$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= -\frac{10}{x^2} \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - \frac{2y'}{x} - \frac{10y}{x^2} = 0$$

The domain of $p(x) = -\frac{2}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $q(x) = -\frac{10}{x^2}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

13.20.2 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 2xrx^{r-1} - 10x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 2r\,x^r - 10x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 2r - 10 = 0$$

Or

$$r^2 - 3r - 10 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$
\begin{aligned}
r_1 &= -2 \\
r_2 &= 5
\end{aligned}
$$

Since the roots are real and distinct, then the general solution is

$$
y = c_1 y_1 + c_2 y_2
$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$
y = \frac{c_1}{x^2} + c_2 x^5
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \frac{c_1}{x^2} + c_2 x^5 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 5$ and $x = 1$ in the above gives

$$
5 = c_1 + c_2 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -\frac{2c_1}{x^3} + 5c_2 x^4
$$

substituting $y' = 4$ and $x = 1$ in the above gives

$$
4 = -2c_1 + 5c_2 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 3 \\
c_2 &= 2
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \frac{2x^7 + 3}{x^2}
$$

Summary

The solution(s) found are the following

$$y = \frac{2x^7 + 3}{x^2} \tag{1}$$

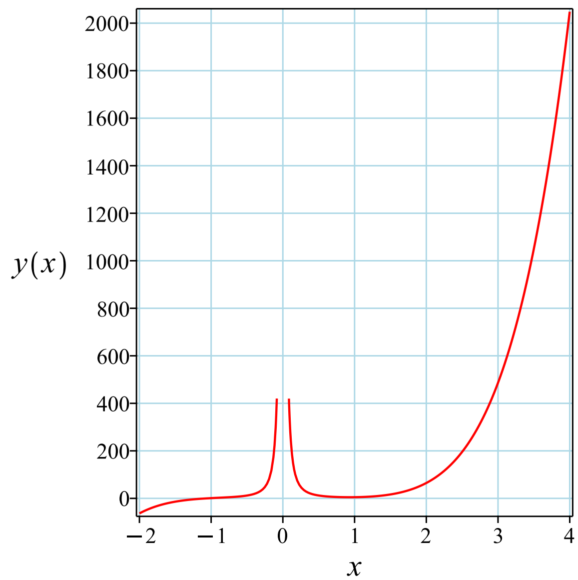

Figure 520: Solution plot

Verification of solutions

$$y = \frac{2x^7 + 3}{x^2}$$

Verified OK.

13.20.3 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2 y'' - 2y'x - 10y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = -\frac{2}{x}$$
$$q(x) = -\frac{10}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'\left(x\right)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'\left(x\right)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int -\frac{2}{x}dx\right)}dx \\
&= \int e^{2\ln(x)}\,dx \\
&= \int x^2 dx \\
&= \frac{x^3}{3}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'\left(x\right)^2} \\
&= \frac{-\frac{10}{x^2}}{x^4} \\
&= -\frac{10}{x^6}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - \frac{10y(\tau)}{x^6} &= 0
\end{aligned}$$

But in terms of τ

$$-\frac{10}{x^6} = -\frac{10}{9\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) - \frac{10y(\tau)}{9\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$9\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 - 10y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$9\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} - 10\tau^r = 0$$

Simplifying gives

$$9r(r-1)\,\tau^r + 0\,\tau^r - 10\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$9r(r-1) + 0 - 10 = 0$$

Or

$$9r^2 - 9r - 10 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -\frac{2}{3}$$
$$r_2 = \frac{5}{3}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = \frac{c_1}{\tau^{\frac{2}{3}}} + c_2\tau^{\frac{5}{3}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{3^{\frac{1}{3}}\left(c_2x^6(x^3)^{\frac{1}{3}} + 9c_1 3^{\frac{1}{3}}\right)}{9\,(x^3)^{\frac{2}{3}}}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{3^{\frac{1}{3}} \left(c_2 x^6 (x^3)^{\frac{1}{3}} + 9 c_1 3^{\frac{1}{3}}\right)}{9 \left(x^3\right)^{\frac{2}{3}}} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 5$ and $x = 1$ in the above gives

$$5 = 3^{\frac{2}{3}} c_1 + \frac{3^{\frac{1}{3}} c_2}{9} \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{3^{\frac{1}{3}} \left(6 c_2 x^5 (x^3)^{\frac{1}{3}} + \frac{c_2 x^8}{(x^3)^{\frac{2}{3}}}\right)}{9 \left(x^3\right)^{\frac{2}{3}}} - \frac{2\, 3^{\frac{1}{3}} \left(c_2 x^6 (x^3)^{\frac{1}{3}} + 9 c_1 3^{\frac{1}{3}}\right) x^2}{9 \left(x^3\right)^{\frac{5}{3}}}$$

substituting $y' = 4$ and $x = 1$ in the above gives

$$4 = -2\, 3^{\frac{2}{3}} c_1 + \frac{5\, 3^{\frac{1}{3}} c_2}{9} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 3^{\frac{1}{3}}$$
$$c_2 = 6\, 3^{\frac{2}{3}}$$

Substituting these values back in above solution results in

$$y = \frac{2x^6 (x^3)^{\frac{1}{3}} + 3}{(x^3)^{\frac{2}{3}}}$$

Summary

The solution(s) found are the following

$$y = \frac{2x^6 (x^3)^{\frac{1}{3}} + 3}{(x^3)^{\frac{2}{3}}} \tag{1}$$

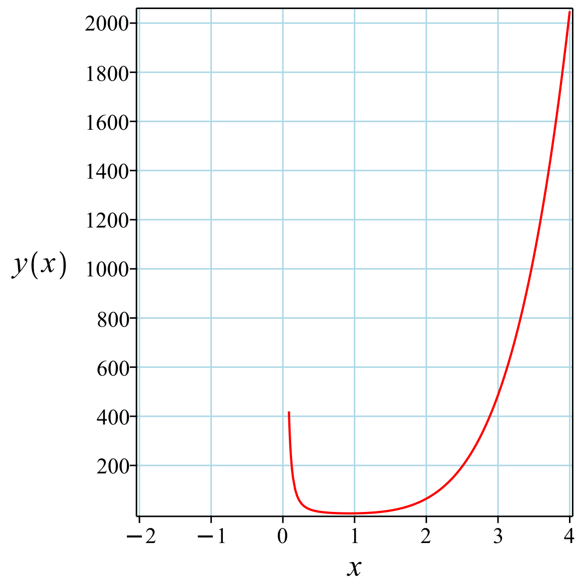

Figure 521: Solution plot

Verification of solutions

$$y = \frac{2x^6 (x^3)^{\frac{1}{3}} + 3}{(x^3)^{\frac{2}{3}}}$$

Verified OK.

13.20.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2 y'' - 2y'x - 10y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = -\frac{2}{x}$$
$$q(x) = -\frac{10}{x^2}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{2n}{x^2} - \frac{10}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 5 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{8v'(x)}{x} &= 0 \\ v''(x) + \frac{8v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{8u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{8u}{x} \end{aligned}$$

Where $f(x) = -\frac{8}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{8}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{8}{x}\,dx \\ \ln(u) &= -8\ln(x) + c_1 \\ u &= e^{-8\ln(x)+c_1} \\ &= \frac{c_1}{x^8} \end{aligned}$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= -\frac{c_1}{7x^7} + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(-\frac{c_1}{7x^7} + c_2\right) x^5 \\
&= \frac{7c_2x^7 - c_1}{7x^2}
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \left(-\frac{c_1}{7x^7} + c_2\right) x^5 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 5$ and $x = 1$ in the above gives

$$
5 = -\frac{c_1}{7} + c_2 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = \frac{c_1}{x^3} + 5\left(-\frac{c_1}{7x^7} + c_2\right) x^4
$$

substituting $y' = 4$ and $x = 1$ in the above gives

$$
4 = \frac{2c_1}{7} + 5c_2 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= -21 \\
c_2 &= 2
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \frac{2x^7 + 3}{x^2}
$$

Summary
The solution(s) found are the following

$$y = \frac{2x^7 + 3}{x^2} \tag{1}$$

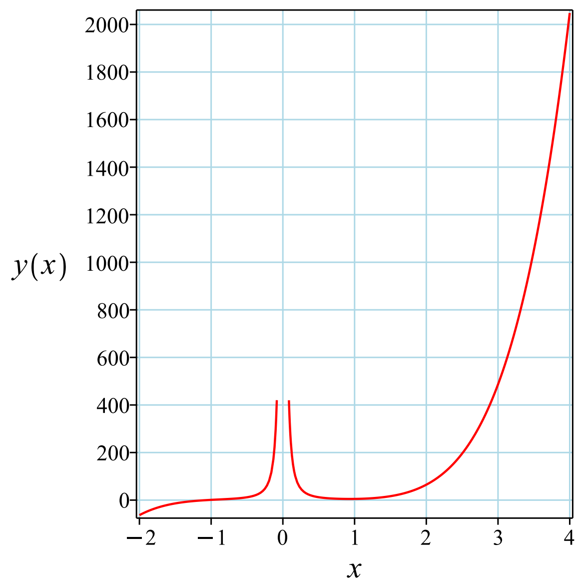

Figure 522: Solution plot

Verification of solutions

$$y = \frac{2x^7 + 3}{x^2}$$

Verified OK.

13.20.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 2y'x - 10y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x \\ C &= -10 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{12}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 12 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{12}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 497: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{12}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition

of r given above. Therefore $b = 12$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 4 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -3 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{12}{x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = 12$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 4 \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -3 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{12}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	4	-3

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	4	-3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = -3$ then

$$\begin{aligned} d &= \alpha_{\infty}^{-} - (\alpha_{c_1}^{-}) \\ &= -3 - (-3) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\ &= -\frac{3}{x} + (-)\,(0) \\ &= -\frac{3}{x} \\ &= -\frac{3}{x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{3}{x}\right)(0) + \left(\left(\frac{3}{x^2}\right) + \left(-\frac{3}{x}\right)^2 - \left(\frac{12}{x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int -\frac{3}{x} dx} \\ &= \frac{1}{x^3} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2}\,dx} \\
&= z_1 e^{\ln(x)} \\
&= z_1(x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x^2}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{x^7}{7}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{1}{x^2}\right) + c_2\left(\frac{1}{x^2}\left(\frac{x^7}{7}\right)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \frac{c_1}{x^2} + \frac{c_2 x^5}{7} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 5$ and $x = 1$ in the above gives

$$5 = c_1 + \frac{c_2}{7} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{2c_1}{x^3} + \frac{5c_2x^4}{7}$$

substituting $y' = 4$ and $x = 1$ in the above gives

$$4 = -2c_1 + \frac{5c_2}{7} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 3$$
$$c_2 = 14$$

Substituting these values back in above solution results in

$$y = \frac{2x^7 + 3}{x^2}$$

Summary

The solution(s) found are the following

$$y = \frac{2x^7 + 3}{x^2} \tag{1}$$

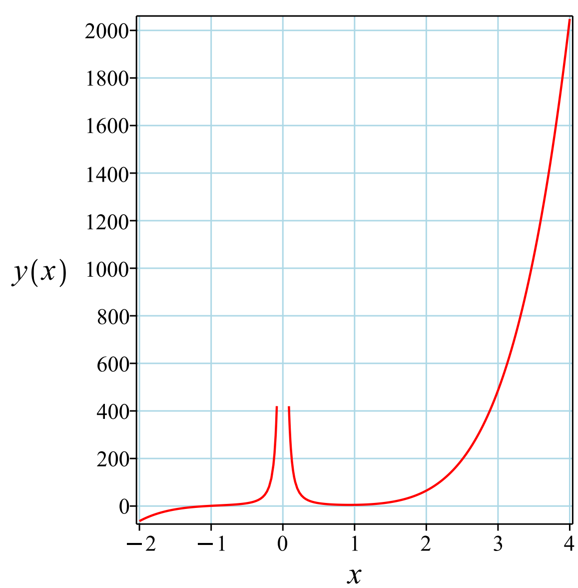

Figure 523: Solution plot

Verification of solutions

$$y = \frac{2x^7 + 3}{x^2}$$

Verified OK.

13.20.6 Maple step by step solution

Let's solve

$$\left[y''x^2 - 2y'x - 10y = 0, y(1) = 5, y'\Big|_{\{x=1\}} = 4\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{2y'}{x} + \frac{10y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{2y'}{x} - \frac{10y}{x^2} = 0$

- Multiply by denominators of the ODE

  $y''x^2 - 2y'x - 10y = 0$

- Make a change of variables

  $t = \ln(x)$

☐ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right)t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

$$\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2}-\frac{\frac{d}{dt}y(t)}{x^2}\right)x^2-2\frac{d}{dt}y(t)-10y(t)=0$$

- Simplify

  $\frac{d^2}{dt^2}y(t)-3\frac{d}{dt}y(t)-10y(t)=0$
- Characteristic polynomial of ODE

  $r^2-3r-10=0$
- Factor the characteristic polynomial

  $(r+2)(r-5)=0$
- Roots of the characteristic polynomial

  $r=(-2,5)$
- 1st solution of the ODE

  $y_1(t)=\mathrm{e}^{-2t}$
- 2nd solution of the ODE

  $y_2(t)=\mathrm{e}^{5t}$
- General solution of the ODE

  $y(t)=c_1y_1(t)+c_2y_2(t)$
- Substitute in solutions

  $y(t)=c_1\mathrm{e}^{-2t}+c_2\mathrm{e}^{5t}$
- Change variables back using $t=\ln(x)$

  $y=\frac{c_1}{x^2}+c_2x^5$
- Simplify

  $y=\frac{c_1}{x^2}+c_2x^5$

☐ Check validity of solution $y=\frac{c_1}{x^2}+c_2x^5$

  - Use initial condition $y(1)=5$

    $5=c_1+c_2$
  - Compute derivative of the solution

    $y'=-\frac{2c_1}{x^3}+5c_2x^4$
  - Use the initial condition $y'\Big|_{\{x=1\}}=4$

    $4=-2c_1+5c_2$

- Solve for c_1 and c_2

  $\{c_1 = 3, c_2 = 2\}$

- Substitute constant values into general solution and simplify

  $y = \frac{3}{x^2} + 2x^5$

- Solution to the IVP

  $y = \frac{3}{x^2} + 2x^5$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 4, Section 4.5. The Cauchy-Euler Equation. Exercises page 169
Problem number: 21.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_1", "second_order_change_of_variable_on_y_method_2", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler], [_2nd_order, _linear, `_with_symmetry_[0,F(
   x)]`]]
```

$$\boxed{x^2y'' - 4y'x + 6y = 0}$$

With initial conditions

$$[y(2) = 0, y'(2) = 4]$$

13.21.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -\frac{4}{x} \\ q(x) &= \frac{6}{x^2} \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - \frac{4y'}{x} + \frac{6y}{x^2} = 0$$

The domain of $p(x) = -\frac{4}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 2$ is inside this domain. The domain of $q(x) = \frac{6}{x^2}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 2$ is also inside this domain. Hence solution exists and is unique.

13.21.2 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 4xrx^{r-1} + 6x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 4r\,x^r + 6x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 4r + 6 = 0$$

Or

$$r^2 - 5r + 6 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$
\begin{aligned}
r_1 &= 2 \\
r_2 &= 3
\end{aligned}
$$

Since the roots are real and distinct, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_2 x^3 + c_1 x^2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_2 x^3 + c_1 x^2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 2$ in the above gives

$$0 = 8c_2 + 4c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 3c_2 x^2 + 2c_1 x$$

substituting $y' = 4$ and $x = 2$ in the above gives

$$4 = 12c_2 + 4c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= -2 \\
c_2 &= 1
\end{aligned}
$$

Substituting these values back in above solution results in

$$y = x^3 - 2x^2$$

Which simplifies to

$$y = (x - 2)\, x^2$$

Summary
The solution(s) found are the following

$$y = (x-2)\,x^2 \tag{1}$$

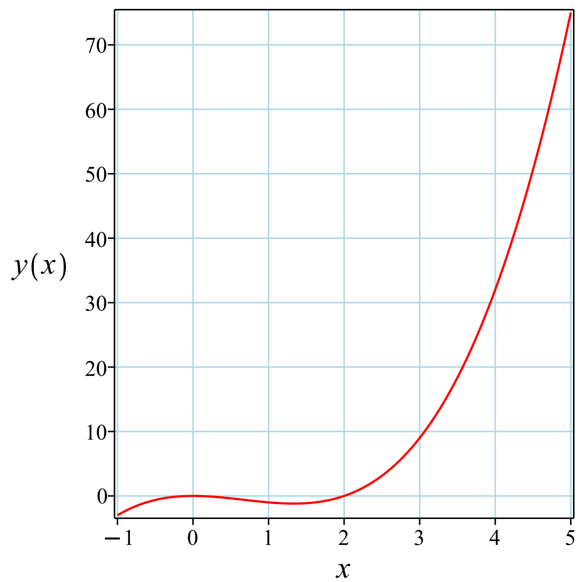

Figure 524: Solution plot

Verification of solutions

$$y = (x-2)\,x^2$$

Verified OK.

13.21.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)$$

Where $p(x) = -\frac{4}{x}$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int -\frac{4}{x}\,dx} \\ &= \frac{1}{x^2} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$(M(x)y)'' = 0$$
$$\left(\frac{y}{x^2}\right)'' = 0$$

Integrating once gives

$$\left(\frac{y}{x^2}\right)' = c_1$$

Integrating again gives

$$\left(\frac{y}{x^2}\right) = c_1 x + c_2$$

Hence the solution is

$$y = \frac{c_1 x + c_2}{\frac{1}{x^2}}$$

Or

$$y = c_1 x^3 + c_2 x^2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 x^3 + c_2 x^2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 2$ in the above gives

$$0 = 8c_1 + 4c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 3c_1 x^2 + 2c_2 x$$

substituting $y' = 4$ and $x = 2$ in the above gives

$$4 = 12c_1 + 4c_2 \tag{2A}$$

Equations $\{1A,2A\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = -2$$

Substituting these values back in above solution results in

$$y = x^3 - 2x^2$$

Which simplifies to

$$y = (x - 2) x^2$$

Summary

The solution(s) found are the following

$$y = (x - 2) x^2 \tag{1}$$

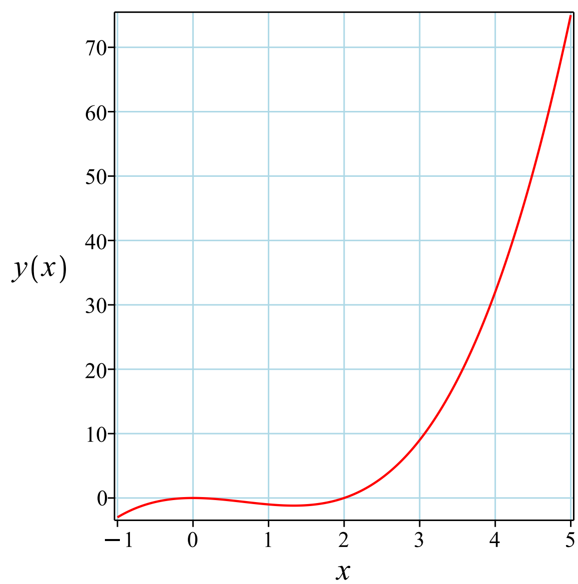

Figure 525: Solution plot

Verification of solutions

$$y = (x - 2) x^2$$

Verified OK.

13.21.4 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2y'' - 4y'x + 6y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{x} \\ q(x) &= \frac{6}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\, \tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\ &= \int \mathrm{e}^{-\left(\int -\frac{4}{x}dx\right)}dx \\ &= \int e^{4\ln(x)}\, dx \\ &= \int x^4 dx \\ &= \frac{x^5}{5} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned} q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{6}{x^2}}{x^8} \\ &= \frac{6}{x^{10}} \end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned} \frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + \frac{6y(\tau)}{x^{10}} &= 0 \end{aligned}$$

But in terms of τ

$$\frac{6}{x^{10}} = \frac{6}{25\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{6y(\tau)}{25\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$25\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 6y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$25\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 6\tau^r = 0$$

Simplifying gives

$$25r(r-1)\,\tau^r + 0\,\tau^r + 6\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$25r(r-1) + 0 + 6 = 0$$

Or

$$25r^2 - 25r + 6 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{2}{5}$$
$$r_2 = \frac{3}{5}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1 \tau^{\frac{2}{5}} + c_2 \tau^{\frac{3}{5}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 5^{\frac{3}{5}} (x^5)^{\frac{2}{5}}}{5} + \frac{c_2 5^{\frac{2}{5}} (x^5)^{\frac{3}{5}}}{5}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1 5^{\frac{3}{5}} (x^5)^{\frac{2}{5}}}{5} + \frac{c_2 5^{\frac{2}{5}} (x^5)^{\frac{3}{5}}}{5} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 2$ in the above gives

$$0 = \frac{4\, 5^{\frac{2}{5}} \left(5^{\frac{1}{5}} c_1 + 2c_2\right)}{5} \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{2c_1 5^{\frac{3}{5}} x^4}{5 (x^5)^{\frac{3}{5}}} + \frac{3c_2 5^{\frac{2}{5}} x^4}{5 (x^5)^{\frac{2}{5}}}$$

substituting $y' = 4$ and $x = 2$ in the above gives

$$4 = \frac{4\left(5^{\frac{1}{5}} c_1 + 3c_2\right) 5^{\frac{2}{5}}}{5} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -2\,5^{\frac{2}{5}}$$
$$c_2 = 5^{\frac{3}{5}}$$

Substituting these values back in above solution results in

$$y = (x^5)^{\frac{3}{5}} - 2(x^5)^{\frac{2}{5}}$$

Summary

The solution(s) found are the following

$$y = (x^5)^{\frac{3}{5}} - 2(x^5)^{\frac{2}{5}} \tag{1}$$

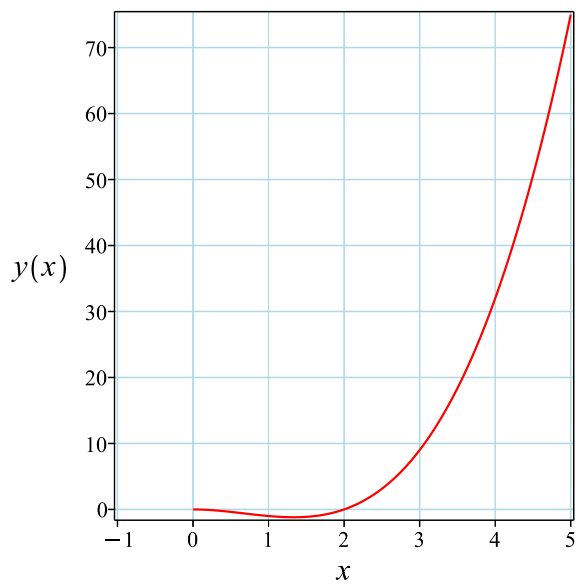

Figure 526: Solution plot

Verification of solutions

$$y = (x^5)^{\frac{3}{5}} - 2(x^5)^{\frac{2}{5}}$$

Verified OK.

13.21.5 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2y'' - 4y'x + 6y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{x} \\ q(x) &= \frac{6}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{\sqrt{6}}{c\sqrt{\frac{1}{x^2}}\,x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{\sqrt{6}}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{4}{x}\frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= -\frac{5c\sqrt{6}}{6} \end{aligned}$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2} y(\tau) - \frac{5c\sqrt{6}\left(\frac{d}{d\tau} y(\tau)\right)}{6} + c^2 y(\tau) &= 0
\end{aligned} \tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = \mathrm{e}^{\frac{5\sqrt{6}\, c\tau}{12}} \left(c_1 \cosh\left(\frac{\sqrt{6}\, c\tau}{12}\right) + i c_2 \sinh\left(\frac{\sqrt{6}\, c\tau}{12}\right)\right)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\, dx \\
&= \frac{\int \sqrt{6}\sqrt{\frac{1}{x^2}} dx}{c} \\
&= \frac{\sqrt{6}\sqrt{\frac{1}{x^2}}\, x \ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = x^{\frac{5}{2}} \left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = x^{\frac{5}{2}} \left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x)}{2}\right)\right) \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 2$ in the above gives

$$
0 = 2ic_2 + 6c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = \frac{5x^{\frac{3}{2}}\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)}{2} + x^{\frac{5}{2}} \left(\frac{c_1 \sinh\left(\frac{\ln(x)}{2}\right)}{2x} + \frac{i c_2 \cosh\left(\frac{\ln(x)}{2}\right)}{2x}\right)
$$

substituting $y' = 4$ and $x = 2$ in the above gives

$$4 = 4ic_2 + 8c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -1$$
$$c_2 = -3i$$

Substituting these values back in above solution results in

$$y = 3x^{\frac{5}{2}} \sinh\left(\frac{\ln(x)}{2}\right) - x^{\frac{5}{2}} \cosh\left(\frac{\ln(x)}{2}\right)$$

Which simplifies to

$$y = -\left(\cosh\left(\frac{\ln(x)}{2}\right) - 3\sinh\left(\frac{\ln(x)}{2}\right)\right) x^{\frac{5}{2}}$$

Summary

The solution(s) found are the following

$$y = -\left(\cosh\left(\frac{\ln(x)}{2}\right) - 3\sinh\left(\frac{\ln(x)}{2}\right)\right) x^{\frac{5}{2}} \tag{1}$$

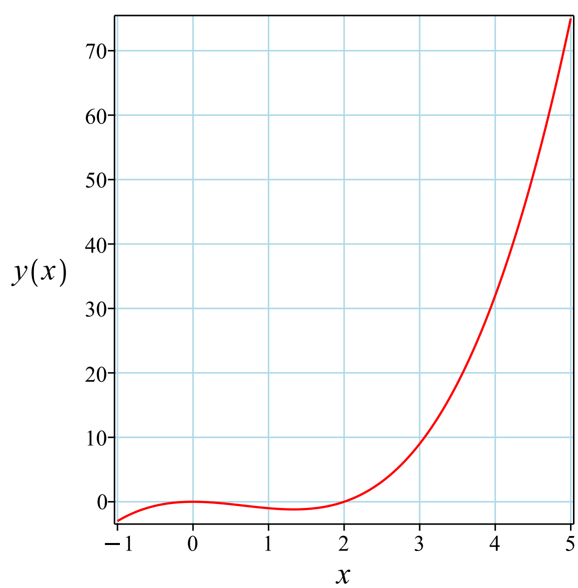

Figure 527: Solution plot

Verification of solutions

$$y=-\left(\cosh\left(\frac{\ln(x)}{2}\right)-3\sinh\left(\frac{\ln(x)}{2}\right)\right)x^{\frac{5}{2}}$$

Verified OK.

13.21.6 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{x}\\ q(x) &= \frac{6}{x^2} \end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$\begin{aligned} Q &= q-\frac{p'}{2}-\frac{p^2}{4}\\ &= \frac{6}{x^2}-\frac{\left(-\frac{4}{x}\right)'}{2}-\frac{\left(-\frac{4}{x}\right)^2}{4}\\ &= \frac{6}{x^2}-\frac{\left(\frac{4}{x^2}\right)}{2}-\frac{\left(\frac{16}{x^2}\right)}{4}\\ &= \frac{6}{x^2}-\left(\frac{2}{x^2}\right)-\frac{4}{x^2}\\ &= 0 \end{aligned}$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y=v(x)\,z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$\begin{aligned} z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2}dx\right)}\\ &= e^{-\int \frac{-\frac{4}{x}}{2}}\\ &= x^2 \end{aligned} \tag{5}$$

Hence (3) becomes

$$y = v(x)\, x^2 \tag{4}$$

Applying this change of variable to the original ode results in

$$x^4 v''(x) = 0$$

Which is now solved for $v(x)$ Integrating twice gives the solution

$$v(x) = c_1 x + c_2$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= (c_1 x + c_2)\,(z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = x^2$$

Hence (7) becomes

$$y = (c_1 x + c_2)\, x^2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = (c_1 x + c_2)\, x^2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 2$ in the above gives

$$0 = 8c_1 + 4c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 x^2 + 2(c_1 x + c_2)\, x$$

substituting $y' = 4$ and $x = 2$ in the above gives

$$4 = 12c_1 + 4c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = -2$$

Substituting these values back in above solution results in

$$y = (x-2)\, x^2$$

Summary

The solution(s) found are the following

$$y = (x-2)\, x^2 \tag{1}$$

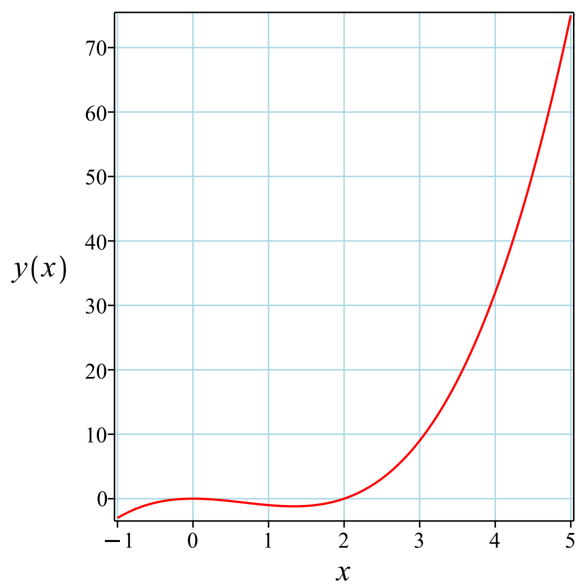

Figure 528: Solution plot

Verification of solutions

$$y = (x-2)\, x^2$$

Verified OK.

13.21.7 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2y'' - 4y'x + 6y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{x} \\ q(x) &= \frac{6}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right)v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right)v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{4n}{x^2} + \frac{6}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 3 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{2v'(x)}{x} &= 0 \\ v''(x) + \frac{2v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{2u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x, u) \\
&= f(x)g(u) \\
&= -\frac{2u}{x}
\end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\, du &= -\frac{2}{x}\, dx \\
\int \frac{1}{u}\, du &= \int -\frac{2}{x}\, dx \\
\ln(u) &= -2\ln(x) + c_1 \\
u &= \mathrm{e}^{-2\ln(x)+c_1} \\
&= \frac{c_1}{x^2}
\end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= -\frac{c_1}{x} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\, x^n \\
&= \left(-\frac{c_1}{x} + c_2\right) x^3 \\
&= (c_2 x - c_1)\, x^2
\end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \left(-\frac{c_1}{x} + c_2\right) x^3 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 2$ in the above gives

$$0 = -4c_1 + 8c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1x + 3\left(-\frac{c_1}{x} + c_2\right)x^2$$

substituting $y' = 4$ and $x = 2$ in the above gives

$$4 = -4c_1 + 12c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 2$$
$$c_2 = 1$$

Substituting these values back in above solution results in

$$y = (x - 2)\,x^2$$

Summary

The solution(s) found are the following

$$y = (x - 2)\,x^2 \tag{1}$$

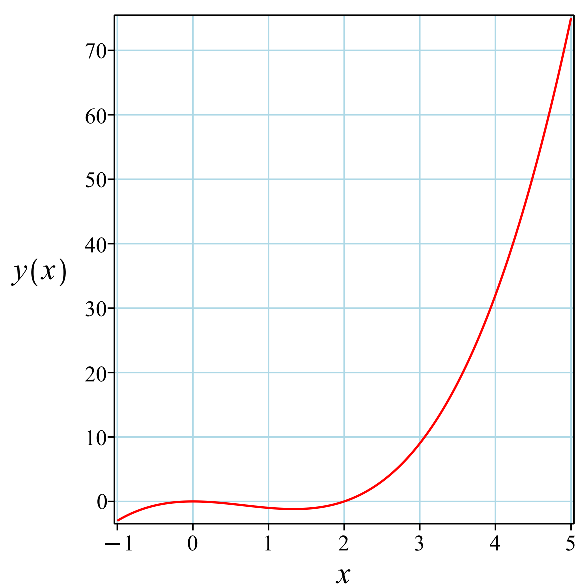

Figure 529: Solution plot

Verification of solutions

$$y = (x - 2)\, x^2$$

Verified OK.

13.21.8 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 4y'x + 6y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -4x \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 499: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x}{x^2}\,dx} \\
&= z_1 e^{2\ln(x)} \\
&= z_1\left(x^2\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^2
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{4\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^2\right) + c_2\left(x^2(x)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_2 x^3 + c_1 x^2 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 2$ in the above gives

$$
0 = 8c_2 + 4c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$y' = 3c_2x^2 + 2c_1x$$

substituting $y' = 4$ and $x = 2$ in the above gives

$$4 = 12c_2 + 4c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -2$$
$$c_2 = 1$$

Substituting these values back in above solution results in

$$y = x^3 - 2x^2$$

Which simplifies to

$$y = (x - 2)\, x^2$$

Summary

The solution(s) found are the following

$$y = (x - 2)\, x^2 \tag{1}$$

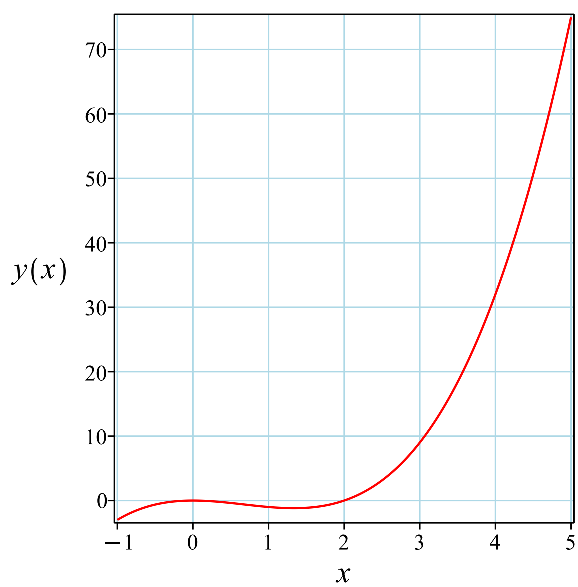

Figure 530: Solution plot

Verification of solutions

$$y = (x - 2)\, x^2$$

Verified OK.

13.21.9 Maple step by step solution

Let's solve

$$\left[y''x^2-4y'x+6y=0, y(2)=0, y'\Big|_{\{x=2\}}=4\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{4y'}{x}-\frac{6y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{4y'}{x}+\frac{6y}{x^2}=0$

- Multiply by denominators of the ODE

  $y''x^2-4y'x+6y=0$

- Make a change of variables

  $t=\ln(x)$

□ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

    $y'=\left(\frac{d}{dt}y(t)\right)t'(x)$

  ◦ Compute derivative

    $y'=\frac{\frac{d}{dt}y(t)}{x}$

  ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y''=\left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2+t''(x)\left(\frac{d}{dt}y(t)\right)$

  ◦ Compute derivative

    $y''=\frac{\frac{d^2}{dt^2}y(t)}{x^2}-\frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2}-\frac{\frac{d}{dt}y(t)}{x^2}\right)x^2-4\frac{d}{dt}y(t)+6y(t)=0$

- Simplify

  $\frac{d^2}{dt^2}y(t)-5\frac{d}{dt}y(t)+6y(t)=0$

- Characteristic polynomial of ODE

$r^2 - 5r + 6 = 0$

- Factor the characteristic polynomial

  $(r-2)(r-3) = 0$

- Roots of the characteristic polynomial

  $r = (2, 3)$

- 1st solution of the ODE

  $y_1(t) = e^{2t}$

- 2nd solution of the ODE

  $y_2(t) = e^{3t}$

- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$

- Substitute in solutions

  $y(t) = c_1 e^{2t} + c_2 e^{3t}$

- Change variables back using $t = \ln(x)$

  $y = c_2 x^3 + c_1 x^2$

- Simplify

  $y = x^2(c_2 x + c_1)$

□ Check validity of solution $y = x^2(c_2 x + c_1)$

  - Use initial condition $y(2) = 0$

    $0 = 8c_2 + 4c_1$

  - Compute derivative of the solution

    $y' = 2x(c_2 x + c_1) + c_2 x^2$

  - Use the initial condition $y'\Big|_{\{x=2\}} = 4$

    $4 = 12c_2 + 4c_1$

  - Solve for c_1 and c_2

    $\{c_1 = -2, c_2 = 1\}$

  - Substitute constant values into general solution and simplify

    $y = (x-2)\, x^2$

- Solution to the IVP

$$y = (x-2)\,x^2$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "exact linear second order ode", "second_order_integrable_as_is", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{x^2y'' + 5y'x + 3y = 0}$$

With initial conditions

$$[y(1) = 1, y'(1) = -5]$$

13.22.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= \frac{5}{x} \\ q(x) &= \frac{3}{x^2} \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + \frac{5y'}{x} + \frac{3y}{x^2} = 0$$

The domain of $p(x) = \frac{5}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $q(x) = \frac{3}{x^2}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

13.22.2 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 5xrx^{r-1} + 3x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 5r\,x^r + 3x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 5r + 3 = 0$$

Or

$$r^2 + 4r + 3 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -3$$
$$r_2 = -1$$

Since the roots are real and distinct, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = \frac{c_1}{x^3} + \frac{c_2}{x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1}{x^3} + \frac{c_2}{x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{3c_1}{x^4} - \frac{c_2}{x^2}$$

substituting $y' = -5$ and $x = 1$ in the above gives

$$-5 = -3c_1 - c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 2$$
$$c_2 = -1$$

Substituting these values back in above solution results in

$$y = -\frac{x^2 - 2}{x^3}$$

Summary
The solution(s) found are the following

$$y = -\frac{x^2 - 2}{x^3} \tag{1}$$

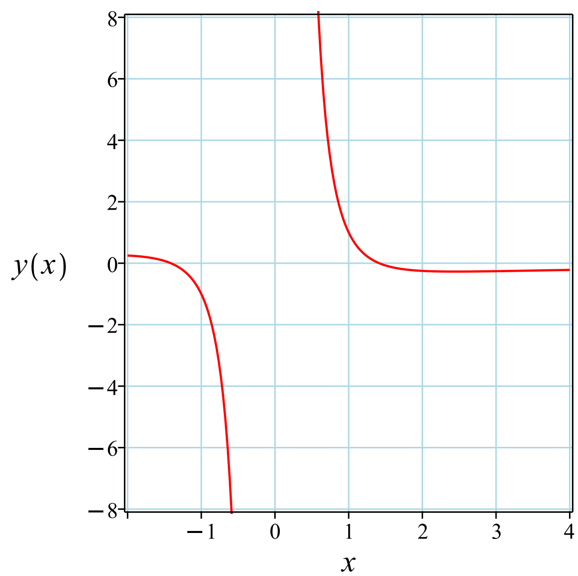

Figure 531: Solution plot

Verification of solutions

$$y = -\frac{x^2 - 2}{x^3}$$

Verified OK.

13.22.3 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2 y'' + 5y'x + 3y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{5}{x} \\ q(x) &= \frac{3}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int \frac{5}{x}dx\right)}dx \\
&= \int e^{-5\ln(x)}\,dx \\
&= \int \frac{1}{x^5}dx \\
&= -\frac{1}{4x^4} \qquad (6)
\end{aligned}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{3}{x^2}}{\frac{1}{x^{10}}} \\
&= 3x^8 \qquad (7)
\end{aligned}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + 3x^8 y(\tau) &= 0
\end{aligned}$$

But in terms of τ

$$3x^8 = \frac{3}{16\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{3y(\tau)}{16\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$16\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 3y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$16\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 3\tau^r = 0$$

Simplifying gives

$$16r(r-1)\,\tau^r + 0\,\tau^r + 3\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$16r(r-1) + 0 + 3 = 0$$

Or

$$16r^2 - 16r + 3 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{4}$$
$$r_2 = \frac{3}{4}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{\frac{1}{4}} + c_2\tau^{\frac{3}{4}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{2}\left(-\frac{1}{x^4}\right)^{\frac{1}{4}}\left(c_2\sqrt{-\frac{1}{x^4}} + 2c_1\right)}{4}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{\sqrt{2}\left(-\frac{1}{x^4}\right)^{\frac{1}{4}}\left(c_2\sqrt{-\frac{1}{x^4}}+2c_1\right)}{4} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = \left(\frac{1}{2}+\frac{i}{2}\right)c_1 + \left(-\frac{1}{4}+\frac{i}{4}\right)c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{\sqrt{2}\left(c_2\sqrt{-\frac{1}{x^4}}+2c_1\right)}{4\left(-\frac{1}{x^4}\right)^{\frac{3}{4}}x^5} + \frac{\sqrt{2}\,c_2}{2\left(-\frac{1}{x^4}\right)^{\frac{1}{4}}x^5}$$

substituting $y' = -5$ and $x = 1$ in the above gives

$$-5 = \left(-\frac{1}{2}-\frac{i}{2}\right)c_1 + \left(\frac{3}{4}-\frac{3i}{4}\right)c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= -1+i \\ c_2 &= -4-4i \end{aligned}$$

Substituting these values back in above solution results in

$$y = -i\sqrt{2}\left(-\frac{1}{x^4}\right)^{\frac{3}{4}} + \frac{i\sqrt{2}\left(-\frac{1}{x^4}\right)^{\frac{1}{4}}}{2} - \sqrt{2}\left(-\frac{1}{x^4}\right)^{\frac{3}{4}} - \frac{\sqrt{2}\left(-\frac{1}{x^4}\right)^{\frac{1}{4}}}{2}$$

<u>Summary</u>

The solution(s) found are the following

$$y = -\left((1+i)\sqrt{-\frac{1}{x^4}}+\frac{1}{2}-\frac{i}{2}\right)\sqrt{2}\left(-\frac{1}{x^4}\right)^{\frac{1}{4}} \tag{1}$$

<u>Verification of solutions</u>

$$y = -\left((1+i)\sqrt{-\frac{1}{x^4}}+\frac{1}{2}-\frac{i}{2}\right)\sqrt{2}\left(-\frac{1}{x^4}\right)^{\frac{1}{4}}$$

Verified OK.

13.22.4 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2y'' + 5y'x + 3y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{5}{x} \\ q(x) &= \frac{3}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{3}\,\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{\sqrt{3}}{c\sqrt{\frac{1}{x^2}}\,x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{\sqrt{3}}{c\sqrt{\frac{1}{x^2}}\,x^3} + \frac{5}{x}\frac{\sqrt{3}\,\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{3}\,\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= \frac{4c\sqrt{3}}{3} \end{aligned}$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2} y(\tau) + \frac{4c\sqrt{3}\left(\frac{d}{d\tau} y(\tau)\right)}{3} + c^2 y(\tau) &= 0
\end{aligned} \tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = \mathrm{e}^{-\frac{2\sqrt{3}\, c\tau}{3}} \left(c_1 \cosh\left(\frac{\sqrt{3}\, c\tau}{3}\right) + i c_2 \sinh\left(\frac{\sqrt{3}\, c\tau}{3}\right)\right)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c} \sqrt{q}\, dx \\
&= \frac{\int \sqrt{3}\, \sqrt{\frac{1}{x^2}} dx}{c} \\
&= \frac{\sqrt{3}\, \sqrt{\frac{1}{x^2}}\, x \ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = \frac{(i c_2 + c_1)\, x^2 - i c_2 + c_1}{2x^3}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \frac{(i c_2 + c_1)\, x^2 - i c_2 + c_1}{2x^3} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$
1 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = \frac{i c_2 + c_1}{x^2} - \frac{3\left((i c_2 + c_1)\, x^2 - i c_2 + c_1\right)}{2x^4}
$$

substituting $y' = -5$ and $x = 1$ in the above gives

$$-5 = ic_2 - 2c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = 3i$$

Substituting these values back in above solution results in

$$y = \frac{-x^2 + 2}{x^3}$$

Summary

The solution(s) found are the following

$$y = \frac{-x^2 + 2}{x^3} \tag{1}$$

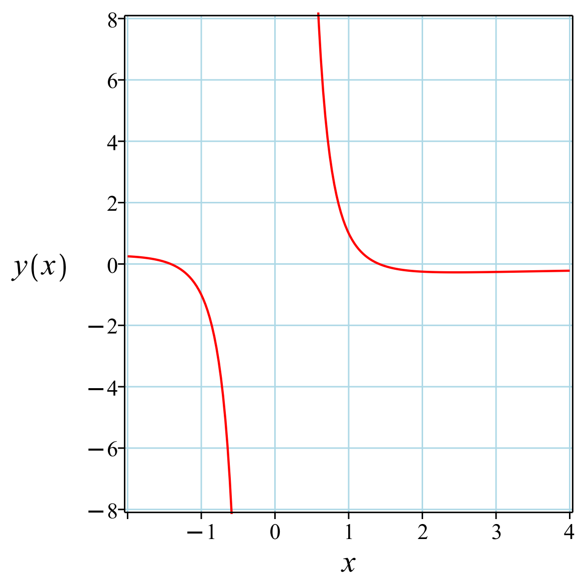

Figure 532: Solution plot

Verification of solutions

$$y = \frac{-x^2 + 2}{x^3}$$

Verified OK.

13.22.5 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2y'' + 5y'x + 3y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{5}{x} \\ q(x) &= \frac{3}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{5n}{x^2} + \frac{3}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = -1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{3v'(x)}{x} &= 0 \\ v''(x) + \frac{3v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{3u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x, u) \\
&= f(x)g(u) \\
&= -\frac{3u}{x}
\end{aligned}$$

Where $f(x) = -\frac{3}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\, du &= -\frac{3}{x}\, dx \\
\int \frac{1}{u}\, du &= \int -\frac{3}{x}\, dx \\
\ln(u) &= -3\ln(x) + c_1 \\
u &= e^{-3\ln(x)+c_1} \\
&= \frac{c_1}{x^3}
\end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= -\frac{c_1}{2x^2} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\, x^n \\
&= \frac{-\frac{c_1}{2x^2} + c_2}{x} \\
&= \frac{2c_2x^2 - c_1}{2x^3}
\end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{-\frac{c_1}{2x^2} + c_2}{x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = -\frac{c_1}{2} + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{c_1}{x^4} - \frac{-\frac{c_1}{2x^2} + c_2}{x^2}$$

substituting $y' = -5$ and $x = 1$ in the above gives

$$-5 = \frac{3c_1}{2} - c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -4$$
$$c_2 = -1$$

Substituting these values back in above solution results in

$$y = -\frac{x^2 - 2}{x^3}$$

Summary

The solution(s) found are the following

$$y = -\frac{x^2 - 2}{x^3} \tag{1}$$

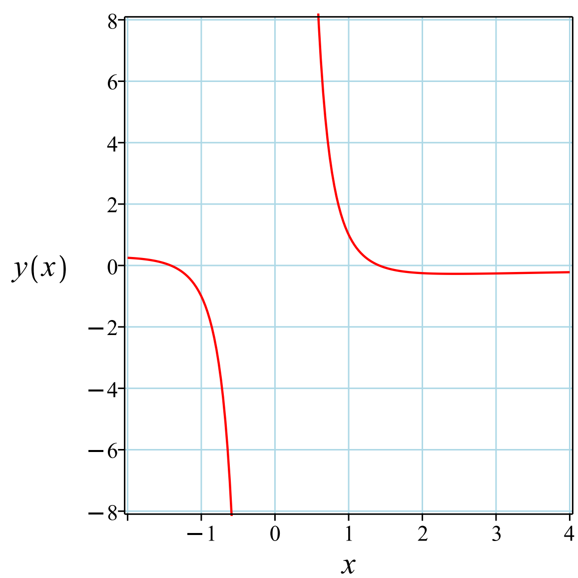

Figure 533: Solution plot

Verification of solutions

$$y = -\frac{x^2 - 2}{x^3}$$

Verified OK.

13.22.6 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(x^2 y'' + 5y'x + 3y\right) dx = 0$$
$$x^2 y' + 3yx = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{3}{x}$$
$$q(x) = \frac{c_1}{x^2}$$

Hence the ode is

$$y' + \frac{3y}{x} = \frac{c_1}{x^2}$$

The integrating factor μ is

$$\mu = e^{\int \frac{3}{x} dx}$$
$$= x^3$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{c_1}{x^2}\right)$$
$$\frac{d}{dx}\left(y\,x^3\right) = \left(x^3\right)\left(\frac{c_1}{x^2}\right)$$
$$d\left(y\,x^3\right) = (c_1 x)\ dx$$

Integrating gives

$$y\,x^3 = \int c_1 x \,dx$$
$$y\,x^3 = \frac{c_1 x^2}{2} + c_2$$

Dividing both sides by the integrating factor $\mu = x^3$ results in

$$y = \frac{c_1}{2x} + \frac{c_2}{x^3}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1}{2x} + \frac{c_2}{x^3} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = c_2 + \frac{c_1}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{c_1}{2x^2} - \frac{3c_2}{x^4}$$

substituting $y' = -5$ and $x = 1$ in the above gives

$$-5 = -\frac{c_1}{2} - 3c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -2$$
$$c_2 = 2$$

Substituting these values back in above solution results in

$$y = -\frac{x^2 - 2}{x^3}$$

Summary
The solution(s) found are the following

$$y = -\frac{x^2 - 2}{x^3} \tag{1}$$

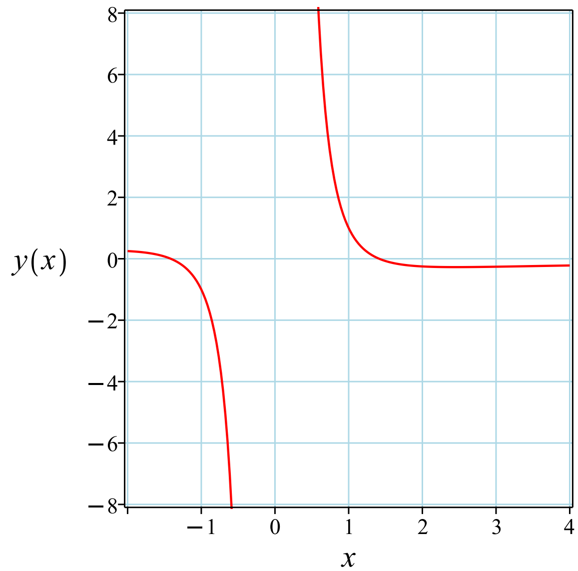

Figure 534: Solution plot

Verification of solutions

$$y = -\frac{x^2 - 2}{x^3}$$

Verified OK.

13.22.7 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$x^2y'' + 5y'x + 3y = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(x^2y'' + 5y'x + 3y\right) dx = 0$$
$$x^2y' + 3yx = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= \frac{3}{x} \\
q(x) &= \frac{c_1}{x^2}
\end{aligned}
$$

Hence the ode is

$$
y' + \frac{3y}{x} = \frac{c_1}{x^2}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int \frac{3}{x} dx} \\
&= x^3
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{c_1}{x^2}\right) \\
\frac{d}{dx}\left(y\, x^3\right) &= \left(x^3\right)\left(\frac{c_1}{x^2}\right) \\
d\left(y\, x^3\right) &= (c_1 x)\ dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
y\, x^3 &= \int c_1 x\, dx \\
y\, x^3 &= \frac{c_1 x^2}{2} + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = x^3$ results in

$$
y = \frac{c_1}{2x} + \frac{c_2}{x^3}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \frac{c_1}{2x} + \frac{c_2}{x^3} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$
1 = c_2 + \frac{c_1}{2} \tag{1A}
$$

Taking derivative of the solution gives

$$y' = -\frac{c_1}{2x^2} - \frac{3c_2}{x^4}$$

substituting $y' = -5$ and $x = 1$ in the above gives

$$-5 = -\frac{c_1}{2} - 3c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -2$$
$$c_2 = 2$$

Substituting these values back in above solution results in

$$y = -\frac{x^2 - 2}{x^3}$$

Summary

The solution(s) found are the following

$$y = -\frac{x^2 - 2}{x^3} \tag{1}$$

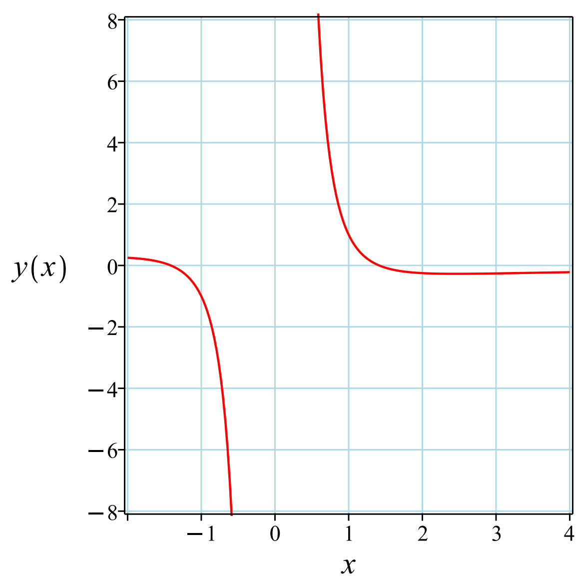

Figure 535: Solution plot

Verification of solutions

$$y = -\frac{x^2 - 2}{x^3}$$

Verified OK.

13.22.8 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + 5y'x + 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 5x \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 501: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{3}{4x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{3}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{2x} + (-)\,(0) \\
&= -\frac{1}{2x} \\
&= -\frac{1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(-\frac{1}{2x}\right)^2 - \left(\frac{3}{4x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int -\frac{1}{2x} dx} \\
&= \frac{1}{\sqrt{x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{5x}{x^2}\,dx} \\
&= z_1 e^{-\frac{5\ln(x)}{2}} \\
&= z_1 \left(\frac{1}{x^{\frac{5}{2}}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x^3}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{5x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-5\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{x^2}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{1}{x^3}\right) + c_2\left(\frac{1}{x^3}\left(\frac{x^2}{2}\right)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \frac{c_1}{x^3} + \frac{c_2}{2x} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = c_1 + \frac{c_2}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{3c_1}{x^4} - \frac{c_2}{2x^2}$$

substituting $y' = -5$ and $x = 1$ in the above gives

$$-5 = -3c_1 - \frac{c_2}{2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 2$$
$$c_2 = -2$$

Substituting these values back in above solution results in

$$y = -\frac{x^2 - 2}{x^3}$$

Summary
The solution(s) found are the following

$$y = -\frac{x^2 - 2}{x^3} \tag{1}$$

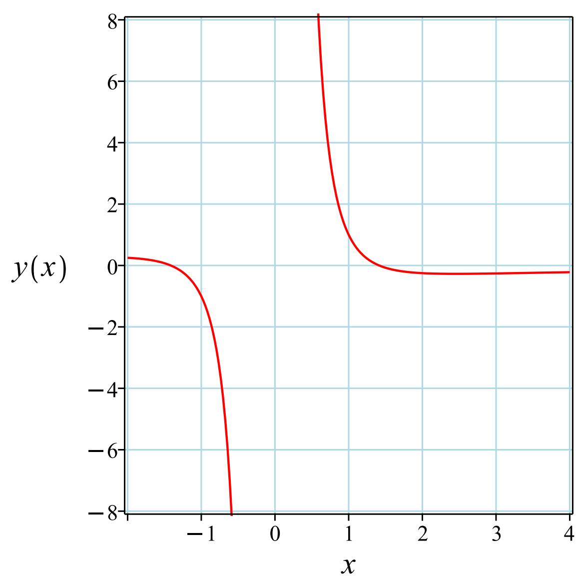

Figure 536: Solution plot

Verification of solutions

$$y = -\frac{x^2 - 2}{x^3}$$

Verified OK.

13.22.9 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}
p(x) &= x^2 \\
q(x) &= 5x \\
r(x) &= 3 \\
s(x) &= 0
\end{aligned}$$

Hence

$$\begin{aligned}
p''(x) &= 2 \\
q'(x) &= 5
\end{aligned}$$

Therefore (1) becomes

$$2 - (5) + (3) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$x^2 y' + 3yx = c_1$$

We now have a first order ode to solve which is

$$x^2y' + 3yx = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= \frac{3}{x} \\ q(x) &= \frac{c_1}{x^2} \end{aligned}$$

Hence the ode is

$$y' + \frac{3y}{x} = \frac{c_1}{x^2}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int \frac{3}{x}dx} \\ &= x^3 \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(\frac{c_1}{x^2}\right) \\ \frac{d}{dx}(y\,x^3) &= (x^3)\left(\frac{c_1}{x^2}\right) \\ d(y\,x^3) &= (c_1 x)\ dx \end{aligned}$$

Integrating gives

$$\begin{aligned} y\,x^3 &= \int c_1 x\,dx \\ y\,x^3 &= \frac{c_1 x^2}{2} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = x^3$ results in

$$y = \frac{c_1}{2x} + \frac{c_2}{x^3}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1}{2x} + \frac{c_2}{x^3} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = c_2 + \frac{c_1}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{c_1}{2x^2} - \frac{3c_2}{x^4}$$

substituting $y' = -5$ and $x = 1$ in the above gives

$$-5 = -\frac{c_1}{2} - 3c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -2$$
$$c_2 = 2$$

Substituting these values back in above solution results in

$$y = -\frac{x^2 - 2}{x^3}$$

Summary

The solution(s) found are the following

$$y = -\frac{x^2 - 2}{x^3} \tag{1}$$

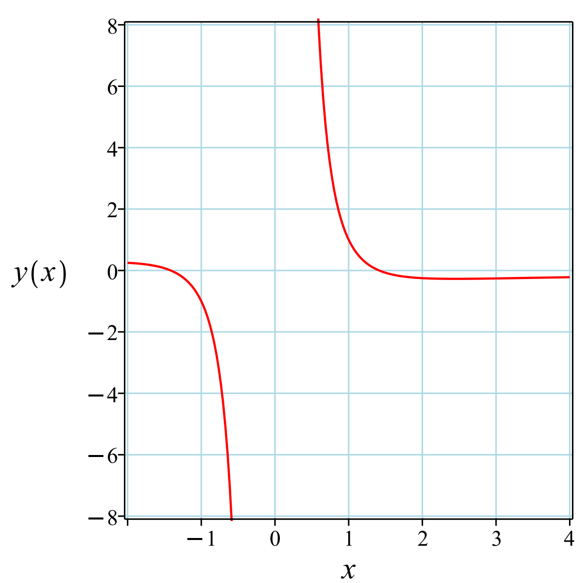

Figure 537: Solution plot

Verification of solutions

$$y = -\frac{x^2-2}{x^3}$$

Verified OK.

13.22.10 Maple step by step solution

Let's solve

$\left[y''x^2+5y'x+3y=0, y(1)=1, y'\Big|_{\{x=1\}}=-5\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{5y'}{x}-\frac{3y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{5y'}{x}+\frac{3y}{x^2}=0$

- Multiply by denominators of the ODE

  $y''x^2+5y'x+3y=0$

- Make a change of variables

  $t=\ln(x)$

□ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

    $y'=\left(\frac{d}{dt}y(t)\right)t'(x)$

  ◦ Compute derivative

    $y'=\frac{\frac{d}{dt}y(t)}{x}$

  ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y''=\left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2+t''(x)\left(\frac{d}{dt}y(t)\right)$

  ◦ Compute derivative

    $y''=\frac{\frac{d^2}{dt^2}y(t)}{x^2}-\frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

$$\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2}-\frac{\frac{d}{dt}y(t)}{x^2}\right)x^2+5\frac{d}{dt}y(t)+3y(t)=0$$

- Simplify

  $\frac{d^2}{dt^2}y(t)+4\frac{d}{dt}y(t)+3y(t)=0$
- Characteristic polynomial of ODE

  $r^2+4r+3=0$
- Factor the characteristic polynomial

  $(r+3)(r+1)=0$
- Roots of the characteristic polynomial

  $r=(-3,-1)$
- 1st solution of the ODE

  $y_1(t)=\mathrm{e}^{-3t}$
- 2nd solution of the ODE

  $y_2(t)=\mathrm{e}^{-t}$
- General solution of the ODE

  $y(t)=c_1y_1(t)+c_2y_2(t)$
- Substitute in solutions

  $y(t)=c_1\mathrm{e}^{-3t}+c_2\mathrm{e}^{-t}$
- Change variables back using $t=\ln(x)$

  $y=\frac{c_1}{x^3}+\frac{c_2}{x}$
- Simplify

  $y=\frac{c_1}{x^3}+\frac{c_2}{x}$

☐ Check validity of solution $y=\frac{c_1}{x^3}+\frac{c_2}{x}$

- Use initial condition $y(1)=1$

  $1=c_1+c_2$
- Compute derivative of the solution

  $y'=-\frac{3c_1}{x^4}-\frac{c_2}{x^2}$
- Use the initial condition $y'\Big|_{\{x=1\}}=-5$

  $-5=-3c_1-c_2$

- Solve for c_1 and c_2

  $\{c_1 = 2, c_2 = -1\}$
- Substitute constant values into general solution and simplify

  $y = \frac{-x^2+2}{x^3}$

- Solution to the IVP

  $y = \frac{-x^2+2}{x^3}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _nonhomogeneous]]
```

$$\boxed{x^2y'' - 2y = 4x - 8}$$

With initial conditions

$$[y(1) = 4, y'(1) = -1]$$

13.23.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= -\frac{2}{x^2} \\ F &= \frac{4x-8}{x^2} \end{aligned}$$

Hence the ode is

$$y'' - \frac{2y}{x^2} = \frac{4x-8}{x^2}$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $q(x) = -\frac{2}{x^2}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is also inside this domain. The domain of $F = \frac{4x-8}{x^2}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

13.23.2 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 0, C = -2, f(x) = 4x - 8$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 2y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 0rx^{r-1} - 2x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 0\,x^r - 2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 0 - 2 = 0$$

Or

$$r^2 - r - 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -1$$
$$r_2 = 2$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = \frac{c_1}{x} + c_2x^2$$

Next, we find the particular solution to the ODE

$$x^2y'' - 2y = 4x - 8$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = x^2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & x^2 \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}(x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & x^2 \\ -\frac{1}{x^2} & 2x \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)(2x) - (x^2)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = 3$$

Which simplifies to

$$W = 3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^2(4x - 8)}{3x^2}\,dx$$

Which simplifies to

$$u_1 = -\int \left(\frac{4x}{3} - \frac{8}{3}\right) dx$$

Hence

$$u_1 = -\frac{2}{3}x^2 + \frac{8}{3}x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{4x-8}{x}}{3x^2}\, dx$$

Which simplifies to

$$u_2 = \int \frac{4x-8}{3x^3} dx$$

Hence

$$u_2 = \frac{4}{3x^2} - \frac{4}{3x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{-\frac{2}{3}x^2 + \frac{8}{3}x}{x} + \left(\frac{4}{3x^2} - \frac{4}{3x}\right) x^2$$

Which simplifies to

$$y_p(x) = -2x + 4$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= -2x + 4 + \frac{c_1}{x} + c_2 x^2 \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -2x + 4 + \frac{c_1}{x} + c_2 x^2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 1$ in the above gives

$$4 = c_1 + c_2 + 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -2 - \frac{c_1}{x^2} + 2c_2x$$

substituting $y' = -1$ and $x = 1$ in the above gives

$$-1 = -2 - c_1 + 2c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = 1$$

Substituting these values back in above solution results in

$$y = \frac{x^3 - 2x^2 + 4x + 1}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{x^3 - 2x^2 + 4x + 1}{x} \tag{1}$$

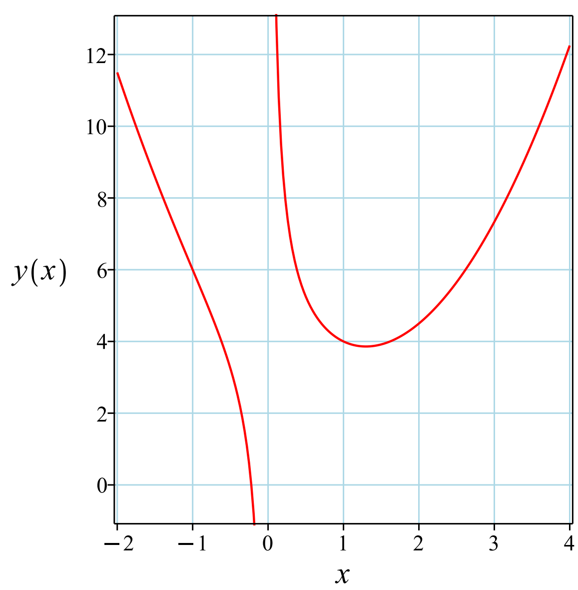

Figure 538: Solution plot

Verification of solutions

$$y = \frac{x^3 - 2x^2 + 4x + 1}{x}$$

Verified OK.

13.23.3 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2y'' - 2y)\,dx = \int (4x - 8)\,dx$$

$$x^2y' - 2yx = 2x^2 - 8x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= -\frac{2}{x}\\ q(x) &= \frac{2x^2 + c_1 - 8x}{x^2}\end{aligned}$$

Hence the ode is

$$y' - \frac{2y}{x} = \frac{2x^2 + c_1 - 8x}{x^2}$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{2}{x}dx}\\ &= \frac{1}{x^2}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{2x^2 + c_1 - 8x}{x^2}\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{x^2}\right) &= \left(\frac{1}{x^2}\right)\left(\frac{2x^2 + c_1 - 8x}{x^2}\right)\\ \mathrm{d}\left(\frac{y}{x^2}\right) &= \left(\frac{2x^2 + c_1 - 8x}{x^4}\right)\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{y}{x^2} &= \int \frac{2x^2 + c_1 - 8x}{x^4}\,\mathrm{d}x\\ \frac{y}{x^2} &= \frac{4}{x^2} - \frac{c_1}{3x^3} - \frac{2}{x} + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$y = x^2 \left(\frac{4}{x^2} - \frac{c_1}{3x^3} - \frac{2}{x}\right) + c_2 x^2$$

which simplifies to

$$y = \frac{3c_2x^3 - 6x^2 - c_1 + 12x}{3x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{3c_2x^3 - 6x^2 - c_1 + 12x}{3x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 1$ in the above gives

$$4 = -\frac{c_1}{3} + c_2 + 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{9c_2x^2 - 12x + 12}{3x} - \frac{3c_2x^3 - 6x^2 - c_1 + 12x}{3x^2}$$

substituting $y' = -1$ and $x = 1$ in the above gives

$$-1 = \frac{c_1}{3} + 2c_2 - 2 \tag{2A}$$

Equations $\{1\text{A}, 2\text{A}\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -3$$
$$c_2 = 1$$

Substituting these values back in above solution results in

$$y = \frac{x^3 - 2x^2 + 4x + 1}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{x^3 - 2x^2 + 4x + 1}{x} \tag{1}$$

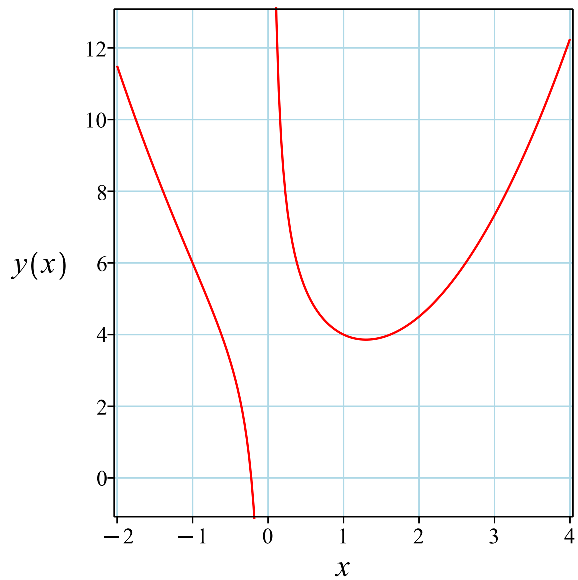

Figure 539: Solution plot

Verification of solutions

$$y = \frac{x^3 - 2x^2 + 4x + 1}{x}$$

Verified OK.

13.23.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$x^2 y'' - 2y = 4x - 8$$

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2 y'' - 2y)\, dx = \int (4x - 8)\, dx$$

$$x^2 y' - 2yx = 2x^2 - 8x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{2}{x} \\
q(x) &= \frac{2x^2 + c_1 - 8x}{x^2}
\end{aligned}
$$

Hence the ode is

$$
y' - \frac{2y}{x} = \frac{2x^2 + c_1 - 8x}{x^2}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int -\frac{2}{x}dx} \\
&= \frac{1}{x^2}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{2x^2 + c_1 - 8x}{x^2}\right) \\
\frac{d}{dx}\left(\frac{y}{x^2}\right) &= \left(\frac{1}{x^2}\right)\left(\frac{2x^2 + c_1 - 8x}{x^2}\right) \\
d\left(\frac{y}{x^2}\right) &= \left(\frac{2x^2 + c_1 - 8x}{x^4}\right) dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\frac{y}{x^2} &= \int \frac{2x^2 + c_1 - 8x}{x^4} dx \\
\frac{y}{x^2} &= \frac{4}{x^2} - \frac{c_1}{3x^3} - \frac{2}{x} + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$
y = x^2\left(\frac{4}{x^2} - \frac{c_1}{3x^3} - \frac{2}{x}\right) + c_2 x^2
$$

which simplifies to

$$
y = \frac{3c_2 x^3 - 6x^2 - c_1 + 12x}{3x}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \frac{3c_2 x^3 - 6x^2 - c_1 + 12x}{3x} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 1$ in the above gives

$$4 = -\frac{c_1}{3} + c_2 + 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{9c_2x^2 - 12x + 12}{3x} - \frac{3c_2x^3 - 6x^2 - c_1 + 12x}{3x^2}$$

substituting $y' = -1$ and $x = 1$ in the above gives

$$-1 = \frac{c_1}{3} + 2c_2 - 2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -3$$
$$c_2 = 1$$

Substituting these values back in above solution results in

$$y = \frac{x^3 - 2x^2 + 4x + 1}{x}$$

Summary
The solution(s) found are the following

$$y = \frac{x^3 - 2x^2 + 4x + 1}{x} \tag{1}$$

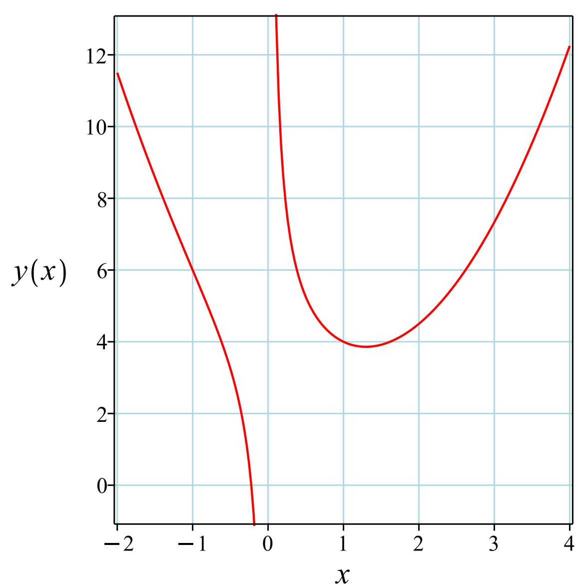

Figure 540: Solution plot

Verification of solutions

$$y = \frac{x^3 - 2x^2 + 4x + 1}{x}$$

Verified OK.

13.23.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 0 \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 2 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 503: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2}{x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_{\infty}^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_{\infty}^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_{\infty}^{-} = -1$ then

$$\begin{aligned}
d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= -1 - (-1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{x} + (-)(0) \\
&= -\frac{1}{x} \\
&= -\frac{1}{x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(-\frac{1}{x}\right)(0) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x}\right)^2 - \left(\frac{2}{x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int -\frac{1}{x} dx} \\ &= \frac{1}{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \frac{1}{x} \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2} \, dx \\ &= \frac{1}{x} \int \frac{1}{\frac{1}{x^2}} \, dx \\ &= \frac{1}{x} \left(\frac{x^3}{3} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{1}{x} \right) + c_2 \left(\frac{1}{x} \left(\frac{x^3}{3} \right) \right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_1}{x} + \frac{c_2x^2}{3}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = \frac{x^2}{3}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x^2}{3} \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(\frac{x^2}{3}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x^2}{3} \\ -\frac{1}{x^2} & \frac{2x}{3} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)\left(\frac{2x}{3}\right) - \left(\frac{x^2}{3}\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = 1$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x^2(4x-8)}{3}}{x^2}\,dx$$

Which simplifies to

$$u_1 = -\int \left(\frac{4x}{3} - \frac{8}{3}\right) dx$$

Hence

$$u_1 = -\frac{2}{3}x^2 + \frac{8}{3}x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{4x-8}{x}}{x^2}\,dx$$

Which simplifies to

$$u_2 = \int \frac{4x - 8}{x^3} dx$$

Hence

$$u_2 = \frac{4}{x^2} - \frac{4}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{-\frac{2}{3}x^2 + \frac{8}{3}x}{x} + \frac{\left(\frac{4}{x^2} - \frac{4}{x}\right) x^2}{3}$$

Which simplifies to

$$y_p(x) = -2x + 4$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x} + \frac{c_2 x^2}{3}\right) + (-2x + 4) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1}{x} + \frac{c_2 x^2}{3} - 2x + 4 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 1$ in the above gives

$$4 = c_1 + \frac{c_2}{3} + 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{c_1}{x^2} + \frac{2c_2 x}{3} - 2$$

substituting $y' = -1$ and $x = 1$ in the above gives

$$-1 = -c_1 + \frac{2c_2}{3} - 2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = 3$$

Substituting these values back in above solution results in

$$y = \frac{x^3 - 2x^2 + 4x + 1}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{x^3 - 2x^2 + 4x + 1}{x} \tag{1}$$

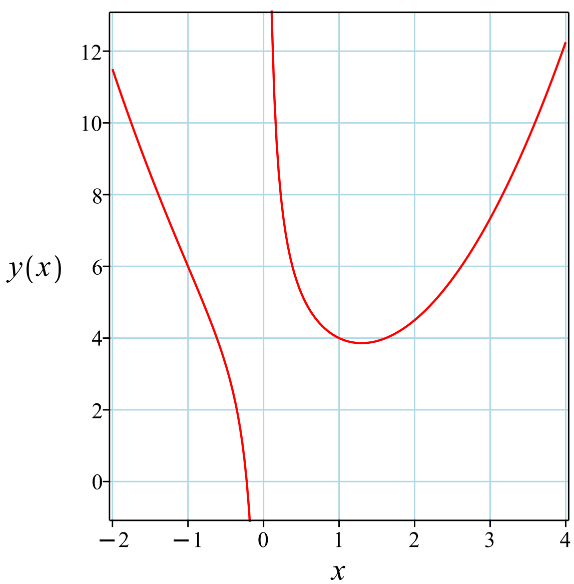

Figure 541: Solution plot

Verification of solutions

$$y = \frac{x^3 - 2x^2 + 4x + 1}{x}$$

Verified OK.

13.23.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y''+q(x)\,y'+r(x)\,y=s(x)$$

is exact if

$$p''(x)-q'(x)+r(x)=0 \tag{1}$$

For the given ode we have

$$\begin{aligned}p(x)&=x^2\\ q(x)&=0\\ r(x)&=-2\\ s(x)&=4x-8\end{aligned}$$

Hence

$$\begin{aligned}p''(x)&=2\\ q'(x)&=0\end{aligned}$$

Therefore (1) becomes

$$2-(0)+(-2)=0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y'+\left(q(x)-p'(x)\right)y\right)'=s(x)$$

Integrating gives

$$p(x)\,y'+\left(q(x)-p'(x)\right)y=\int s(x)\;dx$$

Substituting the above values for p,q,r,s gives

$$x^2y'-2yx=\int 4x-8\,dx$$

We now have a first order ode to solve which is

$$x^2y'-2yx=2x^2+c_1-8x$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= \frac{2x^2 + c_1 - 8x}{x^2} \end{aligned}$$

Hence the ode is

$$y' - \frac{2y}{x} = \frac{2x^2 + c_1 - 8x}{x^2}$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int -\frac{2}{x}dx} \\ &= \frac{1}{x^2} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{2x^2 + c_1 - 8x}{x^2}\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{x^2}\right) &= \left(\frac{1}{x^2}\right)\left(\frac{2x^2 + c_1 - 8x}{x^2}\right) \\ \mathrm{d}\left(\frac{y}{x^2}\right) &= \left(\frac{2x^2 + c_1 - 8x}{x^4}\right)\mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} \frac{y}{x^2} &= \int \frac{2x^2 + c_1 - 8x}{x^4}\,\mathrm{d}x \\ \frac{y}{x^2} &= \frac{4}{x^2} - \frac{c_1}{3x^3} - \frac{2}{x} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$y = x^2\left(\frac{4}{x^2} - \frac{c_1}{3x^3} - \frac{2}{x}\right) + c_2 x^2$$

which simplifies to

$$y = \frac{3c_2x^3 - 6x^2 - c_1 + 12x}{3x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{3c_2 x^3 - 6x^2 - c_1 + 12x}{3x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 1$ in the above gives

$$4 = -\frac{c_1}{3} + c_2 + 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{9c_2 x^2 - 12x + 12}{3x} - \frac{3c_2 x^3 - 6x^2 - c_1 + 12x}{3x^2}$$

substituting $y' = -1$ and $x = 1$ in the above gives

$$-1 = \frac{c_1}{3} + 2c_2 - 2 \tag{2A}$$

Equations $\{1A, 2A\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -3$$
$$c_2 = 1$$

Substituting these values back in above solution results in

$$y = \frac{x^3 - 2x^2 + 4x + 1}{x}$$

Summary
The solution(s) found are the following

$$y = \frac{x^3 - 2x^2 + 4x + 1}{x} \tag{1}$$

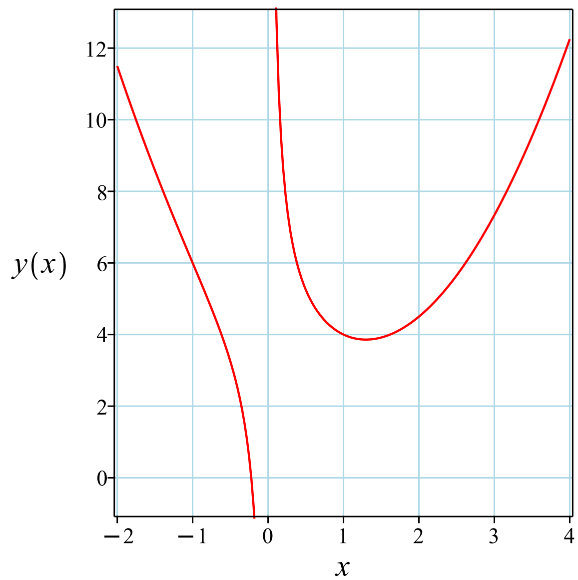

Figure 542: Solution plot

Verification of solutions

$$y = \frac{x^3 - 2x^2 + 4x + 1}{x}$$

Verified OK.

$$\boxed{x^2y'' - 4y'x + 4y = -6x^3 + 4x^2}$$

With initial conditions

$$[y(2) = 4, y'(2) = -1]$$

13.24.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned}p(x) &= -\frac{4}{x}\\ q(x) &= \frac{4}{x^2}\\ F &= \frac{-6x^3 + 4x^2}{x^2}\end{aligned}$$

Hence the ode is

$$y'' - \frac{4y'}{x} + \frac{4y}{x^2} = \frac{-6x^3 + 4x^2}{x^2}$$

The domain of $p(x) = -\frac{4}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 2$ is inside this domain. The domain of $q(x) = \frac{4}{x^2}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 2$ is also inside this domain. The domain of $F = \frac{-6x^3+4x^2}{x^2}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 2$ is also inside this domain. Hence solution exists and is unique.

13.24.2 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -4x, C = 4, f(x) = -6x^3 + 4x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 4y'x + 4y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 4xrx^{r-1} + 4x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 4r\,x^r + 4x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 4r + 4 = 0$$

Or

$$r^2 - 5r + 4 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = 1$$
$$r_2 = 4$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_2x^4 + c_1x$$

Next, we find the particular solution to the ODE

$$x^2y'' - 4y'x + 4y = -6x^3 + 4x^2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$

$$y_2 = x^4$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & x^4 \\ \frac{d}{dx}(x) & \frac{d}{dx}(x^4) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & x^4 \\ 1 & 4x^3 \end{vmatrix}$$

Therefore

$$W = (x)\left(4x^3\right) - \left(x^4\right)(1)$$

Which simplifies to

$$W = 3x^4$$

Which simplifies to

$$W = 3x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^4(-6x^3 + 4x^2)}{3x^6}\, dx$$

Which simplifies to

$$u_1 = -\int \left(-2x + \frac{4}{3}\right) dx$$

Hence

$$u_1 = x^2 - \frac{4}{3}x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(-6x^3 + 4x^2)}{3x^6} dx$$

Which simplifies to

$$u_2 = \int \frac{-6x + 4}{3x^3} dx$$

Hence

$$u_2 = -\frac{2}{3x^2} + \frac{2}{x}$$

Which simplifies to

$$u_1 = x^2 - \frac{4}{3}x$$
$$u_2 = \frac{6x - 2}{3x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(x^2 - \frac{4}{3}x\right) x + \frac{(6x - 2)\, x^2}{3}$$

Which simplifies to

$$y_p(x) = 3x^3 - 2x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= x\left(c_2 x^3 + 3x^2 + c_1 - 2x\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = x(c_2x^3 + 3x^2 + c_1 - 2x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 2$ in the above gives

$$4 = 16c_2 + 16 + 2c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_2x^3 + 3x^2 + c_1 - 2x + x(3c_2x^2 + 6x - 2)$$

substituting $y' = -1$ and $x = 2$ in the above gives

$$-1 = 32c_2 + 28 + c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= \frac{5}{3} \\ c_2 &= -\frac{23}{24} \end{aligned}$$

Substituting these values back in above solution results in

$$y = -\frac{x(23x^3 - 72x^2 + 48x - 40)}{24}$$

Summary

The solution(s) found are the following

$$y = -\frac{x(23x^3 - 72x^2 + 48x - 40)}{24} \tag{1}$$

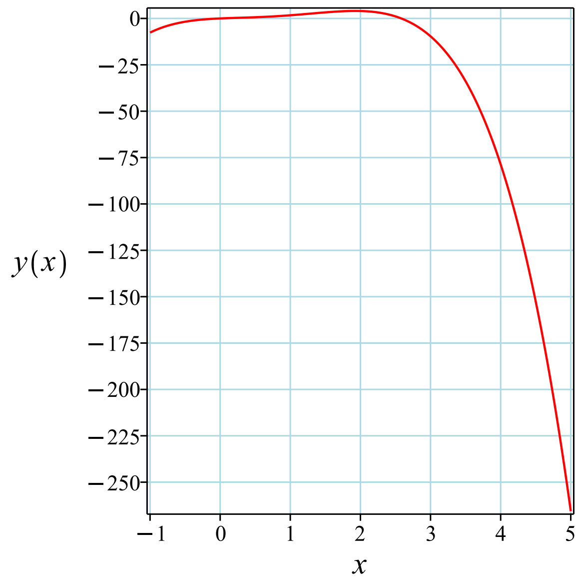

Figure 543: Solution plot

Verification of solutions

$$y = -\frac{x(23x^3 - 72x^2 + 48x - 40)}{24}$$

Verified OK.

13.24.3 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 4y'x + 4y = 0$$

In normal form the ode

$$x^2y'' - 4y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = -\frac{4}{x}$$
$$q(x) = \frac{4}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$
$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int e^{-\left(\int p(x)dx\right)}dx \\
&= \int e^{-\left(\int -\frac{4}{x}dx\right)}dx \\
&= \int e^{4\ln(x)}\,dx \\
&= \int x^4 dx \\
&= \frac{x^5}{5}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{4}{x^2}}{x^8} \\
&= \frac{4}{x^{10}}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) + \frac{4y(\tau)}{x^{10}} = 0$$

But in terms of τ

$$\frac{4}{x^{10}} = \frac{4}{25\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{4y(\tau)}{25\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$25\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 4y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$25\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 4\tau^r = 0$$

Simplifying gives

$$25r(r-1)\,\tau^r + 0\,\tau^r + 4\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$25r(r-1) + 0 + 4 = 0$$

Or

$$25r^2 - 25r + 4 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{5}$$
$$r_2 = \frac{4}{5}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{\frac{1}{5}} + c_2\tau^{\frac{4}{5}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 5^{\frac{4}{5}} (x^5)^{\frac{1}{5}}}{5} + \frac{c_2 5^{\frac{1}{5}} (x^5)^{\frac{4}{5}}}{5}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 5^{\frac{4}{5}} (x^5)^{\frac{1}{5}}}{5} + \frac{c_2 5^{\frac{1}{5}} (x^5)^{\frac{4}{5}}}{5}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = (x^5)^{\frac{1}{5}}$$

$$y_2 = (x^5)^{\frac{4}{5}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^5)^{\frac{1}{5}} & (x^5)^{\frac{4}{5}} \\ \frac{d}{dx}\left((x^5)^{\frac{1}{5}}\right) & \frac{d}{dx}\left((x^5)^{\frac{4}{5}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^5)^{\frac{1}{5}} & (x^5)^{\frac{4}{5}} \\ \frac{x^4}{(x^5)^{\frac{4}{5}}} & \frac{4x^4}{(x^5)^{\frac{1}{5}}} \end{vmatrix}$$

Therefore

$$W = \left((x^5)^{\frac{1}{5}}\right)\left(\frac{4x^4}{(x^5)^{\frac{1}{5}}}\right) - \left((x^5)^{\frac{4}{5}}\right)\left(\frac{x^4}{(x^5)^{\frac{4}{5}}}\right)$$

Which simplifies to

$$W = 3x^4$$

Which simplifies to

$$W = 3x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^5)^{\frac{4}{5}}(-6x^3 + 4x^2)}{3x^6}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{2(x^5)^{\frac{4}{5}}(3x-2)}{3x^4}dx$$

Hence

$$u_1 = \frac{(3x-4)(x^5)^{\frac{4}{5}}}{3x^3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^5)^{\frac{1}{5}}(-6x^3 + 4x^2)}{3x^6}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{2(x^5)^{\frac{1}{5}}(3x-2)}{3x^4}dx$$

Hence

$$u_2 = \frac{2(3x-1)\left(x^5\right)^{\frac{1}{5}}}{3x^3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x^2(3x-4)}{3} + \frac{2(3x-1)\,x^2}{3}$$

Which simplifies to

$$y_p(x) = 3x^3 - 2x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 5^{\frac{4}{5}}\left(x^5\right)^{\frac{1}{5}}}{5} + \frac{c_2 5^{\frac{1}{5}}\left(x^5\right)^{\frac{4}{5}}}{5}\right) + \left(3x^3 - 2x^2\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1 5^{\frac{4}{5}}\left(x^5\right)^{\frac{1}{5}}}{5} + \frac{c_2 5^{\frac{1}{5}}\left(x^5\right)^{\frac{4}{5}}}{5} + 3x^3 - 2x^2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 2$ in the above gives

$$4 = \frac{2c_1 5^{\frac{4}{5}}}{5} + \frac{16c_2 5^{\frac{1}{5}}}{5} + 16 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{c_1 5^{\frac{4}{5}} x^4}{5\left(x^5\right)^{\frac{4}{5}}} + \frac{4c_2 5^{\frac{1}{5}} x^4}{5\left(x^5\right)^{\frac{1}{5}}} + 9x^2 - 4x$$

substituting $y' = -1$ and $x = 2$ in the above gives

$$-1 = \frac{c_1 5^{\frac{4}{5}}}{5} + \frac{32c_2 5^{\frac{1}{5}}}{5} + 28 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{5\,5^{\frac{1}{5}}}{3}$$
$$c_2 = -\frac{23\,5^{\frac{4}{5}}}{24}$$

Substituting these values back in above solution results in

$$y = \frac{5(x^5)^{\frac{1}{5}}}{3} - \frac{23(x^5)^{\frac{4}{5}}}{24} + 3x^3 - 2x^2$$

Summary

The solution(s) found are the following

$$y = \frac{5(x^5)^{\frac{1}{5}}}{3} - \frac{23(x^5)^{\frac{4}{5}}}{24} + 3x^3 - 2x^2 \tag{1}$$

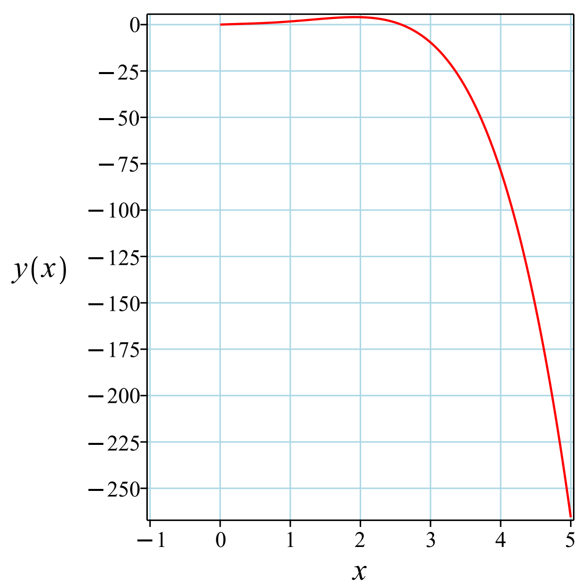

Figure 544: Solution plot

Verification of solutions

$$y = \frac{5(x^5)^{\frac{1}{5}}}{3} - \frac{23(x^5)^{\frac{4}{5}}}{24} + 3x^3 - 2x^2$$

Verified OK.

13.24.4 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -4x, C = 4, f(x) = -6x^3 + 4x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 4y'x + 4y = 0$$

In normal form the ode

$$x^2y'' - 4y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{x} \\ q(x) &= \frac{4}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{2\sqrt{\frac{1}{x^2}}}{c} \qquad (6) \\ \tau'' &= -\frac{2}{c\sqrt{\frac{1}{x^2}}\, x^3} \end{aligned}$$

Substituting the above into (4) results in

$$\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{2}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{4}{x}\frac{2\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{2\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= -\frac{5c}{2}
\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - \frac{5c\left(\frac{d}{d\tau}y(\tau)\right)}{2} + c^2 y(\tau) &= 0 \qquad (7)
\end{aligned}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = e^{\frac{5c\tau}{4}}\left(c_1\cosh\left(\frac{3c\tau}{4}\right) + ic_2\sinh\left(\frac{3c\tau}{4}\right)\right)$$

Now from (6)

$$\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int 2\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{2\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = x^{\frac{5}{2}}\left(c_1\cosh\left(\frac{3\ln(x)}{2}\right) + ic_2\sinh\left(\frac{3\ln(x)}{2}\right)\right)$$

Now the particular solution to this ODE is found

$$x^2y'' - 4y'x + 4y = -6x^3 + 4x^2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(x^5\right)^{\frac{1}{5}}$$
$$y_2 = \left(x^5\right)^{\frac{4}{5}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(x^5\right)^{\frac{1}{5}} & \left(x^5\right)^{\frac{4}{5}} \\ \frac{d}{dx}\left(\left(x^5\right)^{\frac{1}{5}}\right) & \frac{d}{dx}\left(\left(x^5\right)^{\frac{4}{5}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(x^5\right)^{\frac{1}{5}} & \left(x^5\right)^{\frac{4}{5}} \\ \frac{x^4}{\left(x^5\right)^{\frac{4}{5}}} & \frac{4x^4}{\left(x^5\right)^{\frac{1}{5}}} \end{vmatrix}$$

Therefore

$$W = \left(\left(x^5\right)^{\frac{1}{5}}\right)\left(\frac{4x^4}{\left(x^5\right)^{\frac{1}{5}}}\right) - \left(\left(x^5\right)^{\frac{4}{5}}\right)\left(\frac{x^4}{\left(x^5\right)^{\frac{4}{5}}}\right)$$

Which simplifies to

$$W = 3x^4$$

Which simplifies to

$$W = 3x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^5)^{\frac{4}{5}} (-6x^3 + 4x^2)}{3x^6}\, dx$$

Which simplifies to

$$u_1 = -\int -\frac{2(x^5)^{\frac{4}{5}} (3x-2)}{3x^4} dx$$

Hence

$$u_1 = \frac{(3x-4)\,(x^5)^{\frac{4}{5}}}{3x^3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^5)^{\frac{1}{5}} (-6x^3 + 4x^2)}{3x^6}\, dx$$

Which simplifies to

$$u_2 = \int -\frac{2(x^5)^{\frac{1}{5}} (3x-2)}{3x^4} dx$$

Hence

$$u_2 = \frac{2(3x-1)\,(x^5)^{\frac{1}{5}}}{3x^3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x^2(3x-4)}{3} + \frac{2(3x-1)\,x^2}{3}$$

Which simplifies to

$$y_p(x) = 3x^3 - 2x^2$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(x^{\frac{5}{2}} \left(c_1 \cosh\left(\frac{3\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{3\ln(x)}{2}\right)\right)\right) + (3x^3 - 2x^2) \\
&= 3x^3 - 2x^2 + x^{\frac{5}{2}} \left(c_1 \cosh\left(\frac{3\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{3\ln(x)}{2}\right)\right)
\end{aligned}
$$

Which simplifies to

$$
y = i \sinh\left(\frac{3\ln(x)}{2}\right) x^{\frac{5}{2}} c_2 + \cosh\left(\frac{3\ln(x)}{2}\right) x^{\frac{5}{2}} c_1 + 3x^3 - 2x^2
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = i \sinh\left(\frac{3\ln(x)}{2}\right) x^{\frac{5}{2}} c_2 + \cosh\left(\frac{3\ln(x)}{2}\right) x^{\frac{5}{2}} c_1 + 3x^3 - 2x^2 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 2$ in the above gives

$$
4 = 7ic_2 + 9c_1 + 16 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = \frac{3ix^{\frac{3}{2}} \cosh\left(\frac{3\ln(x)}{2}\right) c_2}{2} + \frac{5i \sinh\left(\frac{3\ln(x)}{2}\right) x^{\frac{3}{2}} c_2}{2} + \frac{3x^{\frac{3}{2}} \sinh\left(\frac{3\ln(x)}{2}\right) c_1}{2} + \frac{5 \cosh\left(\frac{3\ln(x)}{2}\right) x^{\frac{3}{2}} c_1}{2} + 9x^2 - 4
$$

substituting $y' = -1$ and $x = 2$ in the above gives

$$
-1 = \frac{31ic_2}{2} + \frac{33c_1}{2} + 28 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= \frac{17}{24} \\
c_2 &= \frac{21i}{8}
\end{aligned}
$$

Substituting these values back in above solution results in

$$y = -\frac{21 \sinh\left(\frac{3\ln(x)}{2}\right) x^{\frac{5}{2}}}{8} + \frac{17 \cosh\left(\frac{3\ln(x)}{2}\right) x^{\frac{5}{2}}}{24} + 3x^3 - 2x^2$$

<u>Summary</u>

The solution(s) found are the following

$$y = -\frac{21 \sinh\left(\frac{3\ln(x)}{2}\right) x^{\frac{5}{2}}}{8} + \frac{17 \cosh\left(\frac{3\ln(x)}{2}\right) x^{\frac{5}{2}}}{24} + 3x^3 - 2x^2 \tag{1}$$

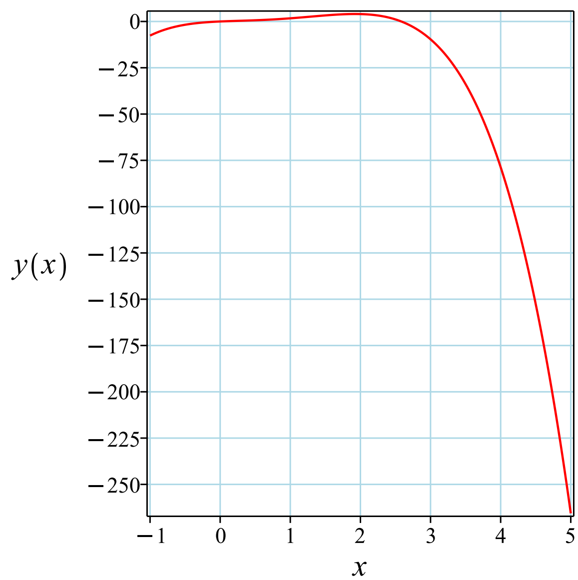

Figure 545: Solution plot

<u>Verification of solutions</u>

$$y = -\frac{21 \sinh\left(\frac{3\ln(x)}{2}\right) x^{\frac{5}{2}}}{8} + \frac{17 \cosh\left(\frac{3\ln(x)}{2}\right) x^{\frac{5}{2}}}{24} + 3x^3 - 2x^2$$

Verified OK.

