos(3\tau) + c_2 \sin(3\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \cos(3\ln(x)) + c_2 \sin(3\ln(x))$$

Summary
The solution(s) found are the following

$$y = c_1 \cos(3\ln(x)) + c_2 \sin(3\ln(x)) \tag{1}$$

Verification of solutions

$$y = c_1 \cos(3\ln(x)) + c_2 \sin(3\ln(x))$$

Verified OK.

13.8.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2y'' + y'x + 9y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{9}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$
$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}\tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{3\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{3}{c\sqrt{\frac{1}{x^2}}\,x^3}\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{3}{c\sqrt{\frac{1}{x^2}}\,x^3} + \frac{1}{x}\frac{3\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{3\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= 0\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$\begin{aligned}\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int 3\sqrt{\frac{1}{x^2}}dx}{c} \\ &= \frac{3\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = c_1 \cos(3\ln(x)) + c_2 \sin(3\ln(x))$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 \cos(3\ln(x)) + c_2 \sin(3\ln(x)) \tag{1}$$

<u>Verification of solutions</u>

$$y = c_1 \cos(3\ln(x)) + c_2 \sin(3\ln(x))$$

Verified OK.

13.8.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2y'' + y'x + 9y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned}p(x) &= \frac{1}{x} \\ q(x) &= \frac{9}{x^2}\end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n}{x^2} + \frac{9}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 3i \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{6i}{x} + \frac{1}{x}\right) v'(x) &= 0 \\ v''(x) + \frac{(1+6i)\, v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(1+6i)\, u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{(-1-6i)\, u}{x} \end{aligned}$$

Where $f(x) = \frac{-1-6i}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= \frac{-1-6i}{x}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{-1-6i}{x}\,dx \\
\ln(u) &= (-1-6i)\ln(x) + c_1 \\
u &= \mathrm{e}^{(-1-6i)\ln(x)+c_1} \\
&= c_1 \mathrm{e}^{(-1-6i)\ln(x)}
\end{aligned}
$$

Which simplifies to

$$
u(x) = \frac{c_1 x^{-6i}}{x}
$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= \frac{i c_1 x^{-6i}}{6} + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\,x^n \\
&= \left(\frac{i c_1 x^{-6i}}{6} + c_2\right) x^{3i} \\
&= x^{3i} c_2 + \frac{i x^{-3i} c_1}{6}
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = \left(\frac{i c_1 x^{-6i}}{6} + c_2\right) x^{3i} \tag{1}
$$

<u>Verification of solutions</u>

$$
y = \left(\frac{i c_1 x^{-6i}}{6} + c_2\right) x^{3i}
$$

Verified OK.

13.8.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + y'x + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-37}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -37 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{37}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 482: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{37}{4x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{37}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + 3i \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - 3i
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = -\frac{37}{4x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{37}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + 3i \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - 3i
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{37}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2} + 3i$	$\frac{1}{2} - 3i$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2} + 3i$	$\frac{1}{2} - 3i$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_\infty^- = \frac{1}{2} - 3i$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\
&= \frac{1}{2} - 3i - \left(\frac{1}{2} - 3i\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{\frac{1}{2} - 3i}{x} + (-)\,(0) \\
&= \frac{\frac{1}{2} - 3i}{x} \\
&= \frac{\frac{1}{2} - 3i}{x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{\frac{1}{2} - 3i}{x}\right)(0) + \left(\left(\frac{-\frac{1}{2} + 3i}{x^2}\right) + \left(\frac{\frac{1}{2} - 3i}{x}\right)^2 - \left(-\frac{37}{4x^2}\right) \right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \frac{\frac{1}{2} - 3i}{x} dx} \\
&= x^{\frac{1}{2} - 3i}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2}\,dx} \\
&= z_1 e^{-\frac{\ln(x)}{2}} \\
&= z_1 \left(\frac{1}{\sqrt{x}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{-3i}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{i x^{6i}}{6}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{-3i}\right) + c_2 \left(x^{-3i}\left(-\frac{i x^{6i}}{6}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = x^{-3i} c_1 - \frac{i c_2 x^{3i}}{6} \tag{1}
$$

Verification of solutions

$$
y = x^{-3i} c_1 - \frac{i c_2 x^{3i}}{6}
$$

Verified OK.

13.8.6 Maple step by step solution

Let's solve

$y''x^2 + y'x + 9y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y'}{x} - \frac{9y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + \frac{9y}{x^2} = 0$

- Multiply by denominators of the ODE

  $y''x^2 + y'x + 9y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  ○ Calculate the 1st derivative of y with respect to x , using the chain rule

  $y' = \left(\frac{d}{dt}y(t)\right)t'(x)$

  ○ Compute derivative

  $y' = \frac{\frac{d}{dt}y(t)}{x}$

  ○ Calculate the 2nd derivative of y with respect to x , using the chain rule

  $y'' = \left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  ○ Compute derivative

  $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right)x^2 + \frac{d}{dt}y(t) + 9y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) + 9y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 + 9 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-36})}{2}$
- Roots of the characteristic polynomial

  $r = (-3\,\mathrm{I}, 3\,\mathrm{I})$
- 1st solution of the ODE

  $y_1(t) = \cos(3t)$
- 2nd solution of the ODE

  $y_2(t) = \sin(3t)$
- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$
- Substitute in solutions

  $y(t) = c_1 \cos(3t) + c_2 \sin(3t)$
- Change variables back using $t = \ln(x)$

  $y = c_1 \cos(3\ln(x)) + c_2 \sin(3\ln(x))$

```

$$\boxed{9x^2y'' + 3y'x + y = 0}$$

13.9.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$9x^2(r(r-1))x^{r-2} + 3xrx^{r-1} + x^r = 0$$

Simplifying gives

$$9r(r-1)\,x^r + 3r\,x^r + x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$9r(r-1) + 3r + 1 = 0$$

Or

$$9r^2 - 6r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{3}$$
$$r_2 = \frac{1}{3}$$

Since the roots are equal, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^r$ and $y_2 = x^r \ln(x)$. Hence

$$y = x^{\frac{1}{3}} c_1 + c_2 x^{\frac{1}{3}} \ln(x)$$

Summary

The solution(s) found are the following

$$y = x^{\frac{1}{3}} c_1 + c_2 x^{\frac{1}{3}} \ln(x) \tag{1}$$

Verification of solutions

$$y = x^{\frac{1}{3}} c_1 + c_2 x^{\frac{1}{3}} \ln(x)$$

Verified OK.

13.9.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$9x^2 y'' + 3y'x + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = \frac{1}{3x}$$
$$q(x) = \frac{1}{9x^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int \frac{1}{3x}dx\right)}dx \\
&= \int e^{-\frac{\ln(x)}{3}}\,dx \\
&= \int \frac{1}{x^{\frac{1}{3}}}dx \\
&= \frac{3x^{\frac{2}{3}}}{2}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{1}{9x^2}}{\frac{1}{x^{\frac{2}{3}}}} \\
&= \frac{1}{9x^{\frac{4}{3}}}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{9x^{\frac{4}{3}}} = 0$$

But in terms of τ

$$\frac{1}{9x^{\frac{4}{3}}} = \frac{1}{4\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{4\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$4\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0$$

Simplifying gives

$$4r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$4r(r-1) + 0 + 1 = 0$$

Or

$$4r^2 - 4r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2}$$
$$r_2 = \frac{1}{2}$$

Since the roots are equal, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^r$ and $y_2 = \tau^r \ln(\tau)$. Hence

$$y(\tau) = c_1\sqrt{\tau} + c_2\sqrt{\tau}\,\ln(\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{6}\,x^{\frac{1}{3}}(2\ln(x)\,c_2 - 3c_2\ln(2) + 3c_2\ln(3) + 3c_1)}{6}$$

Summary
The solution(s) found are the following

$$y = \frac{\sqrt{6}\, x^{\frac{1}{3}} \left(2 \ln \left(x \right) c_{2}-3 c_{2} \ln \left(2\right)+3 c_{2} \ln \left(3\right)+3 c_{1}\right)}{6} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{6}\, x^{\frac{1}{3}} \left(2 \ln \left(x \right) c_{2}-3 c_{2} \ln \left(2\right)+3 c_{2} \ln \left(3\right)+3 c_{1}\right)}{6}$$

Verified OK.

13.9.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$9x^2y''+3y'x+y = 0 \tag{1}$$

Becomes

$$y''+p(x)\, y'+q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{3x}\\ q(x) &= \frac{1}{9x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau)+p_1\left(\frac{d}{d\tau}y(\tau)\right)+q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x)+p(x)\,\tau'(x)}{\tau'\left(x\right)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'\left(x\right)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q}\\ &= \frac{\sqrt{\frac{1}{x^2}}}{3c} \end{aligned} \tag{6}$$

$$\tau'' = -\frac{1}{3c\sqrt{\frac{1}{x^2}}\, x^3}$$

Substituting the above into (4) results in

$$\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{1}{3c\sqrt{\frac{1}{x^2}}\,x^3} + \frac{1}{3x}\frac{\sqrt{\frac{1}{x^2}}}{3c}}{\left(\frac{\sqrt{\frac{1}{x^2}}}{3c}\right)^2} \\
&= -2c
\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - 2c\left(\frac{d}{d\tau}y(\tau)\right) + c^2 y(\tau) &= 0 \qquad (7)
\end{aligned}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = e^{c\tau} c_1$$

Now from (6)

$$\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \frac{\sqrt{\frac{1}{x^2}}}{3}dx}{c} \\
&= \frac{\sqrt{\frac{1}{x^2}}\,x\ln(x)}{3c}
\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = x^{\frac{1}{3}} c_1$$

Summary

The solution(s) found are the following

$$y = x^{\frac{1}{3}} c_1 \qquad (1)$$

Verification of solutions

$$y = x^{\frac{1}{3}} c_1$$

Verified OK.

13.9.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$9x^2y'' + 3y'x + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{3x} \\ q(x) &= \frac{1}{9x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n}{3x^2} + \frac{1}{9x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = \frac{1}{3} \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{v'(x)}{x} &= 0 \\ v''(x) + \frac{v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{u}{x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{1}{x}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{1}{x}\, dx \\ \ln(u) &= -\ln(x) + c_1 \\ u &= \mathrm{e}^{-\ln(x)+c_1} \\ &= \frac{c_1}{x} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= c_1 \ln(x) + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\, x^n \\ &= (c_1 \ln(x) + c_2)\, x^{\frac{1}{3}} \\ &= (c_1 \ln(x) + c_2)\, x^{\frac{1}{3}} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = (c_1 \ln(x) + c_2)\, x^{\frac{1}{3}} \tag{1}$$

Verification of solutions

$$y = (c_1 \ln(x) + c_2)\, x^{\frac{1}{3}}$$

Verified OK.

13.9.5 Solving using Kovacic algorithm

Writing the ode as

$$9x^2y'' + 3y'x + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9x^2 \\ B &= 3x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 484: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\ &= \frac{1}{2x} + (-)\,(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3x}{9x^2}\,dx} \\
&= z_1 e^{-\frac{\ln(x)}{6}} \\
&= z_1 \left(\frac{1}{x^{\frac{1}{6}}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{\frac{1}{3}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x}{9x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{\ln(x)}{3}}}{(y_1)^2}\,dx \\
&= y_1(\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^{\frac{1}{3}}\right) + c_2\left(x^{\frac{1}{3}}(\ln(x))\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = x^{\frac{1}{3}} c_1 + c_2 x^{\frac{1}{3}} \ln(x) \tag{1}
$$

Verification of solutions

$$
y = x^{\frac{1}{3}} c_1 + c_2 x^{\frac{1}{3}} \ln(x)
$$

Verified OK.

13.9.6 Maple step by step solution

Let's solve

$9y''x^2 + 3y'x + y = 0$

- Highest derivative means the order of the ODE is 2

y''

- Isolate 2nd derivative

$y'' = -\frac{y'}{3x} - \frac{y}{9x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' + \frac{y'}{3x} + \frac{y}{9x^2} = 0$

- Multiply by denominators of the ODE

$9y''x^2 + 3y'x + y = 0$

- Make a change of variables

$t = \ln(x)$

- □ Substitute the change of variables back into the ODE
  - ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

  - ◦ Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  - ◦ Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $9\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right)x^2 + 3\frac{d}{dt}y(t) + y(t) = 0$

- Simplify

$9\frac{d^2}{dt^2}y(t) - 6\frac{d}{dt}y(t) + y(t) = 0$

- Isolate 2nd derivative

$\frac{d^2}{dt^2}y(t) = \frac{2\frac{d}{dt}y(t)}{3} - \frac{y(t)}{9}$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dt^2}y(t) - \frac{2\frac{d}{dt}y(t)}{3} + \frac{y(t)}{9} = 0$
- Characteristic polynomial of ODE

  $r^2 - \frac{2}{3}r + \frac{1}{9} = 0$
- Factor the characteristic polynomial

  $\frac{(3r-1)^2}{9} = 0$
- Root of the characteristic polynomial

  $r = \frac{1}{3}$
- 1st solution of the ODE

  $y_1(t) = e^{\frac{t}{3}}$
- Repeated root, multiply $y_1(t)$ by t to ensure linear independence

  $y_2(t) = t\,e^{\frac{t}{3}}$
- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$
- Substitute in solutions

  $y(t) = c_1 e^{\frac{t}{3}} + c_2 t\,e^{\frac{t}{3}}$
- Change variables back using $t = \ln(x)$

  $y = x^{\frac{1}{3}} c_1 + c_2 x^{\frac{1}{3}} \ln(x)$
- Simplify

  $y = (c_1 + \ln(x)\, c_2)\, x^{\frac{1}{3}}$

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^2y'' - 5y'x + 10y = 0}$$

13.10.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 5xrx^{r-1} + 10x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 5r\,x^r + 10x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 5r + 10 = 0$$

Or

$$r^2 - 6r + 10 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= 3 - i \\ r_2 &= 3 + i \end{aligned}$$

The roots are complex conjugate of each others. Let the roots be

$$\begin{aligned} r_1 &= \alpha + i\beta \\ r_2 &= \alpha - i\beta \end{aligned}$$

Where in this case $\alpha = 3$ and $\beta = -1$. Hence the solution becomes

$$\begin{aligned} y &= c_1 x^{r_1} + c_2 x^{r_2} \\ &= c_1 x^{\alpha+i\beta} + c_2 x^{\alpha-i\beta} \\ &= x^\alpha \left(c_1 x^{i\beta} + c_2 x^{-i\beta}\right) \\ &= x^\alpha \left(c_1 e^{\ln\left(x^{i\beta}\right)} + c_2 e^{\ln\left(x^{-i\beta}\right)}\right) \\ &= x^\alpha \left(c_1 e^{i(\beta \ln x)} + c_2 e^{-i(\beta \ln x)}\right) \end{aligned}$$

Using the values for $\alpha = 3, \beta = -1$, the above becomes

$$y = x^3 \left(c_1 e^{-i\ln(x)} + c_2 e^{i\ln(x)}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y = x^3 (c_1 \cos(\ln(x)) + c_2 \sin(\ln(x)))$$

Summary

The solution(s) found are the following

$$y = x^3 (c_1 \cos(\ln(x)) + c_2 \sin(\ln(x))) \tag{1}$$

Verification of solutions

$$y = x^3 (c_1 \cos(\ln(x)) + c_2 \sin(\ln(x)))$$

Verified OK.

13.10.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2y'' - 5y'x + 10y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{5}{x} \\ q(x) &= \frac{10}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\, \tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\ &= \int \mathrm{e}^{-\left(\int -\frac{5}{x}dx\right)}dx \\ &= \int e^{5\ln(x)}\, dx \\ &= \int x^5dx \\ &= \frac{x^6}{6} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned} q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{10}{x^2}}{x^{10}} \\ &= \frac{10}{x^{12}} \end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned} \frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + \frac{10y(\tau)}{x^{12}} &= 0 \end{aligned}$$

But in terms of τ

$$\frac{10}{x^{12}} = \frac{5}{18\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{5y(\tau)}{18\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$18\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 5y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$18\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 5\tau^r = 0$$

Simplifying gives

$$18r(r-1)\,\tau^r + 0\,\tau^r + 5\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$18r(r-1) + 0 + 5 = 0$$

Or

$$18r^2 - 18r + 5 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2} - \frac{i}{6}$$
$$r_2 = \frac{1}{2} + \frac{i}{6}$$

The roots are complex conjugate of each others. Let the roots be

$$r_1 = \alpha + i\beta$$
$$r_2 = \alpha - i\beta$$

Where in this case $\alpha = \frac{1}{2}$ and $\beta = -\frac{1}{6}$. Hence the solution becomes

$$\begin{aligned} y(\tau) &= c_1\tau^{r_1} + c_2\tau^{r_2} \\ &= c_1\tau^{\alpha+i\beta} + c_2\tau^{\alpha-i\beta} \\ &= \tau^{\alpha}\left(c_1\tau^{i\beta} + c_2\tau^{-i\beta}\right) \\ &= \tau^{\alpha}\left(c_1 e^{\ln(\tau^{i\beta})} + c_2 e^{\ln(\tau^{-i\beta})}\right) \\ &= \tau^{\alpha}\left(c_1 e^{i(\beta\ln\tau)} + c_2 e^{-i(\beta\ln\tau)}\right) \end{aligned}$$

Using the values for $\alpha = \frac{1}{2}, \beta = -\frac{1}{6}$, the above becomes

$$y(\tau) = \tau^{\frac{1}{2}}\left(c_1 e^{-\frac{i\ln(\tau)}{6}} + c_2 e^{\frac{i\ln(\tau)}{6}}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y(\tau) = \sqrt{\tau}\left(c_1 \cos\left(\frac{\ln(\tau)}{6}\right) + c_2 \sin\left(\frac{\ln(\tau)}{6}\right)\right)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{6}\,\sqrt{x^6}\left(c_1 \cos\left(-\frac{\ln(2)}{6} - \frac{\ln(3)}{6} + \frac{\ln(x^6)}{6}\right) + c_2 \sin\left(-\frac{\ln(2)}{6} - \frac{\ln(3)}{6} + \frac{\ln(x^6)}{6}\right)\right)}{6}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{6}\,\sqrt{x^6}\left(c_1 \cos\left(-\frac{\ln(2)}{6} - \frac{\ln(3)}{6} + \frac{\ln(x^6)}{6}\right) + c_2 \sin\left(-\frac{\ln(2)}{6} - \frac{\ln(3)}{6} + \frac{\ln(x^6)}{6}\right)\right)}{6} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{6}\,\sqrt{x^6}\left(c_1 \cos\left(-\frac{\ln(2)}{6}-\frac{\ln(3)}{6}+\frac{\ln(x^6)}{6}\right)+c_2 \sin\left(-\frac{\ln(2)}{6}-\frac{\ln(3)}{6}+\frac{\ln(x^6)}{6}\right)\right)}{6}$$

Verified OK.

13.10.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2y'' - 5y'x + 10y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{5}{x} \\ q(x) &= \frac{10}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{10}\,\sqrt{\frac{1}{x^2}}}{c} \qquad (6) \\ \tau'' &= -\frac{\sqrt{10}}{c\sqrt{\frac{1}{x^2}}\,x^3} \end{aligned}$$

Substituting the above into (4) results in

$$\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{\sqrt{10}}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{5}{x}\,\frac{\sqrt{10}\,\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{10}\,\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= -\frac{3c\sqrt{10}}{5}
\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - \frac{3c\sqrt{10}\,\left(\frac{d}{d\tau}y(\tau)\right)}{5} + c^2 y(\tau) &= 0 \qquad (7)
\end{aligned}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = \mathrm{e}^{\frac{3\sqrt{10}\,c\tau}{10}}\left(c_1 \cos\left(\frac{\sqrt{10}\,c\tau}{10}\right) + c_2 \sin\left(\frac{\sqrt{10}\,c\tau}{10}\right)\right)$$

Now from (6)

$$\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{10}\,\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{10}\,\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = x^3(c_1 \cos(\ln(x)) + c_2 \sin(\ln(x)))$$

Summary

The solution(s) found are the following

$$y = x^3(c_1 \cos(\ln(x)) + c_2 \sin(\ln(x))) \qquad (1)$$

Verification of solutions

$$y = x^3(c_1 \cos(\ln(x)) + c_2 \sin(\ln(x)))$$

Verified OK.

13.10.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2y'' - 5y'x + 10y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{5}{x} \\ q(x) &= \frac{10}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right)v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right)v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{5n}{x^2} + \frac{10}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 3 + i \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{6+2i}{x} - \frac{5}{x}\right)v'(x) &= 0 \\ v''(x) + \frac{(1+2i)\,v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(1+2i)\,u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u)\\
&= f(x)g(u)\\
&= \frac{(-1-2i)\,u}{x}
\end{aligned}$$

Where $f(x)=\frac{-1-2i}{x}$ and $g(u)=u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= \frac{-1-2i}{x}\,dx\\
\int \frac{1}{u}\,du &= \int \frac{-1-2i}{x}\,dx\\
\ln(u) &= (-1-2i)\ln(x) + c_1\\
u &= \mathrm{e}^{(-1-2i)\ln(x)+c_1}\\
&= c_1\mathrm{e}^{(-1-2i)\ln(x)}
\end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1 x^{-2i}}{x}$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x)\\
v(x) &= \int u(x)\,dx + c_2\\
&= \frac{i x^{-2i} c_1}{2} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\,x^n\\
&= \left(\frac{i x^{-2i} c_1}{2} + c_2\right) x^{3+i}\\
&= c_2 x^{3+i} + \frac{i c_1 x^{3-i}}{2}
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = \left(\frac{i x^{-2 i} c_1}{2}+c_2\right) x^{3+i} \tag{1}$$

Verification of solutions

$$y = \left(\frac{i x^{-2 i} c_1}{2}+c_2\right) x^{3+i}$$

Verified OK.

13.10.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' - 5y'x + 10y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -5x \\ C &= 10 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-5}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -5 \\
t &= 4x^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(-\frac{5}{4x^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 486: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{5}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + i \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - i
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{5}{4x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{5}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + i \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - i
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{5}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2} + i$	$\frac{1}{2} - i$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}+i$	$\frac{1}{2}-i$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2} - i$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= \frac{1}{2} - i - \left(\frac{1}{2} - i\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{\frac{1}{2}-i}{x} + (-)\,(0) \\ &= \frac{\frac{1}{2}-i}{x} \\ &= \frac{\frac{1}{2}-i}{x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{\frac{1}{2} - i}{x}\right)(0) + \left(\left(\frac{-\frac{1}{2} + i}{x^2}\right) + \left(\frac{\frac{1}{2} - i}{x}\right)^2 - \left(-\frac{5}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{\frac{1}{2} - i}{x} dx} \\ &= x^{\frac{1}{2} - i} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-5x}{x^2} \, dx} \\ &= z_1 e^{\frac{5\ln(x)}{2}} \\ &= z_1\left(x^{\frac{5}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^{3-i}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-5x}{x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{5\ln(x)}}{(y_1)^2} \, dx \\ &= y_1\left(-\frac{i x^{2i}}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(x^{3-i}\right) + c_2 \left(x^{3-i} \left(-\frac{i x^{2i}}{2}\right)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x^{3-i} - \frac{i c_2 x^{3+i}}{2} \tag{1}$$

Verification of solutions

$$y = c_1 x^{3-i} - \frac{i c_2 x^{3+i}}{2}$$

Verified OK.

13.10.6 Maple step by step solution

Let's solve

$y'' x^2 - 5y' x + 10y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{5y'}{x} - \frac{10y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{5y'}{x} + \frac{10y}{x^2} = 0$

- Multiply by denominators of the ODE

  $y'' x^2 - 5y' x + 10y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

- ○ Calculate the 1st derivative of y with respect to x , using the chain rule

  $y' = \left(\frac{d}{dt} y(t)\right) t'(x)$

- Compute derivative

  $y' = \frac{\frac{d}{dt}y(t)}{x}$
- Calculate the 2nd derivative of y with respect to x , using the chain rule

  $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$
- Compute derivative

  $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) x^2 - 5\frac{d}{dt}y(t) + 10y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) - 6\frac{d}{dt}y(t) + 10y(t) = 0$
- Characteristic polynomial of ODE

  $r^2 - 6r + 10 = 0$
- Use quadratic formula to solve for r

  $r = \frac{6 \pm (\sqrt{-4})}{2}$
- Roots of the characteristic polynomial

  $r = (3 - \mathrm{I}, 3 + \mathrm{I})$
- 1st solution of the ODE

  $y_1(t) = \mathrm{e}^{3t} \cos(t)$
- 2nd solution of the ODE

  $y_2(t) = \mathrm{e}^{3t} \sin(t)$
- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$
- Substitute in solutions

  $y(t) = c_1 \mathrm{e}^{3t} \cos(t) + c_2 \mathrm{e}^{3t} \sin(t)$
- Change variables back using $t = \ln(x)$

  $y = c_1 x^3 \cos(\ln(x)) + c_2 x^3 \sin(\ln(x))$
- Simplify

  $y = x^3 (c_1 \cos(\ln(x)) + c_2 \sin(\ln(x)))$

Problem number: 11.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_ODE_non_constant_coefficients_of_type_Euler"**

Maple gives the following as the ode type

`[[_3rd_order, _with_linear_symmetries]]`

$$\boxed{x^3y''' - 3x^2y'' + 6y'x - 6y = 0}$$

This is Euler ODE of higher order. Let $y = x^{\lambda}$. Hence

$$\begin{aligned} y' &= \lambda\, x^{\lambda-1} \\ y'' &= \lambda(\lambda-1)\, x^{\lambda-2} \\ y''' &= \lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} \end{aligned}$$

Substituting these back into

$$x^3y''' - 3x^2y'' + 6y'x - 6y = 0$$

gives

$$6x\lambda\, x^{\lambda-1} - 3x^2\lambda(\lambda-1)\, x^{\lambda-2} + x^3\lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} - 6x^{\lambda} = 0$$

Which simplifies to

$$6\lambda\, x^{\lambda} - 3\lambda(\lambda-1)\, x^{\lambda} + \lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda} - 6x^{\lambda} = 0$$

And since $x^{\lambda} \neq 0$ then dividing through by x^{λ}, the above becomes

$$6\lambda - 3\lambda(\lambda-1) + \lambda(\lambda-1)(\lambda-2) - 6 = 0$$

Simplifying gives the characteristic equation as

$$\lambda^3 - 6\lambda^2 + 11\lambda - 6 = 0$$

Solving the above gives the following roots

$$\lambda_1 = 1$$
$$\lambda_2 = 2$$
$$\lambda_3 = 3$$

This table summarises the result

root	multiplicity	type of root
1	1	real root
2	1	real root
3	1	real root

The solution is generated by going over the above table. For each real root λ of multiplicity one generates a $c_1 x^\lambda$ basis solution. Each real root of multiplicty two, generates $c_1 x^\lambda$ and $c_2 x^\lambda \ln(x)$ basis solutions. Each real root of multiplicty three, generates $c_1 x^\lambda$ and $c_2 x^\lambda \ln(x)$ and $c_3 x^\lambda \ln(x)^2$ basis solutions, and so on. Each complex root $\alpha \pm i\beta$ of multiplicity one generates $x^\alpha(c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity two generates $\ln(x)\, x^\alpha(c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity three generates $\ln(x)^2\, x^\alpha(c_1 \cos(\beta \ln(x)) + c_2$ basis solutions. And so on. Using the above show that the solution is

$$y = c_3 x^3 + c_2 x^2 + c_1 x$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = x$$
$$y_2 = x^2$$
$$y_3 = x^3$$

Summary

The solution(s) found are the following

$$y = c_3 x^3 + c_2 x^2 + c_1 x \tag{1}$$

Verification of solutions

$$y = c_3 x^3 + c_2 x^2 + c_1 x$$

Verified OK.

13.11.1 Maple step by step solution

Let's solve

$x^3 y''' - 3y'' x^2 + 6y' x - 6y = 0$

- Highest derivative means the order of the ODE is 3

  y'''

- Isolate 3rd derivative

  $y''' = \frac{6y}{x^3} + \frac{3(y'' x - 2y')}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''' - \frac{3y''}{x} + \frac{6y'}{x^2} - \frac{6y}{x^3} = 0$

- Multiply by denominators of the ODE

  $x^3 y''' - 3y'' x^2 + 6y' x - 6y = 0$

- Make a change of variables

  $t = \ln(x)$

☐ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

  $y' = \left(\frac{d}{dt} y(t)\right) t'(x)$

  ◦ Compute derivative

  $y' = \frac{\frac{d}{dt} y(t)}{x}$

  ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

  $y'' = \left(\frac{d^2}{dt^2} y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt} y(t)\right)$

  ◦ Compute derivative

  $y'' = \frac{\frac{d^2}{dt^2} y(t)}{x^2} - \frac{\frac{d}{dt} y(t)}{x^2}$

  ◦ Calculate the 3rd derivative of y with respect to x , using the chain rule

  $y''' = \left(\frac{d^3}{dt^3} y(t)\right) t'(x)^3 + 3t'(x) t''(x) \left(\frac{d^2}{dt^2} y(t)\right) + t'''(x) \left(\frac{d}{dt} y(t)\right)$

- Compute derivative

  $y''' = \frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}$

  Substitute the change of variables back into the ODE

  $x^3\left(\frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}\right) - 3\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right)x^2 + 6\frac{d}{dt}y(t) - 6y(t) = 0$

- Simplify

  $\frac{d^3}{dt^3}y(t) - 6\frac{d^2}{dt^2}y(t) + 11\frac{d}{dt}y(t) - 6y(t) = 0$

☐ Convert linear ODE into a system of first order ODEs

- Define new variable $y_1(t)$

  $y_1(t) = y(t)$

- Define new variable $y_2(t)$

  $y_2(t) = \frac{d}{dt}y(t)$

- Define new variable $y_3(t)$

  $y_3(t) = \frac{d^2}{dt^2}y(t)$

- Isolate for $\frac{d}{dt}y_3(t)$ using original ODE

  $\frac{d}{dt}y_3(t) = 6y_3(t) - 11y_2(t) + 6y_1(t)$

  Convert linear ODE into a system of first order ODEs

  $\left[y_2(t) = \frac{d}{dt}y_1(t), y_3(t) = \frac{d}{dt}y_2(t), \frac{d}{dt}y_3(t) = 6y_3(t) - 11y_2(t) + 6y_1(t)\right]$

- Define vector

  $\vec{y}(t) = \begin{bmatrix} y_1(t) \\ y_2(t) \\ y_3(t) \end{bmatrix}$

- System to solve

  $\frac{d}{dt}\vec{y}(t) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 6 & -11 & 6 \end{bmatrix} \cdot \vec{y}(t)$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 6 & -11 & 6 \end{bmatrix}$$

- Rewrite the system as

  $\frac{d}{dt}\vec{y}(t) = A \cdot \vec{y}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

  $$\left[\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

  $$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

  $$\vec{y}_1 = \mathrm{e}^{t} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

  $$\left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

  $$\vec{y}_2 = \mathrm{e}^{2t} \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[3, \left[\begin{array}{c}\frac{1}{9} \\ \frac{1}{3} \\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_3 = e^{3t} \cdot \left[\begin{array}{c}\frac{1}{9} \\ \frac{1}{3} \\ 1\end{array}\right]$$

- General solution to the system of ODEs

$$\overrightarrow{y} = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2 + c_3\overrightarrow{y}_3$$

- Substitute solutions into the general solution

$$\overrightarrow{y} = c_1 e^{t} \cdot \left[\begin{array}{c}1 \\ 1 \\ 1\end{array}\right] + c_2 e^{2t} \cdot \left[\begin{array}{c}\frac{1}{4} \\ \frac{1}{2} \\ 1\end{array}\right] + c_3 e^{3t} \cdot \left[\begin{array}{c}\frac{1}{9} \\ \frac{1}{3} \\ 1\end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y(t) = c_1 e^{t} + \frac{c_2 e^{2t}}{4} + \frac{c_3 e^{3t}}{9}$$

- Change variables back using $t = \ln(x)$

$$y = c_1 x + \frac{1}{4}c_2 x^2 + \frac{1}{9}c_3 x^3$$

Problem number: 12.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_ODE_non_constant_coefficients_of_type_Euler"**

Maple gives the following as the ode type

```
[[_3rd_order, _fully, _exact, _linear]]
```

$$\boxed{x^3y''' + 2x^2y'' - 10y'x - 8y = 0}$$

This is Euler ODE of higher order. Let $y = x^\lambda$. Hence

$$\begin{aligned} y' &= \lambda\, x^{\lambda-1} \\ y'' &= \lambda(\lambda-1)\, x^{\lambda-2} \\ y''' &= \lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} \end{aligned}$$

Substituting these back into

$$x^3y''' + 2x^2y'' - 10y'x - 8y = 0$$

gives

$$-10x\lambda\, x^{\lambda-1} + 2x^2\lambda(\lambda-1)\, x^{\lambda-2} + x^3\lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} - 8x^\lambda = 0$$

Which simplifies to

$$-10\lambda\, x^\lambda + 2\lambda(\lambda-1)\, x^\lambda + \lambda(\lambda-1)\,(\lambda-2)\, x^\lambda - 8x^\lambda = 0$$

And since $x^{\lambda} \neq 0$ then dividing through by x^{λ}, the above becomes

$$-10\lambda + 2\lambda(\lambda - 1) + \lambda(\lambda - 1)(\lambda - 2) - 8 = 0$$

Simplifying gives the characteristic equation as

$$\lambda^3 - \lambda^2 - 10\lambda - 8 = 0$$

Solving the above gives the following roots

$$\lambda_1 = 4$$
$$\lambda_2 = -2$$
$$\lambda_3 = -1$$

This table summarises the result

root	multiplicity	type of root
-1	1	real root
-2	1	real root
4	1	real root

The solution is generated by going over the above table. For each real root λ of multiplicity one generates a $c_1 x^{\lambda}$ basis solution. Each real root of multiplicty two, generates $c_1 x^{\lambda}$ and $c_2 x^{\lambda} \ln(x)$ basis solutions. Each real root of multiplicty three, generates $c_1 x^{\lambda}$ and $c_2 x^{\lambda} \ln(x)$ and $c_3 x^{\lambda} \ln(x)^2$ basis solutions, and so on. Each complex root $\alpha \pm i\beta$ of multiplicity one generates $x^{\alpha}(c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity two generates $\ln(x) x^{\alpha}(c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity three generates $\ln(x)^2 x^{\alpha}(c_1 \cos(\beta \ln(x)) + c_2$ basis solutions. And so on. Using the above show that the solution is

$$y = \frac{c_1}{x} + \frac{c_2}{x^2} + c_3 x^4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = \frac{1}{x}$$
$$y_2 = \frac{1}{x^2}$$
$$y_3 = x^4$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x} + \frac{c_2}{x^2} + c_3 x^4 \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x} + \frac{c_2}{x^2} + c_3 x^4$$

Verified OK.

13.12.1 Maple step by step solution

Let's solve

$x^3 y''' + 2y'' x^2 - 10y' x - 8y = 0$

- Highest derivative means the order of the ODE is 3

  y'''

- Isolate 3rd derivative

  $y''' = \frac{8y}{x^3} - \frac{2(y''x - 5y')}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''' + \frac{2y''}{x} - \frac{10y'}{x^2} - \frac{8y}{x^3} = 0$

- Multiply by denominators of the ODE

  $x^3 y''' + 2y'' x^2 - 10y' x - 8y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt} y(t)\right) t'(x)$

  ◦ Compute derivative

    $y' = \frac{\frac{d}{dt} y(t)}{x}$

  ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2} y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt} y(t)\right)$

  ◦ Compute derivative

$$y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$$

- Calculate the 3rd derivative of y with respect to x , using the chain rule

$$y''' = \left(\frac{d^3}{dt^3}y(t)\right)t'(x)^3 + 3t'(x)\,t''(x)\left(\frac{d^2}{dt^2}y(t)\right) + t'''(x)\left(\frac{d}{dt}y(t)\right)$$

- Compute derivative

$$y''' = \frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}$$

Substitute the change of variables back into the ODE

$$x^3\left(\frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}\right) + 2\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right)x^2 - 10\frac{d}{dt}y(t) - 8y(t) = 0$$

- Simplify

$$\frac{d^3}{dt^3}y(t) - \frac{d^2}{dt^2}y(t) - 10\frac{d}{dt}y(t) - 8y(t) = 0$$

☐ Convert linear ODE into a system of first order ODEs

- Define new variable $y_1(t)$

$$y_1(t) = y(t)$$

- Define new variable $y_2(t)$

$$y_2(t) = \frac{d}{dt}y(t)$$

- Define new variable $y_3(t)$

$$y_3(t) = \frac{d^2}{dt^2}y(t)$$

- Isolate for $\frac{d}{dt}y_3(t)$ using original ODE

$$\frac{d}{dt}y_3(t) = y_3(t) + 10y_2(t) + 8y_1(t)$$

Convert linear ODE into a system of first order ODEs

$$\left[y_2(t) = \frac{d}{dt}y_1(t), y_3(t) = \frac{d}{dt}y_2(t), \frac{d}{dt}y_3(t) = y_3(t) + 10y_2(t) + 8y_1(t)\right]$$

- Define vector

$$\vec{y}(t) = \left[\begin{array}{c} y_1(t) \\ y_2(t) \\ y_3(t) \end{array}\right]$$

- System to solve

$$\frac{d}{dt}\vec{y}(t) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 8 & 10 & 1 \end{bmatrix} \cdot \vec{y}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 8 & 10 & 1 \end{bmatrix}$$

- Rewrite the system as

$$\frac{d}{dt}\vec{y}(t) = A \cdot \vec{y}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2, \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}\right], \left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[4, \begin{bmatrix} \frac{1}{16} \\ \frac{1}{4} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-2, \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{-2t} \cdot \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{-t} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[4, \begin{bmatrix} \frac{1}{16} \\ \frac{1}{4} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = e^{4t} \cdot \begin{bmatrix} \frac{1}{16} \\ \frac{1}{4} \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{y} = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 e^{-2t} \cdot \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix} + c_2 e^{-t} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix} + c_3 e^{4t} \cdot \begin{bmatrix} \frac{1}{16} \\ \frac{1}{4} \\ 1 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y(t) = \frac{(c_3 e^{6t} + 16 c_2 e^{t} + 4 c_1) e^{-2t}}{16}$$

- Change variables back using $t = \ln(x)$

$$y = \frac{c_3 x^6 + 16 c_2 x + 4 c_1}{16 x^2}$$

Problem number: 13.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_ODE_non_constant_coefficients_of_type_Euler"**

Maple gives the following as the ode type