13.24.5 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -4x, C = 4, f(x) = -6x^3 + 4x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 4y'x + 4y = 0$$

In normal form the ode

$$x^2y'' - 4y'x + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{x} \\ q(x) &= \frac{4}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{4n}{x^2} + \frac{4}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 4 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{4v'(x)}{x} &= 0 \\ v''(x) + \frac{4v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{4u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{4u}{x} \end{aligned}$$

Where $f(x) = -\frac{4}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{4}{x}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{4}{x}\, dx \\ \ln(u) &= -4\ln(x) + c_1 \\ u &= e^{-4\ln(x)+c_1} \\ &= \frac{c_1}{x^4} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= -\frac{c_1}{3x^3} + c_2 \end{aligned}$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(-\frac{c_1}{3x^3} + c_2\right) x^4 \\
&= c_2 x^4 - \frac{1}{3} c_1 x
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
x^2 y'' - 4y'x + 4y = -6x^3 + 4x^2
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x \\
y_2 &= x^4
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix} x & x^4 \\ \frac{d}{dx}(x) & \frac{d}{dx}(x^4) \end{vmatrix}
$$

Which gives

$$W = \begin{vmatrix} x & x^4 \\ 1 & 4x^3 \end{vmatrix}$$

Therefore

$$W = (x)\left(4x^3\right) - \left(x^4\right)(1)$$

Which simplifies to

$$W = 3x^4$$

Which simplifies to

$$W = 3x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^4(-6x^3 + 4x^2)}{3x^6}\, dx$$

Which simplifies to

$$u_1 = -\int \left(-2x + \frac{4}{3}\right) dx$$

Hence

$$u_1 = x^2 - \frac{4}{3}x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(-6x^3 + 4x^2)}{3x^6}\, dx$$

Which simplifies to

$$u_2 = \int \frac{-6x + 4}{3x^3} dx$$

Hence

$$u_2 = -\frac{2}{3x^2} + \frac{2}{x}$$

Which simplifies to

$$u_1 = x^2 - \frac{4}{3}x$$
$$u_2 = \frac{6x - 2}{3x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(x^2 - \frac{4}{3}x\right)x + \frac{(6x - 2)\,x^2}{3}$$

Which simplifies to

$$y_p(x) = 3x^3 - 2x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(-\frac{c_1}{3x^3} + c_2\right)x^4\right) + \left(3x^3 - 2x^2\right) \\ &= 3x^3 - 2x^2 + \left(-\frac{c_1}{3x^3} + c_2\right)x^4 \end{aligned}$$

Which simplifies to

$$y = -\frac{x(-3c_2x^3 - 9x^2 + c_1 + 6x)}{3}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{x(-3c_2x^3 - 9x^2 + c_1 + 6x)}{3} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 2$ in the above gives

$$4 = 16c_2 + 16 - \frac{2c_1}{3} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_2x^3 + 3x^2 - \frac{c_1}{3} - 2x - \frac{x(-9c_2x^2 - 18x + 6)}{3}$$

substituting $y' = -1$ and $x = 2$ in the above gives

$$-1 = 32c_2 + 28 - \frac{c_1}{3} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= -5 \\ c_2 &= -\frac{23}{24} \end{aligned}$$

Substituting these values back in above solution results in

$$y = -\frac{x(23x^3 - 72x^2 + 48x - 40)}{24}$$

Summary

The solution(s) found are the following

$$y = -\frac{x(23x^3 - 72x^2 + 48x - 40)}{24} \tag{1}$$

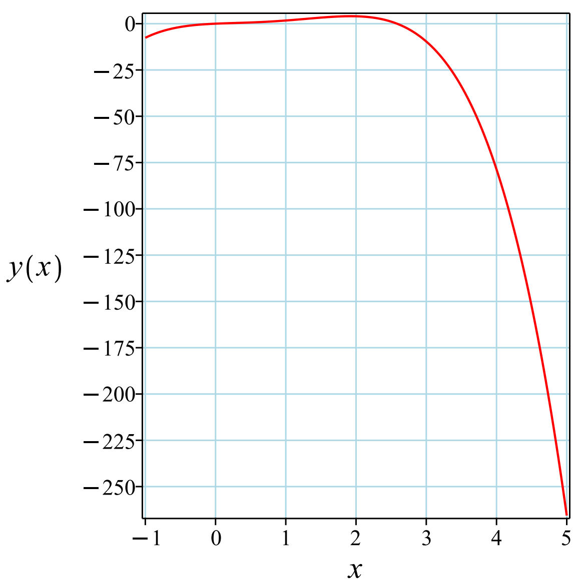

Figure 546: Solution plot

Verification of solutions

$$y = -\frac{x(23x^3 - 72x^2 + 48x - 40)}{24}$$

Verified OK.

13.24.6 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + \left(2AB' + B^2\right) v' + \left(AB'' + BB' + CB\right) v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right) v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned} A &= x^2 \\ B &= -4x \\ C &= 4 \\ F &= -6x^3 + 4x^2 \end{aligned}$$

The above shows that for this ode

$$\begin{aligned} AB'' + BB' + CB &= \left(x^2\right)(0) + (-4x)(-4) + (4)(-4x) \\ &= 0 \end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$-4x^3v'' + (8x^2)\, v' = 0$$

Now by applying $v' = u$ the above becomes

$$-4x^2(u'(x)\, x - 2u(x)) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{2u}{x} \end{aligned}$$

Where $f(x) = \frac{2}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= \frac{2}{x}\, dx \\ \int \frac{1}{u}\, du &= \int \frac{2}{x}\, dx \\ \ln(u) &= 2\ln(x) + c_1 \\ u &= \mathrm{e}^{2\ln(x)+c_1} \\ &= c_1x^2 \end{aligned}$$

The ode for v now becomes

$$\begin{aligned} v' &= u \\ &= c_1x^2 \end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned} v(x) &= \int c_1x^2\, \mathrm{d}x \\ &= \frac{c_1x^3}{3} + c_2 \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= Bv \\ &= (-4x)\left(\frac{c_1x^3}{3} + c_2\right) \\ &= -\frac{4x(c_1x^3 + 3c_2)}{3} \end{aligned}$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= x \\ y_2 &= x^4 \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & x^4 \\ \frac{d}{dx}(x) & \frac{d}{dx}(x^4) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & x^4 \\ 1 & 4x^3 \end{vmatrix}$$

Therefore

$$W = (x)\left(4x^3\right) - \left(x^4\right)(1)$$

Which simplifies to

$$W = 3x^4$$

Which simplifies to

$$W = 3x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^4(-6x^3 + 4x^2)}{3x^6}\, dx$$

Which simplifies to

$$u_1 = -\int \left(-2x + \frac{4}{3}\right) dx$$

Hence

$$u_1 = x^2 - \frac{4}{3}x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(-6x^3 + 4x^2)}{3x^6}\, dx$$

Which simplifies to

$$u_2 = \int \frac{-6x + 4}{3x^3} dx$$

Hence

$$u_2 = -\frac{2}{3x^2} + \frac{2}{x}$$

Which simplifies to

$$u_1 = x^2 - \frac{4}{3}x$$

$$u_2 = \frac{6x - 2}{3x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(x^2 - \frac{4}{3}x\right) x + \frac{(6x - 2)\, x^2}{3}$$

Which simplifies to

$$y_p(x) = 3x^3 - 2x^2$$

Hence the complete solution is

$$\begin{aligned} y(x) &= y_h + y_p \\ &= \left(-\frac{4x(c_1x^3 + 3c_2)}{3}\right) + (3x^3 - 2x^2) \\ &= -\frac{4}{3}c_1x^4 - 4c_2x + 3x^3 - 2x^2 \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{4}{3}c_1x^4 - 4c_2x + 3x^3 - 2x^2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 2$ in the above gives

$$4 = -\frac{64c_1}{3} - 8c_2 + 16 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{16}{3}c_1x^3 - 4c_2 + 9x^2 - 4x$$

substituting $y' = -1$ and $x = 2$ in the above gives

$$-1 = -\frac{128c_1}{3} - 4c_2 + 28 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= \frac{23}{32} \\ c_2 &= -\frac{5}{12} \end{aligned}$$

Substituting these values back in above solution results in

$$y = -\frac{23}{24}x^4 + 3x^3 - 2x^2 + \frac{5}{3}x$$

Summary

The solution(s) found are the following

$$y = -\frac{23}{24}x^4 + 3x^3 - 2x^2 + \frac{5}{3}x \tag{1}$$

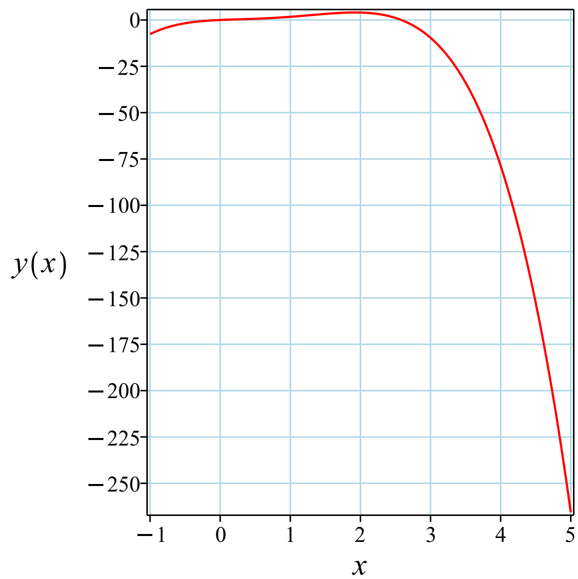

Figure 547: Solution plot

Verification of solutions

$$y = -\frac{23}{24}x^4 + 3x^3 - 2x^2 + \frac{5}{3}x$$

Verified OK.

13.24.7 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 4y'x + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -4x \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 2 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 504: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition

of r given above. Therefore $b = 2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{2}{x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = 2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{2}{x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = -1$ then

$$\begin{aligned}
d &= \alpha_{\infty}^{-} - (\alpha_{c_1}^{-}) \\
&= -1 - (-1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{x} + (-)\,(0) \\
&= -\frac{1}{x} \\
&= -\frac{1}{x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(-\frac{1}{x}\right)(0) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x}\right)^2 - \left(\frac{2}{x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int -\frac{1}{x} dx} \\
&= \frac{1}{x}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x}{x^2}\,dx} \\
&= z_1 e^{2\ln(x)} \\
&= z_1 \left(x^2\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{4\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{x^3}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x) + c_2\left(x\left(\frac{x^3}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' - 4y'x + 4y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 x + \frac{1}{3} c_2 x^4$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$

$$y_2 = \frac{x^4}{3}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & \frac{x^4}{3} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(\frac{x^4}{3}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & \frac{x^4}{3} \\ 1 & \frac{4x^3}{3} \end{vmatrix}$$

Therefore

$$W = (x)\left(\frac{4x^3}{3}\right) - \left(\frac{x^4}{3}\right)(1)$$

Which simplifies to

$$W = x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x^4(-6x^3+4x^2)}{3}}{x^6}\, dx$$

Which simplifies to

$$u_1 = -\int \left(-2x + \frac{4}{3}\right) dx$$

Hence

$$u_1 = x^2 - \frac{4}{3}x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(-6x^3 + 4x^2)}{x^6}\, dx$$

Which simplifies to

$$u_2 = \int \frac{-6x + 4}{x^3} dx$$

Hence

$$u_2 = -\frac{2}{x^2} + \frac{6}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(x^2 - \frac{4}{3}x\right)x + \frac{\left(-\frac{2}{x^2} + \frac{6}{x}\right)x^4}{3}$$

Which simplifies to

$$y_p(x) = 3x^3 - 2x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x + \frac{1}{3} c_2 x^4\right) + (3x^3 - 2x^2) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 x + \frac{1}{3} c_2 x^4 + 3x^3 - 2x^2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 2$ in the above gives

$$4 = 2c_1 + \frac{16c_2}{3} + 16 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 + \frac{4}{3} c_2 x^3 + 9x^2 - 4x$$

substituting $y' = -1$ and $x = 2$ in the above gives

$$-1 = c_1 + \frac{32c_2}{3} + 28 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= \frac{5}{3} \\ c_2 &= -\frac{23}{8} \end{aligned}$$

Substituting these values back in above solution results in

$$y = -\frac{23}{24} x^4 + 3x^3 - 2x^2 + \frac{5}{3} x$$

Summary

The solution(s) found are the following

$$y = -\frac{23}{24}x^4 + 3x^3 - 2x^2 + \frac{5}{3}x \tag{1}$$

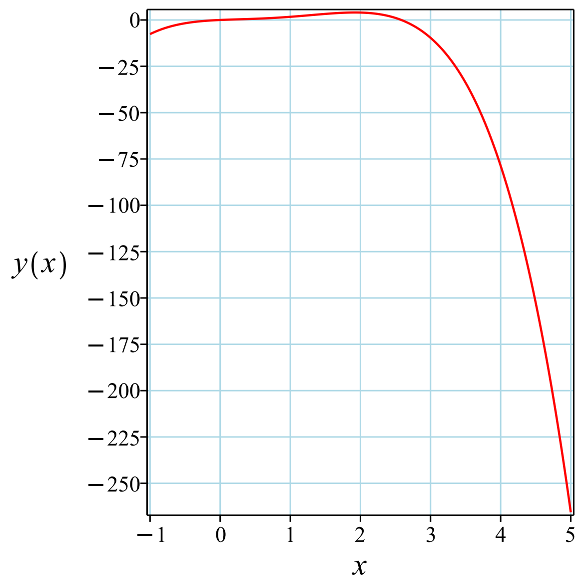

Figure 548: Solution plot

Verification of solutions

$$y = -\frac{23}{24}x^4 + 3x^3 - 2x^2 + \frac{5}{3}x$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + 2y'x - 6y = 10x^2}$$

With initial conditions

$$[y(1) = 1, y'(1) = -6]$$

13.25.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$p(x) = \frac{2}{x}$$
$$q(x) = -\frac{6}{x^2}$$
$$F = 10$$

Hence the ode is

$$y'' + \frac{2y'}{x} - \frac{6y}{x^2} = 10$$

The domain of $p(x) = \frac{2}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $q(x) = -\frac{6}{x^2}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is also inside this domain. The domain of $F = 10$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

13.25.2 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 2x, C = -6, f(x) = 10x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 2y'x - 6y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 2xrx^{r-1} - 6x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 2r\,x^r - 6x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 2r - 6 = 0$$

Or

$$r^2 + r - 6 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -3$$
$$r_2 = 2$$

Since the roots are real and distinct, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = \frac{c_1}{x^3} + c_2 x^2$$

Next, we find the particular solution to the ODE

$$x^2 y'' + 2y' x - 6y = 10x^2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x^3}$$
$$y_2 = x^2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x^3} & x^2 \\ \frac{d}{dx}\left(\frac{1}{x^3}\right) & \frac{d}{dx}(x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^3} & x^2 \\ -\frac{3}{x^4} & 2x \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^3}\right)(2x) - (x^2)\left(-\frac{3}{x^4}\right)$$

Which simplifies to

$$W = \frac{5}{x^2}$$

Which simplifies to

$$W = \frac{5}{x^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{10x^4}{5}\, dx$$

Which simplifies to

$$u_1 = -\int 2x^4 dx$$

Hence

$$u_1 = -\frac{2x^5}{5}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{10}{x}}{5}\, dx$$

Which simplifies to

$$u_2 = \int \frac{2}{x} dx$$

Hence

$$u_2 = 2 \ln (x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{2x^2}{5} + 2x^2 \ln (x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= -\frac{2x^2}{5} + 2x^2 \ln (x) + \frac{c_1}{x^3} + c_2 x^2 \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{2x^2}{5} + 2x^2 \ln (x) + \frac{c_1}{x^3} + c_2 x^2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = c_1 + c_2 - \frac{2}{5} \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{6x}{5} + 4x \ln (x) - \frac{3c_1}{x^4} + 2c_2 x$$

substituting $y' = -6$ and $x = 1$ in the above gives

$$-6 = -3c_1 + 2c_2 + \frac{6}{5} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 2 \\ c_2 &= -\frac{3}{5} \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{2x^5 \ln(x) - x^5 + 2}{x^3}$$

Summary

The solution(s) found are the following

$$y = \frac{2x^5 \ln(x) - x^5 + 2}{x^3} \tag{1}$$

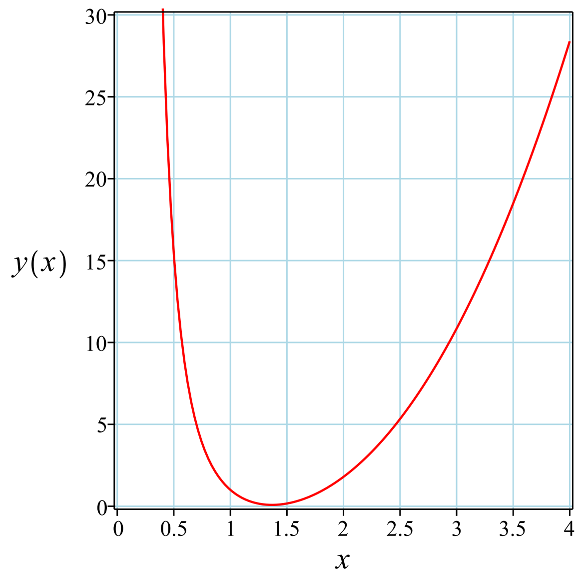

Figure 549: Solution plot

Verification of solutions

$$y = \frac{2x^5 \ln(x) - x^5 + 2}{x^3}$$

Verified OK.

13.25.3 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + 2y'x - 6y = 0$$

In normal form the ode

$$x^2y'' + 2y'x - 6y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{2}{x} \\ q(x) &= -\frac{6}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\, \tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\ &= \int \mathrm{e}^{-\left(\int \frac{2}{x}dx\right)} dx \\ &= \int e^{-2\ln(x)}\, dx \\ &= \int \frac{1}{x^2} dx \\ &= -\frac{1}{x} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{-\frac{6}{x^2}}{\frac{1}{x^4}} \\
&= -6x^2 \qquad (7)
\end{aligned}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - 6x^2 y(\tau) &= 0
\end{aligned}$$

But in terms of τ

$$-6x^2 = -\frac{6}{\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) - \frac{6y(\tau)}{\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 - 6y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} - 6\tau^r = 0$$

Simplifying gives

$$r(r-1)\,\tau^r + 0\,\tau^r - 6\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$r(r-1) + 0 - 6 = 0$$

Or

$$r^2 - r - 6 = 0 \qquad (1)$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$
\begin{aligned}
r_1 &= -2 \\
r_2 &= 3
\end{aligned}
$$

Since the roots are real and distinct, then the general solution is

$$
y(\tau) = c_1 y_1 + c_2 y_2
$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$
y(\tau) = \frac{c_1}{\tau^2} + c_2 \tau^3
$$

The above solution is now transformed back to y using (6) which results in

$$
y = \frac{c_1 x^5 - c_2}{x^3}
$$

Therefore the homogeneous solution y_h is

$$
y_h = \frac{c_1 x^5 - c_2}{x^3}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \frac{1}{x^3} \\
y_2 &= x^2
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x^3} & x^2 \\ \frac{d}{dx}\left(\frac{1}{x^3}\right) & \frac{d}{dx}(x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^3} & x^2 \\ -\frac{3}{x^4} & 2x \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^3}\right)(2x) - (x^2)\left(-\frac{3}{x^4}\right)$$

Which simplifies to

$$W = \frac{5}{x^2}$$

Which simplifies to

$$W = \frac{5}{x^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{10x^4}{5}\, dx$$

Which simplifies to

$$u_1 = -\int 2x^4 dx$$

Hence

$$u_1 = -\frac{2x^5}{5}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{10}{x}}{5}\, dx$$

Which simplifies to

$$u_2 = \int \frac{2}{x} dx$$

Hence

$$u_2 = 2\ln(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{2x^2}{5} + 2x^2 \ln(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 x^5 - c_2}{x^3}\right) + \left(-\frac{2x^2}{5} + 2x^2 \ln(x)\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1 x^5 - c_2}{x^3} - \frac{2x^2}{5} + 2x^2 \ln(x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = c_1 - c_2 - \frac{2}{5} \tag{1A}$$

Taking derivative of the solution gives

$$y' = 5c_1 x - \frac{3(c_1 x^5 - c_2)}{x^4} + \frac{6x}{5} + 4x \ln(x)$$

substituting $y' = -6$ and $x = 1$ in the above gives

$$-6 = 2c_1 + 3c_2 + \frac{6}{5} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= -\frac{3}{5} \\ c_2 &= -2 \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{2x^5 \ln(x) - x^5 + 2}{x^3}$$

Summary

The solution(s) found are the following

$$y = \frac{2x^5 \ln(x) - x^5 + 2}{x^3} \tag{1}$$

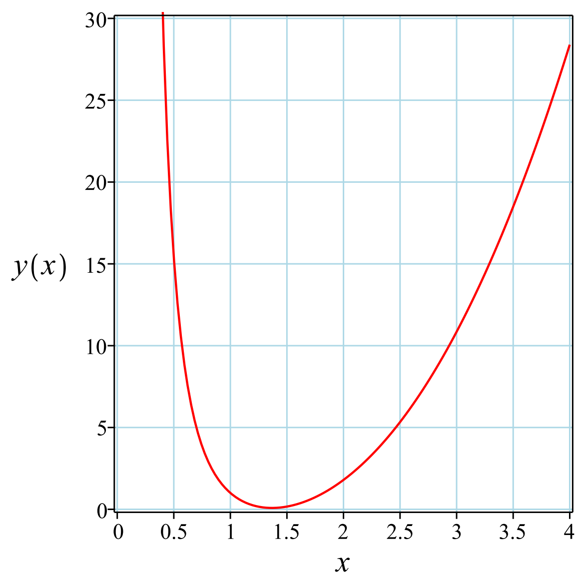

Figure 550: Solution plot

Verification of solutions

$$y = \frac{2x^5 \ln(x) - x^5 + 2}{x^3}$$

Verified OK.

13.25.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 2x, C = -6, f(x) = 10x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. Solving for y_h from

$$x^2y''+2y'x-6y=0$$

In normal form the ode

$$x^2y''+2y'x-6y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned}p(x)&=\frac{2}{x}\\ q(x)&=-\frac{6}{x^2}\end{aligned}$$

Applying change of variables on the depndent variable $y=v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x)+\left(\frac{2n}{x}+p\right)v'(x)+\left(\frac{n(n-1)}{x^2}+\frac{np}{x}+q\right)v(x)=0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2}+\frac{np}{x}+q=0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}+\frac{2n}{x^2}-\frac{6}{x^2}=0 \tag{5}$$

Solving (5) for n gives

$$n=2 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned}v''(x)+\frac{6v'(x)}{x}&=0\\ v''(x)+\frac{6v'(x)}{x}&=0\end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{6u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x, u) \\
&= f(x)g(u) \\
&= -\frac{6u}{x}
\end{aligned}$$

Where $f(x) = -\frac{6}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= -\frac{6}{x}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{6}{x}\,dx \\
\ln(u) &= -6\ln(x) + c_1 \\
u &= \mathrm{e}^{-6\ln(x)+c_1} \\
&= \frac{c_1}{x^6}
\end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= -\frac{c_1}{5x^5} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\,x^n \\
&= \left(-\frac{c_1}{5x^5} + c_2\right) x^2 \\
&= \frac{5c_2x^5 - c_1}{5x^3}
\end{aligned}$$

Now the particular solution to this ODE is found

$$x^2y'' + 2y'x - 6y = 10x^2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x^3}$$
$$y_2 = x^2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x^3} & x^2 \\ \frac{d}{dx}\left(\frac{1}{x^3}\right) & \frac{d}{dx}(x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^3} & x^2 \\ -\frac{3}{x^4} & 2x \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^3}\right)(2x) - \left(x^2\right)\left(-\frac{3}{x^4}\right)$$

Which simplifies to

$$W = \frac{5}{x^2}$$

Which simplifies to

$$W = \frac{5}{x^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\left(\int \frac{10x^4}{5}dx\right)$$

Which simplifies to

$$u_1 = -\left(\int 2x^4 dx\right)$$

Hence

$$u_1 = -\frac{2x^5}{5}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{10}{x}}{5}dx$$

Which simplifies to

$$u_2 = \int \frac{2}{x}dx$$

Hence

$$u_2 = 2\ln(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{2x^2}{5} + 2x^2\ln(x)$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\left(-\frac{c_1}{5x^5} + c_2\right) x^2\right) + \left(-\frac{2x^2}{5} + 2x^2 \ln(x)\right) \\
&= -\frac{2x^2}{5} + 2x^2 \ln(x) + \left(-\frac{c_1}{5x^5} + c_2\right) x^2
\end{aligned}
$$

Which simplifies to

$$
y = \frac{10x^5 \ln(x) + 5c_2x^5 - 2x^5 - c_1}{5x^3}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \frac{10x^5 \ln(x) + 5c_2x^5 - 2x^5 - c_1}{5x^3} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$
1 = -\frac{c_1}{5} + c_2 - \frac{2}{5} \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = \frac{50x^4 \ln(x) + 25c_2x^4}{5x^3} - \frac{3(10x^5 \ln(x) + 5c_2x^5 - 2x^5 - c_1)}{5x^4}
$$

substituting $y' = -6$ and $x = 1$ in the above gives

$$
-6 = \frac{3c_1}{5} + 2c_2 + \frac{6}{5} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= -10 \\
c_2 &= -\frac{3}{5}
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \frac{2x^5 \ln(x) - x^5 + 2}{x^3}
$$

Summary
The solution(s) found are the following

$$y = \frac{2x^5 \ln(x) - x^5 + 2}{x^3} \tag{1}$$

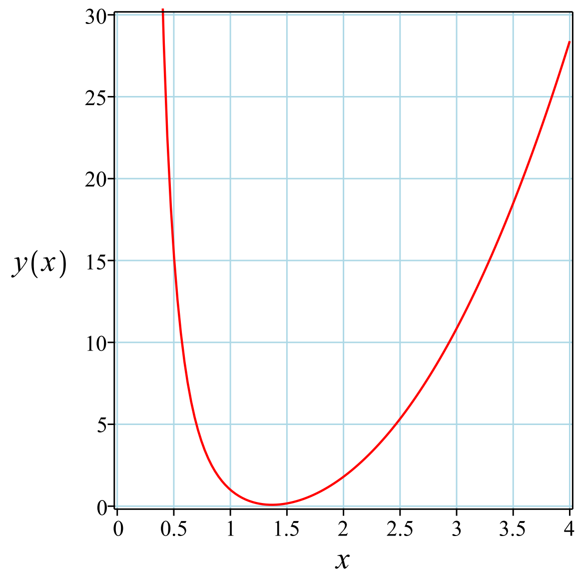

Figure 551: Solution plot

Verification of solutions

$$y = \frac{2x^5 \ln(x) - x^5 + 2}{x^3}$$

Verified OK.

13.25.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + 2y'x - 6y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 2x \\ C &= -6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{6}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 6 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{6}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 505: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{6}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition

of r given above. Therefore $b = 6$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = 3 \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -2
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{6}{x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = 6$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = 3 \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = -2
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{6}{x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	3	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_\infty^- = -2$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= -2 - (-2) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{2}{x} + (-)(0) \\ &= -\frac{2}{x} \\ &= -\frac{2}{x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{2}{x}\right)(0) + \left(\left(\frac{2}{x^2}\right) + \left(-\frac{2}{x}\right)^2 - \left(\frac{6}{x^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int -\frac{2}{x} dx} \\ &= \frac{1}{x^2} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x}{x^2}\,dx} \\
&= z_1 e^{-\ln(x)} \\
&= z_1 \left(\frac{1}{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x^3}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{x^5}{5}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x^3}\right) + c_2 \left(\frac{1}{x^3}\left(\frac{x^5}{5}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$x^2y''+2y'x-6y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h=\frac{c_1}{x^3}+\frac{c_2x^2}{5}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x)=u_1y_1+u_2y_2 \tag{1}$$

Where u_1,u_2 to be determined, and y_1,y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1=\frac{1}{x^3}$$
$$y_2=\frac{x^2}{5}$$

In the Variation of parameters u_1,u_2 are found using

$$u_1=-\int\frac{y_2f(x)}{aW(x)} \tag{2}$$
$$u_2=\int\frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W=\begin{vmatrix}y_1 & y_2\\ y_1' & y_2'\end{vmatrix}$. Hence

$$W=\begin{vmatrix}\frac{1}{x^3} & \frac{x^2}{5}\\ \frac{d}{dx}\left(\frac{1}{x^3}\right) & \frac{d}{dx}\left(\frac{x^2}{5}\right)\end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^3} & \frac{x^2}{5} \\ -\frac{3}{x^4} & \frac{2x}{5} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^3}\right)\left(\frac{2x}{5}\right) - \left(\frac{x^2}{5}\right)\left(-\frac{3}{x^4}\right)$$

Which simplifies to

$$W = \frac{1}{x^2}$$

Which simplifies to

$$W = \frac{1}{x^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2x^4}{1}\,dx$$

Which simplifies to

$$u_1 = -\int 2x^4 dx$$

Hence

$$u_1 = -\frac{2x^5}{5}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{10}{x}}{1}\,dx$$

Which simplifies to

$$u_2 = \int \frac{10}{x} dx$$

Hence

$$u_2 = 10 \ln(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{2x^2}{5} + 2x^2 \ln(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x^3} + \frac{c_2 x^2}{5}\right) + \left(-\frac{2x^2}{5} + 2x^2 \ln(x)\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1}{x^3} + \frac{c_2 x^2}{5} - \frac{2x^2}{5} + 2x^2 \ln(x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = c_1 + \frac{c_2}{5} - \frac{2}{5} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{3c_1}{x^4} + \frac{2c_2 x}{5} + \frac{6x}{5} + 4x \ln(x)$$

substituting $y' = -6$ and $x = 1$ in the above gives

$$-6 = -3c_1 + \frac{2c_2}{5} + \frac{6}{5} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 2 \\ c_2 &= -3 \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{2x^5 \ln(x) - x^5 + 2}{x^3}$$

Summary

The solution(s) found are the following

$$y = \frac{2x^5 \ln(x) - x^5 + 2}{x^3} \tag{1}$$

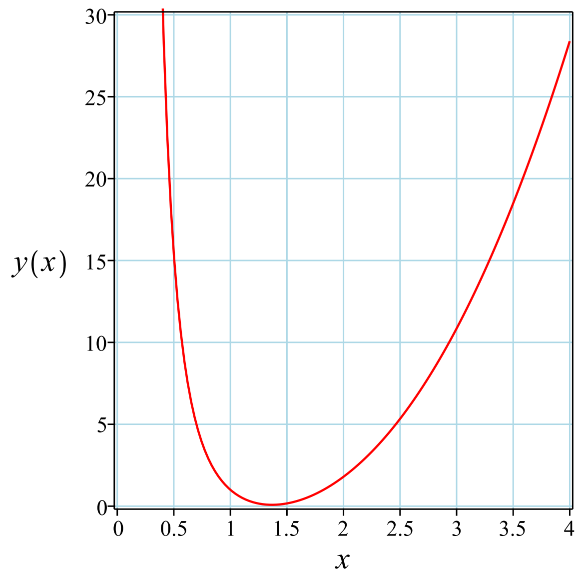

Figure 552: Solution plot

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - 5y'x + 8y = 2x^3}$$

With initial conditions

$$[y(2) = 0, y'(2) = -8]$$

13.26.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -\frac{5}{x} \\ q(x) &= \frac{8}{x^2} \\ F &= 2x \end{aligned}$$

Hence the ode is

$$y'' - \frac{5y'}{x} + \frac{8y}{x^2} = 2x$$

The domain of $p(x) = -\frac{5}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 2$ is inside this domain. The domain of $q(x) = \frac{8}{x^2}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 2$ is also inside this domain. The domain of $F = 2x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 2$ is also inside this domain. Hence solution exists and is unique.

13.26.2 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -5x, C = 8, f(x) = 2x^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 5y'x + 8y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 5xrx^{r-1} + 8x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 5r\,x^r + 8x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 5r + 8 = 0$$

Or

$$r^2 - 6r + 8 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= 2 \\ r_2 &= 4 \end{aligned}$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_2x^4 + c_1x^2$$

Next, we find the particular solution to the ODE

$$x^2y'' - 5y'x + 8y = 2x^3$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= x^2 \\ y_2 &= x^4 \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & x^4 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(x^4) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & x^4 \\ 2x & 4x^3 \end{vmatrix}$$

Therefore

$$W = (x^2)(4x^3) - (x^4)(2x)$$

Which simplifies to

$$W = 2x^5$$

Which simplifies to

$$W = 2x^5$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2x^7}{2x^7}\, dx$$

Which simplifies to

$$u_1 = -\int 1 dx$$

Hence

$$u_1 = -x$$

And Eq. (3) becomes

$$u_2 = \int \frac{2x^5}{2x^7}\, dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x^2} dx$$

Hence

$$u_2 = -\frac{1}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2x^3$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= x^2 \left(c_2 x^2 + c_1 - 2x\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = x^2 \left(c_2 x^2 + c_1 - 2x\right) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 2$ in the above gives

$$0 = 16c_2 + 4c_1 - 16 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2x\left(c_2 x^2 + c_1 - 2x\right) + x^2(2c_2 x - 2)$$

substituting $y' = -8$ and $x = 2$ in the above gives

$$-8 = 32c_2 + 4c_1 - 24 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 4$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = -2(x-2)\,x^2$$

Summary

The solution(s) found are the following

$$y = -2(x-2)\,x^2 \tag{1}$$

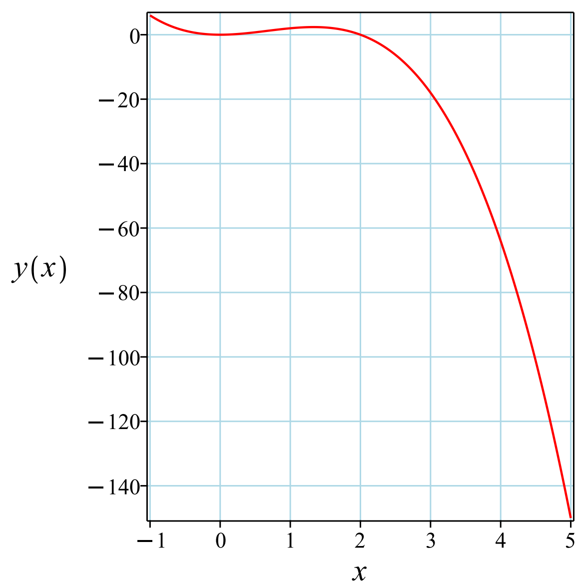

Figure 553: Solution plot

Verification of solutions

$$y = -2(x-2)\,x^2$$

Verified OK.

13.26.3 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 5y'x + 8y = 0$$

In normal form the ode

$$x^2y'' - 5y'x + 8y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{5}{x} \\ q(x) &= \frac{8}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\ &= \int \mathrm{e}^{-\left(\int -\frac{5}{x}dx\right)} dx \\ &= \int e^{5\ln(x)}\, dx \\ &= \int x^5 dx \\ &= \frac{x^6}{6} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned} q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{8}{x^2}}{x^{10}} \\ &= \frac{8}{x^{12}} \end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned} \frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + \frac{8y(\tau)}{x^{12}} &= 0 \end{aligned}$$

But in terms of τ

$$\frac{8}{x^{12}} = \frac{2}{9\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{9\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$9\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 2y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$9\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 2\tau^r = 0$$

Simplifying gives

$$9r(r-1)\,\tau^{r}+0\,\tau^{r}+2\tau^{r}=0$$

Since $\tau^{r}\neq 0$ then dividing throughout by τ^{r} gives

$$9r(r-1)+0+2=0$$

Or

$$9r^{2}-9r+2=0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1=\frac{1}{3}$$
$$r_2=\frac{2}{3}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau)=c_1y_1+c_2y_2$$

Where $y_1=\tau^{r_1}$ and $y_2=\tau^{r_2}$. Hence

$$y(\tau)=c_1\tau^{\frac{1}{3}}+c_2\tau^{\frac{2}{3}}$$

The above solution is now transformed back to y using (6) which results in

$$y=\frac{c_1 6^{\frac{2}{3}}\left(x^{6}\right)^{\frac{1}{3}}}{6}+\frac{c_2 6^{\frac{1}{3}}\left(x^{6}\right)^{\frac{2}{3}}}{6}$$

Therefore the homogeneous solution y_h is

$$y_h=\frac{c_1 6^{\frac{2}{3}}\left(x^{6}\right)^{\frac{1}{3}}}{6}+\frac{c_2 6^{\frac{1}{3}}\left(x^{6}\right)^{\frac{2}{3}}}{6}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x)=u_1y_1+u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(x^6\right)^{\frac{1}{3}}$$

$$y_2 = \left(x^6\right)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(x^6\right)^{\frac{1}{3}} & \left(x^6\right)^{\frac{2}{3}} \\ \frac{d}{dx}\left(\left(x^6\right)^{\frac{1}{3}}\right) & \frac{d}{dx}\left(\left(x^6\right)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(x^6\right)^{\frac{1}{3}} & \left(x^6\right)^{\frac{2}{3}} \\ \frac{2x^5}{\left(x^6\right)^{\frac{2}{3}}} & \frac{4x^5}{\left(x^6\right)^{\frac{1}{3}}} \end{vmatrix}$$

Therefore

$$W = \left(\left(x^6\right)^{\frac{1}{3}}\right)\left(\frac{4x^5}{\left(x^6\right)^{\frac{1}{3}}}\right) - \left(\left(x^6\right)^{\frac{2}{3}}\right)\left(\frac{2x^5}{\left(x^6\right)^{\frac{2}{3}}}\right)$$

Which simplifies to

$$W = 2x^5$$

Which simplifies to

$$W = 2x^5$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2(x^6)^{\frac{2}{3}} x^3}{2x^7} dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^6)^{\frac{2}{3}}}{x^4} dx$$

Hence

$$u_1 = -\frac{(x^6)^{\frac{2}{3}}}{x^3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{2(x^6)^{\frac{1}{3}} x^3}{2x^7} dx$$

Which simplifies to

$$u_2 = \int \frac{(x^6)^{\frac{1}{3}}}{x^4} dx$$

Hence

$$u_2 = -\frac{(x^6)^{\frac{1}{3}}}{x^3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2x^3$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 6^{\frac{2}{3}} (x^6)^{\frac{1}{3}}}{6} + \frac{c_2 6^{\frac{1}{3}} (x^6)^{\frac{2}{3}}}{6}\right) + (-2x^3) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1 6^{\frac{2}{3}} (x^6)^{\frac{1}{3}}}{6} + \frac{c_2 6^{\frac{1}{3}} (x^6)^{\frac{2}{3}}}{6} - 2x^3 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 2$ in the above gives

$$0 = \frac{2c_1 6^{\frac{2}{3}}}{3} + \frac{8c_2 6^{\frac{1}{3}}}{3} - 16 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{c_1 6^{\frac{2}{3}} x^5}{3 (x^6)^{\frac{2}{3}}} + \frac{2c_2 6^{\frac{1}{3}} x^5}{3 (x^6)^{\frac{1}{3}}} - 6x^2$$

substituting $y' = -8$ and $x = 2$ in the above gives

$$-8 = \frac{2c_1 6^{\frac{2}{3}}}{3} + \frac{16c_2 6^{\frac{1}{3}}}{3} - 24 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 4\,6^{\frac{1}{3}}$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = 4(x^6)^{\frac{1}{3}} - 2x^3$$

Summary

The solution(s) found are the following

$$y = 4(x^6)^{\frac{1}{3}} - 2x^3 \tag{1}$$

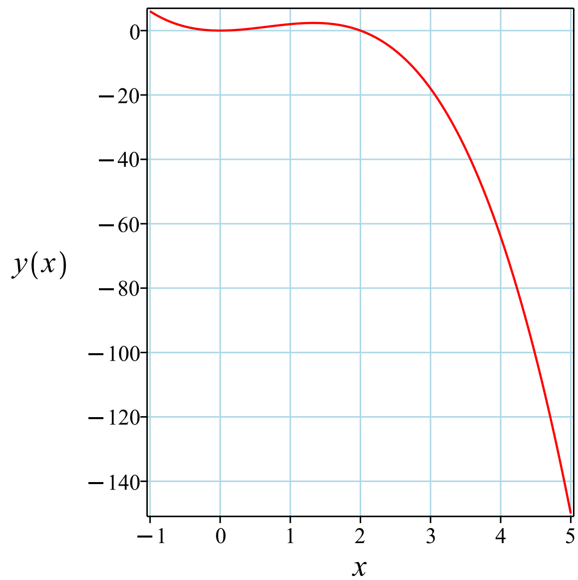

Figure 554: Solution plot

Verification of solutions

$$y = 4\left(x^{6}\right)^{\frac{1}{3}} - 2x^{3}$$

Verified OK.

13.26.4 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -5x, C = 8, f(x) = 2x^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 5y'x + 8y = 0$$

In normal form the ode

$$x^2y'' - 5y'x + 8y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{5}{x} \\ q(x) &= \frac{8}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{2\sqrt{2}\, \sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{2\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\, x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{2\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\, x^3} - \frac{5}{x}\frac{2\sqrt{2}\, \sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{2\sqrt{2}\, \sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= -\frac{3c\sqrt{2}}{2} \end{aligned}$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2} y(\tau) - \frac{3c\sqrt{2}\left(\frac{d}{d\tau} y(\tau)\right)}{2} + c^2 y(\tau) &= 0
\end{aligned} \tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = e^{\frac{3\sqrt{2}\,c\tau}{4}} \left(c_1 \cosh\left(\frac{\sqrt{2}\,c\tau}{4}\right) + i c_2 \sinh\left(\frac{\sqrt{2}\,c\tau}{4}\right)\right)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int 2\sqrt{2}\,\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{2\sqrt{2}\,\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = \frac{x^2((ic_2 + c_1)\,x^2 - ic_2 + c_1)}{2}
$$

Now the particular solution to this ODE is found

$$
x^2 y'' - 5y'x + 8y = 2x^3
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \left(x^6\right)^{\frac{1}{3}} \\
y_2 &= \left(x^6\right)^{\frac{2}{3}}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^6)^{\frac{1}{3}} & (x^6)^{\frac{2}{3}} \\ \frac{d}{dx}\left((x^6)^{\frac{1}{3}}\right) & \frac{d}{dx}\left((x^6)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^6)^{\frac{1}{3}} & (x^6)^{\frac{2}{3}} \\ \frac{2x^5}{(x^6)^{\frac{2}{3}}} & \frac{4x^5}{(x^6)^{\frac{1}{3}}} \end{vmatrix}$$

Therefore

$$W = \left((x^6)^{\frac{1}{3}}\right)\left(\frac{4x^5}{(x^6)^{\frac{1}{3}}}\right) - \left((x^6)^{\frac{2}{3}}\right)\left(\frac{2x^5}{(x^6)^{\frac{2}{3}}}\right)$$

Which simplifies to

$$W = 2x^5$$

Which simplifies to

$$W = 2x^5$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2(x^6)^{\frac{2}{3}}\, x^3}{2x^7}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^6)^{\frac{2}{3}}}{x^4} dx$$

Hence

$$u_1 = -\frac{\left(x^6\right)^{\frac{2}{3}}}{x^3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{2\left(x^6\right)^{\frac{1}{3}} x^3}{2x^7}\, dx$$

Which simplifies to

$$u_2 = \int \frac{\left(x^6\right)^{\frac{1}{3}}}{x^4} dx$$

Hence

$$u_2 = -\frac{\left(x^6\right)^{\frac{1}{3}}}{x^3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2x^3$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{x^2((ic_2 + c_1)\, x^2 - ic_2 + c_1)}{2}\right) + \left(-2x^3\right) \\ &= -2x^3 + \frac{x^2((ic_2 + c_1)\, x^2 - ic_2 + c_1)}{2} \end{aligned}$$

Which simplifies to

$$y = \frac{x^2((ic_2 + c_1)\, x^2 - 4x - ic_2 + c_1)}{2}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{x^2((ic_2 + c_1)\, x^2 - 4x - ic_2 + c_1)}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 2$ in the above gives

$$0 = 6ic_2 + 10c_1 - 16 \tag{1A}$$

Taking derivative of the solution gives

$$y' = x\left((ic_2 + c_1)\, x^2 - 4x - ic_2 + c_1\right) + \frac{x^2(2(ic_2 + c_1)\, x - 4)}{2}$$

substituting $y' = -8$ and $x = 2$ in the above gives

$$-8 = 14ic_2 + 18c_1 - 24 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 4$$
$$c_2 = 4i$$

Substituting these values back in above solution results in

$$y = -2x^3 + 4x^2$$

Summary
The solution(s) found are the following

$$y = -2x^3 + 4x^2 \tag{1}$$

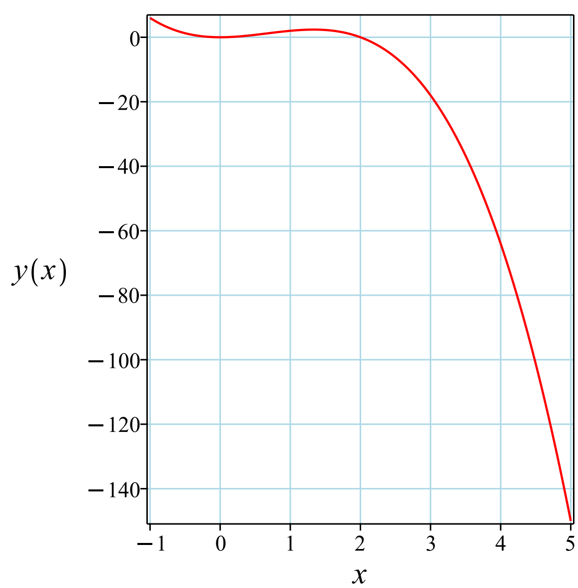

Figure 555: Solution plot

Verification of solutions

$$y = -2x^3 + 4x^2$$

Verified OK.

13.26.5 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -5x, C = 8, f(x) = 2x^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 5y'x + 8y = 0$$

In normal form the ode

$$x^2y'' - 5y'x + 8y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{5}{x} \\ q(x) &= \frac{8}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{5n}{x^2} + \frac{8}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 4 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{3v'(x)}{x} &= 0 \\ v''(x) + \frac{3v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{3u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{3u}{x} \end{aligned}$$

Where $f(x) = -\frac{3}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{3}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{3}{x}\,dx \\ \ln(u) &= -3\ln(x) + c_1 \\ u &= \mathrm{e}^{-3\ln(x)+c_1} \\ &= \frac{c_1}{x^3} \end{aligned}$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= -\frac{c_1}{2x^2} + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(-\frac{c_1}{2x^2} + c_2\right) x^4 \\
&= c_2 x^4 - \frac{1}{2} c_1 x^2
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
x^2 y'' - 5y'x + 8y = 2x^3
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x^2 \\
y_2 &= x^4
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & x^4 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(x^4) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & x^4 \\ 2x & 4x^3 \end{vmatrix}$$

Therefore

$$W = (x^2)(4x^3) - (x^4)(2x)$$

Which simplifies to

$$W = 2x^5$$

Which simplifies to

$$W = 2x^5$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2x^7}{2x^7}\,dx$$

Which simplifies to

$$u_1 = -\int 1dx$$

Hence

$$u_1 = -x$$

And Eq. (3) becomes

$$u_2 = \int \frac{2x^5}{2x^7}\,dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x^2}dx$$

Hence

$$u_2 = -\frac{1}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2x^3$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(-\frac{c_1}{2x^2} + c_2\right) x^4\right) + \left(-2x^3\right) \\ &= -2x^3 + \left(-\frac{c_1}{2x^2} + c_2\right) x^4 \end{aligned}$$

Which simplifies to

$$y = -\frac{x^2(-2c_2x^2 + c_1 + 4x)}{2}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{x^2(-2c_2x^2 + c_1 + 4x)}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 2$ in the above gives

$$0 = 16c_2 - 2c_1 - 16 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -x\left(-2c_2x^2 + c_1 + 4x\right) - \frac{x^2(-4c_2x + 4)}{2}$$

substituting $y' = -8$ and $x = 2$ in the above gives

$$-8 = 32c_2 - 2c_1 - 24 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -8$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = -2(x-2)\,x^2$$

Summary
The solution(s) found are the following

$$y = -2(x-2)\,x^2 \tag{1}$$

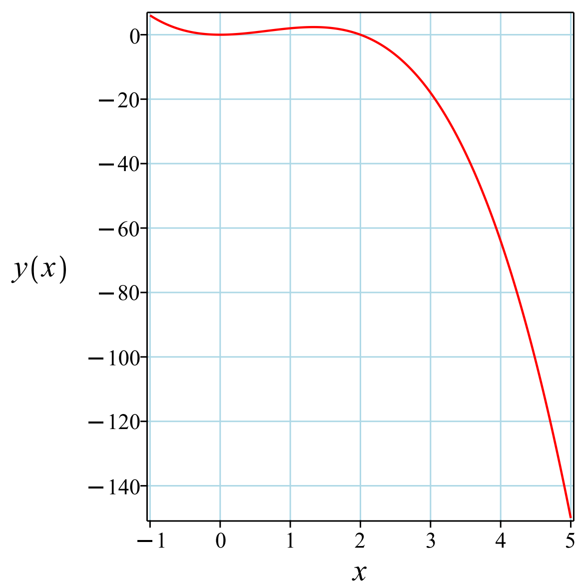

Figure 556: Solution plot

Verification of solutions

$$y = -2(x-2)\,x^2$$

Verified OK.

13.26.6 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 5y'x + 8y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -5x \\ C &= 8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 506: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\ &= -\frac{1}{2x} + (-)\,(0) \\ &= -\frac{1}{2x} \\ &= -\frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(-\frac{1}{2x}\right)^2 - \left(\frac{3}{4x^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int -\frac{1}{2x} dx} \\ &= \frac{1}{\sqrt{x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-5x}{x^2}\,dx} \\
&= z_1 e^{\frac{5\ln(x)}{2}} \\
&= z_1\left(x^{\frac{5}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^2
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-5x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{5\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{x^2}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^2\right) + c_2\left(x^2\left(\frac{x^2}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' - 5y'x + 8y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 x^2 + \frac{1}{2} c_2 x^4$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2$$
$$y_2 = \frac{x^4}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & \frac{x^4}{2} \\ \frac{d}{dx}(x^2) & \frac{d}{dx}\left(\frac{x^4}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & \frac{x^4}{2} \\ 2x & 2x^3 \end{vmatrix}$$

Therefore

$$W = (x^2)(2x^3) - \left(\frac{x^4}{2}\right)(2x)$$

Which simplifies to

$$W = x^5$$

Which simplifies to

$$W = x^5$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^7}{x^7}\, dx$$

Which simplifies to

$$u_1 = -\int 1 dx$$

Hence

$$u_1 = -x$$

And Eq. (3) becomes

$$u_2 = \int \frac{2x^5}{x^7}\, dx$$

Which simplifies to

$$u_2 = \int \frac{2}{x^2} dx$$

Hence

$$u_2 = -\frac{2}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2x^3$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 x^2 + \frac{1}{2} c_2 x^4\right) + \left(-2x^3\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 x^2 + \frac{1}{2} c_2 x^4 - 2x^3 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 2$ in the above gives

$$
0 = 4c_1 + 8c_2 - 16 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = 2c_2 x^3 + 2c_1 x - 6x^2
$$

substituting $y' = -8$ and $x = 2$ in the above gives

$$
-8 = 16c_2 + 4c_1 - 24 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 4 \\
c_2 &= 0
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = -2x^3 + 4x^2
$$

Summary

The solution(s) found are the following

$$
y = -2x^3 + 4x^2 \tag{1}
$$

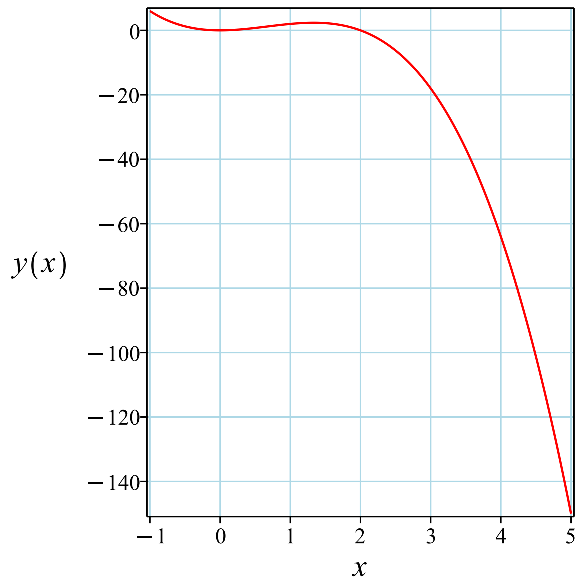

Figure 557: Solution plot

Verification of solutions

$$y = -2x^3 + 4x^2$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2y'' - 6y = \ln(x)}$$

With initial conditions

$$\left[y(1) = \frac{1}{6}, y'(1) = -\frac{1}{6}\right]$$

13.27.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned}
p(x) &= 0 \\
q(x) &= -\frac{6}{x^2} \\
F &= \frac{\ln(x)}{x^2}
\end{aligned}$$

Hence the ode is

$$y'' - \frac{6y}{x^2} = \frac{\ln(x)}{x^2}$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $q(x) = -\frac{6}{x^2}$ is

$$\{x < 0 \vee 0 < x\}$$

And the point $x_0 = 1$ is also inside this domain. The domain of $F = \frac{\ln(x)}{x^2}$ is

$$\{0 < x\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

13.27.2 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 0, C = -6, f(x) = \ln(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 6y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 0rx^{r-1} - 6x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 0\,x^r - 6x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 0 - 6 = 0$$

Or

$$r^2 - r - 6 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= -2 \\ r_2 &= 3 \end{aligned}$$

Since the roots are real and distinct, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = \frac{c_1}{x^2} + c_2 x^3$$

Next, we find the particular solution to the ODE

$$x^2 y'' - 6y = \ln(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \frac{1}{x^2} \\ y_2 &= x^3 \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x^2} & x^3 \\ \frac{d}{dx}\left(\frac{1}{x^2}\right) & \frac{d}{dx}(x^3) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^2} & x^3 \\ -\frac{2}{x^3} & 3x^2 \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^2}\right)(3x^2) - (x^3)\left(-\frac{2}{x^3}\right)$$

Which simplifies to

$$W = 5$$

Which simplifies to

$$W = 5$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^3 \ln(x)}{5x^2}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{x \ln(x)}{5} dx$$

Hence

$$u_1 = -\frac{x^2 \ln(x)}{10} + \frac{x^2}{20}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\ln(x)}{x^2}}{5x^2}\,dx$$

Which simplifies to

$$u_2 = \int \frac{\ln(x)}{5x^4} dx$$

Hence

$$u_2 = -\frac{\ln(x)}{15x^3} - \frac{1}{45x^3}$$

Which simplifies to

$$u_1 = -\frac{x^2(-1 + 2\ln(x))}{20}$$
$$u_2 = \frac{-1 - 3\ln(x)}{45x^3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{1}{36} - \frac{\ln(x)}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \frac{1}{36} - \frac{\ln(x)}{6} + \frac{c_1}{x^2} + c_2 x^3 \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{1}{36} - \frac{\ln(x)}{6} + \frac{c_1}{x^2} + c_2 x^3 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{1}{6}$ and $x = 1$ in the above gives

$$\frac{1}{6} = c_1 + c_2 + \frac{1}{36} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{1}{6x} - \frac{2c_1}{x^3} + 3c_2 x^2$$

substituting $y' = -\frac{1}{6}$ and $x = 1$ in the above gives

$$-\frac{1}{6} = -2c_1 + 3c_2 - \frac{1}{6} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{1}{12}$$
$$c_2 = \frac{1}{18}$$

Substituting these values back in above solution results in

$$y = \frac{2x^5 - 6x^2 \ln(x) + x^2 + 3}{36x^2}$$

Summary

The solution(s) found are the following

$$y = \frac{2x^5 - 6x^2 \ln(x) + x^2 + 3}{36x^2} \tag{1}$$

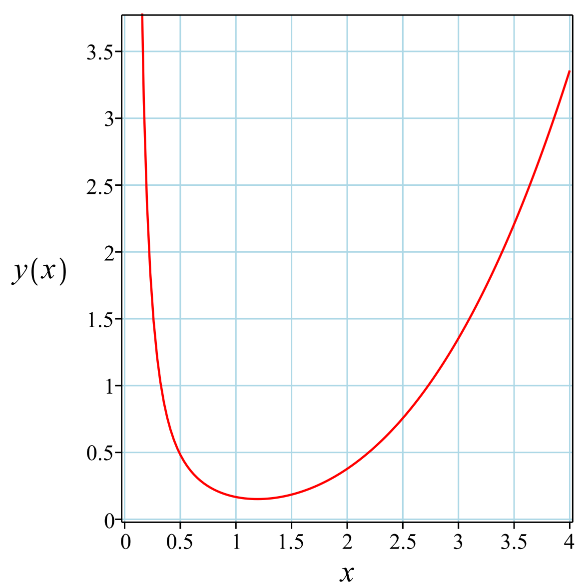

Figure 558: Solution plot

Verification of solutions

$$y = \frac{2x^5 - 6x^2 \ln(x) + x^2 + 3}{36x^2}$$

Verified OK.

13.27.3 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 6y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 0 \\ C &= -6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{6}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 6 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{6}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 507: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{6}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{6}{x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = 6$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -2
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{6}{x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	3	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = -2$ then

$$
\begin{aligned}
d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= -2 - (-2) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{2}{x} + (-)\,(0) \\
&= -\frac{2}{x} \\
&= -\frac{2}{x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{2}{x}\right)(0) + \left(\left(\frac{2}{x^2}\right) + \left(-\frac{2}{x}\right)^2 - \left(\frac{6}{x^2}\right) \right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int -\frac{2}{x} dx} \\
&= \frac{1}{x^2}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \frac{1}{x^2} \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \frac{1}{x^2} \int \frac{1}{\frac{1}{x^4}}\,dx \\ &= \frac{1}{x^2}\left(\frac{x^5}{5}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{1}{x^2}\right) + c_2\left(\frac{1}{x^2}\left(\frac{x^5}{5}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$x^2y''-6y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h=\frac{c_1}{x^2}+\frac{c_2x^3}{5}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x)=u_1y_1+u_2y_2 \tag{1}$$

Where u_1,u_2 to be determined, and y_1,y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1=\frac{1}{x^2}$$
$$y_2=\frac{x^3}{5}$$

In the Variation of parameters u_1,u_2 are found using

$$u_1=-\int\frac{y_2f(x)}{aW(x)} \tag{2}$$
$$u_2=\int\frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W=\begin{vmatrix}y_1 & y_2\\ y_1' & y_2'\end{vmatrix}$. Hence

$$W=\begin{vmatrix}\frac{1}{x^2} & \frac{x^3}{5}\\ \frac{d}{dx}\left(\frac{1}{x^2}\right) & \frac{d}{dx}\left(\frac{x^3}{5}\right)\end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{x^3}{5} \\ -\frac{2}{x^3} & \frac{3x^2}{5} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^2}\right)\left(\frac{3x^2}{5}\right) - \left(\frac{x^3}{5}\right)\left(-\frac{2}{x^3}\right)$$

Which simplifies to

$$W = 1$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x^3 \ln(x)}{5}}{x^2}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{x \ln(x)}{5} dx$$

Hence

$$u_1 = -\frac{x^2 \ln(x)}{10} + \frac{x^2}{20}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\ln(x)}{x^2}}{x^2}\, dx$$

Which simplifies to

$$u_2 = \int \frac{\ln(x)}{x^4} dx$$

Hence

$$u_2 = -\frac{\ln(x)}{3x^3} - \frac{1}{9x^3}$$

Which simplifies to

$$
\begin{aligned}
u_1 &= -\frac{x^2(-1+2\ln(x))}{20} \\
u_2 &= \frac{-1-3\ln(x)}{9x^3}
\end{aligned}
$$

Therefore the particular solution, from equation (1) is

$$
y_p(x) = \frac{1}{36} - \frac{\ln(x)}{6}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\frac{c_1}{x^2} + \frac{c_2 x^3}{5}\right) + \left(\frac{1}{36} - \frac{\ln(x)}{6}\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \frac{c_1}{x^2} + \frac{c_2 x^3}{5} + \frac{1}{36} - \frac{\ln(x)}{6} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{1}{6}$ and $x = 1$ in the above gives

$$
\frac{1}{6} = c_1 + \frac{c_2}{5} + \frac{1}{36} \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -\frac{2c_1}{x^3} + \frac{3c_2 x^2}{5} - \frac{1}{6x}
$$

substituting $y' = -\frac{1}{6}$ and $x = 1$ in the above gives

$$
-\frac{1}{6} = -2c_1 + \frac{3c_2}{5} - \frac{1}{6} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= \frac{1}{12} \\
c_2 &= \frac{5}{18}
\end{aligned}
$$

Substituting these values back in above solution results in

$$y = \frac{2x^5 - 6x^2 \ln(x) + x^2 + 3}{36x^2}$$

Summary

The solution(s) found are the following

$$y = \frac{2x^5 - 6x^2 \ln(x) + x^2 + 3}{36x^2} \tag{1}$$

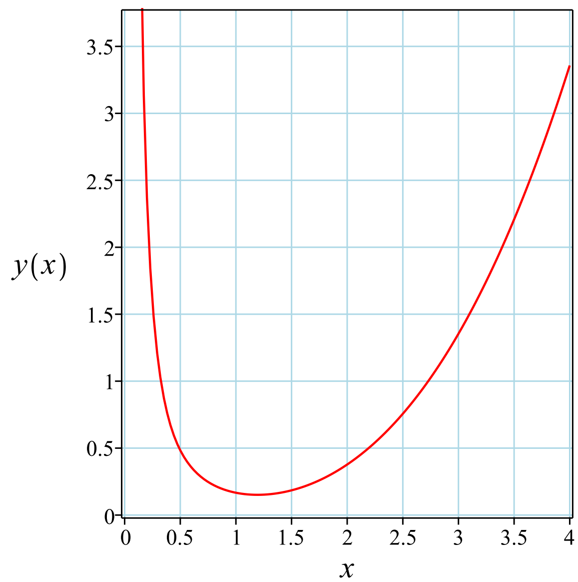

Figure 559: Solution plot

Verification of solutions

$$y = \frac{2x^5 - 6x^2 \ln(x) + x^2 + 3}{36x^2}$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{(x+2)^2 y'' - (x+2) y' - 3y = 0}$$

13.28.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left((x+2)^2 y'' + (-x-2) y' - 3y\right) dx = 0$$
$$(-3x-6) y + \left(x^2+4x+4\right) y' = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{3}{x+2} \\
q(x) &= \frac{c_1}{(x+2)^2}
\end{aligned}
$$

Hence the ode is

$$
y' - \frac{3y}{x+2} = \frac{c_1}{(x+2)^2}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{3}{x+2}dx} \\
&= \frac{1}{(x+2)^3}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{(x+2)^2}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{(x+2)^3}\right) &= \left(\frac{1}{(x+2)^3}\right)\left(\frac{c_1}{(x+2)^2}\right) \\
\mathrm{d}\left(\frac{y}{(x+2)^3}\right) &= \left(\frac{c_1}{(x+2)^5}\right) \mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\frac{y}{(x+2)^3} &= \int \frac{c_1}{(x+2)^5}\, \mathrm{d}x \\
\frac{y}{(x+2)^3} &= -\frac{c_1}{4(x+2)^4} + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{1}{(x+2)^3}$ results in

$$
y = -\frac{c_1}{4(x+2)} + c_2(x+2)^3
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = -\frac{c_1}{4(x+2)} + c_2(x+2)^3 \tag{1}
$$

<u>Verification of solutions</u>

$$
y = -\frac{c_1}{4(x+2)} + c_2(x+2)^3
$$

Verified OK.

13.28.2 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$(x+2)^2 y'' + (-x-2) y' - 3y = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left((x+2)^2 y'' + (-x-2) y' - 3y\right) dx = 0$$
$$(-3x-6) y + \left(x^2+4x+4\right) y' = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{3}{x+2}$$
$$q(x) = \frac{c_1}{(x+2)^2}$$

Hence the ode is

$$y' - \frac{3y}{x+2} = \frac{c_1}{(x+2)^2}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{3}{x+2}dx}$$
$$= \frac{1}{(x+2)^3}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{c_1}{(x+2)^2}\right)$$
$$\frac{d}{dx}\left(\frac{y}{(x+2)^3}\right) = \left(\frac{1}{(x+2)^3}\right)\left(\frac{c_1}{(x+2)^2}\right)$$
$$d\left(\frac{y}{(x+2)^3}\right) = \left(\frac{c_1}{(x+2)^5}\right) dx$$

Integrating gives

$$\frac{y}{(x+2)^3} = \int \frac{c_1}{(x+2)^5} \,\mathrm{d}x$$
$$\frac{y}{(x+2)^3} = -\frac{c_1}{4(x+2)^4} + c_2$$

Dividing both sides by the integrating factor $\mu = \frac{1}{(x+2)^3}$ results in

$$y = -\frac{c_1}{4(x+2)} + c_2(x+2)^3$$

Summary

The solution(s) found are the following

$$y = -\frac{c_1}{4(x+2)} + c_2(x+2)^3 \tag{1}$$

Verification of solutions

$$y = -\frac{c_1}{4(x+2)} + c_2(x+2)^3$$

Verified OK.

13.28.3 Solving using Kovacic algorithm

Writing the ode as

$$(x+2)^2 y'' + (-x-2) y' - 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= (x+2)^2 \\ B &= -x-2 \\ C &= -3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{15}{4\left(x+2\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 15$$
$$t = 4(x+2)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{15}{4\left(x+2\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 508: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x+2)^2$. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{15}{4\left(x+2\right)^2}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(x+2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{15}{4\left(x+2\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{15}{4\left(x+2\right)^{2}}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-2	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = -\frac{3}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\ &= -\frac{3}{2} - \left(-\frac{3}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{3}{2\left(x+2\right)} + (-)\left(0\right) \\ &= -\frac{3}{2\left(x+2\right)} \\ &= -\frac{3}{2\left(x+2\right)} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{3}{2\left(x+2\right)}\right)(0) + \left(\left(\frac{3}{2\left(x+2\right)^2}\right) + \left(-\frac{3}{2\left(x+2\right)}\right)^2 - \left(\frac{15}{4\left(x+2\right)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int -\frac{3}{2(x+2)} dx} \\ &= \frac{1}{\left(x+2\right)^{\frac{3}{2}}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x-2}{(x+2)^2}\, dx} \\ &= z_1 e^{\frac{\ln(x+2)}{2}} \\ &= z_1\left(\sqrt{x+2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x+2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{-x-2}{(x+2)^2} dx}}{(y_1)^2} dx$$
$$= y_1 \int \frac{e^{\ln(x+2)}}{(y_1)^2} dx$$
$$= y_1 \left(\frac{(x+2)^4}{4} \right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{1}{x+2} \right) + c_2 \left(\frac{1}{x+2} \left(\frac{(x+2)^4}{4} \right) \right)$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x+2} + \frac{c_2(x+2)^3}{4} \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x+2} + \frac{c_2(x+2)^3}{4}$$

Verified OK.

13.28.4 Solving as exact linear second order ode ode

An ode of the form

$$p(x) y'' + q(x) y' + r(x) y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$p(x) = (x+2)^2$$
$$q(x) = -x - 2$$
$$r(x) = -3$$
$$s(x) = 0$$

Hence

$$p''(x) = 2$$
$$q'(x) = -1$$

Therefore (1) becomes

$$2 - (-1) + (-3) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$(x+2)^2\, y' + (-3x-6)\, y = c_1$$

We now have a first order ode to solve which is

$$(x+2)^2\, y' + (-3x-6)\, y = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{3}{x+2}$$
$$q(x) = \frac{c_1}{(x+2)^2}$$

Hence the ode is

$$y' - \frac{3y}{x+2} = \frac{c_1}{(x+2)^2}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{3}{x+2}dx}$$
$$= \frac{1}{(x+2)^3}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{c_1}{(x+2)^2}\right)$$

$$\frac{d}{dx}\left(\frac{y}{(x+2)^3}\right) = \left(\frac{1}{(x+2)^3}\right)\left(\frac{c_1}{(x+2)^2}\right)$$

$$d\left(\frac{y}{(x+2)^3}\right) = \left(\frac{c_1}{(x+2)^5}\right)\, dx$$

Integrating gives

$$\frac{y}{(x+2)^3} = \int \frac{c_1}{(x+2)^5}\, dx$$

$$\frac{y}{(x+2)^3} = -\frac{c_1}{4\,(x+2)^4} + c_2$$

Dividing both sides by the integrating factor $\mu = \frac{1}{(x+2)^3}$ results in

$$y = -\frac{c_1}{4\,(x+2)} + c_2(x+2)^3$$

Summary

The solution(s) found are the following

$$y = -\frac{c_1}{4\,(x+2)} + c_2(x+2)^3 \tag{1}$$

Verification of solutions

$$y = -\frac{c_1}{4\,(x+2)} + c_2(x+2)^3$$

Verified OK.

13.28.5 Maple step by step solution

Let's solve

$(x+2)^2\, y'' + (-x-2)\, y' - 3y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{y'}{x+2} + \frac{3y}{(x+2)^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' - \frac{y'}{x+2} - \frac{3y}{(x+2)^2} = 0$

☐ Check to see if $x_0 = -2$ is a regular singular point

  - Define functions

  $\left[P_2(x) = -\frac{1}{x+2}, P_3(x) = -\frac{3}{(x+2)^2}\right]$

  - $(x+2) \cdot P_2(x)$ is analytic at $x = -2$

  $\left((x+2) \cdot P_2(x)\right) \bigg|_{x=-2} = -1$

  - $(x+2)^2 \cdot P_3(x)$ is analytic at $x = -2$

  $\left((x+2)^2 \cdot P_3(x)\right) \bigg|_{x=-2} = -3$

  - $x = -2$is a regular singular point

  Check to see if $x_0 = -2$ is a regular singular point

  $x_0 = -2$

- Multiply by denominators

$(x+2)^2 y'' + (-x-2) y' - 3y = 0$

- Change variables using $x = u - 2$ so that the regular singular point is at $u = 0$

$u^2 \left(\frac{d^2}{du^2} y(u)\right) - u\left(\frac{d}{du} y(u)\right) - 3y(u) = 0$

- Assume series solution for $y(u)$

$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite DE with series expansions

  - Convert $u \cdot \left(\frac{d}{du} y(u)\right)$ to series expansion

  $u \cdot \left(\frac{d}{du} y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r) u^{k+r}$

  - Convert $u^2 \cdot \left(\frac{d^2}{du^2} y(u)\right)$ to series expansion

  $u^2 \cdot \left(\frac{d^2}{du^2} y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1) u^{k+r}$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} a_k (k+r+1)(k+r-3) u^{k+r} = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r = 0$
- Each term in the series must be 0, giving the recursion relation

  $a_k(k+1)(k-3) = 0$
- Recursion relation that defines series solution to ODE

  $a_k = 0$
- Recursion relation for $r = 0$

  $a_k = 0$
- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_k = 0\right]$
- Revert the change of variables $u = x + 2$

  $\left[y = \sum_{k=0}^{\infty} a_k (x+2)^k, a_k = 0\right]$

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(2x-3)^2 y'' - 6(2x-3) y' + 12y = 0}$$

13.29.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$4\left(x-\frac{3}{2}\right)^2 y'' + (-12x+18) y' + 12y = 0 \tag{1}$$

Becomes

$$y'' + p(x) y' + q(x) y = 0 \tag{2}$$

Where

$$p(x) = \frac{6}{-2x+3}$$
$$q(x) = \frac{12}{(2x-3)^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int \frac{6}{-2x+3}dx\right)}dx \\
&= \int e^{3\ln(-2x+3)}\,dx \\
&= \int (-2x+3)^3\,dx \\
&= -\frac{(-2x+3)^4}{8}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{12}{(2x-3)^2}}{(-2x+3)^6} \\
&= \frac{12}{(2x-3)^8}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{12y(\tau)}{(2x-3)^8} &= 0
\end{aligned}$$

But in terms of τ

$$\frac{12}{(2x-3)^8} = \frac{3}{16\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{3y(\tau)}{16\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$16\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 3y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$16\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 3\tau^r = 0$$

Simplifying gives

$$16r(r-1)\,\tau^r + 0\,\tau^r + 3\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$16r(r-1) + 0 + 3 = 0$$

Or

$$16r^2 - 16r + 3 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{4}$$
$$r_2 = \frac{3}{4}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{\frac{1}{4}} + c_2\tau^{\frac{3}{4}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{2^{\frac{1}{4}}\left(-(2x-3)^4\right)^{\frac{1}{4}}\left(c_2\sqrt{2}\,\sqrt{-(2x-3)^4} + 4c_1\right)}{8}$$

Summary

The solution(s) found are the following

$$y = \frac{2^{\frac{1}{4}} \left(-(2x-3)^4\right)^{\frac{1}{4}} \left(c_2 \sqrt{2}\, \sqrt{-\left(2x-3\right)^4}+4c_1\right)}{8} \tag{1}$$

Verification of solutions

$$y = \frac{2^{\frac{1}{4}} \left(-(2x-3)^4\right)^{\frac{1}{4}} \left(c_2 \sqrt{2}\, \sqrt{-\left(2x-3\right)^4}+4c_1\right)}{8}$$

Verified OK.

13.29.2 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + \left(2AB' + B^2\right) v' + \left(AB'' + BB' + CB\right) v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right) v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= 4\left(x-\frac{3}{2}\right)^{2} \\
B &= -12x+18 \\
C &= 12 \\
F &= 0
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= \left(4\left(x-\frac{3}{2}\right)^{2}\right)(0) + (-12x+18)(-12) + (12)(-12x+18) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
-6(2x-3)^{3} v'' + \left(12(2x-3)^{2}\right) v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
-6(2x-3)^{3} u'(x) + 12u(x)(2x-3)^{2} = 0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= \frac{2u}{2x-3}
\end{aligned}
$$

Where $f(x) = \frac{2}{2x-3}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= \frac{2}{2x-3}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{2}{2x-3}\,dx \\
\ln(u) &= \ln(2x-3) + c_1 \\
u &= \mathrm{e}^{\ln(2x-3)+c_1} \\
&= c_1(2x-3)
\end{aligned}
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= c_1(2x-3)
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned} v(x) &= \int c_1(2x-3)\, \mathrm{d}x \\ &= c_1\left(x^2-3x\right)+c_2 \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y(x) &= Bv \\ &= (-12x+18)\left(c_1\left(x^2-3x\right)+c_2\right) \\ &= -12\left(c_1x^2-3c_1x+c_2\right)\left(x-\frac{3}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -12\left(c_1x^2-3c_1x+c_2\right)\left(x-\frac{3}{2}\right) \tag{1}$$

Verification of solutions

$$y = -12\left(c_1x^2-3c_1x+c_2\right)\left(x-\frac{3}{2}\right)$$

Verified OK.

13.29.3 Solving using Kovacic algorithm

Writing the ode as

$$4\left(x-\frac{3}{2}\right)^2 y'' + (-12x+18)\, y' + 12y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4\left(x-\frac{3}{2}\right)^2 \\ B &= -12x+18 \\ C &= 12 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{(2x-3)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= (2x-3)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{(2x-3)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 510: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x-3)^2$. There is a pole at $x = \frac{3}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4\left(x - \frac{3}{2}\right)^2}$$

For the pole at $x = \frac{3}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{3}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3}{(2x-3)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{(2x-3)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$\frac{3}{2}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2\left(x - \frac{3}{2}\right)} + (-)\,(0) \\ &= -\frac{1}{2\left(x - \frac{3}{2}\right)} \\ &= -\frac{1}{2x - 3} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2\left(x-\frac{3}{2}\right)}\right)(0) + \left(\left(\frac{1}{2\left(x-\frac{3}{2}\right)^2}\right) + \left(-\frac{1}{2\left(x-\frac{3}{2}\right)}\right)^2 - \left(\frac{3}{(2x-3)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int -\frac{1}{2\left(x-\frac{3}{2}\right)} dx} \\
&= \frac{1}{\sqrt{2x-3}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-12x+18}{4\left(x-\frac{3}{2}\right)^2} dx} \\
&= z_1 e^{\frac{3\ln(2x-3)}{2}} \\
&= z_1\left((2x-3)^{\frac{3}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = 2x - 3$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-12x+18}{4\left(x-\frac{3}{2}\right)^2}dx}}{\left(y_1\right)^2} dx \\
&= y_1 \int \frac{e^{3\ln(2x-3)}}{\left(y_1\right)^2} dx \\
&= y_1\left(x^2-3x\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(2x-3) + c_2\left(2x-3\left(x^2-3x\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1(2x-3) + c_2\left(2x^3-9x^2+9x\right) \tag{1}
$$

Verification of solutions

$$
y = c_1(2x-3) + c_2\left(2x^3-9x^2+9x\right)
$$

Verified OK.

13.29.4 Maple step by step solution

Let's solve

$4\left(x-\frac{3}{2}\right)^2 y'' + (-12x+18)\,y' + 12y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{6y'}{2x-3} - \frac{12y}{(2x-3)^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{6y'}{2x-3} + \frac{12y}{(2x-3)^2} = 0$

□ Check to see if $x_0 = \frac{3}{2}$ is a regular singular point

  ◦ Define functions

$\left[P_2(x) = -\frac{6}{2x-3}, P_3(x) = \frac{12}{(2x-3)^2}\right]$

- $\left(x-\frac{3}{2}\right) \cdot P_2(x)$ is analytic at $x = \frac{3}{2}$

  $\left(\left(x-\frac{3}{2}\right) \cdot P_2(x)\right)\Bigg|_{x=\frac{3}{2}} = -3$

- $\left(x-\frac{3}{2}\right)^2 \cdot P_3(x)$ is analytic at $x = \frac{3}{2}$

  $\left(\left(x-\frac{3}{2}\right)^2 \cdot P_3(x)\right)\Bigg|_{x=\frac{3}{2}} = 3$

- $x = \frac{3}{2}$is a regular singular point

  Check to see if $x_0 = \frac{3}{2}$ is a regular singular point

  $x_0 = \frac{3}{2}$

- Multiply by denominators

  $(2x-3)^2 y'' + (-12x+18) y' + 12y = 0$

- Change variables using $x = u + \frac{3}{2}$ so that the regular singular point is at $u = 0$

  $4u^2\left(\frac{d^2}{du^2}y(u)\right) - 12u\left(\frac{d}{du}y(u)\right) + 12y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite DE with series expansions

- Convert $u \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion

  $u \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r}$

- Convert $u^2 \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

  $u^2 \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r}$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} 4a_k(k+r-1)\,(k+r-3)\, u^{k+r} = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r = 0$

- Each term in the series must be 0, giving the recursion relation

$$4a_k(k-1)(k-3) = 0$$

- Recursion relation that defines series solution to ODE

$$a_k = 0$$

- Recursion relation for $r = 0$

$$a_k = 0$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_k = 0\right]$$

- Revert the change of variables $u = x - \frac{3}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k \left(x - \frac{3}{2}\right)^k, a_k = 0\right]$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.1. Exercises page 232
Problem number: 1.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{y'' + y'x + y = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using

Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0, y_0, y_0'} + \frac{x^3}{3!} f'|_{x_0, y_0, y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y_0'}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (783) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (784) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -y'x - y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= x^2 y' + yx - 2y' \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= -y'x^3 - x^2 y + 5y'x + 3y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(x^4 - 9x^2 + 8\right) y' + xy\left(x^2 - 7\right) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(-x^5 + 14x^3 - 33x\right) y' - y\left(x^4 - 12x^2 + 15\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -y(0) \\
F_1 &= -2y'(0) \\
F_2 &= 3y(0) \\
F_3 &= 8y'(0) \\
F_4 &= -15y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6\right) y(0) + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5\right) y'(0) + O\left(x^6\right)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard

power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x - \left(\sum_{n=0}^{\infty} a_n x^n\right) \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + a_0 = 0$$

$$a_2 = -\frac{a_0}{2}$$

For $1 \leq n$, the recurrence equation is

$$(n+2)\,a_{n+2}(n+1) + na_n + a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{a_n}{n+2} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$6a_3 + 2a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{a_1}{3}$$

For $n = 2$ the recurrence equation gives

$$12a_4 + 3a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{8}$$

For $n = 3$ the recurrence equation gives

$$20a_5 + 4a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_1}{15}$$

For $n = 4$ the recurrence equation gives

$$30a_6 + 5a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{a_0}{48}$$

For $n = 5$ the recurrence equation gives

$$42a_7 + 6a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{a_1}{105}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x - \frac{1}{2} a_0 x^2 - \frac{1}{3} a_1 x^3 + \frac{1}{8} a_0 x^4 + \frac{1}{15} a_1 x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4\right) a_0 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5\right) a_1 + O\left(x^6\right) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4\right) c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5\right) c_2 + O\left(x^6\right)$$

Summary

The solution(s) found are the following

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6\right) y(0) + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5\right) y'(0) + O\left(x^6\right) \tag{1}$$

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4\right) c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5\right) c_2 + O\left(x^6\right) \tag{2}$$

Verification of solutions

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6\right) y(0) + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5\right) y'(0) + O\left(x^6\right)$$

Verified OK.

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4\right) c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5\right) c_2 + O\left(x^6\right)$$

Verified OK.

14.1.1 Maple step by step solution

Let's solve

$y'' = -y'x - y$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + y'x + y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  ◦ Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert y'' to series expansion

  $y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k- > k+2$

  $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_k(k+1)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k+1)\left(a_{k+2}(k+2) + a_k\right) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k}{k+2}\right]$

Section: Chapter 6, Series solutions of linear differential equations. Section 6.1. Exercises page 232
Problem number: 2.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + 8y'x - 4y = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned} y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\ &= y_0 + xy'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\ &= y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left.\frac{d^n f}{dx^n}\right|_{x_0, y_0, y'_0} \end{aligned}$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (786)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (787)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3)\\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -8y'x + 4y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= 64x^2 y' - 32yx - 4y' \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= 128\left(-4x^3 + x\right) y' + 16y\left(16x^2 - 3\right) \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(4096x^4 - 2304x^2 + 80\right) y' - 2048x\left(x^2 - \frac{1}{2}\right) y \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(-32768x^5 + 32768x^3 - 4224x\right) y' + \left(16384x^4 - 15360x^2 + 1344\right) y
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=y(0)$ and $y'(0)=y'(0)$ gives

$$
\begin{aligned}
F_0 &= 4y(0) \\
F_1 &= -4y'(0) \\
F_2 &= -48y(0) \\
F_3 &= 80y'(0) \\
F_4 &= 1344y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1 + 2x^2 - 2x^4 + \frac{28}{15}x^6\right) y(0) + \left(x - \frac{2}{3}x^3 + \frac{2}{3}x^5\right) y'(0) + O\left(x^6\right)
$$

Since the expansion point $x=0$ is an ordinary, we can also solve this using standard

power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -8\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x + 4\left(\sum_{n=0}^{\infty} a_n x^n\right) \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} 8n\, x^n a_n\right) + \sum_{n=0}^{\infty} (-4 a_n x^n) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \left(\sum_{n=1}^{\infty} 8n\, x^n a_n\right) + \sum_{n=0}^{\infty} (-4 a_n x^n) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 - 4a_0 = 0$$

$$a_2 = 2a_0$$

For $1 \leq n$, the recurrence equation is

$$(n+2) a_{n+2}(n+1) + 8na_n - 4a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{4a_n(2n-1)}{(n+2)(n+1)} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$6a_3 + 4a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{2a_1}{3}$$

For $n = 2$ the recurrence equation gives

$$12a_4 + 12a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -2a_0$$

For $n = 3$ the recurrence equation gives

$$20a_5 + 20a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{2a_1}{3}$$

For $n = 4$ the recurrence equation gives

$$30a_6 + 28a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{28a_0}{15}$$

For $n = 5$ the recurrence equation gives

$$42a_7 + 36a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{4a_1}{7}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + 2a_0 x^2 - \frac{2}{3} a_1 x^3 - 2a_0 x^4 + \frac{2}{3} a_1 x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(-2x^4 + 2x^2 + 1\right) a_0 + \left(x - \frac{2}{3}x^3 + \frac{2}{3}x^5\right) a_1 + O\left(x^6\right) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(-2x^4 + 2x^2 + 1\right) c_1 + \left(x - \frac{2}{3}x^3 + \frac{2}{3}x^5\right) c_2 + O\left(x^6\right)$$

Summary

The solution(s) found are the following

$$y = \left(1 + 2x^2 - 2x^4 + \frac{28}{15}x^6\right) y(0) + \left(x - \frac{2}{3}x^3 + \frac{2}{3}x^5\right) y'(0) + O\left(x^6\right) \tag{1}$$

$$y = \left(-2x^4 + 2x^2 + 1\right) c_1 + \left(x - \frac{2}{3}x^3 + \frac{2}{3}x^5\right) c_2 + O\left(x^6\right) \tag{2}$$

Verification of solutions

$$y = \left(1 + 2x^2 - 2x^4 + \frac{28}{15}x^6\right) y(0) + \left(x - \frac{2}{3}x^3 + \frac{2}{3}x^5\right) y'(0) + O\left(x^6\right)$$

Verified OK.

$$y = \left(-2x^4 + 2x^2 + 1\right) c_1 + \left(x - \frac{2}{3}x^3 + \frac{2}{3}x^5\right) c_2 + O\left(x^6\right)$$

Verified OK.

14.2.1 Maple step by step solution

Let's solve

$y'' = -8y'x + 4y$

- Highest derivative means the order of the ODE is 2

y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' + 8y'x - 4y = 0$

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  ◦ Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert y'' to series expansion

  $y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k- >k+2$

  $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\, x^k$

Rewrite DE with series expansions

$\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)(k+1) + 4a_k(2k-1)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

$(k^2 + 3k + 2)\, a_{k+2} + 8a_k k - 4a_k = 0$

- Recursion relation that defines the series solution to the ODE

$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{4a_k(2k-1)}{k^2+3k+2}\right]$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.1. Exercises page 232
Problem number: 3.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + y'x + \left(2x^2 + 1\right) y = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned} y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\ &= y_0 + xy'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\ &= y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left.\frac{d^n f}{dx^n}\right|_{x_0, y_0, y'_0} \end{aligned}$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (789)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (790)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3)\\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x, y, y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \qquad (7)$$

To find $y(x)$ series solution around $x = 0$. Hence

$$\begin{aligned}
F_0 &= -2x^2 y - y' x - y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= 2yx^3 - x^2 y' - 3yx - 2y' \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \left(3x^3 - 3x\right) y' + y\left(2x^4 + 11x^2 - 1\right) \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(-x^4 + 23x^2 - 4\right) y' - 6xy\left(x^4 - \frac{11}{6}x^2 - \frac{25}{6}\right) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(-5x^5 - 16x^3 + 75x\right) y' + 2\left(x^6 - \frac{75}{2}x^4 + 9x^2 + \frac{29}{2}\right) y
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$\begin{aligned}
F_0 &= -y(0) \\
F_1 &= -2y'(0) \\
F_2 &= -y(0) \\
F_3 &= -4y'(0) \\
F_4 &= 29y(0)
\end{aligned}$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = \left(1 - \frac{1}{2}x^2 - \frac{1}{24}x^4 + \frac{29}{720}x^6\right) y(0) + \left(x - \frac{1}{3}x^3 - \frac{1}{30}x^5\right) y'(0) + O\left(x^6\right)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -2x^2 \left(\sum_{n=0}^{\infty} a_n x^n\right) - \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x - \left(\sum_{n=0}^{\infty} a_n x^n\right) \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \left(\sum_{n=0}^{\infty} 2x^{n+2} a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

$$\sum_{n=0}^{\infty} 2x^{n+2} a_n = \sum_{n=2}^{\infty} 2a_{n-2} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \left(\sum_{n=2}^{\infty} 2a_{n-2} x^n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + a_0 = 0$$

$$a_2 = -\frac{a_0}{2}$$

$n = 1$ gives

$$6a_3 + 2a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -\frac{a_1}{3}$$

For $2 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(n+1) + na_n + 2a_{n-2} + a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{na_n + a_n + 2a_{n-2}}{(n+2)\,(n+1)} \\ &= -\frac{a_n}{n+2} - \frac{2a_{n-2}}{(n+2)\,(n+1)} \end{aligned} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$12a_4 + 3a_2 + 2a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{a_0}{24}$$

For $n = 3$ the recurrence equation gives

$$20a_5 + 4a_3 + 2a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{a_1}{30}$$

For $n = 4$ the recurrence equation gives

$$30a_6 + 5a_4 + 2a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{29a_0}{720}$$

For $n = 5$ the recurrence equation gives

$$42a_7 + 6a_5 + 2a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{13a_1}{630}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x - \frac{1}{2} a_0 x^2 - \frac{1}{3} a_1 x^3 - \frac{1}{24} a_0 x^4 - \frac{1}{30} a_1 x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{1}{2}x^2 - \frac{1}{24}x^4\right) a_0 + \left(x - \frac{1}{3}x^3 - \frac{1}{30}x^5\right) a_1 + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{1}{2}x^2 - \frac{1}{24}x^4\right) c_1 + \left(x - \frac{1}{3}x^3 - \frac{1}{30}x^5\right) c_2 + O(x^6)$$

Summary

The solution(s) found are the following

$$y = \left(1 - \frac{1}{2}x^2 - \frac{1}{24}x^4 + \frac{29}{720}x^6\right) y(0) + \left(x - \frac{1}{3}x^3 - \frac{1}{30}x^5\right) y'(0) + O(x^6) \tag{1}$$

$$y = \left(1 - \frac{1}{2}x^2 - \frac{1}{24}x^4\right) c_1 + \left(x - \frac{1}{3}x^3 - \frac{1}{30}x^5\right) c_2 + O(x^6) \tag{2}$$

Verification of solutions

$$y = \left(1-\frac{1}{2}x^{2}-\frac{1}{24}x^{4}+\frac{29}{720}x^{6}\right)y(0)+\left(x-\frac{1}{3}x^{3}-\frac{1}{30}x^{5}\right)y'(0)+O\left(x^{6}\right)$$

Verified OK.

$$y = \left(1-\frac{1}{2}x^{2}-\frac{1}{24}x^{4}\right)c_{1}+\left(x-\frac{1}{3}x^{3}-\frac{1}{30}x^{5}\right)c_{2}+O\left(x^{6}\right)$$

Verified OK.