```
[[_3rd_order, _with_linear_symmetries]]
```

$$\boxed{x^3y''' - x^2y'' - 6y'x + 18y = 0}$$

This is Euler ODE of higher order. Let $y = x^\lambda$. Hence

$$\begin{aligned}
y' &= \lambda\, x^{\lambda-1} \\
y'' &= \lambda(\lambda-1)\, x^{\lambda-2} \\
y''' &= \lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3}
\end{aligned}$$

Substituting these back into

$$x^3y''' - x^2y'' - 6y'x + 18y = 0$$

gives

$$-6x\lambda\, x^{\lambda-1} - x^2\lambda(\lambda-1)\, x^{\lambda-2} + x^3\lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} + 18x^\lambda = 0$$

Which simplifies to

$$-6\lambda\, x^\lambda - \lambda(\lambda-1)\, x^\lambda + \lambda(\lambda-1)\,(\lambda-2)\, x^\lambda + 18x^\lambda = 0$$

And since $x^\lambda \neq 0$ then dividing through by x^λ, the above becomes

$$
-6\lambda -\lambda(\lambda -1)+\lambda(\lambda -1)(\lambda -2)+18 = 0
$$

Simplifying gives the characteristic equation as

$$
(\lambda +2)(\lambda -3)^{2} = 0
$$

Solving the above gives the following roots

$$
\lambda_1 = -2 \\
\lambda_2 = 3 \\
\lambda_3 = 3
$$

This table summarises the result

root	multiplicity	type of root
-2	1	real root
3	2	real root

The solution is generated by going over the above table. For each real root λ of multiplicity one generates a $c_1 x^{\lambda}$ basis solution. Each real root of multiplicty two, generates $c_1 x^{\lambda}$ and $c_2 x^{\lambda} \ln(x)$ basis solutions. Each real root of multiplicty three, generates $c_1 x^{\lambda}$ and $c_2 x^{\lambda} \ln(x)$ and $c_3 x^{\lambda} \ln(x)^{2}$ basis solutions, and so on. Each complex root $\alpha \pm i\beta$ of multiplicity one generates $x^{\alpha}(c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity two generates $\ln(x)\, x^{\alpha}(c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity three generates $\ln(x)^{2} x^{\alpha}(c_1 \cos(\beta \ln(x)) + c_2$ basis solutions. And so on. Using the above show that the solution is

$$
y = \frac{c_1}{x^{2}}+c_2 x^{3}+c_3 \ln(x)\, x^{3}
$$

The fundamental set of solutions for the homogeneous solution are the following

$$
y_1 = \frac{1}{x^{2}} \\
y_2 = x^{3} \\
y_3 = x^{3} \ln(x)
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1}{x^{2}}+c_2 x^{3}+c_3 \ln(x)\, x^{3} \tag{1}
$$

Verification of solutions

$$y = \frac{c_1}{x^2} + c_2 x^3 + c_3 \ln(x)\, x^3$$

Verified OK.

13.13.1 Maple step by step solution

Let's solve

$x^3 y''' - y'' x^2 - 6y' x + 18y = 0$

- Highest derivative means the order of the ODE is 3

  y'''

- Isolate 3rd derivative

  $y''' = -\frac{18y}{x^3} + \frac{y'' x + 6y'}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''' - \frac{y''}{x} - \frac{6y'}{x^2} + \frac{18y}{x^3} = 0$

- Multiply by denominators of the ODE

  $x^3 y''' - y'' x^2 - 6y' x + 18y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt} y(t)\right) t'(x)$

  ◦ Compute derivative

    $y' = \frac{\frac{d}{dt} y(t)}{x}$

  ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2} y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt} y(t)\right)$

  ◦ Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2} y(t)}{x^2} - \frac{\frac{d}{dt} y(t)}{x^2}$

  ◦ Calculate the 3rd derivative of y with respect to x , using the chain rule

    $y''' = \left(\frac{d^3}{dt^3} y(t)\right) t'(x)^3 + 3t'(x)\, t''(x) \left(\frac{d^2}{dt^2} y(t)\right) + t'''(x) \left(\frac{d}{dt} y(t)\right)$

- Compute derivative

  $y''' = \frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}$

  Substitute the change of variables back into the ODE

  $x^3\left(\frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}\right) - \left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right)x^2 - 6\frac{d}{dt}y(t) + 18y(t) = 0$

- Simplify

  $\frac{d^3}{dt^3}y(t) - 4\frac{d^2}{dt^2}y(t) - 3\frac{d}{dt}y(t) + 18y(t) = 0$

☐ Convert linear ODE into a system of first order ODEs

- Define new variable $y_1(t)$

  $y_1(t) = y(t)$

- Define new variable $y_2(t)$

  $y_2(t) = \frac{d}{dt}y(t)$

- Define new variable $y_3(t)$

  $y_3(t) = \frac{d^2}{dt^2}y(t)$

- Isolate for $\frac{d}{dt}y_3(t)$ using original ODE

  $\frac{d}{dt}y_3(t) = 4y_3(t) + 3y_2(t) - 18y_1(t)$

  Convert linear ODE into a system of first order ODEs

  $\left[y_2(t) = \frac{d}{dt}y_1(t), y_3(t) = \frac{d}{dt}y_2(t), \frac{d}{dt}y_3(t) = 4y_3(t) + 3y_2(t) - 18y_1(t)\right]$

- Define vector

  $$\vec{y}(t) = \begin{bmatrix} y_1(t) \\ y_2(t) \\ y_3(t) \end{bmatrix}$$

- System to solve

  $$\frac{d}{dt}\vec{y}(t) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -18 & 3 & 4 \end{bmatrix} \cdot \vec{y}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -18 & 3 & 4 \end{bmatrix}$$

- Rewrite the system as

  $\frac{d}{dt}\vec{y}(t) = A \cdot \vec{y}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

  $$\left[\left[-2, \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}\right]\right]$$

- Consider eigenpair

  $$\left[-2, \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

  $$\vec{y}_1 = e^{-2t} \cdot \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

  $$\left[3, \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right]$$

- First solution from eigenvalue 3

  $$\vec{y}_2(t) = e^{3t} \cdot \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\vec{p}$ is to be solved for, $\lambda = 3$ is the eigenvalue, an

$$\overrightarrow{y}_3(t) = \mathrm{e}^{\lambda t}\left(t\overrightarrow{v} + \overrightarrow{p}\right)$$

- Note that the t multiplying $\overrightarrow{v}$ makes this solution linearly independent to the 1st solution obta
- Substitute $\overrightarrow{y}_3(t)$ into the homogeneous system

$$\lambda\,\mathrm{e}^{\lambda t}\left(t\overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda t}\overrightarrow{v} = \left(\mathrm{e}^{\lambda t}A\right)\cdot\left(t\overrightarrow{v} + \overrightarrow{p}\right)$$

- Use the fact that $\overrightarrow{v}$ is an eigenvector of A

$$\lambda\,\mathrm{e}^{\lambda t}\left(t\overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda t}\overrightarrow{v} = \mathrm{e}^{\lambda t}\left(\lambda t\overrightarrow{v} + A\cdot\overrightarrow{p}\right)$$

- Simplify equation

$$\lambda\overrightarrow{p} + \overrightarrow{v} = A\cdot\overrightarrow{p}$$

- Make use of the identity matrix I

$$(\lambda\cdot I)\cdot\overrightarrow{p} + \overrightarrow{v} = A\cdot\overrightarrow{p}$$

- Condition $\overrightarrow{p}$ must meet for $\overrightarrow{y}_3(t)$ to be a solution to the homogeneous system

$$(A - \lambda\cdot I)\cdot\overrightarrow{p} = \overrightarrow{v}$$

- Choose $\overrightarrow{p}$ to use in the second solution to the homogeneous system from eigenvalue 3

$$\left(\left[\begin{array}{ccc} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -18 & 3 & 4 \end{array}\right] - 3\cdot\left[\begin{array}{ccc} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{array}\right]\right)\cdot\overrightarrow{p} = \left[\begin{array}{c} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{array}\right]$$

- Choice of $\overrightarrow{p}$

$$\overrightarrow{p} = \left[\begin{array}{c} -\frac{1}{27} \\ 0 \\ 0 \end{array}\right]$$

- Second solution from eigenvalue 3

$$\overrightarrow{y}_3(t) = \mathrm{e}^{3t}\cdot\left(t\cdot\left[\begin{array}{c} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{array}\right] + \left[\begin{array}{c} -\frac{1}{27} \\ 0 \\ 0 \end{array}\right]\right)$$

- General solution to the system of ODEs

$$\overrightarrow{y} = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2(t) + c_3\overrightarrow{y}_3(t)$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 e^{-2t} \cdot \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix} + c_2 e^{3t} \cdot \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix} + c_3 e^{3t} \cdot \left(t \cdot \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix} + \begin{bmatrix} -\frac{1}{27} \\ 0 \\ 0 \end{bmatrix} \right)$$

- First component of the vector is the solution to the ODE

  $y(t) = \frac{e^{-2t}\left(\left(\left(t-\frac{1}{3}\right)c_3+c_2\right)e^{5t}+\frac{9c_1}{4}\right)}{9}$

- Change variables back using $t = \ln(x)$

  $y = \frac{\left(\left(\ln(x)-\frac{1}{3}\right)c_3+c_2\right)x^5+\frac{9c_1}{4}}{9x^2}$

- Simplify

  $y = \frac{c_3 \ln(x) x^3}{9} + \frac{c_2 x^3}{9} - \frac{c_3 x^3}{27} + \frac{c_1}{4x^2}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_1", "second_order_change_of_variable_on_y_method_2", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - 4y'x + 6y = 4x - 6}$$

13.14.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -4x, C = 6, f(x) = 4x - 6$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 4y'x + 6y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 4xrx^{r-1} + 6x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 4r\,x^r + 6x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 4r + 6 = 0$$

Or

$$r^2 - 5r + 6 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = 2$$
$$r_2 = 3$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_2x^3 + c_1x^2$$

Next, we find the particular solution to the ODE

$$x^2y'' - 4y'x + 6y = 4x - 6$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2$$
$$y_2 = x^3$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & x^3 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(x^3) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & x^3 \\ 2x & 3x^2 \end{vmatrix}$$

Therefore

$$W = (x^2)(3x^2) - (x^3)(2x)$$

Which simplifies to

$$W = x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^3(4x-6)}{x^6}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{4x-6}{x^3} dx$$

Hence

$$u_1 = -\frac{3}{x^2} + \frac{4}{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2(4x-6)}{x^6}\, dx$$

Which simplifies to

$$u_2 = \int \frac{4x-6}{x^4} dx$$

Hence

$$u_2 = -\frac{2}{x^2} + \frac{2}{x^3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{3}{x^2} + \frac{4}{x}\right) x^2 + \left(-\frac{2}{x^2} + \frac{2}{x^3}\right) x^3$$

Which simplifies to

$$y_p(x) = 2x - 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= c_2 x^3 + c_1 x^2 + 2x - 1 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_2x^3 + c_1x^2 + 2x - 1 \tag{1}$$

Verification of solutions

$$y = c_2x^3 + c_1x^2 + 2x - 1$$

Verified OK.

13.14.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)$$

Where $p(x) = -\frac{4}{x}$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int -\frac{4}{x}\,dx} \\ &= \frac{1}{x^2} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= \frac{4x-6}{x^4} \\ \left(\frac{y}{x^2}\right)'' &= \frac{4x-6}{x^4} \end{aligned}$$

Integrating once gives

$$\left(\frac{y}{x^2}\right)' = \frac{-2x+2}{x^3} + c_1$$

Integrating again gives

$$\left(\frac{y}{x^2}\right) = \frac{c_1x^3 + 2x - 1}{x^2} + c_2$$

Hence the solution is

$$y = \frac{\frac{c_1x^3+2x-1}{x^2} + c_2}{\frac{1}{x^2}}$$

Or

$$y = c_1 x^3 + c_2 x^2 + 2x - 1$$

Summary
The solution(s) found are the following

$$y = c_1 x^3 + c_2 x^2 + 2x - 1 \tag{1}$$

Verification of solutions

$$y = c_1 x^3 + c_2 x^2 + 2x - 1$$

Verified OK.

13.14.3 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2 y'' - 4y'x + 6y = 0$$

In normal form the ode

$$x^2 y'' - 4y'x + 6y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{x} \\ q(x) &= \frac{6}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int -\frac{4}{x}dx\right)}dx \\
&= \int e^{4\ln(x)}\,dx \\
&= \int x^4 dx \\
&= \frac{x^5}{5}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{6}{x^2}}{x^8} \\
&= \frac{6}{x^{10}}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{6y(\tau)}{x^{10}} &= 0
\end{aligned}$$

But in terms of τ

$$\frac{6}{x^{10}} = \frac{6}{25\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{6y(\tau)}{25\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$25\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 6y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$25\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 6\tau^r = 0$$

Simplifying gives

$$25r(r-1)\,\tau^r + 0\,\tau^r + 6\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$25r(r-1) + 0 + 6 = 0$$

Or

$$25r^2 - 25r + 6 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{2}{5}$$
$$r_2 = \frac{3}{5}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{\frac{2}{5}} + c_2\tau^{\frac{3}{5}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 5^{\frac{3}{5}}\left(x^5\right)^{\frac{2}{5}}}{5} + \frac{c_2 5^{\frac{2}{5}}\left(x^5\right)^{\frac{3}{5}}}{5}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 5^{\frac{3}{5}} (x^5)^{\frac{2}{5}}}{5} + \frac{c_2 5^{\frac{2}{5}} (x^5)^{\frac{3}{5}}}{5}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = (x^5)^{\frac{2}{5}}$$
$$y_2 = (x^5)^{\frac{3}{5}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^5)^{\frac{2}{5}} & (x^5)^{\frac{3}{5}} \\ \frac{d}{dx}\left((x^5)^{\frac{2}{5}}\right) & \frac{d}{dx}\left((x^5)^{\frac{3}{5}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^5)^{\frac{2}{5}} & (x^5)^{\frac{3}{5}} \\ \frac{2x^4}{(x^5)^{\frac{3}{5}}} & \frac{3x^4}{(x^5)^{\frac{2}{5}}} \end{vmatrix}$$

Therefore

$$W = \left(\left(x^5\right)^{\frac{2}{5}}\right)\left(\frac{3x^4}{\left(x^5\right)^{\frac{2}{5}}}\right) - \left(\left(x^5\right)^{\frac{3}{5}}\right)\left(\frac{2x^4}{\left(x^5\right)^{\frac{3}{5}}}\right)$$

Which simplifies to

$$W = x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(x^5\right)^{\frac{3}{5}}\left(4x-6\right)}{x^6}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\left(x^5\right)^{\frac{3}{5}}\left(4x-6\right)}{x^6} dx$$

Hence

$$u_1 = \frac{\left(x^5\right)^{\frac{3}{5}}\left(-3+4x\right)}{x^5}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\left(x^5\right)^{\frac{2}{5}}\left(4x-6\right)}{x^6}\, dx$$

Which simplifies to

$$u_2 = \int \frac{\left(x^5\right)^{\frac{2}{5}}\left(4x-6\right)}{x^6} dx$$

Hence

$$u_2 = -\frac{2\left(x^5\right)^{\frac{2}{5}}\left(x-1\right)}{x^5}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = 2x - 1$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p \\ &= \left(\frac{c_1 5^{\frac{3}{5}} (x^5)^{\frac{2}{5}}}{5} + \frac{c_2 5^{\frac{2}{5}} (x^5)^{\frac{3}{5}}}{5}\right) + (2x - 1)\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 5^{\frac{3}{5}} (x^5)^{\frac{2}{5}}}{5} + \frac{c_2 5^{\frac{2}{5}} (x^5)^{\frac{3}{5}}}{5} + 2x - 1 \tag{1}$$

Verification of solutions

$$y = \frac{c_1 5^{\frac{3}{5}} (x^5)^{\frac{2}{5}}}{5} + \frac{c_2 5^{\frac{2}{5}} (x^5)^{\frac{3}{5}}}{5} + 2x - 1$$

Verified OK.

13.14.4 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -4x, C = 6, f(x) = 4x - 6$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 4y'x + 6y = 0$$

In normal form the ode

$$x^2y'' - 4y'x + 6y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned}p(x) &= -\frac{4}{x} \\ q(x) &= \frac{6}{x^2}\end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}
\tau' &= \frac{1}{c}\sqrt{q} \\
&= \frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{c} \\
\tau'' &= -\frac{\sqrt{6}}{c\sqrt{\frac{1}{x^2}}\,x^3}
\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{\sqrt{6}}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{4}{x}\frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= -\frac{5c\sqrt{6}}{6}
\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - \frac{5c\sqrt{6}\left(\frac{d}{d\tau}y(\tau)\right)}{6} + c^2 y(\tau) &= 0
\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = \mathrm{e}^{\frac{5\sqrt{6}\,c\tau}{12}}\left(c_1 \cosh\left(\frac{\sqrt{6}\,c\tau}{12}\right) + ic_2 \sinh\left(\frac{\sqrt{6}\,c\tau}{12}\right)\right)$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{6}\,\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = x^{\frac{5}{2}}\left(c_1\cosh\left(\frac{\ln(x)}{2}\right) + ic_2\sinh\left(\frac{\ln(x)}{2}\right)\right)
$$

Now the particular solution to this ODE is found

$$
x^2y'' - 4y'x + 6y = 4x - 6
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1y_1 + u_2y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \left(x^5\right)^{\frac{2}{5}} \\
y_2 &= \left(x^5\right)^{\frac{3}{5}}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^5)^{\frac{2}{5}} & (x^5)^{\frac{3}{5}} \\ \frac{d}{dx}\left((x^5)^{\frac{2}{5}}\right) & \frac{d}{dx}\left((x^5)^{\frac{3}{5}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^5)^{\frac{2}{5}} & (x^5)^{\frac{3}{5}} \\ \frac{2x^4}{(x^5)^{\frac{3}{5}}} & \frac{3x^4}{(x^5)^{\frac{2}{5}}} \end{vmatrix}$$

Therefore

$$W = \left((x^5)^{\frac{2}{5}}\right)\left(\frac{3x^4}{(x^5)^{\frac{2}{5}}}\right) - \left((x^5)^{\frac{3}{5}}\right)\left(\frac{2x^4}{(x^5)^{\frac{3}{5}}}\right)$$

Which simplifies to

$$W = x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^5)^{\frac{3}{5}}(4x-6)}{x^6}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^5)^{\frac{3}{5}}(4x-6)}{x^6}dx$$

Hence

$$u_1 = \frac{(x^5)^{\frac{3}{5}}(-3+4x)}{x^5}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^5)^{\frac{2}{5}}(4x-6)}{x^6}\,dx$$

Which simplifies to

$$u_2 = \int \frac{(x^5)^{\frac{2}{5}} (4x-6)}{x^6} dx$$

Hence

$$u_2 = -\frac{2(x^5)^{\frac{2}{5}} (x-1)}{x^5}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = 2x - 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(x^{\frac{5}{2}} \left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)\right) + (2x-1) \\ &= 2x - 1 + x^{\frac{5}{2}} \left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x)}{2}\right)\right) \end{aligned}$$

Which simplifies to

$$y = i x^{\frac{5}{2}} \sinh\left(\frac{\ln(x)}{2}\right) c_2 + x^{\frac{5}{2}} \cosh\left(\frac{\ln(x)}{2}\right) c_1 + 2x - 1$$

Summary

The solution(s) found are the following

$$y = i x^{\frac{5}{2}} \sinh\left(\frac{\ln(x)}{2}\right) c_2 + x^{\frac{5}{2}} \cosh\left(\frac{\ln(x)}{2}\right) c_1 + 2x - 1 \tag{1}$$

Verification of solutions

$$y = i x^{\frac{5}{2}} \sinh\left(\frac{\ln(x)}{2}\right) c_2 + x^{\frac{5}{2}} \cosh\left(\frac{\ln(x)}{2}\right) c_1 + 2x - 1$$

Verified OK.

13.14.5 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 4y'x + 6y = 0$$

In normal form the given ode is written as

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{x} \\ q(x) &= \frac{6}{x^2} \end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$\begin{aligned} Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\ &= \frac{6}{x^2} - \frac{\left(-\frac{4}{x}\right)'}{2} - \frac{\left(-\frac{4}{x}\right)^2}{4} \\ &= \frac{6}{x^2} - \frac{\left(\frac{4}{x^2}\right)}{2} - \frac{\left(\frac{16}{x^2}\right)}{4} \\ &= \frac{6}{x^2} - \left(\frac{2}{x^2}\right) - \frac{4}{x^2} \\ &= 0 \end{aligned}$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y = v(x)\,z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$\begin{aligned} z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2}dx\right)} \\ &= e^{-\int \frac{-\frac{4}{x}}{2}} \\ &= x^2 \end{aligned} \tag{5}$$

Hence (3) becomes

$$y = v(x)\, x^2 \tag{4}$$

Applying this change of variable to the original ode results in

$$x^4 v''(x) = 4x - 6$$

Which is now solved for $v(x)$ Simplyfing the ode gives

$$v''(x) = \frac{4x - 6}{x^4}$$

Integrating once gives

$$v'(x) = -\frac{2}{x^2} + \frac{2}{x^3} + c_1$$

Integrating again gives

$$v(x) = \frac{2}{x} - \frac{1}{x^2} + c_1 x + c_2$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= \left(c_1 x + \frac{2}{x} - \frac{1}{x^2} + c_2\right) (z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = x^2$$

Hence (7) becomes

$$y = \left(c_1 x + \frac{2}{x} - \frac{1}{x^2} + c_2\right) x^2$$

Therefore the homogeneous solution y_h is

$$y_h = \left(c_1 x + \frac{2}{x} - \frac{1}{x^2} + c_2\right) x^2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(x^5\right)^{\frac{2}{5}}$$

$$y_2 = \left(x^5\right)^{\frac{3}{5}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(x^5\right)^{\frac{2}{5}} & \left(x^5\right)^{\frac{3}{5}} \\ \frac{d}{dx}\left(\left(x^5\right)^{\frac{2}{5}}\right) & \frac{d}{dx}\left(\left(x^5\right)^{\frac{3}{5}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(x^5\right)^{\frac{2}{5}} & \left(x^5\right)^{\frac{3}{5}} \\ \frac{2x^4}{\left(x^5\right)^{\frac{3}{5}}} & \frac{3x^4}{\left(x^5\right)^{\frac{2}{5}}} \end{vmatrix}$$