14.3.1 Maple step by step solution

Let's solve

$y'' = -2x^{2}y - y'x - y$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \left(-2x^{2}-1\right)y - y'x$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + y'x + \left(2x^{2}+1\right)y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_{k}x^{k}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^{m}\cdot y$ to series expansion for $m = 0..2$

    $x^{m}\cdot y = \sum_{k=\max(0,-m)}^{\infty} a_{k}x^{k+m}$

  ◦ Shift index using $k- >k-m$

    $x^{m}\cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m}x^{k}$

  ◦ Convert $x\cdot y'$ to series expansion

    $x\cdot y' = \sum_{k=0}^{\infty} a_{k}k\,x^{k}$

  ◦ Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k- >k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite ODE with series expansions

$$2a_2 + a_0 + (6a_3 + 2a_1)\, x + \left(\sum_{k=2}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_k(k+1) + 2a_{k-2}\right) x^k\right) = 0$$

- The coefficients of each power of x must be 0

$$[2a_2 + a_0 = 0, 6a_3 + 2a_1 = 0]$$

- Solve for the dependent coefficient(s)

$$\left\{a_2 = -\frac{a_0}{2}, a_3 = -\frac{a_1}{3}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$(k^2 + 3k + 2)\, a_{k+2} + a_k k + a_k + 2a_{k-2} = 0$$

- Shift index using $k- >k+2$

$$\left((k+2)^2 + 3k + 8\right) a_{k+4} + a_{k+2}(k+2) + a_{k+2} + 2a_k = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{k a_{k+2} + 2a_k + 3a_{k+2}}{k^2 + 7k + 12}, a_2 = -\frac{a_0}{2}, a_3 = -\frac{a_1}{3}\right]$$

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + y'x + \left(x^2 - 4\right) y = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y_0'$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0, y_0, y_0'} + \frac{x^3}{3!} f'|_{x_0, y_0, y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y_0'}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{792}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{793}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}F_n\big|_{x_0,y_0,y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -x^2 y - y' x + 4y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= 3y' + \left(x^3 - 6x\right) y \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \left(x^3 - 9x\right) y' + 6y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(-x^4 + 12x^2 - 3\right) y' + \left(-x^5 + 13x^3 - 36x\right) y \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(-3x^3 - 9x\right) y' + y\left(x^6 - 21x^4 + 90x^2 - 48\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= 4y(0) \\
F_1 &= 3y'(0) \\
F_2 &= 6y(0) \\
F_3 &= -3y'(0) \\
F_4 &= -48y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1 + 2x^2 + \frac{1}{4}x^4 - \frac{1}{15}x^6\right) y(0) + \left(x + \frac{1}{2}x^3 - \frac{1}{40}x^5\right) y'(0) + O\left(x^6\right)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard

power series Let the solution be represented as power series of the form

$$y=\sum_{n=0}^{\infty} a_n x^n$$

Then

$$y'=\sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y''=\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -x^2\left(\sum_{n=0}^{\infty} a_n x^n\right) - \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x + 4\left(\sum_{n=0}^{\infty} a_n x^n\right) \quad (1)$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \left(\sum_{n=0}^{\infty} x^{n+2} a_n\right) + \sum_{n=0}^{\infty} (-4 a_n x^n) = 0 \quad (2)$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$
$$\sum_{n=0}^{\infty} x^{n+2} a_n = \sum_{n=2}^{\infty} a_{n-2} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^n\right) + \sum_{n=0}^{\infty} (-4 a_n x^n) = 0 \quad (3)$$

$n=0$ gives

$$2a_2 - 4a_0 = 0$$

$$a_2 = 2a_0$$

$n = 1$ gives

$$6a_3 - 3a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = \frac{a_1}{2}$$

For $2 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(n+1) + na_n + a_{n-2} - 4a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{na_n - 4a_n + a_{n-2}}{(n+2)\,(n+1)} \\ &= -\frac{(n-4)\, a_n}{(n+2)\,(n+1)} - \frac{a_{n-2}}{(n+2)\,(n+1)} \end{aligned} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$12a_4 - 2a_2 + a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{4}$$

For $n = 3$ the recurrence equation gives

$$20a_5 - a_3 + a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{a_1}{40}$$

For $n = 4$ the recurrence equation gives

$$30a_6 + a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{a_0}{15}$$

For $n = 5$ the recurrence equation gives

$$42a_7 + a_5 + a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{19a_1}{1680}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + 2a_0 x^2 + \frac{1}{2} a_1 x^3 + \frac{1}{4} a_0 x^4 - \frac{1}{40} a_1 x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + 2x^2 + \frac{1}{4}x^4\right) a_0 + \left(x + \frac{1}{2}x^3 - \frac{1}{40}x^5\right) a_1 + O\left(x^6\right) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 + 2x^2 + \frac{1}{4}x^4\right) c_1 + \left(x + \frac{1}{2}x^3 - \frac{1}{40}x^5\right) c_2 + O\left(x^6\right)$$

Summary

The solution(s) found are the following

$$y = \left(1 + 2x^2 + \frac{1}{4}x^4 - \frac{1}{15}x^6\right) y(0) + \left(x + \frac{1}{2}x^3 - \frac{1}{40}x^5\right) y'(0) + O\left(x^6\right) \tag{1}$$

$$y = \left(1 + 2x^2 + \frac{1}{4}x^4\right) c_1 + \left(x + \frac{1}{2}x^3 - \frac{1}{40}x^5\right) c_2 + O\left(x^6\right) \tag{2}$$

Verification of solutions

$$y = \left(1+2x^2+\frac{1}{4}x^4-\frac{1}{15}x^6\right)y(0)+\left(x+\frac{1}{2}x^3-\frac{1}{40}x^5\right)y'(0)+O(x^6)$$

Verified OK.

$$y = \left(1+2x^2+\frac{1}{4}x^4\right)c_1+\left(x+\frac{1}{2}x^3-\frac{1}{40}x^5\right)c_2+O(x^6)$$

Verified OK.

14.4.1 Maple step by step solution

Let's solve

$y'' = -x^2y - y'x + 4y$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = (-x^2+4)\,y - y'x$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + y'x + (x^2-4)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

☐ Rewrite ODE with series expansions

- ∘ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

- ∘ Shift index using $k- >k-m$

  $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

- ∘ Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

- ∘ Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k- >k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^{k}$$

Rewrite ODE with series expansions

$$2a_2 - 4a_0 + (6a_3 - 3a_1)\, x + \left(\sum_{k=2}^{\infty} (a_{k+2}(k+2)\,(k+1) + a_k(k-4) + a_{k-2})\, x^k\right) = 0$$

- The coefficients of each power of x must be 0

$$[2a_2 - 4a_0 = 0, 6a_3 - 3a_1 = 0]$$

- Solve for the dependent coefficient(s)

$$\left\{a_2 = 2a_0, a_3 = \frac{a_1}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$(k^2 + 3k + 2)\, a_{k+2} + a_k k - 4a_k + a_{k-2} = 0$$

- Shift index using $k- >k+2$

$$\left((k+2)^2 + 3k + 8\right) a_{k+4} + a_{k+2}(k+2) - 4a_{k+2} + a_k = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{k a_{k+2} + a_k - 2a_{k+2}}{k^2 + 7k + 12}, a_2 = 2a_0, a_3 = \frac{a_1}{2}\right]$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.1. Exercises page 232
Problem number: 5.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + y'x + (3x + 2)\, y = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned} y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\ &= y_0 + xy'_0 + \frac{x^2}{2} f|_{x_0,y_0,y'_0} + \frac{x^3}{3!} f'|_{x_0,y_0,y'_0} + \cdots \\ &= y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y'_0} \end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{795}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{796}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') && (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 && (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}F_n|_{x_0,y_0,y_0'} \tag{7}
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -y'x - 3yx - 2y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \left(x^2 - 3x - 3\right) y' + 3\left(x^2 + \frac{2}{3}x - 1\right) y \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \left(-x^3 + 6x^2 + 7x - 6\right) y' - 3\left(x^3 - \frac{7}{3}x^2 - 7x - \frac{8}{3}\right) y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(x^4 - 9x^3 - 3x^2 + 39x + 15\right) y' + 3\left(x^4 - \frac{16}{3}x^3 - 14x^2 + 6x + 11\right) y \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(-x^5 + 12x^4 - 9x^3 - 108x^2 - 3x + 72\right) y' - 3\left(x^5 - \frac{25}{3}x^4 - 13x^3 + 53x^2 + 69x + 4\right) y
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=y(0)$ and $y'(0)=y'(0)$ gives

$$
\begin{aligned}
F_0 &= -2y(0) \\
F_1 &= -3y'(0) - 3y(0) \\
F_2 &= -6y'(0) + 8y(0) \\
F_3 &= 15y'(0) + 33y(0) \\
F_4 &= 72y'(0) - 12y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = & \left(1 - x^2 - \frac{1}{2}x^3 + \frac{1}{3}x^4 + \frac{11}{40}x^5 - \frac{1}{60}x^6\right) y(0) \\
& + \left(x - \frac{1}{2}x^3 - \frac{1}{4}x^4 + \frac{1}{8}x^5 + \frac{1}{10}x^6\right) y'(0) + O(x^6)
\end{aligned}
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x - 3\left(\sum_{n=0}^{\infty} a_n x^n\right) x - 2\left(\sum_{n=0}^{\infty} a_n x^n\right) \tag{1}
$$

Which simplifies to

$$
\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \left(\sum_{n=0}^{\infty} 3x^{1+n} a_n\right) + \left(\sum_{n=0}^{\infty} 2a_n x^n\right) = 0 \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} &= \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^n \\
\sum_{n=0}^{\infty} 3x^{1+n} a_n &= \sum_{n=1}^{\infty} 3a_{n-1} x^n
\end{aligned}
$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty}(n+2)\, a_{n+2}(1+n)\, x^{n}\right)+\left(\sum_{n=1}^{\infty}n\, x^{n} a_{n}\right)+\left(\sum_{n=1}^{\infty}3 a_{n-1} x^{n}\right)+\left(\sum_{n=0}^{\infty}2 a_{n} x^{n}\right)=0 \quad (3)$$

$n = 0$ gives

$$2a_2 + 2a_0 = 0$$

$$a_2 = -a_0$$

For $1 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(1+n) + n a_n + 3a_{n-1} + 2a_n = 0 \quad (4)$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{n a_n + 2a_n + 3a_{n-1}}{(n+2)\,(1+n)} \\ &= -\frac{a_n}{1+n} - \frac{3a_{n-1}}{(n+2)\,(1+n)} \end{aligned} \quad (5)$$

For $n = 1$ the recurrence equation gives

$$6a_3 + 3a_1 + 3a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{a_1}{2} - \frac{a_0}{2}$$

For $n = 2$ the recurrence equation gives

$$12a_4 + 4a_2 + 3a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{3} - \frac{a_1}{4}$$

For $n = 3$ the recurrence equation gives

$$20a_5 + 5a_3 + 3a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_1}{8} + \frac{11a_0}{40}$$

For $n = 4$ the recurrence equation gives

$$30a_6 + 6a_4 + 3a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{a_0}{60} + \frac{a_1}{10}$$

For $n = 5$ the recurrence equation gives

$$42a_7 + 7a_5 + 3a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{a_1}{336} - \frac{39a_0}{560}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x - a_0 x^2 + \left(-\frac{a_1}{2} - \frac{a_0}{2}\right) x^3 + \left(\frac{a_0}{3} - \frac{a_1}{4}\right) x^4 + \left(\frac{a_1}{8} + \frac{11a_0}{40}\right) x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - x^2 - \frac{1}{2}x^3 + \frac{1}{3}x^4 + \frac{11}{40}x^5\right) a_0 + \left(x - \frac{1}{2}x^3 - \frac{1}{4}x^4 + \frac{1}{8}x^5\right) a_1 + O(x^6) \quad (3)$$

At $x = 0$ the solution above becomes

$$y = \left(1 - x^2 - \frac{1}{2}x^3 + \frac{1}{3}x^4 + \frac{11}{40}x^5\right) c_1 + \left(x - \frac{1}{2}x^3 - \frac{1}{4}x^4 + \frac{1}{8}x^5\right) c_2 + O(x^6)$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = &\left(1 - x^2 - \frac{1}{2}x^3 + \frac{1}{3}x^4 + \frac{11}{40}x^5 - \frac{1}{60}x^6\right) y(0) \\ &+ \left(x - \frac{1}{2}x^3 - \frac{1}{4}x^4 + \frac{1}{8}x^5 + \frac{1}{10}x^6\right) y'(0) + O(x^6) \end{aligned} \tag{1}$$

$$y = \left(1 - x^2 - \frac{1}{2}x^3 + \frac{1}{3}x^4 + \frac{11}{40}x^5\right) c_1 + \left(x - \frac{1}{2}x^3 - \frac{1}{4}x^4 + \frac{1}{8}x^5\right) c_2 + O(x^6) \tag{2}$$

Verification of solutions

$$\begin{aligned} y = &\left(1 - x^2 - \frac{1}{2}x^3 + \frac{1}{3}x^4 + \frac{11}{40}x^5 - \frac{1}{60}x^6\right) y(0) \\ &+ \left(x - \frac{1}{2}x^3 - \frac{1}{4}x^4 + \frac{1}{8}x^5 + \frac{1}{10}x^6\right) y'(0) + O(x^6) \end{aligned}$$

Verified OK.

$$y = \left(1 - x^2 - \frac{1}{2}x^3 + \frac{1}{3}x^4 + \frac{11}{40}x^5\right) c_1 + \left(x - \frac{1}{2}x^3 - \frac{1}{4}x^4 + \frac{1}{8}x^5\right) c_2 + O(x^6)$$

Verified OK.

14.5.1 Maple step by step solution

Let's solve

$y'' = -y'x - 3yx - 2y$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = (-3x - 2)\, y - y'x$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + y'x + (3x + 2)\, y = 0$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^k$$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..1$

$$x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$$

- Shift index using $k- >k - m$

$$x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$$

- Convert $x \cdot y'$ to series expansion

$$x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$$

- Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k- >k + 2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite ODE with series expansions

$$2a_2 + 2a_0 + \left(\sum_{k=1}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_k(k+2) + 3a_{k-1}\right) x^k\right) = 0$$

- Each term must be 0

$$2a_2 + 2a_0 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$(k^2 + 3k + 2)\, a_{k+2} + a_k k + 2a_k + 3a_{k-1} = 0$$

- Shift index using $k- >k + 1$

$$\left((k+1)^2 + 3k + 5\right) a_{k+3} + a_{k+1}(k+1) + 2a_{k+1} + 3a_k = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = -\frac{k a_{k+1} + 3a_k + 3a_{k+1}}{k^2 + 5k + 6}, 2a_2 + 2a_0 = 0\right]$$

Section: Chapter 6, Series solutions of linear differential equations. Section 6.1. Exercises page 232
Problem number: 6.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - y'x + (3x - 2)\, y = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned} y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\ &= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\ &= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0} \end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (798) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (799) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x, y, y') && (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 && (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y'_0} \tag{7}$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -3yx + y'x + 2y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \left(x^2 - 3x + 3\right) y' - 3\left(x^2 - \frac{2}{3}x + 1\right) y \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \left(x^3 - 6x^2 + 7x - 6\right) y' - 3y\left(x^3 - \frac{11}{3}x^2 + 7x - \frac{8}{3}\right) \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(x^4 - 9x^3 + 21x^2 - 39x + 15\right) y' - 3y\left(x^4 - \frac{20}{3}x^3 + 14x^2 - 18x + 11\right) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(x^5 - 12x^4 + 45x^3 - 108x^2 + 111x - 72\right) y' - 3\left(x^5 - \frac{29}{3}x^4 + 31x^3 - 73x^2 + 69x - 28\right) y
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= 2y(0) \\
F_1 &= 3y'(0) - 3y(0) \\
F_2 &= -6y'(0) + 8y(0) \\
F_3 &= 15y'(0) - 33y(0) \\
F_4 &= -72y'(0) + 84y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = \left(1 + x^2 - \frac{1}{2}x^3 + \frac{1}{3}x^4 - \frac{11}{40}x^5 + \frac{7}{60}x^6\right) y(0) \\ + \left(x + \frac{1}{2}x^3 - \frac{1}{4}x^4 + \frac{1}{8}x^5 - \frac{1}{10}x^6\right) y'(0) + O(x^6)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = -3\left(\sum_{n=0}^{\infty} a_n x^n\right) x + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x + 2\left(\sum_{n=0}^{\infty} a_n x^n\right) \quad (1)$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + \sum_{n=1}^{\infty} (-n\, x^n a_n) + \left(\sum_{n=0}^{\infty} 3x^{1+n} a_n\right) + \sum_{n=0}^{\infty} (-2 a_n x^n) = 0 \quad (2)$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2) a_{n+2}(1+n) x^n$$

$$\sum_{n=0}^{\infty} 3x^{1+n} a_n = \sum_{n=1}^{\infty} 3a_{n-1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^{n}\right)+\sum_{n =1}^{\infty} \left(-n\, x^{n} a_{n}\right)+\left(\sum_{n=1}^{\infty} 3 a_{n-1} x^{n}\right)+\sum_{n =0}^{\infty} \left(-2 a_{n} x^{n}\right) = 0 \tag{3}$$

$n = 0$ gives

$$2 a_{2}-2 a_{0} = 0$$

$$a_{2} = a_{0}$$

For $1 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(1+n)-n a_{n}+3 a_{n-1}-2 a_{n} = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= \frac{n a_{n}+2 a_{n}-3 a_{n-1}}{(n+2)\,(1+n)} \\ &= \frac{a_{n}}{1+n}-\frac{3 a_{n-1}}{(n+2)\,(1+n)} \end{aligned} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$6 a_{3}-3 a_{1}+3 a_{0} = 0$$

Which after substituting the earlier terms found becomes

$$a_{3} = \frac{a_{1}}{2}-\frac{a_{0}}{2}$$

For $n = 2$ the recurrence equation gives

$$12 a_{4}-4 a_{2}+3 a_{1} = 0$$

Which after substituting the earlier terms found becomes

$$a_{4} = \frac{a_{0}}{3}-\frac{a_{1}}{4}$$

For $n = 3$ the recurrence equation gives

$$20a_5 - 5a_3 + 3a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_1}{8} - \frac{11a_0}{40}$$

For $n = 4$ the recurrence equation gives

$$30a_6 - 6a_4 + 3a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{7a_0}{60} - \frac{a_1}{10}$$

For $n = 5$ the recurrence equation gives

$$42a_7 - 7a_5 + 3a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{13a_1}{336} - \frac{39a_0}{560}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + a_0 x^2 + \left(\frac{a_1}{2} - \frac{a_0}{2}\right) x^3 + \left(\frac{a_0}{3} - \frac{a_1}{4}\right) x^4 + \left(\frac{a_1}{8} - \frac{11a_0}{40}\right) x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + x^2 - \frac{1}{2}x^3 + \frac{1}{3}x^4 - \frac{11}{40}x^5\right) a_0 + \left(x + \frac{1}{2}x^3 - \frac{1}{4}x^4 + \frac{1}{8}x^5\right) a_1 + O(x^6) \quad (3)$$

At $x = 0$ the solution above becomes

$$y = \left(1+x^{2}-\frac{1}{2}x^{3}+\frac{1}{3}x^{4}-\frac{11}{40}x^{5}\right) c_{1}+\left(x+\frac{1}{2}x^{3}-\frac{1}{4}x^{4}+\frac{1}{8}x^{5}\right) c_{2}+O\left(x^{6}\right)$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = &\left(1+x^{2}-\frac{1}{2}x^{3}+\frac{1}{3}x^{4}-\frac{11}{40}x^{5}+\frac{7}{60}x^{6}\right) y(0) \\ &+\left(x+\frac{1}{2}x^{3}-\frac{1}{4}x^{4}+\frac{1}{8}x^{5}-\frac{1}{10}x^{6}\right) y'(0)+O\left(x^{6}\right) \end{aligned} \tag{1}$$

$$y = \left(1+x^{2}-\frac{1}{2}x^{3}+\frac{1}{3}x^{4}-\frac{11}{40}x^{5}\right) c_{1}+\left(x+\frac{1}{2}x^{3}-\frac{1}{4}x^{4}+\frac{1}{8}x^{5}\right) c_{2}+O\left(x^{6}\right) \tag{2}$$

Verification of solutions

$$\begin{aligned} y = &\left(1+x^{2}-\frac{1}{2}x^{3}+\frac{1}{3}x^{4}-\frac{11}{40}x^{5}+\frac{7}{60}x^{6}\right) y(0) \\ &+\left(x+\frac{1}{2}x^{3}-\frac{1}{4}x^{4}+\frac{1}{8}x^{5}-\frac{1}{10}x^{6}\right) y'(0)+O\left(x^{6}\right) \end{aligned}$$

Verified OK.

$$y = \left(1+x^{2}-\frac{1}{2}x^{3}+\frac{1}{3}x^{4}-\frac{11}{40}x^{5}\right) c_{1}+\left(x+\frac{1}{2}x^{3}-\frac{1}{4}x^{4}+\frac{1}{8}x^{5}\right) c_{2}+O\left(x^{6}\right)$$

Verified OK.

14.6.1 Maple step by step solution

Let's solve

$y'' = -3yx + y'x + 2y$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = (-3x+2)\,y + y'x$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - y'x + (3x-2)\,y = 0$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^k$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..1$

$$x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.1. Exercises page 232
Problem number: 7.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x^2+1)\,y''+y'x+yx=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0)+(x-x_0)\,y'(x_0)+\frac{(x-x_0)^2}{2}y''(x_0)+\frac{(x-x_0)^3}{3!}y'''(x_0)+\cdots \\
&= y_0+xy'_0+\frac{x^2}{2}f|_{x_0,y_0,y'_0}+\frac{x^3}{3!}f'|_{x_0,y_0,y'_0}+\cdots \\
&= y_0+xy'_0+\sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)\,!}\,\frac{d^nf}{dx^n}\bigg|_{x_0,y_0,y'_0}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{801}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{802}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') && (4)\\
F_1 &= \frac{df}{dx} \\
&= \frac{dF_0}{dx} \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right) \\
&= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y'' \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0 \\
&\vdots \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y'' \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 && (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y'_0} \tag{7}
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{x(y' + y)}{x^2 + 1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{(-x^3 + 2x^2 - x - 1)\, y' + y(2x^2 - 1)}{(x^2 + 1)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{(4x^4 - 6x^3 + 2x^2 + 9x - 2)\, y' + xy(x^3 - 6x^2 + x + 9)}{(x^2 + 1)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{(x^6 - 18x^5 + 26x^4 + 9x^3 - 71x^2 + 27x + 9)\, y' - 6y\left(x^5 - 4x^4 + \frac{1}{3}x^3 + 12x^2 - \frac{2}{3}x - \frac{3}{2}\right)}{(x^2 + 1)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{(-9x^7 + 96x^6 - 132x^5 - 192x^4 + 603x^3 - 252x^2 - 219x + 36)\, y' - y(x^7 - 36x^6 + 122x^5 + 29x^4 - }{(x^2 + 1)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= 0 \\
F_1 &= -y'(0) - y(0) \\
F_2 &= -2y'(0) \\
F_3 &= 9y(0) + 9y'(0) \\
F_4 &= 4y(0) + 36y'(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1 - \frac{1}{6}x^3 + \frac{3}{40}x^5 + \frac{1}{180}x^6\right) y(0) + \left(x - \frac{1}{6}x^3 - \frac{1}{12}x^4 + \frac{3}{40}x^5 + \frac{1}{20}x^6\right) y'(0) + O(x^6)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$(x^2+1)\,y''+y'x+yx=0$$

Let the solution be represented as power series of the form

$$y=\sum_{n=0}^{\infty} a_n x^n$$

Then

$$y'=\sum_{n=1}^{\infty} n a_n x^{n-1}$$

$$y''=\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}$$

Substituting the above back into the ode gives

$$(x^2+1)\left(\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}\right)+\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right)x+\left(\sum_{n=0}^{\infty} a_n x^n\right)x=0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right)+\left(\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}\right)+\left(\sum_{n=1}^{\infty} n a_n x^n\right)+\left(\sum_{n=0}^{\infty} x^{1+n} a_n\right)=0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}=\sum_{n=0}^{\infty} (n+2)\,a_{n+2}(1+n)\,x^n$$

$$\sum_{n=0}^{\infty} x^{1+n} a_n=\sum_{n=1}^{\infty} a_{n-1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\begin{aligned}&\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right)+\left(\sum_{n=0}^{\infty} (n+2)\,a_{n+2}(1+n)\,x^n\right)\\&+\left(\sum_{n=1}^{\infty} n a_n x^n\right)+\left(\sum_{n=1}^{\infty} a_{n-1} x^n\right)=0\end{aligned} \tag{3}$$

$n = 1$ gives

$$6a_3 + a_1 + a_0 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -\frac{a_0}{6} - \frac{a_1}{6}$$

For $2 \leq n$, the recurrence equation is

$$na_n(n-1) + (n+2)\, a_{n+2}(1+n) + na_n + a_{n-1} = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{n^2 a_n + a_{n-1}}{(n+2)\,(1+n)} \\ &= -\frac{n^2 a_n}{(n+2)\,(1+n)} - \frac{a_{n-1}}{(n+2)\,(1+n)} \end{aligned} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$4a_2 + 12a_4 + a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{a_1}{12}$$

For $n = 3$ the recurrence equation gives

$$9a_3 + 20a_5 + a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{3a_0}{40} + \frac{3a_1}{40}$$

For $n = 4$ the recurrence equation gives

$$16a_4 + 30a_6 + a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_1}{20} + \frac{a_0}{180}$$

For $n = 5$ the recurrence equation gives

$$25a_5 + 42a_7 + a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{5a_0}{112} - \frac{43a_1}{1008}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + \left(-\frac{a_0}{6} - \frac{a_1}{6}\right) x^3 - \frac{a_1 x^4}{12} + \left(\frac{3a_0}{40} + \frac{3a_1}{40}\right) x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{1}{6}x^3 + \frac{3}{40}x^5\right) a_0 + \left(x - \frac{1}{6}x^3 - \frac{1}{12}x^4 + \frac{3}{40}x^5\right) a_1 + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{1}{6}x^3 + \frac{3}{40}x^5\right) c_1 + \left(x - \frac{1}{6}x^3 - \frac{1}{12}x^4 + \frac{3}{40}x^5\right) c_2 + O(x^6)$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = &\left(1 - \frac{1}{6}x^3 + \frac{3}{40}x^5 + \frac{1}{180}x^6\right) y(0) \\ &+ \left(x - \frac{1}{6}x^3 - \frac{1}{12}x^4 + \frac{3}{40}x^5 + \frac{1}{20}x^6\right) y'(0) + O(x^6) \end{aligned} \tag{1}$$

$$y = \left(1 - \frac{1}{6}x^3 + \frac{3}{40}x^5\right) c_1 + \left(x - \frac{1}{6}x^3 - \frac{1}{12}x^4 + \frac{3}{40}x^5\right) c_2 + O(x^6) \tag{2}$$

Verification of solutions

$$y = \left(1 - \frac{1}{6}x^3 + \frac{3}{40}x^5 + \frac{1}{180}x^6\right) y(0) + \left(x - \frac{1}{6}x^3 - \frac{1}{12}x^4 + \frac{3}{40}x^5 + \frac{1}{20}x^6\right) y'(0) + O(x^6)$$

Verified OK.

$$y = \left(1 - \frac{1}{6}x^3 + \frac{3}{40}x^5\right) c_1 + \left(x - \frac{1}{6}x^3 - \frac{1}{12}x^4 + \frac{3}{40}x^5\right) c_2 + O(x^6)$$

Verified OK.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x-1)\,y''-(3x-2)\,y'+2yx=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y_0'$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0)+(x-x_0)\,y'(x_0)+\frac{(x-x_0)^2}{2}y''(x_0)+\frac{(x-x_0)^3}{3!}y'''(x_0)+\cdots\\
&= y_0+xy_0'+\frac{x^2}{2}f|_{x_0,y_0,y_0'}+\frac{x^3}{3!}f'|_{x_0,y_0,y_0'}+\cdots\\
&= y_0+xy_0'+\sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)\,!}\,\frac{d^nf}{dx^n}\bigg|_{x_0,y_0,y_0'}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (804)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (805)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3)\\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x, y, y') && (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 && (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}F_n|_{x_0,y_0,y_0'} \tag{7}$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= \frac{3y'x - 2yx - 2y'}{x-1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{(7x-3)\, y' + (-6x-2)\, y}{x-1} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{(15x-4)\, y' + (-14x-8)\, y}{x-1} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{(31x-5)\, y' + (-30x-22)\, y}{x-1} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{(63x-6)\, y' + (-62x-52)\, y}{x-1}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= 2y'(0) \\
F_1 &= 2y(0) + 3y'(0) \\
F_2 &= 8y(0) + 4y'(0) \\
F_3 &= 22y(0) + 5y'(0) \\
F_4 &= 52y(0) + 6y'(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = \left(1+\frac{1}{3}x^3+\frac{1}{3}x^4+\frac{11}{60}x^5+\frac{13}{180}x^6\right)y(0) + \left(x+x^2+\frac{1}{2}x^3+\frac{1}{6}x^4+\frac{1}{24}x^5+\frac{1}{120}x^6\right)y'(0)+O(x^6)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$(x-1)\,y''+(-3x+2)\,y'+2yx = 0$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}$$

Substituting the above back into the ode gives

$$(x-1)\left(\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}\right)+(-3x+2)\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right)+2\left(\sum_{n=0}^{\infty} a_n x^n\right)x = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n\,x^{n-1} a_n(n-1)\right)+\sum_{n=2}^{\infty}\left(-n(n-1)\,a_n x^{n-2}\right) + \sum_{n=1}^{\infty}(-3n a_n x^n)+\left(\sum_{n=1}^{\infty} 2n a_n x^{n-1}\right)+\left(\sum_{n=0}^{\infty} 2x^{1+n}a_n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the

power and the corresponding index gives

$$\sum_{n=2}^{\infty} n\,x^{n-1} a_n(n-1) = \sum_{n=1}^{\infty} (1+n)\,a_{1+n} n\,x^n$$

$$\sum_{n=2}^{\infty} \left(-n(n-1)\,a_n x^{n-2}\right) = \sum_{n=0}^{\infty} \left(-(n+2)\,a_{n+2}(1+n)\,x^n\right)$$

$$\sum_{n=1}^{\infty} 2n a_n x^{n-1} = \sum_{n=0}^{\infty} 2(1+n)\,a_{1+n} x^n$$

$$\sum_{n=0}^{\infty} 2x^{1+n} a_n = \sum_{n=1}^{\infty} 2a_{n-1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=1}^{\infty} (1+n)\,a_{1+n} n\,x^n\right) + \sum_{n=0}^{\infty} \left(-(n+2)\,a_{n+2}(1+n)\,x^n\right) + \sum_{n=1}^{\infty} (-3n a_n x^n) + \left(\sum_{n=0}^{\infty} 2(1+n)\,a_{1+n} x^n\right) + \left(\sum_{n=1}^{\infty} 2a_{n-1} x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$-2a_2 + 2a_1 = 0$$

$$a_2 = a_1$$

For $1 \leq n$, the recurrence equation is

$$(1+n)\,a_{1+n} n - (n+2)\,a_{n+2}(1+n) - 3n a_n + 2(1+n)\,a_{1+n} + 2a_{n-1} = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= \frac{n^2 a_{1+n} - 3n a_n + 3n a_{1+n} + 2a_{1+n} + 2a_{n-1}}{(n+2)\,(1+n)} \\ &= -\frac{3n a_n}{(n+2)\,(1+n)} + \frac{(n^2+3n+2)\,a_{1+n}}{(n+2)\,(1+n)} + \frac{2a_{n-1}}{(n+2)\,(1+n)} \end{aligned} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$6a_2 - 6a_3 - 3a_1 + 2a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{a_1}{2} + \frac{a_0}{3}$$

For $n = 2$ the recurrence equation gives

$$12a_3 - 12a_4 - 6a_2 + 2a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_1}{6} + \frac{a_0}{3}$$

For $n = 3$ the recurrence equation gives

$$20a_4 - 20a_5 - 9a_3 + 2a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_1}{24} + \frac{11a_0}{60}$$

For $n = 4$ the recurrence equation gives

$$30a_5 - 30a_6 - 12a_4 + 2a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_1}{120} + \frac{13a_0}{180}$$

For $n = 5$ the recurrence equation gives

$$42a_6 - 42a_7 - 15a_5 + 2a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{a_1}{720} + \frac{19a_0}{840}$$

And so on. Therefore the solution is

$$
\begin{aligned}
y &= \sum_{n=0}^{\infty} a_n x^n \\
&= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots
\end{aligned}
$$

Substituting the values for a_n found above, the solution becomes

$$
y = a_0 + a_1 x + a_1 x^2 + \left(\frac{a_1}{2} + \frac{a_0}{3}\right) x^3 + \left(\frac{a_1}{6} + \frac{a_0}{3}\right) x^4 + \left(\frac{a_1}{24} + \frac{11a_0}{60}\right) x^5 + \dots
$$

Collecting terms, the solution becomes

$$
y = \left(1 + \frac{1}{3}x^3 + \frac{1}{3}x^4 + \frac{11}{60}x^5\right) a_0 + \left(x + x^2 + \frac{1}{2}x^3 + \frac{1}{6}x^4 + \frac{1}{24}x^5\right) a_1 + O(x^6) \quad (3)
$$

At $x = 0$ the solution above becomes

$$
y = \left(1 + \frac{1}{3}x^3 + \frac{1}{3}x^4 + \frac{11}{60}x^5\right) c_1 + \left(x + x^2 + \frac{1}{2}x^3 + \frac{1}{6}x^4 + \frac{1}{24}x^5\right) c_2 + O(x^6)
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & \left(1 + \frac{1}{3}x^3 + \frac{1}{3}x^4 + \frac{11}{60}x^5 + \frac{13}{180}x^6\right) y(0) \\
& + \left(x + x^2 + \frac{1}{2}x^3 + \frac{1}{6}x^4 + \frac{1}{24}x^5 + \frac{1}{120}x^6\right) y'(0) + O(x^6)
\end{aligned} \quad (1)
$$

$$
y = \left(1 + \frac{1}{3}x^3 + \frac{1}{3}x^4 + \frac{11}{60}x^5\right) c_1 + \left(x + x^2 + \frac{1}{2}x^3 + \frac{1}{6}x^4 + \frac{1}{24}x^5\right) c_2 + O(x^6) \quad (2)
$$

Verification of solutions

$$
\begin{aligned}
y = {} & \left(1 + \frac{1}{3}x^3 + \frac{1}{3}x^4 + \frac{11}{60}x^5 + \frac{13}{180}x^6\right) y(0) \\
& + \left(x + x^2 + \frac{1}{2}x^3 + \frac{1}{6}x^4 + \frac{1}{24}x^5 + \frac{1}{120}x^6\right) y'(0) + O(x^6)
\end{aligned}
$$

Verified OK.

$$
y = \left(1 + \frac{1}{3}x^3 + \frac{1}{3}x^4 + \frac{11}{60}x^5\right) c_1 + \left(x + x^2 + \frac{1}{2}x^3 + \frac{1}{6}x^4 + \frac{1}{24}x^5\right) c_2 + O(x^6)
$$

Verified OK.

14.8.1 Maple step by step solution

Let's solve

$(x-1)\, y''+(-3x+2)\, y'+2yx=0$

- Highest derivative means the order of the ODE is 2

y''

- Isolate 2nd derivative

$y''=-\frac{2xy}{x-1}+\frac{(3x-2)y'}{x-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y''-\frac{(3x-2)y'}{x-1}+\frac{2xy}{x-1}=0$

□ Check to see if $x_0=1$ is a regular singular point

- ◦ Define functions

$\left[P_2(x)=-\frac{3x-2}{x-1}, P_3(x)=\frac{2x}{x-1}\right]$

- ◦ $(x-1)\cdot P_2(x)$ is analytic at $x=1$

$\left((x-1)\cdot P_2(x)\right)\Big|_{x=1}=-1$

- ◦ $(x-1)^2\cdot P_3(x)$ is analytic at $x=1$

$\left((x-1)^2\cdot P_3(x)\right)\Big|_{x=1}=0$

- ◦ $x=1$is a regular singular point

Check to see if $x_0=1$ is a regular singular point

$x_0=1$

- Multiply by denominators

$(x-1)\, y''+(-3x+2)\, y'+2yx=0$

- Change variables using $x=u+1$ so that the regular singular point is at $u=0$

$u\left(\frac{d^2}{du^2}y(u)\right)+(-3u-1)\left(\frac{d}{du}y(u)\right)+(2u+2)\, y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

$$u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$$

- Shift index using $k- >k-m$

$$u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

$$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-1}$$

- Shift index using $k- >k+1$

$$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-2+r)\, u^{-1+r} + (a_1(1+r)\,(-1+r) - a_0(-2+3r))\, u^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+1+r)\,(k+r-1)\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-2+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, 2\}$$

- Each term must be 0

$$a_1(1+r)\,(-1+r) - a_0(-2+3r) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)\,(k+r-1) + a_k(-3k-3r+2) + 2a_{k-1} = 0$$

- Shift index using $k- >k+1$

$$a_{k+2}(k+2+r)\,(k+r) + a_{k+1}(-3k-1-3r) + 2a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = \frac{3k a_{k+1} + 3r a_{k+1} - 2a_k + a_{k+1}}{(k+2+r)(k+r)}$$

- Recursion relation for $r = 0$

  $a_{k+2} = \frac{3k a_{k+1} - 2a_k + a_{k+1}}{(k+2)k}$

- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 0$

  $a_{k+2} = \frac{3k a_{k+1} - 2a_k + a_{k+1}}{(k+2)k}$

- Recursion relation for $r = 2$

  $a_{k+2} = \frac{3k a_{k+1} - 2a_k + 7a_{k+1}}{(k+4)(k+2)}$

- Solution for $r = 2$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+2} = \frac{3k a_{k+1} - 2a_k + 7a_{k+1}}{(k+4)(k+2)}, 3a_1 - 4a_0 = 0\right]$

- Revert the change of variables $u = x - 1$

  $\left[y = \sum_{k=0}^{\infty} a_k (x-1)^{k+2}, a_{k+2} = \frac{3k a_{k+1} - 2a_k + 7a_{k+1}}{(k+4)(k+2)}, 3a_1 - 4a_0 = 0\right]$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.1. Exercises page 232
Problem number: 9.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{\left(x^{3}-1\right) y''+x^{2} y'+y x=0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (807) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (808) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y'_0} \qquad (7)$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{x(y'x+y)}{x^3-1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{x^4 y' + 3y x^3 + 3y'x + y}{(x^3-1)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{-10y x^5 - 24y'x^3 - 18x^2 y - 4y'}{(x^3-1)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= -\frac{10x((x^7 - 16x^4 - 13x)\, y' - 4y(x^6 + 5x^3 + 1))}{(x^3-1)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{(90x^{10} - 1040x^7 - 2390x^4 - 300x)\, y' - 190\left(x^9 + \frac{204}{19}x^6 + \frac{137}{19}x^3 + \frac{4}{19}\right) y}{(x^3-1)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= 0 \\
F_1 &= y(0) \\
F_2 &= 4y'(0) \\
F_3 &= 0 \\
F_4 &= 40y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1 + \frac{1}{6}x^3 + \frac{1}{18}x^6\right) y(0) + \left(x + \frac{1}{6}x^4\right) y'(0) + O\left(x^6\right)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$\left(x^3 - 1\right) y'' + x^2 y' + yx = 0$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\left(x^3 - 1\right) \left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + x^2 \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) x = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n\, x^{1+n} a_n (n-1)\right) + \sum_{n=2}^{\infty} \left(-n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n\, x^{1+n} a_n\right) + \left(\sum_{n=0}^{\infty} x^{1+n} a_n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n\, x^{1+n} a_n (n-1) = \sum_{n=3}^{\infty} (n-1)\, a_{n-1} (n-2)\, x^n$$
$$\sum_{n=2}^{\infty} \left(-n(n-1)\, a_n x^{n-2}\right) = \sum_{n=0}^{\infty} \left(-(n+2)\, a_{n+2} (1+n)\, x^n\right)$$
$$\sum_{n=1}^{\infty} n\, x^{1+n} a_n = \sum_{n=2}^{\infty} (n-1)\, a_{n-1} x^n$$
$$\sum_{n=0}^{\infty} x^{1+n} a_n = \sum_{n=1}^{\infty} a_{n-1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=3}^{\infty} (n-1)\, a_{n-1}(n-2)\, x^{n}\right)+\sum_{n\, =0}^{\infty} \left(-(n+2)\, a_{n+2}(1+n)\, x^{n}\right) \\ +\left(\sum_{n=2}^{\infty} (n-1)\, a_{n-1} x^{n}\right)+\left(\sum_{n=1}^{\infty} a_{n-1} x^{n}\right) = 0 \tag{3}$$

$n = 1$ gives

$$-6a_{3}+a_{0} = 0$$

Which after substituting earlier equations, simplifies to

$$a_{3} = \frac{a_{0}}{6}$$

$n = 2$ gives

$$-12a_{4}+2a_{1} = 0$$

Which after substituting earlier equations, simplifies to

$$a_{4} = \frac{a_{1}}{6}$$

For $3 \le n$, the recurrence equation is

$$(n-1)\, a_{n-1}(n-2)-(n+2)\, a_{n+2}(1+n)+(n-1)\, a_{n-1}+a_{n-1} = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = \frac{a_{n-1}(n^{2}-2n+2)}{(n+2)\, (1+n)} \tag{5}$$

For $n = 3$ the recurrence equation gives

$$5a_{2}-20a_{5} = 0$$

Which after substituting the earlier terms found becomes

$$a_{5} = 0$$

For $n = 4$ the recurrence equation gives

$$10a_3 - 30a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_0}{18}$$

For $n = 5$ the recurrence equation gives

$$17a_4 - 42a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{17a_1}{252}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + \frac{1}{6} a_0 x^3 + \frac{1}{6} a_1 x^4 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + \frac{x^3}{6}\right) a_0 + \left(x + \frac{1}{6} x^4\right) a_1 + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 + \frac{x^3}{6}\right) c_1 + \left(x + \frac{1}{6} x^4\right) c_2 + O(x^6)$$

<u>Summary</u>
The solution(s) found are the following

$$y = \left(1 + \frac{1}{6} x^3 + \frac{1}{18} x^6\right) y(0) + \left(x + \frac{1}{6} x^4\right) y'(0) + O(x^6) \tag{1}$$

$$y = \left(1 + \frac{x^3}{6}\right) c_1 + \left(x + \frac{1}{6} x^4\right) c_2 + O(x^6) \tag{2}$$

Verification of solutions

$$y = \left(1+\frac{1}{6}x^3+\frac{1}{18}x^6\right)y(0)+\left(x+\frac{1}{6}x^4\right)y'(0)+O(x^6)$$

Verified OK.

$$y = \left(1+\frac{x^3}{6}\right)c_1+\left(x+\frac{1}{6}x^4\right)c_2+O(x^6)$$

Verified OK.

14.9.1 Maple step by step solution

Let's solve

$(x^3-1)\,y''+x^2y'+yx=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{x^2y'}{x^3-1}-\frac{xy}{x^3-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{x^2y'}{x^3-1}+\frac{xy}{x^3-1}=0$

☐ Check to see if x_0 is a regular singular point

  ○ Define functions

  $\left[P_2(x)=\frac{x^2}{x^3-1}, P_3(x)=\frac{x}{x^3-1}\right]$

  ○ $(x-1)\cdot P_2(x)$ is analytic at $x=1$

  $\left.((x-1)\cdot P_2(x))\right|_{x=1}=\frac{1}{3}$

  ○ $(x-1)^2\cdot P_3(x)$ is analytic at $x=1$

  $\left.((x-1)^2\cdot P_3(x))\right|_{x=1}=0$

  ○ $x=1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=1$

- Multiply by denominators

$$\left(x^3-1\right) y''+x^2 y'+y x=0$$

- Change variables using $x=u+1$ so that the regular singular point is at $u=0$

$$\left(u^3+3u^2+3u\right)\left(\frac{d^2}{du^2}y(u)\right)+\left(u^2+2u+1\right)\left(\frac{d}{du}y(u)\right)+\left(u+1\right)y(u)=0$$

- Assume series solution for $y(u)$

$$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$$

☐ Rewrite ODE with series expansions

  ◦ Convert $u^m \cdot y(u)$ to series expansion for $m=0..1$

$$u^m \cdot y(u)=\sum_{k=0}^{\infty} a_k u^{k+r+m}$$

  ◦ Shift index using $k->k-m$

$$u^m \cdot y(u)=\sum_{k=m}^{\infty} a_{k-m} u^{k+r}$$

  ◦ Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..2$

$$u^m \cdot \left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$$

  ◦ Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

  ◦ Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..3$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$$

  ◦ Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-2+3r)\,u^{-1+r}+\left(a_1(1+r)(1+3r)+a_0\left(3r^2-r+1\right)\right)u^r+\left(\sum_{k=1}^{\infty}\left(a_{k+1}(k+1+r)(3k+1\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-2+3r)=0$$

- Values of r that satisfy the indicial equation

$$r\in\left\{0,\frac{2}{3}\right\}$$

- Each term must be 0

  $a_1(1+r)(1+3r)+a_0(3r^2-r+1)=0$

- Each term in the series must be 0, giving the recursion relation

  $(3a_k+a_{k-1}+3a_{k+1})k^2+((6a_k+2a_{k-1}+6a_{k+1})r-a_k-2a_{k-1}+4a_{k+1})k+(3a_k+a_{k-1}+3a_$

- Shift index using $k->k+1$

  $(3a_{k+1}+a_k+3a_{k+2})(k+1)^2+((6a_{k+1}+2a_k+6a_{k+2})r-a_{k+1}-2a_k+4a_{k+2})(k+1)+(3a_{k+}$

- Recursion relation that defines series solution to ODE

  $a_{k+2}=-\frac{k^2a_k+3k^2a_{k+1}+2kra_k+6kra_{k+1}+r^2a_k+3r^2a_{k+1}+5ka_{k+1}+5ra_{k+1}+a_k+3a_{k+1}}{3k^2+6kr+3r^2+10k+10r+8}$

- Recursion relation for $r=0$

  $a_{k+2}=-\frac{k^2a_k+3k^2a_{k+1}+5ka_{k+1}+a_k+3a_{k+1}}{3k^2+10k+8}$

- Solution for $r=0$

  $\left[y(u)=\sum_{k=0}^{\infty}a_k u^k, a_{k+2}=-\frac{k^2a_k+3k^2a_{k+1}+5ka_{k+1}+a_k+3a_{k+1}}{3k^2+10k+8}, a_1+a_0=0\right]$

- Revert the change of variables $u=x-1$

  $\left[y=\sum_{k=0}^{\infty}a_k(x-1)^k, a_{k+2}=-\frac{k^2a_k+3k^2a_{k+1}+5ka_{k+1}+a_k+3a_{k+1}}{3k^2+10k+8}, a_1+a_0=0\right]$

- Recursion relation for $r=\frac{2}{3}$

  $a_{k+2}=-\frac{k^2a_k+3k^2a_{k+1}+\frac{4}{3}ka_k+9ka_{k+1}+\frac{13}{9}a_k+\frac{23}{3}a_{k+1}}{3k^2+14k+16}$

- Solution for $r=\frac{2}{3}$

  $\left[y(u)=\sum_{k=0}^{\infty}a_k u^{k+\frac{2}{3}}, a_{k+2}=-\frac{k^2a_k+3k^2a_{k+1}+\frac{4}{3}ka_k+9ka_{k+1}+\frac{13}{9}a_k+\frac{23}{3}a_{k+1}}{3k^2+14k+16}, 5a_1+\frac{5a_0}{3}=0\right]$

- Revert the change of variables $u=x-1$

  $\left[y=\sum_{k=0}^{\infty}a_k(x-1)^{k+\frac{2}{3}}, a_{k+2}=-\frac{k^2a_k+3k^2a_{k+1}+\frac{4}{3}ka_k+9ka_{k+1}+\frac{13}{9}a_k+\frac{23}{3}a_{k+1}}{3k^2+14k+16}, 5a_1+\frac{5a_0}{3}=0\right]$

- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty}a_k(x-1)^k\right)+\left(\sum_{k=0}^{\infty}b_k(x-1)^{k+\frac{2}{3}}\right), a_{k+2}=-\frac{k^2a_k+3k^2a_{1+k}+5ka_{1+k}+a_k+3a_{1+k}}{3k^2+10k+8}, a_1+a_0=0\right.$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.1. Exercises page 232
Problem number: 10.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{(x+3)\,y''+(x+2)\,y'+y=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y'_0$. Using

Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0, y_0, y_0'} + \frac{x^3}{3!} f'|_{x_0, y_0, y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left. \frac{d^n f}{dx^n} \right|_{x_0, y_0, y_0'}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (810) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (811) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') &&(4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f &&(5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 &&(6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y'_0} \tag{7}
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$\begin{aligned}
F_0 &= -\frac{y'x + 2y' + y}{x+3} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{y'x + y}{x+3} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{(-x^2 - x + 6)\, y' - y(x+1)}{(x+3)^2} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{(x^3 + 2x^2 - 13x - 30)\, y' + y(x^2 + 2x - 7)}{(x+3)^3} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{-(x+3)\,(x^3 - 21x - 30)\, y' - y(x^3 + 3x^2 - 15x - 57)}{(x+3)^4}
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$\begin{aligned}
F_0 &= -\frac{y(0)}{3} - \frac{2y'(0)}{3} \\
F_1 &= \frac{y(0)}{3} \\
F_2 &= -\frac{y(0)}{9} + \frac{2y'(0)}{3} \\
F_3 &= -\frac{7y(0)}{27} - \frac{10y'(0)}{9} \\
F_4 &= \frac{19y(0)}{27} + \frac{10y'(0)}{9}
\end{aligned}$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = \left(1-\frac{1}{6}x^2+\frac{1}{18}x^3-\frac{1}{216}x^4-\frac{7}{3240}x^5+\frac{19}{19440}x^6\right)y(0) + \left(x-\frac{1}{3}x^2+\frac{1}{36}x^4-\frac{1}{108}x^5+\frac{1}{648}x^6\right)y'(0)+O(x^6)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$(x+3)\,y''+(x+2)\,y'+y=0$$

Let the solution be represented as power series of the form

$$y=\sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}$$

Substituting the above back into the ode gives

$$(x+3)\left(\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}\right)+(x+2)\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right)+\left(\sum_{n=0}^{\infty} a_n x^n\right)=0 \quad (1)$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n\,x^{n-1} a_n (n-1)\right)+\left(\sum_{n=2}^{\infty} 3n(n-1)\,a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n a_n x^n\right)+\left(\sum_{n=1}^{\infty} 2n a_n x^{n-1}\right)+\left(\sum_{n=0}^{\infty} a_n x^n\right)=0 \quad (2)$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the

power and the corresponding index gives

$$\sum_{n=2}^{\infty} n\, x^{n-1} a_n (n-1) = \sum_{n=1}^{\infty} (n+1)\, a_{n+1} n\, x^{n}$$

$$\sum_{n=2}^{\infty} 3n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} 3(n+2)\, a_{n+2}(n+1)\, x^{n}$$

$$\sum_{n=1}^{\infty} 2n a_n x^{n-1} = \sum_{n=0}^{\infty} 2(n+1)\, a_{n+1} x^{n}$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=1}^{\infty} (n+1)\, a_{n+1} n\, x^{n}\right) + \left(\sum_{n=0}^{\infty} 3(n+2)\, a_{n+2}(n+1)\, x^{n}\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n}\right) + \left(\sum_{n=0}^{\infty} 2(n+1)\, a_{n+1} x^{n}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n}\right) = 0 \tag{3}$$

$n = 0$ gives

$$6a_2 + 2a_1 + a_0 = 0$$

$$a_2 = -\frac{a_0}{6} - \frac{a_1}{3}$$

For $1 \leq n$, the recurrence equation is

$$(n+1)\, a_{n+1} n + 3(n+2)\, a_{n+2}(n+1) + n a_n + 2(n+1)\, a_{n+1} + a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{n a_{n+1} + a_n + 2a_{n+1}}{3\,(n+2)} \\ &= -\frac{a_n}{3\,(n+2)} - \frac{a_{n+1}}{3} \end{aligned} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$6a_2 + 18a_3 + 2a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{a_0}{18}$$

For $n = 2$ the recurrence equation gives

$$12a_3 + 36a_4 + 3a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{a_0}{216} + \frac{a_1}{36}$$

For $n = 3$ the recurrence equation gives

$$20a_4 + 60a_5 + 4a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{7a_0}{3240} - \frac{a_1}{108}$$

For $n = 4$ the recurrence equation gives

$$30a_5 + 90a_6 + 5a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{19a_0}{19440} + \frac{a_1}{648}$$

For $n = 5$ the recurrence equation gives

$$42a_6 + 126a_7 + 6a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{13a_0}{58320} - \frac{a_1}{13608}$$

And so on. Therefore the solution is

$$
\begin{aligned}
y &= \sum_{n=0}^{\infty} a_n x^n \\
&= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots
\end{aligned}
$$

Substituting the values for a_n found above, the solution becomes

$$
y = a_0 + a_1 x + \left(-\frac{a_0}{6} - \frac{a_1}{3}\right) x^2 + \frac{a_0 x^3}{18} + \left(-\frac{a_0}{216} + \frac{a_1}{36}\right) x^4 + \left(-\frac{7a_0}{3240} - \frac{a_1}{108}\right) x^5 + \dots
$$

Collecting terms, the solution becomes

$$
y = \left(1 - \frac{1}{6}x^2 + \frac{1}{18}x^3 - \frac{1}{216}x^4 - \frac{7}{3240}x^5\right) a_0 + \left(x - \frac{1}{3}x^2 + \frac{1}{36}x^4 - \frac{1}{108}x^5\right) a_1 + O\left(x^6\right) \tag{3}
$$

At $x = 0$ the solution above becomes

$$
y = \left(1 - \frac{1}{6}x^2 + \frac{1}{18}x^3 - \frac{1}{216}x^4 - \frac{7}{3240}x^5\right) c_1 + \left(x - \frac{1}{3}x^2 + \frac{1}{36}x^4 - \frac{1}{108}x^5\right) c_2 + O\left(x^6\right)
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = &\left(1 - \frac{1}{6}x^2 + \frac{1}{18}x^3 - \frac{1}{216}x^4 - \frac{7}{3240}x^5 + \frac{19}{19440}x^6\right) y(0) \\
&+ \left(x - \frac{1}{3}x^2 + \frac{1}{36}x^4 - \frac{1}{108}x^5 + \frac{1}{648}x^6\right) y'(0) + O\left(x^6\right)
\end{aligned} \tag{1}
$$

$$
y = \left(1 - \frac{1}{6}x^2 + \frac{1}{18}x^3 - \frac{1}{216}x^4 - \frac{7}{3240}x^5\right) c_1 + \left(x - \frac{1}{3}x^2 + \frac{1}{36}x^4 - \frac{1}{108}x^5\right) c_2 + O\left(x^6\right) \tag{2}
$$

Verification of solutions

$$
\begin{aligned}
y = &\left(1 - \frac{1}{6}x^2 + \frac{1}{18}x^3 - \frac{1}{216}x^4 - \frac{7}{3240}x^5 + \frac{19}{19440}x^6\right) y(0) \\
&+ \left(x - \frac{1}{3}x^2 + \frac{1}{36}x^4 - \frac{1}{108}x^5 + \frac{1}{648}x^6\right) y'(0) + O\left(x^6\right)
\end{aligned}
$$

Verified OK.

$$
y = \left(1 - \frac{1}{6}x^2 + \frac{1}{18}x^3 - \frac{1}{216}x^4 - \frac{7}{3240}x^5\right) c_1 + \left(x - \frac{1}{3}x^2 + \frac{1}{36}x^4 - \frac{1}{108}x^5\right) c_2 + O\left(x^6\right)
$$

Verified OK.

14.10.1 Maple step by step solution

Let's solve

$(x+3)\, y''+(x+2)\, y'+y=0$

- Highest derivative means the order of the ODE is 2

y''

- Isolate 2nd derivative

$y''=-\frac{y}{x+3}-\frac{(x+2)y'}{x+3}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y''+\frac{(x+2)y'}{x+3}+\frac{y}{x+3}=0$

□ Check to see if $x_0=-3$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{x+2}{x+3}, P_3(x)=\frac{1}{x+3}\right]$

  ◦ $(x+3)\cdot P_2(x)$ is analytic at $x=-3$

  $\left((x+3)\cdot P_2(x)\right)\bigg|_{x=-3}=-1$

  ◦ $(x+3)^2\cdot P_3(x)$ is analytic at $x=-3$

  $\left((x+3)^2\cdot P_3(x)\right)\bigg|_{x=-3}=0$

  ◦ $x=-3$is a regular singular point

Check to see if $x_0=-3$ is a regular singular point

$x_0=-3$

- Multiply by denominators

$(x+3)\, y''+(x+2)\, y'+y=0$

- Change variables using $x=u-3$ so that the regular singular point is at $u=0$

$u\left(\frac{d^2}{du^2}y(u)\right)+(u-1)\left(\frac{d}{du}y(u)\right)+y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

$$u^{m}\cdot \left(\frac{d}{du}y \left(u \right)\right)=\sum_{k =0}^{\infty}a_{k} \left(k +r \right) u^{k +r -1+m}$$

- Shift index using $k->k +1-m$

$$u^{m}\cdot \left(\frac{d}{du}y \left(u \right)\right)=\sum_{k =-1+m}^{\infty}a_{k +1-m} \left(k +1-m +r \right) u^{k +r}$$

- Convert $u \cdot \left(\frac{d^{2}}{d u^{2}}y \left(u \right)\right)$ to series expansion

$$u \cdot \left(\frac{d^{2}}{d u^{2}}y \left(u \right)\right)=\sum_{k =0}^{\infty}a_{k} \left(k +r \right) \left(k +r -1\right) u^{k +r -1}$$

- Shift index using $k->k +1$

$$u \cdot \left(\frac{d^{2}}{d u^{2}}y \left(u \right)\right)=\sum_{k =-1}^{\infty}a_{k +1} \left(k +1+r \right) \left(k +r \right) u^{k +r}$$

Rewrite ODE with series expansions

$$a_{0} r \left(-2+r \right) u^{-1+r}+\left(\sum_{k =0}^{\infty}\left(a_{k +1} \left(k +1+r \right) \left(k +r -1\right)+a_{k} \left(k +1+r \right)\right) u^{k +r}\right)=0$$

- a_{0}cannot be 0 by assumption, giving the indicial equation

$$r \left(-2+r \right)=0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, 2\}$$

- Each term in the series must be 0, giving the recursion relation

$$\left(k +1+r \right) \left(a_{k +1} \left(k +r -1\right)+a_{k}\right)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k +1}=-\frac{a_{k}}{k +r -1}$$

- Recursion relation for $r =0$

$$a_{k +1}=-\frac{a_{k}}{k -1}$$

- Series not valid for $r =0$, division by 0 in the recursion relation at $k =1$

$$a_{k +1}=-\frac{a_{k}}{k -1}$$

- Recursion relation for $r =2$

$$a_{k +1}=-\frac{a_{k}}{k +1}$$

- Solution for $r =2$

$$\left[y \left(u \right)=\sum_{k =0}^{\infty}a_{k} u^{k +2}, a_{k +1}=-\frac{a_{k}}{k +1}\right]$$

- Revert the change of variables $u = x + 3$

$$\left[y = \sum_{k=0}^{\infty} a_k (x+3)^{k+2}, a_{k+1} = -\frac{a_k}{k+1}\right]$$

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{y'' - y'x - y = 0}$$

With initial conditions

$$[y(0) = 1, y'(0) = 0]$$

With the expansion point for the power series method at $x = 0$.

14.11.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -x \\ q(x) &= -1 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - y'x - y = 0$$

The domain of $p(x) = -x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{813}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{814}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x, y, y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \qquad (7)$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= y'x + y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= x^2 y' + yx + 2y' \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \left(x^3 + 5x\right) y' + y\left(x^2 + 3\right) \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(x^4 + 9x^2 + 8\right) y' + xy\left(x^2 + 7\right) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(x^5 + 14x^3 + 33x\right) y' + y\left(x^4 + 12x^2 + 15\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = 1$ and $y'(0) = 0$ gives

$$
\begin{aligned}
F_0 &= 1 \\
F_1 &= 0 \\
F_2 &= 3 \\
F_3 &= 0 \\
F_4 &= 15
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = 1 + \frac{x^2}{2} + \frac{x^4}{8} + \frac{x^6}{48} + O\left(x^6\right)
$$

$$
y = 1 + \frac{x^2}{2} + \frac{x^4}{8} + \frac{x^6}{48} + O\left(x^6\right)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x + \left(\sum_{n=0}^{\infty} a_n x^n\right) \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \sum_{n=1}^{\infty} (-n\, x^n a_n) + \sum_{n=0}^{\infty} (-a_n x^n) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \sum_{n=1}^{\infty} (-n\, x^n a_n) + \sum_{n=0}^{\infty} (-a_n x^n) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 - a_0 = 0$$

$$a_2 = \frac{a_0}{2}$$

For $1 \leq n$, the recurrence equation is

$$\left(n+2\right) a_{n+2}(n+1) - n a_n - a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = \frac{a_n}{n+2} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$6a_3 - 2a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{a_1}{3}$$

For $n = 2$ the recurrence equation gives

$$12a_4 - 3a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{8}$$

For $n = 3$ the recurrence equation gives

$$20a_5 - 4a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_1}{15}$$

For $n = 4$ the recurrence equation gives

$$30a_6 - 5a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_0}{48}$$

For $n = 5$ the recurrence equation gives

$$42a_7 - 6a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{a_1}{105}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + \frac{1}{2} a_0 x^2 + \frac{1}{3} a_1 x^3 + \frac{1}{8} a_0 x^4 + \frac{1}{15} a_1 x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + \frac{1}{2}x^2 + \frac{1}{8}x^4\right) a_0 + \left(x + \frac{1}{3}x^3 + \frac{1}{15}x^5\right) a_1 + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 + \frac{1}{2}x^2 + \frac{1}{8}x^4\right) c_1 + \left(x + \frac{1}{3}x^3 + \frac{1}{15}x^5\right) c_2 + O(x^6)$$

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{8} + O(x^6)$$

Summary

The solution(s) found are the following

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{8} + \frac{x^6}{48} + O(x^6) \tag{1}$$

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{8} + O(x^6) \tag{2}$$

Verification of solutions

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{8} + \frac{x^6}{48} + O(x^6)$$

Verified OK.

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{8} + O(x^6)$$

Verified OK.

14.11.2 Maple step by step solution

Let's solve

$\left[y'' = y'x + y, y(0) = 1, y'\Big|_{\{x=0\}} = 0\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - y'x - y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  ◦ Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert y'' to series expansion

    $y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k- >k+2$

    $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) - a_k(k+1)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k+1)(a_{k+2}(k+2)-a_k)=0$

- Recursion relation that defines the series solution to the ODE

  $\left[y=\sum_{k=0}^{\infty} a_k x^k, a_{k+2}=\frac{a_k}{k+2}\right]$

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + y'x - 2y = 0}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1]$$

With the expansion point for the power series method at $x = 0$.

14.12.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= x \\ q(x) &= -2 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + y'x - 2y = 0$$

The domain of $p(x) = x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{816}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{817}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -y'x + 2y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0 \\
&= x^2y' - 2yx + y' \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y}y' + \frac{\partial F_1}{\partial y'}F_1 \\
&= -x\left(x^2+1\right)y' + 2x^2y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y}y' + \frac{\partial F_2}{\partial y'}F_2 \\
&= \left(x^4-1\right)y' + \left(-2x^3+2x\right)y \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y}y' + \frac{\partial F_3}{\partial y'}F_3 \\
&= -\left(x^2-3\right)x\left(\left(x^2+1\right)y' - 2yx\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=0$ and $y'(0)=1$ gives

$$
\begin{aligned}
F_0 &= 0 \\
F_1 &= 1 \\
F_2 &= 0 \\
F_3 &= -1 \\
F_4 &= 0
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = x + \frac{x^3}{6} - \frac{x^5}{120} + O\left(x^6\right)
$$

$$
y = x + \frac{x^3}{6} - \frac{x^5}{120} + O\left(x^6\right)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x + 2\left(\sum_{n=0}^{\infty} a_n x^n\right) \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \sum_{n=0}^{\infty} (-2 a_n x^n) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \sum_{n=0}^{\infty} (-2 a_n x^n) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 - 2a_0 = 0$$

$$a_2 = a_0$$

For $1 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(n+1) + n a_n - 2a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{a_n(n-2)}{(n+2)\,(n+1)} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$6a_3 - a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{a_1}{6}$$

For $n = 2$ the recurrence equation gives

$$12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = 0$$

For $n = 3$ the recurrence equation gives

$$20a_5 + a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{a_1}{120}$$

For $n = 4$ the recurrence equation gives

$$30a_6 + 2a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = 0$$

For $n = 5$ the recurrence equation gives

$$42a_7 + 3a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{a_1}{1680}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + a_0 x^2 + \frac{1}{6} a_1 x^3 - \frac{1}{120} a_1 x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(x^2 + 1\right) a_0 + \left(x + \frac{1}{6}x^3 - \frac{1}{120}x^5\right) a_1 + O\left(x^6\right) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(x^2 + 1\right) c_1 + \left(x + \frac{1}{6}x^3 - \frac{1}{120}x^5\right) c_2 + O\left(x^6\right)$$

$$y = x + \frac{x^3}{6} - \frac{x^5}{120} + O\left(x^6\right)$$

Summary

The solution(s) found are the following

$$y = x + \frac{x^3}{6} - \frac{x^5}{120} + O\left(x^6\right) \tag{1}$$

$$y = x + \frac{x^3}{6} - \frac{x^5}{120} + O\left(x^6\right) \tag{2}$$

Verification of solutions

$$y = x + \frac{x^3}{6} - \frac{x^5}{120} + O(x^6)$$

Verified OK.

$$y = x + \frac{x^3}{6} - \frac{x^5}{120} + O(x^6)$$

Verified OK.

14.12.2 Maple step by step solution

Let's solve

$\left[y'' = -y'x + 2y, y(0) = 0, y'\Big|_{\{x=0\}} = 1\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + y'x - 2y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  ◦ Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k k \, x^k$

  ◦ Convert y'' to series expansion

    $y'' = \sum_{k=2}^{\infty} a_k k(k-1) \, x^{k-2}$

  ◦ Shift index using $k- >k+2$

    $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1) \, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)(k+1) + a_k(k-2)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k^2 + 3k + 2) a_{k+2} + a_k(k - 2) = 0$

- Recursion relation; series terminates at $k = 2$

  $a_{k+2} = -\frac{a_k(k-2)}{k^2+3k+2}$

- Apply recursion relation for $k = 0$

  $a_2 = a_0$

- Terminating series solution of the ODE. Use reduction of order to find the second linearly ind

  $y = A_2x^2 + A_1x + a_0$

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x^2+1)\,y''+y'x+2yx=0}$$

With initial conditions

$$[y(0)=2, y'(0)=3]$$

With the expansion point for the power series method at $x=0$.

14.13.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y''+p(x)y'+q(x)y=F$$

Where here

$$\begin{aligned} p(x) &= \frac{x}{x^2+1} \\ q(x) &= \frac{2x}{x^2+1} \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + \frac{xy'}{x^2+1} + \frac{2xy}{x^2+1} = 0$$

The domain of $p(x) = \frac{x}{x^2+1}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \frac{2x}{x^2+1}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + xy'_0 + \frac{x^2}{2} f|_{x_0,y_0,y'_0} + \frac{x^3}{3!} f'|_{x_0,y_0,y'_0} + \cdots \\
&= y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y'_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (819) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (820) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$\begin{aligned} F_0 &= f(x, y, y') \qquad (4) \\ F_1 &= \frac{df}{dx} \\ &= \frac{dF_0}{dx} \\ &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' \\ &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \qquad (5) \\ &= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\ F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right) \\ &= \frac{d}{dx}(F_1) \\ &= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y'' \\ &= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0 \\ &\vdots \\ F_n &= \frac{d}{dx}(F_{n-1}) \\ &= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y'' \\ &= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 \qquad (6) \end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \qquad (7)$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{x(2y+y')}{x^2+1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0 \\
&= \frac{\left(-2x^3+2x^2-2x-1\right)y' + \left(4x^2-2\right)y}{\left(x^2+1\right)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y}y' + \frac{\partial F_1}{\partial y'}F_1 \\
&= \frac{\left(8x^4-6x^3+4x^2+9x-4\right)y' + 4xy\left(x^3-3x^2+x+\frac{9}{2}\right)}{\left(x^2+1\right)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y}y' + \frac{\partial F_2}{\partial y'}F_2 \\
&= \frac{\left(4x^6-36x^5+32x^4+18x^3-68x^2+54x+9\right)y' - 24\left(x^5-2x^4+\frac{1}{3}x^3+6x^2-\frac{2}{3}x-\frac{3}{4}\right)y}{\left(x^2+1\right)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y}y' + \frac{\partial F_3}{\partial y'}F_3 \\
&= \frac{\left(-36x^7+192x^6-168x^5-384x^4+612x^3-504x^2-201x+72\right)y' - 8\left(x^7-18x^6+32x^5+\frac{29}{2}x^4-\right.}{\left(x^2+1\right)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=2$ and $y'(0)=3$ gives

$$
\begin{aligned}
F_0 &= 0 \\
F_1 &= -7 \\
F_2 &= -12 \\
F_3 &= 63 \\
F_4 &= 248
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = 3x + 2 - \frac{7x^3}{6} - \frac{x^4}{2} + \frac{21x^5}{40} + \frac{31x^6}{90} + O\left(x^6\right)
$$

$$y = 3x + 2 - \frac{7x^3}{6} - \frac{x^4}{2} + \frac{21x^5}{40} + \frac{31x^6}{90} + O(x^6)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$(x^2 + 1)\, y'' + y'x + 2yx = 0$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$(x^2 + 1) \left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x + 2\left(\sum_{n=0}^{\infty} a_n x^n\right) x = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right) + \left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n a_n x^n\right) + \left(\sum_{n=0}^{\infty} 2x^{1+n} a_n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^n$$
$$\sum_{n=0}^{\infty} 2x^{1+n} a_n = \sum_{n=1}^{\infty} 2a_{n-1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right) + \left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^n\right) + \left(\sum_{n=1}^{\infty} n a_n x^n\right) + \left(\sum_{n=1}^{\infty} 2a_{n-1} x^n\right) = 0 \tag{3}$$

$n = 1$ gives

$$6a_3 + a_1 + 2a_0 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -\frac{a_0}{3} - \frac{a_1}{6}$$

For $2 \leq n$, the recurrence equation is

$$n a_n(n-1) + (n+2)\, a_{n+2}(1+n) + n a_n + 2a_{n-1} = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{n^2 a_n + 2a_{n-1}}{(n+2)\,(1+n)} \\ &= -\frac{n^2 a_n}{(n+2)\,(1+n)} - \frac{2a_{n-1}}{(n+2)\,(1+n)} \end{aligned} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$4a_2 + 12a_4 + 2a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{a_1}{6}$$

For $n = 3$ the recurrence equation gives

$$9a_3 + 20a_5 + 2a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{3a_0}{20} + \frac{3a_1}{40}$$

For $n = 4$ the recurrence equation gives

$$16a_4 + 30a_6 + 2a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_1}{10} + \frac{a_0}{45}$$

For $n = 5$ the recurrence equation gives

$$25a_5 + 42a_7 + 2a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{5a_0}{56} - \frac{37a_1}{1008}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + \left(-\frac{a_0}{3} - \frac{a_1}{6}\right) x^3 - \frac{a_1 x^4}{6} + \left(\frac{3a_0}{20} + \frac{3a_1}{40}\right) x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{1}{3}x^3 + \frac{3}{20}x^5\right) a_0 + \left(x - \frac{1}{6}x^3 - \frac{1}{6}x^4 + \frac{3}{40}x^5\right) a_1 + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{1}{3}x^3 + \frac{3}{20}x^5\right) c_1 + \left(x - \frac{1}{6}x^3 - \frac{1}{6}x^4 + \frac{3}{40}x^5\right) c_2 + O(x^6)$$

$$y = 2 - \frac{7x^3}{6} + \frac{21x^5}{40} + 3x - \frac{x^4}{2} + O(x^6)$$

Summary

The solution(s) found are the following

$$y = 3x + 2 - \frac{7x^3}{6} - \frac{x^4}{2} + \frac{21x^5}{40} + \frac{31x^6}{90} + O(x^6) \tag{1}$$

$$y = 2 - \frac{7x^3}{6} + \frac{21x^5}{40} + 3x - \frac{x^4}{2} + O(x^6) \tag{2}$$

Verification of solutions

$$y = 3x + 2 - \frac{7x^3}{6} - \frac{x^4}{2} + \frac{21x^5}{40} + \frac{31x^6}{90} + O(x^6)$$

Verified OK.

$$y = 2 - \frac{7x^3}{6} + \frac{21x^5}{40} + 3x - \frac{x^4}{2} + O(x^6)$$

Verified OK.

Problem number: 14.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(2x^2-3)\, y''-2y'x+y=0}$$

With initial conditions

$$[y(0)=-1, y'(0)=5]$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y'_0$. Using

Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x-x_0)\,y'(x_0) + \frac{(x-x_0)^2}{2}y''(x_0) + \frac{(x-x_0)^3}{3!}y'''(x_0) + \cdots \\
&= y_0 + xy_0' + \frac{x^2}{2}\,f|_{x_0,y_0,y_0'} + \frac{x^3}{3!}\,f'|_{x_0,y_0,y_0'} + \cdots \\
&= y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!}\,\frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y_0'}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (822)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (823)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3)\\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y'_0} \qquad (7)$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= \frac{2y'x - y}{2x^2 - 3}\\
F_1 &= \frac{dF_0}{dx}\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
&= \frac{-2x^2 y' + 2yx - 3y'}{(2x^2 - 3)^2}\\
F_2 &= \frac{dF_1}{dx}\\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1\\
&= \frac{8(x^3 + 3x)\, y' + (-10x^2 - 3)\, y}{(2x^2 - 3)^3}\\
F_3 &= \frac{dF_2}{dx}\\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2\\
&= \frac{(-52x^4 - 240x^2 - 63)\, y' + 72xy(x^2 + 1)}{(2x^2 - 3)^4}\\
F_4 &= \frac{dF_3}{dx}\\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3\\
&= \frac{(456x^5 + 2952x^3 + 2106x)\, y' + (-668x^4 - 1416x^2 - 153)\, y}{(2x^2 - 3)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = -1$ and $y'(0) = 5$ gives

$$
\begin{aligned}
F_0 &= -\frac{1}{3}\\
F_1 &= -\frac{5}{3}\\
F_2 &= -\frac{1}{9}\\
F_3 &= -\frac{35}{9}\\
F_4 &= -\frac{17}{27}
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = 5x - 1 - \frac{x^2}{6} - \frac{5x^3}{18} - \frac{x^4}{216} - \frac{7x^5}{216} - \frac{17x^6}{19440} + O(x^6)$$

$$y = 5x - 1 - \frac{x^2}{6} - \frac{5x^3}{18} - \frac{x^4}{216} - \frac{7x^5}{216} - \frac{17x^6}{19440} + O(x^6)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$\left(2x^2 - 3\right) y'' - 2y'x + y = 0$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\left(2x^2 - 3\right) \left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) - 2\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} 2x^n a_n n(n-1)\right) + \sum_{n=2}^{\infty} \left(-3n(n-1)\, a_n x^{n-2}\right) + \sum_{n=1}^{\infty} \left(-2n a_n x^n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} \left(-3n(n-1)\, a_n x^{n-2}\right) = \sum_{n=0}^{\infty} \left(-3(n+2)\, a_{n+2}(n+1)\, x^n\right)$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=2}^{\infty} 2x^n a_n n(n-1)\right) + \sum_{n=0}^{\infty} \left(-3(n+2) a_{n+2}(n+1) x^n\right) + \sum_{n=1}^{\infty} (-2n a_n x^n) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$-6a_2 + a_0 = 0$$

$$a_2 = \frac{a_0}{6}$$

$n = 1$ gives

$$-18a_3 - a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -\frac{a_1}{18}$$

For $2 \leq n$, the recurrence equation is

$$2na_n(n-1) - 3(n+2) a_{n+2}(n+1) - 2na_n + a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = \frac{a_n(2n^2 - 4n + 1)}{3(n+2)(n+1)} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$a_2 - 36a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{216}$$

For $n = 3$ the recurrence equation gives

$$7a_3 - 60a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{7a_1}{1080}$$

For $n = 4$ the recurrence equation gives

$$17a_4 - 90a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{17a_0}{19440}$$

For $n = 5$ the recurrence equation gives

$$31a_5 - 126a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{31a_1}{19440}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + \frac{1}{6} a_0 x^2 - \frac{1}{18} a_1 x^3 + \frac{1}{216} a_0 x^4 - \frac{7}{1080} a_1 x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + \frac{1}{6}x^2 + \frac{1}{216}x^4\right) a_0 + \left(x - \frac{1}{18}x^3 - \frac{7}{1080}x^5\right) a_1 + O(x^6) \tag{3}$$

At $x=0$ the solution above becomes

$$y = \left(1+\frac{1}{6}x^2+\frac{1}{216}x^4\right)c_1+\left(x-\frac{1}{18}x^3-\frac{7}{1080}x^5\right)c_2+O(x^6)$$

$$y = -1-\frac{x^2}{6}-\frac{x^4}{216}+5x-\frac{5x^3}{18}-\frac{7x^5}{216}+O(x^6)$$

Summary
The solution(s) found are the following

$$y = 5x-1-\frac{x^2}{6}-\frac{5x^3}{18}-\frac{x^4}{216}-\frac{7x^5}{216}-\frac{17x^6}{19440}+O(x^6) \tag{1}$$

$$y = -1-\frac{x^2}{6}-\frac{x^4}{216}+5x-\frac{5x^3}{18}-\frac{7x^5}{216}+O(x^6) \tag{2}$$

Verification of solutions

$$y = 5x-1-\frac{x^2}{6}-\frac{5x^3}{18}-\frac{x^4}{216}-\frac{7x^5}{216}-\frac{17x^6}{19440}+O(x^6)$$

Verified OK.

$$y = -1-\frac{x^2}{6}-\frac{x^4}{216}+5x-\frac{5x^3}{18}-\frac{7x^5}{216}+O(x^6)$$

Verified OK.