Therefore

$$W = \left(\left(x^5\right)^{\frac{2}{5}}\right)\left(\frac{3x^4}{\left(x^5\right)^{\frac{2}{5}}}\right) - \left(\left(x^5\right)^{\frac{3}{5}}\right)\left(\frac{2x^4}{\left(x^5\right)^{\frac{3}{5}}}\right)$$

Which simplifies to

$$W = x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^5)^{\frac{3}{5}} (4x-6)}{x^6} \, dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^5)^{\frac{3}{5}} (4x-6)}{x^6} dx$$

Hence

$$u_1 = \frac{(x^5)^{\frac{3}{5}} (-3+4x)}{x^5}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^5)^{\frac{2}{5}} (4x-6)}{x^6} \, dx$$

Which simplifies to

$$u_2 = \int \frac{(x^5)^{\frac{2}{5}} (4x-6)}{x^6} dx$$

Hence

$$u_2 = -\frac{2(x^5)^{\frac{2}{5}} (x-1)}{x^5}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = 2x - 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(c_1 x + \frac{2}{x} - \frac{1}{x^2} + c_2\right) x^2\right) + (2x - 1) \end{aligned}$$

Which simplifies to

$$y = c_1 x^3 + c_2 x^2 + 4x - 2$$

Summary
The solution(s) found are the following

$$y = c_1x^3 + c_2x^2 + 4x - 2 \tag{1}$$

Verification of solutions

$$y = c_1x^3 + c_2x^2 + 4x - 2$$

Verified OK.

13.14.6 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -4x, C = 6, f(x) = 4x - 6$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 4y'x + 6y = 0$$

In normal form the ode

$$x^2y'' - 4y'x + 6y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = -\frac{4}{x}$$
$$q(x) = \frac{6}{x^2}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right)v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right)v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{4n}{x^2} + \frac{6}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 3 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{2v'(x)}{x} &= 0 \\ v''(x) + \frac{2v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{2u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{2u}{x} \end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{2}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{2}{x}\,dx \\ \ln(u) &= -2\ln(x) + c_1 \\ u &= e^{-2\ln(x)+c_1} \\ &= \frac{c_1}{x^2} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned}v'(x) &= u(x)\\ v(x) &= \int u(x)\, dx + c_2\\ &= -\frac{c_1}{x} + c_2\end{aligned}$$

Hence

$$\begin{aligned}y &= v(x)\, x^n\\ &= \left(-\frac{c_1}{x} + c_2\right) x^3\\ &= x^2(c_2 x - c_1)\end{aligned}$$

Now the particular solution to this ODE is found

$$x^2y'' - 4y'x + 6y = 4x - 6$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}y_1 &= x^2\\ y_2 &= x^3\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & x^3 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(x^3) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & x^3 \\ 2x & 3x^2 \end{vmatrix}$$

Therefore

$$W = (x^2)(3x^2) - (x^3)(2x)$$

Which simplifies to

$$W = x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^3(4x-6)}{x^6}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{4x-6}{x^3}dx$$

Hence

$$u_1 = -\frac{3}{x^2} + \frac{4}{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2(4x-6)}{x^6}\,dx$$

Which simplifies to

$$u_2 = \int \frac{4x - 6}{x^4} dx$$

Hence

$$u_2 = -\frac{2}{x^2} + \frac{2}{x^3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{3}{x^2} + \frac{4}{x}\right) x^2 + \left(-\frac{2}{x^2} + \frac{2}{x^3}\right) x^3$$

Which simplifies to

$$y_p(x) = 2x - 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(-\frac{c_1}{x} + c_2\right) x^3\right) + (2x - 1) \\ &= 2x - 1 + \left(-\frac{c_1}{x} + c_2\right) x^3 \end{aligned}$$

Which simplifies to

$$y = c_2 x^3 - c_1 x^2 + 2x - 1$$

Summary

The solution(s) found are the following

$$y = c_2 x^3 - c_1 x^2 + 2x - 1 \tag{1}$$

Verification of solutions

$$y = c_2 x^3 - c_1 x^2 + 2x - 1$$

Verified OK.

13.14.7 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 4y'x + 6y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -4x \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 491: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x}{x^2}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{2\ln(x)} \\
&= z_1 \left(x^2\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^2
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{x^2}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{4\ln(x)}}{\left(y_1\right)^2}\, dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^2\right) + c_2 \left(x^2(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2 y'' - 4y'x + 6y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_2 x^3 + c_1 x^2
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2$$
$$y_2 = x^3$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & x^3 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(x^3) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & x^3 \\ 2x & 3x^2 \end{vmatrix}$$

Therefore

$$W = (x^2)(3x^2) - (x^3)(2x)$$

Which simplifies to

$$W = x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^3(4x-6)}{x^6}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{4x-6}{x^3} dx$$

Hence

$$u_1 = -\frac{3}{x^2} + \frac{4}{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2(4x-6)}{x^6}\, dx$$

Which simplifies to

$$u_2 = \int \frac{4x-6}{x^4} dx$$

Hence

$$u_2 = -\frac{2}{x^2} + \frac{2}{x^3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{3}{x^2} + \frac{4}{x}\right) x^2 + \left(-\frac{2}{x^2} + \frac{2}{x^3}\right) x^3$$

Which simplifies to

$$y_p(x) = 2x - 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_2 x^3 + c_1 x^2\right) + (2x - 1) \end{aligned}$$

Which simplifies to

$$y = x^2(c_2x + c_1) + 2x - 1$$

Summary

The solution(s) found are the following

$$y = x^2(c_2x + c_1) + 2x - 1 \tag{1}$$

Verification of solutions

$$y = x^2(c_2x + c_1) + 2x - 1$$

Verified OK.

$$\boxed{x^2y'' - 5y'x + 8y = 2x^3}$$

13.15.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -5x, C = 8, f(x) = 2x^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 5y'x + 8y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 5xrx^{r-1} + 8x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 5r\,x^r + 8x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 5r + 8 = 0$$

Or

$$r^2 - 6r + 8 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = 2$$
$$r_2 = 4$$

Since the roots are real and distinct, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_2 x^4 + c_1 x^2$$

Next, we find the particular solution to the ODE

$$x^2 y'' - 5y'x + 8y = 2x^3$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2$$
$$y_2 = x^4$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & x^4 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(x^4) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & x^4 \\ 2x & 4x^3 \end{vmatrix}$$

Therefore

$$W = (x^2)(4x^3) - (x^4)(2x)$$

Which simplifies to

$$W = 2x^5$$

Which simplifies to

$$W = 2x^5$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2x^7}{2x^7}\,dx$$

Which simplifies to

$$u_1 = -\int 1 dx$$

Hence

$$u_1 = -x$$

And Eq. (3) becomes

$$u_2 = \int \frac{2x^5}{2x^7}\, dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x^2} dx$$

Hence

$$u_2 = -\frac{1}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2x^3$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= x^2\left(c_2x^2 + c_1 - 2x\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = x^2\left(c_2x^2 + c_1 - 2x\right) \tag{1}$$

Verification of solutions

$$y = x^2\left(c_2x^2 + c_1 - 2x\right)$$

Verified OK.

13.15.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 5y'x + 8y = 0$$

In normal form the ode

$$x^2y'' - 5y'x + 8y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{5}{x} \\ q(x) &= \frac{8}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'\,(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'\,(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}\,dx \\ &= \int \mathrm{e}^{-\left(\int -\frac{5}{x}dx\right)}\,dx \\ &= \int e^{5\ln(x)}\,dx \\ &= \int x^5 dx \\ &= \frac{x^6}{6} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{8}{x^2}}{x^{10}} \\
&= \frac{8}{x^{12}}
\end{aligned} \tag{7}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{8y(\tau)}{x^{12}} &= 0
\end{aligned}
$$

But in terms of τ

$$
\frac{8}{x^{12}} = \frac{2}{9\tau^2}
$$

Hence the above ode becomes

$$
\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{9\tau^2} = 0
$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$
9\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 2y(\tau) = 0
$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$
9\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 2\tau^r = 0
$$

Simplifying gives

$$
9r(r-1)\,\tau^r + 0\,\tau^r + 2\tau^r = 0
$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$
9r(r-1) + 0 + 2 = 0
$$

Or

$$
9r^2 - 9r + 2 = 0 \tag{1}
$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{3}$$
$$r_2 = \frac{2}{3}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1 \tau^{\frac{1}{3}} + c_2 \tau^{\frac{2}{3}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 6^{\frac{2}{3}} (x^6)^{\frac{1}{3}}}{6} + \frac{c_2 6^{\frac{1}{3}} (x^6)^{\frac{2}{3}}}{6}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 6^{\frac{2}{3}} (x^6)^{\frac{1}{3}}}{6} + \frac{c_2 6^{\frac{1}{3}} (x^6)^{\frac{2}{3}}}{6}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = (x^6)^{\frac{1}{3}}$$
$$y_2 = (x^6)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^6)^{\frac{1}{3}} & (x^6)^{\frac{2}{3}} \\ \frac{d}{dx}\left((x^6)^{\frac{1}{3}}\right) & \frac{d}{dx}\left((x^6)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^6)^{\frac{1}{3}} & (x^6)^{\frac{2}{3}} \\ \frac{2x^5}{(x^6)^{\frac{2}{3}}} & \frac{4x^5}{(x^6)^{\frac{1}{3}}} \end{vmatrix}$$

Therefore

$$W = \left((x^6)^{\frac{1}{3}}\right)\left(\frac{4x^5}{(x^6)^{\frac{1}{3}}}\right) - \left((x^6)^{\frac{2}{3}}\right)\left(\frac{2x^5}{(x^6)^{\frac{2}{3}}}\right)$$

Which simplifies to

$$W = 2x^5$$

Which simplifies to

$$W = 2x^5$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2(x^6)^{\frac{2}{3}}\, x^3}{2x^7}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^6)^{\frac{2}{3}}}{x^4} dx$$

Hence

$$u_1 = -\frac{(x^6)^{\frac{2}{3}}}{x^3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{2(x^6)^{\frac{1}{3}}\, x^3}{2x^7}\, dx$$

Which simplifies to

$$u_2 = \int \frac{(x^6)^{\frac{1}{3}}}{x^4} dx$$

Hence

$$u_2 = -\frac{(x^6)^{\frac{1}{3}}}{x^3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2x^3$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 6^{\frac{2}{3}} (x^6)^{\frac{1}{3}}}{6} + \frac{c_2 6^{\frac{1}{3}} (x^6)^{\frac{2}{3}}}{6}\right) + (-2x^3) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 6^{\frac{2}{3}} (x^6)^{\frac{1}{3}}}{6} + \frac{c_2 6^{\frac{1}{3}} (x^6)^{\frac{2}{3}}}{6} - 2x^3 \tag{1}$$

Verification of solutions

$$y = \frac{c_1 6^{\frac{2}{3}} (x^6)^{\frac{1}{3}}}{6} + \frac{c_2 6^{\frac{1}{3}} (x^6)^{\frac{2}{3}}}{6} - 2x^3$$

Verified OK.

13.15.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -5x, C = 8, f(x) = 2x^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. Solving for y_h from

$$x^2y''-5y'x+8y=0$$

In normal form the ode

$$x^2y''-5y'x+8y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned}p(x)&=-\frac{5}{x}\\ q(x)&=\frac{8}{x^2}\end{aligned}$$

Applying change of variables $\tau=g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau)+p_1\left(\frac{d}{d\tau}y(\tau)\right)+q_1y(\tau)=0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau)=\frac{\tau''(x)+p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau)=\frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1=c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}\tau'&=\frac{1}{c}\sqrt{q}\\ &=\frac{2\sqrt{2}\,\sqrt{\frac{1}{x^2}}}{c} \qquad (6)\\ \tau''&=-\frac{2\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\,x^3}\end{aligned}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'\,(x)^2} \\ &= \frac{-\frac{2\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{5}{x}\,\frac{2\sqrt{2}\,\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{2\sqrt{2}\,\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= -\frac{3c\sqrt{2}}{2} \end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned} y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) - \frac{3c\sqrt{2}\left(\frac{d}{d\tau}y(\tau)\right)}{2} + c^2 y(\tau) &= 0 \end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = \mathrm{e}^{\frac{3\sqrt{2}\,c\tau}{4}}\left(c_1 \cosh\left(\frac{\sqrt{2}\,c\tau}{4}\right) + ic_2 \sinh\left(\frac{\sqrt{2}\,c\tau}{4}\right)\right)$$

Now from (6)

$$\begin{aligned} \tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int 2\sqrt{2}\,\sqrt{\frac{1}{x^2}}dx}{c} \\ &= \frac{2\sqrt{2}\,\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c} \end{aligned}$$

Substituting the above into the solution obtained gives

$$y = \frac{((ic_2 + c_1)\,x^2 - ic_2 + c_1)\,x^2}{2}$$

Now the particular solution to this ODE is found

$$x^2y'' - 5y'x + 8y = 2x^3$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = (x^6)^{\frac{1}{3}}$$
$$y_2 = (x^6)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^6)^{\frac{1}{3}} & (x^6)^{\frac{2}{3}} \\ \frac{d}{dx}\left((x^6)^{\frac{1}{3}}\right) & \frac{d}{dx}\left((x^6)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^6)^{\frac{1}{3}} & (x^6)^{\frac{2}{3}} \\ \frac{2x^5}{(x^6)^{\frac{2}{3}}} & \frac{4x^5}{(x^6)^{\frac{1}{3}}} \end{vmatrix}$$

Therefore

$$W = \left((x^6)^{\frac{1}{3}}\right)\left(\frac{4x^5}{(x^6)^{\frac{1}{3}}}\right) - \left((x^6)^{\frac{2}{3}}\right)\left(\frac{2x^5}{(x^6)^{\frac{2}{3}}}\right)$$

Which simplifies to

$$W = 2x^5$$

Which simplifies to

$$W = 2x^5$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2\left(x^6\right)^{\frac{2}{3}} x^3}{2x^7} \, dx$$

Which simplifies to

$$u_1 = -\int \frac{\left(x^6\right)^{\frac{2}{3}}}{x^4} dx$$

Hence

$$u_1 = -\frac{\left(x^6\right)^{\frac{2}{3}}}{x^3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{2\left(x^6\right)^{\frac{1}{3}} x^3}{2x^7} \, dx$$

Which simplifies to

$$u_2 = \int \frac{\left(x^6\right)^{\frac{1}{3}}}{x^4} dx$$

Hence

$$u_2 = -\frac{\left(x^6\right)^{\frac{1}{3}}}{x^3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2x^3$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{\left(\left(ic_2 + c_1\right) x^2 - ic_2 + c_1\right) x^2}{2}\right) + \left(-2x^3\right) \\ &= -2x^3 + \frac{\left(\left(ic_2 + c_1\right) x^2 - ic_2 + c_1\right) x^2}{2} \end{aligned}$$

Which simplifies to

$$y = \frac{x^2((ic_2 + c_1) x^2 - 4x - ic_2 + c_1)}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2((ic_2 + c_1) x^2 - 4x - ic_2 + c_1)}{2} \tag{1}$$

Verification of solutions

$$y = \frac{x^2((ic_2 + c_1) x^2 - 4x - ic_2 + c_1)}{2}$$

Verified OK.

13.15.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -5x, C = 8, f(x) = 2x^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 5y'x + 8y = 0$$

In normal form the ode

$$x^2y'' - 5y'x + 8y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = -\frac{5}{x}$$
$$q(x) = \frac{8}{x^2}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{5n}{x^2} + \frac{8}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 4 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{3v'(x)}{x} &= 0 \\ v''(x) + \frac{3v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{3u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{3u}{x} \end{aligned}$$

Where $f(x) = -\frac{3}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u} \, du &= -\frac{3}{x} \, dx \\
\int \frac{1}{u} \, du &= \int -\frac{3}{x} \, dx \\
\ln(u) &= -3\ln(x) + c_1 \\
u &= \mathrm{e}^{-3\ln(x)+c_1} \\
&= \frac{c_1}{x^3}
\end{aligned}
$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x) \, dx + c_2 \\
&= -\frac{c_1}{2x^2} + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x) \, x^n \\
&= \left(-\frac{c_1}{2x^2} + c_2\right) x^4 \\
&= c_2 x^4 - \frac{1}{2} c_1 x^2
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
x^2 y'' - 5y'x + 8y = 2x^3
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x^2 \\
y_2 &= x^4
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & x^4 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(x^4) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & x^4 \\ 2x & 4x^3 \end{vmatrix}$$

Therefore

$$W = (x^2)(4x^3) - (x^4)(2x)$$

Which simplifies to

$$W = 2x^5$$

Which simplifies to

$$W = 2x^5$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2x^7}{2x^7} \, dx$$

Which simplifies to

$$u_1 = -\int 1 dx$$

Hence

$$u_1 = -x$$

And Eq. (3) becomes

$$u_2 = \int \frac{2x^5}{2x^7}\, dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x^2} dx$$

Hence

$$u_2 = -\frac{1}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2x^3$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(-\frac{c_1}{2x^2} + c_2\right) x^4\right) + \left(-2x^3\right) \\ &= -2x^3 + \left(-\frac{c_1}{2x^2} + c_2\right) x^4 \end{aligned}$$

Which simplifies to

$$y = -\frac{x^2(-2c_2x^2 + c_1 + 4x)}{2}$$

Summary

The solution(s) found are the following

$$y = -\frac{x^2(-2c_2x^2 + c_1 + 4x)}{2} \tag{1}$$

Verification of solutions

$$y = -\frac{x^2(-2c_2x^2 + c_1 + 4x)}{2}$$

Verified OK.

13.15.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 5y'x + 8y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -5x \\ C &= 8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 492: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{3}{4x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{3}{4x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{3}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{2x} + (-)(0) \\
&= -\frac{1}{2x} \\
&= -\frac{1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(-\frac{1}{2x}\right)^2 - \left(\frac{3}{4x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int -\frac{1}{2x} dx} \\
&= \frac{1}{\sqrt{x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-5x}{x^2}\, dx} \\
&= z_1 e^{\frac{5\ln(x)}{2}} \\
&= z_1 \left(x^{\frac{5}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^2
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-5x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{5\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{x^2}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^2\right) + c_2 \left(x^2 \left(\frac{x^2}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2 y'' - 5y'x + 8y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 x^2 + \frac{1}{2} c_2 x^4$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2$$
$$y_2 = \frac{x^4}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & \frac{x^4}{2} \\ \frac{d}{dx}(x^2) & \frac{d}{dx}\left(\frac{x^4}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & \frac{x^4}{2} \\ 2x & 2x^3 \end{vmatrix}$$

Therefore

$$W = (x^2)(2x^3) - \left(\frac{x^4}{2}\right)(2x)$$

Which simplifies to

$$W = x^5$$

Which simplifies to

$$W = x^5$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^7}{x^7}\, dx$$

Which simplifies to

$$u_1 = -\int 1 dx$$

Hence

$$u_1 = -x$$

And Eq. (3) becomes

$$u_2 = \int \frac{2x^5}{x^7}\, dx$$

Which simplifies to

$$u_2 = \int \frac{2}{x^2} dx$$

Hence

$$u_2 = -\frac{2}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2x^3$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 x^2 + \frac{1}{2} c_2 x^4\right) + \left(-2x^3\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x^2 + \frac{1}{2} c_2 x^4 - 2x^3 \tag{1}
$$

Verification of solutions

$$
y = c_1 x^2 + \frac{1}{2} c_2 x^4 - 2x^3
$$

Verified OK.

$$\boxed{x^2y'' + 4y'x + 2y = 4\ln(x)}$$

13.16.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 4x, C = 2, f(x) = 4\ln(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 4y'x + 2y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 4xrx^{r-1} + 2x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 4r\,x^r + 2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 4r + 2 = 0$$

Or

$$r^2 + 3r + 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -2$$
$$r_2 = -1$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = \frac{c_1}{x^2} + \frac{c_2}{x}$$

Next, we find the particular solution to the ODE

$$x^2y'' + 4y'x + 2y = 4\ln(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x^2}$$
$$y_2 = \frac{1}{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{1}{x} \\ \frac{d}{dx}\left(\frac{1}{x^2}\right) & \frac{d}{dx}\left(\frac{1}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{1}{x} \\ -\frac{2}{x^3} & -\frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^2}\right)\left(-\frac{1}{x^2}\right) - \left(\frac{1}{x}\right)\left(-\frac{2}{x^3}\right)$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{4\ln(x)}{x}}{\frac{1}{x^2}}\, dx$$

Which simplifies to

$$u_1 = -\int 4x \ln (x)\, dx$$

Hence

$$u_1 = -2x^2 \ln (x) + x^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{4\ln(x)}{x^2}}{\frac{1}{x^2}}\, dx$$

Which simplifies to

$$u_2 = \int 4 \ln (x)\, dx$$

Hence

$$u_2 = 4x \ln (x) - 4x$$

Which simplifies to

$$u_1 = x^2(1 - 2\ln (x))$$
$$u_2 = 4x \ln (x) - 4x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = 1 - 2\ln (x) + \frac{4x \ln (x) - 4x}{x}$$

Which simplifies to

$$y_p(x) = -3 + 2\ln (x)$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= -3 + 2\ln(x) + \frac{c_1}{x^2} + \frac{c_2}{x}
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = -3 + 2\ln(x) + \frac{c_1}{x^2} + \frac{c_2}{x} \tag{1}
$$

Verification of solutions

$$
y = -3 + 2\ln(x) + \frac{c_1}{x^2} + \frac{c_2}{x}
$$

Verified OK.

13.16.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$
y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)
$$

Where $p(x) = \frac{4}{x}$. Therefore, there is an integrating factor given by

$$
\begin{aligned}
M(x) &= e^{\frac{1}{2}\int p\,dx} \\
&= e^{\int \frac{4}{x}\,dx} \\
&= x^2
\end{aligned}
$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= 4\ln(x) \\
\left(x^2 y\right)'' &= 4\ln(x)
\end{aligned}
$$

Integrating once gives

$$
\left(x^2 y\right)' = 4x\ln(x) - 4x + c_1
$$

Integrating again gives

$$
\left(x^2 y\right) = x(2x\ln(x) + c_1 - 3x) + c_2
$$

Hence the solution is

$$y = \frac{x(2x \ln(x) + c_1 - 3x) + c_2}{x^2}$$

Or

$$y = 2\ln(x) + \frac{c_1}{x} + \frac{c_2}{x^2} - 3$$

<u>Summary</u>
The solution(s) found are the following

$$y = 2\ln(x) + \frac{c_1}{x} + \frac{c_2}{x^2} - 3 \tag{1}$$

<u>Verification of solutions</u>

$$y = 2\ln(x) + \frac{c_1}{x} + \frac{c_2}{x^2} - 3$$

Verified OK.

13.16.3 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + 4y'x + 2y = 0$$

In normal form the ode

$$x^2y'' + 4y'x + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = \frac{4}{x}$$
$$q(x) = \frac{2}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}\tau &= \int e^{-\left(\int p(x)dx\right)}\,dx \\ &= \int e^{-\left(\int \frac{4}{x}dx\right)}\,dx \\ &= \int e^{-4\ln(x)}\,dx \\ &= \int \frac{1}{x^4}dx \\ &= -\frac{1}{3x^3}\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{2}{x^2}}{\frac{1}{x^8}} \\ &= 2x^6\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + 2x^6 y(\tau) &= 0\end{aligned}$$

But in terms of τ

$$2x^6 = \frac{2}{9\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{9\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$9\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 2y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$9\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 2\tau^r = 0$$

Simplifying gives

$$9r(r-1)\,\tau^r + 0\,\tau^r + 2\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$9r(r-1) + 0 + 2 = 0$$

Or

$$9r^2 - 9r + 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{3}$$
$$r_2 = \frac{2}{3}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{\frac{1}{3}} + c_2\tau^{\frac{2}{3}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 3^{\frac{2}{3}}\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}}\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}}{3}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 3^{\frac{2}{3}} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} \left(-\frac{1}{x^3}\right)^{\frac{2}{3}}}{3}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(-\frac{1}{x^3}\right)^{\frac{1}{3}}$$

$$y_2 = \left(-\frac{1}{x^3}\right)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} & \left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \\ \frac{d}{dx}\left(\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}\right) & \frac{d}{dx}\left(\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} & \left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \\ \frac{1}{\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^4} & \frac{2}{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^4} \end{vmatrix}$$

Therefore

$$W = \left(\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}\right)\left(\frac{2}{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^4}\right) - \left(\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}\right)\left(\frac{1}{\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^4}\right)$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \ln(x)}{\frac{1}{x^2}} dx$$

Which simplifies to

$$u_1 = -\int 4\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \ln(x)\, x^2 dx$$

Hence

$$u_1 = -4\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^3 \ln(x) + 4\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^3$$

And Eq. (3) becomes

$$u_2 = \int \frac{4\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} \ln(x)}{\frac{1}{x^2}} dx$$

Which simplifies to

$$u_2 = \int 4\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} \ln(x)\, x^2 dx$$

Hence

$$u_2 = 2\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3 \ln(x) - \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3$$

Which simplifies to

$$u_1 = -4\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^3(\ln(x) - 1)$$

$$u_2 = \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3(-1 + 2\ln(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -3 + 2\ln(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 3^{\frac{2}{3}} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} \left(-\frac{1}{x^3}\right)^{\frac{2}{3}}}{3}\right) + (-3 + 2\ln(x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 3^{\frac{2}{3}} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} \left(-\frac{1}{x^3}\right)^{\frac{2}{3}}}{3} - 3 + 2\ln(x) \tag{1}$$

Verification of solutions

$$y = \frac{c_1 3^{\frac{2}{3}} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} \left(-\frac{1}{x^3}\right)^{\frac{2}{3}}}{3} - 3 + 2\ln(x)$$

Verified OK.

13.16.4 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 4x, C = 2, f(x) = 4\ln(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 4y'x + 2y = 0$$

In normal form the ode

$$x^2y'' + 4y'x + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{4}{x} \\ q(x) &= \frac{2}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{2}\,\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\,x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\,x^3} + \frac{4}{x}\frac{\sqrt{2}\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{2}\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= \frac{3c\sqrt{2}}{2}
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{3c\sqrt{2}\left(\frac{d}{d\tau}y(\tau)\right)}{2} + c^2 y(\tau) &= 0 \qquad (7)
\end{aligned}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = \mathrm{e}^{-\frac{3\sqrt{2}\,c\tau}{4}}\left(c_1\cosh\left(\frac{\sqrt{2}\,c\tau}{4}\right) + ic_2\sinh\left(\frac{\sqrt{2}\,c\tau}{4}\right)\right)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{2}\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{2}\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = \frac{c_1\cosh\left(\frac{\ln(x)}{2}\right) + ic_2\sinh\left(\frac{\ln(x)}{2}\right)}{x^{\frac{3}{2}}}
$$

Now the particular solution to this ODE is found

$$
x^2y'' + 4y'x + 2y = 4\ln(x)
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(-\frac{1}{x^3}\right)^{\frac{1}{3}}$$

$$y_2 = \left(-\frac{1}{x^3}\right)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} & \left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \\ \frac{d}{dx}\left(\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}\right) & \frac{d}{dx}\left(\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} & \left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \\ \frac{1}{\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^4} & \frac{2}{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^4} \end{vmatrix}$$

Therefore

$$W = \left(\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}\right)\left(\frac{2}{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^4}\right) - \left(\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}\right)\left(\frac{1}{\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^4}\right)$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \ln(x)}{\frac{1}{x^2}} dx$$

Which simplifies to

$$u_1 = -\int 4\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \ln(x)\, x^2 dx$$

Hence

$$u_1 = -4\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^3 \ln(x) + 4\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^3$$

And Eq. (3) becomes

$$u_2 = \int \frac{4\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} \ln(x)}{\frac{1}{x^2}} dx$$

Which simplifies to

$$u_2 = \int 4\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} \ln(x)\, x^2 dx$$

Hence

$$u_2 = 2\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3 \ln(x) - \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3$$

Which simplifies to

$$u_1 = -4\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^3(\ln(x) - 1)$$

$$u_2 = \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3(-1 + 2\ln(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -3 + 2\ln(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)}{x^{\frac{3}{2}}}\right) + (-3 + 2\ln(x)) \\ &= -3 + 2\ln(x) + \frac{c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)}{x^{\frac{3}{2}}} \end{aligned}$$

Which simplifies to

$$y = -3 + 2\ln(x) + \frac{c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)}{x^{\frac{3}{2}}}$$

Summary

The solution(s) found are the following

$$y = -3 + 2\ln(x) + \frac{c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)}{x^{\frac{3}{2}}} \tag{1}$$

Verification of solutions

$$y = -3 + 2\ln(x) + \frac{c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)}{x^{\frac{3}{2}}}$$

Verified OK.

13.16.5 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + 4y'x + 2y = 0$$

In normal form the given ode is written as

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{4}{x} \\ q(x) &= \frac{2}{x^2} \end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$\begin{aligned} Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\ &= \frac{2}{x^2} - \frac{\left(\frac{4}{x}\right)'}{2} - \frac{\left(\frac{4}{x}\right)^2}{4} \\ &= \frac{2}{x^2} - \frac{\left(-\frac{4}{x^2}\right)}{2} - \frac{\left(\frac{16}{x^2}\right)}{4} \\ &= \frac{2}{x^2} - \left(-\frac{2}{x^2}\right) - \frac{4}{x^2} \\ &= 0 \end{aligned}$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y = v(x)\, z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$\begin{aligned} z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\ &= e^{-\int \frac{\frac{4}{x}}{2}} \\ &= \frac{1}{x^2} \end{aligned} \tag{5}$$

Hence (3) becomes

$$y = \frac{v(x)}{x^2} \tag{4}$$

Applying this change of variable to the original ode results in

$$v''(x) = 4 \ln(x)$$

Which is now solved for $v(x)$ Integrating once gives

$$v'(x) = 4x\ln(x) - 4x + c_1$$

Integrating again gives

$$v(x) = 2x^2\ln(x) - 3x^2 + c_1x + c_2$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= \left(-3x^2 + c_1x + 2x^2\ln(x) + c_2\right)(z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = \frac{1}{x^2}$$

Hence (7) becomes

$$y = \frac{-3x^2 + c_1x + 2x^2\ln(x) + c_2}{x^2}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{-3x^2 + c_1x + 2x^2\ln(x) + c_2}{x^2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(-\frac{1}{x^3}\right)^{\frac{1}{3}}$$

$$y_2 = \left(-\frac{1}{x^3}\right)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} & \left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \\ \frac{d}{dx}\left(\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}\right) & \frac{d}{dx}\left(\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} & \left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \\ \frac{1}{\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^4} & \frac{2}{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^4} \end{vmatrix}$$

Therefore

$$W = \left(\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}\right)\left(\frac{2}{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^4}\right) - \left(\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}\right)\left(\frac{1}{\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^4}\right)$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \ln(x)}{\frac{1}{x^2}}\, dx$$

Which simplifies to

$$u_1 = -\int 4\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \ln(x)\, x^2 dx$$

Hence

$$u_1 = -4\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^3 \ln(x) + 4\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^3$$

And Eq. (3) becomes

$$u_2 = \int \frac{4\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} \ln(x)}{\frac{1}{x^2}} dx$$

Which simplifies to

$$u_2 = \int 4\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} \ln(x)\, x^2 dx$$

Hence

$$u_2 = 2\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3 \ln(x) - \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3$$

Which simplifies to

$$u_1 = -4\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^3(\ln(x) - 1)$$

$$u_2 = \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3(-1 + 2\ln(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -3 + 2\ln(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{-3x^2 + c_1 x + 2x^2 \ln(x) + c_2}{x^2}\right) + (-3 + 2\ln(x)) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{-3x^2 + c_1 x + 2x^2 \ln(x) + c_2}{x^2} - 3 + 2\ln(x) \tag{1}$$

Verification of solutions

$$y = \frac{-3x^2 + c_1 x + 2x^2 \ln(x) + c_2}{x^2} - 3 + 2\ln(x)$$

Verified OK.

13.16.6 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 4x, C = 2, f(x) = 4\ln(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 4y'x + 2y = 0$$

In normal form the ode

$$x^2y'' + 4y'x + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = \frac{4}{x}$$
$$q(x) = \frac{2}{x^2}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{4n}{x^2} + \frac{2}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = -1 \tag{6}$$

Substituting this value in (3) gives

$$v''(x) + \frac{2v'(x)}{x} = 0$$
$$v''(x) + \frac{2v'(x)}{x} = 0 \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{2u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{2u}{x} \end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{2}{x}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{2}{x}\, dx \\ \ln(u) &= -2\ln(x) + c_1 \\ u &= \mathrm{e}^{-2\ln(x)+c_1} \\ &= \frac{c_1}{x^2} \end{aligned}$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= -\frac{c_1}{x} + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \frac{-\frac{c_1}{x} + c_2}{x} \\
&= \frac{c_2 x - c_1}{x^2}
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
x^2 y'' + 4y' x + 2y = 4 \ln(x)
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \frac{1}{x^2} \\
y_2 &= \frac{1}{x}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{1}{x} \\ \frac{d}{dx}\left(\frac{1}{x^2}\right) & \frac{d}{dx}\left(\frac{1}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{1}{x} \\ -\frac{2}{x^3} & -\frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^2}\right)\left(-\frac{1}{x^2}\right) - \left(\frac{1}{x}\right)\left(-\frac{2}{x^3}\right)$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{4\ln(x)}{x}}{\frac{1}{x^2}}\,dx$$

Which simplifies to

$$u_1 = -\int 4x \ln(x)\,dx$$

Hence

$$u_1 = -2x^2 \ln(x) + x^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{4\ln(x)}{x^2}}{\frac{1}{x^2}}\,dx$$

Which simplifies to

$$u_2 = \int 4\ln(x)\,dx$$

Hence

$$u_2 = 4x\ln(x) - 4x$$

Which simplifies to

$$u_1 = x^2(1 - 2\ln(x))$$
$$u_2 = 4x\ln(x) - 4x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = 1 - 2\ln(x) + \frac{4x\ln(x) - 4x}{x}$$

Which simplifies to

$$y_p(x) = -3 + 2\ln(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{-\frac{c_1}{x} + c_2}{x}\right) + (-3 + 2\ln(x)) \\ &= -3 + 2\ln(x) + \frac{-\frac{c_1}{x} + c_2}{x} \end{aligned}$$

Which simplifies to

$$y = -3 + 2\ln(x) + \frac{-\frac{c_1}{x} + c_2}{x}$$

Summary
The solution(s) found are the following

$$y = -3 + 2\ln(x) + \frac{-\frac{c_1}{x} + c_2}{x} \tag{1}$$

Verification of solutions

$$y = -3 + 2\ln(x) + \frac{-\frac{c_1}{x} + c_2}{x}$$

Verified OK.

13.16.7 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2 y'' + 4y'x + 2y)\, dx = \int 4\ln(x)\, dx$$
$$x^2 y' + 2yx = 4x \ln(x) - 4x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{2}{x}$$
$$q(x) = \frac{4x\ln(x) - 4x + c_1}{x^2}$$

Hence the ode is

$$y' + \frac{2y}{x} = \frac{4x\ln(x) - 4x + c_1}{x^2}$$

The integrating factor μ is

$$\mu = e^{\int \frac{2}{x} dx}$$
$$= x^2$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{4x\ln(x) - 4x + c_1}{x^2}\right)$$
$$\frac{d}{dx}(x^2 y) = (x^2)\left(\frac{4x\ln(x) - 4x + c_1}{x^2}\right)$$
$$d(x^2 y) = (4x\ln(x) - 4x + c_1)\, dx$$

Integrating gives

$$x^2 y = \int 4x\ln(x) - 4x + c_1\, dx$$
$$x^2 y = -3x^2 + c_1 x + 2x^2 \ln(x) + c_2$$

Dividing both sides by the integrating factor $\mu = x^2$ results in

$$y = \frac{-3x^2 + c_1 x + 2x^2 \ln(x)}{x^2} + \frac{c_2}{x^2}$$

which simplifies to

$$y = \frac{-3x^2 + c_1 x + 2x^2 \ln(x) + c_2}{x^2}$$

Summary

The solution(s) found are the following

$$y = \frac{-3x^2 + c_1 x + 2x^2 \ln(x) + c_2}{x^2} \tag{1}$$

Verification of solutions

$$y = \frac{-3x^2 + c_1 x + 2x^2 \ln(x) + c_2}{x^2}$$

Verified OK.

13.16.8 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$x^2 y'' + 4y'x + 2y = 4\ln(x)$$

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2 y'' + 4y'x + 2y)\, dx = \int 4\ln(x)\, dx$$
$$x^2 y' + 2yx = 4x\ln(x) - 4x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{2}{x}$$
$$q(x) = \frac{4x\ln(x) - 4x + c_1}{x^2}$$

Hence the ode is

$$y' + \frac{2y}{x} = \frac{4x\ln(x) - 4x + c_1}{x^2}$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int \frac{2}{x} dx} \\
&= x^2
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{4x\ln(x) - 4x + c_1}{x^2}\right) \\
\frac{d}{dx}(x^2 y) &= (x^2)\left(\frac{4x\ln(x) - 4x + c_1}{x^2}\right) \\
d(x^2 y) &= (4x\ln(x) - 4x + c_1)\, dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
x^2 y &= \int 4x\ln(x) - 4x + c_1 \, dx \\
x^2 y &= -3x^2 + c_1 x + 2x^2 \ln(x) + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = x^2$ results in

$$
y = \frac{-3x^2 + c_1 x + 2x^2\ln(x)}{x^2} + \frac{c_2}{x^2}
$$

which simplifies to

$$
y = \frac{-3x^2 + c_1 x + 2x^2\ln(x) + c_2}{x^2}
$$

Summary
The solution(s) found are the following

$$
y = \frac{-3x^2 + c_1 x + 2x^2\ln(x) + c_2}{x^2} \tag{1}
$$

Verification of solutions

$$
y = \frac{-3x^2 + c_1 x + 2x^2\ln(x) + c_2}{x^2}
$$

Verified OK.

13.16.9 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + 4y'x + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 4x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 493: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4x}{x^2}\,dx} \end{aligned}$$

$$
\begin{aligned}
&= z_1 e^{-2\ln(x)} \\
&= z_1 \left(\frac{1}{x^2}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x^2}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-4\ln(x)}}{(y_1)^2}\, dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x^2}\right) + c_2 \left(\frac{1}{x^2}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' + 4y'x + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \frac{c_1}{x^2} + \frac{c_2}{x}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x^2}$$

$$y_2 = \frac{1}{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{1}{x} \\ \frac{d}{dx}\left(\frac{1}{x^2}\right) & \frac{d}{dx}\left(\frac{1}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{1}{x} \\ -\frac{2}{x^3} & -\frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^2}\right)\left(-\frac{1}{x^2}\right) - \left(\frac{1}{x}\right)\left(-\frac{2}{x^3}\right)$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{4\ln(x)}{x}}{\frac{1}{x^2}}\,dx$$