Section: Chapter 6, Series solutions of linear differential equations. Section 6.1. Exercises page 232
Problem number: 15.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler], [_2nd_order, _linear, `_with_symmetry_[0,F(
   x)]`]]
```

$$\boxed{x^2y'' + y'x + y = 0}$$

With the expansion point for the power series method at $x = 1$.

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - 1$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\left(\frac{d^2}{dt^2}y(t)\right)(1+t)^2 + \left(\frac{d}{dt}y(t)\right)(1+t) + y(t) = 0$$

With its expansion point and initial conditions now at $t = 0$. The transformed ODE is now solved. Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (825) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (826) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x, y, y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \qquad (7)$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{\left(\frac{d}{dt}y(t)\right)t + \frac{d}{dt}y(t) + y(t)}{(1+t)^2} \\
F_1 &= \frac{dF_0}{dt} \\
&= \frac{\partial F_0}{\partial t} + \frac{\partial F_0}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_0}{\partial \frac{d}{dt}y\left(t\right)}F_0 \\
&= \frac{\left(\frac{d}{dt}y(t)\right)(1+t) + 3y(t)}{(1+t)^3} \\
F_2 &= \frac{dF_1}{dt} \\
&= \frac{\partial F_1}{\partial t} + \frac{\partial F_1}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_1}{\partial \frac{d}{dt}y\left(t\right)}F_1 \\
&= -\frac{10y(t)}{(1+t)^4} \\
F_3 &= \frac{dF_2}{dt} \\
&= \frac{\partial F_2}{\partial t} + \frac{\partial F_2}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_2}{\partial \frac{d}{dt}y\left(t\right)}F_2 \\
&= \frac{(-10t-10)\left(\frac{d}{dt}y(t)\right) + 40y(t)}{(1+t)^5} \\
F_4 &= \frac{dF_3}{dt} \\
&= \frac{\partial F_3}{\partial t} + \frac{\partial F_3}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_3}{\partial \frac{d}{dt}y\left(t\right)}F_3 \\
&= \frac{(90t+90)\left(\frac{d}{dt}y(t)\right) - 190y(t)}{(1+t)^6}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $t = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -y'(0) - y(0) \\
F_1 &= y'(0) + 3y(0) \\
F_2 &= -10y(0) \\
F_3 &= 40y(0) - 10y'(0) \\
F_4 &= -190y(0) + 90y'(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$y(t) = \left(1 - \frac{1}{2}t^2 + \frac{1}{2}t^3 - \frac{5}{12}t^4 + \frac{1}{3}t^5 - \frac{19}{72}t^6\right) y(0) + \left(t - \frac{1}{2}t^2 + \frac{1}{6}t^3 - \frac{1}{12}t^5 + \frac{1}{8}t^6\right) y'(0) + O(t^6)$$

Since the expansion point $t = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$(t^2 + 2t + 1)\left(\frac{d^2}{dt^2}y(t)\right) + \left(\frac{d}{dt}y(t)\right)(1+t) + y(t) = 0$$

Let the solution be represented as power series of the form

$$y(t) = \sum_{n=0}^{\infty} a_n t^n$$

Then

$$\frac{d}{dt}y(t) = \sum_{n=1}^{\infty} n a_n t^{n-1}$$
$$\frac{d^2}{dt^2}y(t) = \sum_{n=2}^{\infty} n(n-1) a_n t^{n-2}$$

Substituting the above back into the ode gives

$$(t^2 + 2t + 1)\left(\sum_{n=2}^{\infty} n(n-1) a_n t^{n-2}\right) + \left(\sum_{n=1}^{\infty} n a_n t^{n-1}\right)(1+t) + \left(\sum_{n=0}^{\infty} a_n t^n\right) = 0 \quad (1)$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} t^n a_n n(n-1)\right) + \left(\sum_{n=2}^{\infty} 2n\, t^{n-1} a_n (n-1)\right) + \left(\sum_{n=2}^{\infty} n(n-1) a_n t^{n-2}\right) + \left(\sum_{n=1}^{\infty} n a_n t^{n-1}\right) + \left(\sum_{n=1}^{\infty} n a_n t^n\right) + \left(\sum_{n=0}^{\infty} a_n t^n\right) = 0 \quad (2)$$

The next step is to make all powers of t be n in each summation term. Going over each summation term above with power of t in it which is not already t^n and adjusting the

power and the corresponding index gives

$$\sum_{n=2}^{\infty} 2n\, t^{n-1} a_n (n-1) = \sum_{n=1}^{\infty} 2(n+1)\, a_{n+1} n\, t^n$$

$$\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2} (n+1)\, t^n$$

$$\sum_{n=1}^{\infty} n a_n t^{n-1} = \sum_{n=0}^{\infty} (n+1)\, a_{n+1} t^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of t are the same and equal to n.

$$\left(\sum_{n=2}^{\infty} t^n a_n n(n-1)\right) + \left(\sum_{n=1}^{\infty} 2(n+1)\, a_{n+1} n\, t^n\right) + \left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2} (n+1)\, t^n\right) \\ + \left(\sum_{n=0}^{\infty} (n+1)\, a_{n+1} t^n\right) + \left(\sum_{n=1}^{\infty} n a_n t^n\right) + \left(\sum_{n=0}^{\infty} a_n t^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + a_1 + a_0 = 0$$

$$a_2 = -\frac{a_0}{2} - \frac{a_1}{2}$$

$n = 1$ gives

$$6a_2 + 6a_3 + 2a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = \frac{a_0}{2} + \frac{a_1}{6}$$

For $2 \leq n$, the recurrence equation is

$$n a_n (n-1) + 2(n+1)\, a_{n+1} n + (n+2)\, a_{n+2} (n+1) + (n+1)\, a_{n+1} + n a_n + a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$
\begin{aligned}
a_{n+2} &= -\frac{n^2 a_n + 2n^2 a_{n+1} + 3n a_{n+1} + a_n + a_{n+1}}{(n+2)(n+1)} \\
&= -\frac{(n^2+1)\, a_n}{(n+2)(n+1)} - \frac{(2n^2+3n+1)\, a_{n+1}}{(n+2)(n+1)}
\end{aligned} \tag{5}
$$

For $n = 2$ the recurrence equation gives

$$5a_2 + 15a_3 + 12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{5a_0}{12}$$

For $n = 3$ the recurrence equation gives

$$10a_3 + 28a_4 + 20a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_0}{3} - \frac{a_1}{12}$$

For $n = 4$ the recurrence equation gives

$$17a_4 + 45a_5 + 30a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{19a_0}{72} + \frac{a_1}{8}$$

For $n = 5$ the recurrence equation gives

$$26a_5 + 66a_6 + 42a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{5a_0}{24} - \frac{73a_1}{504}$$

And so on. Therefore the solution is

$$
\begin{aligned}
y(t) &= \sum_{n=0}^{\infty} a_n t^n \\
&= a_3 t^3 + a_2 t^2 + a_1 t + a_0 + \dots
\end{aligned}
$$

Substituting the values for a_n found above, the solution becomes

$$
y(t) = a_0 + a_1 t + \left(-\frac{a_0}{2} - \frac{a_1}{2}\right) t^2 + \left(\frac{a_0}{2} + \frac{a_1}{6}\right) t^3 - \frac{5 a_0 t^4}{12} + \left(\frac{a_0}{3} - \frac{a_1}{12}\right) t^5 + \dots
$$

Collecting terms, the solution becomes

$$
y(t) = \left(1 - \frac{1}{2}t^2 + \frac{1}{2}t^3 - \frac{5}{12}t^4 + \frac{1}{3}t^5\right) a_0 + \left(t - \frac{1}{2}t^2 + \frac{1}{6}t^3 - \frac{1}{12}t^5\right) a_1 + O(t^6) \quad (3)
$$

At $t = 0$ the solution above becomes

$$
y(t) = \left(1 - \frac{1}{2}t^2 + \frac{1}{2}t^3 - \frac{5}{12}t^4 + \frac{1}{3}t^5\right) c_1 + \left(t - \frac{1}{2}t^2 + \frac{1}{6}t^3 - \frac{1}{12}t^5\right) c_2 + O(t^6)
$$

Replacing t in the above with the original independent variable $x$susing $t = x-1$ results in

$$
\begin{aligned}
y = &\left(1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{2} - \frac{5(x-1)^4}{12} + \frac{(x-1)^5}{3} - \frac{19(x-1)^6}{72}\right) y(1) \\
&+ \left(x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{6} - \frac{(x-1)^5}{12} + \frac{(x-1)^6}{8}\right) y'(1) + O\left((x-1)^6\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = &\left(1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{2} - \frac{5(x-1)^4}{12} + \frac{(x-1)^5}{3} - \frac{19(x-1)^6}{72}\right) y(1) \\
&+ \left(x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{6} - \frac{(x-1)^5}{12} + \frac{(x-1)^6}{8}\right) y'(1) + O\left((x-1)^6\right)
\end{aligned} \quad (1)
$$

Verification of solutions

$$y = \left(1-\frac{(x-1)^2}{2}+\frac{(x-1)^3}{2}-\frac{5(x-1)^4}{12}+\frac{(x-1)^5}{3}-\frac{19(x-1)^6}{72}\right)y(1)$$
$$+\left(x-1-\frac{(x-1)^2}{2}+\frac{(x-1)^3}{6}-\frac{(x-1)^5}{12}+\frac{(x-1)^6}{8}\right)y'(1)+O\left((x-1)^6\right)$$

Verified OK.

14.15.1 Maple step by step solution

Let's solve

$y''x^2 + y'x + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y'}{x} - \frac{y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + \frac{y}{x^2} = 0$

- Multiply by denominators of the ODE

  $y''x^2 + y'x + y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right)t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

Substitute the change of variables back into the ODE

$$\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right)x^2 + \frac{d}{dt}y(t) + y(t) = 0$$

- Simplify

$$\frac{d^2}{dt^2}y(t) + y(t) = 0$$

- Characteristic polynomial of ODE

$$r^2 + 1 = 0$$

- Use quadratic formula to solve for r

$$r = \frac{0 \pm (\sqrt{-4})}{2}$$

- Roots of the characteristic polynomial

$$r = (-\mathrm{I}, \mathrm{I})$$

- 1st solution of the ODE

$$y_1(t) = \cos(t)$$

- 2nd solution of the ODE

$$y_2(t) = \sin(t)$$

- General solution of the ODE

$$y(t) = c_1 y_1(t) + c_2 y_2(t)$$

- Substitute in solutions

$$y(t) = c_1 \cos(t) + c_2 \sin(t)$$

- Change variables back using $t = \ln(x)$

$$y = c_1 \cos(\ln(x)) + c_2 \sin(\ln(x))$$

Problem number: 16.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second_order_change_of_variable_on_x_method_2", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^2y'' + 3y'x - y = 0}$$

With the expansion point for the power series method at $x = 1$.

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - 1$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\left(\frac{d^2}{dt^2}y(t)\right)(1+t)^2 + 3\left(\frac{d}{dt}y(t)\right)(1+t) - y(t) = 0$$

With its expansion point and initial conditions now at $t = 0$. The transformed ODE is now solved. Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left.\frac{d^n f}{dx^n}\right|_{x_0, y_0, y'_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (828) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (829) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} F_n|_{x_0,y_0,y_0'} \qquad (7)$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{3\left(\frac{d}{dt}y(t)\right)t + 3\frac{d}{dt}y(t) - y(t)}{(1+t)^2} \\
F_1 &= \frac{dF_0}{dt} \\
&= \frac{\partial F_0}{\partial t} + \frac{\partial F_0}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_0}{\partial \frac{d}{dt}y\left(t\right)}F_0 \\
&= \frac{13\left(\frac{d}{dt}y(t)\right)(1+t) - 5y(t)}{(1+t)^3} \\
F_2 &= \frac{dF_1}{dt} \\
&= \frac{\partial F_1}{\partial t} + \frac{\partial F_1}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_1}{\partial \frac{d}{dt}y\left(t\right)}F_1 \\
&= \frac{(-70t - 70)\left(\frac{d}{dt}y(t)\right) + 28y(t)}{(1+t)^4} \\
F_3 &= \frac{dF_2}{dt} \\
&= \frac{\partial F_2}{\partial t} + \frac{\partial F_2}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_2}{\partial \frac{d}{dt}y\left(t\right)}F_2 \\
&= \frac{(448t + 448)\left(\frac{d}{dt}y(t)\right) - 182y(t)}{(1+t)^5} \\
F_4 &= \frac{dF_3}{dt} \\
&= \frac{\partial F_3}{\partial t} + \frac{\partial F_3}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_3}{\partial \frac{d}{dt}y\left(t\right)}F_3 \\
&= \frac{(-3318t - 3318)\left(\frac{d}{dt}y(t)\right) + 1358y(t)}{(1+t)^6}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $t = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= y(0) - 3y'(0) \\
F_1 &= -5y(0) + 13y'(0) \\
F_2 &= 28y(0) - 70y'(0) \\
F_3 &= -182y(0) + 448y'(0) \\
F_4 &= 1358y(0) - 3318y'(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y(t) = &\left(1+\frac{1}{2}t^2-\frac{5}{6}t^3+\frac{7}{6}t^4-\frac{91}{60}t^5+\frac{679}{360}t^6\right)y(0)\\
&+\left(t-\frac{3}{2}t^2+\frac{13}{6}t^3-\frac{35}{12}t^4+\frac{56}{15}t^5-\frac{553}{120}t^6\right)y'(0)+O(t^6)
\end{aligned}
$$

Since the expansion point $t = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$
(t^2+2t+1)\left(\frac{d^2}{dt^2}y(t)\right)+(3t+3)\left(\frac{d}{dt}y(t)\right)-y(t)=0
$$

Let the solution be represented as power series of the form

$$
y(t)=\sum_{n=0}^{\infty}a_n t^n
$$

Then

$$
\begin{aligned}
\frac{d}{dt}y(t) &= \sum_{n=1}^{\infty}n a_n t^{n-1}\\
\frac{d^2}{dt^2}y(t) &= \sum_{n=2}^{\infty}n(n-1)\,a_n t^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
(t^2+2t+1)\left(\sum_{n=2}^{\infty}n(n-1)\,a_n t^{n-2}\right)+(3t+3)\left(\sum_{n=1}^{\infty}n a_n t^{n-1}\right)-\left(\sum_{n=0}^{\infty}a_n t^n\right)=0 \quad (1)
$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=2}^{\infty}t^n a_n n(n-1)\right)+\left(\sum_{n=2}^{\infty}2n\,t^{n-1}a_n(n-1)\right)+\left(\sum_{n=2}^{\infty}n(n-1)\,a_n t^{n-2}\right)\\
&+\left(\sum_{n=1}^{\infty}3n a_n t^n\right)+\left(\sum_{n=1}^{\infty}3n a_n t^{n-1}\right)+\sum_{n=0}^{\infty}(-a_n t^n)=0
\end{aligned} \quad (2)
$$

The next step is to make all powers of t be n in each summation term. Going over each summation term above with power of t in it which is not already t^n and adjusting the

power and the corresponding index gives

$$\sum_{n=2}^{\infty} 2n\, t^{n-1} a_n (n-1) = \sum_{n=1}^{\infty} 2(n+1)\, a_{n+1} n\, t^{n}$$

$$\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2} (n+1)\, t^{n}$$

$$\sum_{n=1}^{\infty} 3n a_n t^{n-1} = \sum_{n=0}^{\infty} 3(n+1)\, a_{n+1} t^{n}$$

Substituting all the above in Eq (2) gives the following equation where now all powers of t are the same and equal to n.

$$\left(\sum_{n=2}^{\infty} t^n a_n n(n-1)\right) + \left(\sum_{n=1}^{\infty} 2(n+1)\, a_{n+1} n\, t^n\right) + \left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2} (n+1)\, t^n\right) + \left(\sum_{n=1}^{\infty} 3n a_n t^n\right) + \left(\sum_{n=0}^{\infty} 3(n+1)\, a_{n+1} t^n\right) + \sum_{n=0}^{\infty} (-a_n t^n) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + 3a_1 - a_0 = 0$$

$$a_2 = \frac{a_0}{2} - \frac{3a_1}{2}$$

$n = 1$ gives

$$10a_2 + 6a_3 + 2a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -\frac{5a_0}{6} + \frac{13a_1}{6}$$

For $2 \leq n$, the recurrence equation is

$$n a_n (n-1) + 2(n+1)\, a_{n+1} n + (n+2)\, a_{n+2} (n+1) + 3n a_n + 3(n+1)\, a_{n+1} - a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$
\begin{aligned}
a_{n+2} &= -\frac{n^2 a_n + 2n^2 a_{n+1} + 2n a_n + 5n a_{n+1} - a_n + 3a_{n+1}}{(n+2)(n+1)} \\
&= -\frac{(n^2+2n-1) a_n}{(n+2)(n+1)} - \frac{(2n^2+5n+3) a_{n+1}}{(n+2)(n+1)}
\end{aligned} \tag{5}
$$

For $n = 2$ the recurrence equation gives

$$7a_2 + 21a_3 + 12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{7a_0}{6} - \frac{35a_1}{12}$$

For $n = 3$ the recurrence equation gives

$$14a_3 + 36a_4 + 20a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{91a_0}{60} + \frac{56a_1}{15}$$

For $n = 4$ the recurrence equation gives

$$23a_4 + 55a_5 + 30a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{679a_0}{360} - \frac{553a_1}{120}$$

For $n = 5$ the recurrence equation gives

$$34a_5 + 78a_6 + 42a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{91a_0}{40} + \frac{1993a_1}{360}$$

And so on. Therefore the solution is

$$\begin{aligned}y(t) &= \sum_{n=0}^{\infty} a_n t^n \\ &= a_3 t^3 + a_2 t^2 + a_1 t + a_0 + \dots\end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned}y(t) = a_0 + a_1 t + \left(\frac{a_0}{2} - \frac{3a_1}{2}\right) t^2 + \left(-\frac{5a_0}{6} + \frac{13a_1}{6}\right) t^3 \\ + \left(\frac{7a_0}{6} - \frac{35a_1}{12}\right) t^4 + \left(-\frac{91a_0}{60} + \frac{56a_1}{15}\right) t^5 + \dots\end{aligned}$$

Collecting terms, the solution becomes

$$y(t) = \left(1 + \frac{1}{2}t^2 - \frac{5}{6}t^3 + \frac{7}{6}t^4 - \frac{91}{60}t^5\right) a_0 + \left(t - \frac{3}{2}t^2 + \frac{13}{6}t^3 - \frac{35}{12}t^4 + \frac{56}{15}t^5\right) a_1 + O(t^6) \quad (3)$$

At $t = 0$ the solution above becomes

$$y(t) = \left(1 + \frac{1}{2}t^2 - \frac{5}{6}t^3 + \frac{7}{6}t^4 - \frac{91}{60}t^5\right) c_1 + \left(t - \frac{3}{2}t^2 + \frac{13}{6}t^3 - \frac{35}{12}t^4 + \frac{56}{15}t^5\right) c_2 + O(t^6)$$

Replacing t in the above with the original independent variable $x$using $t = x-1$ results in

$$\begin{aligned}y = &\left(1 + \frac{(x-1)^2}{2} - \frac{5(x-1)^3}{6} + \frac{7(x-1)^4}{6} - \frac{91(x-1)^5}{60} + \frac{679(x-1)^6}{360}\right) y(1) \\ &+ \left(x - 1 - \frac{3(x-1)^2}{2} + \frac{13(x-1)^3}{6} - \frac{35(x-1)^4}{12} + \frac{56(x-1)^5}{15} - \frac{553(x-1)^6}{120}\right) y'(1) \\ &+ O\left((x-1)^6\right)\end{aligned}$$

<u>Summary</u>

The solution(s) found are the following

$$\begin{aligned}y = &\left(1 + \frac{(x-1)^2}{2} - \frac{5(x-1)^3}{6} + \frac{7(x-1)^4}{6} - \frac{91(x-1)^5}{60} + \frac{679(x-1)^6}{360}\right) y(1) \\ &+ \left(x - 1 - \frac{3(x-1)^2}{2} + \frac{13(x-1)^3}{6} - \frac{35(x-1)^4}{12} + \frac{56(x-1)^5}{15} \right. \\ &\left. - \frac{553(x-1)^6}{120}\right) y'(1) + O\left((x-1)^6\right)\end{aligned} \quad (1)$$

Verification of solutions

$$y = \left(1+\frac{(x-1)^{2}}{2}-\frac{5(x-1)^{3}}{6}+\frac{7(x-1)^{4}}{6}-\frac{91(x-1)^{5}}{60}+\frac{679(x-1)^{6}}{360}\right) y(1) + \left(x-1-\frac{3(x-1)^{2}}{2}+\frac{13(x-1)^{3}}{6}-\frac{35(x-1)^{4}}{12}+\frac{56(x-1)^{5}}{15}-\frac{553(x-1)^{6}}{120}\right) y'(1) + O\left((x-1)^{6}\right)$$

Verified OK.

14.16.1 Maple step by step solution

Let's solve

$y''x^2+3y'x-y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{3y'}{x}+\frac{y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{3y'}{x}-\frac{y}{x^2}=0$

- Multiply by denominators of the ODE

  $y''x^2+3y'x-y=0$

- Make a change of variables

  $t=\ln(x)$

□ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

    $y'=\left(\frac{d}{dt}y(t)\right)t'(x)$

  ◦ Compute derivative

    $y'=\frac{\frac{d}{dt}y(t)}{x}$

  ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y''=\left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2+t''(x)\left(\frac{d}{dt}y(t)\right)$

  ◦ Compute derivative

$y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

Substitute the change of variables back into the ODE

$\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right)x^2 + 3\frac{d}{dt}y(t) - y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) + 2\frac{d}{dt}y(t) - y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 + 2r - 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-2)\pm\left(\sqrt{8}\right)}{2}$

- Roots of the characteristic polynomial

  $r = \left(-\sqrt{2} - 1, \sqrt{2} - 1\right)$

- 1st solution of the ODE

  $y_1(t) = \mathrm{e}^{\left(-\sqrt{2}-1\right)t}$

- 2nd solution of the ODE

  $y_2(t) = \mathrm{e}^{\left(\sqrt{2}-1\right)t}$

- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$

- Substitute in solutions

  $y(t) = c_1 \mathrm{e}^{\left(-\sqrt{2}-1\right)t} + c_2 \mathrm{e}^{\left(\sqrt{2}-1\right)t}$

- Change variables back using $t = \ln(x)$

  $y = c_1 \mathrm{e}^{\left(-\sqrt{2}-1\right)\ln(x)} + c_2 \mathrm{e}^{\left(\sqrt{2}-1\right)\ln(x)}$

- Simplify

  $y = \frac{c_1 x^{-\sqrt{2}}}{x} + \frac{c_2 x^{\sqrt{2}}}{x}$

Problem number: 17.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{xy'' + y' + 2y = 0}$$

With initial conditions

$$[y(1) = 2, y'(1) = 4]$$

With the expansion point for the power series method at $x = 1$.

14.17.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{2}{x}$$
$$F = 0$$

Hence the ode is

$$y'' + \frac{y'}{x} + \frac{2y}{x} = 0$$

The domain of $p(x) = \frac{1}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $q(x) = \frac{2}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - 1$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\left(\frac{d^2}{dt^2}y(t)\right)(1+t) + \frac{d}{dt}y(t) + 2y(t) = 0$$

With its expansion point and initial conditions now at $t = 0$. With initial conditions now becoming

$$\begin{aligned} y(0) &= 2 \\ y'(0) &= 4 \end{aligned}$$

The transformed ODE is now solved. Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (831) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (832) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') \qquad (4)\\
F_1 &= \frac{df}{dx} \\
&= \frac{dF_0}{dx} \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right) \\
&= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y'' \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0 \\
&\vdots \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y'' \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{\frac{d}{dt}y(t)+2y(t)}{1+t} \\
F_1 &= \frac{dF_0}{dt} \\
&= \frac{\partial F_0}{\partial t}+\frac{\partial F_0}{\partial y}\frac{d}{dt}y(t)+\frac{\partial F_0}{\partial \frac{d}{dt}y\left(t\right)}F_0 \\
&= \frac{-2\left(\frac{d}{dt}y(t)\right)t+4y(t)}{\left(1+t\right)^2} \\
F_2 &= \frac{dF_1}{dt} \\
&= \frac{\partial F_1}{\partial t}+\frac{\partial F_1}{\partial y}\frac{d}{dt}y(t)+\frac{\partial F_1}{\partial \frac{d}{dt}y\left(t\right)}F_1 \\
&= \frac{(8t+2)\left(\frac{d}{dt}y(t)\right)+4y(t)\left(-2+t\right)}{\left(1+t\right)^3} \\
F_3 &= \frac{dF_2}{dt} \\
&= \frac{\partial F_2}{\partial t}+\frac{\partial F_2}{\partial y}\frac{d}{dt}y(t)+\frac{\partial F_2}{\partial \frac{d}{dt}y\left(t\right)}F_2 \\
&= \frac{(4t^2-28t-8)\left(\frac{d}{dt}y(t)\right)-24y(t)\left(t-1\right)}{\left(1+t\right)^4} \\
F_4 &= \frac{dF_3}{dt} \\
&= \frac{\partial F_3}{\partial t}+\frac{\partial F_3}{\partial y}\frac{d}{dt}y(t)+\frac{\partial F_3}{\partial \frac{d}{dt}y\left(t\right)}F_3 \\
&= \frac{(-36t^2+120t+36)\left(\frac{d}{dt}y(t)\right)-8y(t)\left(t^2-16t+13\right)}{\left(1+t\right)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $t=0$ and $y(0)=2$ and $y'(0)=4$ gives

$$
\begin{aligned}
F_0 &= -8 \\
F_1 &= 8 \\
F_2 &= -8 \\
F_3 &= 16 \\
F_4 &= -64
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$y(t) = -4t^2 + 4t + 2 + \frac{4t^3}{3} - \frac{t^4}{3} + \frac{2t^5}{15} - \frac{4t^6}{45} + O(t^6)$$

$$y(t) = -4t^2 + 4t + 2 + \frac{4t^3}{3} - \frac{t^4}{3} + \frac{2t^5}{15} - \frac{4t^6}{45} + O(t^6)$$

Since the expansion point $t = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$\left(\frac{d^2}{dt^2}y(t)\right)(1+t) + \frac{d}{dt}y(t) + 2y(t) = 0$$

Let the solution be represented as power series of the form

$$y(t) = \sum_{n=0}^{\infty} a_n t^n$$

Then

$$\frac{d}{dt}y(t) = \sum_{n=1}^{\infty} n a_n t^{n-1}$$
$$\frac{d^2}{dt^2}y(t) = \sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}\right)(1+t) + \left(\sum_{n=1}^{\infty} n a_n t^{n-1}\right) + 2\left(\sum_{n=0}^{\infty} a_n t^n\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n\, t^{n-1} a_n (n-1)\right) + \left(\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}\right) + \left(\sum_{n=1}^{\infty} n a_n t^{n-1}\right) + \left(\sum_{n=0}^{\infty} 2a_n t^n\right) = 0 \tag{2}$$

The next step is to make all powers of t be n in each summation term. Going over each summation term above with power of t in it which is not already t^n and adjusting the

power and the corresponding index gives

$$\sum_{n=2}^{\infty} n\, t^{n-1} a_n (n-1) = \sum_{n=1}^{\infty} (n+1)\, a_{n+1} n\, t^n$$

$$\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2} (n+1)\, t^n$$

$$\sum_{n=1}^{\infty} n a_n t^{n-1} = \sum_{n=0}^{\infty} (n+1)\, a_{n+1} t^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of t are the same and equal to n.

$$\left(\sum_{n=1}^{\infty} (n+1)\, a_{n+1} n\, t^n\right) + \left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2} (n+1)\, t^n\right) + \left(\sum_{n=0}^{\infty} (n+1)\, a_{n+1} t^n\right) + \left(\sum_{n=0}^{\infty} 2 a_n t^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + a_1 + 2a_0 = 0$$

$$a_2 = -a_0 - \frac{a_1}{2}$$

For $1 \leq n$, the recurrence equation is

$$(n+1)\, a_{n+1} n + (n+2)\, a_{n+2} (n+1) + (n+1)\, a_{n+1} + 2a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{n^2 a_{n+1} + 2n a_{n+1} + 2a_n + a_{n+1}}{(n+2)\,(n+1)} \\ &= -\frac{2a_n}{(n+2)\,(n+1)} - \frac{(n^2+2n+1)\, a_{n+1}}{(n+2)\,(n+1)} \end{aligned} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$4a_2 + 6a_3 + 2a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{2a_0}{3}$$

For $n = 2$ the recurrence equation gives

$$9a_3 + 12a_4 + 2a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{a_0}{3} + \frac{a_1}{12}$$

For $n = 3$ the recurrence equation gives

$$16a_4 + 20a_5 + 2a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_0}{5} - \frac{a_1}{15}$$

For $n = 4$ the recurrence equation gives

$$25a_5 + 30a_6 + 2a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{13a_0}{90} + \frac{a_1}{20}$$

For $n = 5$ the recurrence equation gives

$$36a_6 + 42a_7 + 2a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{4a_0}{35} - \frac{5a_1}{126}$$

And so on. Therefore the solution is

$$
\begin{aligned}
y(t) &= \sum_{n=0}^{\infty} a_n t^n \\
&= a_3 t^3 + a_2 t^2 + a_1 t + a_0 + \dots
\end{aligned}
$$

Substituting the values for a_n found above, the solution becomes

$$
y(t) = a_0 + a_1 t + \left(-a_0 - \frac{a_1}{2}\right) t^2 + \frac{2a_0 t^3}{3} + \left(-\frac{a_0}{3} + \frac{a_1}{12}\right) t^4 + \left(\frac{a_0}{5} - \frac{a_1}{15}\right) t^5 + \dots
$$

Collecting terms, the solution becomes

$$
y(t) = \left(1 - t^2 + \frac{2}{3}t^3 - \frac{1}{3}t^4 + \frac{1}{5}t^5\right) a_0 + \left(t - \frac{1}{2}t^2 + \frac{1}{12}t^4 - \frac{1}{15}t^5\right) a_1 + O(t^6) \quad (3)
$$

At $t = 0$ the solution above becomes

$$
y(t) = \left(1 - t^2 + \frac{2}{3}t^3 - \frac{1}{3}t^4 + \frac{1}{5}t^5\right) c_1 + \left(t - \frac{1}{2}t^2 + \frac{1}{12}t^4 - \frac{1}{15}t^5\right) c_2 + O(t^6)
$$

$$
y(t) = 2 - 4t^2 + \frac{4t^3}{3} - \frac{t^4}{3} + \frac{2t^5}{15} + 4t + O(t^6)
$$

Replacing t in the above with the original independent variable $x$using $t = x - 1$ results in

$$
y = -4(x-1)^2 + 4x - 2 + \frac{4(x-1)^3}{3} - \frac{(x-1)^4}{3} + \frac{2(x-1)^5}{15} - \frac{4(x-1)^6}{45} + O\left((x-1)^6\right)
$$

Summary

The solution(s) found are the following

$$
y = -4(x-1)^2 + 4x - 2 + \frac{4(x-1)^3}{3} - \frac{(x-1)^4}{3} + \frac{2(x-1)^5}{15} - \frac{4(x-1)^6}{45} + O\left((x-1)^6\right) \quad (1)
$$

Verification of solutions

$$
y = -4(x-1)^2 + 4x - 2 + \frac{4(x-1)^3}{3} - \frac{(x-1)^4}{3} + \frac{2(x-1)^5}{15} - \frac{4(x-1)^6}{45} + O\left((x-1)^6\right)
$$

Verified OK.

14.17.2 Maple step by step solution

Let's solve

$$\left[y''x+y'+2y=0, y(1)=2, y'\Big|_{\{x=1\}}=4\right]$$

- Highest derivative means the order of the ODE is 2

y''

- Isolate 2nd derivative

$y''=-\frac{2y}{x}-\frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y''+\frac{y'}{x}+\frac{2y}{x}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{1}{x}, P_3(x)=\frac{2}{x}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $(x\cdot P_2(x))\Big|_{x=0}=1$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $(x^2\cdot P_3(x))\Big|_{x=0}=0$

  ◦ $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

$y''x+y'+2y=0$

- Assume series solution for y

$y=\sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert y' to series expansion

  $y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1}$

- Shift index using $k->k+1$

  $$y' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, x^{k+r}$$

- Convert $x \cdot y''$ to series expansion

  $$x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$$

- Shift index using $k->k+1$

  $$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0 r^2 x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)^2 + 2a_k\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$r^2 = 0$$

- Values of r that satisfy the indicial equation

  $$r = 0$$

- Each term in the series must be 0, giving the recursion relation

  $$a_{k+1}(k+1)^2 + 2a_k = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+1} = -\frac{2a_k}{(k+1)^2}$$

- Recursion relation for $r = 0$

  $$a_{k+1} = -\frac{2a_k}{(k+1)^2}$$

- Solution for $r = 0$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = -\frac{2a_k}{(k+1)^2}\right]$$

Section: Chapter 6, Series solutions of linear differential equations. Section 6.1. Exercises page 232
Problem number: 18.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

`[_Gegenbauer]`

$$\boxed{\left(-x^{2}+1\right) y''-2y'x+n(n+1)\, y=0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y_0'$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0,y_0,y_0'} + \frac{x^3}{3!} f'|_{x_0,y_0,y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left.\frac{d^n f}{dx^n}\right|_{x_0,y_0,y_0'}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (834)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (835)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3)\\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}F_n|_{x_0,y_0,y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= \frac{yn^2 + yn - 2y'x}{x^2 - 1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{(n^2x^2 + n\,x^2 - n^2 + 6x^2 - n + 2)\,y' - 4ynx(n+1)}{(x^2-1)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{(x-1)\,(-8((n^2+n+3)\,x^2 - n^2 - n + 3)\,xy' + yn(n+1)\,((n^2+n+18)\,x^2 - n^2 - n + 6))\,(x+1)}{(x^2-1)^4} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{(((n^4 + 2n^3 + 59n^2 + 58n + 120)\,x^4 + (-2n^4 - 4n^3 - 46n^2 - 44n + 240)\,x^2 + n^4 + 2n^3 - 13n^2 - 1}{(x^2-1)^5} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{\left(-18\left(\left(n^4 + 2n^3 + \frac{77}{3}n^2 + \frac{74}{3}n + 40\right)x^4 - 2(n^2+n+10)\left(n^2+n-\frac{20}{3}\right)x^2 + n^4 + 2n^3 - 17n^2 - 18n\right.\right.}{}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -y(0)\,n(n+1) \\
F_1 &= -y'(0)\,n^2 - y'(0)\,n + 2y'(0) \\
F_2 &= y(0)\,n^4 + 2y(0)\,n^3 - 5y(0)\,n^2 - 6y(0)\,n \\
F_3 &= y'(0)\,n^4 + 2y'(0)\,n^3 - 13y'(0)\,n^2 - 14y'(0)\,n + 24y'(0) \\
F_4 &= -y(0)\,n^6 - 3y(0)\,n^5 + 23y(0)\,n^4 + 51y(0)\,n^3 - 94y(0)\,n^2 - 120y(0)\,n
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = \left(1-\frac{1}{2}n^{2}x^{2}-\frac{1}{2}n\,x^{2}+\frac{1}{24}n^{4}x^{4}+\frac{1}{12}x^{4}n^{3}-\frac{5}{24}n^{2}x^{4}-\frac{1}{4}n\,x^{4}-\frac{1}{720}x^{6}n^{6}-\frac{1}{240}n^{5}x^{6}\right.$$
$$\left.+\frac{23}{720}n^{4}x^{6}+\frac{17}{240}n^{3}x^{6}-\frac{47}{360}n^{2}x^{6}-\frac{1}{6}x^{6}n\right) y(0)$$
$$+\left(x-\frac{1}{6}n^{2}x^{3}-\frac{1}{6}n\,x^{3}+\frac{1}{3}x^{3}+\frac{1}{120}x^{5}n^{4}+\frac{1}{60}x^{5}n^{3}-\frac{13}{120}x^{5}n^{2}-\frac{7}{60}x^{5}n+\frac{1}{5}x^{5}\right) y'(0)$$
$$+O\left(x^{6}\right)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$\left(-x^{2}+1\right) y''-2y'x+\left(n^{2}+n\right) y = 0$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_{n} x^{n}$$

Then

$$y' = \sum_{n=1}^{\infty} n a_{n} x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_{n} x^{n-2}$$

Substituting the above back into the ode gives

$$\left(-x^{2}+1\right)\left(\sum_{n=2}^{\infty} n(n-1)\, a_{n} x^{n-2}\right)-2\left(\sum_{n=1}^{\infty} n a_{n} x^{n-1}\right) x+\left(n^{2}+n\right)\left(\sum_{n=0}^{\infty} a_{n} x^{n}\right) = 0 \tag{1}$$

Which simplifies to

$$\sum_{n=2}^{\infty}\left(-x^{n} a_{n} n(n-1)\right)+\left(\sum_{n=2}^{\infty} n(n-1)\, a_{n} x^{n-2}\right) \tag{2}$$
$$+\sum_{n=1}^{\infty}\left(-2n a_{n} x^{n}\right)+\left(\sum_{n=0}^{\infty}\left(n^{2}+n\right) a_{n} x^{n}\right) = 0$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\sum_{n=2}^{\infty} \left(-x^n a_n n(n-1)\right) + \left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \sum_{n=1}^{\infty} \left(-2n a_n x^n\right) + \left(\sum_{n=0}^{\infty} \left(n^2+n\right) a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + a_0 n(n+1) = 0$$

$$a_2 = -\frac{1}{2} a_0 n^2 - \frac{1}{2} a_0 n$$

$n = 1$ gives

$$6a_3 - 2a_1 + a_1 n(n+1) = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -\frac{1}{6} a_1 n^2 - \frac{1}{6} a_1 n + \frac{1}{3} a_1$$

For $2 \leq n$, the recurrence equation is

$$-n a_n (n-1) + (n+2)\, a_{n+2}(n+1) - 2n a_n + a_n n(n+1) = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{a_n \left(n^2 - n^2 + n - n\right)}{(n+2)\,(n+1)} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$-6a_2 + 12a_4 + a_2 n(n+1) = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{5}{24}a_0 n^2 - \frac{1}{4}a_0 n + \frac{1}{24}a_0 n^4 + \frac{1}{12}a_0 n^3$$

For $n = 3$ the recurrence equation gives

$$-12a_3 + 20a_5 + a_3 n(n+1) = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{13}{120}a_1 n^2 - \frac{7}{60}a_1 n + \frac{1}{5}a_1 + \frac{1}{120}a_1 n^4 + \frac{1}{60}a_1 n^3$$

For $n = 4$ the recurrence equation gives

$$-20a_4 + 30a_6 + a_4 n(n+1) = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{47}{360}a_0 n^2 - \frac{1}{6}a_0 n + \frac{23}{720}a_0 n^4 + \frac{17}{240}a_0 n^3 - \frac{1}{720}a_0 n^6 - \frac{1}{240}a_0 n^5$$

For $n = 5$ the recurrence equation gives

$$-30a_5 + 42a_7 + a_5 n(n+1) = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{5}{63}a_1 n^2 - \frac{37}{420}a_1 n + \frac{1}{7}a_1 + \frac{41}{5040}a_1 n^4 + \frac{29}{1680}a_1 n^3 - \frac{1}{5040}a_1 n^6 - \frac{1}{1680}a_1 n^5$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$
\begin{aligned}
y = {} & a_0 + a_1 x + \left(-\frac{1}{2} a_0 n^2 - \frac{1}{2} a_0 n\right) x^2 + \left(-\frac{1}{6} a_1 n^2 - \frac{1}{6} a_1 n + \frac{1}{3} a_1\right) x^3 \\
& + \left(-\frac{5}{24} a_0 n^2 - \frac{1}{4} a_0 n + \frac{1}{24} a_0 n^4 + \frac{1}{12} a_0 n^3\right) x^4 \\
& + \left(-\frac{13}{120} a_1 n^2 - \frac{7}{60} a_1 n + \frac{1}{5} a_1 + \frac{1}{120} a_1 n^4 + \frac{1}{60} a_1 n^3\right) x^5 + \dots
\end{aligned}
$$

Collecting terms, the solution becomes

$$
\begin{aligned}
y = {} & \left(1 + \left(-\frac{1}{2} n^2 - \frac{1}{2} n\right) x^2 + \left(-\frac{5}{24} n^2 - \frac{1}{4} n + \frac{1}{24} n^4 + \frac{1}{12} n^3\right) x^4\right) a_0 \\
& + \left(x + \left(-\frac{1}{6} n^2 - \frac{1}{6} n + \frac{1}{3}\right) x^3 + \left(-\frac{13}{120} n^2 - \frac{7}{60} n + \frac{1}{5} + \frac{1}{120} n^4 + \frac{1}{60} n^3\right) x^5\right) a_1 + O\left(x^6\right)
\end{aligned}
\tag{3}
$$

At $x = 0$ the solution above becomes

$$
\begin{aligned}
y = {} & \left(1 + \left(-\frac{1}{2} n^2 - \frac{1}{2} n\right) x^2 + \left(-\frac{5}{24} n^2 - \frac{1}{4} n + \frac{1}{24} n^4 + \frac{1}{12} n^3\right) x^4\right) c_1 \\
& + \left(x + \left(-\frac{1}{6} n^2 - \frac{1}{6} n + \frac{1}{3}\right) x^3 + \left(-\frac{13}{120} n^2 - \frac{7}{60} n + \frac{1}{5} + \frac{1}{120} n^4 + \frac{1}{60} n^3\right) x^5\right) c_2 + O\left(x^6\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & \left(1 - \frac{1}{2} n^2 x^2 - \frac{1}{2} n\, x^2 + \frac{1}{24} n^4 x^4 + \frac{1}{12} x^4 n^3 - \frac{5}{24} n^2 x^4 - \frac{1}{4} n\, x^4 - \frac{1}{720} x^6 n^6 - \frac{1}{240} n^5 x^6 \right. \\
& \left. + \frac{23}{720} n^4 x^6 + \frac{17}{240} n^3 x^6 - \frac{47}{360} n^2 x^6 - \frac{1}{6} x^6 n\right) y(0) + \left(x - \frac{1}{6} n^2 x^3 - \frac{1}{6} n\, x^3 + \frac{1}{3} x^3 \right. \\
& \left. + \frac{1}{120} x^5 n^4 + \frac{1}{60} x^5 n^3 - \frac{13}{120} x^5 n^2 - \frac{7}{60} x^5 n + \frac{1}{5} x^5\right) y'(0) + O\left(x^6\right)
\end{aligned}
\tag{1}
$$

$$
\begin{aligned}
y = {} & \left(1 + \left(-\frac{1}{2} n^2 - \frac{1}{2} n\right) x^2 + \left(-\frac{5}{24} n^2 - \frac{1}{4} n + \frac{1}{24} n^4 + \frac{1}{12} n^3\right) x^4\right) c_1 \\
& + \left(x + \left(-\frac{1}{6} n^2 - \frac{1}{6} n + \frac{1}{3}\right) x^3 + \left(-\frac{13}{120} n^2 - \frac{7}{60} n + \frac{1}{5} + \frac{1}{120} n^4 + \frac{1}{60} n^3\right) x^5\right) c_2 \\
& + O\left(x^6\right)
\end{aligned}
\tag{2}
$$

Verification of solutions

$$y = \left(1-\frac{1}{2}n^{2}x^{2}-\frac{1}{2}n\,x^{2}+\frac{1}{24}n^{4}x^{4}+\frac{1}{12}x^{4}n^{3}-\frac{5}{24}n^{2}x^{4}-\frac{1}{4}n\,x^{4}-\frac{1}{720}x^{6}n^{6}-\frac{1}{240}n^{5}x^{6}+\frac{23}{720}n^{4}x^{6}+\frac{17}{240}n^{3}x^{6}-\frac{47}{360}n^{2}x^{6}-\frac{1}{6}x^{6}n\right)y(0)+\left(x-\frac{1}{6}n^{2}x^{3}-\frac{1}{6}n\,x^{3}+\frac{1}{3}x^{3}+\frac{1}{120}x^{5}n^{4}+\frac{1}{60}x^{5}n^{3}-\frac{13}{120}x^{5}n^{2}-\frac{7}{60}x^{5}n+\frac{1}{5}x^{5}\right)y'(0)+O(x^{6})$$

Verified OK.

$$y = \left(1+\left(-\frac{1}{2}n^{2}-\frac{1}{2}n\right)x^{2}+\left(-\frac{5}{24}n^{2}-\frac{1}{4}n+\frac{1}{24}n^{4}+\frac{1}{12}n^{3}\right)x^{4}\right)c_{1}+\left(x+\left(-\frac{1}{6}n^{2}-\frac{1}{6}n+\frac{1}{3}\right)x^{3}+\left(-\frac{13}{120}n^{2}-\frac{7}{60}n+\frac{1}{5}+\frac{1}{120}n^{4}+\frac{1}{60}n^{3}\right)x^{5}\right)c_{2}+O(x^{6})$$

Verified OK.

14.18.1 Maple step by step solution

Let's solve

$(-x^{2}+1)\,y''-2y'x+(n^{2}+n)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{n(n+1)y}{x^{2}-1}-\frac{2xy'}{x^{2}-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{2xy'}{x^{2}-1}-\frac{n(n+1)y}{x^{2}-1}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_{2}(x)=\frac{2x}{x^{2}-1}, P_{3}(x)=-\frac{n(n+1)}{x^{2}-1}\right]$

- ◦ $(x+1)\cdot P_{2}(x)$ is analytic at $x=-1$

  $\left((x+1)\cdot P_{2}(x)\right)\Big|_{x=-1}=1$

- ◦ $(x+1)^{2}\cdot P_{3}(x)$ is analytic at $x=-1$

$$\left(\left(x+1\right)^{2}\cdot P_{3}(x)\right)\bigg|_{x=-1}=0$$

- $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-1$

- Multiply by denominators

  $y''(x^{2}-1)+2y'x-n(n+1)\,y=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(u^{2}-2u)\left(\frac{d^{2}}{du^{2}}y(u)\right)+(2u-2)\left(\frac{d}{du}y(u)\right)+(-n^{2}-n)\,y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_{k}u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^{m}\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^{m}\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_{k}(k+r)\,u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^{m}\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- Convert $u^{m}\cdot\left(\frac{d^{2}}{du^{2}}y(u)\right)$ to series expansion for $m=1..2$

  $u^{m}\cdot\left(\frac{d^{2}}{du^{2}}y(u)\right)=\sum_{k=0}^{\infty}a_{k}(k+r)\,(k+r-1)\,u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^{m}\cdot\left(\frac{d^{2}}{du^{2}}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $-2a_{0}r^{2}u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-2a_{k+1}(k+1+r)^{2}+a_{k}(r+1+n+k)\,(r-n+k)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2r^{2}=0$

- Values of r that satisfy the indicial equation

$r = 0$

- Each term in the series must be 0, giving the recursion relation

  $-2a_{k+1}(k+1)^2 + a_k(1+n+k)(-n+k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(1+n+k)(-n+k)}{2(k+1)^2}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{a_k(1+n+k)(-n+k)}{2(k+1)^2}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k(1+n+k)(-n+k)}{2(k+1)^2}\right]$

- Revert the change of variables $u = x + 1$

  $\left[y = \sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+1} = \frac{a_k(1+n+k)(-n+k)}{2(k+1)^2}\right]$

Problem number: 1.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x^2 - 3x)\, y'' + (x + 2)\, y' + y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$(x^2 - 3x)\, y'' + (x + 2)\, y' + y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{x + 2}{x\,(x - 3)}$$
$$q(x) = \frac{1}{x\,(x - 3)}$$

Table 527: Table $p(x), q(x)$ singularites.

$p(x) = \frac{x+2}{x(x-3)}$	
singularity	type
$x = 0$	"regular"
$x = 3$	"regular"

$q(x) = \frac{1}{x(x-3)}$	
singularity	type
$x = 0$	"regular"
$x = 3$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, 3, \infty]$

Irregular singular points : $[]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$y''x(x-3) + (x+2)\,y' + y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}\right) x(x-3) + (x+2)\left(\sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-3x^{n+r-1} a_n(n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)\right) + \left(\sum_{n=0}^{\infty} 2(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1) = \sum_{n=1}^{\infty} a_{n-1}(n+r-1)(n+r-2)\, x^{n+r-1}$$

$$\sum_{n=0}^{\infty} x^{n+r} a_n(n+r) = \sum_{n=1}^{\infty} a_{n-1}(n+r-1)\, x^{n+r-1}$$

$$\sum_{n=0}^{\infty} a_n x^{n+r} = \sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1)(n+r-2)\, x^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-3x^{n+r-1} a_n(n+r)(n+r-1)\right) + \left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1)\, x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 2(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$-3x^{n+r-1} a_n(n+r)(n+r-1) + 2(n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$-3x^{-1+r} a_0 r(-1+r) + 2r a_0 x^{-1+r} = 0$$

Or

$$\left(-3x^{-1+r} r(-1+r)+2r\,x^{-1+r}\right) a_0=0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(-3r^2+5r\right) x^{-1+r}=0$$

Since the above is true for all x then the indicial equation becomes

$$-3r^2+5r=0$$

Solving for r gives the roots of the indicial equation as

$$r_1=\frac{5}{3}$$
$$r_2=0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(-3r^2+5r\right) x^{-1+r}=0$$

Solving for r gives the roots of the indicial equation as Since $r_1-r_2=\frac{5}{3}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x)=x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x)=x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x)=\sum_{n=0}^{\infty} a_n x^{n+\frac{5}{3}}$$
$$y_2(x)=\sum_{n=0}^{\infty} b_n x^n$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n=0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0=1$. For $1 \leq n$ the recursive equation is

$$\begin{aligned}&a_{n-1}(n+r-1)(n+r-2)-3a_n(n+r)(n+r-1)\\&+a_{n-1}(n+r-1)+2a_n(n+r)+a_{n-1}=0\end{aligned} \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}(n^2 + 2nr + r^2 - 2n - 2r + 2)}{3n^2 + 6nr + 3r^2 - 5n - 5r} \tag{4}$$

Which for the root $r = \frac{5}{3}$ becomes

$$a_n = \frac{a_{n-1}(9n^2 + 12n + 13)}{27n^2 + 45n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{5}{3}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{r^2 + 1}{3r^2 + r - 2}$$

Which for the root $r = \frac{5}{3}$ becomes

$$a_1 = \frac{17}{36}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r^2+1}{3r^2+r-2}$	$\frac{17}{36}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{(r^2 + 1)(r^2 + 2r + 2)}{9r^4 + 24r^3 + 7r^2 - 12r - 4}$$

Which for the root $r = \frac{5}{3}$ becomes

$$a_2 = \frac{1241}{7128}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r^2+1}{3r^2+r-2}$	$\frac{17}{36}$
a_2	$\frac{(r^2+1)(r^2+2r+2)}{9r^4+24r^3+7r^2-12r-4}$	$\frac{1241}{7128}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)}{27r^6+189r^5+441r^4+343r^3-84r^2-196r-48}$$

Which for the root $r = \frac{5}{3}$ becomes

$$a_3 = \frac{80665}{1347192}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r^2+1}{3r^2+r-2}$	$\frac{17}{36}$
a_2	$\frac{(r^2+1)(r^2+2r+2)}{9r^4+24r^3+7r^2-12r-4}$	$\frac{1241}{7128}$
a_3	$\frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)}{27r^6+189r^5+441r^4+343r^3-84r^2-196r-48}$	$\frac{80665}{1347192}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}{81r^8+1080r^7+5670r^6+14700r^5+18613r^4+7420r^3-6220r^2-6400r-1344}$$

Which for the root $r = \frac{5}{3}$ becomes

$$a_4 = \frac{972725}{48498912}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r^2+1}{3r^2+r-2}$	$\frac{17}{36}$
a_2	$\frac{(r^2+1)(r^2+2r+2)}{9r^4+24r^3+7r^2-12r-4}$	$\frac{1241}{7128}$
a_3	$\frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)}{27r^6+189r^5+441r^4+343r^3-84r^2-196r-48}$	$\frac{80665}{1347192}$
a_4	$\frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}{81r^8+1080r^7+5670r^6+14700r^5+18613r^4+7420r^3-6220r^2-6400r-1344}$	$\frac{972725}{48498912}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}{(81r^8+1080r^7+5670r^6+14700r^5+18613r^4+7420r^3-6220r^2-6400r-1344)(3r^2+25r+50)}$$

Which for the root $r = \frac{5}{3}$ becomes

$$a_5 = \frac{5797441}{872980416}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r^2+1}{3r^2+r-2}$	$\frac{17}{36}$
a_2	$\frac{(r^2+1)(r^2+2r+2)}{9r^4+24r^3+7r^2-12r-4}$	$\frac{1241}{7128}$
a_3	$\frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)}{27r^6+189r^5+441r^4+343r^3-84r^2-196r-48}$	$\frac{80665}{1347192}$
a_4	$\frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}{81r^8+1080r^7+5670r^6+14700r^5+18613r^4+7420r^3-6220r^2-6400r-1344}$	$\frac{972725}{48498912}$
a_5	$\frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}{(81r^8+1080r^7+5670r^6+14700r^5+18613r^4+7420r^3-6220r^2-6400r-1344)(3r^2+25r+50)}$	$\frac{5797441}{872980416}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{5}{3}}\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots\right) \\ &= x^{\frac{5}{3}}\left(1 + \frac{17x}{36} + \frac{1241x^2}{7128} + \frac{80665x^3}{1347192} + \frac{972725x^4}{48498912} + \frac{5797441x^5}{872980416} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$\begin{aligned} b_{n-1}(n+r-1)(n+r-2) - 3b_n(n+r)(n+r-1) \\ + b_{n-1}(n+r-1) + 2(n+r)\, b_n + b_{n-1} = 0 \end{aligned} \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = \frac{b_{n-1}(n^2 + 2nr + r^2 - 2n - 2r + 2)}{3n^2 + 6nr + 3r^2 - 5n - 5r} \tag{4}$$

Which for the root $r = 0$ becomes

$$b_n = \frac{b_{n-1}(n^2 - 2n + 2)}{n(3n - 5)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{r^2 + 1}{3r^2 + r - 2}$$

Which for the root $r = 0$ becomes

$$b_1 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r^2+1}{3r^2+r-2}$	$-\frac{1}{2}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{(r^2 + 1)(r^2 + 2r + 2)}{9r^4 + 24r^3 + 7r^2 - 12r - 4}$$

Which for the root $r = 0$ becomes

$$b_2 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r^2+1}{3r^2+r-2}$	$-\frac{1}{2}$
b_2	$\frac{(r^2+1)(r^2+2r+2)}{9r^4+24r^3+7r^2-12r-4}$	$-\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)}{27r^6+189r^5+441r^4+343r^3-84r^2-196r-48}$$

Which for the root $r = 0$ becomes

$$b_3 = -\frac{5}{24}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r^2+1}{3r^2+r-2}$	$-\frac{1}{2}$
b_2	$\frac{(r^2+1)(r^2+2r+2)}{9r^4+24r^3+7r^2-12r-4}$	$-\frac{1}{2}$
b_3	$\frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)}{27r^6+189r^5+441r^4+343r^3-84r^2-196r-48}$	$-\frac{5}{24}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}{81r^8+1080r^7+5670r^6+14700r^5+18613r^4+7420r^3-6220r^2-6400r-1344}$$

Which for the root $r = 0$ becomes

$$b_4 = -\frac{25}{336}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r^2+1}{3r^2+r-2}$	$-\frac{1}{2}$
b_2	$\frac{(r^2+1)(r^2+2r+2)}{9r^4+24r^3+7r^2-12r-4}$	$-\frac{1}{2}$
b_3	$\frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)}{27r^6+189r^5+441r^4+343r^3-84r^2-196r-48}$	$-\frac{5}{24}$
b_4	$\frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}{81r^8+1080r^7+5670r^6+14700r^5+18613r^4+7420r^3-6220r^2-6400r-1344}$	$-\frac{25}{336}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}{(81r^8+1080r^7+5670r^6+14700r^5+18613r^4+7420r^3-6220r^2-6400r-1344)(3r^2+25r+50)}$$

Which for the root $r = 0$ becomes

$$b_5 = -\frac{17}{672}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r^2+1}{3r^2+r-2}$	$-\frac{1}{2}$
b_2	$\frac{(r^2+1)(r^2+2r+2)}{9r^4+24r^3+7r^2-12r-4}$	$-\frac{1}{2}$
b_3	$\frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)}{27r^6+189r^5+441r^4+343r^3-84r^2-196r-48}$	$-\frac{5}{24}$
b_4	$\frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}{81r^8+1080r^7+5670r^6+14700r^5+18613r^4+7420r^3-6220r^2-6400r-1344}$	$-\frac{25}{336}$
b_5	$\frac{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}{(81r^8+1080r^7+5670r^6+14700r^5+18613r^4+7420r^3-6220r^2-6400r-1344)(3r^2+25r+50)}$	$-\frac{17}{672}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots \\ &= 1 - \frac{x}{2} - \frac{x^2}{2} - \frac{5x^3}{24} - \frac{25x^4}{336} - \frac{17x^5}{672} + O(x^6) \end{aligned}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{\frac{5}{3}} \left(1+\frac{17x}{36}+\frac{1241x^2}{7128}+\frac{80665x^3}{1347192}+\frac{972725x^4}{48498912}+\frac{5797441x^5}{872980416}+O\left(x^6\right)\right) \\
&+ c_2 \left(1-\frac{x}{2}-\frac{x^2}{2}-\frac{5x^3}{24}-\frac{25x^4}{336}-\frac{17x^5}{672}+O\left(x^6\right)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{\frac{5}{3}} \left(1+\frac{17x}{36}+\frac{1241x^2}{7128}+\frac{80665x^3}{1347192}+\frac{972725x^4}{48498912}+\frac{5797441x^5}{872980416}+O\left(x^6\right)\right) \\
&+ c_2 \left(1-\frac{x}{2}-\frac{x^2}{2}-\frac{5x^3}{24}-\frac{25x^4}{336}-\frac{17x^5}{672}+O\left(x^6\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x^{\frac{5}{3}} \left(1+\frac{17x}{36}+\frac{1241x^2}{7128}+\frac{80665x^3}{1347192}+\frac{972725x^4}{48498912}+\frac{5797441x^5}{872980416}+O\left(x^6\right)\right) \\
&+ c_2 \left(1-\frac{x}{2}-\frac{x^2}{2}-\frac{5x^3}{24}-\frac{25x^4}{336}-\frac{17x^5}{672}+O\left(x^6\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 x^{\frac{5}{3}} \left(1+\frac{17x}{36}+\frac{1241x^2}{7128}+\frac{80665x^3}{1347192}+\frac{972725x^4}{48498912}+\frac{5797441x^5}{872980416}+O\left(x^6\right)\right) \\
&+ c_2 \left(1-\frac{x}{2}-\frac{x^2}{2}-\frac{5x^3}{24}-\frac{25x^4}{336}-\frac{17x^5}{672}+O\left(x^6\right)\right)
\end{aligned}
$$

Verified OK.

15.1.1 Maple step by step solution

Let's solve

$y''x(x-3)+(x+2)\,y'+y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{y}{x(x-3)}-\frac{(x+2)y'}{x(x-3)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{(x+2)y'}{x(x-3)}+\frac{y}{x(x-3)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{x+2}{x(x-3)}, P_3(x)=\frac{1}{x(x-3)}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $(x\cdot P_2(x))\bigg|_{x=0}=-\frac{2}{3}$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $(x^2\cdot P_3(x))\bigg|_{x=0}=0$

  ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $y''x(x-3)+(x+2)\,y'+y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot y'$ to series expansion for $m=0..1$

  $x^m\cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot y''$ to series expansion for $m = 1..2$

  $$x^m \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

  $$x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$-a_0 r(-5+3r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-a_{k+1}(k+1+r)\,(3k-2+3r) + a_k(k^2+2kr+r^2+1)\right) x^{k+r}\right) =$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$-r(-5+3r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{0, \frac{5}{3}\right\}$$

- Each term in the series must be 0, giving the recursion relation

  $$-3\left(k-\frac{2}{3}+r\right)(k+1+r)\, a_{k+1} + a_k(k^2+2kr+r^2+1) = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+1} = \frac{a_k(k^2+2kr+r^2+1)}{(3k-2+3r)(k+1+r)}$$

- Recursion relation for $r = 0$

  $$a_{k+1} = \frac{a_k(k^2+1)}{(3k-2)(k+1)}$$

- Solution for $r = 0$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = \frac{a_k(k^2+1)}{(3k-2)(k+1)}\right]$$

- Recursion relation for $r = \frac{5}{3}$

  $$a_{k+1} = \frac{a_k\left(k^2+\frac{10}{3}k+\frac{34}{9}\right)}{(3k+3)\left(k+\frac{8}{3}\right)}$$

- Solution for $r = \frac{5}{3}$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{5}{3}}, a_{k+1} = \frac{a_k\left(k^2+\frac{10}{3}k+\frac{34}{9}\right)}{(3k+3)\left(k+\frac{8}{3}\right)}\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_k x^k\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+\frac{5}{3}}\right), a_{1+k}=\frac{a_k\left(k^2+1\right)}{(3k-2)(1+k)}, b_{1+k}=\frac{b_k\left(k^2+\frac{10}{3}k+\frac{34}{9}\right)}{(3k+3)\left(k+\frac{8}{3}\right)}\right]$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.2 (Frobenius). Exercises page 251
Problem number: 2.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Complex roots"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x^3+x^2)\,y''+(x^2-2x)\,y'+4y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$(x^3+x^2)\,y''+(x^2-2x)\,y'+4y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=\frac{x-2}{x\,(x+1)}$$
$$q(x)=\frac{4}{x^2\,(x+1)}$$

Table 529: Table $p(x), q(x)$ singularites.

$p(x) = \frac{x-2}{x(x+1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

$q(x) = \frac{4}{x^2(x+1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-1, 0, \infty]$

Irregular singular points : $[]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$y''x^2(x+1) + (x^2 - 2x)\, y' + 4y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x^2(x+1) + (x^2 - 2x) \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + 4\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) \tag{2A}$$
$$+ \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-2x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 4a_n x^{n+r}\right) = 0$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1) = \sum_{n=1}^{\infty} a_{n-1}(n+r-1)(n+r-2)\, x^{n+r}$$

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r) = \sum_{n=1}^{\infty} a_{n-1}(n+r-1)\, x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1)(n+r-2)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) \tag{2B}$$
$$+ \left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1)\, x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-2x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 4a_n x^{n+r}\right) = 0$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - 2x^{n+r} a_n (n+r) + 4a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - 2x^r a_0 r + 4a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - 2x^r r + 4x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2 - 3r + 4\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - 3r + 4 = 0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned}
r_1 &= \frac{3}{2} + \frac{i\sqrt{7}}{2} \\
r_2 &= \frac{3}{2} - \frac{i\sqrt{7}}{2}
\end{aligned}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2 - 3r + 4\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since the roots are complex conjugates, then two linearly independent solutions can be constructed using

$$\begin{aligned}
y_1(x) &= x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n \right) \\
y_2(x) &= x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n \right)
\end{aligned}$$

Or

$$\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+\frac{3}{2}+\frac{i\sqrt{7}}{2}} \\
y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+\frac{3}{2}-\frac{i\sqrt{7}}{2}}
\end{aligned}$$

$y_1(x)$ is found first. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$\begin{aligned}
&a_{n-1}(n + r - 1)(n + r - 2) + a_n(n + r)(n + r - 1) \\
&+ a_{n-1}(n + r - 1) - 2a_n(n + r) + 4a_n = 0
\end{aligned} \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}(n^2 + 2nr + r^2 - 2n - 2r + 1)}{n^2 + 2nr + r^2 - 3n - 3r + 4} \tag{4}$$

Which for the root $r = \frac{3}{2} + \frac{i\sqrt{7}}{2}$ becomes

$$a_n = -\frac{a_{n-1}\left(\left(in + \frac{1}{2}i\right)\sqrt{7} + n^2 + n - \frac{3}{2}\right)}{n\left(i\sqrt{7} + n\right)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{3}{2} + \frac{i\sqrt{7}}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{r^2}{r^2 - r + 2}$$

Which for the root $r = \frac{3}{2} + \frac{i\sqrt{7}}{2}$ becomes

$$a_1 = -\frac{\left(3 + i\sqrt{7}\right)^2}{4 + 4i\sqrt{7}}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r^2}{r^2-r+2}$	$-\frac{\left(3+i\sqrt{7}\right)^2}{4+4i\sqrt{7}}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r^2(r+1)^2}{(r^2 - r + 2)(r^2 + r + 2)}$$

Which for the root $r = \frac{3}{2} + \frac{i\sqrt{7}}{2}$ becomes

$$a_2 = \frac{-4\sqrt{7} - 12i}{\left(-\sqrt{7} + i\right)\left(i\sqrt{7} + 2\right)}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r^2}{r^2-r+2}$	$-\frac{\left(3+i\sqrt{7}\right)^2}{4+4i\sqrt{7}}$
a_2	$\frac{r^2(r+1)^2}{(r^2-r+2)(r^2+r+2)}$	$\frac{-4\sqrt{7}-12i}{\left(-\sqrt{7}+i\right)\left(i\sqrt{7}+2\right)}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{r^2(r+1)^2 (r+2)^2}{(r^2-r+2)(r^2+r+2)(r^2+3r+4)}$$

Which for the root $r = \frac{3}{2} + \frac{i\sqrt{7}}{2}$ becomes

$$a_3 = \frac{7\left(3i-\sqrt{7}\right)^2 \left(i\sqrt{7}+5\right)^2}{576i\sqrt{7}-960}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r^2}{r^2-r+2}$	$-\frac{\left(3+i\sqrt{7}\right)^2}{4+4i\sqrt{7}}$
a_2	$\frac{r^2(r+1)^2}{(r^2-r+2)(r^2+r+2)}$	$\frac{-4\sqrt{7}-12i}{\left(-\sqrt{7}+i\right)\left(i\sqrt{7}+2\right)}$
a_3	$-\frac{r^2(r+1)^2(r+2)^2}{(r^2-r+2)(r^2+r+2)(r^2+3r+4)}$	$\frac{7\left(3i-\sqrt{7}\right)^2\left(i\sqrt{7}+5\right)^2}{576i\sqrt{7}-960}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{r^2(r+1)^2 (r+2)^2 (r+3)^2}{(r^2-r+2)(r^2+r+2)(r^2+3r+4)(r^2+5r+8)}$$

Which for the root $r = \frac{3}{2} + \frac{i\sqrt{7}}{2}$ becomes

$$a_4 = \frac{\left(3i-\sqrt{7}\right)\left(i\sqrt{7}+7\right)^2 \left(i\sqrt{7}+5\right)^2 \left(9i\sqrt{7}+37\right)}{3072\left(i\sqrt{7}+4\right)\left(-\sqrt{7}+i\right)\left(i\sqrt{7}+2\right)}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r^2}{r^2-r+2}$	$-\frac{\left(3+i\sqrt{7}\right)^2}{4+4i\sqrt{7}}$
a_2	$\frac{r^2(r+1)^2}{(r^2-r+2)(r^2+r+2)}$	$\frac{-4\sqrt{7}-12i}{\left(-\sqrt{7}+i\right)\left(i\sqrt{7}+2\right)}$
a_3	$-\frac{r^2(r+1)^2(r+2)^2}{(r^2-r+2)(r^2+r+2)(r^2+3r+4)}$	$\frac{7\left(3i-\sqrt{7}\right)^2\left(i\sqrt{7}+5\right)^2}{576i\sqrt{7}-960}$
a_4	$\frac{r^2(r+1)^2(r+2)^2(r+3)^2}{(r^2-r+2)(r^2+r+2)(r^2+3r+4)(r^2+5r+8)}$	$\frac{\left(3i-\sqrt{7}\right)\left(i\sqrt{7}+7\right)^2\left(i\sqrt{7}+5\right)^2\left(9i\sqrt{7}+37\right)}{3072\left(i\sqrt{7}+4\right)\left(-\sqrt{7}+i\right)\left(i\sqrt{7}+2\right)}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{r^2(r+1)^2(r+2)^2(r+3)^2(r+4)^2}{(r^2-r+2)(r^2+r+2)(r^2+3r+4)(r^2+5r+8)(r^2+7r+14)}$$

Which for the root $r = \frac{3}{2} + \frac{i\sqrt{7}}{2}$ becomes

$$a_5 = \frac{11\left(3i-\sqrt{7}\right)\left(i\sqrt{7}+7\right)^2\left(i\sqrt{7}+5\right)\left(i\sqrt{7}+\frac{57}{11}\right)\left(i\sqrt{7}+9\right)^2}{61440\left(i\sqrt{7}+4\right)\left(\sqrt{7}-i\right)\left(i\sqrt{7}+2\right)}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r^2}{r^2-r+2}$	$-\frac{\left(3+i\sqrt{7}\right)^2}{4+4i\sqrt{7}}$
a_2	$\frac{r^2(r+1)^2}{(r^2-r+2)(r^2+r+2)}$	$\frac{-4\sqrt{7}-12i}{\left(-\sqrt{7}+i\right)\left(i\sqrt{7}+2\right)}$
a_3	$-\frac{r^2(r+1)^2(r+2)^2}{(r^2-r+2)(r^2+r+2)(r^2+3r+4)}$	$\frac{7\left(3i-\sqrt{7}\right)^2\left(i\sqrt{7}+5\right)^2}{576i\sqrt{7}-960}$
a_4	$\frac{r^2(r+1)^2(r+2)^2(r+3)^2}{(r^2-r+2)(r^2+r+2)(r^2+3r+4)(r^2+5r+8)}$	$\frac{\left(3i-\sqrt{7}\right)\left(i\sqrt{7}+7\right)^2\left(i\sqrt{7}+5\right)^2\left(9i\sqrt{7}+37\right)}{3072\left(i\sqrt{7}+4\right)\left(-\sqrt{7}+i\right)\left(i\sqrt{7}+2\right)}$
a_5	$-\frac{r^2(r+1)^2(r+2)^2(r+3)^2(r+4)^2}{(r^2-r+2)(r^2+r+2)(r^2+3r+4)(r^2+5r+8)(r^2+7r+14)}$	$\frac{11\left(3i-\sqrt{7}\right)\left(i\sqrt{7}+7\right)^2\left(i\sqrt{7}+5\right)\left(i\sqrt{7}+\frac{57}{11}\right)\left(i\sqrt{7}+9\right)^2}{61440\left(i\sqrt{7}+4\right)\left(\sqrt{7}-i\right)\left(i\sqrt{7}+2\right)}$

Using the above table, then the solution $y_1(x)$ is

$$y_1(x) = x^{\frac{3}{2}+\frac{i\sqrt{7}}{2}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right)$$
$$= x^{\frac{3}{2}+\frac{i\sqrt{7}}{2}}\left(1 - \frac{\left(3+i\sqrt{7}\right)^2 x}{4+4i\sqrt{7}} + \frac{\left(-4\sqrt{7}-12i\right)x^2}{\left(-\sqrt{7}+i\right)\left(i\sqrt{7}+2\right)} + \frac{7\left(3i-\sqrt{7}\right)^2\left(i\sqrt{7}+5\right)^2 x^3}{576i\sqrt{7}-960} + \frac{\left(3i-\sqrt{7}\right)\left(i\sqrt{7}+7\right)^2\left(i\sqrt{7}+5\right)^2\left(9i\sqrt{7}+37\right)x^4}{3072\left(i\sqrt{7}+4\right)\left(-\sqrt{7}+i\right)\left(i\sqrt{7}+2\right)} + \frac{11\left(3i-\sqrt{7}\right)\left(i\sqrt{7}+7\right)^2\left(i\sqrt{7}+5\right)\left(i\sqrt{7}+\frac{57}{11}\right)\left(i\sqrt{7}+9\right)^2 x^5}{61440\left(i\sqrt{7}+4\right)\left(\sqrt{7}-i\right)\left(i\sqrt{7}+2\right)} + O\left(x^6\right)\right)$$

The second solution $y_2(x)$ is found by taking the complex conjugate of $y_1(x)$ which gives

$$y_2(x) = x^{\frac{3}{2}-\frac{i\sqrt{7}}{2}}\left(1 - \frac{\left(3-i\sqrt{7}\right)^2 x}{4-4i\sqrt{7}} + \frac{\left(-4\sqrt{7}+12i\right)x^2}{\left(-\sqrt{7}-i\right)\left(-i\sqrt{7}+2\right)} + \frac{7\left(-3i-\sqrt{7}\right)^2\left(-i\sqrt{7}+5\right)^2 x^3}{-576i\sqrt{7}-960} + \frac{\left(-3i-\sqrt{7}\right)\left(-i\sqrt{7}+7\right)^2\left(-i\sqrt{7}+5\right)^2\left(-9i\sqrt{7}+37\right)x^4}{3072\left(-i\sqrt{7}+4\right)\left(-\sqrt{7}-i\right)\left(-i\sqrt{7}+2\right)} + \frac{11\left(-3i-\sqrt{7}\right)\left(-i\sqrt{7}+7\right)^2\left(-i\sqrt{7}+5\right)\left(-i\sqrt{7}+\frac{57}{11}\right)\left(-i\sqrt{7}+9\right)^2 x^5}{61440\left(-i\sqrt{7}+4\right)\left(\sqrt{7}+i\right)\left(-i\sqrt{7}+2\right)} + O\left(x^6\right)\right)$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 y_1(x) + c_2 y_2(x)$$

$$
\begin{aligned}
&= c_1 x^{\frac{3}{2}+\frac{i\sqrt{7}}{2}} \left(1-\frac{\left(3+i\sqrt{7}\right)^{2} x}{4+4i\sqrt{7}}+\frac{\left(-4\sqrt{7}-12i\right) x^{2}}{\left(-\sqrt{7}+i\right) \left(i\sqrt{7}+2\right)}+\frac{7\left(3i-\sqrt{7}\right)^{2} \left(i\sqrt{7}+5\right)^{2} x^{3}}{576i\sqrt{7}-960}\right. \\
&\quad + \frac{\left(3i-\sqrt{7}\right) \left(i\sqrt{7}+7\right)^{2} \left(i\sqrt{7}+5\right)^{2} \left(9i\sqrt{7}+37\right) x^{4}}{3072 \left(i\sqrt{7}+4\right) \left(-\sqrt{7}+i\right) \left(i\sqrt{7}+2\right)} \\
&\quad \left. + \frac{11\left(3i-\sqrt{7}\right) \left(i\sqrt{7}+7\right)^{2} \left(i\sqrt{7}+5\right) \left(i\sqrt{7}+\frac{57}{11}\right) \left(i\sqrt{7}+9\right)^{2} x^{5}}{61440 \left(i\sqrt{7}+4\right) \left(\sqrt{7}-i\right) \left(i\sqrt{7}+2\right)}+O\left(x^{6}\right)\right) \\
&\quad + c_2 x^{\frac{3}{2}-\frac{i\sqrt{7}}{2}} \left(1-\frac{\left(3-i\sqrt{7}\right)^{2} x}{4-4i\sqrt{7}}+\frac{\left(-4\sqrt{7}+12i\right) x^{2}}{\left(-\sqrt{7}-i\right) \left(-i\sqrt{7}+2\right)}\right. \\
&\quad + \frac{7\left(-3i-\sqrt{7}\right)^{2} \left(-i\sqrt{7}+5\right)^{2} x^{3}}{-576i\sqrt{7}-960} \\
&\quad + \frac{\left(-3i-\sqrt{7}\right) \left(-i\sqrt{7}+7\right)^{2} \left(-i\sqrt{7}+5\right)^{2} \left(-9i\sqrt{7}+37\right) x^{4}}{3072 \left(-i\sqrt{7}+4\right) \left(-\sqrt{7}-i\right) \left(-i\sqrt{7}+2\right)} \\
&\quad + \frac{11\left(-3i-\sqrt{7}\right) \left(-i\sqrt{7}+7\right)^{2} \left(-i\sqrt{7}+5\right) \left(-i\sqrt{7}+\frac{57}{11}\right) \left(-i\sqrt{7}+9\right)^{2} x^{5}}{61440 \left(-i\sqrt{7}+4\right) \left(\sqrt{7}+i\right) \left(-i\sqrt{7}+2\right)} \\
&\quad \left. + O\left(x^{6}\right)\right)
\end{aligned}
$$

Hence the final solution is

$$y = y_h$$

$$= c_1 x^{\frac{3}{2}+\frac{i\sqrt{7}}{2}} \left(1 - \frac{\left(3+i\sqrt{7}\right)^2 x}{4+4i\sqrt{7}} + \frac{\left(-4\sqrt{7}-12i\right) x^2}{\left(-\sqrt{7}+i\right)\left(i\sqrt{7}+2\right)} + \frac{7\left(3i-\sqrt{7}\right)^2 \left(i\sqrt{7}+5\right)^2 x^3}{576i\sqrt{7}-960} + \frac{\left(3i-\sqrt{7}\right)\left(i\sqrt{7}+7\right)^2 \left(i\sqrt{7}+5\right)^2 \left(9i\sqrt{7}+37\right) x^4}{3072\left(i\sqrt{7}+4\right)\left(-\sqrt{7}+i\right)\left(i\sqrt{7}+2\right)} + \frac{11\left(3i-\sqrt{7}\right)\left(i\sqrt{7}+7\right)^2 \left(i\sqrt{7}+5\right)\left(i\sqrt{7}+\frac{57}{11}\right)\left(i\sqrt{7}+9\right)^2 x^5}{61440\left(i\sqrt{7}+4\right)\left(\sqrt{7}-i\right)\left(i\sqrt{7}+2\right)} + O\left(x^6\right)\right) + c_2 x^{\frac{3}{2}-\frac{i\sqrt{7}}{2}} \left(1 - \frac{\left(3-i\sqrt{7}\right)^2 x}{4-4i\sqrt{7}} + \frac{\left(-4\sqrt{7}+12i\right) x^2}{\left(-\sqrt{7}-i\right)\left(-i\sqrt{7}+2\right)} + \frac{7\left(-3i-\sqrt{7}\right)^2 \left(-i\sqrt{7}+5\right)^2 x^3}{-576i\sqrt{7}-960} + \frac{\left(-3i-\sqrt{7}\right)\left(-i\sqrt{7}+7\right)^2 \left(-i\sqrt{7}+5\right)^2 \left(-9i\sqrt{7}+37\right) x^4}{3072\left(-i\sqrt{7}+4\right)\left(-\sqrt{7}-i\right)\left(-i\sqrt{7}+2\right)} + \frac{11\left(-3i-\sqrt{7}\right)\left(-i\sqrt{7}+7\right)^2 \left(-i\sqrt{7}+5\right)\left(-i\sqrt{7}+\frac{57}{11}\right)\left(-i\sqrt{7}+9\right)^2 x^5}{61440\left(-i\sqrt{7}+4\right)\left(\sqrt{7}+i\right)\left(-i\sqrt{7}+2\right)} + O\left(x^6\right)\right)$$

Summary

The solution(s) found are the following

$$y = c_1 x^{\frac{3}{2}+\frac{i\sqrt{7}}{2}} \left(1 - \frac{\left(3+i\sqrt{7}\right)^2 x}{4+4i\sqrt{7}} + \frac{\left(-4\sqrt{7}-12i\right) x^2}{\left(-\sqrt{7}+i\right)\left(i\sqrt{7}+2\right)} + \frac{7\left(3i-\sqrt{7}\right)^2 \left(i\sqrt{7}+5\right)^2 x^3}{576i\sqrt{7}-960} + \frac{\left(3i-\sqrt{7}\right)\left(i\sqrt{7}+7\right)^2 \left(i\sqrt{7}+5\right)^2 \left(9i\sqrt{7}+37\right) x^4}{3072\left(i\sqrt{7}+4\right)\left(-\sqrt{7}+i\right)\left(i\sqrt{7}+2\right)} + \frac{11\left(3i-\sqrt{7}\right)\left(i\sqrt{7}+7\right)^2 \left(i\sqrt{7}+5\right)\left(i\sqrt{7}+\frac{57}{11}\right)\left(i\sqrt{7}+9\right)^2 x^5}{61440\left(i\sqrt{7}+4\right)\left(\sqrt{7}-i\right)\left(i\sqrt{7}+2\right)} + O\left(x^6\right)\right) + c_2 x^{\frac{3}{2}-\frac{i\sqrt{7}}{2}} \left(1 - \frac{\left(3-i\sqrt{7}\right)^2 x}{4-4i\sqrt{7}} + \frac{\left(-4\sqrt{7}+12i\right) x^2}{\left(-\sqrt{7}-i\right)\left(-i\sqrt{7}+2\right)} + \frac{7\left(-3i-\sqrt{7}\right)^2 \left(-i\sqrt{7}+5\right)^2 x^3}{-576i\sqrt{7}-960} + \frac{\left(-3i-\sqrt{7}\right)\left(-i\sqrt{7}+7\right)^2 \left(-i\sqrt{7}+5\right)^2 \left(-9i\sqrt{7}+37\right) x^4}{3072\left(-i\sqrt{7}+4\right)\left(-\sqrt{7}-i\right)\left(-i\sqrt{7}+2\right)} + \frac{11\left(-3i-\sqrt{7}\right)\left(-i\sqrt{7}+7\right)^2 \left(-i\sqrt{7}+5\right)\left(-i\sqrt{7}+\frac{57}{11}\right)\left(-i\sqrt{7}+9\right)^2 x^5}{61440\left(-i\sqrt{7}+4\right)\left(\sqrt{7}+i\right)\left(-i\sqrt{7}+2\right)} + O\left(x^6\right)\right) \tag{1}$$

Verification of solutions

$$y = c_1 x^{\frac{3}{2}+\frac{i\sqrt{7}}{2}} \left(1 - \frac{\left(3+i\sqrt{7}\right)^2 x}{4+4i\sqrt{7}} + \frac{\left(-4\sqrt{7}-12i\right) x^2}{\left(-\sqrt{7}+i\right)\left(i\sqrt{7}+2\right)} + \frac{7\left(3i-\sqrt{7}\right)^2 \left(i\sqrt{7}+5\right)^2 x^3}{576i\sqrt{7}-960} + \frac{\left(3i-\sqrt{7}\right)\left(i\sqrt{7}+7\right)^2 \left(i\sqrt{7}+5\right)^2 \left(9i\sqrt{7}+37\right) x^4}{3072\left(i\sqrt{7}+4\right)\left(-\sqrt{7}+i\right)\left(i\sqrt{7}+2\right)} + \frac{11\left(3i-\sqrt{7}\right)\left(i\sqrt{7}+7\right)^2 \left(i\sqrt{7}+5\right)\left(i\sqrt{7}+\frac{57}{11}\right)\left(i\sqrt{7}+9\right)^2 x^5}{61440\left(i\sqrt{7}+4\right)\left(\sqrt{7}-i\right)\left(i\sqrt{7}+2\right)} + O(x^6)\right)$$
$$+ c_2 x^{\frac{3}{2}-\frac{i\sqrt{7}}{2}} \left(1 - \frac{\left(3-i\sqrt{7}\right)^2 x}{4-4i\sqrt{7}} + \frac{\left(-4\sqrt{7}+12i\right) x^2}{\left(-\sqrt{7}-i\right)\left(-i\sqrt{7}+2\right)} + \frac{7\left(-3i-\sqrt{7}\right)^2 \left(-i\sqrt{7}+5\right)^2 x^3}{-576i\sqrt{7}-960} + \frac{\left(-3i-\sqrt{7}\right)\left(-i\sqrt{7}+7\right)^2 \left(-i\sqrt{7}+5\right)^2 \left(-9i\sqrt{7}+37\right) x^4}{3072\left(-i\sqrt{7}+4\right)\left(-\sqrt{7}-i\right)\left(-i\sqrt{7}+2\right)} + \frac{11\left(-3i-\sqrt{7}\right)\left(-i\sqrt{7}+7\right)^2 \left(-i\sqrt{7}+5\right)\left(-i\sqrt{7}+\frac{57}{11}\right)\left(-i\sqrt{7}+9\right)^2 x^5}{61440\left(-i\sqrt{7}+4\right)\left(\sqrt{7}+i\right)\left(-i\sqrt{7}+2\right)} + O(x^6)\right)$$

Verified OK.

15.2.1 Maple step by step solution

Let's solve

$y''x^2(x+1) + (x^2-2x)\,y' + 4y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{4y}{x^2(x+1)} - \frac{(x-2)y'}{x(x+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(x-2)y'}{x(x+1)} + \frac{4y}{x^2(x+1)} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{x-2}{x(x+1)}, P_3(x) = \frac{4}{x^2(x+1)}\right]$

  - $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

$$\left((x+1)\cdot P_2(x)\right)\bigg|_{x=-1} = 3$$

- $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

$$\left((x+1)^2\cdot P_3(x)\right)\bigg|_{x=-1} = 0$$

- $x=-1$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-1$

- Multiply by denominators

$y''x^2(x+1)+x(x-2)\,y'+4y=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

$(u^3-2u^2+u)\left(\frac{d^2}{du^2}y(u)\right)+(u^2-4u+3)\left(\frac{d}{du}y(u)\right)+4y(u)=0$

- Assume series solution for $y(u)$

$$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..2$

$$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

- Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..3$

$$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$a_0r(2+r)\,u^{-1+r}+\left(a_1(1+r)\,(3+r)-2a_0(2+r)\,(-1+r)\right)u^r+\left(\sum_{k=1}^{\infty}\left(a_{k+1}(k+1+r)\,(k+3+\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-2, 0\}$

- Each term must be 0

  $a_1(1+r)(3+r) - 2a_0(2+r)(-1+r) = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)(k+3+r) - 2a_k(k+r+2)(k+r-1) + a_{k-1}(k+r-1)^2 = 0$

- Shift index using $k- > k+1$

  $a_{k+2}(k+r+2)(k+4+r) - 2a_{k+1}(k+3+r)(k+r) + a_k(k+r)^2 = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} + 2kra_k - 4kra_{k+1} + r^2a_k - 2r^2a_{k+1} - 6ka_{k+1} - 6ra_{k+1}}{(k+r+2)(k+4+r)}$

- Recursion relation for $r = -2$; series terminates at $k = 2$

  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} - 4ka_k + 2ka_{k+1} + 4a_k + 4a_{k+1}}{k(k+2)}$

- Series not valid for $r = -2$, division by 0 in the recursion relation at $k = 0$

  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} - 4ka_k + 2ka_{k+1} + 4a_k + 4a_{k+1}}{k(k+2)}$

- Recursion relation for $r = 0$; series terminates at $k = 0$

  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} - 6ka_{k+1}}{(k+2)(k+4)}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} - 6ka_{k+1}}{(k+2)(k+4)}, 3a_1 + 4a_0 = 0\right]$

- Revert the change of variables $u = x+1$

  $\left[y = \sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} - 6ka_{k+1}}{(k+2)(k+4)}, 3a_1 + 4a_0 = 0\right]$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.2 (Frobenius). Exercises page 251
Problem number: 3.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Irregular singular point"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

Unable to solve or complete the solution.

$$\boxed{\left(x^4-2x^3+x^2\right)y''+2(x-1)\,y'+x^2y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(x^4-2x^3+x^2\right)y''+(2x-2)\,y'+x^2y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$\begin{aligned}
p(x) &= \frac{2}{x^2\,(x-1)} \\
q(x) &= \frac{1}{(x-1)^2}
\end{aligned}$$

Table 531: Table $p(x), q(x)$ singularites.

$p(x) = \frac{2}{x^2(x-1)}$	
singularity	type
$x = 0$	"irregular"
$x = 1$	"regular"

$q(x) = \frac{1}{(x-1)^2}$	
singularity	type
$x = 1$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[1, \infty]$

Irregular singular points : $[0]$

Since $x = 0$ is not an ordinary point, then we will now check if it is a regular singular point. Unable to solve since $x = 0$ is not regular singular point. Terminating.

Verification of solutions N/A

15.3.1 Maple step by step solution

Let's solve

$y''x^2(x-1)^2 + (2x-2)\, y' + x^2 y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{2y'}{(x-1)x^2} - \frac{y}{(x-1)^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{2y'}{(x-1)x^2} + \frac{y}{(x-1)^2} = 0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x) = \frac{2}{x^2(x-1)}, P_3(x) = \frac{1}{(x-1)^2}\right]$

- ◦ $(x-1) \cdot P_2(x)$ is analytic at $x = 1$

  $\left((x-1) \cdot P_2(x)\right)\Big|_{x=1} = 2$

- $(x-1)^2 \cdot P_3(x)$ is analytic at $x=1$

  $\left((x-1)^2 \cdot P_3(x)\right)\Big|_{x=1} = 1$

- $x=1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 1$

- Multiply by denominators

  $y''x^2(x-1)^2 + (2x-2)\,y' + x^2 y = 0$

- Change variables using $x = u+1$ so that the regular singular point is at $u=0$

  $(u^4 + 2u^3 + u^2)\left(\frac{d^2}{du^2}y(u)\right) + 2u\left(\frac{d}{du}y(u)\right) + (u^2 + 2u + 1)\,y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot y(u)$ to series expansion for $m = 0..2$

  $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$

- Shift index using $k->k-m$

  $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

- Convert $u \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion

  $u \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 2..4$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $a_0(r^2+r+1)\,u^r + \left((r^2+3r+3)\,a_1 + 2a_0(r^2-r+1)\right) u^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k^2+2kr+r^2+k+r+\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r^2 + r + 1 = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-\frac{1}{2} - \frac{I\sqrt{3}}{2}, -\frac{1}{2} + \frac{I\sqrt{3}}{2}\right\}$

- Each term must be 0

  $(r^2 + 3r + 3)\, a_1 + 2a_0(r^2 - r + 1) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = -\frac{2a_0(r^2-r+1)}{r^2+3r+3}$

- Each term in the series must be 0, giving the recursion relation

  $(a_k + a_{k-2} + 2a_{k-1})\, k^2 + ((2a_k + 2a_{k-2} + 4a_{k-1})\, r + a_k - 5a_{k-2} - 6a_{k-1})\, k + (a_k + a_{k-2} + 2a_{k-1}$

- Shift index using $k- >k + 2$

  $(a_{k+2} + a_k + 2a_{k+1})\,(k+2)^2 + ((2a_{k+2} + 2a_k + 4a_{k+1})\, r + a_{k+2} - 5a_k - 6a_{k+1})\,(k+2) + (a_{k+2}$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{k^2a_k+2k^2a_{k+1}+2kra_k+4kra_{k+1}+r^2a_k+2r^2a_{k+1}-ka_k+2ka_{k+1}-ra_k+2ra_{k+1}+a_k+2a_{k+1}}{k^2+2kr+r^2+5k+5r+7}$

- Recursion relation for $r = -\frac{1}{2} - \frac{I\sqrt{3}}{2}$

  $a_{k+2} = -\frac{k^2a_k+2k^2a_{k+1}+2k\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)a_k+4k\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)a_{k+1}+\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^2a_k+2\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^2a_{k+1}-ka_k+2ka_{k+1}-\left(-\frac{1}{2}-\right.}{k^2+2k\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)+\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^2+5k+\frac{9}{2}-\frac{5I\sqrt{3}}{2}}$

- Solution for $r = -\frac{1}{2} - \frac{I\sqrt{3}}{2}$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{1}{2}-\frac{I\sqrt{3}}{2}}, a_{k+2} = -\frac{k^2a_k+2k^2a_{k+1}+2k\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)a_k+4k\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)a_{k+1}+\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^2a_k+2\left(-\frac{1}{2}-\right.}{k^2+2k\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)+\left(-\frac{1}{2}-\right.}\right.$

- Revert the change of variables $u = x - 1$

  $\left[y = \sum_{k=0}^{\infty} a_k (x-1)^{k-\frac{1}{2}-\frac{I\sqrt{3}}{2}}, a_{k+2} = -\frac{k^2a_k+2k^2a_{k+1}+2k\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)a_k+4k\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)a_{k+1}+\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^2a_k+2\left(-\right.}{k^2+2k\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)+\left(-\right.}\right.$

- Recursion relation for $r = -\frac{1}{2} + \frac{I\sqrt{3}}{2}$

  $a_{k+2} = -\frac{k^2a_k+2k^2a_{k+1}+2k\left(-\frac{1}{2}+\frac{I\sqrt{3}}{2}\right)a_k+4k\left(-\frac{1}{2}+\frac{I\sqrt{3}}{2}\right)a_{k+1}+\left(-\frac{1}{2}+\frac{I\sqrt{3}}{2}\right)^2a_k+2\left(-\frac{1}{2}+\frac{I\sqrt{3}}{2}\right)^2a_{k+1}-ka_k+2ka_{k+1}-\left(-\frac{1}{2}+\right.}{k^2+2k\left(-\frac{1}{2}+\frac{I\sqrt{3}}{2}\right)+\left(-\frac{1}{2}+\frac{I\sqrt{3}}{2}\right)^2+5k+\frac{9}{2}+\frac{5I\sqrt{3}}{2}}$

- Solution for $r = -\frac{1}{2} + \frac{I\sqrt{3}}{2}$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{1}{2}+\frac{I\sqrt{3}}{2}}, a_{k+2} = -\frac{k^2a_k+2k^2a_{k+1}+2k\left(-\frac{1}{2}+\frac{I\sqrt{3}}{2}\right)a_k+4k\left(-\frac{1}{2}+\frac{I\sqrt{3}}{2}\right)a_{k+1}+\left(-\frac{1}{2}+\frac{I\sqrt{3}}{2}\right)^2a_k+2\left(-\frac{1}{2}+\right.}{k^2+2k\left(-\frac{1}{2}+\frac{I\sqrt{3}}{2}\right)+\left(-\frac{1}{2}+\right.}\right.$

- Revert the change of variables $u = x - 1$

$$\left[y = \sum_{k=0}^{\infty} a_k (x-1)^{k-\frac{1}{2}+\frac{\mathrm{I}\sqrt{3}}{2}}, a_{k+2} = -\frac{k^2 a_k + 2k^2 a_{k+1} + 2k\left(-\frac{1}{2}+\frac{\mathrm{I}\sqrt{3}}{2}\right)a_k + 4k\left(-\frac{1}{2}+\frac{\mathrm{I}\sqrt{3}}{2}\right)a_{k+1} + \left(-\frac{1}{2}+\frac{\mathrm{I}\sqrt{3}}{2}\right)^2 a_k + 2\left(-\frac{1}{2}\right.}{k^2 + 2k\left(-\frac{1}{2}+\frac{\mathrm{I}\sqrt{3}}{2}\right) + \left(-\frac{1}{2}\right.}\right.$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k (x-1)^{k-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k (x-1)^{k-\frac{1}{2}+\frac{\mathrm{I}\sqrt{3}}{2}}\right), a_{k+2} = -\frac{k^2 a_k + 2k^2 a_{1+k} + 2k\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)a_k + 4k}{}\right.$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.2 (Frobenius). Exercises page 251
Problem number: 4.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Irregular singular point"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

Unable to solve or complete the solution.

$$\boxed{(x^5 + x^4 - 6x^3)\, y'' + x^2 y' + y(x-2) = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$(x^5 + x^4 - 6x^3)\, y'' + x^2 y' + y(x-2) = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x\,(x^2 + x - 6)} \\ q(x) &= \frac{1}{x^3\,(x+3)} \end{aligned}$$

Table 533: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{x(x^2+x-6)}$	
singularity	type
$x = -3$	"regular"
$x = 0$	"regular"
$x = 2$	"regular"

$q(x) = \frac{1}{x^3(x+3)}$	
singularity	type
$x = -3$	"regular"
$x = 0$	"irregular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-3, 2, \infty]$

Irregular singular points : $[0]$

Since $x = 0$ is not an ordinary point, then we will now check if it is a regular singular point. Unable to solve since $x = 0$ is not regular singular point. Terminating.

Verification of solutions N/A

15.4.1 Maple step by step solution

Let's solve

$(x^5 + x^4 - 6x^3)\, y'' + x^2 y' + y(x-2) = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y}{x^3(x+3)} - \frac{y'}{x(x^2+x-6)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x(x^2+x-6)} + \frac{y}{x^3(x+3)} = 0$

☐ Check to see if x_0 is a regular singular point

- ∘ Define functions

  $\left[P_2(x) = \frac{1}{x(x^2+x-6)}, P_3(x) = \frac{1}{x^3(x+3)}\right]$

- ∘ $(x+3) \cdot P_2(x)$ is analytic at $x = -3$

$$\left((x+3)\cdot P_2(x)\right)\bigg|_{x=-3} = \frac{1}{15}$$

- $(x+3)^2 \cdot P_3(x)$ is analytic at $x=-3$

$$\left((x+3)^2 \cdot P_3(x)\right)\bigg|_{x=-3} = 0$$

- $x=-3$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0 = -3$

- Multiply by denominators

$$y'' x^3(x^2+x-6)(x+3) + y' x^2(x+3) + y(x^2+x-6) = 0$$

- Change variables using $x = u-3$ so that the regular singular point is at $u=0$

$$(u^6 - 14u^5 + 72u^4 - 162u^3 + 135u^2)\left(\frac{d^2}{du^2}y(u)\right) + (u^3 - 6u^2 + 9u)\left(\frac{d}{du}y(u)\right) + (u^2 - 5u)\,y(u) = 0$$

- Assume series solution for $y(u)$

$$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $u^m \cdot y(u)$ to series expansion for $m = 1..2$

$$u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$$

- Shift index using $k- >k-m$

$$u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..3$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 2..6$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$u^{m} \cdot \left(\frac{d^{2}}{du^{2}}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$9a_{0}r(-14+15r)\, u^{r} + (9a_{1}(1+r)(1+15r) - a_{0}(162r^{2}-156r+5))\, u^{1+r} + (9a_{2}(2+r)(16+15$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$9r(-14+15r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{0, \frac{14}{15}\right\}$$

- The coefficients of each power of u must be 0

  $$[9a_{1}(1+r)(1+15r) - a_{0}(162r^{2}-156r+5) = 0, 9a_{2}(2+r)(16+15r) - a_{1}(162r^{2}+168r+11$$

- Solve for the dependent coefficient(s)

  $$\left\{a_{1} = \frac{a_{0}(162r^{2}-156r+5)}{9(15r^{2}+16r+1)}, a_{2} = \frac{a_{0}(16524r^{4}+1161r^{3}-14175r^{2}-381r+46)}{81(225r^{4}+930r^{3}+1231r^{2}+558r+32)}, a_{3} = \frac{a_{0}(1357398r^{6}+4208274r^{5}+2090772r^{4}-31}{729(3375r^{6}+31050r^{5}+110070r^{4}+18}\right.$$

- Each term in the series must be 0, giving the recursion relation

  $$(135a_{k} + a_{k-4} - 14a_{k-3} + 72a_{k-2} - 162a_{k-1})\, k^{2} + (2(135a_{k} + a_{k-4} - 14a_{k-3} + 72a_{k-2} - 162a_{k-}$$

- Shift index using $k- > k+4$

  $$(135a_{k+4} + a_{k} - 14a_{k+1} + 72a_{k+2} - 162a_{k+3})\,(k+4)^{2} + (2(135a_{k+4} + a_{k} - 14a_{k+1} + 72a_{k+2} - 1$$

- Recursion relation that defines series solution to ODE

  $$a_{k+4} = -\frac{k^{2}a_{k} - 14k^{2}a_{k+1} + 72k^{2}a_{k+2} - 162k^{2}a_{k+3} + 2kra_{k} - 28kra_{k+1} + 144kra_{k+2} - 324kra_{k+3} + r^{2}a_{k} - 14r^{2}a_{k+1} + 72r^{2}a_{k+2} - 16}{9(15k^{2}+30kr+15r^{2}+106}$$

- Recursion relation for $r = 0$

  $$a_{k+4} = -\frac{k^{2}a_{k} - 14k^{2}a_{k+1} + 72k^{2}a_{k+2} - 162k^{2}a_{k+3} - ka_{k} - 14ka_{k+1} + 217ka_{k+2} - 816ka_{k+3} + 147a_{k+2} - 995a_{k+3}}{9(15k^{2}+106k+184)}$$

- Solution for $r = 0$

  $$\left[y(u) = \sum_{k=0}^{\infty} a_{k}u^{k}, a_{k+4} = -\frac{k^{2}a_{k} - 14k^{2}a_{k+1} + 72k^{2}a_{k+2} - 162k^{2}a_{k+3} - ka_{k} - 14ka_{k+1} + 217ka_{k+2} - 816ka_{k+3} + 147a_{k+2} - 99}{9(15k^{2}+106k+184)}\right.$$

- Revert the change of variables $u = x+3$

  $$\left[y = \sum_{k=0}^{\infty} a_{k}(x+3)^{k}, a_{k+4} = -\frac{k^{2}a_{k} - 14k^{2}a_{k+1} + 72k^{2}a_{k+2} - 162k^{2}a_{k+3} - ka_{k} - 14ka_{k+1} + 217ka_{k+2} - 816ka_{k+3} + 147a_{k+2}}{9(15k^{2}+106k+184)}\right.$$

- Recursion relation for $r = \frac{14}{15}$

  $$a_{k+4} = -\frac{k^{2}a_{k} - 14k^{2}a_{k+1} + 72k^{2}a_{k+2} - 162k^{2}a_{k+3} + \frac{13}{15}ka_{k} - \frac{602}{15}ka_{k+1} + \frac{1757}{5}ka_{k+2} - \frac{5592}{5}ka_{k+3} - \frac{14}{225}a_{k} - \frac{5684}{225}a_{k+1} + \frac{30919}{75}a_{k+2}}{9(15k^{2}+134k+296)}$$

- Solution for $r = \frac{14}{15}$

$$\left[y(u)=\sum_{k=0}^{\infty} a_k u^{k+\frac{14}{15}}, a_{k+4}=-\frac{k^2 a_k-14k^2 a_{k+1}+72k^2 a_{k+2}-162k^2 a_{k+3}+\frac{13}{15} k a_k-\frac{602}{15} k a_{k+1}+\frac{1757}{5} k a_{k+2}-\frac{5592}{5} k a_{k+3}-\frac{1}{2}}{9(15k^2+134k+296)}\right.$$

- Revert the change of variables $u=x+3$

$$\left[y=\sum_{k=0}^{\infty} a_k (x+3)^{k+\frac{14}{15}}, a_{k+4}=-\frac{k^2 a_k-14k^2 a_{k+1}+72k^2 a_{k+2}-162k^2 a_{k+3}+\frac{13}{15} k a_k-\frac{602}{15} k a_{k+1}+\frac{1757}{5} k a_{k+2}-\frac{5592}{5} k a_{k+}}{9(15k^2+134k+296)}\right.$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_k (x+3)^k\right)+\left(\sum_{k=0}^{\infty} b_k (x+3)^{k+\frac{14}{15}}\right), a_{k+4}=-\frac{k^2 a_k-14k^2 a_{1+k}+72k^2 a_{k+2}-162k^2 a_{k+3}-k a_k-14k a}{9(15k^2+106}\right.$$

Section: Chapter 6, Series solutions of linear differential equations. Section 6.2 (Frobenius). Exercises page 251
Problem number: 5.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{2x^2y'' + y'x + y(x^2 - 1) = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2x^2y'' + y'x + y(x^2 - 1) = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1}{2x}$$
$$q(x) = \frac{x^2 - 1}{2x^2}$$

Table 535: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{2x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{x^2-1}{2x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2x^2y'' + y'x + y(x^2 - 1) = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x^2 + \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) x + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) (x^2 - 1) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r+2} a_n\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r} a_n (n+r)(n+r-1) + x^{n+r} a_n (n+r) - a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$2x^r a_0 r(-1+r) + x^r a_0 r - a_0 x^r = 0$$

Or

$$\left(2x^r r(-1+r) + x^r r - x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(2r^2 - r - 1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 - r - 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = -\frac{1}{2}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(2r^2 - r - 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{3}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+1}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-\frac{1}{2}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$2a_n(n+r)(n+r-1) + a_n(n+r) + a_{n-2} - a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-2}}{2n^2 + 4nr + 2r^2 - n - r - 1} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = -\frac{a_{n-2}}{n(2n+3)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{1}{2r^2 + 7r + 5}$$

Which for the root $r = 1$ becomes

$$a_2 = -\frac{1}{14}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{2r^2+7r+5}$	$-\frac{1}{14}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{2r^2+7r+5}$	$-\frac{1}{14}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{4r^4 + 44r^3 + 169r^2 + 264r + 135}$$

Which for the root $r = 1$ becomes

$$a_4 = \frac{1}{616}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{2r^2+7r+5}$	$-\frac{1}{14}$
a_3	0	0
a_4	$\frac{1}{4r^4+44r^3+169r^2+264r+135}$	$\frac{1}{616}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{2r^2+7r+5}$	$-\frac{1}{14}$
a_3	0	0
a_4	$\frac{1}{4r^4+44r^3+169r^2+264r+135}$	$\frac{1}{616}$
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x\left(1 - \frac{x^2}{14} + \frac{x^4}{616} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$b_1 = 0$$

For $2 \leq n$ the recursive equation is

$$2b_n(n+r)(n+r-1) + b_n(n+r) + b_{n-2} - b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{b_{n-2}}{2n^2 + 4nr + 2r^2 - n - r - 1} \tag{4}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_n = -\frac{b_{n-2}}{n(2n-3)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{1}{2r^2 + 7r + 5}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_2 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{2r^2+7r+5}$	$-\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{2r^2+7r+5}$	$-\frac{1}{2}$
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{4r^4 + 44r^3 + 169r^2 + 264r + 135}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_4 = \frac{1}{40}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{2r^2+7r+5}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{1}{4r^4+44r^3+169r^2+264r+135}$	$\frac{1}{40}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{2r^2+7r+5}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{1}{4r^4+44r^3+169r^2+264r+135}$	$\frac{1}{40}$
b_5	0	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= x\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\ &= \frac{1 - \frac{x^2}{2} + \frac{x^4}{40} + O(x^6)}{\sqrt{x}} \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x\left(1 - \frac{x^2}{14} + \frac{x^4}{616} + O\left(x^6\right)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{40} + O(x^6)\right)}{\sqrt{x}} \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= c_1 x\left(1 - \frac{x^2}{14} + \frac{x^4}{616} + O\left(x^6\right)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{40} + O(x^6)\right)}{\sqrt{x}} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x\left(1 - \frac{x^2}{14} + \frac{x^4}{616} + O\left(x^6\right)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{40} + O(x^6)\right)}{\sqrt{x}} \tag{1}$$

Verification of solutions

$$y = c_1 x\left(1 - \frac{x^2}{14} + \frac{x^4}{616} + O\left(x^6\right)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{40} + O(x^6)\right)}{\sqrt{x}}$$

Verified OK.

15.5.1 Maple step by step solution

Let's solve

$2y''x^2 + y'x + y(x^2 - 1) = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

$y'' = -\frac{(x^2-1)y}{2x^2} - \frac{y'}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{2x} + \frac{(x^2-1)y}{2x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{1}{2x}, P_3(x) = \frac{x^2-1}{2x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = \frac{1}{2}$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -\frac{1}{2}$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2y''x^2 + y'x + y(x^2 - 1) = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  ◦ Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  ◦ Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k (k + r) x^{k+r}$

  ◦ Convert $x^2 \cdot y''$ to series expansion

$$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(1+2r)(-1+r)\, x^r + a_1(3+2r)\, r\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(2k+2r+1)(k+r-1) + a_{k-2}\right) x^{k+r}\right) =$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(1+2r)(-1+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{1, -\frac{1}{2}\right\}$$

- Each term must be 0

$$a_1(3+2r)\, r = 0$$

- Solve for the dependent coefficient(s)

$$a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$2(k+r-1)\left(k+r+\frac{1}{2}\right) a_k + a_{k-2} = 0$$

- Shift index using $k- >k+2$

$$2(k+1+r)\left(k+\frac{5}{2}+r\right) a_{k+2} + a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{a_k}{(k+1+r)(2k+5+2r)}$$

- Recursion relation for $r = 1$

$$a_{k+2} = -\frac{a_k}{(k+2)(2k+7)}$$

- Solution for $r = 1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k}{(k+2)(2k+7)}, a_1 = 0\right]$$

- Recursion relation for $r = -\frac{1}{2}$

$$a_{k+2} = -\frac{a_k}{\left(k+\frac{1}{2}\right)(2k+4)}$$

- Solution for $r = -\frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = -\frac{a_k}{\left(k+\frac{1}{2}\right)(2k+4)}, a_1 = 0\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_k x^{1+k}\right)+\left(\sum_{k=0}^{\infty} b_k x^{k-\frac{1}{2}}\right), a_{k+2}=-\frac{a_k}{(k+2)(2k+7)}, a_1=0, b_{k+2}=-\frac{b_k}{(k+\frac{1}{2})(2k+4)}, b_1=0\right]$$

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{2x^2y'' + y'x + \left(2x^2 - 3\right)y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2x^2y'' + y'x + \left(2x^2 - 3\right)y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$\begin{aligned} p(x) &= \frac{1}{2x} \\ q(x) &= \frac{2x^2 - 3}{2x^2} \end{aligned}$$

Table 537: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{2x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{2x^2-3}{2x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2x^2y'' + y'x + (2x^2 - 3)\, y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x^2 + \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) x + (2x^2 - 3)\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 2x^{n+r+2} a_n\right) + \sum_{n=0}^{\infty} \left(-3 a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2x^{n+r+2} a_n = \sum_{n=2}^{\infty} 2a_{n-2} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \left(\sum_{n=2}^{\infty} 2a_{n-2} x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-3 a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r} a_n (n+r)(n+r-1) + x^{n+r} a_n (n+r) - 3 a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$2x^r a_0 r(-1+r) + x^r a_0 r - 3 a_0 x^r = 0$$

Or

$$\left(2x^r r(-1+r) + x^r r - 3x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(2r^2 - r - 3\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 - r - 3 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{3}{2}$$
$$r_2 = -1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(2r^2 - r - 3\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{5}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{3}{2}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-1}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$2a_n(n+r)(n+r-1) + a_n(n+r) + 2a_{n-2} - 3a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{2a_{n-2}}{2n^2 + 4nr + 2r^2 - n - r - 3} \tag{4}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_n = -\frac{2a_{n-2}}{n(2n+5)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{3}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{2}{2r^2 + 7r + 3}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_2 = -\frac{1}{9}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{2}{2r^2+7r+3}$	$-\frac{1}{9}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{2}{2r^2+7r+3}$	$-\frac{1}{9}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{4}{(2r^2 + 7r + 3)(2r^2 + 15r + 25)}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_4 = \frac{1}{234}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{2}{2r^2+7r+3}$	$-\frac{1}{9}$
a_3	0	0
a_4	$\frac{4}{(2r^2+7r+3)(2r^2+15r+25)}$	$\frac{1}{234}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{2}{2r^2+7r+3}$	$-\frac{1}{9}$
a_3	0	0
a_4	$\frac{4}{(2r^2+7r+3)(2r^2+15r+25)}$	$\frac{1}{234}$
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{3}{2}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^{\frac{3}{2}}\left(1 - \frac{x^2}{9} + \frac{x^4}{234} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$b_1 = 0$$

For $2 \leq n$ the recursive equation is

$$2b_n(n+r)(n+r-1) + b_n(n+r) + 2b_{n-2} - 3b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{2b_{n-2}}{2n^2 + 4nr + 2r^2 - n - r - 3} \tag{4}$$

Which for the root $r = -1$ becomes

$$b_n = -\frac{2b_{n-2}}{n(2n-5)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{2}{2r^2 + 7r + 3}$$

Which for the root $r = -1$ becomes

$$b_2 = 1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{2}{2r^2+7r+3}$	1

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{2}{2r^2+7r+3}$	1
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{4}{(2r^2 + 7r + 3)(2r^2 + 15r + 25)}$$

Which for the root $r = -1$ becomes

$$b_4 = -\frac{1}{6}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{2}{2r^2+7r+3}$	1
b_3	0	0
b_4	$\frac{4}{(2r^2+7r+3)(2r^2+15r+25)}$	$-\frac{1}{6}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{2}{2r^2+7r+3}$	1
b_3	0	0
b_4	$\frac{4}{(2r^2+7r+3)(2r^2+15r+25)}$	$-\frac{1}{6}$
b_5	0	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned}y_2(x) &= x^{\frac{3}{2}}\left(b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 \dots\right) \\ &= \frac{1 + x^2 - \frac{x^4}{6} + O(x^6)}{x}\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}y_h(x) &= c_1y_1(x) + c_2y_2(x) \\ &= c_1x^{\frac{3}{2}}\left(1 - \frac{x^2}{9} + \frac{x^4}{234} + O(x^6)\right) + \frac{c_2\left(1 + x^2 - \frac{x^4}{6} + O(x^6)\right)}{x}\end{aligned}$$

Hence the final solution is

$$\begin{aligned}y &= y_h \\ &= c_1x^{\frac{3}{2}}\left(1 - \frac{x^2}{9} + \frac{x^4}{234} + O(x^6)\right) + \frac{c_2\left(1 + x^2 - \frac{x^4}{6} + O(x^6)\right)}{x}\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1x^{\frac{3}{2}}\left(1 - \frac{x^2}{9} + \frac{x^4}{234} + O(x^6)\right) + \frac{c_2\left(1 + x^2 - \frac{x^4}{6} + O(x^6)\right)}{x} \tag{1}$$

Verification of solutions

$$y = c_1x^{\frac{3}{2}}\left(1 - \frac{x^2}{9} + \frac{x^4}{234} + O(x^6)\right) + \frac{c_2\left(1 + x^2 - \frac{x^4}{6} + O(x^6)\right)}{x}$$

Verified OK.

15.6.1 Maple step by step solution

Let's solve

$2y''x^2 + y'x + (2x^2 - 3)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

$$y'' = -\frac{(2x^2-3)y}{2x^2} - \frac{y'}{2x}$$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$$y'' + \frac{y'}{2x} + \frac{(2x^2-3)y}{2x^2} = 0$$

□ Check to see if $x_0 = 0$ is a regular singular point

- ◦ Define functions

$$\left[P_2(x) = \frac{1}{2x}, P_3(x) = \frac{2x^2-3}{2x^2}\right]$$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

$$(x \cdot P_2(x))\bigg|_{x=0} = \frac{1}{2}$$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$$(x^2 \cdot P_3(x))\bigg|_{x=0} = -\frac{3}{2}$$

- ◦ $x = 0$is a regular singular point

Check to see if $x_0 = 0$ is a regular singular point

$$x_0 = 0$$

- Multiply by denominators

$$2y''x^2 + y'x + (2x^2 - 3)\, y = 0$$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

$$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- ◦ Shift index using $k- >k - m$

$$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- ◦ Convert $x \cdot y'$ to series expansion

$$x \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r}$$

- ◦ Convert $x^2 \cdot y''$ to series expansion

$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r}$

Rewrite ODE with series expansions

$a_0(1+r)(-3+2r)\, x^r + a_1(2+r)(-1+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r+1)(2k+2r-3) + 2a_{k-2}\right)\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)(-3+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-1, \frac{3}{2}\right\}$

- Each term must be 0

  $a_1(2+r)(-1+2r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $2\left(k+r-\frac{3}{2}\right)(k+r+1)\, a_k + 2a_{k-2} = 0$

- Shift index using $k- >k+2$

  $2\left(k+\frac{1}{2}+r\right)(k+3+r)\, a_{k+2} + 2a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{2a_k}{(2k+1+2r)(k+3+r)}$

- Recursion relation for $r = -1$

  $a_{k+2} = -\frac{2a_k}{(2k-1)(k+2)}$

- Solution for $r = -1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2} = -\frac{2a_k}{(2k-1)(k+2)}, a_1 = 0\right]$

- Recursion relation for $r = \frac{3}{2}$

  $a_{k+2} = -\frac{2a_k}{(2k+4)\left(k+\frac{9}{2}\right)}$

- Solution for $r = \frac{3}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{3}{2}}, a_{k+2} = -\frac{2a_k}{(2k+4)\left(k+\frac{9}{2}\right)}, a_1 = 0\right]$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{3}{2}}\right), a_{k+2} = -\frac{2a_k}{(2k-1)(k+2)}, a_1 = 0, b_{k+2} = -\frac{2b_k}{(2k+4)(k+\frac{9}{2})}, b_1 = 0\right]$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.2 (Frobenius). Exercises page 251
Problem number: 7.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - y'x + \left(x^2 + \frac{8}{9}\right) y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' - y'x + \left(x^2 + \frac{8}{9}\right) y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{1}{x}$$
$$q(x) = \frac{9x^2 + 8}{9x^2}$$

Table 539: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{9x^2+8}{9x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' - y'x + \left(x^2 + \frac{8}{9}\right) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}\right) x^2 - \left(\sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}\right) x + \left(x^2 + \frac{8}{9}\right) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r+2} a_n\right) + \left(\sum_{n=0}^{\infty} \frac{8 a_n x^{n+r}}{9}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r}\right) + \left(\sum_{n=0}^{\infty} \frac{8 a_n x^{n+r}}{9}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - x^{n+r} a_n (n+r) + \frac{8 a_n x^{n+r}}{9} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - x^r a_0 r + \frac{8 a_0 x^r}{9} = 0$$

Or

$$\left(x^r r(-1+r) - x^r r + \frac{8 x^r}{9}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\frac{(9r^2 - 18r + 8)\, x^r}{9} = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - 2r + \frac{8}{9} = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{4}{3}$$
$$r_2 = \frac{2}{3}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\frac{(9r^2 - 18r + 8) x^r}{9} = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{2}{3}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{4}{3}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n+\frac{2}{3}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n + r)(n + r - 1) - a_n(n + r) + a_{n-2} + \frac{8a_n}{9} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{9a_{n-2}}{9n^2 + 18nr + 9r^2 - 18n - 18r + 8} \tag{4}$$

Which for the root $r = \frac{4}{3}$ becomes

$$a_n = -\frac{3a_{n-2}}{n(3n+2)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{4}{3}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{9}{9r^2 + 18r + 8}$$

Which for the root $r = \frac{4}{3}$ becomes

$$a_2 = -\frac{3}{16}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{9}{9r^2+18r+8}$	$-\frac{3}{16}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{9}{9r^2+18r+8}$	$-\frac{3}{16}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{81}{(9r^2 + 18r + 8)(9r^2 + 54r + 80)}$$

Which for the root $r = \frac{4}{3}$ becomes

$$a_4 = \frac{9}{896}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{9}{9r^2+18r+8}$	$-\frac{3}{16}$
a_3	0	0
a_4	$\frac{81}{(9r^2+18r+8)(9r^2+54r+80)}$	$\frac{9}{896}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{9}{9r^2+18r+8}$	$-\frac{3}{16}$
a_3	0	0
a_4	$\frac{81}{(9r^2+18r+8)(9r^2+54r+80)}$	$\frac{9}{896}$
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= x^{\frac{4}{3}} (a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots) \\
&= x^{\frac{4}{3}} \left(1 - \frac{3x^2}{16} + \frac{9x^4}{896} + O(x^6)\right)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$b_1 = 0$$

For $2 \leq n$ the recursive equation is

$$b_n(n+r)(n+r-1) - b_n(n+r) + b_{n-2} + \frac{8b_n}{9} = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{9b_{n-2}}{9n^2 + 18nr + 9r^2 - 18n - 18r + 8} \tag{4}$$

Which for the root $r = \frac{2}{3}$ becomes

$$b_n = -\frac{3b_{n-2}}{n(3n-2)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{2}{3}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{9}{9r^2 + 18r + 8}$$

Which for the root $r = \frac{2}{3}$ becomes

$$b_2 = -\frac{3}{8}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{9}{9r^2+18r+8}$	$-\frac{3}{8}$

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{9}{9r^2+18r+8}$	$-\frac{3}{8}$
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{81}{(9r^2 + 18r + 8)(9r^2 + 54r + 80)}$$

Which for the root $r = \frac{2}{3}$ becomes

$$b_4 = \frac{9}{320}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{9}{9r^2+18r+8}$	$-\frac{3}{8}$
b_3	0	0
b_4	$\frac{81}{(9r^2+18r+8)(9r^2+54r+80)}$	$\frac{9}{320}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{9}{9r^2+18r+8}$	$-\frac{3}{8}$
b_3	0	0
b_4	$\frac{81}{(9r^2+18r+8)(9r^2+54r+80)}$	$\frac{9}{320}$
b_5	0	0

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x^{\frac{4}{3}}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= x^{\frac{2}{3}}\left(1 - \frac{3x^2}{8} + \frac{9x^4}{320} + O\left(x^6\right)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{\frac{4}{3}}\left(1 - \frac{3x^2}{16} + \frac{9x^4}{896} + O\left(x^6\right)\right) + c_2 x^{\frac{2}{3}}\left(1 - \frac{3x^2}{8} + \frac{9x^4}{320} + O\left(x^6\right)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{\frac{4}{3}}\left(1 - \frac{3x^2}{16} + \frac{9x^4}{896} + O\left(x^6\right)\right) + c_2 x^{\frac{2}{3}}\left(1 - \frac{3x^2}{8} + \frac{9x^4}{320} + O\left(x^6\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x^{\frac{4}{3}}\left(1 - \frac{3x^2}{16} + \frac{9x^4}{896} + O\left(x^6\right)\right) + c_2 x^{\frac{2}{3}}\left(1 - \frac{3x^2}{8} + \frac{9x^4}{320} + O\left(x^6\right)\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 x^{\frac{4}{3}}\left(1 - \frac{3x^2}{16} + \frac{9x^4}{896} + O\left(x^6\right)\right) + c_2 x^{\frac{2}{3}}\left(1 - \frac{3x^2}{8} + \frac{9x^4}{320} + O\left(x^6\right)\right)
$$

Verified OK.

15.7.1 Maple step by step solution

Let's solve

$y''x^2 - y'x + \left(x^2 + \frac{8}{9}\right) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(9x^2+8)y}{9x^2} + \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{y'}{x} + \frac{(9x^2+8)y}{9x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = -\frac{1}{x}, P_3(x) = \frac{9x^2+8}{9x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\bigg|_{x=0} = -1$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\bigg|_{x=0} = \frac{8}{9}$

  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $9y''x^2 - 9y'x + (9x^2 + 8) y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $x^{m} \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$

- Convert $x^2 \cdot y''$ to series expansion

  $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-2+3r)\,(-4+3r)\, x^{r} + a_1(1+3r)\,(-1+3r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(3k+3r-2)\,(3k+3r-4)+9\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2+3r)\,(-4+3r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{\frac{2}{3}, \frac{4}{3}\right\}$

- Each term must be 0

  $a_1(1+3r)\,(-1+3r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $9\left(k-\frac{2}{3}+r\right)\left(k+r-\frac{4}{3}\right) a_k + 9a_{k-2} = 0$

- Shift index using $k->k+2$

  $9\left(k+\frac{4}{3}+r\right)\left(k+\frac{2}{3}+r\right) a_{k+2} + 9a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{9a_k}{(3k+4+3r)(3k+2+3r)}$

- Recursion relation for $r = \frac{2}{3}$

  $a_{k+2} = -\frac{9a_k}{(3k+6)(3k+4)}$

- Solution for $r = \frac{2}{3}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{2}{3}}, a_{k+2} = -\frac{9a_k}{(3k+6)(3k+4)}, a_1 = 0\right]$

- Recursion relation for $r = \frac{4}{3}$

  $a_{k+2} = -\frac{9a_k}{(3k+8)(3k+6)}$

- Solution for $r = \frac{4}{3}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{4}{3}}, a_{k+2} = -\frac{9a_k}{(3k+8)(3k+6)}, a_1 = 0\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+\frac{2}{3}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{4}{3}}\right), a_{k+2} = -\frac{9a_k}{(3k+6)(3k+4)}, a_1 = 0, b_{k+2} = -\frac{9b_k}{(3k+8)(3k+6)}, b_1 = 0\right]$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.2 (Frobenius). Exercises page 251
Problem number: 8.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - y'x + \left(2x^2 + \frac{5}{9}\right) y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' - y'x + \left(2x^2 + \frac{5}{9}\right) y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= \frac{18x^2 + 5}{9x^2} \end{aligned}$$

Table 541: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{18x^2+5}{9x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' - y'x + \left(2x^2 + \frac{5}{9}\right) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x^2 - \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) x + \left(2x^2 + \frac{5}{9}\right) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 2x^{n+r+2} a_n\right) + \left(\sum_{n=0}^{\infty} \frac{5a_n x^{n+r}}{9}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2x^{n+r+2} a_n = \sum_{n=2}^{\infty} 2a_{n-2} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=2}^{\infty} 2a_{n-2} x^{n+r}\right) + \left(\sum_{n=0}^{\infty} \frac{5a_n x^{n+r}}{9}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - x^{n+r} a_n (n+r) + \frac{5a_n x^{n+r}}{9} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - x^r a_0 r + \frac{5a_0 x^r}{9} = 0$$

Or

$$\left(x^r r(-1+r) - x^r r + \frac{5x^r}{9}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\frac{(9r^2 - 18r + 5)\, x^r}{9} = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - 2r + \frac{5}{9} = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{5}{3}$$
$$r_2 = \frac{1}{3}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\frac{(9r^2 - 18r + 5)\, x^r}{9} = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{4}{3}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n \right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n \right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{5}{3}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n+\frac{1}{3}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - a_n(n+r) + 2a_{n-2} + \frac{5a_n}{9} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{18a_{n-2}}{9n^2 + 18nr + 9r^2 - 18n - 18r + 5} \tag{4}$$

Which for the root $r = \frac{5}{3}$ becomes

$$a_n = -\frac{6a_{n-2}}{n\,(3n+4)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{5}{3}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{18}{9r^2 + 18r + 5}$$

Which for the root $r = \frac{5}{3}$ becomes

$$a_2 = -\frac{3}{10}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{18}{9r^2+18r+5}$	$-\frac{3}{10}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{18}{9r^2+18r+5}$	$-\frac{3}{10}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{324}{(9r^2 + 18r + 5)(9r^2 + 54r + 77)}$$

Which for the root $r = \frac{5}{3}$ becomes

$$a_4 = \frac{9}{320}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{18}{9r^2+18r+5}$	$-\frac{3}{10}$
a_3	0	0
a_4	$\frac{324}{(9r^2+18r+5)(9r^2+54r+77)}$	$\frac{9}{320}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{18}{9r^2+18r+5}$	$-\frac{3}{10}$
a_3	0	0
a_4	$\frac{324}{(9r^2+18r+5)(9r^2+54r+77)}$	$\frac{9}{320}$
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{5}{3}}\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots\right) \\ &= x^{\frac{5}{3}}\left(1 - \frac{3x^2}{10} + \frac{9x^4}{320} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$b_1 = 0$$

For $2 \leq n$ the recursive equation is

$$b_n(n+r)(n+r-1) - b_n(n+r) + 2b_{n-2} + \frac{5b_n}{9} = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{18b_{n-2}}{9n^2 + 18nr + 9r^2 - 18n - 18r + 5} \tag{4}$$

Which for the root $r = \frac{1}{3}$ becomes

$$b_n = -\frac{6b_{n-2}}{n(3n-4)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{1}{3}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{18}{9r^2 + 18r + 5}$$

Which for the root $r = \frac{1}{3}$ becomes

$$b_2 = -\frac{3}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{18}{9r^2+18r+5}$	$-\frac{3}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{18}{9r^2+18r+5}$	$-\frac{3}{2}$
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{324}{(9r^2 + 18r + 5)(9r^2 + 54r + 77)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$b_4 = \frac{9}{32}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{18}{9r^2+18r+5}$	$-\frac{3}{2}$
b_3	0	0
b_4	$\frac{324}{(9r^2+18r+5)(9r^2+54r+77)}$	$\frac{9}{32}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{18}{9r^2+18r+5}$	$-\frac{3}{2}$
b_3	0	0
b_4	$\frac{324}{(9r^2+18r+5)(9r^2+54r+77)}$	$\frac{9}{32}$
b_5	0	0

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x^{\frac{5}{3}}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= x^{\frac{1}{3}}\left(1 - \frac{3x^2}{2} + \frac{9x^4}{32} + O(x^6)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{\frac{5}{3}}\left(1 - \frac{3x^2}{10} + \frac{9x^4}{320} + O(x^6)\right) + c_2 x^{\frac{1}{3}}\left(1 - \frac{3x^2}{2} + \frac{9x^4}{32} + O(x^6)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{\frac{5}{3}}\left(1 - \frac{3x^2}{10} + \frac{9x^4}{320} + O(x^6)\right) + c_2 x^{\frac{1}{3}}\left(1 - \frac{3x^2}{2} + \frac{9x^4}{32} + O(x^6)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x^{\frac{5}{3}}\left(1 - \frac{3x^2}{10} + \frac{9x^4}{320} + O(x^6)\right) + c_2 x^{\frac{1}{3}}\left(1 - \frac{3x^2}{2} + \frac{9x^4}{32} + O(x^6)\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 x^{\frac{5}{3}}\left(1 - \frac{3x^2}{10} + \frac{9x^4}{320} + O(x^6)\right) + c_2 x^{\frac{1}{3}}\left(1 - \frac{3x^2}{2} + \frac{9x^4}{32} + O(x^6)\right)
$$

Verified OK.

15.8.1 Maple step by step solution

Let's solve

$y''x^2 - y'x + \left(2x^2 + \frac{5}{9}\right) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(18x^2+5)y}{9x^2} + \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{y'}{x} + \frac{(18x^2+5)y}{9x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + y'x + \left(x^2 - \frac{1}{9}\right)y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + y'x + \left(x^2 - \frac{1}{9}\right)y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{9x^2 - 1}{9x^2}$$

Table 543: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{9x^2-1}{9x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' + y'x + \left(x^2 - \frac{1}{9}\right) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x^2 + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) x + \left(x^2 - \frac{1}{9}\right)\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)\right) \\ +\left(\sum_{n=0}^{\infty} x^{n+r+2} a_n\right)+\sum_{n=0}^{\infty}\left(-\frac{a_n x^{n+r}}{9}\right)=0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n=\sum_{n=2}^{\infty} a_{n-2} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)\right) \\ +\left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r}\right)+\sum_{n=0}^{\infty}\left(-\frac{a_n x^{n+r}}{9}\right)=0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n(n+r)(n+r-1)+x^{n+r} a_n(n+r)-\frac{a_n x^{n+r}}{9}=0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r)+x^r a_0 r-\frac{a_0 x^r}{9}=0$$

Or

$$\left(x^r r(-1+r)+x^r r-\frac{x^r}{9}\right) a_0=0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\frac{\left(9 r^2-1\right) x^r}{9}=0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - \frac{1}{9} = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{3}$$
$$r_2 = -\frac{1}{3}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\frac{(9r^2 - 1)\, x^r}{9} = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{2}{3}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{3}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-\frac{1}{3}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n + r)\,(n + r - 1) + a_n(n + r) + a_{n-2} - \frac{a_n}{9} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{9a_{n-2}}{9n^2 + 18nr + 9r^2 - 1} \tag{4}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_n = -\frac{3a_{n-2}}{n(3n+2)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{3}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{9}{9r^2 + 36r + 35}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_2 = -\frac{3}{16}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{9}{9r^2+36r+35}$	$-\frac{3}{16}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{9}{9r^2+36r+35}$	$-\frac{3}{16}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{81}{(9r^2 + 36r + 35)(9r^2 + 72r + 143)}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_4 = \frac{9}{896}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{9}{9r^2+36r+35}$	$-\frac{3}{16}$
a_3	0	0
a_4	$\frac{81}{(9r^2+36r+35)(9r^2+72r+143)}$	$\frac{9}{896}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{9}{9r^2+36r+35}$	$-\frac{3}{16}$
a_3	0	0
a_4	$\frac{81}{(9r^2+36r+35)(9r^2+72r+143)}$	$\frac{9}{896}$
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{1}{3}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^{\frac{1}{3}}\left(1 - \frac{3x^2}{16} + \frac{9x^4}{896} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$b_1 = 0$$

For $2 \leq n$ the recursive equation is

$$b_n(n+r)(n+r-1) + b_n(n+r) + b_{n-2} - \frac{b_n}{9} = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{9b_{n-2}}{9n^2 + 18nr + 9r^2 - 1} \tag{4}$$

Which for the root $r = -\frac{1}{3}$ becomes

$$b_n = -\frac{3b_{n-2}}{n(3n-2)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{1}{3}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{9}{9r^2 + 36r + 35}$$

Which for the root $r = -\frac{1}{3}$ becomes

$$b_2 = -\frac{3}{8}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{9}{9r^2+36r+35}$	$-\frac{3}{8}$

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{9}{9r^2+36r+35}$	$-\frac{3}{8}$
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{81}{(9r^2 + 36r + 35)(9r^2 + 72r + 143)}$$

Which for the root $r = -\frac{1}{3}$ becomes

$$b_4 = \frac{9}{320}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{9}{9r^2+36r+35}$	$-\frac{3}{8}$
b_3	0	0
b_4	$\frac{81}{(9r^2+36r+35)(9r^2+72r+143)}$	$\frac{9}{320}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{9}{9r^2+36r+35}$	$-\frac{3}{8}$
b_3	0	0
b_4	$\frac{81}{(9r^2+36r+35)(9r^2+72r+143)}$	$\frac{9}{320}$
b_5	0	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned}
y_2(x) &= x^{\frac{1}{3}}\left(b_0+b_1x+b_2x^2+b_3x^3+b_4x^4+b_5x^5+b_6x^6\dots\right) \\
&= \frac{1-\frac{3x^2}{8}+\frac{9x^4}{320}+O(x^6)}{x^{\frac{1}{3}}}
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= c_1y_1(x)+c_2y_2(x) \\
&= c_1x^{\frac{1}{3}}\left(1-\frac{3x^2}{16}+\frac{9x^4}{896}+O(x^6)\right)+\frac{c_2\left(1-\frac{3x^2}{8}+\frac{9x^4}{320}+O(x^6)\right)}{x^{\frac{1}{3}}}
\end{aligned}$$

Hence the final solution is

$$\begin{aligned}
y &= y_h \\
&= c_1x^{\frac{1}{3}}\left(1-\frac{3x^2}{16}+\frac{9x^4}{896}+O(x^6)\right)+\frac{c_2\left(1-\frac{3x^2}{8}+\frac{9x^4}{320}+O(x^6)\right)}{x^{\frac{1}{3}}}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1x^{\frac{1}{3}}\left(1-\frac{3x^2}{16}+\frac{9x^4}{896}+O(x^6)\right)+\frac{c_2\left(1-\frac{3x^2}{8}+\frac{9x^4}{320}+O(x^6)\right)}{x^{\frac{1}{3}}} \tag{1}$$

Verification of solutions

$$y = c_1x^{\frac{1}{3}}\left(1-\frac{3x^2}{16}+\frac{9x^4}{896}+O(x^6)\right)+\frac{c_2\left(1-\frac{3x^2}{8}+\frac{9x^4}{320}+O(x^6)\right)}{x^{\frac{1}{3}}}$$

Verified OK.

15.9.1 Maple step by step solution

Let's solve

$y''x^2 + y'x + \left(x^2 - \frac{1}{9}\right) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(9x^2-1)y}{9x^2} - \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + \frac{(9x^2-1)y}{9x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- ◦ Define functions

  $\left[P_2(x) = \frac{1}{x}, P_3(x) = \frac{9x^2-1}{9x^2}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = 1$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = -\frac{1}{9}$

- ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $9y''x^2 + 9y'x + (9x^2 - 1)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k-m$

  $$x^{m}\cdot y=\sum_{k=m}^{\infty} a_{k-m}x^{k+r}$$

- Convert $x\cdot y'$ to series expansion

  $$x\cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r}$$

- Convert $x^2\cdot y''$ to series expansion

  $$x^2\cdot y''=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(1+3r)\,(-1+3r)\, x^{r}+a_1(4+3r)\,(2+3r)\, x^{1+r}+\left(\sum_{k=2}^{\infty} \left(a_k(3k+3r+1)\,(3k+3r-1)+9a_{k-\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$(1+3r)\,(-1+3r)=0$$

- Values of r that satisfy the indicial equation

  $$r\in\left\{-\frac{1}{3}, \frac{1}{3}\right\}$$

- Each term must be 0

  $$a_1(4+3r)\,(2+3r)=0$$

- Solve for the dependent coefficient(s)

  $$a_1=0$$

- Each term in the series must be 0, giving the recursion relation

  $$a_k(3k+3r+1)\,(3k+3r-1)+9a_{k-2}=0$$

- Shift index using $k- >k+2$

  $$a_{k+2}(3k+7+3r)\,(3k+5+3r)+9a_k=0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2}=-\frac{9a_k}{(3k+7+3r)(3k+5+3r)}$$

- Recursion relation for $r=-\frac{1}{3}$

  $$a_{k+2}=-\frac{9a_k}{(3k+6)(3k+4)}$$

- Solution for $r=-\frac{1}{3}$

  $$\left[y=\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{3}}, a_{k+2}=-\frac{9a_k}{(3k+6)(3k+4)}, a_1=0\right]$$

- Recursion relation for $r = \frac{1}{3}$

  $a_{k+2} = -\frac{9a_k}{(3k+8)(3k+6)}$

- Solution for $r = \frac{1}{3}$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = -\frac{9a_k}{(3k+8)(3k+6)}, a_1 = 0\right]$$

- Combine solutions and rename parameters

  $$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{3}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+2} = -\frac{9a_k}{(3k+6)(3k+4)}, a_1 = 0, b_{k+2} = -\frac{9b_k}{(3k+8)(3k+6)}, b_1 = 0\right]$$

singularity	type
$x = 0$	"regular"

$q(x) = \frac{1}{x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2xy'' + y' + 2y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2a_n x^{n+r} = \sum_{n=1}^{\infty} 2a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} 2a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r-1} a_n (n+r)(n+r-1) + (n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$2x^{-1+r} a_0 r(-1+r) + r a_0 x^{-1+r} = 0$$

Or

$$\left(2x^{-1+r} r(-1+r) + r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, x^{-1+r}(-1+2r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 - r = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{2}$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\, x^{-1+r}(-1+2r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{2}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^n$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$2a_n(n + r)(n + r - 1) + a_n(n + r) + 2a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{2a_{n-1}}{2n^2 + 4nr + 2r^2 - n - r} \tag{4}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_n = -\frac{2a_{n-1}}{2n^2 + n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{2}{2r^2 + 3r + 1}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_1 = -\frac{2}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2}{2r^2+3r+1}$	$-\frac{2}{3}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{4}{4r^4 + 20r^3 + 35r^2 + 25r + 6}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_2 = \frac{2}{15}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2}{2r^2+3r+1}$	$-\frac{2}{3}$
a_2	$\frac{4}{4r^4+20r^3+35r^2+25r+6}$	$\frac{2}{15}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{8}{8r^6 + 84r^5 + 350r^4 + 735r^3 + 812r^2 + 441r + 90}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_3 = -\frac{4}{315}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2}{2r^2+3r+1}$	$-\frac{2}{3}$
a_2	$\frac{4}{4r^4+20r^3+35r^2+25r+6}$	$\frac{2}{15}$
a_3	$-\frac{8}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$-\frac{4}{315}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{16}{16r^8 + 288r^7 + 2184r^6 + 9072r^5 + 22449r^4 + 33642r^3 + 29531r^2 + 13698r + 2520}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_4 = \frac{2}{2835}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2}{2r^2+3r+1}$	$-\frac{2}{3}$
a_2	$\frac{4}{4r^4+20r^3+35r^2+25r+6}$	$\frac{2}{15}$
a_3	$-\frac{8}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$-\frac{4}{315}$
a_4	$\frac{16}{16r^8+288r^7+2184r^6+9072r^5+22449r^4+33642r^3+29531r^2+13698r+2520}$	$\frac{2}{2835}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{32}{32r^{10} + 880r^9 + 10560r^8 + 72600r^7 + 315546r^6 + 902055r^5 + 1708465r^4 + 2102375r^3 + 1594197r}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_5 = -\frac{4}{155925}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2}{2r^2+3r+1}$	$-\frac{2}{3}$
a_2	$\frac{4}{4r^4+20r^3+35r^2+25r+6}$	$\frac{2}{15}$
a_3	$-\frac{8}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$-\frac{4}{315}$
a_4	$\frac{16}{16r^8+288r^7+2184r^6+9072r^5+22449r^4+33642r^3+29531r^2+13698r+2520}$	$\frac{2}{2835}$
a_5	$-\frac{32}{32r^{10}+880r^9+10560r^8+72600r^7+315546r^6+902055r^5+1708465r^4+2102375r^3+1594197r^2+664290r+113400}$	$-\frac{4}{155925}$

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= \sqrt{x}\,(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots) \\
&= \sqrt{x}\left(1 - \frac{2x}{3} + \frac{2x^2}{15} - \frac{4x^3}{315} + \frac{2x^4}{2835} - \frac{4x^5}{155925} + O(x^6)\right)
\end{aligned}
$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$
2b_n(n+r)(n+r-1) + (n+r)\,b_n + 2b_{n-1} = 0 \tag{3}
$$

Solving for b_n from recursive equation (4) gives

$$
b_n = -\frac{2b_{n-1}}{2n^2 + 4nr + 2r^2 - n - r} \tag{4}
$$

Which for the root $r = 0$ becomes

$$
b_n = -\frac{2b_{n-1}}{n\,(2n-1)} \tag{5}
$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$
b_1 = -\frac{2}{2r^2 + 3r + 1}
$$

Which for the root $r = 0$ becomes

$$
b_1 = -2
$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{2}{2r^2+3r+1}$	-2

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{4}{4r^4 + 20r^3 + 35r^2 + 25r + 6}$$

Which for the root $r = 0$ becomes

$$b_2 = \frac{2}{3}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{2}{2r^2+3r+1}$	-2
b_2	$\frac{4}{4r^4+20r^3+35r^2+25r+6}$	$\frac{2}{3}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{8}{8r^6 + 84r^5 + 350r^4 + 735r^3 + 812r^2 + 441r + 90}$$

Which for the root $r = 0$ becomes

$$b_3 = -\frac{4}{45}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{2}{2r^2+3r+1}$	-2
b_2	$\frac{4}{4r^4+20r^3+35r^2+25r+6}$	$\frac{2}{3}$
b_3	$-\frac{8}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$-\frac{4}{45}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{16}{16r^8 + 288r^7 + 2184r^6 + 9072r^5 + 22449r^4 + 33642r^3 + 29531r^2 + 13698r + 2520}$$

Which for the root $r = 0$ becomes

$$b_4 = \frac{2}{315}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{2}{2r^2+3r+1}$	-2
b_2	$\frac{4}{4r^4+20r^3+35r^2+25r+6}$	$\frac{2}{3}$
b_3	$-\frac{8}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$-\frac{4}{45}$
b_4	$\frac{16}{16r^8+288r^7+2184r^6+9072r^5+22449r^4+33642r^3+29531r^2+13698r+2520}$	$\frac{2}{315}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{32}{32r^{10} + 880r^9 + 10560r^8 + 72600r^7 + 315546r^6 + 902055r^5 + 1708465r^4 + 2102375r^3 + 1594197r}$$

Which for the root $r = 0$ becomes

$$b_5 = -\frac{4}{14175}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{2}{2r^2+3r+1}$	-2
b_2	$\frac{4}{4r^4+20r^3+35r^2+25r+6}$	$\frac{2}{3}$
b_3	$-\frac{8}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$-\frac{4}{45}$
b_4	$\frac{16}{16r^8+288r^7+2184r^6+9072r^5+22449r^4+33642r^3+29531r^2+13698r+2520}$	$\frac{2}{315}$
b_5	$-\frac{32}{32r^{10}+880r^9+10560r^8+72600r^7+315546r^6+902055r^5+1708465r^4+2102375r^3+1594197r^2+664290r+113400}$	$-\frac{4}{14175}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots \\ &= 1 - 2x + \frac{2x^2}{3} - \frac{4x^3}{45} + \frac{2x^4}{315} - \frac{4x^5}{14175} + O(x^6) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 \sqrt{x} \left(1 - \frac{2x}{3} + \frac{2x^2}{15} - \frac{4x^3}{315} + \frac{2x^4}{2835} - \frac{4x^5}{155925} + O(x^6)\right) \\ &\quad + c_2 \left(1 - 2x + \frac{2x^2}{3} - \frac{4x^3}{45} + \frac{2x^4}{315} - \frac{4x^5}{14175} + O(x^6)\right) \end{aligned}$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1\sqrt{x}\left(1-\frac{2x}{3}+\frac{2x^2}{15}-\frac{4x^3}{315}+\frac{2x^4}{2835}-\frac{4x^5}{155925}+O\left(x^6\right)\right) \\
&\quad + c_2\left(1-2x+\frac{2x^2}{3}-\frac{4x^3}{45}+\frac{2x^4}{315}-\frac{4x^5}{14175}+O\left(x^6\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = c_1\sqrt{x}\left(1-\frac{2x}{3}+\frac{2x^2}{15}-\frac{4x^3}{315}+\frac{2x^4}{2835}-\frac{4x^5}{155925}+O\left(x^6\right)\right) \\
+ c_2\left(1-2x+\frac{2x^2}{3}-\frac{4x^3}{45}+\frac{2x^4}{315}-\frac{4x^5}{14175}+O\left(x^6\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = c_1\sqrt{x}\left(1-\frac{2x}{3}+\frac{2x^2}{15}-\frac{4x^3}{315}+\frac{2x^4}{2835}-\frac{4x^5}{155925}+O\left(x^6\right)\right) \\
+ c_2\left(1-2x+\frac{2x^2}{3}-\frac{4x^3}{45}+\frac{2x^4}{315}-\frac{4x^5}{14175}+O\left(x^6\right)\right)
\end{aligned}
$$

Verified OK.

15.10.1 Maple step by step solution

Let's solve

$2y''x + y' + 2y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y'}{2x} - \frac{y}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{2x} + \frac{y}{x} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{1}{2x}, P_3(x) = \frac{1}{x}\right]$

- $x \cdot P_2(x)$ is analytic at $x=0$

  $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = \frac{1}{2}$

- $x^2 \cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 0$

- $x=0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2y''x + y' + 2y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert y' to series expansion

  $y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1}$

- Shift index using $k->k+1$

  $y' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, x^{k+r}$

- Convert $x \cdot y''$ to series expansion

  $x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$

- Shift index using $k->k+1$

  $x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(-1+2r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(2k+1+2r) + 2a_k\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, \frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $2\left(k+r+\frac{1}{2}\right)(k+1+r)\, a_{k+1}+2a_k=0$

- Recursion relation that defines series solution to ODE

  $a_{k+1}=-\frac{2a_k}{(2k+1+2r)(k+1+r)}$

- Recursion relation for $r=0$

  $a_{k+1}=-\frac{2a_k}{(2k+1)(k+1)}$

- Solution for $r=0$

  $\left[y=\sum_{k=0}^{\infty} a_k x^k, a_{k+1}=-\frac{2a_k}{(2k+1)(k+1)}\right]$

- Recursion relation for $r=\frac{1}{2}$

  $a_{k+1}=-\frac{2a_k}{(2k+2)\left(k+\frac{3}{2}\right)}$

- Solution for $r=\frac{1}{2}$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1}=-\frac{2a_k}{(2k+2)\left(k+\frac{3}{2}\right)}\right]$

- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty} a_k x^k\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{1+k}=-\frac{2a_k}{(2k+1)(1+k)}, b_{1+k}=-\frac{2b_k}{(2k+2)\left(k+\frac{3}{2}\right)}\right]$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.2 (Frobenius). Exercises page 251
Problem number: 11.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{3xy'' - (x-2)\,y' - 2y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$3xy'' + (-x+2)\,y' - 2y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$\begin{aligned} p(x) &= -\frac{x-2}{3x} \\ q(x) &= -\frac{2}{3x} \end{aligned}$$

Table 547: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x-2}{3x}$	
singularity	type
$x = 0$	"regular"

$q(x) = -\frac{2}{3x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$3xy'' + (-x + 2)\,y' - 2y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$3\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}\right) x + (-x+2)\left(\sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}\right) - 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 3x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 2(n+r) a_n x^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-2a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) = \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1) x^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty} \left(-2a_n x^{n+r}\right) = \sum_{n=1}^{\infty} \left(-2a_{n-1} x^{n+r-1}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} 3x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1) x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 2(n+r) a_n x^{n+r-1}\right) + \sum_{n=1}^{\infty} \left(-2a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$3x^{n+r-1} a_n (n+r)(n+r-1) + 2(n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$3x^{-1+r} a_0 r(-1+r) + 2r a_0 x^{-1+r} = 0$$

Or

$$\left(3x^{-1+r} r(-1+r) + 2r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, x^{-1+r}(-1+3r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$3r^2 - r = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{3}$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\, x^{-1+r}(-1 + 3r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{3}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{3}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^n$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$3a_n(n + r)(n + r - 1) - a_{n-1}(n + r - 1) + 2a_n(n + r) - 2a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}(n + r + 1)}{3n^2 + 6nr + 3r^2 - n - r} \tag{4}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_n = \frac{3na_{n-1} + 4a_{n-1}}{9n^2 + 3n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{3}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{2 + r}{3r^2 + 5r + 2}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_1 = \frac{7}{12}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2+r}{3r^2+5r+2}$	$\frac{7}{12}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{3 + r}{9r^3 + 30r^2 + 31r + 10}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_2 = \frac{5}{36}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2+r}{3r^2+5r+2}$	$\frac{7}{12}$
a_2	$\frac{3+r}{9r^3+30r^2+31r+10}$	$\frac{5}{36}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{4 + r}{27r^4 + 162r^3 + 333r^2 + 278r + 80}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_3 = \frac{13}{648}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2+r}{3r^2+5r+2}$	$\frac{7}{12}$
a_2	$\frac{3+r}{9r^3+30r^2+31r+10}$	$\frac{5}{36}$
a_3	$\frac{4+r}{27r^4+162r^3+333r^2+278r+80}$	$\frac{13}{648}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{5+r}{81r^5 + 783r^4 + 2781r^3 + 4497r^2 + 3298r + 880}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_4 = \frac{1}{486}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2+r}{3r^2+5r+2}$	$\frac{7}{12}$
a_2	$\frac{3+r}{9r^3+30r^2+31r+10}$	$\frac{5}{36}$
a_3	$\frac{4+r}{27r^4+162r^3+333r^2+278r+80}$	$\frac{13}{648}$
a_4	$\frac{5+r}{81r^5+783r^4+2781r^3+4497r^2+3298r+880}$	$\frac{1}{486}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{6+r}{243r^6 + 3483r^5 + 19305r^4 + 52425r^3 + 72852r^2 + 48812r + 12320}$$

Which for the root $r = \frac{1}{3}$ becomes

$$a_5 = \frac{19}{116640}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2+r}{3r^2+5r+2}$	$\frac{7}{12}$
a_2	$\frac{3+r}{9r^3+30r^2+31r+10}$	$\frac{5}{36}$
a_3	$\frac{4+r}{27r^4+162r^3+333r^2+278r+80}$	$\frac{13}{648}$
a_4	$\frac{5+r}{81r^5+783r^4+2781r^3+4497r^2+3298r+880}$	$\frac{1}{486}$
a_5	$\frac{6+r}{243r^6+3483r^5+19305r^4+52425r^3+72852r^2+48812r+12320}$	$\frac{19}{116640}$

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= x^{\frac{1}{3}}\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots\right) \\
&= x^{\frac{1}{3}}\left(1 + \frac{7x}{12} + \frac{5x^2}{36} + \frac{13x^3}{648} + \frac{x^4}{486} + \frac{19x^5}{116640} + O(x^6)\right)
\end{aligned}
$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$
3b_n(n+r)(n+r-1) - b_{n-1}(n+r-1) + 2(n+r)b_n - 2b_{n-1} = 0 \tag{3}
$$

Solving for b_n from recursive equation (4) gives

$$
b_n = \frac{b_{n-1}(n+r+1)}{3n^2 + 6nr + 3r^2 - n - r} \tag{4}
$$

Which for the root $r = 0$ becomes

$$
b_n = \frac{b_{n-1}(n+1)}{n(3n-1)} \tag{5}
$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{2 + r}{3r^2 + 5r + 2}$$

Which for the root $r = 0$ becomes

$$b_1 = 1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2+r}{3r^2+5r+2}$	1

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{3 + r}{9r^3 + 30r^2 + 31r + 10}$$

Which for the root $r = 0$ becomes

$$b_2 = \frac{3}{10}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2+r}{3r^2+5r+2}$	1
b_2	$\frac{3+r}{9r^3+30r^2+31r+10}$	$\frac{3}{10}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{4 + r}{27r^4 + 162r^3 + 333r^2 + 278r + 80}$$

Which for the root $r = 0$ becomes

$$b_3 = \frac{1}{20}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2+r}{3r^2+5r+2}$	1
b_2	$\frac{3+r}{9r^3+30r^2+31r+10}$	$\frac{3}{10}$
b_3	$\frac{4+r}{27r^4+162r^3+333r^2+278r+80}$	$\frac{1}{20}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{5+r}{81r^5 + 783r^4 + 2781r^3 + 4497r^2 + 3298r + 880}$$

Which for the root $r = 0$ becomes

$$b_4 = \frac{1}{176}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2+r}{3r^2+5r+2}$	1
b_2	$\frac{3+r}{9r^3+30r^2+31r+10}$	$\frac{3}{10}$
b_3	$\frac{4+r}{27r^4+162r^3+333r^2+278r+80}$	$\frac{1}{20}$
b_4	$\frac{5+r}{81r^5+783r^4+2781r^3+4497r^2+3298r+880}$	$\frac{1}{176}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{6+r}{243r^6 + 3483r^5 + 19305r^4 + 52425r^3 + 72852r^2 + 48812r + 12320}$$

Which for the root $r = 0$ becomes

$$b_5 = \frac{3}{6160}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2+r}{3r^2+5r+2}$	1
b_2	$\frac{3+r}{9r^3+30r^2+31r+10}$	$\frac{3}{10}$
b_3	$\frac{4+r}{27r^4+162r^3+333r^2+278r+80}$	$\frac{1}{20}$
b_4	$\frac{5+r}{81r^5+783r^4+2781r^3+4497r^2+3298r+880}$	$\frac{1}{176}$
b_5	$\frac{6+r}{243r^6+3483r^5+19305r^4+52425r^3+72852r^2+48812r+12320}$	$\frac{3}{6160}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots \\ &= 1 + x + \frac{3x^2}{10} + \frac{x^3}{20} + \frac{x^4}{176} + \frac{3x^5}{6160} + O(x^6) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^{\frac{1}{3}} \left(1 + \frac{7x}{12} + \frac{5x^2}{36} + \frac{13x^3}{648} + \frac{x^4}{486} + \frac{19x^5}{116640} + O(x^6)\right) \\ &\quad + c_2 \left(1 + x + \frac{3x^2}{10} + \frac{x^3}{20} + \frac{x^4}{176} + \frac{3x^5}{6160} + O(x^6)\right) \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= c_1 x^{\frac{1}{3}} \left(1 + \frac{7x}{12} + \frac{5x^2}{36} + \frac{13x^3}{648} + \frac{x^4}{486} + \frac{19x^5}{116640} + O(x^6)\right) \\ &\quad + c_2 \left(1 + x + \frac{3x^2}{10} + \frac{x^3}{20} + \frac{x^4}{176} + \frac{3x^5}{6160} + O(x^6)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y &= c_1 x^{\frac{1}{3}} \left(1 + \frac{7x}{12} + \frac{5x^2}{36} + \frac{13x^3}{648} + \frac{x^4}{486} + \frac{19x^5}{116640} + O(x^6)\right) \\ &\quad + c_2 \left(1 + x + \frac{3x^2}{10} + \frac{x^3}{20} + \frac{x^4}{176} + \frac{3x^5}{6160} + O(x^6)\right) \end{aligned} \tag{1}$$

Verification of solutions

$$\begin{aligned} y &= c_1 x^{\frac{1}{3}} \left(1 + \frac{7x}{12} + \frac{5x^2}{36} + \frac{13x^3}{648} + \frac{x^4}{486} + \frac{19x^5}{116640} + O(x^6)\right) \\ &\quad + c_2 \left(1 + x + \frac{3x^2}{10} + \frac{x^3}{20} + \frac{x^4}{176} + \frac{3x^5}{6160} + O(x^6)\right) \end{aligned}$$

Verified OK.

15.11.1 Maple step by step solution

Let's solve

$3y''x+(-x+2)\,y'-2y=0$

- Highest derivative means the order of the ODE is 2

y''

- Isolate 2nd derivative

$y''=\frac{2y}{3x}+\frac{(x-2)y'}{3x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y''-\frac{(x-2)y'}{3x}-\frac{2y}{3x}=0$

□ Check to see if $x_0=0$ is a regular singular point

- ◦ Define functions

$\left[P_2(x)=-\frac{x-2}{3x},P_3(x)=-\frac{2}{3x}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

$\left(x\cdot P_2(x)\right)\Big|_{x=0}=\frac{2}{3}$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

$\left(x^2\cdot P_3(x)\right)\Big|_{x=0}=0$

- ◦ $x=0$is a regular singular point

Check to see if $x_0=0$ is a regular singular point

$x_0=0$

- Multiply by denominators

$3y''x+(-x+2)\,y'-2y=0$

- Assume series solution for y

$y=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot y'$ to series expansion for $m=0..1$

$x^m\cdot y'=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x \cdot y''$ to series expansion

  $$x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$$

- Shift index using $k- >k+1$

  $$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0 r(-1+3r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(3k+2+3r) - a_k(k+r+2)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$r(-1+3r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{0, \frac{1}{3}\right\}$$

- Each term in the series must be 0, giving the recursion relation

  $$3\left(k+\frac{2}{3}+r\right)(k+1+r)\, a_{k+1} - a_k(k+r+2) = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+1} = \frac{a_k(k+r+2)}{(3k+2+3r)(k+1+r)}$$

- Recursion relation for $r = 0$

  $$a_{k+1} = \frac{a_k(k+2)}{(3k+2)(k+1)}$$

- Solution for $r = 0$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = \frac{a_k(k+2)}{(3k+2)(k+1)}\right]$$

- Recursion relation for $r = \frac{1}{3}$

  $$a_{k+1} = \frac{a_k\left(k+\frac{7}{3}\right)}{(3k+3)\left(k+\frac{4}{3}\right)}$$

- Solution for $r = \frac{1}{3}$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+1} = \frac{a_k\left(k+\frac{7}{3}\right)}{(3k+3)\left(k+\frac{4}{3}\right)}\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_k x^k\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{1+k}=\frac{a_k(k+2)}{(3k+2)(1+k)}, b_{1+k}=\frac{b_k\left(k+\frac{7}{3}\right)}{(3k+3)\left(k+\frac{4}{3}\right)}\right]$$

Problem number: 12.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[_Lienard]
```