Which simplifies to

$$u_1 = -\int 4x\ln(x)\,dx$$

Hence

$$u_1 = -2x^2\ln(x) + x^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{4\ln(x)}{x^2}}{\frac{1}{x^2}}\,dx$$

Which simplifies to

$$u_2 = \int 4\ln(x)\,dx$$

Hence

$$u_2 = 4x\ln(x) - 4x$$

Which simplifies to

$$u_1 = x^2(1 - 2\ln(x))$$
$$u_2 = 4x\ln(x) - 4x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = 1 - 2\ln(x) + \frac{4x\ln(x) - 4x}{x}$$

Which simplifies to

$$y_p(x) = -3 + 2\ln(x)$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\frac{c_1}{x^2} + \frac{c_2}{x}\right) + (-3 + 2\ln(x))
\end{aligned}
$$

Which simplifies to

$$
y = \frac{c_2 x + c_1}{x^2} - 3 + 2\ln(x)
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_2 x + c_1}{x^2} - 3 + 2\ln(x) \tag{1}
$$

Verification of solutions

$$
y = \frac{c_2 x + c_1}{x^2} - 3 + 2\ln(x)
$$

Verified OK.

13.16.10 Solving as exact linear second order ode ode

An ode of the form

$$
p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)
$$

is exact if

$$
p''(x) - q'(x) + r(x) = 0 \tag{1}
$$

For the given ode we have

$$
\begin{aligned}
p(x) &= x^2 \\
q(x) &= 4x \\
r(x) &= 2 \\
s(x) &= 4\ln(x)
\end{aligned}
$$

Hence

$$
\begin{aligned}
p''(x) &= 2 \\
q'(x) &= 4
\end{aligned}
$$

Therefore (1) becomes

$$2-(4)+(2)=0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y'+(q(x)-p'(x))\,y)'=s(x)$$

Integrating gives

$$p(x)\,y'+(q(x)-p'(x))\,y=\int s(x)\;dx$$

Substituting the above values for p, q, r, s gives

$$x^2y'+2yx=\int 4\ln\left(x\right)\;dx$$

We now have a first order ode to solve which is

$$x^2y'+2yx=4x\ln\left(x\right)-4x+c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$\begin{aligned}p(x)&=\frac{2}{x}\\ q(x)&=\frac{4x\ln\left(x\right)-4x+c_1}{x^2}\end{aligned}$$

Hence the ode is

$$y'+\frac{2y}{x}=\frac{4x\ln\left(x\right)-4x+c_1}{x^2}$$

The integrating factor μ is

$$\begin{aligned}\mu&=\mathrm{e}^{\int\frac{2}{x}dx}\\ &=x^2\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y)&=(\mu)\left(\frac{4x\ln\left(x\right)-4x+c_1}{x^2}\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}(x^2y)&=(x^2)\left(\frac{4x\ln\left(x\right)-4x+c_1}{x^2}\right)\\ \mathrm{d}(x^2y)&=(4x\ln\left(x\right)-4x+c_1)\;\mathrm{d}x\end{aligned}$$

Integrating gives

$$x^2y = \int 4x\ln(x) - 4x + c_1\, \mathrm{d}x$$
$$x^2y = -3x^2 + c_1x + 2x^2\ln(x) + c_2$$

Dividing both sides by the integrating factor $\mu = x^2$ results in

$$y = \frac{-3x^2 + c_1x + 2x^2\ln(x)}{x^2} + \frac{c_2}{x^2}$$

which simplifies to

$$y = \frac{-3x^2 + c_1x + 2x^2\ln(x) + c_2}{x^2}$$

Summary

The solution(s) found are the following

$$y = \frac{-3x^2 + c_1x + 2x^2\ln(x) + c_2}{x^2} \tag{1}$$

Verification of solutions

$$y = \frac{-3x^2 + c_1x + 2x^2\ln(x) + c_2}{x^2}$$

Verified OK.

$$\boxed{x^2y'' + y'x + 4y = 2x\ln(x)}$$

13.17.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = 4, f(x) = 2x\ln(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + y'x + 4y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + xrx^{r-1} + 4x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + r\,x^r + 4x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + r + 4 = 0$$

Or

$$r^2 + 4 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= -2i \\ r_2 &= 2i \end{aligned}$$

The roots are complex conjugate of each others. Let the roots be

$$\begin{aligned} r_1 &= \alpha + i\beta \\ r_2 &= \alpha - i\beta \end{aligned}$$

Where in this case $\alpha = 0$ and $\beta = -2$. Hence the solution becomes

$$\begin{aligned} y &= c_1 x^{r_1} + c_2 x^{r_2} \\ &= c_1 x^{\alpha+i\beta} + c_2 x^{\alpha-i\beta} \\ &= x^\alpha \left(c_1 x^{i\beta} + c_2 x^{-i\beta}\right) \\ &= x^\alpha \left(c_1 e^{\ln(x^{i\beta})} + c_2 e^{\ln(x^{-i\beta})}\right) \\ &= x^\alpha \left(c_1 e^{i(\beta \ln x)} + c_2 e^{-i(\beta \ln x)}\right) \end{aligned}$$

Using the values for $\alpha = 0, \beta = -2$, the above becomes

$$y = x^0 \left(c_1 e^{-2i \ln(x)} + c_2 e^{2i \ln(x)}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

Next, we find the particular solution to the ODE

$$x^2y'' + y'x + 4y = 2x\ln(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}y_1 &= \cos(2\ln(x))\\ y_2 &= -\sin(2\ln(x))\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(2\ln(x)) & -\sin(2\ln(x)) \\ \frac{d}{dx}(\cos(2\ln(x))) & \frac{d}{dx}(-\sin(2\ln(x))) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(2\ln(x)) & -\sin(2\ln(x)) \\ -\frac{2\sin(2\ln(x))}{x} & -\frac{2\cos(2\ln(x))}{x} \end{vmatrix}$$

Therefore

$$W = (\cos(2\ln(x)))\left(-\frac{2\cos(2\ln(x))}{x}\right) - (-\sin(2\ln(x)))\left(-\frac{2\sin(2\ln(x))}{x}\right)$$

Which simplifies to

$$W = -\frac{2\left(\cos\left(2\ln\left(x\right)\right)^{2}+\sin\left(2\ln\left(x\right)\right)^{2}\right)}{x}$$

Which simplifies to

$$W = -\frac{2}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-2\sin\left(2\ln\left(x\right)\right) x\ln\left(x\right)}{-2x}\, dx$$

Which simplifies to

$$u_1 = -\int \sin\left(2\ln\left(x\right)\right)\ln\left(x\right) dx$$

Hence

$$u_1 = -\left(-\frac{2\ln\left(x\right)}{5}+\frac{4}{25}\right) x\cos\left(2\ln\left(x\right)\right) - \left(\frac{\ln\left(x\right)}{5}+\frac{3}{25}\right) x\sin\left(2\ln\left(x\right)\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{2\cos\left(2\ln\left(x\right)\right) x\ln\left(x\right)}{-2x}\, dx$$

Which simplifies to

$$u_2 = \int -\cos\left(2\ln\left(x\right)\right)\ln\left(x\right) dx$$

Hence

$$u_2 = -\left(\frac{\ln\left(x\right)}{5}+\frac{3}{25}\right) x\cos\left(2\ln\left(x\right)\right) + \left(-\frac{2\ln\left(x\right)}{5}+\frac{4}{25}\right) x\sin\left(2\ln\left(x\right)\right)$$

Which simplifies to

$$u_1 = \left(-\frac{2\left(\frac{2}{5}-\ln\left(x\right)\right)\cos\left(2\ln\left(x\right)\right)}{5} - \frac{\left(\frac{3}{5}+\ln\left(x\right)\right)\sin\left(2\ln\left(x\right)\right)}{5}\right) x$$

$$u_2 = \left(-\frac{\left(\frac{3}{5}+\ln\left(x\right)\right)\cos\left(2\ln\left(x\right)\right)}{5} + \frac{2\left(\frac{2}{5}-\ln\left(x\right)\right)\sin\left(2\ln\left(x\right)\right)}{5}\right) x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{2\left(\frac{2}{5}-\ln(x)\right)\cos(2\ln(x))}{5} - \frac{\left(\frac{3}{5}+\ln(x)\right)\sin(2\ln(x))}{5}\right)x\cos(2\ln(x)) - \left(-\frac{\left(\frac{3}{5}+\ln(x)\right)\cos(2\ln(x))}{5} + \frac{2\left(\frac{2}{5}-\ln(x)\right)\sin(2\ln(x))}{5}\right)x\sin(2\ln(x))$$

Which simplifies to

$$y_p(x) = \frac{2x\ln(x)}{5} - \frac{4x}{25}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \frac{2x\ln(x)}{5} - \frac{4x}{25} + c_1\cos(2\ln(x)) + c_2\sin(2\ln(x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{2x\ln(x)}{5} - \frac{4x}{25} + c_1\cos(2\ln(x)) + c_2\sin(2\ln(x)) \tag{1}$$

Verification of solutions

$$y = \frac{2x\ln(x)}{5} - \frac{4x}{25} + c_1\cos(2\ln(x)) + c_2\sin(2\ln(x))$$

Verified OK.

13.17.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + y'x + 4y = 0$$

In normal form the ode

$$x^2y'' + y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned}
p(x) &= \frac{1}{x} \\
q(x) &= \frac{4}{x^2}
\end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\, \tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int e^{-\left(\int p(x) dx\right)} dx \\
&= \int e^{-\left(\int \frac{1}{x} dx\right)} dx \\
&= \int e^{-\ln(x)}\, dx \\
&= \int \frac{1}{x} dx \\
&= \ln(x)
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{4}{x^2}}{\frac{1}{x^2}} \\
&= 4
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) + 4y(\tau) = 0$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = 4$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda\tau} + 4\,\mathrm{e}^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(4)} \\ &= \pm 2i\end{aligned}$$

Hence

$$\lambda_1 = +2i$$
$$\lambda_2 = -2i$$

Which simplifies to

$$\lambda_1 = 2i$$
$$\lambda_2 = -2i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y(\tau) = e^{\alpha\tau}(c_1 \cos(\beta\tau) + c_2 \sin(\beta\tau))$$

Which becomes

$$y(\tau) = e^{0}(c_1 \cos(2\tau) + c_2 \sin(2\tau))$$

Or

$$y(\tau) = c_1 \cos(2\tau) + c_2 \sin(2\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sin(\ln(x))\cos(\ln(x))$$

$$y_2 = 2\cos(\ln(x))^2 - 1$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sin(\ln(x))\cos(\ln(x)) & 2\cos(\ln(x))^2 - 1 \\ \frac{d}{dx}(\sin(\ln(x))\cos(\ln(x))) & \frac{d}{dx}\left(2\cos(\ln(x))^2 - 1\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sin(\ln(x))\cos(\ln(x)) & 2\cos(\ln(x))^2 - 1 \\ \frac{\cos(\ln(x))^2}{x} - \frac{\sin(\ln(x))^2}{x} & -\frac{4\cos(\ln(x))\sin(\ln(x))}{x} \end{vmatrix}$$

Therefore

$$W = (\sin(\ln(x))\cos(\ln(x)))\left(-\frac{4\cos(\ln(x))\sin(\ln(x))}{x}\right) - \left(2\cos(\ln(x))^2 - 1\right)\left(\frac{\cos(\ln(x))^2}{x} - \frac{\sin(\ln(x))^2}{x}\right)$$

Which simplifies to

$$W = -\frac{2\sin(\ln(x))^2\cos(\ln(x))^2 + 2\cos(\ln(x))^4 + \sin(\ln(x))^2 - \cos(\ln(x))^2}{x}$$

Which simplifies to

$$W = -\frac{1}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2\left(2\cos(\ln(x))^2 - 1\right)x\ln(x)}{-x}\,dx$$

Which simplifies to

$$u_1 = -\int -2\cos(2\ln(x))\ln(x)\,dx$$

Hence

$$u_1 = 2\left(\frac{\ln(x)}{5} + \frac{3}{25}\right)x\cos(2\ln(x)) - 2\left(-\frac{2\ln(x)}{5} + \frac{4}{25}\right)x\sin(2\ln(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{2\sin(\ln(x))\cos(\ln(x))\, x\ln(x)}{-x}\, dx$$

Which simplifies to

$$u_2 = \int -\sin(2\ln(x))\ln(x)\, dx$$

Hence

$$u_2 = -\left(-\frac{2\ln(x)}{5} + \frac{4}{25}\right) x\cos(2\ln(x)) - \left(\frac{\ln(x)}{5} + \frac{3}{25}\right) x\sin(2\ln(x))$$

Which simplifies to

$$u_1 = \left(\frac{2\left(\frac{3}{5} + \ln(x)\right)\cos(2\ln(x))}{5} - \frac{4\left(\frac{2}{5} - \ln(x)\right)\sin(2\ln(x))}{5}\right) x$$

$$u_2 = \left(-\frac{2\left(\frac{2}{5} - \ln(x)\right)\cos(2\ln(x))}{5} - \frac{\left(\frac{3}{5} + \ln(x)\right)\sin(2\ln(x))}{5}\right) x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{2\left(\frac{3}{5} + \ln(x)\right)\cos(2\ln(x))}{5} - \frac{4\left(\frac{2}{5} - \ln(x)\right)\sin(2\ln(x))}{5}\right) x\sin(\ln(x))\cos(\ln(x)) + \left(-\frac{2\left(\frac{2}{5} - \ln(x)\right)\cos(2\ln(x))}{5} - \frac{\left(\frac{3}{5} + \ln(x)\right)\sin(2\ln(x))}{5}\right) x\left(2\cos(\ln(x))^2 - 1\right)$$

Which simplifies to

$$y_p(x) = \frac{2x\ln(x)}{5} - \frac{4x}{25}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))) + \left(\frac{2x\ln(x)}{5} - \frac{4x}{25}\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = \frac{2x\ln(x)}{5} - \frac{4x}{25} + c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x)) \tag{1}
$$

Verification of solutions

$$
y = \frac{2x\ln(x)}{5} - \frac{4x}{25} + c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))
$$

Verified OK.

13.17.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$
Ay''(x) + By'(x) + Cy(x) = f(x)
$$

Where $A = x^2, B = x, C = 4, f(x) = 2x\ln(x)$. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$
x^2y'' + y'x + 4y = 0
$$

In normal form the ode

$$
x^2y'' + y'x + 4y = 0 \tag{1}
$$

Becomes

$$
y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= \frac{1}{x} \\
q(x) &= \frac{4}{x^2}
\end{aligned}
$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}\tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{2\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{2}{c\sqrt{\frac{1}{x^2}}\,x^3}\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{2}{c\sqrt{\frac{1}{x^2}}\,x^3} + \frac{1}{x}\frac{2\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{2\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= 0\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int 2\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{2\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = c_1\cos(2\ln(x)) + c_2\sin(2\ln(x))$$

Now the particular solution to this ODE is found

$$x^2y'' + y'x + 4y = 2x\ln(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= \sin(\ln(x))\cos(\ln(x)) \\
y_2 &= 2\cos(\ln(x))^2 - 1
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sin(\ln(x))\cos(\ln(x)) & 2\cos(\ln(x))^2 - 1 \\ \frac{d}{dx}(\sin(\ln(x))\cos(\ln(x))) & \frac{d}{dx}\left(2\cos(\ln(x))^2 - 1\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sin(\ln(x))\cos(\ln(x)) & 2\cos(\ln(x))^2 - 1 \\ \frac{\cos(\ln(x))^2}{x} - \frac{\sin(\ln(x))^2}{x} & -\frac{4\cos(\ln(x))\sin(\ln(x))}{x} \end{vmatrix}$$

Therefore

$$W = (\sin(\ln(x))\cos(\ln(x)))\left(-\frac{4\cos(\ln(x))\sin(\ln(x))}{x}\right) - \left(2\cos(\ln(x))^2 - 1\right)\left(\frac{\cos(\ln(x))^2}{x} - \frac{\sin(\ln(x))^2}{x}\right)$$

Which simplifies to

$$W = -\frac{2\sin(\ln(x))^2\cos(\ln(x))^2 + 2\cos(\ln(x))^4 + \sin(\ln(x))^2 - \cos(\ln(x))^2}{x}$$

Which simplifies to

$$W = -\frac{1}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2\left(2\cos(\ln(x))^2 - 1\right)x\ln(x)}{-x}\,dx$$

Which simplifies to

$$u_1 = -\int -2\cos(2\ln(x))\ln(x)\,dx$$

Hence

$$u_1 = 2\left(\frac{\ln(x)}{5} + \frac{3}{25}\right)x\cos(2\ln(x)) - 2\left(-\frac{2\ln(x)}{5} + \frac{4}{25}\right)x\sin(2\ln(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{2 \sin (\ln (x)) \cos (\ln (x)) x \ln (x)}{-x} dx$$

Which simplifies to

$$u_2 = \int -\sin (2 \ln (x)) \ln (x) dx$$

Hence

$$u_2 = -\left(-\frac{2 \ln (x)}{5} + \frac{4}{25}\right) x \cos (2 \ln (x)) - \left(\frac{\ln (x)}{5} + \frac{3}{25}\right) x \sin (2 \ln (x))$$

Which simplifies to

$$u_1 = \left(\frac{2\left(\frac{3}{5} + \ln (x)\right) \cos (2 \ln (x))}{5} - \frac{4\left(\frac{2}{5} - \ln (x)\right) \sin (2 \ln (x))}{5}\right) x$$
$$u_2 = \left(-\frac{2\left(\frac{2}{5} - \ln (x)\right) \cos (2 \ln (x))}{5} - \frac{\left(\frac{3}{5} + \ln (x)\right) \sin (2 \ln (x))}{5}\right) x$$

Therefore the particular solution, from equation (1) is

$$\begin{aligned} y_p(x) = &\left(\frac{2\left(\frac{3}{5} + \ln (x)\right) \cos (2 \ln (x))}{5} \right. \\ &\left. - \frac{4\left(\frac{2}{5} - \ln (x)\right) \sin (2 \ln (x))}{5}\right) x \sin (\ln (x)) \cos (\ln (x)) \\ &+ \left(-\frac{2\left(\frac{2}{5} - \ln (x)\right) \cos (2 \ln (x))}{5} - \frac{\left(\frac{3}{5} + \ln (x)\right) \sin (2 \ln (x))}{5}\right) x\left(2 \cos (\ln (x))^2 \right. \\ &\left. - 1\right) \end{aligned}$$

Which simplifies to

$$y_p(x) = \frac{2x \ln (x)}{5} - \frac{4x}{25}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))) + \left(\frac{2x\ln(x)}{5} - \frac{4x}{25}\right) \\
&= \frac{2x\ln(x)}{5} - \frac{4x}{25} + c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))
\end{aligned}$$

Which simplifies to

$$y = \frac{2x\ln(x)}{5} - \frac{4x}{25} + c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

Summary
The solution(s) found are the following

$$y = \frac{2x\ln(x)}{5} - \frac{4x}{25} + c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x)) \tag{1}$$

Verification of solutions

$$y = \frac{2x\ln(x)}{5} - \frac{4x}{25} + c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

Verified OK.

13.17.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = 4, f(x) = 2x\ln(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + y'x + 4y = 0$$

In normal form the ode

$$x^2y'' + y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= \frac{4}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n}{x^2} + \frac{4}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 2i \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{4i}{x} + \frac{1}{x}\right) v'(x) &= 0 \\ v''(x) + \frac{(1+4i)\,v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(1+4i)\, u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{(-1-4i)\, u}{x} \end{aligned}$$

Where $f(x) = \frac{-1-4i}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= \frac{-1-4i}{x}\, dx \\ \int \frac{1}{u}\, du &= \int \frac{-1-4i}{x}\, dx \\ \ln(u) &= (-1-4i)\ln(x) + c_1 \\ u &= e^{(-1-4i)\ln(x)+c_1} \\ &= c_1 e^{(-1-4i)\ln(x)} \end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1 x^{-4i}}{x}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= \frac{i c_1 x^{-4i}}{4} + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\, x^n \\ &= \left(\frac{i c_1 x^{-4i}}{4} + c_2\right) x^{2i} \\ &= x^{2i} c_2 + \frac{i x^{-2i} c_1}{4} \end{aligned}$$

Now the particular solution to this ODE is found

$$x^2y'' + y'x + 4y = 2x\ln(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^{2i}$$
$$y_2 = x^{2i}x^{-4i}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^{2i} & x^{2i}x^{-4i} \\ \frac{d}{dx}(x^{2i}) & \frac{d}{dx}(x^{2i}x^{-4i}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^{2i} & x^{2i}x^{-4i} \\ \frac{2ix^{2i}}{x} & -\frac{2ix^{2i}x^{-4i}}{x} \end{vmatrix}$$

Therefore

$$W = \left(x^{2i}\right)\left(-\frac{2ix^{2i}x^{-4i}}{x}\right) - \left(x^{2i}x^{-4i}\right)\left(\frac{2ix^{2i}}{x}\right)$$

Which simplifies to

$$W = -\frac{4i x^{4i} x^{-4i}}{x}$$

Which simplifies to

$$W = -\frac{4i}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\left(\int \frac{2x^{2i} x^{-4i} x \ln(x)}{-4ix}\, dx\right)$$

Which simplifies to

$$u_1 = -\left(\int \frac{i x^{-2i} \ln(x)}{2} dx\right)$$

Hence

$$u_1 = -\frac{(4 + 3i + (-10 + 5i) \ln(x))\, x^{1-2i}}{50}$$

And Eq. (3) becomes

$$u_2 = \int \frac{2x^{2i} x \ln(x)}{-4ix}\, dx$$

Which simplifies to

$$u_2 = \int \frac{i x^{2i} \ln(x)}{2} dx$$

Hence

$$u_2 = \frac{(-4 + 3i + (10 + 5i) \ln(x))\, x^{1+2i}}{50}$$

Which simplifies to

$$u_1 = -\frac{x^{1-2i} \left(\frac{4}{5} + \frac{3i}{5} + (-2 + i) \ln(x)\right)}{10}$$

$$u_2 = \frac{(-4 + 3i + (10 + 5i) \ln(x))\, x^{1+2i}}{50}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^{1-2i}\left(\frac{4}{5}+\frac{3i}{5}+(-2+i)\ln(x)\right)x^{2i}}{10} + \frac{(-4+3i+(10+5i)\ln(x))\,x^{1+2i}x^{2i}x^{-4i}}{50}$$

Which simplifies to

$$y_p(x) = \frac{2x\ln(x)}{5} - \frac{4x}{25}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(\frac{ic_1x^{-4i}}{4} + c_2\right)x^{2i}\right) + \left(\frac{2x\ln(x)}{5} - \frac{4x}{25}\right) \\ &= \frac{2x\ln(x)}{5} - \frac{4x}{25} + \left(\frac{ic_1x^{-4i}}{4} + c_2\right)x^{2i} \end{aligned}$$

Which simplifies to

$$y = \frac{2x\ln(x)}{5} + x^{2i}c_2 - \frac{4x}{25} + \frac{ix^{-2i}c_1}{4}$$

Summary

The solution(s) found are the following

$$y = \frac{2x\ln(x)}{5} + x^{2i}c_2 - \frac{4x}{25} + \frac{ix^{-2i}c_1}{4} \tag{1}$$

Verification of solutions

$$y = \frac{2x\ln(x)}{5} + x^{2i}c_2 - \frac{4x}{25} + \frac{ix^{-2i}c_1}{4}$$

Verified OK.

13.17.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + y'x + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-17}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -17 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{17}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 494: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{17}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{17}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + 2i \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - 2i
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = -\frac{17}{4x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{17}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + 2i \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - 2i
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{17}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2} + 2i$	$\frac{1}{2} - 2i$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2} + 2i$	$\frac{1}{2} - 2i$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_\infty^- = \frac{1}{2} - 2i$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= \frac{1}{2} - 2i - \left(\frac{1}{2} - 2i\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{\frac{1}{2} - 2i}{x} + (-)\,(0) \\ &= \frac{\frac{1}{2} - 2i}{x} \\ &= \frac{\frac{1}{2} - 2i}{x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{\frac{1}{2} - 2i}{x}\right)(0) + \left(\left(\frac{-\frac{1}{2} + 2i}{x^2}\right) + \left(\frac{\frac{1}{2} - 2i}{x}\right)^2 - \left(-\frac{17}{4x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \frac{\frac{1}{2} - 2i}{x} dx} \\ &= x^{\frac{1}{2} - 2i} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2}\,dx} \\