$$\boxed{xy'' + 2y' + yx = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$xy'' + 2y' + yx = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{2}{x}$$
$$q(x) = 1$$

Table 549: Table $p(x), q(x)$ singularites.

$p(x) = \frac{2}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = 1$	
singularity	type

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$xy'' + 2y' + yx = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r) (n+r-1) a_n x^{n+r-2}\right) x + 2\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) x = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r) (n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r-1} a_n (n+r)(n+r-1) + 2(n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$x^{-1+r} a_0 r(-1+r) + 2r a_0 x^{-1+r} = 0$$

Or

$$\left(x^{-1+r} r(-1+r) + 2r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, x^{-1+r}(1+r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$r(1+r) = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = -1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\, x^{-1+r}(1+r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 1$ is an integer, then we can construct two linearly independent solutions

$$
\begin{aligned}
y_1(x) &= x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right) \\
y_2(x) &= C y_1(x)\ln(x) + x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^n \\
y_2(x) &= C y_1(x)\ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x}
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^n \\
y_2(x) &= C y_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-1}\right)
\end{aligned}
$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$
a_1 = 0
$$

For $2 \le n$ the recursive equation is

$$
a_n(n+r)(n+r-1) + 2a_n(n+r) + a_{n-2} = 0 \tag{3}
$$

Solving for a_n from recursive equation (4) gives

$$
a_n = -\frac{a_{n-2}}{n^2 + 2nr + r^2 + n + r} \tag{4}
$$

Which for the root $r = 0$ becomes

$$
a_n = -\frac{a_{n-2}}{n(1+n)} \tag{5}
$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{1}{r^2 + 5r + 6}$$

Which for the root $r = 0$ becomes

$$a_2 = -\frac{1}{6}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{6}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{6}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{r^4 + 14r^3 + 71r^2 + 154r + 120}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{120}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{6}$
a_3	0	0
a_4	$\frac{1}{r^4+14r^3+71r^2+154r+120}$	$\frac{1}{120}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{6}$
a_3	0	0
a_4	$\frac{1}{r^4+14r^3+71r^2+154r+120}$	$\frac{1}{120}$
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots \\ &= 1 - \frac{x^2}{6} + \frac{x^4}{120} + O(x^6) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 1$. Now we need to determine if

C is zero or not. This is done by finding $\lim_{r\rightarrow r_2} a_1(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$
\begin{aligned}
a_N &= a_1 \\
&= 0
\end{aligned}
$$

Therefore

$$
\begin{aligned}
\lim_{r\rightarrow r_2} 0 &= \lim_{r\rightarrow -1} 0 \\
&= 0
\end{aligned}
$$

The limit is 0. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$
\begin{aligned}
y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\
&= \sum_{n=0}^{\infty} b_n x^{n-1}
\end{aligned}
$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$
b_1 = 0
$$

For $2 \leq n$ the recursive equation is

$$
b_n(n+r)(n+r-1) + 2(n+r) b_n + b_{n-2} = 0 \tag{4}
$$

Which for for the root $r = -1$ becomes

$$
b_n(n-1)(n-2) + 2(n-1) b_n + b_{n-2} = 0 \tag{4A}
$$

Solving for b_n from the recursive equation (4) gives

$$
b_n = -\frac{b_{n-2}}{n^2 + 2nr + r^2 + n + r} \tag{5}
$$

Which for the root $r = -1$ becomes

$$
b_n = -\frac{b_{n-2}}{n^2 - n} \tag{6}
$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{1}{r^2 + 5r + 6}$$

Which for the root $r = -1$ becomes

$$b_2 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{2}$
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{(r^2 + 5r + 6)(r^2 + 9r + 20)}$$

Which for the root $r = -1$ becomes

$$b_4 = \frac{1}{24}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{1}{r^4+14r^3+71r^2+154r+120}$	$\frac{1}{24}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{1}{r^4+14r^3+71r^2+154r+120}$	$\frac{1}{24}$
b_5	0	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned}
y_2(x) &= 1\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= \frac{1 - \frac{x^2}{2} + \frac{x^4}{24} + O(x^6)}{x}
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 \left(1 - \frac{x^2}{6} + \frac{x^4}{120} + O(x^6)\right) + \frac{c_2 \left(1 - \frac{x^2}{2} + \frac{x^4}{24} + O(x^6)\right)}{x}
\end{aligned}$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1\left(1-\frac{x^2}{6}+\frac{x^4}{120}+O\left(x^6\right)\right)+\frac{c_2\left(1-\frac{x^2}{2}+\frac{x^4}{24}+O(x^6)\right)}{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1\left(1-\frac{x^2}{6}+\frac{x^4}{120}+O\left(x^6\right)\right)+\frac{c_2\left(1-\frac{x^2}{2}+\frac{x^4}{24}+O(x^6)\right)}{x} \tag{1}
$$

Verification of solutions

$$
y = c_1\left(1-\frac{x^2}{6}+\frac{x^4}{120}+O\left(x^6\right)\right)+\frac{c_2\left(1-\frac{x^2}{2}+\frac{x^4}{24}+O(x^6)\right)}{x}
$$

Verified OK.

15.12.1 Maple step by step solution

Let's solve

$y''x+2y'+yx=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{2y'}{x}-y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{2y'}{x}+y=0$

□ Check to see if $x_0=0$ is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{2}{x}, P_3(x)=1\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left.(x\cdot P_2(x))\right|_{x=0}=2$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

$$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 0$$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x + 2y' + yx = 0$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

- Rewrite ODE with series expansions

  - Convert $x \cdot y$ to series expansion

    $$x \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+1}$$

  - Shift index using $k- >k - 1$

    $$x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^{k+r}$$

  - Convert y' to series expansion

    $$y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1}$$

  - Shift index using $k- >k + 1$

    $$y' = \sum_{k=-1}^{\infty} a_{k+1}(k+r+1)\, x^{k+r}$$

  - Convert $x \cdot y''$ to series expansion

    $$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$$

  - Shift index using $k- >k + 1$

    $$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+r+1)\,(k+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0 r(1+r)\, x^{-1+r} + a_1(1+r)\,(2+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+r+1)\,(k+2+r) + a_{k-1}\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-1, 0\}$

- Each term must be 0

  $a_1(1+r)(2+r) = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+r+1)(k+2+r) + a_{k-1} = 0$

- Shift index using $k->k+1$

  $a_{k+2}(k+2+r)(k+3+r) + a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k}{(k+2+r)(k+3+r)}$

- Recursion relation for $r = -1$

  $a_{k+2} = -\frac{a_k}{(k+1)(k+2)}$

- Solution for $r = -1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2} = -\frac{a_k}{(k+1)(k+2)}, 0 = 0\right]$

- Recursion relation for $r = 0$

  $a_{k+2} = -\frac{a_k}{(k+2)(k+3)}$

- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k}{(k+2)(k+3)}, 2a_1 = 0\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^k\right), a_{k+2} = -\frac{a_k}{(1+k)(k+2)}, 0 = 0, b_{k+2} = -\frac{b_k}{(k+2)(k+3)}, 2b_1 = 0\right]$

Problem number: 13.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + y'x + \left(x^2 - \frac{1}{4}\right) y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + y'x + \left(x^2 - \frac{1}{4}\right) y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{4x^2 - 1}{4x^2}$$

Table 551: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{4x^2-1}{4x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' + y'x + \left(x^2 - \frac{1}{4}\right) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x^2 + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) x + \left(x^2 - \frac{1}{4}\right)\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$
\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r+2} a_n\right) + \sum_{n=0}^{\infty} \left(-\frac{a_n x^{n+r}}{4}\right) = 0 \tag{2A}
$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$
\sum_{n=0}^{\infty} x^{n+r+2} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$
\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-\frac{a_n x^{n+r}}{4}\right) = 0 \tag{2B}
$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$
x^{n+r} a_n (n+r)(n+r-1) + x^{n+r} a_n (n+r) - \frac{a_n x^{n+r}}{4} = 0
$$

When $n=0$ the above becomes

$$
x^r a_0 r(-1+r) + x^r a_0 r - \frac{a_0 x^r}{4} = 0
$$

Or

$$
\left(x^r r(-1+r) + x^r r - \frac{x^r}{4}\right) a_0 = 0
$$

Since $a_0 \neq 0$ then the above simplifies to

$$
\frac{(4r^2-1)\, x^r}{4} = 0
$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - \frac{1}{4} = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{2}$$
$$r_2 = -\frac{1}{2}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\frac{(4r^2 - 1)\, x^r}{4} = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 1$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sqrt{x} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{\sqrt{x}}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{2}}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-\frac{1}{2}}\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + a_n(n+r) + a_{n-2} - \frac{a_n}{4} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{4a_{n-2}}{4n^2 + 8nr + 4r^2 - 1} \tag{4}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_n = -\frac{a_{n-2}}{n(n+1)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{4}{4r^2 + 16r + 15}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_2 = -\frac{1}{6}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{6}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{6}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{16}{(4r^2 + 16r + 15)(4r^2 + 32r + 63)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_4 = \frac{1}{120}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{6}$
a_3	0	0
a_4	$\frac{16}{(4r^2+16r+15)(4r^2+32r+63)}$	$\frac{1}{120}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{6}$
a_3	0	0
a_4	$\frac{16}{(4r^2+16r+15)(4r^2+32r+63)}$	$\frac{1}{120}$
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= \sqrt{x}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\
&= \sqrt{x}\left(1 - \frac{x^2}{6} + \frac{x^4}{120} + O(x^6)\right)
\end{aligned}
$$

Now the second solution $y_2(x)$ is found. Let

$$
r_1 - r_2 = N
$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 1$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \to r_2} a_1(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$
\begin{aligned}
a_N &= a_1 \\
&= 0
\end{aligned}
$$

Therefore

$$
\begin{aligned}
\lim_{r \to r_2} 0 &= \lim_{r \to -\frac{1}{2}} 0 \\
&= 0
\end{aligned}
$$

The limit is 0. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$
\begin{aligned}
y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\
&= \sum_{n=0}^{\infty} b_n x^{n-\frac{1}{2}}
\end{aligned}
$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$
b_1 = 0
$$

For $2 \leq n$ the recursive equation is

$$
b_n(n+r)(n+r-1) + b_n(n+r) + b_{n-2} - \frac{b_n}{4} = 0 \tag{4}
$$

Which for for the root $r = -\frac{1}{2}$ becomes

$$b_n\left(n-\frac{1}{2}\right)\left(n-\frac{3}{2}\right)+b_n\left(n-\frac{1}{2}\right)+b_{n-2}-\frac{b_n}{4}=0 \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = -\frac{4b_{n-2}}{4n^2+8nr+4r^2-1} \tag{5}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_n = -\frac{4b_{n-2}}{4n^2-4n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{4}{4r^2+16r+15}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_2 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{2}$
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{16}{(4r^2 + 16r + 15)(4r^2 + 32r + 63)}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_4 = \frac{1}{24}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{16}{(4r^2+16r+15)(4r^2+32r+63)}$	$\frac{1}{24}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{16}{(4r^2+16r+15)(4r^2+32r+63)}$	$\frac{1}{24}$
b_5	0	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= \sqrt{x}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\ &= \frac{1 - \frac{x^2}{2} + \frac{x^4}{24} + O(x^6)}{\sqrt{x}} \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 \sqrt{x}\left(1 - \frac{x^2}{6} + \frac{x^4}{120} + O(x^6)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{24} + O(x^6)\right)}{\sqrt{x}} \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= c_1 \sqrt{x}\left(1 - \frac{x^2}{6} + \frac{x^4}{120} + O(x^6)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{24} + O(x^6)\right)}{\sqrt{x}} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \sqrt{x}\left(1 - \frac{x^2}{6} + \frac{x^4}{120} + O(x^6)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{24} + O(x^6)\right)}{\sqrt{x}} \tag{1}$$

Verification of solutions

$$y = c_1 \sqrt{x}\left(1 - \frac{x^2}{6} + \frac{x^4}{120} + O(x^6)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{24} + O(x^6)\right)}{\sqrt{x}}$$

Verified OK.

15.13.1 Maple step by step solution

Let's solve

$y'' x^2 + y' x + \left(x^2 - \frac{1}{4}\right) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(4x^2-1)y}{4x^2} - \frac{y'}{x}$
- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + \frac{(4x^2-1)y}{4x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- ○ Define functions

  $\left[P_2(x) = \frac{1}{x}, P_3(x) = \frac{4x^2-1}{4x^2}\right]$
- ○ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\bigg|_{x=0} = 1$
- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = -\frac{1}{4}$
- ○ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4y''x^2 + 4y'x + (4x^2 - 1)\, y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
- ○ Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
- ○ Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r}$

- Convert $x^2 \cdot y''$ to series expansion

  $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1) x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+2r)(-1+2r) x^r + a_1(3+2r)(1+2r) x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r+1)(2k+2r-1) + 4a_{k-}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+2r)(-1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$

- Each term must be 0

  $a_1(3+2r)(1+2r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(4k^2 + 8kr + 4r^2 - 1) + 4a_{k-2} = 0$

- Shift index using $k- >k+2$

  $a_{k+2}\left(4(k+2)^2 + 8(k+2) r + 4r^2 - 1\right) + 4a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{4a_k}{4k^2+8kr+4r^2+16k+16r+15}$

- Recursion relation for $r = -\frac{1}{2}$

  $a_{k+2} = -\frac{4a_k}{4k^2+12k+8}$

- Solution for $r = -\frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = -\frac{4a_k}{4k^2+12k+8}, a_1 = 0\right]$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -\frac{4a_k}{4k^2+20k+24}$

- Solution for $r = \frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{4a_k}{4k^2+20k+24}, a_1 = 0\right]$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+2}=-\frac{4a_k}{4k^2+12k+8}, a_1=0, b_{k+2}=-\frac{4b_k}{4k^2+20k+24}, b_1=0\right]$$

Problem number: 14.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + \left(x^4 + x\right)y' - y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + \left(x^4 + x\right)y' - y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{x^3 + 1}{x}$$
$$q(x) = -\frac{1}{x^2}$$

Table 553: Table $p(x), q(x)$ singularites.

$p(x) = \frac{x^3+1}{x}$	
singularity	type
$x = 0$	"regular"
$x = \infty$	"regular"
$x = -\infty$	"regular"

$q(x) = -\frac{1}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, \infty, -\infty]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' + (x^4 + x) y' - y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}\right) x^2 + (x^4 + x) \left(\sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r+3} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r+3} a_n (n+r) = \sum_{n=3}^{\infty} a_{n-3}(n-3+r)\, x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=3}^{\infty} a_{n-3}(n-3+r)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) + x^{n+r} a_n (n+r) - a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) + x^r a_0 r - a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) + x^r r - x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2 - 1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = -1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2 - 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 2$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+1}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-1}\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

Substituting $n = 2$ in Eq. (2B) gives

$$a_2 = 0$$

For $3 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + a_{n-3}(n-3+r) + a_n(n+r) - a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-3}(n-3+r)}{n^2+2nr+r^2-1} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = -\frac{a_{n-3}(n-2)}{n(n+2)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{r}{r^2+6r+8}$$

Which for the root $r = 1$ becomes

$$a_3 = -\frac{1}{15}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	$-\frac{r}{r^2+6r+8}$	$-\frac{1}{15}$

For $n = 4$, using the above recursive equation gives

$$a_4 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	$-\frac{r}{r^2+6r+8}$	$-\frac{1}{15}$
a_4	0	0

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	$-\frac{r}{r^2+6r+8}$	$-\frac{1}{15}$
a_4	0	0
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots\right) \\ &= x\left(1 - \frac{x^3}{15} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 2$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_2(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_2 \\ &= 0 \end{aligned}$$

Therefore

$$\begin{aligned}\lim_{r\to r_2} 0 &= \lim_{r\to -1} 0 \\ &= 0\end{aligned}$$

The limit is 0. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$\begin{aligned}y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\ &= \sum_{n=0}^{\infty} b_n x^{n-1}\end{aligned}$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$b_1 = 0$$

Substituting $n = 2$ in Eq(3) gives

$$b_2 = 0$$

For $3 \le n$ the recursive equation is

$$b_n(n+r)(n+r-1) + b_{n-3}(n-3+r) + b_n(n+r) - b_n = 0 \tag{4}$$

Which for for the root $r = -1$ becomes

$$b_n(n-1)(n-2) + b_{n-3}(n-4) + b_n(n-1) - b_n = 0 \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = -\frac{b_{n-3}(n-3+r)}{n^2+2nr+r^2-1} \tag{5}$$

Which for the root $r = -1$ becomes

$$b_n = -\frac{b_{n-3}(n-4)}{n^2-2n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{r}{r^2 + 6r + 8}$$

Which for the root $r = -1$ becomes

$$b_3 = \frac{1}{3}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	$-\frac{r}{r^2+6r+8}$	$\frac{1}{3}$

For $n = 4$, using the above recursive equation gives

$$b_4 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	$-\frac{r}{r^2+6r+8}$	$\frac{1}{3}$
b_4	0	0

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	$-\frac{r}{r^2+6r+8}$	$\frac{1}{3}$
b_4	0	0
b_5	0	0

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= \frac{1 + \frac{x^3}{3} + O(x^6)}{x}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x \left(1 - \frac{x^3}{15} + O(x^6)\right) + \frac{c_2 \left(1 + \frac{x^3}{3} + O(x^6)\right)}{x}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x \left(1 - \frac{x^3}{15} + O(x^6)\right) + \frac{c_2 \left(1 + \frac{x^3}{3} + O(x^6)\right)}{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x \left(1 - \frac{x^3}{15} + O(x^6)\right) + \frac{c_2 \left(1 + \frac{x^3}{3} + O(x^6)\right)}{x} \tag{1}
$$

Verification of solutions

$$
y = c_1 x \left(1 - \frac{x^3}{15} + O(x^6)\right) + \frac{c_2 \left(1 + \frac{x^3}{3} + O(x^6)\right)}{x}
$$

Verified OK.

15.14.1 Maple step by step solution

Let's solve

$y''x^2 + (x^4 + x)\, y' - y = 0$

- Highest derivative means the order of the ODE is 2

y''

- Isolate 2nd derivative

$y'' = \frac{y}{x^2} - \frac{(x^3+1)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' + \frac{(x^3+1)y'}{x} - \frac{y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- ○ Define functions

$\left[P_2(x) = \frac{x^3+1}{x}, P_3(x) = -\frac{1}{x^2}\right]$

- ○ $x \cdot P_2(x)$ is analytic at $x = 0$

$\left(x \cdot P_2(x)\right)\bigg|_{x=0} = 1$

- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = -1$

- ○ $x = 0$is a regular singular point

Check to see if $x_0 = 0$ is a regular singular point

$x_0 = 0$

- Multiply by denominators

$y''x^2 + x(x^3 + 1)\, y' - y = 0$

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y'$ to series expansion for $m = 1..4$

$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^2 \cdot y''$ to series expansion

  $$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(1+r)\,(-1+r)\, x^r + a_1(2+r)\, r\, x^{1+r} + a_2(3+r)\,(1+r)\, x^{2+r} + \left(\sum_{k=3}^{\infty} (a_k(k+r+1)\,(k+r-$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(-1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-1, 1\}$

- The coefficients of each power of x must be 0

  $[a_1(2+r)\, r = 0, a_2(3+r)\,(1+r) = 0]$

- Solve for the dependent coefficient(s)

  $\{a_1 = 0, a_2 = 0\}$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+1)\,(k+r-1) + a_{k-3}(k-3+r) = 0$

- Shift index using $k->k+3$

  $a_{k+3}(k+4+r)\,(k+2+r) + a_k(k+r) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+3} = -\frac{a_k(k+r)}{(k+4+r)(k+2+r)}$

- Recursion relation for $r = -1$

  $a_{k+3} = -\frac{a_k(k-1)}{(k+3)(k+1)}$

- Solution for $r = -1$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+3} = -\frac{a_k(k-1)}{(k+3)(k+1)}, a_1 = 0, a_2 = 0\right]$$

- Recursion relation for $r = 1$

  $a_{k+3} = -\frac{a_k(k+1)}{(k+5)(k+3)}$

- Solution for $r = 1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+3} = -\frac{a_k(k+1)}{(k+5)(k+3)}, a_1 = 0, a_2 = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{1+k}\right), a_{k+3} = -\frac{a_k(k-1)}{(k+3)(1+k)}, a_1 = 0, a_2 = 0, b_{k+3} = -\frac{b_k(1+k)}{(k+5)(k+3)}, b_1 =\right.$$

Problem number: 15.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

`[_Lienard]`

$$\boxed{xy'' - (x^2 + 2) y' + yx = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$xy'' + (-x^2 - 2) y' + yx = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{x^2 + 2}{x}$$
$$q(x) = 1$$

Table 555: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x^2+2}{x}$	
singularity	type
$x = 0$	"regular"
$x = \infty$	"regular"
$x = -\infty$	"regular"

$q(x) = 1$	
singularity	type

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, \infty, -\infty]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$xy'' + (-x^2 - 2)\, y' + yx = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}$$
$$y'' = \sum_{n=0}^{\infty} (n + r)\, (n + r - 1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n + r)\, (n + r - 1)\, a_n x^{n+r-2}\right) x + (-x^2 - 2) \left(\sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) x = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-2(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)\right) = \sum_{n=2}^{\infty} \left(-a_{n-2}(n+r-2)\, x^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=2}^{\infty} \left(-a_{n-2}(n+r-2)\, x^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-2(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r-1} a_n (n+r)(n+r-1) - 2(n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$x^{-1+r} a_0 r(-1+r) - 2r a_0 x^{-1+r} = 0$$

Or

$$\left(x^{-1+r} r(-1+r) - 2r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, x^{-1+r}(-3+r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$r(-3+r) = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 3$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\,x^{-1+r}(-3+r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 3$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x^3\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+3}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - a_{n-2}(n+r-2) - 2a_n(n+r) + a_{n-2} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-2}}{n+r} \tag{4}$$

Which for the root $r = 3$ becomes

$$a_n = \frac{a_{n-2}}{n+3} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 3$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{2+r}$$

Which for the root $r = 3$ becomes

$$a_2 = \frac{1}{5}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{1}{2+r}$	$\frac{1}{5}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{1}{2+r}$	$\frac{1}{5}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{(2+r)(4+r)}$$

Which for the root $r = 3$ becomes

$$a_4 = \frac{1}{35}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{1}{2+r}$	$\frac{1}{5}$
a_3	0	0
a_4	$\frac{1}{(2+r)(4+r)}$	$\frac{1}{35}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{1}{2+r}$	$\frac{1}{5}$
a_3	0	0
a_4	$\frac{1}{(2+r)(4+r)}$	$\frac{1}{35}$
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^3\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^3\left(1 + \frac{x^2}{5} + \frac{x^4}{35} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 3$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \to r_2} a_3(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_3 \\ &= 0 \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r \to r_2} 0 &= \lim_{r \to 0} 0 \\ &= 0 \end{aligned}$$

The limit is 0. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$\begin{aligned} y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\ &= \sum_{n=0}^{\infty} b_n x^n \end{aligned}$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$b_1 = 0$$

For $2 \leq n$ the recursive equation is

$$b_n(n+r)(n+r-1) - b_{n-2}(n+r-2) - 2(n+r)b_n + b_{n-2} = 0 \tag{4}$$

Which for for the root $r = 0$ becomes

$$b_n n(n-1) - b_{n-2}(n-2) - 2nb_n + b_{n-2} = 0 \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = \frac{b_{n-2}}{n+r} \tag{5}$$

Which for the root $r = 0$ becomes

$$b_n = \frac{b_{n-2}}{n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{1}{2+r}$$

Which for the root $r = 0$ becomes

$$b_2 = \frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$\frac{1}{2+r}$	$\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$\frac{1}{2+r}$	$\frac{1}{2}$
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{(2+r)(4+r)}$$

Which for the root $r = 0$ becomes

$$b_4 = \frac{1}{8}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$\frac{1}{2+r}$	$\frac{1}{2}$
b_3	0	0
b_4	$\frac{1}{(2+r)(4+r)}$	$\frac{1}{8}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$\frac{1}{2+r}$	$\frac{1}{2}$
b_3	0	0
b_4	$\frac{1}{(2+r)(4+r)}$	$\frac{1}{8}$
b_5	0	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots \\ &= 1 + \frac{x^2}{2} + \frac{x^4}{8} + O(x^6) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^3 \left(1 + \frac{x^2}{5} + \frac{x^4}{35} + O(x^6)\right) + c_2 \left(1 + \frac{x^2}{2} + \frac{x^4}{8} + O(x^6)\right) \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= c_1 x^3 \left(1 + \frac{x^2}{5} + \frac{x^4}{35} + O(x^6)\right) + c_2 \left(1 + \frac{x^2}{2} + \frac{x^4}{8} + O(x^6)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x^3 \left(1 + \frac{x^2}{5} + \frac{x^4}{35} + O(x^6)\right) + c_2 \left(1 + \frac{x^2}{2} + \frac{x^4}{8} + O(x^6)\right) \tag{1}$$

Verification of solutions

$$y = c_1 x^3 \left(1 + \frac{x^2}{5} + \frac{x^4}{35} + O(x^6)\right) + c_2 \left(1 + \frac{x^2}{2} + \frac{x^4}{8} + O(x^6)\right)$$

Verified OK.

$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+r+1)(k+r)\, x^{k+r}$

Rewrite ODE with series expansions

$a_0 r(-3+r)\, x^{-1+r} + a_1(1+r)(-2+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+r+1)(k-2+r) - a_{k-1}(k-2+r\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-3+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{0, 3\}$
- Each term must be 0

  $a_1(1+r)(-2+r) = 0$
- Each term in the series must be 0, giving the recursion relation

  $(k-2+r)(a_{k+1}(k+r+1) - a_{k-1}) = 0$
- Shift index using $k- >k+1$

  $(k+r-1)(a_{k+2}(k+2+r) - a_k) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{a_k}{k+2+r}$
- Recursion relation for $r = 0$

  $a_{k+2} = \frac{a_k}{k+2}$
- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = \frac{a_k}{k+2}, -2a_1 = 0\right]$
- Recursion relation for $r = 3$

  $a_{k+2} = \frac{a_k}{k+5}$
- Solution for $r = 3$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+2} = \frac{a_k}{k+5}, 4a_1 = 0\right]$
- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+3}\right), a_{k+2} = \frac{a_k}{k+2}, -2a_1 = 0, b_{k+2} = \frac{b_k}{k+5}, 4b_1 = 0\right]$

Problem number: 16.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + x^2y' - 2y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + x^2y' - 2y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = 1$$
$$q(x) = -\frac{2}{x^2}$$

Table 557: Table $p(x), q(x)$ singularites.

$p(x) = 1$	
singularity	type

$q(x) = -\frac{2}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' + x^2y' - 2y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x^2 + x^2 \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) - 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-2a_n x^{n+r}\right) = 0 \quad \text{(2A)}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n(n+r) = \sum_{n=1}^{\infty} a_{n-1}(n+r-1)\, x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)\,(n+r-1)\right) + \left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1)\, x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-2a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n(n+r)\,(n+r-1) - 2a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - 2a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - 2x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2 - r - 2\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - r - 2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 2$$
$$r_2 = -1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2 - r - 2\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 3$ is an integer, then we can construct two linearly independent solutions

$$
\begin{aligned}
y_1(x) &= x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right) \\
y_2(x) &= C y_1(x) \ln(x) + x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= x^2\left(\sum_{n=0}^{\infty} a_n x^n\right) \\
y_2(x) &= C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x}
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+2} \\
y_2(x) &= C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-1}\right)
\end{aligned}
$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$
a_n(n+r)(n+r-1) + a_{n-1}(n+r-1) - 2a_n = 0 \tag{3}
$$

Solving for a_n from recursive equation (4) gives

$$
a_n = -\frac{a_{n-1}(n+r-1)}{n^2 + 2nr + r^2 - n - r - 2} \tag{4}
$$

Which for the root $r = 2$ becomes

$$
a_n = -\frac{a_{n-1}(1+n)}{n(n+3)} \tag{5}
$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{r}{r^2 + r - 2}$$

Which for the root $r = 2$ becomes

$$a_1 = -\frac{1}{2}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r}{r^2+r-2}$	$-\frac{1}{2}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1 + r}{r^3 + 4r^2 + r - 6}$$

Which for the root $r = 2$ becomes

$$a_2 = \frac{3}{20}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r}{r^2+r-2}$	$-\frac{1}{2}$
a_2	$\frac{1+r}{r^3+4r^2+r-6}$	$\frac{3}{20}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{1}{r^3 + 6r^2 + 5r - 12}$$

Which for the root $r = 2$ becomes

$$a_3 = -\frac{1}{30}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r}{r^2+r-2}$	$-\frac{1}{2}$
a_2	$\frac{1+r}{r^3+4r^2+r-6}$	$\frac{3}{20}$
a_3	$-\frac{1}{r^3+6r^2+5r-12}$	$-\frac{1}{30}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{r^4 + 10r^3 + 27r^2 + 2r - 40}$$

Which for the root $r = 2$ becomes

$$a_4 = \frac{1}{168}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r}{r^2+r-2}$	$-\frac{1}{2}$
a_2	$\frac{1+r}{r^3+4r^2+r-6}$	$\frac{3}{20}$
a_3	$-\frac{1}{r^3+6r^2+5r-12}$	$-\frac{1}{30}$
a_4	$\frac{1}{r^4+10r^3+27r^2+2r-40}$	$\frac{1}{168}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1}{(r^2 + 9r + 18)(r^3 + 6r^2 + 3r - 10)}$$

Which for the root $r = 2$ becomes

$$a_5 = -\frac{1}{1120}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{r}{r^2+r-2}$	$-\frac{1}{2}$
a_2	$\frac{1+r}{r^3+4r^2+r-6}$	$\frac{3}{20}$
a_3	$-\frac{1}{r^3+6r^2+5r-12}$	$-\frac{1}{30}$
a_4	$\frac{1}{r^4+10r^3+27r^2+2r-40}$	$\frac{1}{168}$
a_5	$-\frac{1}{(r^2+9r+18)(r^3+6r^2+3r-10)}$	$-\frac{1}{1120}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= x^2\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\
&= x^2\left(1 - \frac{x}{2} + \frac{3x^2}{20} - \frac{x^3}{30} + \frac{x^4}{168} - \frac{x^5}{1120} + O(x^6)\right)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 3$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_3(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned}
a_N &= a_3 \\
&= -\frac{1}{r^3 + 6r^2 + 5r - 12}
\end{aligned}$$

Therefore

$$\begin{aligned}
\lim_{r\to r_2} -\frac{1}{r^3 + 6r^2 + 5r - 12} &= \lim_{r\to -1} -\frac{1}{r^3 + 6r^2 + 5r - 12} \\
&= \frac{1}{12}
\end{aligned}$$

The limit is $\frac{1}{12}$. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$\begin{aligned}
y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\
&= \sum_{n=0}^{\infty} b_n x^{n-1}
\end{aligned}$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$b_n(n+r)(n+r-1) + b_{n-1}(n+r-1) - 2b_n = 0 \tag{4}$$

Which for for the root $r = -1$ becomes

$$b_n(n-1)(n-2) + b_{n-1}(n-2) - 2b_n = 0 \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = -\frac{b_{n-1}(n+r-1)}{n^2 + 2nr + r^2 - n - r - 2} \tag{5}$$

Which for the root $r = -1$ becomes

$$b_n = -\frac{b_{n-1}(n-2)}{n^2 - 3n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = -\frac{r}{r^2 + r - 2}$$

Which for the root $r = -1$ becomes

$$b_1 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{r}{r^2+r-2}$	$-\frac{1}{2}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{1+r}{(r^2+r-2)(r+3)}$$

Which for the root $r = -1$ becomes

$$b_2 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{r}{r^2+r-2}$	$-\frac{1}{2}$
b_2	$\frac{1+r}{r^3+4r^2+r-6}$	0

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{1}{(r+4)(r+3)(-1+r)}$$

Which for the root $r = -1$ becomes

$$b_3 = \frac{1}{12}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{r}{r^2+r-2}$	$-\frac{1}{2}$
b_2	$\frac{1+r}{r^3+4r^2+r-6}$	0
b_3	$-\frac{1}{(r+4)(r+3)(-1+r)}$	$\frac{1}{12}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{(r+4)(-1+r)(r^2+7r+10)}$$

Which for the root $r = -1$ becomes

$$b_4 = -\frac{1}{24}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{r}{r^2+r-2}$	$-\frac{1}{2}$
b_2	$\frac{1+r}{r^3+4r^2+r-6}$	0
b_3	$-\frac{1}{(r+4)(r+3)(-1+r)}$	$\frac{1}{12}$
b_4	$\frac{1}{(5+r)(2+r)(r+4)(-1+r)}$	$-\frac{1}{24}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{1}{(-1+r)\,(r^2+7r+10)\,(r^2+9r+18)}$$

Which for the root $r = -1$ becomes

$$b_5 = \frac{1}{80}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{r}{r^2+r-2}$	$-\frac{1}{2}$
b_2	$\frac{1+r}{r^3+4r^2+r-6}$	0
b_3	$-\frac{1}{(r+4)(r+3)(-1+r)}$	$\frac{1}{12}$
b_4	$\frac{1}{(5+r)(2+r)(r+4)(-1+r)}$	$-\frac{1}{24}$
b_5	$-\frac{1}{(r+6)(r+3)(5+r)(-1+r)(2+r)}$	$\frac{1}{80}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned}
y_2(x) &= x^2\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= \frac{1 - \frac{x}{2} + \frac{x^3}{12} - \frac{x^4}{24} + \frac{x^5}{80} + O(x^6)}{x}
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^2\left(1 - \frac{x}{2} + \frac{3x^2}{20} - \frac{x^3}{30} + \frac{x^4}{168} - \frac{x^5}{1120} + O(x^6)\right) + \frac{c_2\left(1 - \frac{x}{2} + \frac{x^3}{12} - \frac{x^4}{24} + \frac{x^5}{80} + O(x^6)\right)}{x}
\end{aligned}$$

Hence the final solution is

$$y = y_h$$

$$= c_1 x^2 \left(1 - \frac{x}{2} + \frac{3x^2}{20} - \frac{x^3}{30} + \frac{x^4}{168} - \frac{x^5}{1120} + O(x^6)\right) + \frac{c_2 \left(1 - \frac{x}{2} + \frac{x^3}{12} - \frac{x^4}{24} + \frac{x^5}{80} + O(x^6)\right)}{x}$$

Summary

The solution(s) found are the following

$$y = c_1 x^2 \left(1 - \frac{x}{2} + \frac{3x^2}{20} - \frac{x^3}{30} + \frac{x^4}{168} - \frac{x^5}{1120} + O(x^6)\right) + \frac{c_2 \left(1 - \frac{x}{2} + \frac{x^3}{12} - \frac{x^4}{24} + \frac{x^5}{80} + O(x^6)\right)}{x} \tag{1}$$

Verification of solutions

$$y = c_1 x^2 \left(1 - \frac{x}{2} + \frac{3x^2}{20} - \frac{x^3}{30} + \frac{x^4}{168} - \frac{x^5}{1120} + O(x^6)\right) + \frac{c_2 \left(1 - \frac{x}{2} + \frac{x^3}{12} - \frac{x^4}{24} + \frac{x^5}{80} + O(x^6)\right)}{x}$$

Verified OK.

15.16.1 Maple step by step solution

Let's solve

$y''x^2 + x^2y' - 2y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -y' + \frac{2y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + y' - \frac{2y}{x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = 1, P_3(x) = -\frac{2}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

$$\left(x \cdot P_2(x)\right)\bigg|_{x=0} = 0$$

- ∘ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = -2$$

- ∘ $x = 0$is a regular singular point

Check to see if $x_0 = 0$ is a regular singular point

$x_0 = 0$

- Multiply by denominators

$y''x^2 + x^2y' - 2y = 0$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

- ∘ Convert $x^2 \cdot y'$ to series expansion

$$x^2 \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r+1}$$

- ∘ Shift index using $k- > k-1$

$$x^2 \cdot y' = \sum_{k=1}^{\infty} a_{k-1}(k-1+r)\, x^{k+r}$$

- ∘ Convert $x^2 \cdot y''$ to series expansion

$$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k-1+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(1+r)\,(-2+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+1)\,(k+r-2) + a_{k-1}(k-1+r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(1+r)\,(-2+r) = 0$

- Values of r that satisfy the indicial equation

$r \in \{-1, 2\}$

- Each term in the series must be 0, giving the recursion relation

$a_k(k+r+1)\,(k+r-2) + a_{k-1}(k-1+r) = 0$

- Shift index using $k->k+1$

  $a_{k+1}(k+2+r)(k-1+r)+a_k(k+r)=0$
- Recursion relation that defines series solution to ODE

  $a_{k+1}=-\frac{a_k(k+r)}{(k+2+r)(k-1+r)}$
- Recursion relation for $r=-1$; series terminates at $k=1$

  $a_{k+1}=-\frac{a_k(k-1)}{(k+1)(k-2)}$
- Apply recursion relation for $k=0$

  $a_1=-\frac{a_0}{2}$
- Terminating series solution of the ODE for $r=-1$. Use reduction of order to find the second

  $y=a_0\cdot\left(-\frac{x}{2}+1\right)$
- Recursion relation for $r=2$

  $a_{k+1}=-\frac{a_k(k+2)}{(k+4)(k+1)}$
- Solution for $r=2$

  $\left[y=\sum_{k=0}^{\infty}a_kx^{k+2}, a_{k+1}=-\frac{a_k(k+2)}{(k+4)(k+1)}\right]$
- Combine solutions and rename parameters

  $\left[y=a_0\cdot\left(-\frac{x}{2}+1\right)+\left(\sum_{k=0}^{\infty}b_kx^{k+2}\right), b_{1+k}=-\frac{b_k(k+2)}{(k+4)(1+k)}\right]$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.2 (Frobenius). Exercises page 251
Problem number: 17.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{\left(2x^2-x\right)y''+(2x-2)\,y'+\left(-2x^2+3x-2\right)y=0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(2x^2-x\right)y''+(2x-2)\,y'+\left(-2x^2+3x-2\right)y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=\frac{2x-2}{x\,(2x-1)}$$
$$q(x)=-\frac{2x^2-3x+2}{x\,(2x-1)}$$

Table 559: Table $p(x), q(x)$ singularites.

$p(x) = \frac{2x-2}{x(2x-1)}$	
singularity	type
$x = 0$	"regular"
$x = \frac{1}{2}$	"regular"

$q(x) = -\frac{2x^2-3x+2}{x(2x-1)}$	
singularity	type
$x = 0$	"regular"
$x = \frac{1}{2}$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $\left[0, \frac{1}{2}\right]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$y''x(2x-1) + (2x-2)\,y' + \left(-2x^2 + 3x - 2\right)y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}$$
$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}\right) x(2x-1) + (2x-2)\left(\sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}\right) + \left(-2x^2+3x-2\right)\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r-1} a_n (n+r)(n+r-1)\right) \\
&+ \left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-2(n+r) a_n x^{n+r-1}\right) \\
&+ \sum_{n=0}^{\infty} \left(-2x^{n+r+2} a_n\right) + \left(\sum_{n=0}^{\infty} 3x^{1+n+r} a_n\right) + \sum_{n=0}^{\infty} \left(-2a_n x^{n+r}\right) = 0
\end{aligned}
\tag{2A}
$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1) &= \sum_{n=1}^{\infty} 2a_{n-1}(n+r-1)(n+r-2)\, x^{n+r-1} \\
\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r) &= \sum_{n=1}^{\infty} 2a_{n-1}(n+r-1)\, x^{n+r-1} \\
\sum_{n=0}^{\infty} \left(-2x^{n+r+2} a_n\right) &= \sum_{n=3}^{\infty} \left(-2a_{n-3} x^{n+r-1}\right) \\
\sum_{n=0}^{\infty} 3x^{1+n+r} a_n &= \sum_{n=2}^{\infty} 3a_{n-2} x^{n+r-1} \\
\sum_{n=0}^{\infty} \left(-2a_n x^{n+r}\right) &= \sum_{n=1}^{\infty} \left(-2a_{n-1} x^{n+r-1}\right)
\end{aligned}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=1}^{\infty} 2a_{n-1}(n+r-1)\,(n+r-2)\,x^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-x^{n+r-1}a_n(n+r)\,(n+r-1)\right) + \left(\sum_{n=1}^{\infty} 2a_{n-1}(n+r-1)\,x^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-2(n+r)\,a_n x^{n+r-1}\right) + \sum_{n=3}^{\infty} \left(-2a_{n-3}x^{n+r-1}\right) + \left(\sum_{n=2}^{\infty} 3a_{n-2}x^{n+r-1}\right) + \sum_{n=1}^{\infty} \left(-2a_{n-1}x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$-x^{n+r-1}a_n(n+r)\,(n+r-1) - 2(n+r)\,a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$-x^{-1+r}a_0 r(-1+r) - 2r a_0 x^{-1+r} = 0$$

Or

$$\left(-x^{-1+r}r(-1+r) - 2r\,x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\,x^{-1+r}(-1-r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$-r(1+r) = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = -1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\,x^{-1+r}(-1-r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 1$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = Cy_1(x)\ln(x) + x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^n$$
$$y_2(x) = Cy_1(x)\ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^n$$
$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-1}\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = \frac{-2 + 2r}{r + 2}$$

Substituting $n = 2$ in Eq. (2B) gives

$$a_2 = \frac{4r^2 - 4r + 3}{r^2 + 5r + 6}$$

For $3 \leq n$ the recursive equation is

$$\begin{aligned} &2a_{n-1}(n + r - 1)(n + r - 2) - a_n(n + r)(n + r - 1) \\ &+ 2a_{n-1}(n + r - 1) - 2a_n(n + r) - 2a_{n-3} + 3a_{n-2} - 2a_{n-1} = 0 \end{aligned} \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{2n^2 a_{n-1} + 4nr a_{n-1} + 2r^2 a_{n-1} - 4n a_{n-1} - 4r a_{n-1} - 2a_{n-3} + 3a_{n-2}}{n^2 + 2nr + r^2 + n + r} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = \frac{2n^2 a_{n-1} - 4n a_{n-1} - 2a_{n-3} + 3a_{n-2}}{n(1+n)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+2r}{r+2}$	-1
a_2	$\frac{4r^2-4r+3}{r^2+5r+6}$	$\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{8r^3 + 2r - 4}{(r+4)(r+3)(r+2)}$$

Which for the root $r = 0$ becomes

$$a_3 = -\frac{1}{6}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+2r}{r+2}$	-1
a_2	$\frac{4r^2-4r+3}{r^2+5r+6}$	$\frac{1}{2}$
a_3	$\frac{8r^3+2r-4}{(r+4)(r+3)(r+2)}$	$-\frac{1}{6}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{16r^4 + 32r^3 + 12r^2 - 20r + 5}{(r^2+5r+6)(r^2+9r+20)}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{24}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+2r}{r+2}$	-1
a_2	$\frac{4r^2-4r+3}{r^2+5r+6}$	$\frac{1}{2}$
a_3	$\frac{8r^3+2r-4}{(r+4)(r+3)(r+2)}$	$-\frac{1}{6}$
a_4	$\frac{16r^4+32r^3+12r^2-20r+5}{(r^2+5r+6)(r^2+9r+20)}$	$\frac{1}{24}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{32r^5 + 160r^4 + 232r^3 + 8r^2 - 78r - 6}{(r+6)(r+5)(r+4)(r+3)(r+2)}$$

Which for the root $r = 0$ becomes

$$a_5 = -\frac{1}{120}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+2r}{r+2}$	-1
a_2	$\frac{4r^2-4r+3}{r^2+5r+6}$	$\frac{1}{2}$
a_3	$\frac{8r^3+2r-4}{(r+4)(r+3)(r+2)}$	$-\frac{1}{6}$
a_4	$\frac{16r^4+32r^3+12r^2-20r+5}{(r^2+5r+6)(r^2+9r+20)}$	$\frac{1}{24}$
a_5	$\frac{32r^5+160r^4+232r^3+8r^2-78r-6}{(r+6)(r+5)(r+4)(r+3)(r+2)}$	$-\frac{1}{120}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots \\
&= 1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + O(x^6)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 1$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_1(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_1 \\ &= \frac{-2+2r}{r+2} \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r\to r_2} \frac{-2+2r}{r+2} &= \lim_{r\to -1} \frac{-2+2r}{r+2} \\ &= -4 \end{aligned}$$

The limit is -4. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$\begin{aligned} y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\ &= \sum_{n=0}^{\infty} b_n x^{n-1} \end{aligned}$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$b_1 = \frac{-2+2r}{r+2}$$

Substituting $n = 2$ in Eq(3) gives

$$b_2 = \frac{4r^2-4r+3}{r^2+5r+6}$$

For $3 \leq n$ the recursive equation is

$$\begin{aligned} &2b_{n-1}(n+r-1)(n+r-2) - b_n(n+r)(n+r-1) \\ &+ 2b_{n-1}(n+r-1) - 2(n+r)b_n - 2b_{n-3} + 3b_{n-2} - 2b_{n-1} = 0 \end{aligned} \tag{4}$$

Which for for the root $r = -1$ becomes

$$\begin{aligned} &2b_{n-1}(n-2)(n-3) - b_n(n-1)(n-2) + 2b_{n-1}(n-2) \\ &- 2(n-1)b_n - 2b_{n-3} + 3b_{n-2} - 2b_{n-1} = 0 \end{aligned} \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = \frac{2n^2 b_{n-1} + 4nr b_{n-1} + 2r^2 b_{n-1} - 4n b_{n-1} - 4r b_{n-1} - 2b_{n-3} + 3b_{n-2}}{n^2 + 2nr + r^2 + n + r} \tag{5}$$

Which for the root $r = -1$ becomes

$$b_n = \frac{2n^2 b_{n-1} - 8n b_{n-1} - 2b_{n-3} + 3b_{n-2} + 6b_{n-1}}{n^2 - n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-2+2r}{r+2}$	-4
b_2	$\frac{4r^2-4r+3}{r^2+5r+6}$	$\frac{11}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{8r^3 + 2r - 4}{(r^2 + 7r + 12)(r + 2)}$$

Which for the root $r = -1$ becomes

$$b_3 = -\frac{7}{3}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-2+2r}{r+2}$	-4
b_2	$\frac{4r^2-4r+3}{r^2+5r+6}$	$\frac{11}{2}$
b_3	$\frac{8r^3+2r-4}{(r+4)(r+3)(r+2)}$	$-\frac{7}{3}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{16r^4 + 32r^3 + 12r^2 - 20r + 5}{(r + 3)(r + 2)(r^2 + 9r + 20)}$$

Which for the root $r = -1$ becomes

$$b_4 = \frac{7}{8}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-2+2r}{r+2}$	-4
b_2	$\frac{4r^2-4r+3}{r^2+5r+6}$	$\frac{11}{2}$
b_3	$\frac{8r^3+2r-4}{(r+4)(r+3)(r+2)}$	$-\frac{7}{3}$
b_4	$\frac{16r^4+32r^3+12r^2-20r+5}{(r+5)(r+4)(r+3)(r+2)}$	$\frac{7}{8}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{32r^5 + 160r^4 + 232r^3 + 8r^2 - 78r - 6}{(r^2 + 7r + 12)(r + 2)(r^2 + 11r + 30)}$$

Which for the root $r = -1$ becomes

$$b_5 = -\frac{1}{5}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-2+2r}{r+2}$	-4
b_2	$\frac{4r^2-4r+3}{r^2+5r+6}$	$\frac{11}{2}$
b_3	$\frac{8r^3+2r-4}{(r+4)(r+3)(r+2)}$	$-\frac{7}{3}$
b_4	$\frac{16r^4+32r^3+12r^2-20r+5}{(r+5)(r+4)(r+3)(r+2)}$	$\frac{7}{8}$
b_5	$\frac{32r^5+160r^4+232r^3+8r^2-78r-6}{(r+6)(r+5)(r+4)(r+3)(r+2)}$	$-\frac{1}{5}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned}
y_2(x) &= 1\left(b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 \dots\right) \\
&= \frac{1 - 4x + \frac{11x^2}{2} - \frac{7x^3}{3} + \frac{7x^4}{8} - \frac{x^5}{5} + O(x^6)}{x}
\end{aligned}$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 y_1(x) + c_2 y_2(x)$$

$$= c_1 \left(1-x+\frac{x^2}{2}-\frac{x^3}{6}+\frac{x^4}{24}-\frac{x^5}{120}+O(x^6)\right)+\frac{c_2 \left(1-4x+\frac{11x^2}{2}-\frac{7x^3}{3}+\frac{7x^4}{8}-\frac{x^5}{5}+O(x^6)\right)}{x}$$

Hence the final solution is

$$y = y_h$$

$$= c_1 \left(1-x+\frac{x^2}{2}-\frac{x^3}{6}+\frac{x^4}{24}-\frac{x^5}{120}+O(x^6)\right)+\frac{c_2 \left(1-4x+\frac{11x^2}{2}-\frac{7x^3}{3}+\frac{7x^4}{8}-\frac{x^5}{5}+O(x^6)\right)}{x}$$

Summary
The solution(s) found are the following

$$y = c_1 \left(1-x+\frac{x^2}{2}-\frac{x^3}{6}+\frac{x^4}{24}-\frac{x^5}{120}+O(x^6)\right) + \frac{c_2 \left(1-4x+\frac{11x^2}{2}-\frac{7x^3}{3}+\frac{7x^4}{8}-\frac{x^5}{5}+O(x^6)\right)}{x} \tag{1}$$

Verification of solutions

$$y = c_1 \left(1-x+\frac{x^2}{2}-\frac{x^3}{6}+\frac{x^4}{24}-\frac{x^5}{120}+O(x^6)\right) + \frac{c_2 \left(1-4x+\frac{11x^2}{2}-\frac{7x^3}{3}+\frac{7x^4}{8}-\frac{x^5}{5}+O(x^6)\right)}{x}$$

Verified OK.

15.17.1 Maple step by step solution

Let's solve

$y''x(2x-1) + (2x-2)\, y' + (-2x^2+3x-2)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{(2x^2-3x+2)y}{x(2x-1)} - \frac{2(x-1)y'}{x(2x-1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{2(x-1)y'}{x(2x-1)}-\frac{(2x^2-3x+2)y}{x(2x-1)}=0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{2(x-1)}{x(2x-1)}, P_3(x)=-\frac{2x^2-3x+2}{x(2x-1)}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=2$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=0$

  ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $y''x(2x-1)+(2x-2)y'+(-2x^2+3x-2)y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot y$ to series expansion for $m=0..2$

  $x^m\cdot y=\sum_{k=0}^{\infty}a_k x^{k+r+m}$

  ◦ Shift index using $k->k-m$

  $x^m\cdot y=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  ◦ Convert $x^m\cdot y'$ to series expansion for $m=0..1$

  $x^m\cdot y'=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $x^m\cdot y'=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^m \cdot y''$ to series expansion for $m = 1..2$

  $$x^m \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

  $$x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$-a_0 r(1+r)\, x^{-1+r} + (-a_1(1+r)(2+r) + 2a_0(1+r)(-1+r))\, x^r + (-a_2(2+r)(3+r) + 2a_1($$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$-r(1+r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \{-1, 0\}$$

- The coefficients of each power of x must be 0

  $$[-a_1(1+r)(2+r) + 2a_0(1+r)(-1+r) = 0, -a_2(2+r)(3+r) + 2a_1(2+r)\, r + 3a_0 = 0]$$

- Solve for the dependent coefficient(s)

  $$\left\{a_1 = \frac{2a_0(-1+r)}{2+r}, a_2 = \frac{a_0(4r^2-4r+3)}{r^2+5r+6}\right\}$$

- Each term in the series must be 0, giving the recursion relation

  $$-a_{k+1}(k+r+1)(k+2+r) + 2k^2a_k + 4kra_k + 2r^2a_k - 2a_k - 2a_{k-2} + 3a_{k-1} = 0$$

- Shift index using $k- >k+2$

  $$-a_{k+3}(k+3+r)(k+4+r) + 2(k+2)^2\, a_{k+2} + 4(k+2)\, ra_{k+2} + 2r^2a_{k+2} - 2a_{k+2} - 2a_k + 3a_{k+}$$

- Recursion relation that defines series solution to ODE

  $$a_{k+3} = \frac{2k^2a_{k+2} + 4kra_{k+2} + 2r^2a_{k+2} + 8ka_{k+2} + 8ra_{k+2} - 2a_k + 3a_{k+1} + 6a_{k+2}}{(k+3+r)(k+4+r)}$$

- Recursion relation for $r = -1$

  $$a_{k+3} = \frac{2k^2a_{k+2} + 4ka_{k+2} - 2a_k + 3a_{k+1}}{(k+2)(k+3)}$$

- Solution for $r = -1$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+3} = \frac{2k^2a_{k+2} + 4ka_{k+2} - 2a_k + 3a_{k+1}}{(k+2)(k+3)}, a_1 = -4a_0, a_2 = \frac{11a_0}{2}\right]$$

- Recursion relation for $r = 0$

  $$a_{k+3} = \frac{2k^2a_{k+2} + 8ka_{k+2} - 2a_k + 3a_{k+1} + 6a_{k+2}}{(k+3)(k+4)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = \frac{2k^2 a_{k+2} + 8k a_{k+2} - 2a_k + 3a_{k+1} + 6a_{k+2}}{(k+3)(k+4)}, a_1 = -a_0, a_2 = \frac{a_0}{2}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^k\right), a_{k+3} = \frac{2k^2 a_{k+2} + 4k a_{k+2} - 2a_k + 3a_{1+k}}{(k+2)(k+3)}, a_1 = -4a_0, a_2 = \frac{11a_0}{2}, b_{k+3} = \right.$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.2 (Frobenius). Exercises page 251
Problem number: 18.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler], [_2nd_order, _linear, `_with_symmetry_[0,F(
   x)]`]]
```

$$\boxed{x^2y'' - y'x + \frac{3y}{4} = 0}$$

With the expansion point for the power series method at $x = 0$.

The ode can be written as

$$4x^2y'' - 4y'x + 3y = 0$$

Which shows it is a Euler ODE. The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$4x^2y'' - 4y'x + 3y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{1}{x}$$
$$q(x) = \frac{3}{4x^2}$$

Table 561: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{3}{4x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, \infty]$

Irregular singular points : []

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$4x^2y'' - 4y'x + 3y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$
$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$
\begin{aligned}
&4\left(\sum_{n=0}^{\infty}(n+r)(n+r-1)\,a_n x^{n+r-2}\right)x^2 \\
&-4\left(\sum_{n=0}^{\infty}(n+r)\,a_n x^{n+r-1}\right)x+3\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right)=0
\end{aligned}
\tag{1}
$$

Which simplifies to

$$
\left(\sum_{n=0}^{\infty}4x^{n+r}a_n(n+r)(n+r-1)\right)+\sum_{n=0}^{\infty}\left(-4x^{n+r}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}3a_n x^{n+r}\right)=0 \tag{2A}
$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$
\left(\sum_{n=0}^{\infty}4x^{n+r}a_n(n+r)(n+r-1)\right)+\sum_{n=0}^{\infty}\left(-4x^{n+r}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}3a_n x^{n+r}\right)=0 \tag{2B}
$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$
4x^{n+r}a_n(n+r)(n+r-1)-4x^{n+r}a_n(n+r)+3a_n x^{n+r}=0
$$

When $n=0$ the above becomes

$$
4x^r a_0 r(-1+r)-4x^r a_0 r+3a_0 x^r=0
$$

Or

$$
\left(4x^r r(-1+r)-4x^r r+3x^r\right)a_0=0
$$

Since $a_0\neq 0$ then the above simplifies to

$$
\left(4r^2-8r+3\right)x^r=0
$$

Since the above is true for all x then the indicial equation becomes

$$
4r^2-8r+3=0
$$

Solving for r gives the roots of the indicial equation as

$$
\begin{aligned}
r_1 &= \frac{3}{2} \\
r_2 &= \frac{1}{2}
\end{aligned}
$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$
(4r^2 - 8r + 3)\, x^r = 0
$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 1$ is an integer, then we can construct two linearly independent solutions

$$
\begin{aligned}
y_1(x) &= x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right) \\
y_2(x) &= C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= x^{\frac{3}{2}} \left(\sum_{n=0}^{\infty} a_n x^n\right) \\
y_2(x) &= C y_1(x) \ln(x) + \sqrt{x} \left(\sum_{n=0}^{\infty} b_n x^n\right)
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+\frac{3}{2}} \\
y_2(x) &= C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+\frac{1}{2}}\right)
\end{aligned}
$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $0 \leq n$ the recursive equation is

$$
4a_n(n+r)(n+r-1) - 4a_n(n+r) + 3a_n = 0 \tag{3}
$$

Solving for a_n from recursive equation (4) gives

$$
a_n = 0 \tag{4}
$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_n = 0 \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{3}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{3}{2}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^{\frac{3}{2}}\left(1 + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 1$. Now we need to determine if

C is zero or not. This is done by finding $\lim_{r\rightarrow r_2} a_1(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$
\begin{aligned}
a_N &= a_1 \\
&= 0
\end{aligned}
$$

Therefore

$$
\begin{aligned}
\lim_{r\rightarrow r_2} 0 &= \lim_{r\rightarrow \frac{1}{2}} 0 \\
&= 0
\end{aligned}
$$

The limit is 0. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$
\begin{aligned}
y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\
&= \sum_{n=0}^{\infty} b_n x^{n+\frac{1}{2}}
\end{aligned}
$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $0 \leq n$ the recursive equation is

$$
4b_n(n+r)(n+r-1) - 4b_n(n+r) + 3b_n = 0 \tag{4}
$$

Which for for the root $r = \frac{1}{2}$ becomes

$$
4b_n\left(n+\frac{1}{2}\right)\left(n-\frac{1}{2}\right) - 4b_n\left(n+\frac{1}{2}\right) + 3b_n = 0 \tag{4A}
$$

Solving for b_n from the recursive equation (4) gives

$$
b_n = 0 \tag{5}
$$

Which for the root $r = \frac{1}{2}$ becomes

$$
b_n = 0 \tag{6}
$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	0	0

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	0	0
b_5	0	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= x^{\frac{3}{2}}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\ &= \sqrt{x}\left(1 + O(x^6)\right) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^{\frac{3}{2}}\left(1 + O(x^6)\right) + c_2\sqrt{x}\left(1 + O(x^6)\right) \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= c_1 x^{\frac{3}{2}}\left(1 + O(x^6)\right) + c_2\sqrt{x}\left(1 + O(x^6)\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 x^{\frac{3}{2}} \left(1 + O(x^6)\right) + c_2 \sqrt{x}\, \left(1 + O(x^6)\right) \tag{1}$$

Verification of solutions

$$y = c_1 x^{\frac{3}{2}} \left(1 + O(x^6)\right) + c_2 \sqrt{x}\, \left(1 + O(x^6)\right)$$

Verified OK.

15.18.1 Maple step by step solution

Let's solve

$4y''x^2 - 4y'x + 3y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{y'}{x} - \frac{3y}{4x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{y'}{x} + \frac{3y}{4x^2} = 0$

- Multiply by denominators of the ODE

  $4y''x^2 - 4y'x + 3y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt} y(t)\right) t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt} y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2} y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt} y(t)\right)$

  - Compute derivative

$y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

Substitute the change of variables back into the ODE

$4\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right)x^2 - 4\frac{d}{dt}y(t) + 3y(t) = 0$

- Simplify

  $4\frac{d^2}{dt^2}y(t) - 8\frac{d}{dt}y(t) + 3y(t) = 0$

- Isolate 2nd derivative

  $\frac{d^2}{dt^2}y(t) = 2\frac{d}{dt}y(t) - \frac{3y(t)}{4}$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dt^2}y(t) - 2\frac{d}{dt}y(t) + \frac{3y(t)}{4} = 0$

- Characteristic polynomial of ODE

  $r^2 - 2r + \frac{3}{4} = 0$

- Factor the characteristic polynomial

  $\frac{(2r-1)(2r-3)}{4} = 0$

- Roots of the characteristic polynomial

  $r = \left(\frac{1}{2}, \frac{3}{2}\right)$

- 1st solution of the ODE

  $y_1(t) = e^{\frac{t}{2}}$

- 2nd solution of the ODE

  $y_2(t) = e^{\frac{3t}{2}}$

- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$

- Substitute in solutions

  $y(t) = c_1 e^{\frac{t}{2}} + c_2 e^{\frac{3t}{2}}$

- Change variables back using $t = \ln(x)$

  $y = c_1\sqrt{x} + c_2 x^{\frac{3}{2}}$

- Simplify

  $y = \sqrt{x}\,(c_2 x + c_1)$

Problem number: 19.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + y'x + y(x-1) = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + y'x + y(x-1) = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{x-1}{x^2}$$

Table 563: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{x-1}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' + y'x + y(x-1) = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x^2 + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) x + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) (x-1) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) \\ + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n = \sum_{n=1}^{\infty} a_{n-1} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) \\ + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) + x^{n+r} a_n (n+r) - a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) + x^r a_0 r - a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) + x^r r - x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2-1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = -1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2 - 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 2$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{1+n}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-1}\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + a_n(n+r) + a_{n-1} - a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}}{n^2 + 2nr + r^2 - 1} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = -\frac{a_{n-1}}{n(n+2)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{1}{r(r+2)}$$

Which for the root $r = 1$ becomes

$$a_1 = -\frac{1}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r(r+2)}$	$-\frac{1}{3}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{r(r+2)(r+3)(r+1)}$$

Which for the root $r = 1$ becomes

$$a_2 = \frac{1}{24}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r(r+2)}$	$-\frac{1}{3}$
a_2	$\frac{1}{r(r+2)(r+3)(r+1)}$	$\frac{1}{24}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{1}{r(r+2)^2(r+3)(r+1)(r+4)}$$

Which for the root $r = 1$ becomes

$$a_3 = -\frac{1}{360}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r(r+2)}$	$-\frac{1}{3}$
a_2	$\frac{1}{r(r+2)(r+3)(r+1)}$	$\frac{1}{24}$
a_3	$-\frac{1}{r(r+2)^2(r+3)(r+1)(r+4)}$	$-\frac{1}{360}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{r(r+2)^2(r+3)^2(r+1)(r+4)(r+5)}$$

Which for the root $r = 1$ becomes

$$a_4 = \frac{1}{8640}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r(r+2)}$	$-\frac{1}{3}$
a_2	$\frac{1}{r(r+2)(r+3)(r+1)}$	$\frac{1}{24}$
a_3	$-\frac{1}{r(r+2)^2(r+3)(r+1)(r+4)}$	$-\frac{1}{360}$
a_4	$\frac{1}{r(r+2)^2(r+3)^2(r+1)(r+4)(r+5)}$	$\frac{1}{8640}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1}{r(r+2)^2(r+3)^2(r+1)(r+4)^2(r+5)(r+6)}$$

Which for the root $r = 1$ becomes

$$a_5 = -\frac{1}{302400}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r(r+2)}$	$-\frac{1}{3}$
a_2	$\frac{1}{r(r+2)(r+3)(r+1)}$	$\frac{1}{24}$
a_3	$-\frac{1}{r(r+2)^2(r+3)(r+1)(r+4)}$	$-\frac{1}{360}$
a_4	$\frac{1}{r(r+2)^2(r+3)^2(r+1)(r+4)(r+5)}$	$\frac{1}{8640}$
a_5	$-\frac{1}{r(r+2)^2(r+3)^2(r+1)(r+4)^2(r+5)(r+6)}$	$-\frac{1}{302400}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\
&= x\left(1 - \frac{x}{3} + \frac{x^2}{24} - \frac{x^3}{360} + \frac{x^4}{8640} - \frac{x^5}{302400} + O(x^6)\right)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 2$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \to r_2} a_2(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned}
a_N &= a_2 \\
&= \frac{1}{r(r+2)(r+3)(r+1)}
\end{aligned}$$

Therefore

$$\begin{aligned}
\lim_{r \to r_2} \frac{1}{r(r+2)(r+3)(r+1)} &= \lim_{r \to -1} \frac{1}{r(r+2)(r+3)(r+1)} \\
&= \textit{undefined}
\end{aligned}$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Therefore

$$\begin{aligned}
\frac{d}{dx}y_2(x) &= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) \\
&= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n(n+r_2)\right) \\
\frac{d^2}{dx^2}y_2(x) &= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} \\
&\quad + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right) \\
&= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n(n+r_2)(-1+n+r_2)\right)
\end{aligned}$$

Substituting these back into the given ode $x^2y'' + y'x + y(x-1) = 0$ gives

$$\begin{aligned}
&\left(Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2}\right. \\
&\left. + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right) x^2 \\
&+ \left(Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right)\right) x \\
&+ \left(Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)\right)(x-1) = 0
\end{aligned}$$

Which can be written as

$$\left(\left(\left(y_1''(x)\,x^2+y_1'(x)\,x+y_1(x)\,(x-1)\right)\ln(x)+\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)x^2+y_1(x)\right)C \\ +\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x^2 \\ +\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)x+\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)(x-1)=0 \tag{7}$$

But since $y_1(x)$ is a solution to the ode, then

$$y_1''(x)\,x^2+y_1'(x)\,x+y_1(x)\,(x-1)=0$$

Eq (7) simplifes to

$$\left(\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)x^2+y_1(x)\right)C \\ +\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x^2 \\ +\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)x+\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)(x-1)=0 \tag{8}$$

Substituting $y_1=\sum_{n=0}^{\infty}a_n x^{n+r_1}$ into the above gives

$$\left(\sum_{n=0}^{\infty}x^{-2+n+r_2}b_n(n+r_2)\,(-1+n+r_2)\right)x^2+2x\left(\sum_{n=0}^{\infty}x^{-1+n+r_1}a_n(n+r_1)\right)C \\ +\left(\sum_{n=0}^{\infty}x^{-1+n+r_2}b_n(n+r_2)\right)x+\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)(x-1)=0 \tag{9}$$

Since $r_1=1$ and $r_2=-1$ then the above becomes

$$\left(\sum_{n=0}^{\infty}x^{-3+n}b_n(n-1)\,(-2+n)\right)x^2+2x\left(\sum_{n=0}^{\infty}x^{n}a_n(1+n)\right)C \\ +\left(\sum_{n=0}^{\infty}x^{-2+n}b_n(n-1)\right)x+\left(\sum_{n=0}^{\infty}b_n x^{n-1}\right)(x-1)=0 \tag{10}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n-1} b_n \left(n^2-3n+2\right)\right)+\left(\sum_{n=0}^{\infty} 2C\, x^{1+n} a_n (1+n)\right) \\ +\left(\sum_{n=0}^{\infty} x^{n-1} b_n (n-1)\right)+\left(\sum_{n=0}^{\infty} b_n x^n\right)+\sum_{n=0}^{\infty} \left(-b_n x^{n-1}\right)=0 \tag{2A}$$

The next step is to make all powers of x be $n-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2C\, x^{1+n} a_n (1+n)=\sum_{n=2}^{\infty} 2C a_{-2+n} (n-1)\, x^{n-1}$$

$$\sum_{n=0}^{\infty} b_n x^n=\sum_{n=1}^{\infty} b_{n-1} x^{n-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n-1$.

$$\left(\sum_{n=0}^{\infty} x^{n-1} b_n \left(n^2-3n+2\right)\right)+\left(\sum_{n=2}^{\infty} 2C a_{-2+n} (n-1)\, x^{n-1}\right) \\ +\left(\sum_{n=0}^{\infty} x^{n-1} b_n (n-1)\right)+\left(\sum_{n=1}^{\infty} b_{n-1} x^{n-1}\right)+\sum_{n=0}^{\infty} \left(-b_n x^{n-1}\right)=0 \tag{2B}$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0=1$. For $n=1$, Eq (2B) gives

$$b_0-b_1=0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$1-b_1=0$$

Solving the above for b_1 gives

$$b_1=1$$

For $n=N$, where $N=2$ which is the difference between the two roots, we are free to choose $b_2=0$. Hence for $n=2$, Eq (2B) gives

$$2C+1=0$$

Which is solved for C. Solving for C gives

$$C = -\frac{1}{2}$$

For $n = 3$, Eq (2B) gives

$$4Ca_1 + b_2 + 3b_3 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$3b_3 + \frac{2}{3} = 0$$

Solving the above for b_3 gives

$$b_3 = -\frac{2}{9}$$

For $n = 4$, Eq (2B) gives

$$6Ca_2 + b_3 + 8b_4 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$8b_4 - \frac{25}{72} = 0$$

Solving the above for b_4 gives

$$b_4 = \frac{25}{576}$$

For $n = 5$, Eq (2B) gives

$$8Ca_3 + b_4 + 15b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$15b_5 + \frac{157}{2880} = 0$$

Solving the above for b_5 gives

$$b_5 = -\frac{157}{43200}$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = -\frac{1}{2}$ and all b_n, then the second solution becomes

$$y_2(x) = -\frac{1}{2}\left(x\left(1 - \frac{x}{3} + \frac{x^2}{24} - \frac{x^3}{360} + \frac{x^4}{8640} - \frac{x^5}{302400} + O(x^6)\right)\right)\ln(x) + \frac{1 + x - \frac{2x^3}{9} + \frac{25x^4}{576} - \frac{157x^5}{43200} + O(x^6)}{x}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x \left(1-\frac{x}{3}+\frac{x^2}{24}-\frac{x^3}{360}+\frac{x^4}{8640}-\frac{x^5}{302400}+O\left(x^6\right)\right) \\
&\quad + c_2 \left(-\frac{1}{2}\left(x\left(1-\frac{x}{3}+\frac{x^2}{24}-\frac{x^3}{360}+\frac{x^4}{8640}-\frac{x^5}{302400}+O\left(x^6\right)\right)\right)\ln\left(x\right) \right. \\
&\quad \left. + \frac{1+x-\frac{2x^3}{9}+\frac{25x^4}{576}-\frac{157x^5}{43200}+O(x^6)}{x}\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x \left(1-\frac{x}{3}+\frac{x^2}{24}-\frac{x^3}{360}+\frac{x^4}{8640}-\frac{x^5}{302400}+O\left(x^6\right)\right) \\
&\quad + c_2 \left(-\frac{x\left(1-\frac{x}{3}+\frac{x^2}{24}-\frac{x^3}{360}+\frac{x^4}{8640}-\frac{x^5}{302400}+O(x^6)\right)\ln\left(x\right)}{2} \right. \\
&\quad \left. + \frac{1+x-\frac{2x^3}{9}+\frac{25x^4}{576}-\frac{157x^5}{43200}+O(x^6)}{x}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x \left(1-\frac{x}{3}+\frac{x^2}{24}-\frac{x^3}{360}+\frac{x^4}{8640}-\frac{x^5}{302400}+O\left(x^6\right)\right) \\
&\quad + c_2 \left(-\frac{x\left(1-\frac{x}{3}+\frac{x^2}{24}-\frac{x^3}{360}+\frac{x^4}{8640}-\frac{x^5}{302400}+O(x^6)\right)\ln\left(x\right)}{2} \right. \\
&\quad \left. + \frac{1+x-\frac{2x^3}{9}+\frac{25x^4}{576}-\frac{157x^5}{43200}+O(x^6)}{x}\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$y = c_1 x \left(1 - \frac{x}{3} + \frac{x^2}{24} - \frac{x^3}{360} + \frac{x^4}{8640} - \frac{x^5}{302400} + O(x^6)\right) + c_2 \left(-\frac{x\left(1 - \frac{x}{3} + \frac{x^2}{24} - \frac{x^3}{360} + \frac{x^4}{8640} - \frac{x^5}{302400} + O(x^6)\right) \ln(x)}{2} + \frac{1 + x - \frac{2x^3}{9} + \frac{25x^4}{576} - \frac{157x^5}{43200} + O(x^6)}{x}\right)$$

Verified OK.

15.19.1 Maple step by step solution

Let's solve

$y''x^2 + y'x + y(x-1) = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y'}{x} - \frac{(x-1)y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + \frac{(x-1)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{1}{x}, P_3(x) = \frac{x-1}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -1$

  ◦ $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $y''x^2 + y'x + y(x-1) = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- > k - m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r}$
  - Convert $x^2 \cdot y''$ to series expansion

    $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)\,(-1+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+1)\,(k+r-1) + a_{k-1}\right) x^{k+r}\right) = 0$
- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(-1+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{-1, 1\}$
- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+1)\,(k+r-1) + a_{k-1} = 0$
- Shift index using $k- > k + 1$

  $a_{k+1}(k+2+r)\,(k+r) + a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k}{(k+2+r)(k+r)}$
- Recursion relation for $r = -1$

$$a_{k+1} = -\frac{a_k}{(k+1)(k-1)}$$

- Series not valid for $r = -1$, division by 0 in the recursion relation at $k = 1$

$$a_{k+1} = -\frac{a_k}{(k+1)(k-1)}$$

- Recursion relation for $r = 1$

$$a_{k+1} = -\frac{a_k}{(k+3)(k+1)}$$

- Solution for $r = 1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+1} = -\frac{a_k}{(k+3)(k+1)}\right]$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.2 (Frobenius). Exercises page 251
Problem number: 20.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + \left(x^3 - x\right)y' - 3y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + \left(x^3 - x\right)y' - 3y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{x^2 - 1}{x}$$
$$q(x) = -\frac{3}{x^2}$$

Table 565: Table $p(x), q(x)$ singularites.

$p(x) = \frac{x^2-1}{x}$	
singularity	type
$x = 0$	"regular"
$x = \infty$	"regular"
$x = -\infty$	"regular"

$q(x) = -\frac{3}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, \infty, -\infty]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2 y'' + (x^3 - x) y' - 3y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x^2 + (x^3 - x) \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) - 3\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty} x^{n+r+2} a_n(n+r)\right) + \sum_{n=0}^{\infty}\left(-x^{n+r} a_n(n+r)\right)+\sum_{n=0}^{\infty}\left(-3 a_n x^{n+r}\right)=0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n(n+r)=\sum_{n=2}^{\infty} a_{n-2}(n+r-2) x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right)+\left(\sum_{n=2}^{\infty} a_{n-2}(n+r-2) x^{n+r}\right) + \sum_{n=0}^{\infty}\left(-x^{n+r} a_n(n+r)\right)+\sum_{n=0}^{\infty}\left(-3 a_n x^{n+r}\right)=0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n(n+r)(n+r-1)-x^{n+r} a_n(n+r)-3 a_n x^{n+r}=0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r)-x^r a_0 r-3 a_0 x^r=0$$

Or

$$\left(x^r r(-1+r)-x^r r-3 x^r\right) a_0=0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2-2 r-3\right) x^r=0$$

Since the above is true for all x then the indicial equation becomes

$$r^2-2 r-3=0$$

Solving for r gives the roots of the indicial equation as

$$
\begin{aligned}
r_1 &= 3 \\
r_2 &= -1
\end{aligned}
$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$
(r^2 - 2r - 3)\, x^r = 0
$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 4$ is an integer, then we can construct two linearly independent solutions

$$
\begin{aligned}
y_1(x) &= x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n \right) \\
y_2(x) &= C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n \right)
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= x^3 \left(\sum_{n=0}^{\infty} a_n x^n \right) \\
y_2(x) &= C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x}
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+3} \\
y_2(x) &= C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-1} \right)
\end{aligned}
$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$
a_1 = 0
$$

For $2 \leq n$ the recursive equation is

$$
a_n(n+r)(n+r-1) + a_{n-2}(n+r-2) - a_n(n+r) - 3a_n = 0 \tag{3}
$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-2}(n+r-2)}{n^2+2nr+r^2-2n-2r-3} \tag{4}$$

Which for the root $r = 3$ becomes

$$a_n = -\frac{a_{n-2}(n+1)}{n\,(n+4)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 3$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{r}{r^2+2r-3}$$

Which for the root $r = 3$ becomes

$$a_2 = -\frac{1}{4}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{r}{r^2+2r-3}$	$-\frac{1}{4}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{r}{r^2+2r-3}$	$-\frac{1}{4}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{r(2+r)}{r^4 + 8r^3 + 14r^2 - 8r - 15}$$

Which for the root $r = 3$ becomes

$$a_4 = \frac{5}{128}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{r}{r^2+2r-3}$	$-\frac{1}{4}$
a_3	0	0
a_4	$\frac{r(2+r)}{r^4+8r^3+14r^2-8r-15}$	$\frac{5}{128}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{r}{r^2+2r-3}$	$-\frac{1}{4}$
a_3	0	0
a_4	$\frac{r(2+r)}{r^4+8r^3+14r^2-8r-15}$	$\frac{5}{128}$
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^3 \left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^3 \left(1 - \frac{x^2}{4} + \frac{5x^4}{128} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 4$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_4(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_4 \\ &= \frac{r(2+r)}{r^4 + 8r^3 + 14r^2 - 8r - 15} \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r\to r_2} \frac{r(2+r)}{r^4 + 8r^3 + 14r^2 - 8r - 15} &= \lim_{r\to -1} \frac{r(2+r)}{r^4 + 8r^3 + 14r^2 - 8r - 15} \\ &= \textit{undefined} \end{aligned}$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Therefore

$$\begin{aligned} \frac{d}{dx} y_2(x) &= C y_1'(x) \ln(x) + \frac{C y_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) \\ &= C y_1'(x) \ln(x) + \frac{C y_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n (n+r_2)\right) \\ \frac{d^2}{dx^2} y_2(x) &= C y_1''(x) \ln(x) + \frac{2C y_1'(x)}{x} - \frac{C y_1(x)}{x^2} \\ &\quad + \sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right) \\ &= C y_1''(x) \ln(x) + \frac{2C y_1'(x)}{x} - \frac{C y_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n (n+r_2)(-1+n+r_2)\right) \end{aligned}$$

Substituting these back into the given ode $x^2y'' + (x^3 - x)\,y' - 3y = 0$ gives

$$\left(Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x^2 + (x^3 - x)\left(Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)\right) - 3Cy_1(x)\ln(x) - 3\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0$$

Which can be written as

$$\left(\left(y_1''(x)\,x^2 + (x^3 - x)\,y_1'(x) - 3y_1(x)\right)\ln(x) + \left(\frac{2y_1'(x)}{x} - \frac{y_1(x)}{x^2}\right)x^2 + \frac{(x^3 - x)\,y_1(x)}{x}\right)C + \left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x^2 + (x^3 - x)\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right) - 3\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0 \tag{7}$$

But since $y_1(x)$ is a solution to the ode, then

$$y_1''(x)\,x^2 + (x^3 - x)\,y_1'(x) - 3y_1(x) = 0$$

Eq (7) simplifes to

$$\left(\left(\frac{2y_1'(x)}{x} - \frac{y_1(x)}{x^2}\right)x^2 + \frac{(x^3 - x)\,y_1(x)}{x}\right)C + \left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x^2 + (x^3 - x)\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right) - 3\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0 \tag{8}$$

Substituting $y_1 = \sum_{n=0}^{\infty} a_n x^{n+r_1}$ into the above gives

$$
\begin{aligned}
&\left(2\left(\sum_{n=0}^{\infty} x^{-1+n+r_1} a_n (n+r_1)\right) x + (x^2-2)\left(\sum_{n=0}^{\infty} a_n x^{n+r_1}\right)\right) C \\
&+ \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n (n+r_2)(-1+n+r_2)\right) x^2 \\
&+ (x^3-x)\left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n (n+r_2)\right) - 3\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0
\end{aligned} \tag{9}
$$

Since $r_1 = 3$ and $r_2 = -1$ then the above becomes

$$
\begin{aligned}
&\left(2\left(\sum_{n=0}^{\infty} x^{2+n} a_n (n+3)\right) x + (x^2-2)\left(\sum_{n=0}^{\infty} a_n x^{n+3}\right)\right) C \\
&+ \left(\sum_{n=0}^{\infty} x^{-3+n} b_n (n-1)(n-2)\right) x^2 \\
&+ (x^3-x)\left(\sum_{n=0}^{\infty} x^{n-2} b_n (n-1)\right) - 3\left(\sum_{n=0}^{\infty} b_n x^{n-1}\right) = 0
\end{aligned} \tag{10}
$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} 2C\, x^{n+3} a_n (n+3)\right) + \left(\sum_{n=0}^{\infty} C\, x^{n+5} a_n\right) + \sum_{n=0}^{\infty} \left(-2C\, x^{n+3} a_n\right) \\
&+ \left(\sum_{n=0}^{\infty} x^{n-1} b_n (n^2-3n+2)\right) + \left(\sum_{n=0}^{\infty} x^{n+1} b_n (n-1)\right) \\
&+ \sum_{n=0}^{\infty} \left(-x^{n-1} b_n (n-1)\right) + \sum_{n=0}^{\infty} \left(-3 b_n x^{n-1}\right) = 0
\end{aligned} \tag{2A}
$$

The next step is to make all powers of x be $n-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2C\, x^{n+3} a_n (n+3) = \sum_{n=4}^{\infty} 2C a_{n-4} (n-1)\, x^{n-1}$$

$$\sum_{n=0}^{\infty} C\, x^{n+5} a_n = \sum_{n=6}^{\infty} C a_{n-6} x^{n-1}$$

$$\sum_{n=0}^{\infty} \left(-2C\, x^{n+3} a_n\right) = \sum_{n=4}^{\infty} \left(-2C a_{n-4} x^{n-1}\right)$$

$$\sum_{n=0}^{\infty} x^{n+1} b_n (n-1) = \sum_{n=2}^{\infty} b_{n-2} (-3+n)\, x^{n-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n-1$.

$$\begin{aligned} \left(\sum_{n=4}^{\infty} 2C a_{n-4} (n-1)\, x^{n-1}\right) + \left(\sum_{n=6}^{\infty} C a_{n-6} x^{n-1}\right) + \sum_{n=4}^{\infty} \left(-2C a_{n-4} x^{n-1}\right) \\ + \left(\sum_{n=0}^{\infty} x^{n-1} b_n \left(n^2 - 3n + 2\right)\right) + \left(\sum_{n=2}^{\infty} b_{n-2} (-3+n)\, x^{n-1}\right) \\ + \sum_{n=0}^{\infty} \left(-x^{n-1} b_n (n-1)\right) + \sum_{n=0}^{\infty} \left(-3 b_n x^{n-1}\right) = 0 \end{aligned} \tag{2B}$$

For $n = 0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0 = 1$. For $n = 1$, Eq (2B) gives

$$-3b_1 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-3b_1 = 0$$

Solving the above for b_1 gives

$$b_1 = 0$$

For $n = 2$, Eq (2B) gives

$$-b_0 - 4b_2 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-1 - 4b_2 = 0$$

Solving the above for b_2 gives

$$b_2 = -\frac{1}{4}$$

For $n = 3$, Eq (2B) gives

$$-3b_3 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-3b_3 = 0$$

Solving the above for b_3 gives

$$b_3 = 0$$

For $n = N$, where $N = 4$ which is the difference between the two roots, we are free to choose $b_4 = 0$. Hence for $n = 4$, Eq (2B) gives

$$4C - \frac{1}{4} = 0$$

Which is solved for C. Solving for C gives

$$C = \frac{1}{16}$$

For $n = 5$, Eq (2B) gives

$$6Ca_1 + 2b_3 + 5b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$5b_5 = 0$$

Solving the above for b_5 gives

$$b_5 = 0$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = \frac{1}{16}$ and all b_n, then the second solution becomes

$$y_2(x) = \frac{1}{16}\left(x^3\left(1 - \frac{x^2}{4} + \frac{5x^4}{128} + O(x^6)\right)\right)\ln(x) + \frac{1 - \frac{x^2}{4} + O(x^6)}{x}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^3 \left(1 - \frac{x^2}{4} + \frac{5x^4}{128} + O(x^6)\right) \\
&\quad + c_2 \left(\frac{1}{16} \left(x^3 \left(1 - \frac{x^2}{4} + \frac{5x^4}{128} + O(x^6)\right)\right) \ln(x) + \frac{1 - \frac{x^2}{4} + O(x^6)}{x}\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^3 \left(1 - \frac{x^2}{4} + \frac{5x^4}{128} + O(x^6)\right) \\
&\quad + c_2 \left(\frac{x^3 \left(1 - \frac{x^2}{4} + \frac{5x^4}{128} + O(x^6)\right) \ln(x)}{16} + \frac{1 - \frac{x^2}{4} + O(x^6)}{x}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x^3 \left(1 - \frac{x^2}{4} + \frac{5x^4}{128} + O(x^6)\right) \\
&\quad + c_2 \left(\frac{x^3 \left(1 - \frac{x^2}{4} + \frac{5x^4}{128} + O(x^6)\right) \ln(x)}{16} + \frac{1 - \frac{x^2}{4} + O(x^6)}{x}\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 x^3 \left(1 - \frac{x^2}{4} + \frac{5x^4}{128} + O(x^6)\right) \\
&\quad + c_2 \left(\frac{x^3 \left(1 - \frac{x^2}{4} + \frac{5x^4}{128} + O(x^6)\right) \ln(x)}{16} + \frac{1 - \frac{x^2}{4} + O(x^6)}{x}\right)
\end{aligned}
$$

Verified OK.

15.20.1 Maple step by step solution

Let's solve

$y''x^2 + (x^3 - x)\, y' - 3y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{3y}{x^2} - \frac{(x^2-1)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(x^2-1)y'}{x} - \frac{3y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{x^2-1}{x}, P_3(x) = -\frac{3}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\bigg|_{x=0} = -1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = -3$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x^2 + (x^2 - 1)\, xy' - 3y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $x^{m}\cdot y'=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^{2}\cdot y''$ to series expansion

  $x^{2}\cdot y''=\sum_{k=0}^{\infty} a_{k}(k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_{0}(1+r)\,(-3+r)\, x^{r}+a_{1}(2+r)\,(-2+r)\, x^{1+r}+\left(\sum_{k=2}^{\infty} (a_{k}(k+r+1)\,(k+r-3)+a_{k-2}(k-2-$

- a_{0}cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(-3+r)=0$

- Values of r that satisfy the indicial equation

  $r\in\{-1,3\}$

- Each term must be 0

  $a_{1}(2+r)\,(-2+r)=0$

- Solve for the dependent coefficient(s)

  $a_{1}=0$

- Each term in the series must be 0, giving the recursion relation

  $a_{k}(k+r+1)\,(k+r-3)+a_{k-2}(k-2+r)=0$

- Shift index using $k->k+2$

  $a_{k+2}(k+3+r)\,(k+r-1)+a_{k}(k+r)=0$

- Recursion relation that defines series solution to ODE

  $a_{k+2}=-\frac{a_{k}(k+r)}{(k+3+r)(k+r-1)}$

- Recursion relation for $r=-1$

  $a_{k+2}=-\frac{a_{k}(k-1)}{(k+2)(k-2)}$

- Series not valid for $r=-1$, division by 0 in the recursion relation at $k=2$

  $a_{k+2}=-\frac{a_{k}(k-1)}{(k+2)(k-2)}$

- Recursion relation for $r=3$

  $a_{k+2}=-\frac{a_{k}(k+3)}{(k+6)(k+2)}$

- Solution for $r=3$

$$\left[y=\sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+2}=-\frac{a_k(k+3)}{(k+6)(k+2)}, a_1=0\right]$$

Section: Chapter 6, Series solutions of linear differential equations. Section 6.2 (Frobenius). Exercises page 251
Problem number: 21.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - y'x + 8y(x^2 - 1) = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' - y'x + (8x^2 - 8) y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{1}{x}$$
$$q(x) = \frac{8x^2 - 8}{x^2}$$

Table 567: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{8x^2-8}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' - y'x + (8x^2 - 8)\, y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x^2 - \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) x + (8x^2 - 8) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 8x^{n+r+2} a_n\right) + \sum_{n=0}^{\infty} \left(-8a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 8x^{n+r+2} a_n = \sum_{n=2}^{\infty} 8a_{n-2} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=2}^{\infty} 8a_{n-2} x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-8a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - x^{n+r} a_n (n+r) - 8a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - x^r a_0 r - 8a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - x^r r - 8x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2 - 2r - 8\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - 2r - 8 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 4$$
$$r_2 = -2$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2 - 2r - 8\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 6$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x^4 \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x^2}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+4}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-2}\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n + r)(n + r - 1) - a_n(n + r) + 8a_{n-2} - 8a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{8a_{n-2}}{n^2 + 2nr + r^2 - 2n - 2r - 8} \tag{4}$$

Which for the root $r = 4$ becomes

$$a_n = -\frac{8a_{n-2}}{n(n+6)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 4$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{8}{r^2 + 2r - 8}$$

Which for the root $r = 4$ becomes

$$a_2 = -\frac{1}{2}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{8}{r^2+2r-8}$	$-\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{8}{r^2+2r-8}$	$-\frac{1}{2}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{64}{(r+4)(r-2)\, r\, (r+6)}$$

Which for the root $r = 4$ becomes

$$a_4 = \frac{1}{10}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{8}{r^2+2r-8}$	$-\frac{1}{2}$
a_3	0	0
a_4	$\frac{64}{(r+4)(r-2)r(r+6)}$	$\frac{1}{10}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{8}{r^2+2r-8}$	$-\frac{1}{2}$
a_3	0	0
a_4	$\frac{64}{(r+4)(r-2)r(r+6)}$	$\frac{1}{10}$
a_5	0	0

For $n = 6$, using the above recursive equation gives

$$a_6 = -\frac{512}{(r+4)(r-2)\, r\, (r+6)(r+8)(r+2)}$$

Which for the root $r = 4$ becomes

$$a_6 = -\frac{1}{90}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{8}{r^2+2r-8}$	$-\frac{1}{2}$
a_3	0	0
a_4	$\frac{64}{(r+4)(r-2)r(r+6)}$	$\frac{1}{10}$
a_5	0	0
a_6	$-\frac{512}{(r+4)(r-2)r(r+6)(r+8)(r+2)}$	$-\frac{1}{90}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}y_1(x) &= x^4\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 + a_7x^7 \dots\right) \\ &= x^4\left(1 - \frac{x^2}{2} + \frac{x^4}{10} - \frac{x^6}{90} + O\left(x^7\right)\right)\end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 6$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \to r_2} a_6(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned}a_N &= a_6 \\ &= -\frac{512}{(r+4)(r-2)r(r+6)(r+8)(r+2)}\end{aligned}$$

Therefore

$$\begin{aligned}\lim_{r \to r_2} -\frac{512}{(r+4)(r-2)r(r+6)(r+8)(r+2)} &= \lim_{r \to -2} -\frac{512}{(r+4)(r-2)r(r+6)(r+8)(r+2)} \\ &= \mathit{undefined}\end{aligned}$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Therefore

$$
\begin{aligned}
\frac{d}{dx}y_2(x) &= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) \\
&= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n(n+r_2)\right) \\
\frac{d^2}{dx^2}y_2(x) &= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} \\
&\quad + \sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right) \\
&= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n(n+r_2)(-1+n+r_2)\right)
\end{aligned}
$$

Substituting these back into the given ode $x^2y'' - y'x + (8x^2-8)\,y = 0$ gives

$$
\begin{aligned}
&\left(Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2}\right. \\
&\left.+ \sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right) x^2 \\
&- \left(Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right)\right) x \\
&+ (8x^2-8)\left(Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)\right) = 0
\end{aligned}
$$

Which can be written as

$$
\begin{aligned}
&\left(\left(y_1''(x)\,x^2 - y_1'(x)\,x + (8x^2-8)\,y_1(x)\right)\ln(x) + \left(\frac{2y_1'(x)}{x} - \frac{y_1(x)}{x^2}\right)x^2\right. \\
&\left.- y_1(x)\right) C + \left(\sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right) x^2 \\
&- \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) x + (8x^2-8)\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0
\end{aligned}
\tag{7}
$$

But since $y_1(x)$ is a solution to the ode, then

$$y_1''(x)\,x^2 - y_1'(x)\,x + \left(8x^2 - 8\right) y_1(x) = 0$$

Eq (7) simplifes to

$$\begin{aligned}
&\left(\left(\frac{2y_1'(x)}{x} - \frac{y_1(x)}{x^2}\right) x^2 - y_1(x)\right) C \\
&+ \left(\sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2} (n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2} (n+r_2)}{x^2}\right)\right) x^2 \\
&- \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2} (n+r_2)}{x}\right) x + \left(8x^2 - 8\right) \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0
\end{aligned} \tag{8}$$

Substituting $y_1 = \sum_{n=0}^{\infty} a_n x^{n+r_1}$ into the above gives

$$\begin{aligned}
&\left(2\left(\sum_{n=0}^{\infty} x^{-1+n+r_1} a_n (n+r_1)\right) x - 2\left(\sum_{n=0}^{\infty} a_n x^{n+r_1}\right)\right) C \\
&+ \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n (n+r_2)(-1+n+r_2)\right) x^2 + 8\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) x^2 \\
&- \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n (n+r_2)\right) x - 8\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0
\end{aligned} \tag{9}$$

Since $r_1 = 4$ and $r_2 = -2$ then the above becomes

$$\begin{aligned}
&\left(2\left(\sum_{n=0}^{\infty} x^{3+n} a_n (n+4)\right) x - 2\left(\sum_{n=0}^{\infty} a_n x^{n+4}\right)\right) C \\
&+ \left(\sum_{n=0}^{\infty} x^{-4+n} b_n (n-2)(-3+n)\right) x^2 + 8\left(\sum_{n=0}^{\infty} b_n x^{n-2}\right) x^2 \\
&- \left(\sum_{n=0}^{\infty} x^{-3+n} b_n (n-2)\right) x - 8\left(\sum_{n=0}^{\infty} b_n x^{n-2}\right) = 0
\end{aligned} \tag{10}$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} 2C\, x^{n+4} a_n (n+4)\right) + \sum_{n=0}^{\infty} \left(-2C a_n x^{n+4}\right) + \left(\sum_{n=0}^{\infty} x^{n-2} b_n \left(n^2-5n+6\right)\right) \\
&+ \left(\sum_{n=0}^{\infty} 8 b_n x^n\right) + \sum_{n=0}^{\infty} \left(-x^{n-2} b_n (n-2)\right) + \sum_{n=0}^{\infty} \left(-8 b_n x^{n-2}\right) = 0
\end{aligned}
\tag{2A}
$$

The next step is to make all powers of x be $n-2$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n-2} and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=0}^{\infty} 2C\, x^{n+4} a_n (n+4) &= \sum_{n=6}^{\infty} 2C a_{n-6} (n-2)\, x^{n-2} \\
\sum_{n=0}^{\infty} \left(-2C a_n x^{n+4}\right) &= \sum_{n=6}^{\infty} \left(-2C a_{n-6} x^{n-2}\right) \\
\sum_{n=0}^{\infty} 8 b_n x^n &= \sum_{n=2}^{\infty} 8 b_{n-2} x^{n-2}
\end{aligned}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n-2$.

$$
\begin{aligned}
&\left(\sum_{n=6}^{\infty} 2C a_{n-6} (n-2)\, x^{n-2}\right) + \sum_{n=6}^{\infty} \left(-2C a_{n-6} x^{n-2}\right) \\
&+ \left(\sum_{n=0}^{\infty} x^{n-2} b_n \left(n^2-5n+6\right)\right) + \left(\sum_{n=2}^{\infty} 8 b_{n-2} x^{n-2}\right) \\
&+ \sum_{n=0}^{\infty} \left(-x^{n-2} b_n (n-2)\right) + \sum_{n=0}^{\infty} \left(-8 b_n x^{n-2}\right) = 0
\end{aligned}
\tag{2B}
$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0 = 1$. For $n=1$, Eq (2B) gives

$$
-5b_1 = 0
$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$
-5b_1 = 0
$$

Solving the above for b_1 gives

$$b_1 = 0$$

For $n = 2$, Eq (2B) gives

$$8b_0 - 8b_2 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$8 - 8b_2 = 0$$

Solving the above for b_2 gives

$$b_2 = 1$$

For $n = 3$, Eq (2B) gives

$$8b_1 - 9b_3 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-9b_3 = 0$$

Solving the above for b_3 gives

$$b_3 = 0$$

For $n = 4$, Eq (2B) gives

$$8b_2 - 8b_4 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$8 - 8b_4 = 0$$

Solving the above for b_4 gives

$$b_4 = 1$$

For $n = 5$, Eq (2B) gives

$$-5b_5 + 8b_3 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-5b_5 = 0$$

Solving the above for b_5 gives

$$b_5 = 0$$

For $n = N$, where $N = 6$ which is the difference between the two roots, we are free to choose $b_6 = 0$. Hence for $n = 6$, Eq (2B) gives

$$6C + 8 = 0$$

Which is solved for C. Solving for C gives

$$C = -\frac{4}{3}$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = -\frac{4}{3}$ and all b_n, then the second solution becomes

$$y_2(x) = -\frac{4}{3}\left(x^4\left(1 - \frac{x^2}{2} + \frac{x^4}{10} - \frac{x^6}{90} + O(x^7)\right)\right) \ln(x) + \frac{1 + x^2 + x^4 + O(x^7)}{x^2}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^4\left(1 - \frac{x^2}{2} + \frac{x^4}{10} - \frac{x^6}{90} + O(x^7)\right) \\ &\quad + c_2\left(-\frac{4}{3}\left(x^4\left(1 - \frac{x^2}{2} + \frac{x^4}{10} - \frac{x^6}{90} + O(x^7)\right)\right) \ln(x) + \frac{1 + x^2 + x^4 + O(x^7)}{x^2}\right) \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= c_1 x^4\left(1 - \frac{x^2}{2} + \frac{x^4}{10} - \frac{x^6}{90} + O(x^7)\right) \\ &\quad + c_2\left(-\frac{4x^4\left(1 - \frac{x^2}{2} + \frac{x^4}{10} - \frac{x^6}{90} + O(x^7)\right) \ln(x)}{3} + \frac{1 + x^2 + x^4 + O(x^7)}{x^2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y &= c_1 x^4\left(1 - \frac{x^2}{2} + \frac{x^4}{10} - \frac{x^6}{90} + O(x^7)\right) \\ &\quad + c_2\left(-\frac{4x^4\left(1 - \frac{x^2}{2} + \frac{x^4}{10} - \frac{x^6}{90} + O(x^7)\right) \ln(x)}{3} + \frac{1 + x^2 + x^4 + O(x^7)}{x^2}\right) \end{aligned} \tag{1}$$

Verification of solutions

$$y = c_1 x^4 \left(1 - \frac{x^2}{2} + \frac{x^4}{10} - \frac{x^6}{90} + O(x^7)\right) + c_2 \left(-\frac{4x^4 \left(1 - \frac{x^2}{2} + \frac{x^4}{10} - \frac{x^6}{90} + O(x^7)\right) \ln(x)}{3} + \frac{1 + x^2 + x^4 + O(x^7)}{x^2}\right)$$

Verified OK.

15.21.1 Maple step by step solution

Let's solve

$y''x^2 - y'x + (8x^2 - 8) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{8(x^2-1)y}{x^2} + \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{y'}{x} + \frac{8(x^2-1)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -\frac{1}{x}, P_3(x) = \frac{8(x^2-1)}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\Big|_{x=0} = -1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\Big|_{x=0} = -8$

  ◦ $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $y''x^2 - y'x + (8x^2 - 8) y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k- > k - m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r}$

  - Convert $x^2 \cdot y''$ to series expansion

    $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(2+r)(-4+r)\, x^r + a_1(3+r)(-3+r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r+2)(k+r-4) + 8a_{k-2})\, x^{k+r}\right)$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(2+r)(-4+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-2, 4\}$

- Each term must be 0

  $a_1(3+r)(-3+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+2)(k+r-4) + 8a_{k-2} = 0$

- Shift index using $k- > k + 2$

  $a_{k+2}(k+4+r)(k-2+r) + 8a_k = 0$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{8a_k}{(k+4+r)(k-2+r)}$$

- Recursion relation for $r = -2$

$$a_{k+2} = -\frac{8a_k}{(k+2)(k-4)}$$

- Series not valid for $r = -2$, division by 0 in the recursion relation at $k = 4$

$$a_{k+2} = -\frac{8a_k}{(k+2)(k-4)}$$

- Recursion relation for $r = 4$

$$a_{k+2} = -\frac{8a_k}{(k+8)(k+2)}$$

- Solution for $r = 4$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+4}, a_{k+2} = -\frac{8a_k}{(k+8)(k+2)}, a_1 = 0\right]$$

Problem number: 22.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + x^2y' - \frac{3y}{4} = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + x^2y' - \frac{3y}{4} = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = 1$$
$$q(x) = -\frac{3}{4x^2}$$

Table 569: Table $p(x), q(x)$ singularites.

$p(x) = 1$	
singularity	type

$q(x) = -\frac{3}{4x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2 y'' + x^2 y' - \frac{3y}{4} = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x^2 + x^2 \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) - \frac{3\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right)}{4} = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\,(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-\frac{3 a_n x^{n+r}}{4}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r) = \sum_{n=1}^{\infty} a_{n-1} (n+r-1)\, x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\,(n+r-1)\right) + \left(\sum_{n=1}^{\infty} a_{n-1} (n+r-1)\, x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-\frac{3 a_n x^{n+r}}{4}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)\,(n+r-1) - \frac{3 a_n x^{n+r}}{4} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - \frac{3 a_0 x^r}{4} = 0$$

Or

$$\left(x^r r(-1+r) - \frac{3 x^r}{4}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\frac{(4r^2 - 4r - 3)\, x^r}{4} = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - r - \frac{3}{4} = 0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned} r_1 &= \frac{3}{2} \\ r_2 &= -\frac{1}{2} \end{aligned}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\frac{(4r^2 - 4r - 3)\, x^r}{4} = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 2$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x^{\frac{3}{2}} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{\sqrt{x}}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{3}{2}}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-\frac{1}{2}}\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + a_{n-1}(n+r-1) - \frac{3a_n}{4} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{4a_{n-1}(n+r-1)}{4n^2 + 8nr + 4r^2 - 4n - 4r - 3} \tag{4}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_n = -\frac{a_{n-1}(2n+1)}{2n\,(n+2)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{3}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{4r}{4r^2 + 4r - 3}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_1 = -\frac{1}{2}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4r}{4r^2+4r-3}$	$-\frac{1}{2}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{16r(1 + r)}{(4r^2 + 4r - 3)(4r^2 + 12r + 5)}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_2 = \frac{5}{32}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4r}{4r^2+4r-3}$	$-\frac{1}{2}$
a_2	$\frac{16r(1+r)}{(4r^2+4r-3)(4r^2+12r+5)}$	$\frac{5}{32}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{64r(1 + r)(2 + r)}{(4r^2 + 4r - 3)(4r^2 + 12r + 5)(4r^2 + 20r + 21)}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_3 = -\frac{7}{192}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4r}{4r^2+4r-3}$	$-\frac{1}{2}$
a_2	$\frac{16r(1+r)}{(4r^2+4r-3)(4r^2+12r+5)}$	$\frac{5}{32}$
a_3	$-\frac{64r(1+r)(2+r)}{(4r^2+4r-3)(4r^2+12r+5)(4r^2+20r+21)}$	$-\frac{7}{192}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{256r(1+r)(2+r)(3+r)}{(4r^2+4r-3)(4r^2+12r+5)(4r^2+20r+21)(4r^2+28r+45)}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_4 = \frac{7}{1024}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4r}{4r^2+4r-3}$	$-\frac{1}{2}$
a_2	$\frac{16r(1+r)}{(4r^2+4r-3)(4r^2+12r+5)}$	$\frac{5}{32}$
a_3	$-\frac{64r(1+r)(2+r)}{(4r^2+4r-3)(4r^2+12r+5)(4r^2+20r+21)}$	$-\frac{7}{192}$
a_4	$\frac{256r(1+r)(2+r)(3+r)}{(4r^2+4r-3)(4r^2+12r+5)(4r^2+20r+21)(4r^2+28r+45)}$	$\frac{7}{1024}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1024r(1+r)(2+r)(3+r)(4+r)}{(2r+9)(2r-1)(2r+11)(2r+3)^2(2r+1)(2r+7)^2(2r+5)^2}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_5 = -\frac{11}{10240}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4r}{4r^2+4r-3}$	$-\frac{1}{2}$
a_2	$\frac{16r(1+r)}{(4r^2+4r-3)(4r^2+12r+5)}$	$\frac{5}{32}$
a_3	$-\frac{64r(1+r)(2+r)}{(4r^2+4r-3)(4r^2+12r+5)(4r^2+20r+21)}$	$-\frac{7}{192}$
a_4	$\frac{256r(1+r)(2+r)(3+r)}{(4r^2+4r-3)(4r^2+12r+5)(4r^2+20r+21)(4r^2+28r+45)}$	$\frac{7}{1024}$
a_5	$-\frac{1024r(1+r)(2+r)(3+r)(4+r)}{(2r+9)(2r-1)(2r+11)(2r+3)^2(2r+1)(2r+7)^2(2r+5)^2}$	$-\frac{11}{10240}$

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= x^{\frac{3}{2}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\
&= x^{\frac{3}{2}}\left(1 - \frac{x}{2} + \frac{5x^2}{32} - \frac{7x^3}{192} + \frac{7x^4}{1024} - \frac{11x^5}{10240} + O(x^6)\right)
\end{aligned}
$$

Now the second solution $y_2(x)$ is found. Let

$$
r_1 - r_2 = N
$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 2$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_2(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$
\begin{aligned}
a_N &= a_2 \\
&= \frac{16r(1+r)}{(4r^2+4r-3)(4r^2+12r+5)}
\end{aligned}
$$

Therefore

$$
\begin{aligned}
\lim_{r\to r_2} \frac{16r(1+r)}{(4r^2+4r-3)(4r^2+12r+5)} &= \lim_{r\to -\frac{1}{2}} \frac{16r(1+r)}{(4r^2+4r-3)(4r^2+12r+5)} \\
&= \textit{undefined}
\end{aligned}
$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$
y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)
$$

Therefore

$$\frac{d}{dx}y_2(x) = Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right)$$
$$= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n(n+r_2)\right)$$
$$\frac{d^2}{dx^2}y_2(x) = Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)$$
$$= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n(n+r_2)(-1+n+r_2)\right)$$

Substituting these back into the given ode $x^2y'' + x^2y' - \frac{3y}{4} = 0$ gives

$$\left(Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x^2 + x^2\left(Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right)\right) - \frac{3Cy_1(x)\ln(x)}{4} - \frac{3\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)}{4} = 0$$

Which can be written as

$$\left(\left(y_1''(x)x^2 + x^2y_1'(x) - \frac{3y_1(x)}{4}\right)\ln(x) + \left(\frac{2y_1'(x)}{x} - \frac{y_1(x)}{x^2}\right)x^2 + y_1(x)x\right)C + \left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x^2 + x^2\left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) - \frac{3\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)}{4} = 0 \tag{7}$$

But since $y_1(x)$ is a solution to the ode, then

$$y_1''(x)\,x^2 + x^2 y_1'(x) - \frac{3y_1(x)}{4} = 0$$

Eq (7) simplifes to

$$\begin{aligned}&\left(\left(\frac{2y_1'(x)}{x} - \frac{y_1(x)}{x^2}\right)x^2 + y_1(x)\,x\right)C\\&+\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x^2\\&+x^2\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right) - \frac{3\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)}{4} = 0\end{aligned} \tag{8}$$

Substituting $y_1 = \sum_{n=0}^{\infty} a_n x^{n+r_1}$ into the above gives

$$\begin{aligned}&\left(2\left(\sum_{n=0}^{\infty} x^{-1+n+r_1} a_n (n+r_1)\right)x + (x-1)\left(\sum_{n=0}^{\infty} a_n x^{n+r_1}\right)\right)C\\&+\left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n (n+r_2)(-1+n+r_2)\right)x^2\\&+x^2\left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n (n+r_2)\right) - \frac{3\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)}{4} = 0\end{aligned} \tag{9}$$

Since $r_1 = \frac{3}{2}$ and $r_2 = -\frac{1}{2}$ then the above becomes

$$\begin{aligned}&\left(2\left(\sum_{n=0}^{\infty} x^{n+\frac{1}{2}} a_n \left(n+\frac{3}{2}\right)\right)x + (x-1)\left(\sum_{n=0}^{\infty} a_n x^{n+\frac{3}{2}}\right)\right)C\\&+\left(\sum_{n=0}^{\infty} x^{-\frac{5}{2}+n} b_n \left(n-\frac{1}{2}\right)\left(-\frac{3}{2}+n\right)\right)x^2\\&+x^2\left(\sum_{n=0}^{\infty} x^{-\frac{3}{2}+n} b_n \left(n-\frac{1}{2}\right)\right) - \frac{3\left(\sum_{n=0}^{\infty} b_n x^{n-\frac{1}{2}}\right)}{4} = 0\end{aligned} \tag{10}$$

Expanding $C\,x^{\frac{5}{2}}$ as Taylor series around $x = 0$ and keeping only the first 6 terms gives

$$
\begin{aligned}
C\,x^{\frac{5}{2}} &= C\,x^{\frac{5}{2}} + \dots \\
&= C\,x^{\frac{5}{2}}
\end{aligned}
$$

Expanding $-C\,x^{\frac{3}{2}}$ as Taylor series around $x = 0$ and keeping only the first 6 terms gives

$$
\begin{aligned}
-C\,x^{\frac{3}{2}} &= -C\,x^{\frac{3}{2}} + \dots \\
&= -C\,x^{\frac{3}{2}}
\end{aligned}
$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} C\,x^{n+\frac{3}{2}} a_n (2n+3)\right) + \left(\sum_{n=0}^{\infty} C\,x^{n+\frac{5}{2}} a_n\right) \\
&+ \sum_{n=0}^{\infty} \left(-C\,x^{n+\frac{3}{2}} a_n\right) + \left(\sum_{n=0}^{\infty} \frac{x^{n-\frac{1}{2}} b_n (4n^2 - 8n + 3)}{4}\right) \\
&+ \left(\sum_{n=0}^{\infty} \frac{x^{n+\frac{1}{2}} b_n (2n-1)}{2}\right) + \sum_{n=0}^{\infty} \left(-\frac{3 b_n x^{n-\frac{1}{2}}}{4}\right) = 0
\end{aligned} \tag{2A}
$$

The next step is to make all powers of x be $n - \frac{1}{2}$ in each summation term. Going over each summation term above with power of x in it which is not already $x^{n-\frac{1}{2}}$ and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=0}^{\infty} C\,x^{n+\frac{3}{2}} a_n (2n+3) &= \sum_{n=2}^{\infty} C a_{n-2} (2n-1)\, x^{n-\frac{1}{2}} \\
\sum_{n=0}^{\infty} C\,x^{n+\frac{5}{2}} a_n &= \sum_{n=3}^{\infty} C a_{n-3} x^{n-\frac{1}{2}} \\
\sum_{n=0}^{\infty} \left(-C\,x^{n+\frac{3}{2}} a_n\right) &= \sum_{n=2}^{\infty} \left(-C a_{n-2} x^{n-\frac{1}{2}}\right) \\
\sum_{n=0}^{\infty} \frac{x^{n+\frac{1}{2}} b_n (2n-1)}{2} &= \sum_{n=1}^{\infty} \frac{b_{n-1} (-3+2n)\, x^{n-\frac{1}{2}}}{2}
\end{aligned}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n-\frac{1}{2}$.

$$\begin{aligned}&\left(\sum_{n=2}^{\infty} C a_{n-2}(2n-1)\, x^{n-\frac{1}{2}}\right)+\left(\sum_{n=3}^{\infty} C a_{n-3} x^{n-\frac{1}{2}}\right)\\&+\sum_{n=2}^{\infty}\left(-C a_{n-2} x^{n-\frac{1}{2}}\right)+\left(\sum_{n=0}^{\infty} \frac{x^{n-\frac{1}{2}} b_n(4n^2-8n+3)}{4}\right)\\&+\left(\sum_{n=1}^{\infty} \frac{b_{n-1}(-3+2n)\, x^{n-\frac{1}{2}}}{2}\right)+\sum_{n=0}^{\infty}\left(-\frac{3 b_n x^{n-\frac{1}{2}}}{4}\right)=0\end{aligned} \tag{2B}$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0=1$. For $n=1$, Eq (2B) gives

$$-b_1-\frac{b_0}{2}=0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-b_1-\frac{1}{2}=0$$

Solving the above for b_1 gives

$$b_1=-\frac{1}{2}$$

For $n=N$, where $N=2$ which is the difference between the two roots, we are free to choose $b_2=0$. Hence for $n=2$, Eq (2B) gives

$$2C-\frac{1}{4}=0$$

Which is solved for C. Solving for C gives

$$C=\frac{1}{8}$$

For $n=3$, Eq (2B) gives

$$(a_0+4a_1)\, C+\frac{3b_2}{2}+3b_3=0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-\frac{1}{8}+3b_3=0$$

Solving the above for b_3 gives

$$b_3=\frac{1}{24}$$

For $n = 4$, Eq (2B) gives

$$(a_1 + 6a_2)\, C + \frac{5b_3}{2} + 8b_4 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$\frac{61}{384} + 8b_4 = 0$$

Solving the above for b_4 gives

$$b_4 = -\frac{61}{3072}$$

For $n = 5$, Eq (2B) gives

$$(a_2 + 8a_3)\, C + \frac{7b_4}{2} + 15b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-\frac{177}{2048} + 15b_5 = 0$$

Solving the above for b_5 gives

$$b_5 = \frac{59}{10240}$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = \frac{1}{8}$ and all b_n, then the second solution becomes

$$y_2(x) = \frac{1}{8}\left(x^{\frac{3}{2}}\left(1 - \frac{x}{2} + \frac{5x^2}{32} - \frac{7x^3}{192} + \frac{7x^4}{1024} - \frac{11x^5}{10240} + O\left(x^6\right)\right)\right)\ln(x) + \frac{1 - \frac{x}{2} + \frac{x^3}{24} - \frac{61x^4}{3072} + \frac{59x^5}{10240} + O(x^6)}{\sqrt{x}}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^{\frac{3}{2}}\left(1 - \frac{x}{2} + \frac{5x^2}{32} - \frac{7x^3}{192} + \frac{7x^4}{1024} - \frac{11x^5}{10240} + O\left(x^6\right)\right) \\ &\quad + c_2\left(\frac{1}{8}\left(x^{\frac{3}{2}}\left(1 - \frac{x}{2} + \frac{5x^2}{32} - \frac{7x^3}{192} + \frac{7x^4}{1024} - \frac{11x^5}{10240} + O\left(x^6\right)\right)\right)\ln(x) \right. \\ &\quad \left. + \frac{1 - \frac{x}{2} + \frac{x^3}{24} - \frac{61x^4}{3072} + \frac{59x^5}{10240} + O(x^6)}{\sqrt{x}}\right) \end{aligned}$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{\frac{3}{2}} \left(1-\frac{x}{2}+\frac{5 x^2}{32}-\frac{7 x^3}{192}+\frac{7 x^4}{1024}-\frac{11 x^5}{10240}+O\left(x^6\right)\right) \\
&\quad + c_2 \left(\frac{x^{\frac{3}{2}} \left(1-\frac{x}{2}+\frac{5 x^2}{32}-\frac{7 x^3}{192}+\frac{7 x^4}{1024}-\frac{11 x^5}{10240}+O(x^6)\right) \ln \left(x\right)}{8} \right. \\
&\quad \left. + \frac{1-\frac{x}{2}+\frac{x^3}{24}-\frac{61 x^4}{3072}+\frac{59 x^5}{10240}+O(x^6)}{\sqrt{x}}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x^{\frac{3}{2}} \left(1-\frac{x}{2}+\frac{5 x^2}{32}-\frac{7 x^3}{192}+\frac{7 x^4}{1024}-\frac{11 x^5}{10240}+O\left(x^6\right)\right) \\
&\quad + c_2 \left(\frac{x^{\frac{3}{2}} \left(1-\frac{x}{2}+\frac{5 x^2}{32}-\frac{7 x^3}{192}+\frac{7 x^4}{1024}-\frac{11 x^5}{10240}+O(x^6)\right) \ln \left(x\right)}{8} \right. \\
&\quad \left. + \frac{1-\frac{x}{2}+\frac{x^3}{24}-\frac{61 x^4}{3072}+\frac{59 x^5}{10240}+O(x^6)}{\sqrt{x}}\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 x^{\frac{3}{2}} \left(1-\frac{x}{2}+\frac{5 x^2}{32}-\frac{7 x^3}{192}+\frac{7 x^4}{1024}-\frac{11 x^5}{10240}+O\left(x^6\right)\right) \\
&\quad + c_2 \left(\frac{x^{\frac{3}{2}} \left(1-\frac{x}{2}+\frac{5 x^2}{32}-\frac{7 x^3}{192}+\frac{7 x^4}{1024}-\frac{11 x^5}{10240}+O(x^6)\right) \ln \left(x\right)}{8} \right. \\
&\quad \left. + \frac{1-\frac{x}{2}+\frac{x^3}{24}-\frac{61 x^4}{3072}+\frac{59 x^5}{10240}+O(x^6)}{\sqrt{x}}\right)
\end{aligned}
$$

Verified OK.

15.22.1 Maple step by step solution

Let's solve

$y''x^2 + x^2y' - \frac{3y}{4} = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -y' + \frac{3y}{4x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + y' - \frac{3y}{4x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = 1, P_3(x) = -\frac{3}{4x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\bigg|_{x=0} = 0$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\bigg|_{x=0} = -\frac{3}{4}$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4x^2y' + 4y''x^2 - 3y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^2 \cdot y'$ to series expansion

    $x^2 \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r+1}$

  ◦ Shift index using $k- >k-1$

$$x^2 \cdot y' = \sum_{k=1}^{\infty} a_{k-1}(k-1+r)\, x^{k+r}$$

- Convert $x^2 \cdot y''$ to series expansion

  $$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k-1+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(1+2r)\,(-3+2r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(2k+2r+1)\,(2k+2r-3)+4a_{k-1}(k-1+r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$(1+2r)\,(-3+2r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{-\frac{1}{2}, \frac{3}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

  $$4\left(k+r-\frac{3}{2}\right)\left(k+r+\frac{1}{2}\right) a_k + 4a_{k-1}(k-1+r) = 0$$

- Shift index using $k- >k+1$

  $$4\left(k-\frac{1}{2}+r\right)\left(k+\frac{3}{2}+r\right) a_{k+1} + 4a_k(k+r) = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+1} = -\frac{4a_k(k+r)}{(2k-1+2r)(2k+3+2r)}$$

- Recursion relation for $r = -\frac{1}{2}$

  $$a_{k+1} = -\frac{4a_k\left(k-\frac{1}{2}\right)}{(2k-2)(2k+2)}$$

- Series not valid for $r = -\frac{1}{2}$, division by 0 in the recursion relation at $k = 1$

  $$a_{k+1} = -\frac{4a_k\left(k-\frac{1}{2}\right)}{(2k-2)(2k+2)}$$

- Recursion relation for $r = \frac{3}{2}$

  $$a_{k+1} = -\frac{4a_k\left(k+\frac{3}{2}\right)}{(2k+2)(2k+6)}$$

- Solution for $r = \frac{3}{2}$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{3}{2}}, a_{k+1} = -\frac{4a_k\left(k+\frac{3}{2}\right)}{(2k+2)(2k+6)}\right]$$

Problem number: 23.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{xy'' + y' + 2y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$xy'' + y' + 2y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{2}{x}$$

Table 571: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{2}{x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$xy'' + y' + 2y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2a_n x^{n+r} = \sum_{n=1}^{\infty} 2a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} 2a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r-1} a_n (n+r)(n+r-1) + (n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$x^{-1+r} a_0 r(-1+r) + r a_0 x^{-1+r} = 0$$

Or

$$\left(x^{-1+r} r(-1+r) + r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$x^{-1+r} r^2 = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$x^{-1+r} r^2 = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + a_n(n+r) + 2a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{2a_{n-1}}{n^2 + 2nr + r^2} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = -\frac{2a_{n-1}}{n^2} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{2}{(r+1)^2}$$

Which for the root $r = 0$ becomes

$$a_1 = -2$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2}{(r+1)^2}$	-2

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{4}{(r+1)^2 (r+2)^2}$$

Which for the root $r = 0$ becomes

$$a_2 = 1$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2}{(r+1)^2}$	-2
a_2	$\frac{4}{(r+1)^2(r+2)^2}$	1

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{8}{(r+1)^2 (r+2)^2 (r+3)^2}$$

Which for the root $r = 0$ becomes

$$a_3 = -\frac{2}{9}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2}{(r+1)^2}$	-2
a_2	$\frac{4}{(r+1)^2(r+2)^2}$	1
a_3	$-\frac{8}{(r+1)^2(r+2)^2(r+3)^2}$	$-\frac{2}{9}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{16}{(r+1)^2 (r+2)^2 (r+3)^2 (r+4)^2}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{36}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2}{(r+1)^2}$	-2
a_2	$\frac{4}{(r+1)^2(r+2)^2}$	1
a_3	$-\frac{8}{(r+1)^2(r+2)^2(r+3)^2}$	$-\frac{2}{9}$
a_4	$\frac{16}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2}$	$\frac{1}{36}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{32}{(r+1)^2 (r+2)^2 (r+3)^2 (r+4)^2 (r+5)^2}$$

Which for the root $r = 0$ becomes

$$a_5 = -\frac{1}{450}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2}{(r+1)^2}$	-2
a_2	$\frac{4}{(r+1)^2(r+2)^2}$	1
a_3	$-\frac{8}{(r+1)^2(r+2)^2(r+3)^2}$	$-\frac{2}{9}$
a_4	$\frac{16}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2}$	$\frac{1}{36}$
a_5	$-\frac{32}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2(r+5)^2}$	$-\frac{1}{450}$

Using the above table, then the first solution $y_1(x)$ becomes

$$y_1(x) = a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots$$
$$= x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O(x^6)$$

Now the second solution is found. The second solution is given by

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)$$

Where b_n is found using

$$b_n = \frac{d}{dr} a_{n,r}$$

And the above is then evaluated at $r = 0$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr}a_{n,r}$	$b_n(r=0)$
b_0	1	1	N/A since b_n starts from 1	N/A
b_1	$-\frac{2}{(r+1)^2}$	-2	$\frac{4}{(r+1)^3}$	4
b_2	$\frac{4}{(r+1)^2(r+2)^2}$	1	$\frac{-16r-24}{(r+1)^3(r+2)^3}$	-3
b_3	$-\frac{8}{(r+1)^2(r+2)^2(r+3)^2}$	$-\frac{2}{9}$	$\frac{48r^2+192r+176}{(r+1)^3(r+2)^3(r+3)^3}$	$\frac{22}{27}$
b_4	$\frac{16}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2}$	$\frac{1}{36}$	$-\frac{64(2r^3+15r^2+35r+25)}{(r+1)^3(r+2)^3(r+3)^3(r+4)^3}$	$-\frac{25}{216}$
b_5	$-\frac{32}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2(r+5)^2}$	$-\frac{1}{450}$	$\frac{320r^4+3840r^3+16320r^2+28800r+17536}{(r+1)^3(r+2)^3(r+3)^3(r+4)^3(r+5)^3}$	$\frac{137}{13500}$

The above table gives all values of b_n needed. Hence the second solution is

$$y_2(x) = y_1(x) \ln(x) + b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 \dots$$
$$= \left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O(x^6)\right) \ln(x) - 3x^2 + 4x + \frac{22x^3}{27} - \frac{25x^4}{216} + \frac{137x^5}{13500}$$
$$+ O(x^6)$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 \left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O\left(x^6\right)\right) \\
&\quad + c_2 \left(\left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O\left(x^6\right)\right) \ln\left(x\right) - 3x^2 + 4x + \frac{22x^3}{27} \right. \\
&\quad \left. - \frac{25x^4}{216} + \frac{137x^5}{13500} + O\left(x^6\right)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 \left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O\left(x^6\right)\right) \\
&\quad + c_2 \left(\left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O\left(x^6\right)\right) \ln\left(x\right) - 3x^2 + 4x + \frac{22x^3}{27} - \frac{25x^4}{216} \right. \\
&\quad \left. + \frac{137x^5}{13500} + O\left(x^6\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 \left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O\left(x^6\right)\right) \\
&\quad + c_2 \left(\left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O\left(x^6\right)\right) \ln\left(x\right) - 3x^2 + 4x + \frac{22x^3}{27} \right. \\
&\quad \left. - \frac{25x^4}{216} + \frac{137x^5}{13500} + O\left(x^6\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 \left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O\left(x^6\right)\right) \\
&\quad + c_2 \left(\left(x^2 - 2x + 1 - \frac{2x^3}{9} + \frac{x^4}{36} - \frac{x^5}{450} + O\left(x^6\right)\right) \ln\left(x\right) - 3x^2 + 4x + \frac{22x^3}{27} - \frac{25x^4}{216} \right. \\
&\quad \left. + \frac{137x^5}{13500} + O\left(x^6\right)\right)
\end{aligned}
$$

Verified OK.

15.23.1 Maple step by step solution

Let's solve

$y''x + y' + 2y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{2y}{x} - \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + \frac{2y}{x} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{1}{x}, P_3(x) = \frac{2}{x}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\Big|_{x=0} = 1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\Big|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $y''x + y' + 2y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert y' to series expansion

    $y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1}$

  ◦ Shift index using $k- > k+1$

$$y' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, x^{k+r}$$

- Convert $x \cdot y''$ to series expansion

  $$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$$

- Shift index using $k->k+1$

  $$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0 r^2 x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)^2 + 2a_k\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$r^2 = 0$$

- Values of r that satisfy the indicial equation

  $$r = 0$$

- Each term in the series must be 0, giving the recursion relation

  $$a_{k+1}(k+1)^2 + 2a_k = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+1} = -\frac{2a_k}{(k+1)^2}$$

- Recursion relation for $r = 0$

  $$a_{k+1} = -\frac{2a_k}{(k+1)^2}$$

- Solution for $r = 0$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = -\frac{2a_k}{(k+1)^2}\right]$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.2 (Frobenius). Exercises page 251
Problem number: 24.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{2xy'' + 6y' + y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2xy'' + 6y' + y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{3}{x}$$
$$q(x) = \frac{1}{2x}$$

Table 573: Table $p(x), q(x)$ singularites.

$p(x) = \frac{3}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{1}{2x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2xy'' + 6y' + y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x + 6\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)\,(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 6(n+r)\, a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} a_n x^{n+r} = \sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 6(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r-1} a_n (n+r)(n+r-1) + 6(n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$2x^{-1+r} a_0 r(-1+r) + 6r a_0 x^{-1+r} = 0$$

Or

$$\left(2x^{-1+r} r(-1+r) + 6r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$2r\, x^{-1+r}(2+r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r(2+r) = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = -2$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$2r\, x^{-1+r}(2+r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 2$ is an integer, then we can construct two linearly independent solutions

$$
\begin{aligned}
y_1(x) &= x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right) \\
y_2(x) &= C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^n \\
y_2(x) &= C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x^2}
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^n \\
y_2(x) &= C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-2}\right)
\end{aligned}
$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$
2a_n(n+r)(n+r-1) + 6a_n(n+r) + a_{n-1} = 0 \tag{3}
$$

Solving for a_n from recursive equation (4) gives

$$
a_n = -\frac{a_{n-1}}{2(n^2 + 2nr + r^2 + 2n + 2r)} \tag{4}
$$

Which for the root $r = 0$ becomes

$$
a_n = -\frac{a_{n-1}}{2n(n+2)} \tag{5}
$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{1}{2r^2 + 8r + 6}$$

Which for the root $r = 0$ becomes

$$a_1 = -\frac{1}{6}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+8r+6}$	$-\frac{1}{6}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{4r^4 + 40r^3 + 140r^2 + 200r + 96}$$

Which for the root $r = 0$ becomes

$$a_2 = \frac{1}{96}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+8r+6}$	$-\frac{1}{6}$
a_2	$\frac{1}{4r^4+40r^3+140r^2+200r+96}$	$\frac{1}{96}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{1}{8\left(r+3\right)^2 \left(r+1\right) \left(r+4\right) \left(2+r\right) \left(r+5\right)}$$

Which for the root $r = 0$ becomes

$$a_3 = -\frac{1}{2880}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+8r+6}$	$-\frac{1}{6}$
a_2	$\frac{1}{4r^4+40r^3+140r^2+200r+96}$	$\frac{1}{96}$
a_3	$-\frac{1}{8(r+3)^2(r+1)(r+4)(2+r)(r+5)}$	$-\frac{1}{2880}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{16\left(r+3\right)^2\left(r+1\right)\left(r+4\right)^2\left(2+r\right)\left(r+5\right)\left(r+6\right)}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{138240}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+8r+6}$	$-\frac{1}{6}$
a_2	$\frac{1}{4r^4+40r^3+140r^2+200r+96}$	$\frac{1}{96}$
a_3	$-\frac{1}{8(r+3)^2(r+1)(r+4)(2+r)(r+5)}$	$-\frac{1}{2880}$
a_4	$\frac{1}{16(r+3)^2(r+1)(r+4)^2(2+r)(r+5)(r+6)}$	$\frac{1}{138240}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1}{32\left(r+3\right)^2\left(r+1\right)\left(r+4\right)^2\left(2+r\right)\left(r+5\right)^2\left(r+6\right)\left(r+7\right)}$$

Which for the root $r = 0$ becomes

$$a_5 = -\frac{1}{9676800}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{2r^2+8r+6}$	$-\frac{1}{6}$
a_2	$\frac{1}{4r^4+40r^3+140r^2+200r+96}$	$\frac{1}{96}$
a_3	$-\frac{1}{8(r+3)^2(r+1)(r+4)(2+r)(r+5)}$	$-\frac{1}{2880}$
a_4	$\frac{1}{16(r+3)^2(r+1)(r+4)^2(2+r)(r+5)(r+6)}$	$\frac{1}{138240}$
a_5	$-\frac{1}{32(r+3)^2(r+1)(r+4)^2(2+r)(r+5)^2(r+6)(r+7)}$	$-\frac{1}{9676800}$

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \ldots \\
&= 1 - \frac{x}{6} + \frac{x^2}{96} - \frac{x^3}{2880} + \frac{x^4}{138240} - \frac{x^5}{9676800} + O(x^6)
\end{aligned}
$$

Now the second solution $y_2(x)$ is found. Let

$$
r_1 - r_2 = N
$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 2$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \to r_2} a_2(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$
\begin{aligned}
a_N &= a_2 \\
&= \frac{1}{4r^4 + 40r^3 + 140r^2 + 200r + 96}
\end{aligned}
$$

Therefore

$$
\begin{aligned}
\lim_{r \to r_2} \frac{1}{4r^4 + 40r^3 + 140r^2 + 200r + 96} &= \lim_{r \to -2} \frac{1}{4r^4 + 40r^3 + 140r^2 + 200r + 96} \\
&= \textit{undefined}
\end{aligned}
$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$
y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2} \right)
$$

Therefore

$$\frac{d}{dx}y_2(x) = Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right)$$
$$= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n(n+r_2)\right)$$

$$\frac{d^2}{dx^2}y_2(x) = Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)$$
$$= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n(n+r_2)(-1+n+r_2)\right)$$

Substituting these back into the given ode $2xy'' + 6y' + y = 0$ gives

$$2\left(Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x + 6Cy_1'(x)\ln(x) + \frac{6Cy_1(x)}{x} + 6\left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) + Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0$$

Which can be written as

$$\left((2y_1''(x)\,x + y_1(x) + 6y_1'(x))\ln(x) + 2\left(\frac{2y_1'(x)}{x} - \frac{y_1(x)}{x^2}\right)x + \frac{6y_1(x)}{x}\right)C + 2\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x + 6\left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0 \tag{7}$$

But since $y_1(x)$ is a solution to the ode, then

$$2y_1''(x)\,x + y_1(x) + 6y_1'(x) = 0$$

Eq (7) simplifes to

$$\left(2\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)x+\frac{6y_1(x)}{x}\right)C \\ +2\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x \\ +6\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)+\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0 \tag{8}$$

Substituting $y_1=\sum_{n=0}^{\infty}a_n x^{n+r_1}$ into the above gives

$$\frac{\left(4\left(\sum_{n=0}^{\infty}x^{-1+n+r_1}a_n(n+r_1)\right)x+4\left(\sum_{n=0}^{\infty}a_n x^{n+r_1}\right)\right)C}{x} \\ +\frac{2\left(\sum_{n=0}^{\infty}x^{-2+n+r_2}b_n(n+r_2)(-1+n+r_2)\right)x^2+\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)x+6\left(\sum_{n=0}^{\infty}x^{-1+n+r_2}b_n(n+r_2)\right)x}{x} \\ =0 \tag{9}$$

Since $r_1=0$ and $r_2=-2$ then the above becomes

$$\frac{\left(4\left(\sum_{n=0}^{\infty}x^{n-1}a_n n\right)x+4\left(\sum_{n=0}^{\infty}a_n x^{n}\right)\right)C}{x} \\ +\frac{2\left(\sum_{n=0}^{\infty}x^{-4+n}b_n(n-2)(-3+n)\right)x^2+\left(\sum_{n=0}^{\infty}b_n x^{n-2}\right)x+6\left(\sum_{n=0}^{\infty}x^{-3+n}b_n(n-2)\right)x}{x} \\ =0 \tag{10}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty}4C\,x^{n-1}a_n n\right)+\left(\sum_{n=0}^{\infty}4C\,x^{n-1}a_n\right)+\left(\sum_{n=0}^{\infty}2x^{-3+n}b_n(n-2)(-3+n)\right) \\ +\left(\sum_{n=0}^{\infty}b_n x^{n-2}\right)+\left(\sum_{n=0}^{\infty}6x^{-3+n}b_n(n-2)\right)=0 \tag{2A}$$

The next step is to make all powers of x be $-3+n$ in each summation term. Going over each summation term above with power of x in it which is not already x^{-3+n} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 4C\, x^{n-1} a_n n = \sum_{n=2}^{\infty} 4C(n-2)\, a_{n-2} x^{-3+n}$$

$$\sum_{n=0}^{\infty} 4C\, x^{n-1} a_n = \sum_{n=2}^{\infty} 4C a_{n-2} x^{-3+n}$$

$$\sum_{n=0}^{\infty} b_n x^{n-2} = \sum_{n=1}^{\infty} b_{n-1} x^{-3+n}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $-3+n$.

$$\begin{aligned} &\left(\sum_{n=2}^{\infty} 4C(n-2)\, a_{n-2} x^{-3+n}\right) + \left(\sum_{n=2}^{\infty} 4C a_{n-2} x^{-3+n}\right) \\ &+ \left(\sum_{n=0}^{\infty} 2x^{-3+n} b_n (n-2)\,(-3+n)\right) \\ &+ \left(\sum_{n=1}^{\infty} b_{n-1} x^{-3+n}\right) + \left(\sum_{n=0}^{\infty} 6x^{-3+n} b_n (n-2)\right) = 0 \end{aligned} \tag{2B}$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0 = 1$. For $n=1$, Eq (2B) gives

$$-2b_1 + b_0 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-2b_1 + 1 = 0$$

Solving the above for b_1 gives

$$b_1 = \frac{1}{2}$$

For $n=N$, where $N=2$ which is the difference between the two roots, we are free to choose $b_2 = 0$. Hence for $n=2$, Eq (2B) gives

$$4C + \frac{1}{2} = 0$$

Which is solved for C. Solving for C gives

$$C = -\frac{1}{8}$$

For $n = 3$, Eq (2B) gives

$$8Ca_1 + b_2 + 6b_3 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$6b_3 + \frac{1}{6} = 0$$

Solving the above for b_3 gives

$$b_3 = -\frac{1}{36}$$

For $n = 4$, Eq (2B) gives

$$12Ca_2 + b_3 + 16b_4 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$16b_4 - \frac{25}{576} = 0$$

Solving the above for b_4 gives

$$b_4 = \frac{25}{9216}$$

For $n = 5$, Eq (2B) gives

$$16Ca_3 + b_4 + 30b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$30b_5 + \frac{157}{46080} = 0$$

Solving the above for b_5 gives

$$b_5 = -\frac{157}{1382400}$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = -\frac{1}{8}$ and all b_n, then the second solution becomes

$$y_2(x) = -\frac{1}{8}\left(1 - \frac{x}{6} + \frac{x^2}{96} - \frac{x^3}{2880} + \frac{x^4}{138240} - \frac{x^5}{9676800} + O(x^6)\right)\ln(x) + \frac{1 + \frac{x}{2} - \frac{x^3}{36} + \frac{25x^4}{9216} - \frac{157x^5}{1382400} + O(x^6)}{x^2}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 \left(1-\frac{x}{6}+\frac{x^2}{96}-\frac{x^3}{2880}+\frac{x^4}{138240}-\frac{x^5}{9676800}+O\left(x^6\right)\right) \\
&\quad + c_2 \left(-\frac{1}{8}\left(1-\frac{x}{6}+\frac{x^2}{96}-\frac{x^3}{2880}+\frac{x^4}{138240}-\frac{x^5}{9676800}+O\left(x^6\right)\right)\ln\left(x\right) \right. \\
&\quad \left. + \frac{1+\frac{x}{2}-\frac{x^3}{36}+\frac{25x^4}{9216}-\frac{157x^5}{1382400}+O(x^6)}{x^2}\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 \left(1-\frac{x}{6}+\frac{x^2}{96}-\frac{x^3}{2880}+\frac{x^4}{138240}-\frac{x^5}{9676800}+O\left(x^6\right)\right) \\
&\quad + c_2 \left(\left(-\frac{1}{8}+\frac{x}{48}-\frac{x^2}{768}+\frac{x^3}{23040}-\frac{x^4}{1105920}+\frac{x^5}{77414400}-\frac{O(x^6)}{8}\right)\ln\left(x\right) \right. \\
&\quad \left. + \frac{1+\frac{x}{2}-\frac{x^3}{36}+\frac{25x^4}{9216}-\frac{157x^5}{1382400}+O(x^6)}{x^2}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 \left(1-\frac{x}{6}+\frac{x^2}{96}-\frac{x^3}{2880}+\frac{x^4}{138240}-\frac{x^5}{9676800}+O\left(x^6\right)\right) \\
&\quad + c_2 \left(\left(-\frac{1}{8}+\frac{x}{48}-\frac{x^2}{768}+\frac{x^3}{23040}-\frac{x^4}{1105920}+\frac{x^5}{77414400}-\frac{O(x^6)}{8}\right)\ln\left(x\right) \right. \\
&\quad \left. + \frac{1+\frac{x}{2}-\frac{x^3}{36}+\frac{25x^4}{9216}-\frac{157x^5}{1382400}+O(x^6)}{x^2}\right) \qquad (1)
\end{aligned}
$$

Verification of solutions

$$y = c_1\left(1-\frac{x}{6}+\frac{x^2}{96}-\frac{x^3}{2880}+\frac{x^4}{138240}-\frac{x^5}{9676800}+O(x^6)\right) + c_2\left(\left(-\frac{1}{8}+\frac{x}{48}-\frac{x^2}{768}+\frac{x^3}{23040}-\frac{x^4}{1105920}+\frac{x^5}{77414400}-\frac{O(x^6)}{8}\right)\ln(x) + \frac{1+\frac{x}{2}-\frac{x^3}{36}+\frac{25x^4}{9216}-\frac{157x^5}{1382400}+O(x^6)}{x^2}\right)$$

Verified OK.

15.24.1 Maple step by step solution

Let's solve

$2y''x+6y'+y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{3y'}{x}-\frac{y}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{3y'}{x}+\frac{y}{2x}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{3}{x}, P_3(x)=\frac{1}{2x}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left(x\cdot P_2(x)\right)\Big|_{x=0}=3$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2\cdot P_3(x)\right)\Big|_{x=0}=0$

  ◦ $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

$2y''x+6y'+y=0$

- Assume series solution for y

$y=\sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert y' to series expansion

  $y'=\sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1}$

  - Shift index using $k->k+1$

  $y'=\sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, x^{k+r}$

  - Convert $x\cdot y''$ to series expansion

  $x\cdot y''=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$

  - Shift index using $k->k+1$

  $x\cdot y''=\sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$

  Rewrite ODE with series expansions

$2a_0r(2+r)\, x^{-1+r}+\left(\sum_{k=0}^{\infty} (2a_{k+1}(k+1+r)\,(k+3+r)+a_k)\, x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$2r(2+r)=0$

- Values of r that satisfy the indicial equation

$r\in\{-2,0\}$

- Each term in the series must be 0, giving the recursion relation

$2a_{k+1}(k+1+r)\,(k+3+r)+a_k=0$

- Recursion relation that defines series solution to ODE

$a_{k+1}=-\frac{a_k}{2(k+1+r)(k+3+r)}$

- Recursion relation for $r=-2$

$a_{k+1}=-\frac{a_k}{2(k-1)(k+1)}$

- Series not valid for $r=-2$, division by 0 in the recursion relation at $k=1$

$$a_{k+1} = -\frac{a_k}{2(k-1)(k+1)}$$

- Recursion relation for $r = 0$

$$a_{k+1} = -\frac{a_k}{2(k+1)(k+3)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = -\frac{a_k}{2(k+1)(k+3)}\right]$$

Section: Chapter 6, Series solutions of linear differential equations. Section 6.2 (Frobenius). Exercises page 251
Problem number: 25.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - y'x + (x^2+1)\,y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' - y'x + (x^2+1)\,y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{1}{x}$$
$$q(x) = \frac{x^2+1}{x^2}$$

Table 575: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{x^2+1}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2 y'' - y' x + (x^2 + 1) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}\right) x^2 - \left(\sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}\right) x + (x^2 + 1) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r+2} a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - x^{n+r} a_n (n+r) + a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - x^r a_0 r + a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - x^r r + x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$(-1+r)^2 x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$(-1+r)^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = 1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$(-1+r)^2 x^r = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. Using the value of the indicial root found earlier, $r = 1$, Eqs (1A,1B) become

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+1}$$
$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+1}\right)$$

We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - a_n(n+r) + a_{n-2} + a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-2}}{n^2 + 2nr + r^2 - 2n - 2r + 1} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = -\frac{a_{n-2}}{n^2} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{1}{(1+r)^2}$$

Which for the root $r = 1$ becomes

$$a_2 = -\frac{1}{4}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{(1+r)^2}$	$-\frac{1}{4}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{(1+r)^2}$	$-\frac{1}{4}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{(1+r)^2 (r+3)^2}$$

Which for the root $r = 1$ becomes

$$a_4 = \frac{1}{64}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{(1+r)^2}$	$-\frac{1}{4}$
a_3	0	0
a_4	$\frac{1}{(1+r)^2(r+3)^2}$	$\frac{1}{64}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{(1+r)^2}$	$-\frac{1}{4}$
a_3	0	0
a_4	$\frac{1}{(1+r)^2(r+3)^2}$	$\frac{1}{64}$
a_5	0	0

Using the above table, then the first solution $y_1(x)$ is

$$y_1(x) = x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right)$$
$$= x\left(1 - \frac{x^2}{4} + \frac{x^4}{64} + O(x^6)\right)$$

Now the second solution is found. The second solution is given by

$$y_2(x) = y_1(x)\ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)$$

Where b_n is found using

$$b_n = \frac{d}{dr} a_{n,r}$$

And the above is then evaluated at $r = 1$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr} a_{n,r}$	$b_n(r=1)$
b_0	1	1	N/A since b_n starts from 1	N/A
b_1	0	0	0	0
b_2	$-\frac{1}{(1+r)^2}$	$-\frac{1}{4}$	$\frac{2}{(1+r)^3}$	$\frac{1}{4}$
b_3	0	0	0	0
b_4	$\frac{1}{(1+r)^2(r+3)^2}$	$\frac{1}{64}$	$\frac{-4r-8}{(1+r)^3(r+3)^3}$	$-\frac{3}{128}$
b_5	0	0	0	0

The above table gives all values of b_n needed. Hence the second solution is

$$\begin{aligned}
y_2(x) &= y_1(x)\ln(x) + b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots \\
&= x\left(1 - \frac{x^2}{4} + \frac{x^4}{64} + O(x^6)\right)\ln(x) + x\left(\frac{x^2}{4} - \frac{3x^4}{128} + O(x^6)\right)
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x\left(1 - \frac{x^2}{4} + \frac{x^4}{64} + O(x^6)\right) \\
&\quad + c_2\left(x\left(1 - \frac{x^2}{4} + \frac{x^4}{64} + O(x^6)\right)\ln(x) + x\left(\frac{x^2}{4} - \frac{3x^4}{128} + O(x^6)\right)\right)
\end{aligned}$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x \left(1-\frac{x^2}{4}+\frac{x^4}{64}+O(x^6)\right) \\
&\quad + c_2 \left(x \left(1-\frac{x^2}{4}+\frac{x^4}{64}+O(x^6)\right) \ln(x) + x \left(\frac{x^2}{4}-\frac{3x^4}{128}+O(x^6)\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x \left(1-\frac{x^2}{4}+\frac{x^4}{64}+O(x^6)\right) \\
&\quad + c_2 \left(x \left(1-\frac{x^2}{4}+\frac{x^4}{64}+O(x^6)\right) \ln(x) + x \left(\frac{x^2}{4}-\frac{3x^4}{128}+O(x^6)\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 x \left(1-\frac{x^2}{4}+\frac{x^4}{64}+O(x^6)\right) \\
&\quad + c_2 \left(x \left(1-\frac{x^2}{4}+\frac{x^4}{64}+O(x^6)\right) \ln(x) + x \left(\frac{x^2}{4}-\frac{3x^4}{128}+O(x^6)\right)\right)
\end{aligned}
$$

Verified OK.

15.25.1 Maple step by step solution

Let's solve

$y''x^2 - y'x + (x^2+1) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(x^2+1)y}{x^2} + \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{y'}{x} + \frac{(x^2+1)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ○ Define functions

$\left[P_2(x) = -\frac{1}{x}, P_3(x) = \frac{x^2+1}{x^2}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $$\left(x \cdot P_2(x)\right)\bigg|_{x=0} = -1$$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 1$$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $$y''x^2 - y'x + (x^2+1)\, y = 0$$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k-m$

  $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x \cdot y'$ to series expansion

  $$x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$$

- Convert $x^2 \cdot y''$ to series expansion

  $$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(-1+r)^2\, x^r + a_1 r^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k (k+r-1)^2 + a_{k-2}\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(-1+r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = 1$

- Each term must be 0

  $a_1 r^2 = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r-1)^2 + a_{k-2} = 0$

- Shift index using $k- >k+2$

  $a_{k+2}(k+1+r)^2 + a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k}{(k+1+r)^2}$

- Recursion relation for $r = 1$

  $a_{k+2} = -\frac{a_k}{(k+2)^2}$

- Solution for $r = 1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k}{(k+2)^2}, a_1 = 0\right]$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 6, Series solutions of linear differential equations. Section 6.2 (Frobenius). Exercises page 251
Problem number: 26.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - y'x + (x^2 - 3)\, y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' - y'x + (x^2 - 3)\, y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= \frac{x^2 - 3}{x^2} \end{aligned}$$

Table 577: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{x^2-3}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' - y'x + (x^2 - 3)\, y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x^2 - \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) x + (x^2 - 3) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r+2} a_n\right) + \sum_{n=0}^{\infty} \left(-3 a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-3 a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - x^{n+r} a_n (n+r) - 3 a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - x^r a_0 r - 3 a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - x^r r - 3x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2 - 2r - 3\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - 2r - 3 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 3$$
$$r_2 = -1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2 - 2r - 3\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 4$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x^3 \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+3}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-1}\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - a_n(n+r) + a_{n-2} - 3a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-2}}{n^2 + 2nr + r^2 - 2n - 2r - 3} \tag{4}$$

Which for the root $r = 3$ becomes

$$a_n = -\frac{a_{n-2}}{n(n+4)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 3$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{1}{r^2 + 2r - 3}$$

Which for the root $r = 3$ becomes

$$a_2 = -\frac{1}{12}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+2r-3}$	$-\frac{1}{12}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+2r-3}$	$-\frac{1}{12}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{r^4 + 8r^3 + 14r^2 - 8r - 15}$$

Which for the root $r = 3$ becomes

$$a_4 = \frac{1}{384}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+2r-3}$	$-\frac{1}{12}$
a_3	0	0
a_4	$\frac{1}{r^4+8r^3+14r^2-8r-15}$	$\frac{1}{384}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+2r-3}$	$-\frac{1}{12}$
a_3	0	0
a_4	$\frac{1}{r^4+8r^3+14r^2-8r-15}$	$\frac{1}{384}$
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= x^3 \left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\
&= x^3 \left(1 - \frac{x^2}{12} + \frac{x^4}{384} + O(x^6)\right)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 4$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\rightarrow r_2} a_4(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_4 \\ &= \frac{1}{r^4 + 8r^3 + 14r^2 - 8r - 15} \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r\rightarrow r_2} \frac{1}{r^4 + 8r^3 + 14r^2 - 8r - 15} &= \lim_{r\rightarrow -1} \frac{1}{r^4 + 8r^3 + 14r^2 - 8r - 15} \\ &= \textit{undefined} \end{aligned}$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$y_2(x) = Cy_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Therefore

$$\begin{aligned} \frac{d}{dx} y_2(x) &= Cy_1'(x) \ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n + r_2)}{x}\right) \\ &= Cy_1'(x) \ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n(n + r_2)\right) \\ \frac{d^2}{dx^2} y_2(x) &= Cy_1''(x) \ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} \\ &\quad + \sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2}(n + r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n + r_2)}{x^2}\right) \\ &= Cy_1''(x) \ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n(n + r_2)(-1 + n + r_2)\right) \end{aligned}$$

Substituting these back into the given ode $x^2 y'' - y' x + (x^2 - 3) y = 0$ gives

$$\left(C y_1''(x) \ln(x) + \frac{2C y_1'(x)}{x} - \frac{C y_1(x)}{x^2} + \sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2} (n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2} (n+r_2)}{x^2}\right)\right) x^2 - \left(C y_1'(x) \ln(x) + \frac{C y_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2} (n+r_2)}{x}\right)\right) x + (x^2 - 3) \left(C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)\right) = 0$$

Which can be written as

$$\left(\left(y_1''(x) x^2 - y_1'(x) x + (x^2 - 3) y_1(x)\right) \ln(x) + \left(\frac{2 y_1'(x)}{x} - \frac{y_1(x)}{x^2}\right) x^2 - y_1(x)\right) C + \left(\sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2} (n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2} (n+r_2)}{x^2}\right)\right) x^2 - \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2} (n+r_2)}{x}\right) x + (x^2 - 3) \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0 \tag{7}$$

But since $y_1(x)$ is a solution to the ode, then

$$y_1''(x) x^2 - y_1'(x) x + (x^2 - 3) y_1(x) = 0$$

Eq (7) simplifes to

$$\left(\left(\frac{2 y_1'(x)}{x} - \frac{y_1(x)}{x^2}\right) x^2 - y_1(x)\right) C + \left(\sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2} (n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2} (n+r_2)}{x^2}\right)\right) x^2 - \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2} (n+r_2)}{x}\right) x + (x^2 - 3) \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0 \tag{8}$$

Substituting $y_1 = \sum_{n=0}^{\infty} a_n x^{n+r_1}$ into the above gives

$$\begin{aligned}
&\left(2\left(\sum_{n=0}^{\infty} x^{-1+n+r_1} a_n (n+r_1)\right) x - 2\left(\sum_{n=0}^{\infty} a_n x^{n+r_1}\right)\right) C \\
&+ \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) x^2 + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n (n+r_2)(-1+n+r_2)\right) x^2 \\
&- \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n (n+r_2)\right) x - 3\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0
\end{aligned} \tag{9}$$

Since $r_1 = 3$ and $r_2 = -1$ then the above becomes

$$\begin{aligned}
&\left(2\left(\sum_{n=0}^{\infty} x^{2+n} a_n (n+3)\right) x - 2\left(\sum_{n=0}^{\infty} a_n x^{n+3}\right)\right) C \\
&+ \left(\sum_{n=0}^{\infty} b_n x^{n-1}\right) x^2 + \left(\sum_{n=0}^{\infty} x^{-3+n} b_n (n-1)(n-2)\right) x^2 \\
&- \left(\sum_{n=0}^{\infty} x^{n-2} b_n (n-1)\right) x - 3\left(\sum_{n=0}^{\infty} b_n x^{n-1}\right) = 0
\end{aligned} \tag{10}$$

Which simplifies to

$$\begin{aligned}
&\left(\sum_{n=0}^{\infty} 2C\, x^{n+3} a_n (n+3)\right) + \sum_{n=0}^{\infty} \left(-2C a_n x^{n+3}\right) \\
&+ \left(\sum_{n=0}^{\infty} x^{1+n} b_n\right) + \left(\sum_{n=0}^{\infty} x^{n-1} b_n (n^2 - 3n + 2)\right) \\
&+ \sum_{n=0}^{\infty} \left(-x^{n-1} b_n (n-1)\right) + \sum_{n=0}^{\infty} \left(-3 b_n x^{n-1}\right) = 0
\end{aligned} \tag{2A}$$

The next step is to make all powers of x be $n-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2C\, x^{n+3} a_n (n+3) = \sum_{n=4}^{\infty} 2C a_{n-4} (n-1)\, x^{n-1}$$

$$\sum_{n=0}^{\infty} \left(-2C a_n x^{n+3}\right) = \sum_{n=4}^{\infty} \left(-2C a_{n-4} x^{n-1}\right)$$

$$\sum_{n=0}^{\infty} x^{1+n} b_n = \sum_{n=2}^{\infty} b_{n-2} x^{n-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n-1$.

$$\begin{aligned}
&\left(\sum_{n=4}^{\infty} 2C a_{n-4}(n-1)\, x^{n-1}\right) + \sum_{n=4}^{\infty} \left(-2C a_{n-4} x^{n-1}\right) \\
&+ \left(\sum_{n=2}^{\infty} b_{n-2} x^{n-1}\right) + \left(\sum_{n=0}^{\infty} x^{n-1} b_n \left(n^2 - 3n + 2\right)\right) \\
&+ \sum_{n=0}^{\infty} \left(-x^{n-1} b_n (n-1)\right) + \sum_{n=0}^{\infty} \left(-3 b_n x^{n-1}\right) = 0
\end{aligned} \tag{2B}$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0 = 1$. For $n=1$, Eq (2B) gives

$$-3b_1 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-3b_1 = 0$$

Solving the above for b_1 gives

$$b_1 = 0$$

For $n=2$, Eq (2B) gives

$$b_0 - 4b_2 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$1 - 4b_2 = 0$$

Solving the above for b_2 gives

$$b_2 = \frac{1}{4}$$

For $n = 3$, Eq (2B) gives

$$b_1 - 3b_3 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-3b_3 = 0$$

Solving the above for b_3 gives

$$b_3 = 0$$

For $n = N$, where $N = 4$ which is the difference between the two roots, we are free to choose $b_4 = 0$. Hence for $n = 4$, Eq (2B) gives

$$4C + \frac{1}{4} = 0$$

Which is solved for C. Solving for C gives

$$C = -\frac{1}{16}$$

For $n = 5$, Eq (2B) gives

$$6Ca_1 + b_3 + 5b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$5b_5 = 0$$

Solving the above for b_5 gives

$$b_5 = 0$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = -\frac{1}{16}$ and all b_n, then the second solution becomes

$$y_2(x) = -\frac{1}{16}\left(x^3\left(1 - \frac{x^2}{12} + \frac{x^4}{384} + O(x^6)\right)\right)\ln(x) + \frac{1 + \frac{x^2}{4} + O(x^6)}{x}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^3\left(1 - \frac{x^2}{12} + \frac{x^4}{384} + O(x^6)\right) \\
&\quad + c_2\left(-\frac{1}{16}\left(x^3\left(1 - \frac{x^2}{12} + \frac{x^4}{384} + O(x^6)\right)\right)\ln(x) + \frac{1 + \frac{x^2}{4} + O(x^6)}{x}\right)
\end{aligned}$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^3 \left(1-\frac{x^2}{12}+\frac{x^4}{384}+O(x^6)\right) \\
&+ c_2 \left(-\frac{x^3\left(1-\frac{x^2}{12}+\frac{x^4}{384}+O(x^6)\right)\ln(x)}{16}+\frac{1+\frac{x^2}{4}+O(x^6)}{x}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = c_1 x^3 \left(1-\frac{x^2}{12}+\frac{x^4}{384}+O(x^6)\right) \\
+ c_2 \left(-\frac{x^3\left(1-\frac{x^2}{12}+\frac{x^4}{384}+O(x^6)\right)\ln(x)}{16}+\frac{1+\frac{x^2}{4}+O(x^6)}{x}\right)
\end{aligned}
\tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = c_1 x^3 \left(1-\frac{x^2}{12}+\frac{x^4}{384}+O(x^6)\right) \\
+ c_2 \left(-\frac{x^3\left(1-\frac{x^2}{12}+\frac{x^4}{384}+O(x^6)\right)\ln(x)}{16}+\frac{1+\frac{x^2}{4}+O(x^6)}{x}\right)
\end{aligned}
$$

Verified OK.

15.26.1 Maple step by step solution

Let's solve

$y''x^2 - y'x + (x^2-3)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(x^2-3)y}{x^2} + \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{y'}{x} + \frac{(x^2-3)y}{x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

- Define functions

  $\left[P_2(x) = -\frac{1}{x}, P_3(x) = \frac{x^2-3}{x^2}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\bigg|_{x=0} = -1$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = -3$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x^2 - y'x + (x^2 - 3)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r}$

- Convert $x^2 \cdot y''$ to series expansion

  $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k + r)\, (k + r - 1)\, x^{k+r}$

  Rewrite ODE with series expansions

$$a_0(1+r)(-3+r)x^r + a_1(2+r)(-2+r)x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r+1)(k+r-3) + a_{k-2}\right) x^{k+r}\right)$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)(-3+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{-1, 3\}$
- Each term must be 0

  $a_1(2+r)(-2+r) = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+1)(k+r-3) + a_{k-2} = 0$
- Shift index using $k- >k+2$

  $a_{k+2}(k+3+r)(k+r-1) + a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k}{(k+3+r)(k+r-1)}$
- Recursion relation for $r = -1$

  $a_{k+2} = -\frac{a_k}{(k+2)(k-2)}$
- Series not valid for $r = -1$, division by 0 in the recursion relation at $k = 2$

  $a_{k+2} = -\frac{a_k}{(k+2)(k-2)}$
- Recursion relation for $r = 3$

  $a_{k+2} = -\frac{a_k}{(k+6)(k+2)}$
- Solution for $r = 3$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+2} = -\frac{a_k}{(k+6)(k+2)}, a_1 = 0\right]$

Section: Chapter 7, Systems of linear differential equations. Section 7.1. Exercises page 277
Problem number: 1.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) + y'(t) = 2x(t) + 4y(t) + e^t$$
$$x'(t) + y'(t) = y(t) + e^{4t}$$

The system is

$$x'(t) + y'(t) = 2x(t) + 4y(t) + e^t \tag{1}$$
$$x'(t) + y'(t) = y(t) + e^{4t} \tag{2}$$

Since the left side is the same, this implies

$$2x(t) + 4y(t) + e^t = y(t) + e^{4t}$$
$$y(t) = \frac{e^{4t}}{3} - \frac{2x(t)}{3} - \frac{e^t}{3} \tag{3}$$

Taking derivative of the above w.r.t. t gives

$$y'(t) = \frac{4\,e^{4t}}{3} - \frac{2x'(t)}{3} - \frac{e^t}{3} \tag{4}$$

Substituting (3,4) in (1) to eliminate $y(t)\,, y'(t)$ gives

$$\frac{x'(t)}{3} + \frac{4\,e^{4t}}{3} - \frac{e^t}{3} = -\frac{2x(t)}{3} + \frac{4\,e^{4t}}{3} - \frac{e^t}{3}$$
$$x'(t) = -2x(t) \tag{5}$$

Which is now solved for $x(t)$. Integrating both sides gives

$$\int -\frac{1}{2x}dx = \int dt$$
$$-\frac{\ln(x)}{2} = t + c_1$$

Raising both side to exponential gives

$$\frac{1}{\sqrt{x}} = \mathrm{e}^{t+c_1}$$

Which simplifies to

$$\frac{1}{\sqrt{x}} = c_2 \mathrm{e}^{t}$$

Given now that we have the solution

$$x(t) = \frac{\mathrm{e}^{-2t}}{c_2^2} \tag{6}$$

Then substituting (6) into (3) gives

$$y(t) = \frac{\left(\mathrm{e}^{6t} c_2^2 - c_2^2 \mathrm{e}^{3t} - 2\right) \mathrm{e}^{-2t}}{3 c_2^2} \tag{7}$$

✓ Solution by Maple

Problem number: 2.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) + y'(t) &= x(t) - 2t \\
x'(t) + y'(t) &= t^2 + 3x(t) + y(t)
\end{aligned}
$$

The system is

$$
x'(t) + y'(t) = x(t) - 2t \tag{1}
$$

$$
x'(t) + y'(t) = t^2 + 3x(t) + y(t) \tag{2}
$$

Since the left side is the same, this implies

$$
\begin{aligned}
x(t) - 2t &= t^2 + 3x(t) + y(t) \\
y(t) &= -t^2 - 2x(t) - 2t \qquad (3)
\end{aligned}
$$

Taking derivative of the above w.r.t. t gives

$$
y'(t) = -2t - 2x'(t) - 2 \tag{4}
$$

Substituting (3,4) in (1) to eliminate $y(t), y'(t)$ gives

$$
\begin{aligned}
-x'(t) - 2t - 2 &= x(t) - 2t \\
x'(t) &= -x(t) - 2 \qquad (5)
\end{aligned}
$$

Which is now solved for $x(t)$. Integrating both sides gives

$$
\begin{aligned}
\int \frac{1}{-x-2} dx &= \int dt \\
-\ln(-x-2) &= t + c_1
\end{aligned}
$$

Raising both side to exponential gives

$$\frac{1}{-x-2} = e^{t+c_1}$$

Which simplifies to

$$\frac{1}{-x-2} = c_2 e^t$$

Given now that we have the solution

$$x(t) = -\frac{e^{-t}}{c_2} - 2 \tag{6}$$

Then substituting (6) into (3) gives

$$y(t) = -\frac{(t^2 c_2 e^t + 2c_2 t\, e^t - 4c_2 e^t - 2)\, e^{-t}}{c_2} \tag{7}$$

✓ Solution by Maple

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 7, Systems of linear differential equations. Section 7.1. Exercises page 277
Problem number: 3.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$\begin{aligned} x'(t) + y'(t) &= x(t) + 3y(t) + e^t \\ x'(t) + y'(t) &= -x(t) + e^{3t} \end{aligned}$$

The system is

$$x'(t) + y'(t) = x(t) + 3y(t) + e^t \tag{1}$$
$$x'(t) + y'(t) = -x(t) + e^{3t} \tag{2}$$

Since the left side is the same, this implies

$$x(t) + 3y(t) + e^t = -x(t) + e^{3t}$$
$$y(t) = \frac{e^{3t}}{3} - \frac{2x(t)}{3} - \frac{e^t}{3} \tag{3}$$

Taking derivative of the above w.r.t. t gives

$$y'(t) = e^{3t} - \frac{2x'(t)}{3} - \frac{e^t}{3} \tag{4}$$

Substituting (3,4) in (1) to eliminate $y(t), y'(t)$ gives

$$\frac{x'(t)}{3} + e^{3t} - \frac{e^t}{3} = -x(t) + e^{3t}$$
$$x'(t) = -3x(t) + e^t \tag{5}$$

Which is now solved for $x(t)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$x'(t) + p(t)x(t) = q(t)$$

Where here

$$
\begin{aligned}
p(t) &= 3 \\
q(t) &= \mathrm{e}^{t}
\end{aligned}
$$

Hence the ode is

$$
x'(t) + 3x(t) = \mathrm{e}^{t}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int 3 dt} \\
&= \mathrm{e}^{3t}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}t}(\mu x) &= (\mu)\left(\mathrm{e}^{t}\right) \\
\frac{\mathrm{d}}{\mathrm{d}t}\left(\mathrm{e}^{3t} x\right) &= \left(\mathrm{e}^{3t}\right)\left(\mathrm{e}^{t}\right) \\
\mathrm{d}\left(\mathrm{e}^{3t} x\right) &= \mathrm{e}^{4t}\, \mathrm{d}t
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{3t} x &= \int \mathrm{e}^{4t}\, \mathrm{d}t \\
\mathrm{e}^{3t} x &= \frac{\mathrm{e}^{4t}}{4} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{3t}$ results in

$$
x(t) = \frac{\mathrm{e}^{-3t} \mathrm{e}^{4t}}{4} + \mathrm{e}^{-3t} c_1
$$

which simplifies to

$$
x(t) = \frac{\left(\mathrm{e}^{4t} + 4c_1\right) \mathrm{e}^{-3t}}{4}
$$

Given now that we have the solution

$$
x(t) = \frac{\left(\mathrm{e}^{4t} + 4c_1\right) \mathrm{e}^{-3t}}{4} \tag{6}
$$

Then substituting (6) into (3) gives

$$
y(t) = \frac{\mathrm{e}^{3t}}{3} - \frac{\mathrm{e}^{-3t} \mathrm{e}^{4t}}{6} - \frac{2\, \mathrm{e}^{-3t} c_1}{3} - \frac{\mathrm{e}^{t}}{3} \tag{7}
$$

✓ Solution by Maple

Time used: 0.032 (sec). Leaf size: 37