&= z_1 e^{-\frac{\ln(x)}{2}} \\
&= z_1 \left(\frac{1}{\sqrt{x}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{-2i}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{i x^{4i}}{4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{-2i}\right) + c_2 \left(x^{-2i}\left(-\frac{i x^{4i}}{4}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$x^2y''+y'x+4y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = x^{-2i}c_1 - \frac{ic_2x^{2i}}{4}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^{-2i}$$
$$y_2 = -\frac{ix^{2i}}{4}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^{-2i} & -\frac{ix^{2i}}{4} \\ \frac{d}{dx}(x^{-2i}) & \frac{d}{dx}\left(-\frac{ix^{2i}}{4}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^{-2i} & -\frac{i x^{2i}}{4} \\ -\frac{2i x^{-2i}}{x} & \frac{x^{2i}}{2x} \end{vmatrix}$$

Therefore

$$W = \left(x^{-2i}\right)\left(\frac{x^{2i}}{2x}\right) - \left(-\frac{i x^{2i}}{4}\right)\left(-\frac{2i x^{-2i}}{x}\right)$$

Which simplifies to

$$W = \frac{x^{-2i} x^{2i}}{x}$$

Which simplifies to

$$W = \frac{1}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{i x^{2i} x \ln(x)}{2}}{x} \, dx$$

Which simplifies to

$$u_1 = -\int -\frac{i x^{2i} \ln(x)}{2} dx$$

Hence

$$u_1 = \frac{x^{1+2i}\left(-\frac{4}{5} + \frac{3i}{5} + (2+i)\ln(x)\right)}{10}$$

And Eq. (3) becomes

$$u_2 = \int \frac{2x \ln(x)\, x^{-2i}}{x} \, dx$$

Which simplifies to

$$u_2 = \int 2x^{-2i} \ln(x) \, dx$$

Hence

$$u_2 = \frac{2x^{1-2i}(3 - 4i + (5+10i)\ln(x))}{25}$$

Which simplifies to

$$u_1 = \frac{(-4 + 3i + (10 + 5i)\ln(x))\, x^{1+2i}}{50}$$

$$u_2 = \frac{2x^{1-2i}(3 - 4i + (5 + 10i)\ln(x))}{25}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{(-4 + 3i + (10 + 5i)\ln(x))\, x^{1+2i} x^{-2i}}{50} - \frac{i x^{1-2i}(3 - 4i + (5 + 10i)\ln(x))\, x^{2i}}{50}$$

Which simplifies to

$$y_p(x) = \frac{2x\ln(x)}{5} - \frac{4x}{25}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(x^{-2i}c_1 - \frac{i c_2 x^{2i}}{4}\right) + \left(\frac{2x\ln(x)}{5} - \frac{4x}{25}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = x^{-2i}c_1 - \frac{i c_2 x^{2i}}{4} + \frac{2x\ln(x)}{5} - \frac{4x}{25} \tag{1}$$

Verification of solutions

$$y = x^{-2i}c_1 - \frac{i c_2 x^{2i}}{4} + \frac{2x\ln(x)}{5} - \frac{4x}{25}$$

Verified OK.

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{x^2y'' + y'x + 4y = 4\sin(\ln(x))}$$

13.18.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = 4, f(x) = 4\sin(\ln(x))$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + y'x + 4y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + xrx^{r-1} + 4x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + r\,x^r + 4x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + r + 4 = 0$$

Or

$$r^2 + 4 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= -2i \\ r_2 &= 2i \end{aligned}$$

The roots are complex conjugate of each others. Let the roots be

$$\begin{aligned} r_1 &= \alpha + i\beta \\ r_2 &= \alpha - i\beta \end{aligned}$$

Where in this case $\alpha = 0$ and $\beta = -2$. Hence the solution becomes

$$\begin{aligned} y &= c_1 x^{r_1} + c_2 x^{r_2} \\ &= c_1 x^{\alpha+i\beta} + c_2 x^{\alpha-i\beta} \\ &= x^\alpha \left(c_1 x^{i\beta} + c_2 x^{-i\beta}\right) \\ &= x^\alpha \left(c_1 e^{\ln(x^{i\beta})} + c_2 e^{\ln(x^{-i\beta})}\right) \\ &= x^\alpha \left(c_1 e^{i(\beta \ln x)} + c_2 e^{-i(\beta \ln x)}\right) \end{aligned}$$

Using the values for $\alpha = 0, \beta = -2$, the above becomes

$$y = x^0 \left(c_1 e^{-2i\ln(x)} + c_2 e^{2i\ln(x)}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

Next, we find the particular solution to the ODE

$$x^2y'' + y'x + 4y = 4\sin(\ln(x))$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(2\ln(x))$$
$$y_2 = -\sin(2\ln(x))$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(2\ln(x)) & -\sin(2\ln(x)) \\ \frac{d}{dx}(\cos(2\ln(x))) & \frac{d}{dx}(-\sin(2\ln(x))) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(2\ln(x)) & -\sin(2\ln(x)) \\ -\frac{2\sin(2\ln(x))}{x} & -\frac{2\cos(2\ln(x))}{x} \end{vmatrix}$$

Therefore

$$W = (\cos(2\ln(x)))\left(-\frac{2\cos(2\ln(x))}{x}\right) - (-\sin(2\ln(x)))\left(-\frac{2\sin(2\ln(x))}{x}\right)$$

Which simplifies to

$$W = -\frac{2\left(\cos\left(2\ln\left(x\right)\right)^2 + \sin\left(2\ln\left(x\right)\right)^2\right)}{x}$$

Which simplifies to

$$W = -\frac{2}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-4\sin\left(2\ln\left(x\right)\right)\sin\left(\ln\left(x\right)\right)}{-2x}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\cos\left(\ln\left(x\right)\right) - \cos\left(3\ln\left(x\right)\right)}{x}dx$$

Hence

$$u_1 = \frac{\sin\left(3\ln\left(x\right)\right)}{3} - \sin\left(\ln\left(x\right)\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{4\cos\left(2\ln\left(x\right)\right)\sin\left(\ln\left(x\right)\right)}{-2x}\,dx$$

Which simplifies to

$$u_2 = \int \frac{-\sin\left(3\ln\left(x\right)\right) + \sin\left(\ln\left(x\right)\right)}{x}dx$$

Hence

$$u_2 = \frac{\cos\left(3\ln\left(x\right)\right)}{3} - \cos\left(\ln\left(x\right)\right)$$

Which simplifies to

$$u_1 = -\frac{4\sin\left(\ln\left(x\right)\right)^3}{3}$$

$$u_2 = \frac{4\cos\left(\ln\left(x\right)\right)^3}{3} - 2\cos\left(\ln\left(x\right)\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{4 \sin(\ln(x))^3 \cos(2\ln(x))}{3} - \left(\frac{4 \cos(\ln(x))^3}{3} - 2\cos(\ln(x))\right) \sin(2\ln(x))$$

Which simplifies to

$$y_p(x) = \frac{4 \sin(\ln(x))}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \frac{4 \sin(\ln(x))}{3} + c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{4 \sin(\ln(x))}{3} + c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x)) \tag{1}$$

Verification of solutions

$$y = \frac{4 \sin(\ln(x))}{3} + c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

Verified OK.

13.18.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + y'x + 4y = 0$$

In normal form the ode

$$x^2y'' + y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= \frac{4}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\ &= \int \mathrm{e}^{-\left(\int \frac{1}{x}dx\right)}dx \\ &= \int e^{-\ln(x)}\,dx \\ &= \int \frac{1}{x}dx \\ &= \ln(x) \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned} q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{4}{x^2}}{\frac{1}{x^2}} \\ &= 4 \end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + 4y(\tau) &= 0
\end{aligned}
$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$
Ay''(\tau) + By'(\tau) + Cy(\tau) = 0
$$

Where in the above $A = 1, B = 0, C = 4$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$
\lambda^2 \mathrm{e}^{\lambda\tau} + 4\,\mathrm{e}^{\lambda\tau} = 0 \tag{1}
$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$
\lambda^2 + 4 = 0 \tag{2}
$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$
\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}
$$

Substituting $A = 1, B = 0, C = 4$ into the above gives

$$
\begin{aligned}
\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(4)} \\
&= \pm 2i
\end{aligned}
$$

Hence

$$
\begin{aligned}
\lambda_1 &= +2i \\
\lambda_2 &= -2i
\end{aligned}
$$

Which simplifies to

$$
\begin{aligned}
\lambda_1 &= 2i \\
\lambda_2 &= -2i
\end{aligned}
$$

Since roots are complex conjugate of each others, then let the roots be

$$
\lambda_{1,2} = \alpha \pm i\beta
$$

Where $\alpha = 0$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y(\tau) = e^{\alpha\tau}(c_1 \cos(\beta\tau) + c_2 \sin(\beta\tau))$$

Which becomes

$$y(\tau) = e^0(c_1 \cos(2\tau) + c_2 \sin(2\tau))$$

Or

$$y(\tau) = c_1 \cos(2\tau) + c_2 \sin(2\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sin(\ln(x))\cos(\ln(x))$$
$$y_2 = 2\cos(\ln(x))^2 - 1$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sin(\ln(x))\cos(\ln(x)) & 2\cos(\ln(x))^2 - 1 \\ \frac{d}{dx}(\sin(\ln(x))\cos(\ln(x))) & \frac{d}{dx}\left(2\cos(\ln(x))^2 - 1\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sin(\ln(x))\cos(\ln(x)) & 2\cos(\ln(x))^2 - 1 \\ \frac{\cos(\ln(x))^2}{x} - \frac{\sin(\ln(x))^2}{x} & -\frac{4\cos(\ln(x))\sin(\ln(x))}{x} \end{vmatrix}$$

Therefore

$$\begin{aligned} W = {} & (\sin(\ln(x))\cos(\ln(x)))\left(-\frac{4\cos(\ln(x))\sin(\ln(x))}{x}\right) \\ & - \left(2\cos(\ln(x))^2 - 1\right)\left(\frac{\cos(\ln(x))^2}{x} - \frac{\sin(\ln(x))^2}{x}\right) \end{aligned}$$

Which simplifies to

$$W = -\frac{2\sin(\ln(x))^2\cos(\ln(x))^2 + 2\cos(\ln(x))^4 + \sin(\ln(x))^2 - \cos(\ln(x))^2}{x}$$

Which simplifies to

$$W = -\frac{1}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4\left(2\cos(\ln(x))^2 - 1\right)\sin(\ln(x))}{-x}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{-8\sin(\ln(x))\cos(\ln(x))^2 + 4\sin(\ln(x))}{x}dx$$

Hence

$$u_1 = -\frac{8\cos(\ln(x))^3}{3} + 4\cos(\ln(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{4 \sin(\ln(x))^2 \cos(\ln(x))}{-x} dx$$

Which simplifies to

$$u_2 = \int -\frac{4 \sin(\ln(x))^2 \cos(\ln(x))}{x} dx$$

Hence

$$u_2 = -\frac{4 \sin(\ln(x))^3}{3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{8 \cos(\ln(x))^3}{3} + 4 \cos(\ln(x))\right) \sin(\ln(x)) \cos(\ln(x)) \\ - \frac{4 \sin(\ln(x))^3 \left(2 \cos(\ln(x))^2 - 1\right)}{3}$$

Which simplifies to

$$y_p(x) = \frac{4 \sin(\ln(x))}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))) + \left(\frac{4 \sin(\ln(x))}{3}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{4 \sin(\ln(x))}{3} + c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x)) \tag{1}$$

Verification of solutions

$$y = \frac{4 \sin(\ln(x))}{3} + c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))$$

Verified OK.

13.18.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = 4, f(x) = 4\sin(\ln(x))$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + y'x + 4y = 0$$

In normal form the ode

$$x^2y'' + y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= \frac{4}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{2\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{2}{c\sqrt{\frac{1}{x^2}}\,x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{2}{c\sqrt{\frac{1}{x^2}}\,x^3} + \frac{1}{x}\frac{2\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{2\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= 0
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0 \qquad (7)
\end{aligned}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int 2\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{2\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = c_1 \cos(2\ln(x)) + c_2 \sin(2\ln(x))
$$

Now the particular solution to this ODE is found

$$
x^2 y'' + y'x + 4y = 4\sin(\ln(x))
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sin(\ln(x))\cos(\ln(x))$$
$$y_2 = 2\cos(\ln(x))^2 - 1$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sin(\ln(x))\cos(\ln(x)) & 2\cos(\ln(x))^2 - 1 \\ \frac{d}{dx}(\sin(\ln(x))\cos(\ln(x))) & \frac{d}{dx}(2\cos(\ln(x))^2 - 1) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sin(\ln(x))\cos(\ln(x)) & 2\cos(\ln(x))^2 - 1 \\ \frac{\cos(\ln(x))^2}{x} - \frac{\sin(\ln(x))^2}{x} & -\frac{4\cos(\ln(x))\sin(\ln(x))}{x} \end{vmatrix}$$

Therefore

$$W = (\sin(\ln(x))\cos(\ln(x)))\left(-\frac{4\cos(\ln(x))\sin(\ln(x))}{x}\right) - \left(2\cos(\ln(x))^2 - 1\right)\left(\frac{\cos(\ln(x))^2}{x} - \frac{\sin(\ln(x))^2}{x}\right)$$

Which simplifies to

$$W = -\frac{2\sin(\ln(x))^2\cos(\ln(x))^2 + 2\cos(\ln(x))^4 + \sin(\ln(x))^2 - \cos(\ln(x))^2}{x}$$

Which simplifies to

$$W = -\frac{1}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4(2\cos(\ln(x))^2 - 1)\sin(\ln(x))}{-x}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{-8\sin(\ln(x))\cos(\ln(x))^2 + 4\sin(\ln(x))}{x}dx$$

Hence

$$u_1 = -\frac{8\cos(\ln(x))^3}{3} + 4\cos(\ln(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{4\sin(\ln(x))^2\cos(\ln(x))}{-x}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{4\sin(\ln(x))^2\cos(\ln(x))}{x}dx$$

Hence

$$u_2 = -\frac{4\sin(\ln(x))^3}{3}$$

Therefore the particular solution, from equation (1) is

$$\begin{aligned} y_p(x) = &\left(-\frac{8\cos(\ln(x))^3}{3} + 4\cos(\ln(x))\right)\sin(\ln(x))\cos(\ln(x)) \\ &- \frac{4\sin(\ln(x))^3\left(2\cos(\ln(x))^2 - 1\right)}{3} \end{aligned}$$

Which simplifies to

$$y_p(x) = \frac{4\sin(\ln(x))}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(2\ln(x)) + c_2\sin(2\ln(x))) + \left(\frac{4\sin(\ln(x))}{3}\right) \\ &= \frac{4\sin(\ln(x))}{3} + c_1\cos(2\ln(x)) + c_2\sin(2\ln(x)) \end{aligned}$$

Which simplifies to

$$y = \frac{4\sin(\ln(x))}{3} + c_1\cos(2\ln(x)) + c_2\sin(2\ln(x))$$

Summary
The solution(s) found are the following

$$y = \frac{4\sin(\ln(x))}{3} + c_1\cos(2\ln(x)) + c_2\sin(2\ln(x)) \tag{1}$$

Verification of solutions

$$y = \frac{4\sin(\ln(x))}{3} + c_1\cos(2\ln(x)) + c_2\sin(2\ln(x))$$

Verified OK.

13.18.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = 4, f(x) = 4\sin(\ln(x))$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + y'x + 4y = 0$$

In normal form the ode

$$x^2y'' + y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= \frac{4}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n}{x^2} + \frac{4}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 2i \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{4i}{x} + \frac{1}{x}\right) v'(x) &= 0 \\ v''(x) + \frac{(1+4i)\,v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x)+\frac{(1+4i)\,u(x)}{x}=0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}u' &= F(x,u)\\ &= f(x)g(u)\\ &= \frac{(-1-4i)\,u}{x}\end{aligned}$$

Where $f(x)=\frac{-1-4i}{x}$ and $g(u)=u$. Integrating both sides gives

$$\begin{aligned}\frac{1}{u}\,du &= \frac{-1-4i}{x}\,dx\\ \int\frac{1}{u}\,du &= \int\frac{-1-4i}{x}\,dx\\ \ln(u) &= (-1-4i)\ln(x)+c_1\\ u &= \mathrm{e}^{(-1-4i)\ln(x)+c_1}\\ &= c_1\mathrm{e}^{(-1-4i)\ln(x)}\end{aligned}$$

Which simplifies to

$$u(x)=\frac{c_1x^{-4i}}{x}$$

Now that $u(x)$ is known, then

$$\begin{aligned}v'(x) &= u(x)\\ v(x) &= \int u(x)\,dx+c_2\\ &= \frac{ic_1x^{-4i}}{4}+c_2\end{aligned}$$

Hence

$$\begin{aligned}y &= v(x)\,x^n\\ &= \left(\frac{ic_1x^{-4i}}{4}+c_2\right)x^{2i}\\ &= x^{2i}c_2+\frac{ix^{-2i}c_1}{4}\end{aligned}$$

Now the particular solution to this ODE is found

$$x^2y'' + y'x + 4y = 4\sin(\ln(x))$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^{2i}$$
$$y_2 = x^{2i}x^{-4i}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^{2i} & x^{2i}x^{-4i} \\ \frac{d}{dx}(x^{2i}) & \frac{d}{dx}(x^{2i}x^{-4i}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^{2i} & x^{2i}x^{-4i} \\ \frac{2ix^{2i}}{x} & -\frac{2ix^{2i}x^{-4i}}{x} \end{vmatrix}$$

Therefore

$$W = (x^{2i})\left(-\frac{2ix^{2i}x^{-4i}}{x}\right) - (x^{2i}x^{-4i})\left(\frac{2ix^{2i}}{x}\right)$$

Which simplifies to

$$W = -\frac{4i x^{4i} x^{-4i}}{x}$$

Which simplifies to

$$W = -\frac{4i}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4x^{2i} x^{-4i} \sin(\ln(x))}{-4ix} dx$$

Which simplifies to

$$u_1 = -\int i x^{-1-2i} \sin(\ln(x)) dx$$

Hence

$$u_1 = undefined$$

And Eq. (3) becomes

$$u_2 = \int \frac{4x^{2i} \sin(\ln(x))}{-4ix} dx$$

Which simplifies to

$$u_2 = \int i x^{-1+2i} \sin(\ln(x)) dx$$

Hence

$$u_2 = undefined$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \text{undefined } x^{2i} + \text{undefined } x^{2i} x^{-4i}$$

Which simplifies to

$$y_p(x) = \text{undefined} \left(x^{2i} + x^{-2i}\right)$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\left(\frac{ic_1 x^{-4i}}{4} + c_2\right) x^{2i}\right) + \left(\text{undefined}\left(x^{2i} + x^{-2i}\right)\right) \\
&= \text{undefined}\left(x^{2i} + x^{-2i}\right) + \left(\frac{ic_1 x^{-4i}}{4} + c_2\right) x^{2i}
\end{aligned}
$$

Which simplifies to

$$
y = \frac{(ic_1 + \text{undefined})\, x^{-2i}}{4} + (\text{undefined} + c_2)\, x^{2i}
$$

Summary

The solution(s) found are the following

$$
y = \frac{(ic_1 + \text{undefined})\, x^{-2i}}{4} + (\text{undefined} + c_2)\, x^{2i} \tag{1}
$$

Verification of solutions

$$
y = \frac{(ic_1 + \text{undefined})\, x^{-2i}}{4} + (\text{undefined} + c_2)\, x^{2i}
$$

Verified OK.

13.18.5 Solving using Kovacic algorithm

Writing the ode as

$$
x^2 y'' + y' x + 4y = 0 \tag{1}
$$
$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x^2 \\
B &= x \\
C &= 4
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-17}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -17 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{17}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 495: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 2 - 0\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{17}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{17}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + 2i\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - 2i\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{17}{4x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{17}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + 2i\\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - 2i\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{17}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}+2i$	$\frac{1}{2}-2i$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}+2i$	$\frac{1}{2}-2i$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2} - 2i$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= \frac{1}{2} - 2i - \left(\frac{1}{2} - 2i\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{\frac{1}{2} - 2i}{x} + (-)(0) \\ &= \frac{\frac{1}{2} - 2i}{x} \\ &= \frac{\frac{1}{2} - 2i}{x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{\frac{1}{2} - 2i}{x}\right)(0) + \left(\left(\frac{-\frac{1}{2} + 2i}{x^2}\right) + \left(\frac{\frac{1}{2} - 2i}{x}\right)^2 - \left(-\frac{17}{4x^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \frac{\frac{1}{2} - 2i}{x} dx} \\ &= x^{\frac{1}{2} - 2i} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2}\, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2}} \\ &= z_1\left(\frac{1}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^{-2i}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{i x^{4i}}{4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{-2i}\right) + c_2 \left(x^{-2i} \left(-\frac{i x^{4i}}{4}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2 y'' + y' x + 4y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = x^{-2i} c_1 - \frac{i c_2 x^{2i}}{4}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^{-2i}$$

$$y_2 = -\frac{i x^{2i}}{4}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^{-2i} & -\frac{i x^{2i}}{4} \\ \frac{d}{dx}\left(x^{-2i}\right) & \frac{d}{dx}\left(-\frac{i x^{2i}}{4}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^{-2i} & -\frac{i x^{2i}}{4} \\ -\frac{2i x^{-2i}}{x} & \frac{x^{2i}}{2x} \end{vmatrix}$$

Therefore

$$W = \left(x^{-2i}\right)\left(\frac{x^{2i}}{2x}\right) - \left(-\frac{i x^{2i}}{4}\right)\left(-\frac{2i x^{-2i}}{x}\right)$$

Which simplifies to

$$W = \frac{x^{-2i} x^{2i}}{x}$$

Which simplifies to

$$W = \frac{1}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-ix^{2i} \sin(\ln(x))}{x} dx$$

Which simplifies to

$$u_1 = -\int -ix^{-1+2i} \sin(\ln(x)) dx$$

Hence

$$u_1 = undefined$$

And Eq. (3) becomes

$$u_2 = \int \frac{4x^{-2i} \sin(\ln(x))}{x} dx$$

Which simplifies to

$$u_2 = \int 4x^{-1-2i} \sin(\ln(x)) dx$$

Hence

$$u_2 = undefined$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \text{undefined } x^{-2i} - i \text{ undefined } x^{2i}$$

Which simplifies to

$$y_p(x) = (ix^{2i} + x^{-2i}) \text{ undefined}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(x^{-2i}c_1 - \frac{ic_2x^{2i}}{4}\right) + \left((ix^{2i} + x^{-2i}) \text{ undefined}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = x^{-2i}c_1 - \frac{ic_2x^{2i}}{4} + (ix^{2i} + x^{-2i}) \text{ undefined} \tag{1}$$

Verification of solutions

$$y = x^{-2i}c_1 - \frac{ic_2x^{2i}}{4} + \left(ix^{2i} + x^{-2i}\right) \text{undefined}$$

Verified OK.

The type(s) of ODE detected by this program : **"higher_order_ODE_non_constant_coefficients_of_type_Euler"**

Maple gives the following as the ode type