```
dsolve([diff(x(t),t)+diff(y(t),t)-x(t)-3*y(t)=exp(t),diff(x(t),t)+diff(y(t),t)+x(t)=exp(3*t)
```

$$
\begin{aligned}
x(t) &= \frac{e^{t}}{4}+c_1 e^{-3t} \\
y(t) &= \frac{e^{3t}}{3}-\frac{e^{t}}{2}-\frac{2c_1 e^{-3t}}{3}
\end{aligned}
$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) + y'(t) = x(t) + 2y(t) + 2\,\mathrm{e}^{t}$$
$$x'(t) + y'(t) = 3x(t) + 4y(t) + \mathrm{e}^{2t}$$

The system is

$$x'(t) + y'(t) = x(t) + 2y(t) + 2\,\mathrm{e}^{t} \tag{1}$$
$$x'(t) + y'(t) = 3x(t) + 4y(t) + \mathrm{e}^{2t} \tag{2}$$

Since the left side is the same, this implies

$$x(t) + 2y(t) + 2\,\mathrm{e}^{t} = 3x(t) + 4y(t) + \mathrm{e}^{2t}$$
$$y(t) = -\frac{\mathrm{e}^{2t}}{2} - x(t) + \mathrm{e}^{t} \tag{3}$$

Taking derivative of the above w.r.t. t gives

$$y'(t) = -\mathrm{e}^{2t} - x'(t) + \mathrm{e}^{t} \tag{4}$$

Substituting (3,4) in (1) to eliminate $y(t)\,, y'(t)$ gives

$$-\mathrm{e}^{2t} + \mathrm{e}^{t} = -x(t) - \mathrm{e}^{2t} + 4\,\mathrm{e}^{t}$$
$$x(t) = 3\,\mathrm{e}^{t} \tag{5}$$

Substituting (5) into (3) gives

$$y(t) = -\frac{\mathrm{e}^{2t}}{2} - 2\,\mathrm{e}^{t} \tag{7}$$

Since $x(t) = 3\,e^t$, is missing derivative in x then it is an algebraic equation. Solving for $x(t)$.

$$x(t) = 3\,e^t$$

Given now that we have the solution

$$x(t) = 3\,e^t \tag{6}$$

Then substituting (6) into (3) gives

$$y(t) = -\frac{e^{2t}}{2} - 2\,e^t \tag{7}$$

✓ Solution by Maple

Section: Chapter 7, Systems of linear differential equations. Section 7.1. Exercises page 277
Problem number: 5.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 3x(t) + 2y(t) - \mathrm{e}^{t} + \mathrm{e}^{-t} \\
y'(t) &= -5x(t) - 3y(t) + 2\,\mathrm{e}^{t} - \mathrm{e}^{-t}
\end{aligned}
$$

16.5.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 3 & 2 \\ -5 & -3 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -\mathrm{e}^{t} + \mathrm{e}^{-t} \\ 2\,\mathrm{e}^{t} - \mathrm{e}^{-t} \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \cos(t)+3\sin(t) & 2\sin(t) \\ -5\sin(t) & \cos(t)-3\sin(t) \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} \cos(t)+3\sin(t) & 2\sin(t) \\ -5\sin(t) & \cos(t)-3\sin(t) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} (\cos(t)+3\sin(t))\, c_1 + 2\sin(t)\, c_2 \\ -5\sin(t)\, c_1 + (\cos(t)-3\sin(t))\, c_2 \end{bmatrix} \\ &= \begin{bmatrix} (3c_1+2c_2)\sin(t) + c_1\cos(t) \\ (-5c_1-3c_2)\sin(t) + c_2\cos(t) \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\, dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} \cos(t)-3\sin(t) & -2\sin(t) \\ 5\sin(t) & \cos(t)+3\sin(t) \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} \cos(t)+3\sin(t) & 2\sin(t) \\ -5\sin(t) & \cos(t)-3\sin(t) \end{bmatrix} \int \begin{bmatrix} \cos(t)-3\sin(t) & -2\sin(t) \\ 5\sin(t) & \cos(t)+3\sin(t) \end{bmatrix} \begin{bmatrix} -e^{t}+e^{-t} \\ 2\,e^{t}-e^{-t} \end{bmatrix} \\ &= \begin{bmatrix} \cos(t)+3\sin(t) & 2\sin(t) \\ -5\sin(t) & \cos(t)-3\sin(t) \end{bmatrix} \begin{bmatrix} -\sin(t)\,(e^{t}-e^{-t}) \\ \frac{(\cos(t)+3\sin(t))\,(e^{t}-e^{-t})}{2} \end{bmatrix} \\ &= \begin{bmatrix} 0 \\ \frac{e^{t}}{2} - \frac{e^{-t}}{2} \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$
\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
&= \left[\begin{array}{c} (3c_1 + 2c_2)\sin(t) + c_1\cos(t) \\ (-5c_1 - 3c_2)\sin(t) + c_2\cos(t) + \frac{e^t}{2} - \frac{e^{-t}}{2} \end{array}\right]
\end{aligned}
$$

16.5.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\left[\begin{array}{c} x'(t) \\ y'(t) \end{array}\right] = \left[\begin{array}{cc} 3 & 2 \\ -5 & -3 \end{array}\right] \left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] + \left[\begin{array}{c} -e^t + e^{-t} \\ 2\,e^t - e^{-t} \end{array}\right]
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$
\det(A - \lambda I) = 0
$$

Expanding gives

$$
\det\left(\left[\begin{array}{cc} 3 & 2 \\ -5 & -3 \end{array}\right] - \lambda \left[\begin{array}{cc} 1 & 0 \\ 0 & 1 \end{array}\right]\right) = 0
$$

Therefore

$$
\det\left(\left[\begin{array}{cc} 3-\lambda & 2 \\ -5 & -3-\lambda \end{array}\right]\right) = 0
$$

Which gives the characteristic equation

$$
\lambda^2 + 1 = 0
$$

The roots of the above are the eigenvalues.

$$\lambda_1 = i$$
$$\lambda_2 = -i$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
i	1	complex eigenvalue
$-i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & 2 \\ -5 & -3 \end{bmatrix} - (-i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 3+i & 2 \\ -5 & -3+i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 3+i & 2 & 0 \\ -5 & -3+i & 0 \end{array}\right]$$

$$R_2 = R_2 + \left(\frac{3}{2} - \frac{i}{2}\right)R_1 \Longrightarrow \left[\begin{array}{cc|c} 3+i & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 3+i & 2 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \left(-\frac{3}{5} + \frac{i}{5}\right)t\right\}$

Hence the solution is

$$\begin{bmatrix} \left(-\frac{3}{5}+\frac{I}{5}\right)t \\ t \end{bmatrix} = \begin{bmatrix} \left(-\frac{3}{5}+\frac{i}{5}\right)t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \left(-\frac{3}{5}+\frac{I}{5}\right)t \\ t \end{bmatrix} = t\begin{bmatrix} -\frac{3}{5}+\frac{i}{5} \\ 1 \end{bmatrix}$$

Let $t=1$ the eigenvector becomes

$$\begin{bmatrix} \left(-\frac{3}{5}+\frac{I}{5}\right)t \\ t \end{bmatrix} = \begin{bmatrix} -\frac{3}{5}+\frac{i}{5} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \left(-\frac{3}{5}+\frac{I}{5}\right)t \\ t \end{bmatrix} = \begin{bmatrix} -3+i \\ 5 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A-\lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & 2 \\ -5 & -3 \end{bmatrix} - (i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 3-i & 2 \\ -5 & -3-i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 3-i & 2 & 0 \\ -5 & -3-i & 0 \end{array}\right]$$

$$R_2 = R_2 + \left(\frac{3}{2}+\frac{i}{2}\right)R_1 \Longrightarrow \left[\begin{array}{cc|c} 3-i & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 3-i & 2 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \left(-\frac{3}{5} - \frac{i}{5}\right) t\right\}$

Hence the solution is

$$\begin{bmatrix} \left(-\frac{3}{5} - \frac{I}{5}\right) t \\ t \end{bmatrix} = \begin{bmatrix} \left(-\frac{3}{5} - \frac{i}{5}\right) t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \left(-\frac{3}{5} - \frac{I}{5}\right) t \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{3}{5} - \frac{i}{5} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \left(-\frac{3}{5} - \frac{I}{5}\right) t \\ t \end{bmatrix} = \begin{bmatrix} -\frac{3}{5} - \frac{i}{5} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \left(-\frac{3}{5} - \frac{I}{5}\right) t \\ t \end{bmatrix} = \begin{bmatrix} -3 - i \\ 5 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
i	1	1	No	$\begin{bmatrix} -\frac{3}{5} - \frac{i}{5} \\ 1 \end{bmatrix}$
$-i$	1	1	No	$\begin{bmatrix} -\frac{3}{5} + \frac{i}{5} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \left(-\frac{3}{5} - \frac{i}{5}\right) e^{it} \\ e^{it} \end{bmatrix} + c_2 \begin{bmatrix} \left(-\frac{3}{5} + \frac{i}{5}\right) e^{-it} \\ e^{-it} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} \left(-\frac{3}{5} - \frac{i}{5}\right) e^{it} & \left(-\frac{3}{5} + \frac{i}{5}\right) e^{-it} \\ e^{it} & e^{-it} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1}\vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{5i e^{-it}}{2} & \left(\frac{1}{2} + \frac{3i}{2}\right) e^{-it} \\ -\frac{5i e^{it}}{2} & \left(\frac{1}{2} - \frac{3i}{2}\right) e^{it} \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \left(-\frac{3}{5} - \frac{i}{5}\right) e^{it} & \left(-\frac{3}{5} + \frac{i}{5}\right) e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} \frac{5i e^{-it}}{2} & \left(\frac{1}{2} + \frac{3i}{2}\right) e^{-it} \\ -\frac{5i e^{it}}{2} & \left(\frac{1}{2} - \frac{3i}{2}\right) e^{it} \end{bmatrix} \begin{bmatrix} -e^{t} + e^{-t} \\ 2\, e^{t} - e^{-t} \end{bmatrix} dt \\
&= \begin{bmatrix} \left(-\frac{3}{5} - \frac{i}{5}\right) e^{it} & \left(-\frac{3}{5} + \frac{i}{5}\right) e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} \left(-\frac{1}{2} + i\right) e^{(-1-i)t} + \left(1 + \frac{i}{2}\right) e^{(1-i)t} \\ \left(-\frac{1}{2} - i\right) e^{(-1+i)t} + \left(1 - \frac{i}{2}\right) e^{(1+i)t} \end{bmatrix} dt \\
&= \begin{bmatrix} \left(-\frac{3}{5} - \frac{i}{5}\right) e^{it} & \left(-\frac{3}{5} + \frac{i}{5}\right) e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \begin{bmatrix} \left(\frac{1}{4} + \frac{3i}{4}\right) \left(-e^{(-1-i)t} + e^{(1-i)t}\right) \\ \left(\frac{1}{4} - \frac{3i}{4}\right) \left(-e^{(-1+i)t} + e^{(1+i)t}\right) \end{bmatrix} \\
&= \begin{bmatrix} 0 \\ \frac{e^{t}}{2} - \frac{e^{-t}}{2} \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \left(-\frac{3}{5}-\frac{i}{5}\right) c_1 \mathrm{e}^{it} \\ c_1 \mathrm{e}^{it} \end{bmatrix} + \begin{bmatrix} \left(-\frac{3}{5}+\frac{i}{5}\right) c_2 \mathrm{e}^{-it} \\ c_2 \mathrm{e}^{-it} \end{bmatrix} + \begin{bmatrix} 0 \\ \frac{\mathrm{e}^{t}}{2} - \frac{\mathrm{e}^{-t}}{2} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \left(-\frac{3}{5}-\frac{i}{5}\right) c_1 \mathrm{e}^{it} + \left(-\frac{3}{5}+\frac{i}{5}\right) c_2 \mathrm{e}^{-it} \\ c_1 \mathrm{e}^{it} + c_2 \mathrm{e}^{-it} + \frac{\mathrm{e}^{t}}{2} - \frac{\mathrm{e}^{-t}}{2} \end{bmatrix}$$

16.5.3 Maple step by step solution

Let's solve

$\left[x'(t) = 3x(t) + 2y(t) - \mathrm{e}^{t} + \frac{1}{\mathrm{e}^{t}}, y'(t) = -5x(t) - 3y(t) + 2\,\mathrm{e}^{t} - \frac{1}{\mathrm{e}^{t}}\right]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 3 & 2 \\ -5 & -3 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} \frac{3x(t)\mathrm{e}^{t} + 2y(t)\mathrm{e}^{t} - (\mathrm{e}^{t})^2 + 1}{\mathrm{e}^{t}} - 3x(t) - 2y(t) \\ -\frac{5x(t)\mathrm{e}^{t} + 3y(t)\mathrm{e}^{t} - 2(\mathrm{e}^{t})^2 + 1}{\mathrm{e}^{t}} + 5x(t) + 3y(t) \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 3 & 2 \\ -5 & -3 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 3 & 2 \\ -5 & -3 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A

- Eigenpairs of A

$$\left[\left[-\mathrm{I}, \left[\begin{array}{c} -\frac{3}{5}+\frac{\mathrm{I}}{5} \\ 1 \end{array}\right]\right], \left[\mathrm{I}, \left[\begin{array}{c} -\frac{3}{5}-\frac{\mathrm{I}}{5} \\ 1 \end{array}\right]\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \left[\begin{array}{c} -\frac{3}{5}+\frac{\mathrm{I}}{5} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$\mathrm{e}^{-\mathrm{I}t} \cdot \left[\begin{array}{c} -\frac{3}{5}+\frac{\mathrm{I}}{5} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(t) - \mathrm{I}\sin(t)) \cdot \left[\begin{array}{c} -\frac{3}{5}+\frac{\mathrm{I}}{5} \\ 1 \end{array}\right]$$

- Simplify expression

$$\left[\begin{array}{c} \left(-\frac{3}{5}+\frac{\mathrm{I}}{5}\right)(\cos(t) - \mathrm{I}\sin(t)) \\ \cos(t) - \mathrm{I}\sin(t) \end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{x}_1(t) = \left[\begin{array}{c} -\frac{3\cos(t)}{5}+\frac{\sin(t)}{5} \\ \cos(t) \end{array}\right], \vec{x}_2(t) = \left[\begin{array}{c} \frac{3\sin(t)}{5}+\frac{\cos(t)}{5} \\ -\sin(t) \end{array}\right]\right]$$

- General solution to the system of ODEs

$$\vec{x} = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

- Substitute solutions into the general solution

$$\vec{x} = \left[\begin{array}{c} c_2\left(\frac{3\sin(t)}{5}+\frac{\cos(t)}{5}\right) + c_1\left(-\frac{3\cos(t)}{5}+\frac{\sin(t)}{5}\right) \\ c_1\cos(t) - c_2\sin(t) \end{array}\right]$$

- Substitute in vector of dependent variables

$$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} \frac{(-3c_1+c_2)\cos(t)}{5}+\frac{\sin(t)(c_1+3c_2)}{5} \\ c_1\cos(t) - c_2\sin(t) \end{array}\right]$$

- Solution to the system of ODEs

$$\left\{x(t) = \frac{(-3c_1+c_2)\cos(t)}{5} + \frac{\sin(t)(c_1+3c_2)}{5}, y(t) = c_1\cos(t) - c_2\sin(t)\right\}$$

Problem number: 6.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= -x(t) + t - \mathrm{e}^t \\
y'(t) &= 5x(t) + y(t) - t + 2\,\mathrm{e}^t
\end{aligned}
$$

16.6.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -1 & 0 \\ 5 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} t - \mathrm{e}^t \\ -t + 2\,\mathrm{e}^t \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} e^{-t} & 0 \\ \frac{5\,e^{t}}{2} - \frac{5\,e^{-t}}{2} & e^{t} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}\vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} e^{-t} & 0 \\ \frac{5\,e^{t}}{2} - \frac{5\,e^{-t}}{2} & e^{t} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} e^{-t} c_1 \\ \left(\frac{5\,e^{t}}{2} - \frac{5\,e^{-t}}{2}\right) c_1 + e^{t} c_2 \end{bmatrix}\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\, dt$$

But

$$\begin{aligned}e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} e^{t} & 0 \\ -\frac{5\,e^{t}}{2} + \frac{5\,e^{-t}}{2} & e^{-t} \end{bmatrix}\end{aligned}$$

Hence

$$\begin{aligned}\vec{x}_p(t) &= \begin{bmatrix} e^{-t} & 0 \\ \frac{5\,e^{t}}{2} - \frac{5\,e^{-t}}{2} & e^{t} \end{bmatrix} \int \begin{bmatrix} e^{t} & 0 \\ -\frac{5\,e^{t}}{2} + \frac{5\,e^{-t}}{2} & e^{-t} \end{bmatrix} \begin{bmatrix} t - e^{t} \\ -t + 2\,e^{t} \end{bmatrix} dt \\ &= \begin{bmatrix} e^{-t} & 0 \\ \frac{5\,e^{t}}{2} - \frac{5\,e^{-t}}{2} & e^{t} \end{bmatrix} \begin{bmatrix} -\frac{e^{2t}}{2} + e^{t}(t-1) \\ \frac{3(-1-t)e^{-t}}{2} + \frac{5\,e^{2t}}{4} + \frac{5\,e^{t}(1-t)}{2} - \frac{t}{2} \end{bmatrix} \\ &= \begin{bmatrix} t - 1 - \frac{e^{t}}{2} \\ \frac{(-2t+5)e^{t}}{4} - 4t + 1 \end{bmatrix}\end{aligned}$$

Hence the complete solution is

$$\begin{aligned}\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\ &= \begin{bmatrix} e^{-t} c_1 + t - 1 - \frac{e^{t}}{2} \\ -\frac{5\,e^{-t} c_1}{2} + \frac{(-2t+10c_1+4c_2+5)e^{t}}{4} - 4t + 1 \end{bmatrix}\end{aligned}$$

16.6.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -1 & 0 \\ 5 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} t - e^{t} \\ -t + 2\,e^{t} \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} -1 & 0 \\ 5 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -1-\lambda & 0 \\ 5 & 1-\lambda \end{bmatrix}\right) = 0$$

Since the matrix A is triangular matrix, then the determinant is the product of the elements along the diagonal. Therefore the above becomes

$$(-1-\lambda)(1-\lambda) = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 1$$
$$\lambda_2 = -1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
1	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -1 & 0 \\ 5 & 1 \end{bmatrix} - (-1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 0 & 0 \\ 5 & 2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 0 & 0 & 0 \\ 5 & 2 & 0 \end{array}\right]$$

Since the current pivot $A(1,1)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 1 and row 2 gives

$$\left[\begin{array}{cc|c} 5 & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 5 & 2 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{2t}{5}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{2t}{5} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{2t}{5} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{2t}{5} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{2}{5} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{2t}{5} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{2}{5} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{2t}{5} \\ t \end{bmatrix} = \begin{bmatrix} -2 \\ 5 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -1 & 0 \\ 5 & 1 \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -2 & 0 \\ 5 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -2 & 0 & 0 \\ 5 & 0 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{5R_1}{2} \Longrightarrow \left[\begin{array}{cc|c} -2 & 0 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 0\}$

Hence the solution is

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = t \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
1	1	1	No	$\begin{bmatrix} 0 \\ 1 \end{bmatrix}$
-1	1	1	No	$\begin{bmatrix} -\frac{2}{5} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^t \\ &= \begin{bmatrix} 0 \\ 1 \end{bmatrix} e^t \end{aligned}$$

Since eigenvalue -1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{-t} \\ &= \begin{bmatrix} -\frac{2}{5} \\ 1 \end{bmatrix} e^{-t}\end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} 0 \\ \mathrm{e}^{t} \end{bmatrix} + c_2 \begin{bmatrix} -\frac{2\,\mathrm{e}^{-t}}{5} \\ \mathrm{e}^{-t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} 0 & -\frac{2\,\mathrm{e}^{-t}}{5} \\ \mathrm{e}^{t} & \mathrm{e}^{-t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{5\,\mathrm{e}^{-t}}{2} & \mathrm{e}^{-t} \\ -\frac{5\,\mathrm{e}^{t}}{2} & 0 \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} 0 & -\frac{2\,\mathrm{e}^{-t}}{5} \\ \mathrm{e}^{t} & \mathrm{e}^{-t} \end{bmatrix} \int \begin{bmatrix} \frac{5\,\mathrm{e}^{-t}}{2} & \mathrm{e}^{-t} \\ -\frac{5\,\mathrm{e}^{t}}{2} & 0 \end{bmatrix} \begin{bmatrix} t-\mathrm{e}^{t} \\ -t+2\,\mathrm{e}^{t} \end{bmatrix} dt$$

$$= \begin{bmatrix} 0 & -\frac{2\,\mathrm{e}^{-t}}{5} \\ \mathrm{e}^{t} & \mathrm{e}^{-t} \end{bmatrix} \int \begin{bmatrix} -\frac{1}{2}+\frac{3t\,\mathrm{e}^{-t}}{2} \\ \frac{5\,\mathrm{e}^{t}(-t+\mathrm{e}^{t})}{2} \end{bmatrix} dt$$

$$= \begin{bmatrix} 0 & -\frac{2\,\mathrm{e}^{-t}}{5} \\ \mathrm{e}^{t} & \mathrm{e}^{-t} \end{bmatrix} \begin{bmatrix} \frac{(-3t-3)\mathrm{e}^{-t}}{2}-\frac{t}{2} \\ \frac{5\,\mathrm{e}^{2t}}{4}+\frac{5\,\mathrm{e}^{t}(1-t)}{2} \end{bmatrix}$$

$$= \begin{bmatrix} t-1-\frac{\mathrm{e}^{t}}{2} \\ \frac{(-2t+5)\mathrm{e}^{t}}{4}-4t+1 \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t)+\vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} 0 \\ c_1\mathrm{e}^{t} \end{bmatrix} + \begin{bmatrix} -\frac{2c_2\mathrm{e}^{-t}}{5} \\ c_2\mathrm{e}^{-t} \end{bmatrix} + \begin{bmatrix} t-1-\frac{\mathrm{e}^{t}}{2} \\ \frac{(-2t+5)\mathrm{e}^{t}}{4}-4t+1 \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{2c_2\mathrm{e}^{-t}}{5}+t-1-\frac{\mathrm{e}^{t}}{2} \\ c_2\mathrm{e}^{-t}+\frac{(-2t+4c_1+5)\mathrm{e}^{t}}{4}-4t+1 \end{bmatrix}$$

16.6.3 Maple step by step solution

Let's solve

$[x'(t) = -x(t)+t-\mathrm{e}^{t}, y'(t) = 5x(t)+y(t)-t+2\,\mathrm{e}^{t}]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} -1 & 0 \\ 5 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} t-\mathrm{e}^{t} \\ -t+2\,\mathrm{e}^{t} \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} -1 & 0 \\ 5 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} t - e^{t} \\ -t + 2\,e^{t} \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} t - e^{t} \\ -t + 2\,e^{t} \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} -1 & 0 \\ 5 & 1 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} -\frac{2}{5} \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 0 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} -\frac{2}{5} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = e^{-t} \cdot \begin{bmatrix} -\frac{2}{5} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 0 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = e^{t} \cdot \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{x}_p($

  $\overrightarrow{x}(t) = c_1\overrightarrow{x}_1 + c_2\overrightarrow{x}_2 + \overrightarrow{x}_p(t)$

☐ Fundamental matrix

  - Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

    $\phi(t) = \begin{bmatrix} -\frac{2\,e^{-t}}{5} & 0 \\ e^{-t} & e^{t} \end{bmatrix}$

  - The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

    $\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$

  - Substitute the value of $\phi(t)$ and $\phi(0)$

    $\Phi(t) = \begin{bmatrix} -\frac{2\,e^{-t}}{5} & 0 \\ e^{-t} & e^{t} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -\frac{2}{5} & 0 \\ 1 & 1 \end{bmatrix}}$

  - Evaluate and simplify to get the fundamental matrix

    $\Phi(t) = \begin{bmatrix} e^{-t} & 0 \\ \frac{5\,e^{t}}{2} - \frac{5\,e^{-t}}{2} & e^{t} \end{bmatrix}$

☐ Find a particular solution of the system of ODEs using variation of parameters

  - Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

    $\overrightarrow{x}_p(t) = \Phi(t) \cdot \overrightarrow{v}(t)$

  - Take the derivative of the particular solution

    $\overrightarrow{x}'_p(t) = \Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t)$

  - Substitute particular solution and its derivative into the system of ODEs

    $\Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

  - The fundamental matrix has columns that are solutions to the homogeneous system so its der

    $A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

  - Cancel like terms

    $\Phi(t) \cdot \overrightarrow{v}'(t) = \overrightarrow{f}(t)$

  - Multiply by the inverse of the fundamental matrix

$\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$

- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{x}_p(t) = \begin{bmatrix} -\frac{e^t}{2} + t - 1 + \frac{3e^{-t}}{2} \\ -\frac{15e^{-t}}{4} + \frac{(-2t+11)e^t}{4} - 4t + 1 \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \begin{bmatrix} -\frac{e^t}{2} + t - 1 + \frac{3e^{-t}}{2} \\ -\frac{15e^{-t}}{4} + \frac{(-2t+11)e^t}{4} - 4t + 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{2c_1e^{-t}}{5} - \frac{e^t}{2} + t - 1 + \frac{3e^{-t}}{2} \\ \frac{(4c_1-15)e^{-t}}{4} + \frac{(-2t+4c_2+11)e^t}{4} - 4t + 1 \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = -\frac{2c_1e^{-t}}{5} - \frac{e^t}{2} + t - 1 + \frac{3e^{-t}}{2}, y(t) = \frac{(4c_1-15)e^{-t}}{4} + \frac{(-2t+4c_2+11)e^t}{4} - 4t + 1\right\}$$

Problem number: 7.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= -t + 2\,\mathrm{e}^{3t} + 6y(t) \\
y'(t) &= x(t) + t - \mathrm{e}^{3t}
\end{aligned}
$$

16.7.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & 6 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 2\,\mathrm{e}^{3t} - t \\ -\mathrm{e}^{3t} + t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{e^{\sqrt{6}\,t}}{2} + \frac{e^{-\sqrt{6}\,t}}{2} & \frac{\left(-e^{-\sqrt{6}\,t}+e^{\sqrt{6}\,t}\right)\sqrt{6}}{2} \\ \frac{\left(-e^{-\sqrt{6}\,t}+e^{\sqrt{6}\,t}\right)\sqrt{6}}{12} & \frac{e^{\sqrt{6}\,t}}{2} + \frac{e^{-\sqrt{6}\,t}}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} \frac{e^{\sqrt{6}\,t}}{2} + \frac{e^{-\sqrt{6}\,t}}{2} & \frac{\left(-e^{-\sqrt{6}\,t}+e^{\sqrt{6}\,t}\right)\sqrt{6}}{2} \\ \frac{\left(-e^{-\sqrt{6}\,t}+e^{\sqrt{6}\,t}\right)\sqrt{6}}{12} & \frac{e^{\sqrt{6}\,t}}{2} + \frac{e^{-\sqrt{6}\,t}}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} \left(\frac{e^{\sqrt{6}\,t}}{2} + \frac{e^{-\sqrt{6}\,t}}{2}\right) c_1 + \frac{\left(-e^{-\sqrt{6}\,t}+e^{\sqrt{6}\,t}\right)\sqrt{6}\,c_2}{2} \\ \frac{\left(-e^{-\sqrt{6}\,t}+e^{\sqrt{6}\,t}\right)\sqrt{6}\,c_1}{12} + \left(\frac{e^{\sqrt{6}\,t}}{2} + \frac{e^{-\sqrt{6}\,t}}{2}\right) c_2 \end{bmatrix} \\ &= \begin{bmatrix} \frac{\left(-c_2\sqrt{6}+c_1\right)e^{-\sqrt{6}\,t}}{2} + \frac{e^{\sqrt{6}\,t}\left(c_2\sqrt{6}+c_1\right)}{2} \\ \frac{\left(-c_1\sqrt{6}+6c_2\right)e^{-\sqrt{6}\,t}}{12} + \frac{e^{\sqrt{6}\,t}\left(c_1\sqrt{6}+6c_2\right)}{12} \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned} e^{-At} &= \left(e^{At}\right)^{-1} \\ &= \begin{bmatrix} \frac{e^{\sqrt{6}\,t}}{2} + \frac{e^{-\sqrt{6}\,t}}{2} & -\frac{\left(-e^{-\sqrt{6}\,t}+e^{\sqrt{6}\,t}\right)\sqrt{6}}{2} \\ -\frac{\left(-e^{-\sqrt{6}\,t}+e^{\sqrt{6}\,t}\right)\sqrt{6}}{12} & \frac{e^{\sqrt{6}\,t}}{2} + \frac{e^{-\sqrt{6}\,t}}{2} \end{bmatrix} \end{aligned}$$

Hence

$$
\vec{x}_p(t) = \left[\begin{array}{cc} \frac{e^{\sqrt{6}\, t}}{2}+\frac{e^{-\sqrt{6}\, t}}{2} & \frac{\left(-e^{-\sqrt{6}\, t}+e^{\sqrt{6}\, t}\right) \sqrt{6}}{2} \\ \frac{\left(-e^{-\sqrt{6}\, t}+e^{\sqrt{6}\, t}\right) \sqrt{6}}{12} & \frac{e^{\sqrt{6}\, t}}{2}+\frac{e^{-\sqrt{6}\, t}}{2} \end{array}\right] \int \left[\begin{array}{cc} \frac{e^{\sqrt{6}\, t}}{2}+\frac{e^{-\sqrt{6}\, t}}{2} & -\frac{\left(-e^{-\sqrt{6}\, t}+e^{\sqrt{6}\, t}\right) \sqrt{6}}{2} \\ -\frac{\left(-e^{-\sqrt{6}\, t}+e^{\sqrt{6}\, t}\right) \sqrt{6}}{12} & \frac{e^{\sqrt{6}\, t}}{2}+\frac{e^{-\sqrt{6}\, t}}{2} \end{array}\right] \left[\begin{array}{c} 2\, e^{3 t}-t \\ -e^{3 t}+t \end{array}\right.
$$

$$
= \left[\begin{array}{cc} \frac{e^{\sqrt{6}\, t}}{2}+\frac{e^{-\sqrt{6}\, t}}{2} & \frac{\left(-e^{-\sqrt{6}\, t}+e^{\sqrt{6}\, t}\right) \sqrt{6}}{2} \\ \frac{\left(-e^{-\sqrt{6}\, t}+e^{\sqrt{6}\, t}\right) \sqrt{6}}{12} & \frac{e^{\sqrt{6}\, t}}{2}+\frac{e^{-\sqrt{6}\, t}}{2} \end{array}\right] \left[\begin{array}{c} -\frac{\sqrt{6}\, e^{-t \left(\sqrt{6}-3\right)}}{6}+\frac{\left(\sqrt{6}\, (t-1)-6 t+1\right) e^{-\sqrt{6}\, t}}{12}+\frac{\sqrt{6}\, e^{t \left(\sqrt{6}+3\right)}}{6}-\frac{e^{\sqrt{6}\, t} \left(\cdots\right.}{\cdots} \\ -\frac{e^{-t \left(\sqrt{6}-3\right)}}{6}+\frac{\left(\left(-6 t+1\right) \sqrt{6}+6 t-6\right) e^{-\sqrt{6}\, t}}{72}-\frac{e^{t \left(\sqrt{6}+3\right)}}{6}+\frac{\left(\left(6 t-1\right)\cdots\right.}{\cdots} \end{array}\right.
$$

$$
= \left[\begin{array}{c} -t+\frac{1}{6} \\ \frac{t}{6}-\frac{e^{3 t}}{3}-\frac{1}{6} \end{array}\right]
$$

Hence the complete solution is

$$
\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t)+\vec{x}_p(t) \\
&= \left[\begin{array}{c} \frac{\left(-3 c_2 \sqrt{6}+3 c_1\right) e^{-\sqrt{6}\, t}}{6}+\frac{\left(3 c_2 \sqrt{6}+3 c_1\right) e^{\sqrt{6}\, t}}{6}-t+\frac{1}{6} \\ \frac{\left(-c_1 \sqrt{6}+6 c_2\right) e^{-\sqrt{6}\, t}}{12}+\frac{e^{\sqrt{6}\, t} \left(c_1 \sqrt{6}+6 c_2\right)}{12}+\frac{t}{6}-\frac{e^{3 t}}{3}-\frac{1}{6} \end{array}\right]
\end{aligned}
$$

16.7.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\, \vec{x}(t) + \vec{G}(t)
$$

Or

$$
\left[\begin{array}{c} x'(t) \\ y'(t) \end{array}\right] = \left[\begin{array}{cc} 0 & 6 \\ 1 & 0 \end{array}\right] \left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] + \left[\begin{array}{c} 2\, e^{3 t}-t \\ -e^{3 t}+t \end{array}\right]
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\, \vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\, \vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$
\det\left(A - \lambda I\right) = 0
$$

Expanding gives

$$\det\left(\begin{bmatrix} 0 & 6 \\ 1 & 0 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -\lambda & 6 \\ 1 & -\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 6 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = \sqrt{6}$$
$$\lambda_2 = -\sqrt{6}$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$\sqrt{6}$	1	real eigenvalue
$-\sqrt{6}$	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = \sqrt{6}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & 6 \\ 1 & 0 \end{bmatrix} - \left(\sqrt{6}\right) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -\sqrt{6} & 6 \\ 1 & -\sqrt{6} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -\sqrt{6} & 6 & 0 \\ 1 & -\sqrt{6} & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{\sqrt{6}\,R_1}{6} \Longrightarrow \left[\begin{array}{cc|c} -\sqrt{6} & 6 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -\sqrt{6} & 6 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\sqrt{6}\}$

Hence the solution is

$$\begin{bmatrix} t\sqrt{6} \\ t \end{bmatrix} = \begin{bmatrix} t\sqrt{6} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t\sqrt{6} \\ t \end{bmatrix} = t \begin{bmatrix} \sqrt{6} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t\sqrt{6} \\ t \end{bmatrix} = \begin{bmatrix} \sqrt{6} \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = -\sqrt{6}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & 6 \\ 1 & 0 \end{bmatrix} - \left(-\sqrt{6}\right) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} \sqrt{6} & 6 \\ 1 & \sqrt{6} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} \sqrt{6} & 6 & 0 \\ 1 & \sqrt{6} & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{\sqrt{6}\, R_1}{6} \implies \left[\begin{array}{cc|c} \sqrt{6} & 6 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} \sqrt{6} & 6 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\sqrt{6}\}$

Hence the solution is

$$\begin{bmatrix} -t\sqrt{6} \\ t \end{bmatrix} = \begin{bmatrix} -t\sqrt{6} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t\sqrt{6} \\ t \end{bmatrix} = t \begin{bmatrix} -\sqrt{6} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t\sqrt{6} \\ t \end{bmatrix} = \begin{bmatrix} -\sqrt{6} \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
$\sqrt{6}$	1	1	No	$\begin{bmatrix} \sqrt{6} \\ 1 \end{bmatrix}$
$-\sqrt{6}$	1	1	No	$\begin{bmatrix} -\sqrt{6} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue $\sqrt{6}$ is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^{\sqrt{6}\, t}\\ &= \left[\begin{array}{c}\sqrt{6}\\ 1\end{array}\right] e^{\sqrt{6}\, t}\end{aligned}$$

Since eigenvalue $-\sqrt{6}$ is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{-\sqrt{6}\, t}\\ &= \left[\begin{array}{c}-\sqrt{6}\\ 1\end{array}\right] e^{-\sqrt{6}\, t}\end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

Which is written as

$$\left[\begin{array}{c}x(t)\\ y(t)\end{array}\right] = c_1\left[\begin{array}{c}\sqrt{6}\, \mathrm{e}^{\sqrt{6}\, t}\\ \mathrm{e}^{\sqrt{6}\, t}\end{array}\right] + c_2\left[\begin{array}{c}-\sqrt{6}\, \mathrm{e}^{-\sqrt{6}\, t}\\ \mathrm{e}^{-\sqrt{6}\, t}\end{array}\right]$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \left[\vec{x}_1 \quad \vec{x}_2 \quad \cdots\right]$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \left[\begin{array}{cc}\sqrt{6}\, \mathrm{e}^{\sqrt{6}\, t} & -\sqrt{6}\, \mathrm{e}^{-\sqrt{6}\, t}\\ \mathrm{e}^{\sqrt{6}\, t} & \mathrm{e}^{-\sqrt{6}\, t}\end{array}\right]$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1}\vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{\sqrt{6}\,e^{-\sqrt{6}\,t}}{12} & \frac{e^{-\sqrt{6}\,t}}{2} \\ -\frac{\sqrt{6}\,e^{\sqrt{6}\,t}}{12} & \frac{e^{\sqrt{6}\,t}}{2} \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \sqrt{6}\,e^{\sqrt{6}\,t} & -\sqrt{6}\,e^{-\sqrt{6}\,t} \\ e^{\sqrt{6}\,t} & e^{-\sqrt{6}\,t} \end{bmatrix} \int \begin{bmatrix} \frac{\sqrt{6}\,e^{-\sqrt{6}\,t}}{12} & \frac{e^{-\sqrt{6}\,t}}{2} \\ -\frac{\sqrt{6}\,e^{\sqrt{6}\,t}}{12} & \frac{e^{\sqrt{6}\,t}}{2} \end{bmatrix} \begin{bmatrix} 2\,e^{3t} - t \\ -e^{3t} + t \end{bmatrix} dt \\
&= \begin{bmatrix} \sqrt{6}\,e^{\sqrt{6}\,t} & -\sqrt{6}\,e^{-\sqrt{6}\,t} \\ e^{\sqrt{6}\,t} & e^{-\sqrt{6}\,t} \end{bmatrix} \int \begin{bmatrix} \frac{\left(\sqrt{6}-3\right)e^{-t\left(\sqrt{6}-3\right)}}{6} - \frac{t\,e^{-\sqrt{6}\,t}\left(\sqrt{6}-6\right)}{12} \\ \frac{\left(-\sqrt{6}-3\right)e^{t\left(\sqrt{6}+3\right)}}{6} + \frac{t\,e^{\sqrt{6}\,t}\left(\sqrt{6}+6\right)}{12} \end{bmatrix} dt \\
&= \begin{bmatrix} \sqrt{6}\,e^{\sqrt{6}\,t} & -\sqrt{6}\,e^{-\sqrt{6}\,t} \\ e^{\sqrt{6}\,t} & e^{-\sqrt{6}\,t} \end{bmatrix} \begin{bmatrix} -\frac{\left(2\,e^{3t}+\left(t-\frac{1}{6}\right)\sqrt{6}-t+1\right)e^{-\sqrt{6}\,t}}{12} \\ -\frac{e^{t\left(\sqrt{6}+3\right)}}{6} + \frac{\left((6t-1)\sqrt{6}+6t-6\right)e^{\sqrt{6}\,t}}{72} \end{bmatrix} \\
&= \begin{bmatrix} -t + \frac{1}{6} \\ \frac{t}{6} - \frac{e^{3t}}{3} - \frac{1}{6} \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} &= \begin{bmatrix} c_1\sqrt{6}\,e^{\sqrt{6}\,t} \\ c_1 e^{\sqrt{6}\,t} \end{bmatrix} + \begin{bmatrix} -c_2\sqrt{6}\,e^{-\sqrt{6}\,t} \\ c_2 e^{-\sqrt{6}\,t} \end{bmatrix} + \begin{bmatrix} -t + \frac{1}{6} \\ \frac{t}{6} - \frac{e^{3t}}{3} - \frac{1}{6} \end{bmatrix}
\end{aligned}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1\sqrt{6}\,e^{\sqrt{6}\,t} - c_2\sqrt{6}\,e^{-\sqrt{6}\,t} - t + \frac{1}{6} \\ c_1 e^{\sqrt{6}\,t} + c_2 e^{-\sqrt{6}\,t} + \frac{t}{6} - \frac{e^{3t}}{3} - \frac{1}{6} \end{bmatrix}$$

16.7.3 Maple step by step solution

Let's solve

$$\left[x'(t) = -t + 2\left(e^{t}\right)^{3} + 6y(t)\,, y'(t) = x(t) + t - \left(e^{t}\right)^{3}\right]$$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 0 & 6 \\ 1 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 2(e^t)^3 - t \\ -(e^t)^3 + t \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 0 & 6 \\ 1 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 2(e^t)^3 - t \\ -(e^t)^3 + t \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} 2(e^t)^3 - t \\ -(e^t)^3 + t \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 6 \\ 1 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[\sqrt{6}, \begin{bmatrix} \sqrt{6} \\ 1 \end{bmatrix}\right], \left[-\sqrt{6}, \begin{bmatrix} -\sqrt{6} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[\sqrt{6}, \begin{bmatrix} \sqrt{6} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = e^{\sqrt{6}\,t} \cdot \begin{bmatrix} \sqrt{6} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[-\sqrt{6}, \left[\begin{array}{c} -\sqrt{6} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \mathrm{e}^{-\sqrt{6}\,t} \cdot \left[\begin{array}{c} -\sqrt{6} \\ 1 \end{array}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

$$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \vec{x}_p(t)$$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syste

$$\phi(t) = \left[\begin{array}{cc} \sqrt{6}\,\mathrm{e}^{\sqrt{6}\,t} & -\sqrt{6}\,\mathrm{e}^{-\sqrt{6}\,t} \\ \mathrm{e}^{\sqrt{6}\,t} & \mathrm{e}^{-\sqrt{6}\,t} \end{array}\right]$$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$$\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$$

- Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \left[\begin{array}{cc} \sqrt{6}\,\mathrm{e}^{\sqrt{6}\,t} & -\sqrt{6}\,\mathrm{e}^{-\sqrt{6}\,t} \\ \mathrm{e}^{\sqrt{6}\,t} & \mathrm{e}^{-\sqrt{6}\,t} \end{array}\right] \cdot \frac{1}{\left[\begin{array}{cc} \sqrt{6} & -\sqrt{6} \\ 1 & 1 \end{array}\right]}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \left[\begin{array}{cc} \frac{\mathrm{e}^{\sqrt{6}\,t}}{2} + \frac{\mathrm{e}^{-\sqrt{6}\,t}}{2} & \frac{\left(-\mathrm{e}^{-\sqrt{6}\,t} + \mathrm{e}^{\sqrt{6}\,t}\right)\sqrt{6}}{2} \\ \frac{\left(-\mathrm{e}^{-\sqrt{6}\,t} + \mathrm{e}^{\sqrt{6}\,t}\right)\sqrt{6}}{12} & \frac{\mathrm{e}^{\sqrt{6}\,t}}{2} + \frac{\mathrm{e}^{-\sqrt{6}\,t}}{2} \end{array}\right]$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

$$\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$$

- Take the derivative of the particular solution

$$\vec{x}_p'(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$$

- Substitute particular solution and its derivative into the system of ODEs

$$\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$
- Cancel like terms

  $\Phi(t) \cdot \vec{v}'(t) = \vec{f}(t)$
- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$
- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$
- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$
- Plug in the fundamental matrix and the forcing function and compute

  $$\vec{x}_p(t) = \left[\begin{array}{c} \frac{\left(-3\sqrt{6}-1\right)e^{-\sqrt{6}\,t}}{12} + \frac{\left(3\sqrt{6}-1\right)e^{\sqrt{6}\,t}}{12} - t + \frac{1}{6} \\ \frac{\left(\sqrt{6}+18\right)e^{-\sqrt{6}\,t}}{72} + \frac{\left(-\sqrt{6}+18\right)e^{\sqrt{6}\,t}}{72} + \frac{t}{6} - \frac{e^{3t}}{3} - \frac{1}{6} \end{array}\right]$$

- Plug particular solution back into general solution

  $$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \left[\begin{array}{c} \frac{\left(-3\sqrt{6}-1\right)e^{-\sqrt{6}\,t}}{12} + \frac{\left(3\sqrt{6}-1\right)e^{\sqrt{6}\,t}}{12} - t + \frac{1}{6} \\ \frac{\left(\sqrt{6}+18\right)e^{-\sqrt{6}\,t}}{72} + \frac{\left(-\sqrt{6}+18\right)e^{\sqrt{6}\,t}}{72} + \frac{t}{6} - \frac{e^{3t}}{3} - \frac{1}{6} \end{array}\right]$$

- Substitute in vector of dependent variables

  $$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} \frac{\left(-1+(-12c_2-3)\sqrt{6}\right)e^{-\sqrt{6}\,t}}{12} + \frac{\left(-1+(12c_1+3)\sqrt{6}\right)e^{\sqrt{6}\,t}}{12} - t + \frac{1}{6} \\ \frac{\left(72c_2+\sqrt{6}+18\right)e^{-\sqrt{6}\,t}}{72} + \frac{\left(72c_1-\sqrt{6}+18\right)e^{\sqrt{6}\,t}}{72} + \frac{t}{6} - \frac{e^{3t}}{3} - \frac{1}{6} \end{array}\right]$$

- Solution to the system of ODEs

  $$\left\{x(t) = \frac{\left(-1+(-12c_2-3)\sqrt{6}\right)e^{-\sqrt{6}\,t}}{12} + \frac{\left(-1+(12c_1+3)\sqrt{6}\right)e^{\sqrt{6}\,t}}{12} - t + \frac{1}{6}, y(t) = \frac{\left(72c_2+\sqrt{6}+18\right)e^{-\sqrt{6}\,t}}{72} + \frac{\left(72c_1-\sqrt{6}-\right.}{72}\right.$$

✓ Solution by Maple

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 6t - 1 + 3y(t) \\
y'(t) &= x(t) - 3t + 1
\end{aligned}
$$

16.8.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & 3 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 6t - 1 \\ 1 - 3t \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{e^{\sqrt{3}\,t}}{2} + \frac{e^{-\sqrt{3}\,t}}{2} & \frac{\left(-e^{-\sqrt{3}\,t}+e^{\sqrt{3}\,t}\right)\sqrt{3}}{2} \\ \frac{\left(-e^{-\sqrt{3}\,t}+e^{\sqrt{3}\,t}\right)\sqrt{3}}{6} & \frac{e^{\sqrt{3}\,t}}{2} + \frac{e^{-\sqrt{3}\,t}}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} \frac{e^{\sqrt{3}\,t}}{2} + \frac{e^{-\sqrt{3}\,t}}{2} & \frac{\left(-e^{-\sqrt{3}\,t}+e^{\sqrt{3}\,t}\right)\sqrt{3}}{2} \\ \frac{\left(-e^{-\sqrt{3}\,t}+e^{\sqrt{3}\,t}\right)\sqrt{3}}{6} & \frac{e^{\sqrt{3}\,t}}{2} + \frac{e^{-\sqrt{3}\,t}}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} \left(\frac{e^{\sqrt{3}\,t}}{2} + \frac{e^{-\sqrt{3}\,t}}{2}\right) c_1 + \frac{\left(-e^{-\sqrt{3}\,t}+e^{\sqrt{3}\,t}\right)\sqrt{3}\,c_2}{2} \\ \frac{\left(-e^{-\sqrt{3}\,t}+e^{\sqrt{3}\,t}\right)\sqrt{3}\,c_1}{6} + \left(\frac{e^{\sqrt{3}\,t}}{2} + \frac{e^{-\sqrt{3}\,t}}{2}\right) c_2 \end{bmatrix} \\ &= \begin{bmatrix} \frac{\left(-c_2\sqrt{3}+c_1\right)e^{-\sqrt{3}\,t}}{2} + \frac{e^{\sqrt{3}\,t}\left(c_2\sqrt{3}+c_1\right)}{2} \\ \frac{\left(-c_1\sqrt{3}+3c_2\right)e^{-\sqrt{3}\,t}}{6} + \frac{e^{\sqrt{3}\,t}\left(c_1\sqrt{3}+3c_2\right)}{6} \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned} e^{-At} &= \left(e^{At}\right)^{-1} \\ &= \begin{bmatrix} \frac{e^{\sqrt{3}\,t}}{2} + \frac{e^{-\sqrt{3}\,t}}{2} & -\frac{\left(-e^{-\sqrt{3}\,t}+e^{\sqrt{3}\,t}\right)\sqrt{3}}{2} \\ -\frac{\left(-e^{-\sqrt{3}\,t}+e^{\sqrt{3}\,t}\right)\sqrt{3}}{6} & \frac{e^{\sqrt{3}\,t}}{2} + \frac{e^{-\sqrt{3}\,t}}{2} \end{bmatrix} \end{aligned}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} \frac{e^{\sqrt{3}\,t}}{2}+\frac{e^{-\sqrt{3}\,t}}{2} & \frac{\left(-e^{-\sqrt{3}\,t}+e^{\sqrt{3}\,t}\right)\sqrt{3}}{2} \\ \frac{\left(-e^{-\sqrt{3}\,t}+e^{\sqrt{3}\,t}\right)\sqrt{3}}{6} & \frac{e^{\sqrt{3}\,t}}{2}+\frac{e^{-\sqrt{3}\,t}}{2} \end{bmatrix} \int \begin{bmatrix} \frac{e^{\sqrt{3}\,t}}{2}+\frac{e^{-\sqrt{3}\,t}}{2} & -\frac{\left(-e^{-\sqrt{3}\,t}+e^{\sqrt{3}\,t}\right)\sqrt{3}}{2} \\ -\frac{\left(-e^{-\sqrt{3}\,t}+e^{\sqrt{3}\,t}\right)\sqrt{3}}{6} & \frac{e^{\sqrt{3}\,t}}{2}+\frac{e^{-\sqrt{3}\,t}}{2} \end{bmatrix} \begin{bmatrix} 6t-1 \\ 1-3t \end{bmatrix}$$

$$= \begin{bmatrix} \frac{e^{\sqrt{3}\,t}}{2}+\frac{e^{-\sqrt{3}\,t}}{2} & \frac{\left(-e^{-\sqrt{3}\,t}+e^{\sqrt{3}\,t}\right)\sqrt{3}}{2} \\ \frac{\left(-e^{-\sqrt{3}\,t}+e^{\sqrt{3}\,t}\right)\sqrt{3}}{6} & \frac{e^{\sqrt{3}\,t}}{2}+\frac{e^{-\sqrt{3}\,t}}{2} \end{bmatrix} \begin{bmatrix} \frac{\left((4-6t)\sqrt{3}+9t-9\right)e^{-\sqrt{3}\,t}}{6} + e^{\sqrt{3}\,t}\left(\left(t-\frac{2}{3}\right)\sqrt{3}+\frac{3t}{2}-\frac{3}{2}\right) \\ \frac{\left((3t-3)\sqrt{3}-6t+4\right)e^{-\sqrt{3}\,t}}{6} - \frac{e^{\sqrt{3}\,t}\left(\sqrt{3}\,(t-1)+2t-\frac{4}{3}\right)}{2} \end{bmatrix}$$

$$= \begin{bmatrix} 3t-3 \\ -2t+\frac{4}{3} \end{bmatrix}$$

Hence the complete solution is

$$\begin{aligned} \vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\ &= \begin{bmatrix} \frac{\left(-c_2\sqrt{3}+c_1\right)e^{-\sqrt{3}\,t}}{2} + \frac{e^{\sqrt{3}\,t}\left(c_2\sqrt{3}+c_1\right)}{2} + 3t - 3 \\ \frac{\left(-c_1\sqrt{3}+3c_2\right)e^{-\sqrt{3}\,t}}{6} + \frac{e^{\sqrt{3}\,t}\left(c_1\sqrt{3}+3c_2\right)}{6} - 2t + \frac{4}{3} \end{bmatrix} \end{aligned}$$

16.8.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & 3 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 6t-1 \\ 1-3t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix}0 & 3\\ 1 & 0\end{bmatrix} - \lambda\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix}-\lambda & 3\\ 1 & -\lambda\end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 3 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = \sqrt{3}$$
$$\lambda_2 = -\sqrt{3}$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$\sqrt{3}$	1	real eigenvalue
$-\sqrt{3}$	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = \sqrt{3}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix}0 & 3\\ 1 & 0\end{bmatrix} - \left(\sqrt{3}\right)\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}\right)\begin{bmatrix}v_1\\ v_2\end{bmatrix} = \begin{bmatrix}0\\ 0\end{bmatrix}$$
$$\begin{bmatrix}-\sqrt{3} & 3\\ 1 & -\sqrt{3}\end{bmatrix}\begin{bmatrix}v_1\\ v_2\end{bmatrix} = \begin{bmatrix}0\\ 0\end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c}-\sqrt{3} & 3 & 0\\ 1 & -\sqrt{3} & 0\end{array}\right]$$

$$R_2 = R_2 + \frac{\sqrt{3}\,R_1}{3} \implies \left[\begin{array}{cc|c} -\sqrt{3} & 3 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -\sqrt{3} & 3 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\sqrt{3}\}$

Hence the solution is

$$\begin{bmatrix} t\sqrt{3} \\ t \end{bmatrix} = \begin{bmatrix} t\sqrt{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t\sqrt{3} \\ t \end{bmatrix} = t \begin{bmatrix} \sqrt{3} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t\sqrt{3} \\ t \end{bmatrix} = \begin{bmatrix} \sqrt{3} \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = -\sqrt{3}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & 3 \\ 1 & 0 \end{bmatrix} - \left(-\sqrt{3}\right) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} \sqrt{3} & 3 \\ 1 & \sqrt{3} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} \sqrt{3} & 3 & 0 \\ 1 & \sqrt{3} & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{\sqrt{3}\,R_1}{3} \implies \left[\begin{array}{cc|c} \sqrt{3} & 3 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} \sqrt{3} & 3 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\sqrt{3}\}$

Hence the solution is

$$\begin{bmatrix} -t\sqrt{3} \\ t \end{bmatrix} = \begin{bmatrix} -t\sqrt{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t\sqrt{3} \\ t \end{bmatrix} = t \begin{bmatrix} -\sqrt{3} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t\sqrt{3} \\ t \end{bmatrix} = \begin{bmatrix} -\sqrt{3} \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
$\sqrt{3}$	1	1	No	$\begin{bmatrix} \sqrt{3} \\ 1 \end{bmatrix}$
$-\sqrt{3}$	1	1	No	$\begin{bmatrix} -\sqrt{3} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue $\sqrt{3}$ is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^{\sqrt{3}\,t} \\ &= \begin{bmatrix} \sqrt{3} \\ 1 \end{bmatrix} e^{\sqrt{3}\,t}\end{aligned}$$

Since eigenvalue $-\sqrt{3}$ is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{-\sqrt{3}\,t} \\ &= \begin{bmatrix} -\sqrt{3} \\ 1 \end{bmatrix} e^{-\sqrt{3}\,t}\end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \sqrt{3}\,\mathrm{e}^{\sqrt{3}\,t} \\ \mathrm{e}^{\sqrt{3}\,t} \end{bmatrix} + c_2 \begin{bmatrix} -\sqrt{3}\,\mathrm{e}^{-\sqrt{3}\,t} \\ \mathrm{e}^{-\sqrt{3}\,t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} \sqrt{3}\,\mathrm{e}^{\sqrt{3}\,t} & -\sqrt{3}\,\mathrm{e}^{-\sqrt{3}\,t} \\ \mathrm{e}^{\sqrt{3}\,t} & \mathrm{e}^{-\sqrt{3}\,t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1}\vec{G}(t)\,dt$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{\sqrt{3}\,\mathrm{e}^{-\sqrt{3}\,t}}{6} & \frac{\mathrm{e}^{-\sqrt{3}\,t}}{2} \\ -\frac{\sqrt{3}\,\mathrm{e}^{\sqrt{3}\,t}}{6} & \frac{\mathrm{e}^{\sqrt{3}\,t}}{2} \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \sqrt{3}\,\mathrm{e}^{\sqrt{3}\,t} & -\sqrt{3}\,\mathrm{e}^{-\sqrt{3}\,t} \\ \mathrm{e}^{\sqrt{3}\,t} & \mathrm{e}^{-\sqrt{3}\,t} \end{bmatrix} \int \begin{bmatrix} \frac{\sqrt{3}\,\mathrm{e}^{-\sqrt{3}\,t}}{6} & \frac{\mathrm{e}^{-\sqrt{3}\,t}}{2} \\ -\frac{\sqrt{3}\,\mathrm{e}^{\sqrt{3}\,t}}{6} & \frac{\mathrm{e}^{\sqrt{3}\,t}}{2} \end{bmatrix} \begin{bmatrix} 6t-1 \\ 1-3t \end{bmatrix} dt \\
&= \begin{bmatrix} \sqrt{3}\,\mathrm{e}^{\sqrt{3}\,t} & -\sqrt{3}\,\mathrm{e}^{-\sqrt{3}\,t} \\ \mathrm{e}^{\sqrt{3}\,t} & \mathrm{e}^{-\sqrt{3}\,t} \end{bmatrix} \int \begin{bmatrix} \frac{\left(\sqrt{3}\,(6t-1)-9t+3\right)\mathrm{e}^{-\sqrt{3}\,t}}{6} \\ \frac{\left((-6t+1)\sqrt{3}-9t+3\right)\mathrm{e}^{\sqrt{3}\,t}}{6} \end{bmatrix} dt \\
&= \begin{bmatrix} \sqrt{3}\,\mathrm{e}^{\sqrt{3}\,t} & -\sqrt{3}\,\mathrm{e}^{-\sqrt{3}\,t} \\ \mathrm{e}^{\sqrt{3}\,t} & \mathrm{e}^{-\sqrt{3}\,t} \end{bmatrix} \begin{bmatrix} -\frac{\left(3\sqrt{3}\,t+\sqrt{3}+6\right)\mathrm{e}^{-\sqrt{3}\,t}\left(6\sqrt{3}\,t-\sqrt{3}-9t+3\right)}{54t+18+18\sqrt{3}} \\ \frac{\left(3\sqrt{3}\,t+\sqrt{3}-6\right)\mathrm{e}^{\sqrt{3}\,t}\left(6\sqrt{3}\,t-\sqrt{3}+9t-3\right)}{-54t-18+18\sqrt{3}} \end{bmatrix} \\
&= \begin{bmatrix} \frac{27t^3-9t^2-24t+6}{9t^2+6t-2} \\ \frac{-54t^3+36t-8}{-9+3(3t+1)^2} \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1\sqrt{3}\,\mathrm{e}^{\sqrt{3}\,t} \\ c_1\mathrm{e}^{\sqrt{3}\,t} \end{bmatrix} + \begin{bmatrix} -c_2\sqrt{3}\,\mathrm{e}^{-\sqrt{3}\,t} \\ c_2\mathrm{e}^{-\sqrt{3}\,t} \end{bmatrix} + \begin{bmatrix} \frac{27t^3-9t^2-24t+6}{9t^2+6t-2} \\ \frac{-54t^3+36t-8}{-9+3(3t+1)^2} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1\sqrt{3}\,\mathrm{e}^{\sqrt{3}\,t} - c_2\sqrt{3}\,\mathrm{e}^{-\sqrt{3}\,t} + 3t - 3 \\ c_1\mathrm{e}^{\sqrt{3}\,t} + c_2\mathrm{e}^{-\sqrt{3}\,t} - 2t + \frac{4}{3} \end{bmatrix}$$

16.8.3 Maple step by step solution

Let's solve

$[x'(t) = 6t - 1 + 3y(t)\,, y'(t) = x(t) - 3t + 1]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 0 & 3 \\ 1 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 6t-1 \\ 1-3t \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 0 & 3 \\ 1 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 6t-1 \\ 1-3t \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} 6t-1 \\ 1-3t \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 3 \\ 1 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[\sqrt{3}, \begin{bmatrix} \sqrt{3} \\ 1 \end{bmatrix}\right], \left[-\sqrt{3}, \begin{bmatrix} -\sqrt{3} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[\sqrt{3}, \begin{bmatrix} \sqrt{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^{\sqrt{3}\,t} \cdot \begin{bmatrix} \sqrt{3} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[-\sqrt{3}, \left[\begin{array}{c} -\sqrt{3} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = e^{-\sqrt{3}\,t} \cdot \left[\begin{array}{c} -\sqrt{3} \\ 1 \end{array}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

$$\vec{x}(t) = c_1 \vec{x}_1 + c_2 \vec{x}_2 + \vec{x}_p(t)$$

□ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(t) = \left[\begin{array}{cc} \sqrt{3}\, e^{\sqrt{3}\,t} & -\sqrt{3}\, e^{-\sqrt{3}\,t} \\ e^{\sqrt{3}\,t} & e^{-\sqrt{3}\,t} \end{array}\right]$$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$$\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$$

- Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \left[\begin{array}{cc} \sqrt{3}\, e^{\sqrt{3}\,t} & -\sqrt{3}\, e^{-\sqrt{3}\,t} \\ e^{\sqrt{3}\,t} & e^{-\sqrt{3}\,t} \end{array}\right] \cdot \frac{1}{\left[\begin{array}{cc} \sqrt{3} & -\sqrt{3} \\ 1 & 1 \end{array}\right]}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \left[\begin{array}{cc} \frac{e^{\sqrt{3}\,t}}{2} + \frac{e^{-\sqrt{3}\,t}}{2} & \frac{\left(-e^{-\sqrt{3}\,t} + e^{\sqrt{3}\,t}\right)\sqrt{3}}{2} \\ \frac{\left(-e^{-\sqrt{3}\,t} + e^{\sqrt{3}\,t}\right)\sqrt{3}}{6} & \frac{e^{\sqrt{3}\,t}}{2} + \frac{e^{-\sqrt{3}\,t}}{2} \end{array}\right]$$

□ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

$$\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$$

- Take the derivative of the particular solution

$$\vec{x}_p'(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$$

- Substitute particular solution and its derivative into the system of ODEs

$$\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$

- Cancel like terms

  $\Phi(t) \cdot \vec{v}'(t) = \vec{f}(t)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$

- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\vec{x}_p(t) = \begin{bmatrix} \frac{\left(4\sqrt{3}+9\right)e^{-\sqrt{3}\,t}}{6} + \frac{\left(-4\sqrt{3}+9\right)e^{\sqrt{3}\,t}}{6} + 3t - 3 \\ \frac{\left(-3\sqrt{3}-4\right)e^{-\sqrt{3}\,t}}{6} + \frac{\left(3\sqrt{3}-4\right)e^{\sqrt{3}\,t}}{6} - 2t + \frac{4}{3} \end{bmatrix}$$

- Plug particular solution back into general solution

  $$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \begin{bmatrix} \frac{\left(4\sqrt{3}+9\right)e^{-\sqrt{3}\,t}}{6} + \frac{\left(-4\sqrt{3}+9\right)e^{\sqrt{3}\,t}}{6} + 3t - 3 \\ \frac{\left(-3\sqrt{3}-4\right)e^{-\sqrt{3}\,t}}{6} + \frac{\left(3\sqrt{3}-4\right)e^{\sqrt{3}\,t}}{6} - 2t + \frac{4}{3} \end{bmatrix}$$

- Substitute in vector of dependent variables

  $$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{\left(9+(-6c_2+4)\sqrt{3}\right)e^{-\sqrt{3}\,t}}{6} + \frac{\left(9+(-4+6c_1)\sqrt{3}\right)e^{\sqrt{3}\,t}}{6} + 3t - 3 \\ \frac{\left(6c_2-3\sqrt{3}-4\right)e^{-\sqrt{3}\,t}}{6} + \frac{\left(6c_1+3\sqrt{3}-4\right)e^{\sqrt{3}\,t}}{6} - 2t + \frac{4}{3} \end{bmatrix}$$

- Solution to the system of ODEs

  $$\left\{x(t) = \frac{\left(9+(-6c_2+4)\sqrt{3}\right)e^{-\sqrt{3}\,t}}{6} + \frac{\left(9+(-4+6c_1)\sqrt{3}\right)e^{\sqrt{3}\,t}}{6} + 3t - 3, y(t) = \frac{\left(6c_2-3\sqrt{3}-4\right)e^{-\sqrt{3}\,t}}{6} + \frac{\left(6c_1+3\sqrt{3}-4\right)\right.}{6}$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 7, Systems of linear differential equations. Section 7.1. Exercises page 277
Problem number: 9.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) + y'(t) = -2y(t) + \sin(t)$$
$$x'(t) + y'(t) = x(t) + y(t)$$

The system is

$$x'(t) + y'(t) = -2y(t) + \sin(t) \tag{1}$$
$$x'(t) + y'(t) = x(t) + y(t) \tag{2}$$

Since the left side is the same, this implies

$$-2y(t) + \sin(t) = x(t) + y(t)$$
$$y(t) = -\frac{x(t)}{3} + \frac{\sin(t)}{3} \tag{3}$$

Taking derivative of the above w.r.t. t gives

$$y'(t) = -\frac{x'(t)}{3} + \frac{\cos(t)}{3} \tag{4}$$

Substituting (3,4) in (1) to eliminate $y(t), y'(t)$ gives

$$\frac{2x'(t)}{3} + \frac{\cos(t)}{3} = \frac{2x(t)}{3} + \frac{\sin(t)}{3}$$
$$x'(t) = x(t) + \frac{\sin(t)}{2} - \frac{\cos(t)}{2} \tag{5}$$

Which is now solved for $x(t)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$x'(t) + p(t)x(t) = q(t)$$

Where here

$$\begin{aligned} p(t) &= -1 \\ q(t) &= \frac{\sin(t)}{2} - \frac{\cos(t)}{2} \end{aligned}$$

Hence the ode is

$$-x(t) + x'(t) = \frac{\sin(t)}{2} - \frac{\cos(t)}{2}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int(-1)dt} \\ &= e^{-t} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dt}(\mu x) &= (\mu)\left(\frac{\sin(t)}{2} - \frac{\cos(t)}{2}\right) \\ \frac{d}{dt}(e^{-t}x) &= (e^{-t})\left(\frac{\sin(t)}{2} - \frac{\cos(t)}{2}\right) \\ d(e^{-t}x) &= \left(\frac{(\sin(t) - \cos(t))e^{-t}}{2}\right) dt \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{-t}x &= \int \frac{(\sin(t) - \cos(t))e^{-t}}{2} dt \\ e^{-t}x &= -\frac{e^{-t}\sin(t)}{2} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-t}$ results in

$$x(t) = -\frac{e^{t}e^{-t}\sin(t)}{2} + c_1e^{t}$$

which simplifies to

$$x(t) = c_1e^{t} - \frac{\sin(t)}{2}$$

Given now that we have the solution

$$x(t) = c_1 \mathrm{e}^t - \frac{\sin(t)}{2} \tag{6}$$

Then substituting (6) into (3) gives

$$y(t) = -\frac{c_1 \mathrm{e}^t}{3} + \frac{\sin(t)}{2} \tag{7}$$

✓ Solution by Maple

Time used: 0.062 (sec). Leaf size: 27

$$
\begin{aligned}
x'(t) &= \frac{3x(t)}{2} - \frac{3y(t)}{2} + \frac{t}{2} + \frac{1}{2} \\
y'(t) &= -\frac{x(t)}{2} + \frac{5y(t)}{2} - \frac{t}{2} + \frac{1}{2}
\end{aligned}
$$

16.10.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} \frac{3}{2} & -\frac{3}{2} \\ -\frac{1}{2} & \frac{5}{2} \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \frac{t}{2} + \frac{1}{2} \\ -\frac{t}{2} + \frac{1}{2} \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{3\,e^{t}}{4}+\frac{e^{3t}}{4} & -\frac{3\,e^{3t}}{4}+\frac{3\,e^{t}}{4} \\ -\frac{e^{3t}}{4}+\frac{e^{t}}{4} & \frac{e^{t}}{4}+\frac{3\,e^{3t}}{4} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{3\,e^{t}}{4}+\frac{e^{3t}}{4} & -\frac{3\,e^{3t}}{4}+\frac{3\,e^{t}}{4} \\ -\frac{e^{3t}}{4}+\frac{e^{t}}{4} & \frac{e^{t}}{4}+\frac{3\,e^{3t}}{4} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{3\,e^{t}}{4}+\frac{e^{3t}}{4}\right) c_1 + \left(-\frac{3\,e^{3t}}{4}+\frac{3\,e^{t}}{4}\right) c_2 \\ \left(-\frac{e^{3t}}{4}+\frac{e^{t}}{4}\right) c_1 + \left(\frac{e^{t}}{4}+\frac{3\,e^{3t}}{4}\right) c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(c_1-3c_2)e^{3t}}{4}+\frac{3\,e^{t}(c_1+c_2)}{4} \\ \frac{(-c_1+3c_2)e^{3t}}{4}+\frac{e^{t}(c_1+c_2)}{4} \end{bmatrix}
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At}\int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \begin{bmatrix} \frac{e^{-3t}(3\,e^{2t}+1)}{4} & \frac{3\,e^{-3t}(e^{2t}-1)}{4} \\ \frac{e^{-3t}(e^{2t}-1)}{4} & \frac{e^{-3t}(e^{2t}+3)}{4} \end{bmatrix}
\end{aligned}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \frac{3\,e^{t}}{4}+\frac{e^{3t}}{4} & -\frac{3\,e^{3t}}{4}+\frac{3\,e^{t}}{4} \\ -\frac{e^{3t}}{4}+\frac{e^{t}}{4} & \frac{e^{t}}{4}+\frac{3\,e^{3t}}{4} \end{bmatrix} \int \begin{bmatrix} \frac{e^{-3t}(3\,e^{2t}+1)}{4} & \frac{3\,e^{-3t}(e^{2t}-1)}{4} \\ \frac{e^{-3t}(e^{2t}-1)}{4} & \frac{e^{-3t}(e^{2t}+3)}{4} \end{bmatrix} \begin{bmatrix} \frac{t}{2}+\frac{1}{2} \\ -\frac{t}{2}+\frac{1}{2} \end{bmatrix} dt \\
&= \begin{bmatrix} \frac{3\,e^{t}}{4}+\frac{e^{3t}}{4} & -\frac{3\,e^{3t}}{4}+\frac{3\,e^{t}}{4} \\ -\frac{e^{3t}}{4}+\frac{e^{t}}{4} & \frac{e^{t}}{4}+\frac{3\,e^{3t}}{4} \end{bmatrix} \begin{bmatrix} \frac{(-6t+1)e^{-3t}}{36}-\frac{3\,e^{-t}}{4} \\ \frac{(6t-1)e^{-3t}}{36}-\frac{e^{-t}}{4} \end{bmatrix} \\
&= \begin{bmatrix} -\frac{13}{18}-\frac{t}{6} \\ -\frac{5}{18}+\frac{t}{6} \end{bmatrix}
\end{aligned}$$

Hence the complete solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$= \begin{bmatrix} \frac{(c_1-3c_2)e^{3t}}{4} + \frac{3\,e^t(c_1+c_2)}{4} - \frac{13}{18} - \frac{t}{6} \\ \frac{(-c_1+3c_2)e^{3t}}{4} + \frac{e^t(c_1+c_2)}{4} - \frac{5}{18} + \frac{t}{6} \end{bmatrix}$$

16.10.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} \frac{3}{2} & -\frac{3}{2} \\ -\frac{1}{2} & \frac{5}{2} \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \frac{t}{2} + \frac{1}{2} \\ -\frac{t}{2} + \frac{1}{2} \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} \frac{3}{2} & -\frac{3}{2} \\ -\frac{1}{2} & \frac{5}{2} \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} \frac{3}{2} - \lambda & -\frac{3}{2} \\ -\frac{1}{2} & \frac{5}{2} - \lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 4\lambda + 3 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 3$$
$$\lambda_2 = 1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue
3	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} \frac{3}{2} & -\frac{3}{2} \\ -\frac{1}{2} & \frac{5}{2} \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} \frac{1}{2} & -\frac{3}{2} \\ -\frac{1}{2} & \frac{3}{2} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} \frac{1}{2} & -\frac{3}{2} & 0 \\ -\frac{1}{2} & \frac{3}{2} & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} \frac{1}{2} & -\frac{3}{2} & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} \frac{1}{2} & -\frac{3}{2} \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 3t\}$

Hence the solution is

$$\begin{bmatrix} 3t \\ t \end{bmatrix} = \begin{bmatrix} 3t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 3t \\ t \end{bmatrix} = t \begin{bmatrix} 3 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 3t \\ t \end{bmatrix} = \begin{bmatrix} 3 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} \frac{3}{2} & -\frac{3}{2} \\ -\frac{1}{2} & \frac{5}{2} \end{bmatrix} - (3) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -\frac{3}{2} & -\frac{3}{2} \\ -\frac{1}{2} & -\frac{1}{2} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -\frac{3}{2} & -\frac{3}{2} & 0 \\ -\frac{1}{2} & -\frac{1}{2} & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{3} \implies \left[\begin{array}{cc|c} -\frac{3}{2} & -\frac{3}{2} & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -\frac{3}{2} & -\frac{3}{2} \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
3	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$
1	1	1	No	$\begin{bmatrix} 3 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 3 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{3t} \\ &= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{3t} \end{aligned}$$

Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^t$$
$$= \begin{bmatrix} 3 \\ 1 \end{bmatrix} e^t$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\mathrm{e}^{3t} \\ \mathrm{e}^{3t} \end{bmatrix} + c_2 \begin{bmatrix} 3\,\mathrm{e}^{t} \\ \mathrm{e}^{t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -\mathrm{e}^{3t} & 3\,\mathrm{e}^{t} \\ \mathrm{e}^{3t} & \mathrm{e}^{t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{\mathrm{e}^{-3t}}{4} & \frac{3\,\mathrm{e}^{-3t}}{4} \\ \frac{\mathrm{e}^{-t}}{4} & \frac{\mathrm{e}^{-t}}{4} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} -e^{3t} & 3\,e^{t} \\ e^{3t} & e^{t} \end{bmatrix} \int \begin{bmatrix} -\frac{e^{-3t}}{4} & \frac{3\,e^{-3t}}{4} \\ \frac{e^{-t}}{4} & \frac{e^{-t}}{4} \end{bmatrix} \begin{bmatrix} \frac{t}{2}+\frac{1}{2} \\ -\frac{t}{2}+\frac{1}{2} \end{bmatrix} dt$$

$$= \begin{bmatrix} -e^{3t} & 3\,e^{t} \\ e^{3t} & e^{t} \end{bmatrix} \int \begin{bmatrix} -\frac{e^{-3t}(2t-1)}{4} \\ \frac{e^{-t}}{4} \end{bmatrix} dt$$

$$= \begin{bmatrix} -e^{3t} & 3\,e^{t} \\ e^{3t} & e^{t} \end{bmatrix} \begin{bmatrix} \frac{(6t-1)e^{-3t}}{36} \\ -\frac{e^{-t}}{4} \end{bmatrix}$$

$$= \begin{bmatrix} -\frac{13}{18}-\frac{t}{6} \\ -\frac{5}{18}+\frac{t}{6} \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -c_1 e^{3t} \\ c_1 e^{3t} \end{bmatrix} + \begin{bmatrix} 3c_2 e^{t} \\ c_2 e^{t} \end{bmatrix} + \begin{bmatrix} -\frac{13}{18}-\frac{t}{6} \\ -\frac{5}{18}+\frac{t}{6} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -c_1 e^{3t} + 3c_2 e^{t} - \frac{13}{18} - \frac{t}{6} \\ c_1 e^{3t} + c_2 e^{t} - \frac{5}{18} + \frac{t}{6} \end{bmatrix}$$

16.10.3 Maple step by step solution

Let's solve

$$\left[x'(t) = \frac{3x(t)}{2} - \frac{3y(t)}{2} + \frac{t}{2} + \frac{1}{2}, y'(t) = -\frac{x(t)}{2} + \frac{5y(t)}{2} - \frac{t}{2} + \frac{1}{2}\right]$$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\overrightarrow{x}'(t) = \left[\begin{array}{cc} \frac{3}{2} & -\frac{3}{2} \\ -\frac{1}{2} & \frac{5}{2} \end{array}\right] \cdot \overrightarrow{x}(t) + \left[\begin{array}{c} \frac{t}{2}+\frac{1}{2} \\ -\frac{t}{2}+\frac{1}{2} \end{array}\right]$$

- System to solve

$$\overrightarrow{x}'(t) = \left[\begin{array}{cc} \frac{3}{2} & -\frac{3}{2} \\ -\frac{1}{2} & \frac{5}{2} \end{array}\right] \cdot \overrightarrow{x}(t) + \left[\begin{array}{c} \frac{t}{2}+\frac{1}{2} \\ -\frac{t}{2}+\frac{1}{2} \end{array}\right]$$

- Define the forcing function

$$\overrightarrow{f}(t) = \left[\begin{array}{c} \frac{t}{2}+\frac{1}{2} \\ -\frac{t}{2}+\frac{1}{2} \end{array}\right]$$

- Define the coefficient matrix

$$A = \left[\begin{array}{cc} \frac{3}{2} & -\frac{3}{2} \\ -\frac{1}{2} & \frac{5}{2} \end{array}\right]$$

- Rewrite the system as

$$\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t) + \overrightarrow{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \left[\begin{array}{c} 3 \\ 1 \end{array}\right]\right], \left[3, \left[\begin{array}{c} -1 \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c} 3 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{x}_1 = \mathrm{e}^{t} \cdot \left[\begin{array}{c} 3 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[3, \left[\begin{array}{c} -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$\vec{x}_2 = e^{3t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix}$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

  $\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \vec{x}_p(t)$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

  $\phi(t) = \begin{bmatrix} 3\,e^{t} & -e^{3t} \\ e^{t} & e^{3t} \end{bmatrix}$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

  $\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(t)$ and $\phi(0)$

  $\Phi(t) = \begin{bmatrix} 3\,e^{t} & -e^{3t} \\ e^{t} & e^{3t} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 3 & -1 \\ 1 & 1 \end{bmatrix}}$

- Evaluate and simplify to get the fundamental matrix

  $\Phi(t) = \begin{bmatrix} \frac{3\,e^{t}}{4} + \frac{e^{3t}}{4} & -\frac{3\,e^{3t}}{4} + \frac{3\,e^{t}}{4} \\ -\frac{e^{3t}}{4} + \frac{e^{t}}{4} & \frac{e^{t}}{4} + \frac{3\,e^{3t}}{4} \end{bmatrix}$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

  $\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$

- Take the derivative of the particular solution

  $\vec{x}_p'(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$

- Cancel like terms

$\Phi(t) \cdot \vec{v}'(t) = \vec{f}(t)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$

- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $\vec{x}_p(t) = \begin{bmatrix} \frac{3\,e^t}{4} - \frac{13}{18} - \frac{e^{3t}}{36} - \frac{t}{6} \\ \frac{e^{3t}}{36} + \frac{t}{6} - \frac{5}{18} + \frac{e^t}{4} \end{bmatrix}$

- Plug particular solution back into general solution

  $\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \begin{bmatrix} \frac{3\,e^t}{4} - \frac{13}{18} - \frac{e^{3t}}{36} - \frac{t}{6} \\ \frac{e^{3t}}{36} + \frac{t}{6} - \frac{5}{18} + \frac{e^t}{4} \end{bmatrix}$

- Substitute in vector of dependent variables

  $\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} 3c_1 e^t - c_2 e^{3t} + \frac{3\,e^t}{4} - \frac{13}{18} - \frac{e^{3t}}{36} - \frac{t}{6} \\ c_1 e^t + c_2 e^{3t} + \frac{e^{3t}}{36} + \frac{t}{6} - \frac{5}{18} + \frac{e^t}{4} \end{bmatrix}$

- Solution to the system of ODEs

  $\left\{x(t) = 3c_1 e^t - c_2 e^{3t} + \frac{3\,e^t}{4} - \frac{13}{18} - \frac{e^{3t}}{36} - \frac{t}{6}, y(t) = c_1 e^t + c_2 e^{3t} + \frac{e^{3t}}{36} + \frac{t}{6} - \frac{5}{18} + \frac{e^t}{4}\right\}$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= -2 + x(t) - 3y(t) + 4t \\
y'(t) &= 4 - 3x(t) + y(t) - 4t
\end{aligned}
$$

16.11.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & -3 \\ -3 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 4t-2 \\ 4-4t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{e^{-2t}}{2} + \frac{e^{4t}}{2} & -\frac{e^{4t}}{2} + \frac{e^{-2t}}{2} \\ -\frac{e^{4t}}{2} + \frac{e^{-2t}}{2} & \frac{e^{-2t}}{2} + \frac{e^{4t}}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{e^{-2t}}{2} + \frac{e^{4t}}{2} & -\frac{e^{4t}}{2} + \frac{e^{-2t}}{2} \\ -\frac{e^{4t}}{2} + \frac{e^{-2t}}{2} & \frac{e^{-2t}}{2} + \frac{e^{4t}}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{e^{-2t}}{2} + \frac{e^{4t}}{2}\right) c_1 + \left(-\frac{e^{4t}}{2} + \frac{e^{-2t}}{2}\right) c_2 \\ \left(-\frac{e^{4t}}{2} + \frac{e^{-2t}}{2}\right) c_1 + \left(\frac{e^{-2t}}{2} + \frac{e^{4t}}{2}\right) c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{e^{-2t}(c_1+c_2)}{2} + \frac{e^{4t}(c_1-c_2)}{2} \\ \frac{e^{-2t}(c_1+c_2)}{2} - \frac{e^{4t}(c_1-c_2)}{2} \end{bmatrix}
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\, dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \begin{bmatrix} \frac{(e^{6t}+1)e^{-4t}}{2} & \frac{(e^{6t}-1)e^{-4t}}{2} \\ \frac{(e^{6t}-1)e^{-4t}}{2} & \frac{(e^{6t}+1)e^{-4t}}{2} \end{bmatrix}
\end{aligned}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \frac{e^{-2t}}{2} + \frac{e^{4t}}{2} & -\frac{e^{4t}}{2} + \frac{e^{-2t}}{2} \\ -\frac{e^{4t}}{2} + \frac{e^{-2t}}{2} & \frac{e^{-2t}}{2} + \frac{e^{4t}}{2} \end{bmatrix} \int \begin{bmatrix} \frac{(e^{6t}+1)e^{-4t}}{2} & \frac{(e^{6t}-1)e^{-4t}}{2} \\ \frac{(e^{6t}-1)e^{-4t}}{2} & \frac{(e^{6t}+1)e^{-4t}}{2} \end{bmatrix} \begin{bmatrix} 4t-2 \\ 4-4t \end{bmatrix} dt \\
&= \begin{bmatrix} \frac{e^{-2t}}{2} + \frac{e^{4t}}{2} & -\frac{e^{4t}}{2} + \frac{e^{-2t}}{2} \\ -\frac{e^{4t}}{2} + \frac{e^{-2t}}{2} & \frac{e^{-2t}}{2} + \frac{e^{4t}}{2} \end{bmatrix} \begin{bmatrix} \frac{(e^{6t}-2t+1)e^{-4t}}{2} \\ \frac{(e^{6t}+2t-1)e^{-4t}}{2} \end{bmatrix} \\
&= \begin{bmatrix} 1-t \\ t \end{bmatrix}
\end{aligned}$$

Hence the complete solution is

$$
\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
&= \begin{bmatrix} \frac{\mathrm{e}^{-2t}(c_1+c_2)}{2} + \frac{\mathrm{e}^{4t}(c_1-c_2)}{2} + 1 - t \\ \frac{\mathrm{e}^{-2t}(c_1+c_2)}{2} + \frac{(-c_1+c_2)\mathrm{e}^{4t}}{2} + t \end{bmatrix}
\end{aligned}
$$

16.11.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & -3 \\ -3 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 4t-2 \\ 4-4t \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$
\det(A - \lambda I) = 0
$$

Expanding gives

$$
\det\left(\begin{bmatrix} 1 & -3 \\ -3 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0
$$

Therefore

$$
\det\left(\begin{bmatrix} 1-\lambda & -3 \\ -3 & 1-\lambda \end{bmatrix}\right) = 0
$$

Which gives the characteristic equation

$$
\lambda^2 - 2\lambda - 8 = 0
$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -2$$
$$\lambda_2 = 4$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-2	1	real eigenvalue
4	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & -3 \\ -3 & 1 \end{bmatrix} - (-2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 3 & -3 \\ -3 & 3 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 3 & -3 & 0 \\ -3 & 3 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} 3 & -3 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 3 & -3 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 4$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & -3 \\ -3 & 1 \end{bmatrix} - (4) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -3 & -3 \\ -3 & -3 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -3 & -3 & 0 \\ -3 & -3 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} -3 & -3 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -3 & -3 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-2	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$
4	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -2 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{-2t} \\ &= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{-2t} \end{aligned}$$

Since eigenvalue 4 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{4t}$$
$$= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{4t}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} e^{-2t} \\ e^{-2t} \end{bmatrix} + c_2 \begin{bmatrix} -e^{4t} \\ e^{4t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} e^{-2t} & -e^{4t} \\ e^{-2t} & e^{4t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t) \, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{e^{2t}}{2} & \frac{e^{2t}}{2} \\ -\frac{e^{-4t}}{2} & \frac{e^{-4t}}{2} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} e^{-2t} & -e^{4t} \\ e^{-2t} & e^{4t} \end{bmatrix} \int \begin{bmatrix} \frac{e^{2t}}{2} & \frac{e^{2t}}{2} \\ -\frac{e^{-4t}}{2} & \frac{e^{-4t}}{2} \end{bmatrix} \begin{bmatrix} 4t-2 \\ 4-4t \end{bmatrix} dt$$
$$= \begin{bmatrix} e^{-2t} & -e^{4t} \\ e^{-2t} & e^{4t} \end{bmatrix} \int \begin{bmatrix} e^{2t} \\ e^{-4t}(-4t+3) \end{bmatrix} dt$$
$$= \begin{bmatrix} e^{-2t} & -e^{4t} \\ e^{-2t} & e^{4t} \end{bmatrix} \begin{bmatrix} \frac{e^{2t}}{2} \\ \frac{e^{-4t}(2t-1)}{2} \end{bmatrix}$$
$$= \begin{bmatrix} 1-t \\ t \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 e^{-2t} \\ c_1 e^{-2t} \end{bmatrix} + \begin{bmatrix} -c_2 e^{4t} \\ c_2 e^{4t} \end{bmatrix} + \begin{bmatrix} 1-t \\ t \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 e^{-2t} - c_2 e^{4t} + 1 - t \\ c_1 e^{-2t} + c_2 e^{4t} + t \end{bmatrix}$$

16.11.3 Maple step by step solution

Let's solve

$[x'(t) = -2 + x(t) - 3y(t) + 4t, y'(t) = 4 - 3x(t) + y(t) - 4t]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & -3 \\ -3 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 4t-2 \\ 4-4t \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \left[\begin{array}{cc} 1 & -3 \\ -3 & 1 \end{array}\right] \cdot \vec{x}(t) + \left[\begin{array}{c} 4t-2 \\ 4-4t \end{array}\right]$$

- Define the forcing function

$$\vec{f}(t) = \left[\begin{array}{c} 4t-2 \\ 4-4t \end{array}\right]$$

- Define the coefficient matrix

$$A = \left[\begin{array}{cc} 1 & -3 \\ -3 & 1 \end{array}\right]$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2, \left[\begin{array}{c} 1 \\ 1 \end{array}\right]\right], \left[4, \left[\begin{array}{c} -1 \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-2, \left[\begin{array}{c} 1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = e^{-2t} \cdot \left[\begin{array}{c} 1 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[4, \left[\begin{array}{c} -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = e^{4t} \cdot \left[\begin{array}{c} -1 \\ 1 \end{array}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{x}_p($

$\overrightarrow{x}(t) = c_1\overrightarrow{x}_1 + c_2\overrightarrow{x}_2 + \overrightarrow{x}_p(t)$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(t) = \begin{bmatrix} e^{-2t} & -e^{4t} \\ e^{-2t} & e^{4t} \end{bmatrix}$$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} e^{-2t} & -e^{4t} \\ e^{-2t} & e^{4t} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} \frac{e^{-2t}}{2} + \frac{e^{4t}}{2} & -\frac{e^{4t}}{2} + \frac{e^{-2t}}{2} \\ -\frac{e^{4t}}{2} + \frac{e^{-2t}}{2} & \frac{e^{-2t}}{2} + \frac{e^{4t}}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

$\overrightarrow{x}_p(t) = \Phi(t) \cdot \overrightarrow{v}(t)$

- Take the derivative of the particular solution

$\overrightarrow{x}'_p(t) = \Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

$\Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- Cancel like terms

$\Phi(t) \cdot \overrightarrow{v}'(t) = \overrightarrow{f}(t)$

- Multiply by the inverse of the fundamental matrix

$\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$

- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\vec{x}_p(t) = \left[\begin{array}{c} 1 - \frac{e^{-2t}}{2} - \frac{e^{4t}}{2} - t \\ \frac{e^{4t}}{2} + t - \frac{e^{-2t}}{2} \end{array}\right]$$

- Plug particular solution back into general solution

  $$\vec{x}(t) = c_1 \vec{x}_1 + c_2 \vec{x}_2 + \left[\begin{array}{c} 1 - \frac{e^{-2t}}{2} - \frac{e^{4t}}{2} - t \\ \frac{e^{4t}}{2} + t - \frac{e^{-2t}}{2} \end{array}\right]$$

- Substitute in vector of dependent variables

  $$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} \frac{(2c_1-1)e^{-2t}}{2} + \frac{(-2c_2-1)e^{4t}}{2} - t + 1 \\ \frac{(2c_1-1)e^{-2t}}{2} + \frac{(2c_2+1)e^{4t}}{2} + t \end{array}\right]$$

- Solution to the system of ODEs

  $$\left\{x(t) = \frac{(2c_1-1)e^{-2t}}{2} + \frac{(-2c_2-1)e^{4t}}{2} - t + 1, y(t) = \frac{(2c_1-1)e^{-2t}}{2} + \frac{(2c_2+1)e^{4t}}{2} + t\right\}$$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 2t^2 - 6y(t) - 2t - 1 \\
y'(t) &= -t^2 + x(t) + y(t) + 2t + 1
\end{aligned}
$$

16.12.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & -6 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 2t^2 - 2t - 1 \\ -t^2 + 2t + 1 \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$
e^{At} = \begin{bmatrix} e^{\frac{t}{2}} \cos\left(\frac{\sqrt{23}\,t}{2}\right) - \frac{\sqrt{23}\, e^{\frac{t}{2}} \sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} & -\frac{12\sqrt{23}\, e^{\frac{t}{2}} \sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} \\ \frac{2\sqrt{23}\, e^{\frac{t}{2}} \sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} & e^{\frac{t}{2}} \cos\left(\frac{\sqrt{23}\,t}{2}\right) + \frac{\sqrt{23}\, e^{\frac{t}{2}} \sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} \end{bmatrix}
$$

$$
= \begin{bmatrix} -\frac{e^{\frac{t}{2}}\left(\sqrt{23}\sin\left(\frac{\sqrt{23}\,t}{2}\right) - 23\cos\left(\frac{\sqrt{23}\,t}{2}\right)\right)}{23} & -\frac{12\sqrt{23}\, e^{\frac{t}{2}} \sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} \\ \frac{2\sqrt{23}\, e^{\frac{t}{2}} \sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} & \frac{e^{\frac{t}{2}}\left(\sqrt{23}\sin\left(\frac{\sqrt{23}\,t}{2}\right) + 23\cos\left(\frac{\sqrt{23}\,t}{2}\right)\right)}{23} \end{bmatrix}
$$

Therefore the homogeneous solution is

$$
\vec{x}_h(t) = e^{At}\vec{c}
$$

$$
= \begin{bmatrix} -\frac{e^{\frac{t}{2}}\left(\sqrt{23}\sin\left(\frac{\sqrt{23}\,t}{2}\right) - 23\cos\left(\frac{\sqrt{23}\,t}{2}\right)\right)}{23} & -\frac{12\sqrt{23}\, e^{\frac{t}{2}} \sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} \\ \frac{2\sqrt{23}\, e^{\frac{t}{2}} \sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} & \frac{e^{\frac{t}{2}}\left(\sqrt{23}\sin\left(\frac{\sqrt{23}\,t}{2}\right) + 23\cos\left(\frac{\sqrt{23}\,t}{2}\right)\right)}{23} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix}
$$

$$
= \begin{bmatrix} -\frac{e^{\frac{t}{2}}\left(\sqrt{23}\sin\left(\frac{\sqrt{23}\,t}{2}\right) - 23\cos\left(\frac{\sqrt{23}\,t}{2}\right)\right)c_1}{23} - \frac{12\sqrt{23}\, e^{\frac{t}{2}} \sin\left(\frac{\sqrt{23}\,t}{2}\right)c_2}{23} \\ \frac{2\sqrt{23}\, e^{\frac{t}{2}} \sin\left(\frac{\sqrt{23}\,t}{2}\right)c_1}{23} + \frac{e^{\frac{t}{2}}\left(\sqrt{23}\sin\left(\frac{\sqrt{23}\,t}{2}\right) + 23\cos\left(\frac{\sqrt{23}\,t}{2}\right)\right)c_2}{23} \end{bmatrix}
$$

$$
= \begin{bmatrix} -\frac{e^{\frac{t}{2}}\left(\sqrt{23}\,(c_1+12c_2)\sin\left(\frac{\sqrt{23}\,t}{2}\right) - 23\cos\left(\frac{\sqrt{23}\,t}{2}\right)c_1\right)}{23} \\ \frac{2\left(\sqrt{23}\,\left(c_1+\frac{c_2}{2}\right)\sin\left(\frac{\sqrt{23}\,t}{2}\right) + \frac{23\cos\left(\frac{\sqrt{23}\,t}{2}\right)c_2}{2}\right)e^{\frac{t}{2}}}{23} \end{bmatrix}
$$

The particular solution given by

$$
\vec{x}_p(t) = e^{At}\int e^{-At}\vec{G}(t)\,dt
$$

But

$$
e^{-At} = (e^{At})^{-1}
$$

$$
= \begin{bmatrix} \frac{\left(\sqrt{23}\sin\left(\frac{\sqrt{23}\,t}{2}\right) + 23\cos\left(\frac{\sqrt{23}\,t}{2}\right)\right)e^{-\frac{t}{2}}}{23} & \frac{12\sin\left(\frac{\sqrt{23}\,t}{2}\right)\sqrt{23}\, e^{-\frac{t}{2}}}{23} \\ -\frac{2\sin\left(\frac{\sqrt{23}\,t}{2}\right)\sqrt{23}\, e^{-\frac{t}{2}}}{23} & -\frac{\left(\sqrt{23}\sin\left(\frac{\sqrt{23}\,t}{2}\right) - 23\cos\left(\frac{\sqrt{23}\,t}{2}\right)\right)e^{-\frac{t}{2}}}{23} \end{bmatrix}
$$

Hence

$$
\vec{x}_p(t) = \begin{bmatrix} -\frac{e^{\frac{t}{2}}\left(\sqrt{23}\,\sin\left(\frac{\sqrt{23}\,t}{2}\right)-23\cos\left(\frac{\sqrt{23}\,t}{2}\right)\right)}{23} & -\frac{12\sqrt{23}\,e^{\frac{t}{2}}\sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} \\ \frac{2\sqrt{23}\,e^{\frac{t}{2}}\sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} & \frac{e^{\frac{t}{2}}\left(\sqrt{23}\,\sin\left(\frac{\sqrt{23}\,t}{2}\right)+23\cos\left(\frac{\sqrt{23}\,t}{2}\right)\right)}{23} \end{bmatrix} \int \begin{bmatrix} \frac{\left(\sqrt{23}\,\sin\left(\frac{\sqrt{23}\,t}{2}\right)+23\cos\left(\frac{\sqrt{23}\,t}{2}\right)\right)e}{23} \\ -\frac{2\sin\left(\frac{\sqrt{23}\,t}{2}\right)\sqrt{23}\,e^{-\frac{t}{2}}}{23} \end{bmatrix}
$$

$$
= \begin{bmatrix} -\frac{e^{\frac{t}{2}}\left(\sqrt{23}\,\sin\left(\frac{\sqrt{23}\,t}{2}\right)-23\cos\left(\frac{\sqrt{23}\,t}{2}\right)\right)}{23} & -\frac{12\sqrt{23}\,e^{\frac{t}{2}}\sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} \\ \frac{2\sqrt{23}\,e^{\frac{t}{2}}\sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} & \frac{e^{\frac{t}{2}}\left(\sqrt{23}\,\sin\left(\frac{\sqrt{23}\,t}{2}\right)+23\cos\left(\frac{\sqrt{23}\,t}{2}\right)\right)}{23} \end{bmatrix} \begin{bmatrix} \frac{14\,e^{-\frac{t}{2}}\left(\left(\frac{23}{7}t^2-\frac{23}{6}t-\frac{943}{126}\right)\cos\left(\frac{\sqrt{23}\,t}{2}\right)+\right.}{69} \\ -\frac{5\,e^{-\frac{t}{2}}\left(\left(-\frac{23}{5}t^2+\frac{23}{3}t+\frac{23}{45}\right)\cos\left(\frac{\sqrt{23}\,t}{2}\right)\right.}{69} \end{bmatrix}
$$

$$
= \begin{bmatrix} \frac{2}{3}t^2 - \frac{7}{9}t - \frac{41}{27} \\ \frac{1}{3}t^2 - \frac{5}{9}t - \frac{1}{27} \end{bmatrix}
$$

Hence the complete solution is

$$
\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
&= \begin{bmatrix} -\frac{e^{\frac{t}{2}}\sqrt{23}\,(c_1+12c_2)\sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} + e^{\frac{t}{2}}\cos\left(\frac{\sqrt{23}\,t}{2}\right)c_1 + \frac{2t^2}{3} - \frac{7t}{9} - \frac{41}{27} \\ \frac{2\,e^{\frac{t}{2}}\sqrt{23}\,(c_1+\frac{c_2}{2})\sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} + e^{\frac{t}{2}}\cos\left(\frac{\sqrt{23}\,t}{2}\right)c_2 + \frac{t^2}{3} - \frac{5t}{9} - \frac{1}{27} \end{bmatrix}
\end{aligned}
$$

16.12.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & -6 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 2t^2 - 2t - 1 \\ -t^2 + 2t + 1 \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$
\det\left(A - \lambda I\right) = 0
$$

Expanding gives

$$\det\left(\begin{bmatrix}0 & -6\\1 & 1\end{bmatrix} - \lambda\begin{bmatrix}1 & 0\\0 & 1\end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix}-\lambda & -6\\1 & 1-\lambda\end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - \lambda + 6 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = \frac{1}{2} + \frac{i\sqrt{23}}{2}$$
$$\lambda_2 = \frac{1}{2} - \frac{i\sqrt{23}}{2}$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$\frac{1}{2} - \frac{i\sqrt{23}}{2}$	1	complex eigenvalue
$\frac{1}{2} + \frac{i\sqrt{23}}{2}$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = \frac{1}{2} - \frac{i\sqrt{23}}{2}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix}0 & -6\\1 & 1\end{bmatrix} - \left(\frac{1}{2} - \frac{i\sqrt{23}}{2}\right)\begin{bmatrix}1 & 0\\0 & 1\end{bmatrix}\right)\begin{bmatrix}v_1\\v_2\end{bmatrix} = \begin{bmatrix}0\\0\end{bmatrix}$$
$$\begin{bmatrix}-\frac{1}{2} + \frac{i\sqrt{23}}{2} & -6\\1 & \frac{1}{2} + \frac{i\sqrt{23}}{2}\end{bmatrix}\begin{bmatrix}v_1\\v_2\end{bmatrix} = \begin{bmatrix}0\\0\end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c}-\frac{1}{2} + \frac{i\sqrt{23}}{2} & -6 & 0\\1 & \frac{1}{2} + \frac{i\sqrt{23}}{2} & 0\end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{-\frac{1}{2}+\frac{i\sqrt{23}}{2}} \Longrightarrow \left[\begin{array}{cc|c} -\frac{1}{2}+\frac{i\sqrt{23}}{2} & -6 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -\frac{1}{2}+\frac{i\sqrt{23}}{2} & -6 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{12t}{i\sqrt{23}-1}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{12t}{\mathrm{I}\sqrt{23}-1} \\ t \end{bmatrix} = \begin{bmatrix} \frac{12t}{i\sqrt{23}-1} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{12t}{\mathrm{I}\sqrt{23}-1} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{12}{i\sqrt{23}-1} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{12t}{\mathrm{I}\sqrt{23}-1} \\ t \end{bmatrix} = \begin{bmatrix} \frac{12}{i\sqrt{23}-1} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{12t}{\mathrm{I}\sqrt{23}-1} \\ t \end{bmatrix} = \begin{bmatrix} \frac{12}{i\sqrt{23}-1} \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = \frac{1}{2} + \frac{i\sqrt{23}}{2}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & -6 \\ 1 & 1 \end{bmatrix} - \left(\frac{1}{2}+\frac{i\sqrt{23}}{2}\right)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -\frac{1}{2}-\frac{i\sqrt{23}}{2} & -6 \\ 1 & \frac{1}{2}-\frac{i\sqrt{23}}{2} \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -\frac{1}{2}-\frac{i\sqrt{23}}{2} & -6 & 0 \\ 1 & \frac{1}{2}-\frac{i\sqrt{23}}{2} & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{-\frac{1}{2}-\frac{i\sqrt{23}}{2}} \Longrightarrow \left[\begin{array}{cc|c} -\frac{1}{2}-\frac{i\sqrt{23}}{2} & -6 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -\frac{1}{2}-\frac{i\sqrt{23}}{2} & -6 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{12t}{1+i\sqrt{23}}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{12t}{1+\mathrm{I}\sqrt{23}} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{12t}{1+i\sqrt{23}} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{12t}{1+\mathrm{I}\sqrt{23}} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{12}{1+i\sqrt{23}} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{12t}{1+\mathrm{I}\sqrt{23}} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{12}{1+i\sqrt{23}} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{12t}{1+\mathrm{I}\sqrt{23}} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{12}{1+i\sqrt{23}} \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m-k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
$\frac{1}{2}+\frac{i\sqrt{23}}{2}$	1	1	No	$\left[\begin{array}{c} -\frac{6}{\frac{1}{2}+\frac{i\sqrt{23}}{2}} \\ 1 \end{array}\right]$
$\frac{1}{2}-\frac{i\sqrt{23}}{2}$	1	1	No	$\left[\begin{array}{c} -\frac{6}{\frac{1}{2}-\frac{i\sqrt{23}}{2}} \\ 1 \end{array}\right]$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

Which is written as

$$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = c_1 \left[\begin{array}{c} -\frac{6\,\mathrm{e}^{\left(\frac{1}{2}+\frac{i\sqrt{23}}{2}\right)t}}{\frac{1}{2}+\frac{i\sqrt{23}}{2}} \\ \mathrm{e}^{\left(\frac{1}{2}+\frac{i\sqrt{23}}{2}\right)t} \end{array}\right] + c_2 \left[\begin{array}{c} -\frac{6\,\mathrm{e}^{\left(\frac{1}{2}-\frac{i\sqrt{23}}{2}\right)t}}{\frac{1}{2}-\frac{i\sqrt{23}}{2}} \\ \mathrm{e}^{\left(\frac{1}{2}-\frac{i\sqrt{23}}{2}\right)t} \end{array}\right]$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \left[\vec{x}_1 \quad \vec{x}_2 \quad \cdots\right]$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \left[\begin{array}{cc} -\frac{6\,\mathrm{e}^{\left(\frac{1}{2}+\frac{i\sqrt{23}}{2}\right)t}}{\frac{1}{2}+\frac{i\sqrt{23}}{2}} & -\frac{6\,\mathrm{e}^{\left(\frac{1}{2}-\frac{i\sqrt{23}}{2}\right)t}}{\frac{1}{2}-\frac{i\sqrt{23}}{2}} \\ \mathrm{e}^{\left(\frac{1}{2}+\frac{i\sqrt{23}}{2}\right)t} & \mathrm{e}^{\left(\frac{1}{2}-\frac{i\sqrt{23}}{2}\right)t} \end{array}\right]$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1}\vec{G}(t)\,dt$$

But

$$
\Phi^{-1} = \left[\begin{array}{cc} -\frac{i\sqrt{23}\,{\mathrm e}^{-\frac{\left(1+i\sqrt{23}\right)t}{2}}}{23} & -\frac{\sqrt{23}\,{\mathrm e}^{-\frac{\left(1+i\sqrt{23}\right)t}{2}}\left(i-\sqrt{23}\right)}{46} \\ \frac{i\sqrt{23}\,{\mathrm e}^{\frac{\left(i\sqrt{23}-1\right)t}{2}}}{23} & \frac{\sqrt{23}\,{\mathrm e}^{\frac{\left(i\sqrt{23}-1\right)t}{2}}\left(\sqrt{23}+i\right)}{46} \end{array}\right]
$$

Hence

$$
\vec{x}_p(t) = \left[\begin{array}{cc} -\frac{6\,{\mathrm e}^{\left(\frac{1}{2}+\frac{i\sqrt{23}}{2}\right)t}}{\frac{1}{2}+\frac{i\sqrt{23}}{2}} & -\frac{6\,{\mathrm e}^{\left(\frac{1}{2}-\frac{i\sqrt{23}}{2}\right)t}}{\frac{1}{2}-\frac{i\sqrt{23}}{2}} \\ {\mathrm e}^{\left(\frac{1}{2}+\frac{i\sqrt{23}}{2}\right)t} & {\mathrm e}^{\left(\frac{1}{2}-\frac{i\sqrt{23}}{2}\right)t} \end{array}\right] \int \left[\begin{array}{cc} -\frac{i\sqrt{23}\,{\mathrm e}^{-\frac{\left(1+i\sqrt{23}\right)t}{2}}}{23} & -\frac{\sqrt{23}\,{\mathrm e}^{-\frac{\left(1+i\sqrt{23}\right)t}{2}}\left(i-\sqrt{23}\right)}{46} \\ \frac{i\sqrt{23}\,{\mathrm e}^{\frac{\left(i\sqrt{23}-1\right)t}{2}}}{23} & \frac{\sqrt{23}\,{\mathrm e}^{\frac{\left(i\sqrt{23}-1\right)t}{2}}\left(\sqrt{23}+i\right)}{46} \end{array}\right] \left[\begin{array}{c} 2t^2-2t-1\cdots \\ -t^2+2t+1\cdots \end{array}\right.
$$

$$
= \left[\begin{array}{cc} -\frac{6\,{\mathrm e}^{\left(\frac{1}{2}+\frac{i\sqrt{23}}{2}\right)t}}{\frac{1}{2}+\frac{i\sqrt{23}}{2}} & -\frac{6\,{\mathrm e}^{\left(\frac{1}{2}-\frac{i\sqrt{23}}{2}\right)t}}{\frac{1}{2}-\frac{i\sqrt{23}}{2}} \\ {\mathrm e}^{\left(\frac{1}{2}+\frac{i\sqrt{23}}{2}\right)t} & {\mathrm e}^{\left(\frac{1}{2}-\frac{i\sqrt{23}}{2}\right)t} \end{array}\right] \int \left[\begin{array}{c} -\frac{3\,{\mathrm e}^{-\frac{\left(1+i\sqrt{23}\right)t}{2}}\left(i\left(t+\frac{1}{3}\right)(t-1)\sqrt{23}+\frac{23t^2}{3}-\frac{46t}{3}-\frac{23}{3}\right)}{46} \\ \frac{3\,{\mathrm e}^{\frac{\left(i\sqrt{23}-1\right)t}{2}}\left(i\left(t+\frac{1}{3}\right)(t-1)\sqrt{23}-\frac{23t^2}{3}+\frac{46t}{3}+\frac{23}{3}\right)}{46} \end{array}\right] dt
$$

$$
= \left[\begin{array}{cc} -\frac{6\,{\mathrm e}^{\left(\frac{1}{2}+\frac{i\sqrt{23}}{2}\right)t}}{\frac{1}{2}+\frac{i\sqrt{23}}{2}} & -\frac{6\,{\mathrm e}^{\left(\frac{1}{2}-\frac{i\sqrt{23}}{2}\right)t}}{\frac{1}{2}-\frac{i\sqrt{23}}{2}} \\ {\mathrm e}^{\left(\frac{1}{2}+\frac{i\sqrt{23}}{2}\right)t} & {\mathrm e}^{\left(\frac{1}{2}-\frac{i\sqrt{23}}{2}\right)t} \end{array}\right] \left[\begin{array}{c} \frac{\sqrt{23}\,{\mathrm e}^{-\frac{\left(1+i\sqrt{23}\right)t}{2}}\left(-36i\sqrt{23}\,t^2+51i\sqrt{23}\,t+43i\sqrt{23}+36t^2-87t+113\right)\left(-3it^2-\sqrt{23}\,t^2\cdots\right.}{16146-1242i(2t+1)\sqrt{23}-19872t^2+32292t} \\ -\frac{\sqrt{23}\,{\mathrm e}^{\frac{\left(i\sqrt{23}-1\right)t}{2}}\left(-36\sqrt{23}\,t^2+51\sqrt{23}\,t+43\sqrt{23}+36it^2-87it+113i\right)\left(3it^2-\sqrt{23}\,t^2\cdots\right.}{(2484t+1242)\sqrt{23}+19872it^2-32292it-16146i} \end{array}\right.
$$

$$
= \left[\begin{array}{c} \frac{-\frac{128}{3}t^6+\frac{1696}{9}t^5-\frac{3328}{27}t^4-\frac{10136}{27}t^3+\frac{6776}{27}t^2+\frac{2960}{9}t+\frac{656}{9}}{\left(-\frac{13}{2}+i\left(t+\frac{1}{2}\right)\sqrt{23}+8t^2-13t\right)\left(\frac{13}{2}+i\left(t+\frac{1}{2}\right)\sqrt{23}-8t^2+13t\right)} \\ \frac{-\frac{64}{3}t^6+\frac{944}{9}t^5-\frac{3848}{27}t^4-\frac{616}{27}t^3+\frac{2536}{27}t^2+\frac{304}{9}t+\frac{16}{9}}{\left(-\frac{13}{2}+i\left(t+\frac{1}{2}\right)\sqrt{23}+8t^2-13t\right)\left(\frac{13}{2}+i\left(t+\frac{1}{2}\right)\sqrt{23}-8t^2+13t\right)} \end{array}\right]
$$

Now that we found particular solution, the final solution is

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

$$
\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} -\frac{6c_1{\mathrm e}^{\left(\frac{1}{2}+\frac{i\sqrt{23}}{2}\right)t}}{\frac{1}{2}+\frac{i\sqrt{23}}{2}} \\ c_1{\mathrm e}^{\left(\frac{1}{2}+\frac{i\sqrt{23}}{2}\right)t} \end{array}\right] + \left[\begin{array}{c} -\frac{6c_2{\mathrm e}^{\left(\frac{1}{2}-\frac{i\sqrt{23}}{2}\right)t}}{\frac{1}{2}-\frac{i\sqrt{23}}{2}} \\ c_2{\mathrm e}^{\left(\frac{1}{2}-\frac{i\sqrt{23}}{2}\right)t} \end{array}\right] + \left[\begin{array}{c} \frac{-\frac{128}{3}t^6+\frac{1696}{9}t^5-\frac{3328}{27}t^4-\frac{10136}{27}t^3+\frac{6776}{27}t^2+\frac{2960}{9}t+\frac{656}{9}}{\left(-\frac{13}{2}+i\left(t+\frac{1}{2}\right)\sqrt{23}+8t^2-13t\right)\left(\frac{13}{2}+i\left(t+\frac{1}{2}\right)\sqrt{23}-8t^2+13t\right)} \\ \frac{-\frac{64}{3}t^6+\frac{944}{9}t^5-\frac{3848}{27}t^4-\frac{616}{27}t^3+\frac{2536}{27}t^2+\frac{304}{9}t+\frac{16}{9}}{\left(-\frac{13}{2}+i\left(t+\frac{1}{2}\right)\sqrt{23}+8t^2-13t\right)\left(\frac{13}{2}+i\left(t+\frac{1}{2}\right)\sqrt{23}-8t^2+13t\right)} \end{array}\right]
$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{32\left(-t^4+\frac{13}{4}t^3-\frac{11}{8}t^2-3t-\frac{3}{4}\right)\left(-\frac{82}{27}+\left(i\sqrt{23}-1\right)c_1 \mathrm{e}^{\frac{\left(1+i\sqrt{23}\right)t}{2}}+c_2\left(-1-i\sqrt{23}\right)\mathrm{e}^{-\frac{\left(i\sqrt{23}-1\right)t}{2}}+\frac{4t^2}{3}-\frac{14t}{9}\right)}{\left(-\frac{13}{2}+i\left(t+\frac{1}{2}\right)\sqrt{23}+8t^2-13t\right)\left(\frac{13}{2}+i\left(t+\frac{1}{2}\right)\sqrt{23}-8t^2+13t\right)} \\ \frac{8\left(-8t^4+26t^3-11t^2-24t-6\right)\left(27c_2 \mathrm{e}^{-\frac{\left(i\sqrt{23}-1\right)t}{2}}+27c_1 \mathrm{e}^{\frac{\left(1+i\sqrt{23}\right)t}{2}}+9t^2-15t-1\right)}{27\left(-\frac{13}{2}+i\left(t+\frac{1}{2}\right)\sqrt{23}+8t^2-13t\right)\left(\frac{13}{2}+i\left(t+\frac{1}{2}\right)\sqrt{23}-8t^2+13t\right)} \end{bmatrix}$$

16.12.3 Maple step by step solution

Let's solve

$[x'(t) = 2t^2 - 6y(t) - 2t - 1, y'(t) = -t^2 + x(t) + y(t) + 2t + 1]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 0 & -6 \\ 1 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 2t^2 - 2t - 1 \\ -t^2 + 2t + 1 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 0 & -6 \\ 1 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 2t^2 - 2t - 1 \\ -t^2 + 2t + 1 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} 2t^2 - 2t - 1 \\ -t^2 + 2t + 1 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & -6 \\ 1 & 1 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[\frac{1}{2}-\frac{\mathrm{I}\sqrt{23}}{2}, \left[\begin{array}{c} -\frac{6}{\frac{1}{2}-\frac{\mathrm{I}\sqrt{23}}{2}} \\ 1 \end{array}\right]\right], \left[\frac{1}{2}+\frac{\mathrm{I}\sqrt{23}}{2}, \left[\begin{array}{c} -\frac{6}{\frac{1}{2}+\frac{\mathrm{I}\sqrt{23}}{2}} \\ 1 \end{array}\right]\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[\frac{1}{2}-\frac{\mathrm{I}\sqrt{23}}{2}, \left[\begin{array}{c} -\frac{6}{\frac{1}{2}-\frac{\mathrm{I}\sqrt{23}}{2}} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$\mathrm{e}^{\left(\frac{1}{2}-\frac{\mathrm{I}\sqrt{23}}{2}\right)t} \cdot \left[\begin{array}{c} -\frac{6}{\frac{1}{2}-\frac{\mathrm{I}\sqrt{23}}{2}} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$\mathrm{e}^{\frac{t}{2}} \cdot \left(\cos\left(\frac{\sqrt{23}\, t}{2}\right)-\mathrm{I}\sin\left(\frac{\sqrt{23}\, t}{2}\right)\right) \cdot \left[\begin{array}{c} -\frac{6}{\frac{1}{2}-\frac{\mathrm{I}\sqrt{23}}{2}} \\ 1 \end{array}\right]$$

- Simplify expression

$$\mathrm{e}^{\frac{t}{2}} \cdot \left[\begin{array}{c} -\frac{6\left(\cos\left(\frac{\sqrt{23}\, t}{2}\right)-\mathrm{I}\sin\left(\frac{\sqrt{23}\, t}{2}\right)\right)}{\frac{1}{2}-\frac{\mathrm{I}\sqrt{23}}{2}} \\ \cos\left(\frac{\sqrt{23}\, t}{2}\right)-\mathrm{I}\sin\left(\frac{\sqrt{23}\, t}{2}\right) \end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{x}_1(t)=\mathrm{e}^{\frac{t}{2}} \cdot \left[\begin{array}{c} -\frac{\cos\left(\frac{\sqrt{23}\, t}{2}\right)}{2}-\frac{\sqrt{23}\,\sin\left(\frac{\sqrt{23}\, t}{2}\right)}{2} \\ \cos\left(\frac{\sqrt{23}\, t}{2}\right) \end{array}\right], \vec{x}_2(t)=\mathrm{e}^{\frac{t}{2}} \cdot \left[\begin{array}{c} -\frac{\sqrt{23}\,\cos\left(\frac{\sqrt{23}\, t}{2}\right)}{2}+\frac{\sin\left(\frac{\sqrt{23}\, t}{2}\right)}{2} \\ -\sin\left(\frac{\sqrt{23}\, t}{2}\right) \end{array}\right]\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

$\vec{x}(t)=c_1\vec{x}_1(t)+c_2\vec{x}_2(t)+\vec{x}_p(t)$

- ☐ Fundamental matrix
  - Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syste

$$\phi(t) = \begin{bmatrix} e^{\frac{t}{2}}\left(-\frac{\cos\left(\frac{\sqrt{23}\,t}{2}\right)}{2} - \frac{\sqrt{23}\sin\left(\frac{\sqrt{23}\,t}{2}\right)}{2}\right) & e^{\frac{t}{2}}\left(-\frac{\sqrt{23}\cos\left(\frac{\sqrt{23}\,t}{2}\right)}{2} + \frac{\sin\left(\frac{\sqrt{23}\,t}{2}\right)}{2}\right) \\ e^{\frac{t}{2}}\cos\left(\frac{\sqrt{23}\,t}{2}\right) & -e^{\frac{t}{2}}\sin\left(\frac{\sqrt{23}\,t}{2}\right) \end{bmatrix}$$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

  $\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} e^{\frac{t}{2}}\left(-\frac{\cos\left(\frac{\sqrt{23}\,t}{2}\right)}{2} - \frac{\sqrt{23}\sin\left(\frac{\sqrt{23}\,t}{2}\right)}{2}\right) & e^{\frac{t}{2}}\left(-\frac{\sqrt{23}\cos\left(\frac{\sqrt{23}\,t}{2}\right)}{2} + \frac{\sin\left(\frac{\sqrt{23}\,t}{2}\right)}{2}\right) \\ e^{\frac{t}{2}}\cos\left(\frac{\sqrt{23}\,t}{2}\right) & -e^{\frac{t}{2}}\sin\left(\frac{\sqrt{23}\,t}{2}\right) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -\frac{1}{2} & -\frac{\sqrt{23}}{2} \\ 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} \frac{\left(\sqrt{23}\cos\left(\frac{\sqrt{23}\,t}{2}\right) - \sin\left(\frac{\sqrt{23}\,t}{2}\right)\right)\sqrt{23}\,e^{\frac{t}{2}}}{23} & -\frac{12\sqrt{23}\,e^{\frac{t}{2}}\sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} \\ \frac{2\sqrt{23}\,e^{\frac{t}{2}}\sin\left(\frac{\sqrt{23}\,t}{2}\right)}{23} & \frac{e^{\frac{t}{2}}\left(\sqrt{23}\sin\left(\frac{\sqrt{23}\,t}{2}\right) + 23\cos\left(\frac{\sqrt{23}\,t}{2}\right)\right)}{23} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

  $\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$

- Take the derivative of the particular solution

  $\vec{x}'_p(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$

- Cancel like terms

  $\Phi(t) \cdot \vec{v}'(t) = \vec{f}(t)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$

- Integrate to solve for $\vec{v}(t)$

$$\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$$

- Plug $\vec{v}(t)$ into the equation for the particular solution

$$\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{x}_p(t) = \begin{bmatrix} -\frac{53\sqrt{23}\,e^{\frac{t}{2}} \sin\left(\frac{\sqrt{23}\,t}{2}\right)}{621} + \frac{41\,e^{\frac{t}{2}} \cos\left(\frac{\sqrt{23}\,t}{2}\right)}{27} + \frac{2t^2}{3} - \frac{7t}{9} - \frac{41}{27} \\ \frac{83\sqrt{23}\,e^{\frac{t}{2}} \sin\left(\frac{\sqrt{23}\,t}{2}\right)}{621} + \frac{e^{\frac{t}{2}} \cos\left(\frac{\sqrt{23}\,t}{2}\right)}{27} + \frac{t^2}{3} - \frac{5t}{9} - \frac{1}{27} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{x}(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + \begin{bmatrix} -\frac{53\sqrt{23}\,e^{\frac{t}{2}} \sin\left(\frac{\sqrt{23}\,t}{2}\right)}{621} + \frac{41\,e^{\frac{t}{2}} \cos\left(\frac{\sqrt{23}\,t}{2}\right)}{27} + \frac{2t^2}{3} - \frac{7t}{9} - \frac{41}{27} \\ \frac{83\sqrt{23}\,e^{\frac{t}{2}} \sin\left(\frac{\sqrt{23}\,t}{2}\right)}{621} + \frac{e^{\frac{t}{2}} \cos\left(\frac{\sqrt{23}\,t}{2}\right)}{27} + \frac{t^2}{3} - \frac{5t}{9} - \frac{1}{27} \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{e^{\frac{t}{2}}\left(c_2\sqrt{23}+c_1-\frac{82}{27}\right)\cos\left(\frac{\sqrt{23}\,t}{2}\right)}{2} - \frac{e^{\frac{t}{2}}\left(\left(c_1+\frac{106}{621}\right)\sqrt{23}-c_2\right)\sin\left(\frac{\sqrt{23}\,t}{2}\right)}{2} + \frac{2t^2}{3} - \frac{7t}{9} - \frac{41}{27} \\ -\frac{1}{27} + \frac{(27c_1+1)e^{\frac{t}{2}}\cos\left(\frac{\sqrt{23}\,t}{2}\right)}{27} - e^{\frac{t}{2}}\left(c_2 - \frac{83\sqrt{23}}{621}\right)\sin\left(\frac{\sqrt{23}\,t}{2}\right) + \frac{t^2}{3} - \frac{5t}{9} \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = -\frac{e^{\frac{t}{2}}\left(c_2\sqrt{23}+c_1-\frac{82}{27}\right)\cos\left(\frac{\sqrt{23}\,t}{2}\right)}{2} - \frac{e^{\frac{t}{2}}\left(\left(c_1+\frac{106}{621}\right)\sqrt{23}-c_2\right)\sin\left(\frac{\sqrt{23}\,t}{2}\right)}{2} + \frac{2t^2}{3} - \frac{7t}{9} - \frac{41}{27}, y(t) = -\frac{1}{27} + \frac{(2\right.$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= -t^2 + x(t) + y(t) + 6t \\
y'(t) &= 3t^2 - 3x(t) - 3y(t) - 8t
\end{aligned}
$$

16.13.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ -3 & -3 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -t^2 + 6t \\ 3t^2 - 8t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} -\frac{e^{-2t}}{2} + \frac{3}{2} & \frac{1}{2} - \frac{e^{-2t}}{2} \\ -\frac{3}{2} + \frac{3\,e^{-2t}}{2} & \frac{3\,e^{-2t}}{2} - \frac{1}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} -\frac{e^{-2t}}{2} + \frac{3}{2} & \frac{1}{2} - \frac{e^{-2t}}{2} \\ -\frac{3}{2} + \frac{3\,e^{-2t}}{2} & \frac{3\,e^{-2t}}{2} - \frac{1}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} \left(-\frac{e^{-2t}}{2} + \frac{3}{2}\right) c_1 + \left(\frac{1}{2} - \frac{e^{-2t}}{2}\right) c_2 \\ \left(-\frac{3}{2} + \frac{3\,e^{-2t}}{2}\right) c_1 + \left(\frac{3\,e^{-2t}}{2} - \frac{1}{2}\right) c_2 \end{bmatrix} \\ &= \begin{bmatrix} \frac{(-c_1-c_2)e^{-2t}}{2} + \frac{3c_1}{2} + \frac{c_2}{2} \\ \frac{(3c_1+3c_2)e^{-2t}}{2} - \frac{3c_1}{2} - \frac{c_2}{2} \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} \frac{3}{2} - \frac{e^{2t}}{2} & -\frac{e^{2t}}{2} + \frac{1}{2} \\ \frac{3\,e^{2t}}{2} - \frac{3}{2} & -\frac{1}{2} + \frac{3\,e^{2t}}{2} \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} -\frac{e^{-2t}}{2} + \frac{3}{2} & \frac{1}{2} - \frac{e^{-2t}}{2} \\ -\frac{3}{2} + \frac{3\,e^{-2t}}{2} & \frac{3\,e^{-2t}}{2} - \frac{1}{2} \end{bmatrix} \int \begin{bmatrix} \frac{3}{2} - \frac{e^{2t}}{2} & -\frac{e^{2t}}{2} + \frac{1}{2} \\ \frac{3\,e^{2t}}{2} - \frac{3}{2} & -\frac{1}{2} + \frac{3\,e^{2t}}{2} \end{bmatrix} \begin{bmatrix} -t^2 + 6t \\ 3t^2 - 8t \end{bmatrix} dt \\ &= \begin{bmatrix} -\frac{e^{-2t}}{2} + \frac{3}{2} & \frac{1}{2} - \frac{e^{-2t}}{2} \\ -\frac{3}{2} + \frac{3\,e^{-2t}}{2} & \frac{3\,e^{-2t}}{2} - \frac{1}{2} \end{bmatrix} \begin{bmatrix} -\frac{(t-1)^2 e^{2t}}{2} + \frac{5t^2}{2} \\ \frac{3(t-1)^2 e^{2t}}{2} - \frac{5t^2}{2} \end{bmatrix} \\ &= \begin{bmatrix} 2t^2 + t - \frac{1}{2} \\ -t^2 - 3t + \frac{3}{2} \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$= \begin{bmatrix} \frac{(-c_1-c_2)e^{-2t}}{2} + \frac{3c_1}{2} + \frac{c_2}{2} + 2t^2 + t - \frac{1}{2} \\ \frac{(3c_1+3c_2)e^{-2t}}{2} - \frac{3c_1}{2} - \frac{c_2}{2} - t^2 - 3t + \frac{3}{2} \end{bmatrix}$$

16.13.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ -3 & -3 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -t^2 + 6t \\ 3t^2 - 8t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & 1 \\ -3 & -3 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & 1 \\ -3 & -3-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 2\lambda = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -2$$
$$\lambda_2 = 0$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
0	1	real eigenvalue
-2	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 \\ -3 & -3 \end{bmatrix} - (-2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 3 & 1 \\ -3 & -1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 3 & 1 & 0 \\ -3 & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} 3 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 3 & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{t}{3}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{t}{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{3} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{3} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 3 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 0$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 \\ -3 & -3 \end{bmatrix} - (0) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 1 & 1 \\ -3 & -3 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 & 1 & 0 \\ -3 & -3 & 0 \end{array}\right]$$

$$R_2 = R_2 + 3R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-2	1	1	No	$\begin{bmatrix} -\frac{1}{3} \\ 1 \end{bmatrix}$
0	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -2 is real and distinct then the

corresponding eigenvector solution is

$$\vec{x}_1(t) = \vec{v}_1 e^{-2t}$$
$$= \begin{bmatrix} -\frac{1}{3} \\ 1 \end{bmatrix} e^{-2t}$$

Since eigenvalue 0 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{0}$$
$$= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{0}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\frac{e^{-2t}}{3} \\ e^{-2t} \end{bmatrix} + c_2 \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -\frac{e^{-2t}}{3} & -1 \\ e^{-2t} & 1 \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{3\, e^{2t}}{2} & \frac{3\, e^{2t}}{2} \\ -\frac{3}{2} & -\frac{1}{2} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} -\frac{e^{-2t}}{3} & -1 \\ e^{-2t} & 1 \end{bmatrix} \int \begin{bmatrix} \frac{3\,e^{2t}}{2} & \frac{3\,e^{2t}}{2} \\ -\frac{3}{2} & -\frac{1}{2} \end{bmatrix} \begin{bmatrix} -t^2+6t \\ 3t^2-8t \end{bmatrix} dt$$

$$= \begin{bmatrix} -\frac{e^{-2t}}{3} & -1 \\ e^{-2t} & 1 \end{bmatrix} \int \begin{bmatrix} 3\,e^{2t}t(t-1) \\ -5t \end{bmatrix} dt$$

$$= \begin{bmatrix} -\frac{e^{-2t}}{3} & -1 \\ e^{-2t} & 1 \end{bmatrix} \begin{bmatrix} \frac{3(t-1)^2 e^{2t}}{2} \\ -\frac{5t^2}{2} \end{bmatrix}$$

$$= \begin{bmatrix} 2t^2+t-\frac{1}{2} \\ -t^2-3t+\frac{3}{2} \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{c_1 e^{-2t}}{3} \\ c_1 e^{-2t} \end{bmatrix} + \begin{bmatrix} -c_2 \\ c_2 \end{bmatrix} + \begin{bmatrix} 2t^2+t-\frac{1}{2} \\ -t^2-3t+\frac{3}{2} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{c_1 e^{-2t}}{3} - c_2 + 2t^2 + t - \frac{1}{2} \\ c_1 e^{-2t} + c_2 - t^2 - 3t + \frac{3}{2} \end{bmatrix}$$

16.13.3 Maple step by step solution

Let's solve

$[x'(t) = -t^2 + x(t) + y(t) + 6t, y'(t) = 3t^2 - 3x(t) - 3y(t) - 8t]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & 1 \\ -3 & -3 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} -t^2+6t \\ 3t^2-8t \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & 1 \\ -3 & -3 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} -t^2+6t \\ 3t^2-8t \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} -t^2+6t \\ 3t^2-8t \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & 1 \\ -3 & -3 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2, \begin{bmatrix} -\frac{1}{3} \\ 1 \end{bmatrix}\right], \left[0, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-2, \begin{bmatrix} -\frac{1}{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^{-2t} \cdot \begin{bmatrix} -\frac{1}{3} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{x}_p($

  $\overrightarrow{x}(t) = c_1\overrightarrow{x}_1 + c_2\overrightarrow{x}_2 + \overrightarrow{x}_p(t)$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

  $\phi(t) = \begin{bmatrix} -\frac{e^{-2t}}{3} & -1 \\ e^{-2t} & 1 \end{bmatrix}$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

  $\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(t)$ and $\phi(0)$

  $\Phi(t) = \begin{bmatrix} -\frac{e^{-2t}}{3} & -1 \\ e^{-2t} & 1 \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -\frac{1}{3} & -1 \\ 1 & 1 \end{bmatrix}}$

- Evaluate and simplify to get the fundamental matrix

  $\Phi(t) = \begin{bmatrix} -\frac{e^{-2t}}{2} + \frac{3}{2} & \frac{1}{2} - \frac{e^{-2t}}{2} \\ -\frac{3}{2} + \frac{3\,e^{-2t}}{2} & \frac{3\,e^{-2t}}{2} - \frac{1}{2} \end{bmatrix}$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

  $\overrightarrow{x}_p(t) = \Phi(t) \cdot \overrightarrow{v}(t)$

- Take the derivative of the particular solution

  $\overrightarrow{x}'_p(t) = \Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- Cancel like terms

  $\Phi(t) \cdot \overrightarrow{v}'(t) = \overrightarrow{f}(t)$

- Multiply by the inverse of the fundamental matrix

$\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$

- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\vec{x}_p(t) = \begin{bmatrix} 2t^2 + \frac{e^{-2t}}{2} + t - \frac{1}{2} \\ -t^2 + \frac{3}{2} - \frac{3\,e^{-2t}}{2} - 3t \end{bmatrix}$$

- Plug particular solution back into general solution

  $$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \begin{bmatrix} 2t^2 + \frac{e^{-2t}}{2} + t - \frac{1}{2} \\ -t^2 + \frac{3}{2} - \frac{3\,e^{-2t}}{2} - 3t \end{bmatrix}$$

- Substitute in vector of dependent variables

  $$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{(-2c_1+3)e^{-2t}}{6} + 2t^2 + t - c_2 - \frac{1}{2} \\ c_1 e^{-2t} - t^2 + \frac{3}{2} - \frac{3\,e^{-2t}}{2} - 3t + c_2 \end{bmatrix}$$

- Solution to the system of ODEs

  $$\left\{x(t) = \frac{(-2c_1+3)e^{-2t}}{6} + 2t^2 + t - c_2 - \frac{1}{2}, y(t) = c_1 e^{-2t} - t^2 + \frac{3}{2} - \frac{3\,e^{-2t}}{2} - 3t + c_2\right\}$$

Section: Chapter 7, Systems of linear differential equations. Section 7.1. Exercises page 277
Problem number: 14.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= -5 - x(t) - t - y(t) \\
y'(t) &= 7 + 2x(t) + 2t + y(t)
\end{aligned}
$$

16.14.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -1 & -1 \\ 2 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -5-t \\ 2t+7 \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \cos(t) - \sin(t) & -\sin(t) \\ 2\sin(t) & \cos(t) + \sin(t) \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \cos(t) - \sin(t) & -\sin(t) \\ 2\sin(t) & \cos(t) + \sin(t) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} (\cos(t) - \sin(t))\, c_1 - \sin(t)\, c_2 \\ 2\sin(t)\, c_1 + (\cos(t) + \sin(t))\, c_2 \end{bmatrix} \\
&= \begin{bmatrix} (-c_1 - c_2)\sin(t) + c_1 \cos(t) \\ (2c_1 + c_2)\sin(t) + c_2 \cos(t) \end{bmatrix}
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\, dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \begin{bmatrix} \cos(t) + \sin(t) & \sin(t) \\ -2\sin(t) & \cos(t) - \sin(t) \end{bmatrix}
\end{aligned}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \cos(t) - \sin(t) & -\sin(t) \\ 2\sin(t) & \cos(t) + \sin(t) \end{bmatrix} \int \begin{bmatrix} \cos(t) + \sin(t) & \sin(t) \\ -2\sin(t) & \cos(t) - \sin(t) \end{bmatrix} \begin{bmatrix} -5 - t \\ 2t + 7 \end{bmatrix} dt \\
&= \begin{bmatrix} \cos(t) - \sin(t) & -\sin(t) \\ 2\sin(t) & \cos(t) + \sin(t) \end{bmatrix} \begin{bmatrix} (-3 - t)\cos(t) - \sin(t)(t + 4) \\ \sin(t)(2t + 7) - \cos(t) \end{bmatrix} \\
&= \begin{bmatrix} -3 - t \\ -1 \end{bmatrix}
\end{aligned}$$

Hence the complete solution is

$$\begin{aligned}\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\ &= \begin{bmatrix} (-c_1 - c_2)\sin(t) + c_1\cos(t) - 3 - t \\ (2c_1 + c_2)\sin(t) + c_2\cos(t) - 1 \end{bmatrix}\end{aligned}$$

16.14.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -1 & -1 \\ 2 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -5 - t \\ 2t + 7 \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} -1 & -1 \\ 2 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -1 - \lambda & -1 \\ 2 & 1 - \lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 1 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = i$$
$$\lambda_2 = -i$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
i	1	complex eigenvalue
$-i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -1 & -1 \\ 2 & 1 \end{bmatrix} - (-i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} -1+i & -1 \\ 2 & 1+i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -1+i & -1 & 0 \\ 2 & 1+i & 0 \end{array}\right]$$

$$R_2 = R_2 + (1+i)\,R_1 \Longrightarrow \left[\begin{array}{cc|c} -1+i & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1+i & -1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \left(-\frac{1}{2} - \frac{i}{2}\right)t\right\}$

Hence the solution is

$$\begin{bmatrix} \left(-\frac{1}{2}-\frac{I}{2}\right)t \\ t \end{bmatrix} = \begin{bmatrix} \left(-\frac{1}{2}-\frac{i}{2}\right)t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \left(-\frac{1}{2}-\frac{I}{2}\right)t \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{2}-\frac{i}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \left(-\frac{1}{2}-\frac{I}{2}\right)t \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{2}-\frac{i}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \left(-\frac{1}{2}-\frac{I}{2}\right)t \\ t \end{bmatrix} = \begin{bmatrix} -1-i \\ 2 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -1 & -1 \\ 2 & 1 \end{bmatrix} - (i) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -1-i & -1 \\ 2 & 1-i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -1-i & -1 & 0 \\ 2 & 1-i & 0 \end{array}\right]$$

$$R_2 = R_2 + (1-i)\,R_1 \Longrightarrow \left[\begin{array}{cc|c} -1-i & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1-i & -1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \left(-\frac{1}{2} + \frac{i}{2}\right) t\right\}$

Hence the solution is

$$\begin{bmatrix} \left(-\frac{1}{2} + \frac{I}{2}\right) t \\ t \end{bmatrix} = \begin{bmatrix} \left(-\frac{1}{2} + \frac{i}{2}\right) t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \left(-\frac{1}{2} + \frac{I}{2}\right) t \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{2} + \frac{i}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \left(-\frac{1}{2} + \frac{I}{2}\right) t \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{2} + \frac{i}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \left(-\frac{1}{2} + \frac{I}{2}\right) t \\ t \end{bmatrix} = \begin{bmatrix} -1+i \\ 2 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
i	1	1	No	$\begin{bmatrix} -\frac{1}{2}+\frac{i}{2} \\ 1 \end{bmatrix}$
$-i$	1	1	No	$\begin{bmatrix} -\frac{1}{2}-\frac{i}{2} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \left(-\frac{1}{2}+\frac{i}{2}\right) e^{it} \\ e^{it} \end{bmatrix} + c_2 \begin{bmatrix} \left(-\frac{1}{2}-\frac{i}{2}\right) e^{-it} \\ e^{-it} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} \left(-\frac{1}{2}+\frac{i}{2}\right) e^{it} & \left(-\frac{1}{2}-\frac{i}{2}\right) e^{-it} \\ e^{it} & e^{-it} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t) \, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -i e^{-it} & \left(\frac{1}{2}-\frac{i}{2}\right) e^{-it} \\ i e^{it} & \left(\frac{1}{2}+\frac{i}{2}\right) e^{it} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} \left(-\frac{1}{2}+\frac{i}{2}\right) e^{it} & \left(-\frac{1}{2}-\frac{i}{2}\right) e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} -i e^{-it} & \left(\frac{1}{2}-\frac{i}{2}\right) e^{-it} \\ i e^{it} & \left(\frac{1}{2}+\frac{i}{2}\right) e^{it} \end{bmatrix} \begin{bmatrix} -5-t \\ 2t+7 \end{bmatrix} dt$$

$$= \begin{bmatrix} \left(-\frac{1}{2}+\frac{i}{2}\right) e^{it} & \left(-\frac{1}{2}-\frac{i}{2}\right) e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} \frac{e^{-it}(7+3i+2t)}{2} \\ -\frac{e^{it}(-7+3i-2t)}{2} \end{bmatrix} dt$$

$$= \begin{bmatrix} \left(-\frac{1}{2}+\frac{i}{2}\right) e^{it} & \left(-\frac{1}{2}-\frac{i}{2}\right) e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \begin{bmatrix} \frac{e^{-it}(2it+7i-1)}{2} \\ -\frac{e^{it}(2it+7i+1)}{2} \end{bmatrix}$$

$$= \begin{bmatrix} -3-t \\ -1 \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \left(-\frac{1}{2}+\frac{i}{2}\right) c_1 e^{it} \\ c_1 e^{it} \end{bmatrix} + \begin{bmatrix} \left(-\frac{1}{2}-\frac{i}{2}\right) c_2 e^{-it} \\ c_2 e^{-it} \end{bmatrix} + \begin{bmatrix} -3-t \\ -1 \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \left(-\frac{1}{2}+\frac{i}{2}\right) c_1 e^{it} + \left(-\frac{1}{2}-\frac{i}{2}\right) c_2 e^{-it} - 3 - t \\ c_1 e^{it} + c_2 e^{-it} - 1 \end{bmatrix}$$

16.14.3 Maple step by step solution

Let's solve

$[x'(t) = -5 - x(t) - t - y(t), y'(t) = 7 + 2x(t) + 2t + y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} -1 & -1 \\ 2 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} -5-t \\ 2t+7 \end{bmatrix}$$

- System to solve

$$\overrightarrow{x}'(t) = \begin{bmatrix} -1 & -1 \\ 2 & 1 \end{bmatrix} \cdot \overrightarrow{x}(t) + \begin{bmatrix} -5-t \\ 2t+7 \end{bmatrix}$$

- Define the forcing function

$$\overrightarrow{f}(t) = \begin{bmatrix} -5-t \\ 2t+7 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} -1 & -1 \\ 2 & 1 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t) + \overrightarrow{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-\mathrm{I}, \begin{bmatrix} -\frac{1}{2}-\frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} -\frac{1}{2}+\frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} -\frac{1}{2}-\frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$\mathrm{e}^{-\mathrm{I}t} \cdot \begin{bmatrix} -\frac{1}{2}-\frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$(\cos(t) - \mathrm{I}\sin(t)) \cdot \begin{bmatrix} -\frac{1}{2}-\frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} \left(-\frac{1}{2}-\frac{\mathrm{I}}{2}\right)(\cos(t) - \mathrm{I}\sin(t)) \\ \cos(t) - \mathrm{I}\sin(t) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{x}_1(t) = \begin{bmatrix} -\frac{\cos(t)}{2} - \frac{\sin(t)}{2} \\ \cos(t) \end{bmatrix}, \vec{x}_2(t) = \begin{bmatrix} \frac{\sin(t)}{2} - \frac{\cos(t)}{2} \\ -\sin(t) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

$\vec{x}(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + \vec{x}_p(t)$

☐ Fundamental matrix

  - Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(t) = \begin{bmatrix} -\frac{\cos(t)}{2} - \frac{\sin(t)}{2} & \frac{\sin(t)}{2} - \frac{\cos(t)}{2} \\ \cos(t) & -\sin(t) \end{bmatrix}$$

  - The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$

  - Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} -\frac{\cos(t)}{2} - \frac{\sin(t)}{2} & \frac{\sin(t)}{2} - \frac{\cos(t)}{2} \\ \cos(t) & -\sin(t) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -\frac{1}{2} & -\frac{1}{2} \\ 1 & 0 \end{bmatrix}}$$

  - Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} \cos(t) - \sin(t) & -\sin(t) \\ 2\sin(t) & \cos(t) + \sin(t) \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

  - Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

$\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$

  - Take the derivative of the particular solution

$\vec{x}_p'(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$

  - Substitute particular solution and its derivative into the system of ODEs

$\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$

  - The fundamental matrix has columns that are solutions to the homogeneous system so its der

$A \cdot \Phi(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$

  - Cancel like terms

$\Phi(t)\cdot \vec{v}'(t)=\vec{f}(t)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(t)=\frac{1}{\Phi(t)}\cdot \vec{f}(t)$

- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t)=\int_0^t \frac{1}{\Phi(s)}\cdot \vec{f}(s)\,ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t)=\Phi(t)\cdot\left(\int_0^t \frac{1}{\Phi(s)}\cdot \vec{f}(s)\,ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\vec{x}_p(t)=\left[\begin{array}{c} -t-3+3\cos(t)-4\sin(t) \\ -1+\cos(t)+7\sin(t) \end{array}\right]$$

- Plug particular solution back into general solution

  $$\vec{x}(t)=c_1\vec{x}_1(t)+c_2\vec{x}_2(t)+\left[\begin{array}{c} -t-3+3\cos(t)-4\sin(t) \\ -1+\cos(t)+7\sin(t) \end{array}\right]$$

- Substitute in vector of dependent variables

  $$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right]=\left[\begin{array}{c} \frac{(6-c_1-c_2)\cos(t)}{2}+\frac{(-c_1+c_2-8)\sin(t)}{2}-t-3 \\ (1+c_1)\cos(t)-1+(-c_2+7)\sin(t) \end{array}\right]$$

- Solution to the system of ODEs

  $$\left\{x(t)=\frac{(6-c_1-c_2)\cos(t)}{2}+\frac{(-c_1+c_2-8)\sin(t)}{2}-t-3, y(t)=(1+c_1)\cos(t)-1+(-c_2+7)\sin(t)\right\}$$

✓ Solution by Maple

ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= -\frac{7x(t)}{2} - \frac{9y(t)}{2} + \frac{\mathrm{e}^t}{2} \\
y'(t) &= \frac{3x(t)}{2} + \frac{5y(t)}{2} + \frac{\mathrm{e}^t}{2}
\end{aligned}
$$

16.15.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -\frac{7}{2} & -\frac{9}{2} \\ \frac{3}{2} & \frac{5}{2} \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \frac{\mathrm{e}^t}{2} \\ \frac{\mathrm{e}^t}{2} \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} -\frac{(e^{3t}-3)e^{-2t}}{2} & -\frac{3(e^{3t}-1)e^{-2t}}{2} \\ \frac{(e^{3t}-1)e^{-2t}}{2} & \frac{(3e^{3t}-1)e^{-2t}}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} -\frac{(e^{3t}-3)e^{-2t}}{2} & -\frac{3(e^{3t}-1)e^{-2t}}{2} \\ \frac{(e^{3t}-1)e^{-2t}}{2} & \frac{(3e^{3t}-1)e^{-2t}}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} -\frac{(e^{3t}-3)e^{-2t}c_1}{2} - \frac{3(e^{3t}-1)e^{-2t}c_2}{2} \\ \frac{(e^{3t}-1)e^{-2t}c_1}{2} + \frac{(3e^{3t}-1)e^{-2t}c_2}{2} \end{bmatrix} \\ &= \begin{bmatrix} -\frac{((c_1+3c_2)e^{3t}-3c_1-3c_2)e^{-2t}}{2} \\ \frac{((c_1+3c_2)e^{3t}-c_1-c_2)e^{-2t}}{2} \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\, dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} \frac{3e^{2t}}{2} - \frac{e^{-t}}{2} & \frac{3e^{2t}}{2} - \frac{3e^{-t}}{2} \\ -\frac{e^{2t}}{2} + \frac{e^{-t}}{2} & -\frac{e^{2t}}{2} + \frac{3e^{-t}}{2} \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} -\frac{(e^{3t}-3)e^{-2t}}{2} & -\frac{3(e^{3t}-1)e^{-2t}}{2} \\ \frac{(e^{3t}-1)e^{-2t}}{2} & \frac{(3e^{3t}-1)e^{-2t}}{2} \end{bmatrix} \int \begin{bmatrix} \frac{3e^{2t}}{2} - \frac{e^{-t}}{2} & \frac{3e^{2t}}{2} - \frac{3e^{-t}}{2} \\ -\frac{e^{2t}}{2} + \frac{e^{-t}}{2} & -\frac{e^{2t}}{2} + \frac{3e^{-t}}{2} \end{bmatrix} \begin{bmatrix} \frac{e^{t}}{2} \\ \frac{e^{t}}{2} \end{bmatrix} dt \\ &= \begin{bmatrix} -\frac{(e^{3t}-3)e^{-2t}}{2} & -\frac{3(e^{3t}-1)e^{-2t}}{2} \\ \frac{(e^{3t}-1)e^{-2t}}{2} & \frac{(3e^{3t}-1)e^{-2t}}{2} \end{bmatrix} \begin{bmatrix} -t + \frac{e^{3t}}{2} \\ t - \frac{e^{3t}}{6} \end{bmatrix} \\ &= \begin{bmatrix} e^{t}\left(\frac{1}{2} - t\right) \\ e^{t}\left(t - \frac{1}{6}\right) \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$= \begin{bmatrix} -\left(\left(t+\frac{c_1}{2}+\frac{3c_2}{2}-\frac{1}{2}\right)e^{3t}-\frac{3c_1}{2}-\frac{3c_2}{2}\right)e^{-2t} \\ \left(\left(\frac{c_1}{2}+\frac{3c_2}{2}+t-\frac{1}{6}\right)e^{3t}-\frac{c_1}{2}-\frac{c_2}{2}\right)e^{-2t} \end{bmatrix}$$

16.15.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -\frac{7}{2} & -\frac{9}{2} \\ \frac{3}{2} & \frac{5}{2} \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \frac{e^t}{2} \\ \frac{e^t}{2} \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} -\frac{7}{2} & -\frac{9}{2} \\ \frac{3}{2} & \frac{5}{2} \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -\frac{7}{2}-\lambda & -\frac{9}{2} \\ \frac{3}{2} & \frac{5}{2}-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + \lambda - 2 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -2$$
$$\lambda_2 = 1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-2	1	real eigenvalue
1	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -\frac{7}{2} & -\frac{9}{2} \\ \frac{3}{2} & \frac{5}{2} \end{bmatrix} - (-2) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} -\frac{3}{2} & -\frac{9}{2} \\ \frac{3}{2} & \frac{9}{2} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -\frac{3}{2} & -\frac{9}{2} & 0 \\ \frac{3}{2} & \frac{9}{2} & 0 \end{array} \right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} -\frac{3}{2} & -\frac{9}{2} & 0 \\ 0 & 0 & 0 \end{array} \right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -\frac{3}{2} & -\frac{9}{2} \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -3t\}$

Hence the solution is

$$\begin{bmatrix} -3t \\ t \end{bmatrix} = \begin{bmatrix} -3t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -3t \\ t \end{bmatrix} = t \begin{bmatrix} -3 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -3t \\ t \end{bmatrix} = \begin{bmatrix} -3 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -\frac{7}{2} & -\frac{9}{2} \\ \frac{3}{2} & \frac{5}{2} \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -\frac{9}{2} & -\frac{9}{2} \\ \frac{3}{2} & \frac{3}{2} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -\frac{9}{2} & -\frac{9}{2} & 0 \\ \frac{3}{2} & \frac{3}{2} & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{3} \implies \left[\begin{array}{cc|c} -\frac{9}{2} & -\frac{9}{2} & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -\frac{9}{2} & -\frac{9}{2} \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-2	1	1	No	$\begin{bmatrix} -3 \\ 1 \end{bmatrix}$
1	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -2 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{-2t} \\ &= \begin{bmatrix} -3 \\ 1 \end{bmatrix} e^{-2t} \end{aligned}$$

Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^t \\ &= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^t\end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -3\,\mathrm{e}^{-2t} \\ \mathrm{e}^{-2t} \end{bmatrix} + c_2 \begin{bmatrix} -\mathrm{e}^{t} \\ \mathrm{e}^{t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -3\,\mathrm{e}^{-2t} & -\mathrm{e}^{t} \\ \mathrm{e}^{-2t} & \mathrm{e}^{t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{\mathrm{e}^{2t}}{2} & -\frac{\mathrm{e}^{2t}}{2} \\ \frac{\mathrm{e}^{-t}}{2} & \frac{3\,\mathrm{e}^{-t}}{2} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} -3\,\mathrm{e}^{-2t} & -\mathrm{e}^{t} \\ \mathrm{e}^{-2t} & \mathrm{e}^{t} \end{bmatrix} \int \begin{bmatrix} -\frac{\mathrm{e}^{2t}}{2} & -\frac{\mathrm{e}^{2t}}{2} \\ \frac{\mathrm{e}^{-t}}{2} & \frac{3\,\mathrm{e}^{-t}}{2} \end{bmatrix} \begin{bmatrix} \frac{\mathrm{e}^{t}}{2} \\ \frac{\mathrm{e}^{t}}{2} \end{bmatrix} dt$$

$$= \begin{bmatrix} -3\,\mathrm{e}^{-2t} & -\mathrm{e}^{t} \\ \mathrm{e}^{-2t} & \mathrm{e}^{t} \end{bmatrix} \int \begin{bmatrix} -\frac{\mathrm{e}^{3t}}{2} \\ 1 \end{bmatrix} dt$$

$$= \begin{bmatrix} -3\,\mathrm{e}^{-2t} & -\mathrm{e}^{t} \\ \mathrm{e}^{-2t} & \mathrm{e}^{t} \end{bmatrix} \begin{bmatrix} -\frac{\mathrm{e}^{3t}}{6} \\ t \end{bmatrix}$$

$$= \begin{bmatrix} \mathrm{e}^{t}\left(\frac{1}{2} - t\right) \\ \mathrm{e}^{t}\left(t - \frac{1}{6}\right) \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -3c_1\mathrm{e}^{-2t} \\ c_1\mathrm{e}^{-2t} \end{bmatrix} + \begin{bmatrix} -c_2\mathrm{e}^{t} \\ c_2\mathrm{e}^{t} \end{bmatrix} + \begin{bmatrix} \mathrm{e}^{t}\left(\frac{1}{2} - t\right) \\ \mathrm{e}^{t}\left(t - \frac{1}{6}\right) \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\left(\left(t + c_2 - \frac{1}{2}\right)\mathrm{e}^{3t} + 3c_1\right)\mathrm{e}^{-2t} \\ \mathrm{e}^{-2t}\left(\left(c_2 + t - \frac{1}{6}\right)\mathrm{e}^{3t} + c_1\right) \end{bmatrix}$$

16.15.3 Maple step by step solution

Let's solve

$$\left[x'(t) = -\frac{7x(t)}{2} - \frac{9y(t)}{2} + \frac{\mathrm{e}^{t}}{2}, y'(t) = \frac{3x(t)}{2} + \frac{5y(t)}{2} + \frac{\mathrm{e}^{t}}{2}\right]$$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} -\frac{7}{2} & -\frac{9}{2} \\ \frac{3}{2} & \frac{5}{2} \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} \frac{\mathrm{e}^{t}}{2} \\ \frac{\mathrm{e}^{t}}{2} \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \left[\begin{array}{cc} -\frac{7}{2} & -\frac{9}{2} \\ \frac{3}{2} & \frac{5}{2} \end{array}\right] \cdot \vec{x}(t) + \left[\begin{array}{c} \frac{e^{t}}{2} \\ \frac{e^{t}}{2} \end{array}\right]$$

- Define the forcing function

$$\vec{f}(t) = \left[\begin{array}{c} \frac{e^{t}}{2} \\ \frac{e^{t}}{2} \end{array}\right]$$

- Define the coefficient matrix

$$A = \left[\begin{array}{cc} -\frac{7}{2} & -\frac{9}{2} \\ \frac{3}{2} & \frac{5}{2} \end{array}\right]$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2, \left[\begin{array}{c} -3 \\ 1 \end{array}\right]\right], \left[1, \left[\begin{array}{c} -1 \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-2, \left[\begin{array}{c} -3 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = e^{-2t} \cdot \left[\begin{array}{c} -3 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c} -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = e^{t} \cdot \left[\begin{array}{c} -1 \\ 1 \end{array}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

  $\vec{x}(t)=c_1\vec{x}_1+c_2\vec{x}_2+\vec{x}_p(t)$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

  $\phi(t)=\begin{bmatrix} -3\,\mathrm{e}^{-2t} & -\mathrm{e}^{t} \\ \mathrm{e}^{-2t} & \mathrm{e}^{t} \end{bmatrix}$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0)=I$ where I is th

  $\Phi(t)=\phi(t)\cdot\frac{1}{\phi(0)}$

- Substitute the value of $\phi(t)$ and $\phi(0)$

  $\Phi(t)=\begin{bmatrix} -3\,\mathrm{e}^{-2t} & -\mathrm{e}^{t} \\ \mathrm{e}^{-2t} & \mathrm{e}^{t} \end{bmatrix}\cdot\frac{1}{\begin{bmatrix} -3 & -1 \\ 1 & 1 \end{bmatrix}}$

- Evaluate and simplify to get the fundamental matrix

  $\Phi(t)=\begin{bmatrix} -\frac{(\mathrm{e}^{3t}-3)\mathrm{e}^{-2t}}{2} & -\frac{3(\mathrm{e}^{3t}-1)\mathrm{e}^{-2t}}{2} \\ \frac{(\mathrm{e}^{3t}-1)\mathrm{e}^{-2t}}{2} & \frac{(3\,\mathrm{e}^{3t}-1)\mathrm{e}^{-2t}}{2} \end{bmatrix}$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

  $\vec{x}_p(t)=\Phi(t)\cdot\vec{v}(t)$

- Take the derivative of the particular solution

  $\vec{x}_p'(t)=\Phi'(t)\cdot\vec{v}(t)+\Phi(t)\cdot\vec{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t)\cdot\vec{v}(t)+\Phi(t)\cdot\vec{v}'(t)=A\cdot\Phi(t)\cdot\vec{v}(t)+\vec{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A\cdot\Phi(t)\cdot\vec{v}(t)+\Phi(t)\cdot\vec{v}'(t)=A\cdot\Phi(t)\cdot\vec{v}(t)+\vec{f}(t)$

- Cancel like terms

  $\Phi(t)\cdot\vec{v}'(t)=\vec{f}(t)$

- Multiply by the inverse of the fundamental matrix

$\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$

- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\vec{x}_p(t) = \begin{bmatrix} \frac{(1-2t)e^{-2t}e^{3t}}{2} - \frac{e^{-2t}}{2} \\ \frac{(6t-1)e^{-2t}e^{3t}}{6} + \frac{e^{-2t}}{6} \end{bmatrix}$$

- Plug particular solution back into general solution

  $$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \begin{bmatrix} \frac{(1-2t)e^{-2t}e^{3t}}{2} - \frac{e^{-2t}}{2} \\ \frac{(6t-1)e^{-2t}e^{3t}}{6} + \frac{e^{-2t}}{6} \end{bmatrix}$$

- Substitute in vector of dependent variables

  $$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\left(\left(t + c_2 - \frac{1}{2}\right)e^{3t} + 3c_1 + \frac{1}{2}\right)e^{-2t} \\ \left(\left(c_2 + t - \frac{1}{6}\right)e^{3t} + c_1 + \frac{1}{6}\right)e^{-2t} \end{bmatrix}$$

- Solution to the system of ODEs

  $$\left\{x(t) = -\left(\left(t + c_2 - \frac{1}{2}\right)e^{3t} + 3c_1 + \frac{1}{2}\right)e^{-2t}, y(t) = \left(\left(c_2 + t - \frac{1}{6}\right)e^{3t} + c_1 + \frac{1}{6}\right)e^{-2t}\right\}$$

✓ Solution by Maple

Time used: 0.032 (sec). Leaf size: 45