```
[[_3rd_order, _with_linear_symmetries]]
```

$$\boxed{x^3y''' - x^2y'' + 2y'x - 2y = x^3}$$

This is higher order nonhomogeneous Euler type ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous Euler ODE And y_p is a particular solution to the nonhomogeneous Euler ODE. y_h is the solution to

$$x^3y''' - x^2y'' + 2y'x - 2y = 0$$

This is Euler ODE of higher order. Let $y = x^\lambda$. Hence

$$\begin{aligned} y' &= \lambda\, x^{\lambda-1} \\ y'' &= \lambda(\lambda-1)\, x^{\lambda-2} \\ y''' &= \lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} \end{aligned}$$

Substituting these back into

$$x^3y''' - x^2y'' + 2y'x - 2y = x^3$$

gives

$$2x\lambda\, x^{\lambda-1} - x^2\lambda(\lambda-1)\, x^{\lambda-2} + x^3\lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} - 2x^\lambda = 0$$

Which simplifies to

$$2\lambda\, x^\lambda - \lambda(\lambda-1)\, x^\lambda + \lambda(\lambda-1)\,(\lambda-2)\, x^\lambda - 2x^\lambda = 0$$

And since $x^\lambda \neq 0$ then dividing through by x^λ, the above becomes

$$2\lambda - \lambda(\lambda-1) + \lambda(\lambda-1)\,(\lambda-2) - 2 = 0$$

Simplifying gives the characteristic equation as

$$(\lambda-2)\,(\lambda-1)^2 = 0$$

Solving the above gives the following roots

$$\lambda_1 = 2$$
$$\lambda_2 = 1$$
$$\lambda_3 = 1$$

This table summarises the result

root	multiplicity	type of root
1	2	real root
2	1	real root

The solution is generated by going over the above table. For each real root λ of multiplicity one generates a $c_1 x^\lambda$ basis solution. Each real root of multiplicty two, generates $c_1 x^\lambda$ and $c_2 x^\lambda \ln(x)$ basis solutions. Each real root of multiplicty three, generates $c_1 x^\lambda$ and $c_2 x^\lambda \ln(x)$ and $c_3 x^\lambda \ln(x)^2$ basis solutions, and so on. Each complex root $\alpha \pm i\beta$ of multiplicity one generates $x^\alpha (c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity two generates $\ln(x)\, x^\alpha (c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity three generates $\ln(x)^2\, x^\alpha (c_1 \cos(\beta \ln(x)) + c_2$ basis solutions. And so on. Using the above show that the solution is

$$y = c_1 x + c_2 \ln(x)\, x + c_3 x^2$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= x \\
y_2 &= x \ln(x) \\
y_3 &= x^2
\end{aligned}
$$

Now the particular solution to the given ODE is found

$$
x^3 y''' - x^2 y'' + 2y' x - 2y = x^3
$$

Let the particular solution be

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$
U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)} \, dx
$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$
W(x) = \begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}
$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$
W = \begin{bmatrix} x & x \ln(x) & x^2 \\ 1 & \ln(x) + 1 & 2x \\ 0 & \frac{1}{x} & 2 \end{bmatrix}
$$

$$
|W| = x
$$

The determinant simplifies to

$$
|W| = x
$$

Now we determine W_i for each U_i.

$$\begin{aligned} W_1(x) &= \det \begin{bmatrix} x\ln(x) & x^2 \\ \ln(x)+1 & 2x \end{bmatrix} \\ &= x^2(\ln(x) - 1) \end{aligned}$$

$$\begin{aligned} W_2(x) &= \det \begin{bmatrix} x & x^2 \\ 1 & 2x \end{bmatrix} \\ &= x^2 \end{aligned}$$

$$\begin{aligned} W_3(x) &= \det \begin{bmatrix} x & x\ln(x) \\ 1 & \ln(x)+1 \end{bmatrix} \\ &= x \end{aligned}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned} U_1 &= (-1)^{3-1} \int \frac{F(x)W_1(x)}{aW(x)}\,dx \\ &= (-1)^2 \int \frac{(x^3)\,(x^2(\ln(x)-1))}{(x^3)\,(x)}\,dx \\ &= \int \frac{x^5(\ln(x)-1)}{x^4}\,dx \\ &= \int (x(\ln(x)-1))\,dx \\ &= \frac{x^2\ln(x)}{2} - \frac{3x^2}{4} \end{aligned}$$

$$\begin{aligned} U_2 &= (-1)^{3-2} \int \frac{F(x)W_2(x)}{aW(x)}\,dx \\ &= (-1)^1 \int \frac{(x^3)\,(x^2)}{(x^3)\,(x)}\,dx \\ &= -\int \frac{x^5}{x^4}\,dx \\ &= -\int (x)\,dx \\ &= -\frac{x^2}{2} \end{aligned}$$

$$
\begin{aligned}
U_3 &= (-1)^{3-3} \int \frac{F(x)W_3(x)}{aW(x)}\,dx \\
&= (-1)^0 \int \frac{(x^3)\,(x)}{(x^3)\,(x)}\,dx \\
&= \int \frac{x^4}{x^4}\,dx \\
&= \int (1)\,dx \\
&= x
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Hence

$$
\begin{aligned}
y_p = &\left(\frac{x^2 \ln (x)}{2} - \frac{3x^2}{4}\right)(x) \\
&+ \left(-\frac{x^2}{2}\right)(x \ln (x)) \\
&+ (x)\,(x^2)
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = \frac{x^3}{4}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 x + c_2 \ln (x)\,x + c_3 x^2) + \left(\frac{x^3}{4}\right)
\end{aligned}
$$

Which simplifies to

$$
y = x(\ln (x)\,c_2 + c_3 x + c_1) + \frac{x^3}{4}
$$

<u>Summary</u>
The solution(s) found are the following

$$
y = x(\ln (x)\,c_2 + c_3 x + c_1) + \frac{x^3}{4} \tag{1}
$$

Verification of solutions

$$y = x(\ln(x) c_2 + c_3 x + c_1) + \frac{x^3}{4}$$

Verified OK.

13.19.1 Maple step by step solution

Let's solve

$x^3 y''' - y'' x^2 + 2y' x - 2y = x^3$

- Highest derivative means the order of the ODE is 3

y'''

Maple trace

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.5. The Cauchy-Euler Equation. Exercises page 169
Problem number: 20.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler], [_2nd_order, _linear, `_with_symmetry_[0,F(
   x)]`]]
```

$$\boxed{x^2y'' - 2y'x - 10y = 0}$$

With initial conditions

$$[y(1) = 5, y'(1) = 4]$$

13.20.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$