```
dsolve([2*diff(x(t),t)+4*diff(y(t),t)+x(t)-y(t)=3*exp(t),diff(x(t),t)+diff(y(t),t)+2*x(t)+2*
```

$$x(t) = c_2 e^t + c_1 e^{-2t} - e^t t$$

$$y(t) = -c_2 e^t - \frac{c_1 e^{-2t}}{3} + e^t t + \frac{e^t}{3}$$

✓ Solution by Mathematica

Time used: 0.014 (sec). Leaf size: 76

```
DSolve[{2*x'[t]+4*y'[t]+x[t]-y[t]==3*Exp[t],x'[t]+y'[t]+2*x[t]+2*y[t]==Exp[t]},{x[t],y[t]},t
```

$$x(t) \to \frac{3}{2}(c_1 + c_2)e^{-2t} - \frac{1}{2}e^t(2t - 1 + c_1 + 3c_2)$$
$$y(t) \to \frac{1}{6}e^t(6t - 1 + 3c_1 + 9c_2) - \frac{1}{2}(c_1 + c_2)e^{-2t}$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 2x(t) - 2t - t^2 \\
y'(t) &= -3x(t) + y(t) + 2t + 2t^2
\end{aligned}
$$

16.16.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 2 & 0 \\ -3 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -t^2 - 2t \\ 2t^2 + 2t \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} e^{2t} & 0 \\ -3\,e^{2t}+3\,e^{t} & e^{t} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} e^{2t} & 0 \\ -3\,e^{2t}+3\,e^{t} & e^{t} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} e^{2t}c_1 \\ (-3\,e^{2t}+3\,e^{t})\,c_1 + e^{t}c_2 \end{bmatrix}
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At}\int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \begin{bmatrix} e^{-2t} & 0 \\ 3\,e^{-2t}(e^{t}-1) & e^{-t} \end{bmatrix}
\end{aligned}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} e^{2t} & 0 \\ -3\,e^{2t}+3\,e^{t} & e^{t} \end{bmatrix} \int \begin{bmatrix} e^{-2t} & 0 \\ 3\,e^{-2t}(e^{t}-1) & e^{-t} \end{bmatrix} \begin{bmatrix} -t^2-2t \\ 2t^2+2t \end{bmatrix} dt \\
&= \begin{bmatrix} e^{2t} & 0 \\ -3\,e^{2t}+3\,e^{t} & e^{t} \end{bmatrix} \begin{bmatrix} \frac{e^{-2t}(2t^2+6t+3)}{4} \\ \frac{3(-2t^2-6t-3)e^{-2t}}{4} + e^{-t}(t^2+6t+6) \end{bmatrix} \\
&= \begin{bmatrix} \frac{1}{2}t^2+\frac{3}{2}t+\frac{3}{4} \\ -\frac{1}{2}t^2+\frac{3}{2}t+\frac{15}{4} \end{bmatrix}
\end{aligned}$$

Hence the complete solution is

$$\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
&= \begin{bmatrix} e^{2t}c_1 + \frac{t^2}{2} + \frac{3t}{2} + \frac{3}{4} \\ \frac{15}{4} - 3\,e^{2t}c_1 + e^{t}(3c_1+c_2) - \frac{t^2}{2} + \frac{3t}{2} \end{bmatrix}
\end{aligned}$$

16.16.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 2 & 0 \\ -3 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -t^2 - 2t \\ 2t^2 + 2t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 2 & 0 \\ -3 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 2-\lambda & 0 \\ -3 & 1-\lambda \end{bmatrix}\right) = 0$$

Since the matrix A is triangular matrix, then the determinant is the product of the elements along the diagonal. Therefore the above becomes

$$(2-\lambda)(1-\lambda) = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 2$$
$$\lambda_2 = 1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue
2	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & 0 \\ -3 & 1 \end{bmatrix} - (1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 1 & 0 \\ -3 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 & 0 & 0 \\ -3 & 0 & 0 \end{array}\right]$$

$$R_2 = R_2 + 3R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 & 0 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 0\}$

Hence the solution is

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = t\begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & 0 \\ -3 & 1 \end{bmatrix} - (2) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 0 & 0 \\ -3 & -1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 0 & 0 & 0 \\ -3 & -1 & 0 \end{array}\right]$$

Since the current pivot $A(1,1)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 1 and row 2 gives

$$\left[\begin{array}{cc|c} -3 & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -3 & -1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{t}{3}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{t}{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{3} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{3} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 3 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
2	1	1	No	$\begin{bmatrix} -\frac{1}{3} \\ 1 \end{bmatrix}$
1	1	1	No	$\begin{bmatrix} 0 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 2 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{2t} \\ &= \begin{bmatrix} -\frac{1}{3} \\ 1 \end{bmatrix} e^{2t} \end{aligned}$$

Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_2(t) &= \vec{v}_2 e^{t} \\ &= \begin{bmatrix} 0 \\ 1 \end{bmatrix} e^{t} \end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\frac{e^{2t}}{3} \\ e^{2t} \end{bmatrix} + c_2 \begin{bmatrix} 0 \\ e^{t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -\frac{e^{2t}}{3} & 0 \\ e^{2t} & e^{t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1}\vec{G}(t)\,dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -3\,e^{-2t} & 0 \\ 3\,e^{-t} & e^{-t} \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} -\frac{e^{2t}}{3} & 0 \\ e^{2t} & e^{t} \end{bmatrix} \int \begin{bmatrix} -3\,e^{-2t} & 0 \\ 3\,e^{-t} & e^{-t} \end{bmatrix} \begin{bmatrix} -t^2 - 2t \\ 2t^2 + 2t \end{bmatrix} dt \\
&= \begin{bmatrix} -\frac{e^{2t}}{3} & 0 \\ e^{2t} & e^{t} \end{bmatrix} \int \begin{bmatrix} 3\,e^{-2t}t(t+2) \\ -e^{-t}t(t+4) \end{bmatrix} dt \\
&= \begin{bmatrix} -\frac{e^{2t}}{3} & 0 \\ e^{2t} & e^{t} \end{bmatrix} \begin{bmatrix} -\frac{3\,e^{-2t}(2t^2+6t+3)}{4} \\ e^{-t}(t^2+6t+6) \end{bmatrix} \\
&= \begin{bmatrix} \frac{1}{2}t^2 + \frac{3}{2}t + \frac{3}{4} \\ -\frac{1}{2}t^2 + \frac{3}{2}t + \frac{15}{4} \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{c_1 e^{2t}}{3} \\ c_1 e^{2t} \end{bmatrix} + \begin{bmatrix} 0 \\ c_2 e^{t} \end{bmatrix} + \begin{bmatrix} \frac{1}{2}t^2 + \frac{3}{2}t + \frac{3}{4} \\ -\frac{1}{2}t^2 + \frac{3}{2}t + \frac{15}{4} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{c_1 e^{2t}}{3} + \frac{t^2}{2} + \frac{3t}{2} + \frac{3}{4} \\ c_1 e^{2t} + c_2 e^{t} - \frac{t^2}{2} + \frac{3t}{2} + \frac{15}{4} \end{bmatrix}$$

16.16.3 Maple step by step solution

Let's solve

$[x'(t) = 2x(t) - 2t - t^2, y'(t) = -3x(t) + y(t) + 2t + 2t^2]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 2 & 0 \\ -3 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} -t^2 - 2t \\ 2t^2 + 2t \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 2 & 0 \\ -3 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} -t^2 - 2t \\ 2t^2 + 2t \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} -t^2 - 2t \\ 2t^2 + 2t \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 2 & 0 \\ -3 & 1 \end{bmatrix}$$

- Rewrite the system as

  $\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t) + \overrightarrow{f}$
- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

  $$\left[\left[1, \left[\begin{array}{c} 0 \\ 1 \end{array}\right]\right], \left[2, \left[\begin{array}{c} -\frac{1}{3} \\ 1 \end{array}\right]\right]\right]$$
- Consider eigenpair

  $$\left[1, \left[\begin{array}{c} 0 \\ 1 \end{array}\right]\right]$$
- Solution to homogeneous system from eigenpair

  $$\overrightarrow{x}_1 = e^t \cdot \left[\begin{array}{c} 0 \\ 1 \end{array}\right]$$
- Consider eigenpair

  $$\left[2, \left[\begin{array}{c} -\frac{1}{3} \\ 1 \end{array}\right]\right]$$
- Solution to homogeneous system from eigenpair

  $$\overrightarrow{x}_2 = e^{2t} \cdot \left[\begin{array}{c} -\frac{1}{3} \\ 1 \end{array}\right]$$
- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{x}_p($

  $\overrightarrow{x}(t) = c_1 \overrightarrow{x}_1 + c_2 \overrightarrow{x}_2 + \overrightarrow{x}_p(t)$

□ Fundamental matrix

  - Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

    $$\phi(t) = \left[\begin{array}{cc} 0 & -\frac{e^{2t}}{3} \\ e^t & e^{2t} \end{array}\right]$$
  - The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

    $\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$
  - Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} 0 & -\frac{e^{2t}}{3} \\ e^{t} & e^{2t} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 0 & -\frac{1}{3} \\ 1 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} e^{2t} & 0 \\ -3\,e^{2t} + 3\,e^{t} & e^{t} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

$$\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$$

- Take the derivative of the particular solution

$$\vec{x}'_p(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$$

- Substitute particular solution and its derivative into the system of ODEs

$$\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$$A \cdot \Phi(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$$

- Cancel like terms

$$\Phi(t) \cdot \vec{v}'(t) = \vec{f}(t)$$

- Multiply by the inverse of the fundamental matrix

$$\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$$

- Integrate to solve for $\vec{v}(t)$

$$\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\,ds$$

- Plug $\vec{v}(t)$ into the equation for the particular solution

$$\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\,ds\right)$$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{x}_p(t) = \begin{bmatrix} \frac{t^2}{2} - \frac{3\,e^{2t}}{4} + \frac{3t}{2} + \frac{3}{4} \\ -\frac{t^2}{2} + \frac{9\,e^{2t}}{4} - 6\,e^{t} + \frac{3t}{2} + \frac{15}{4} \end{bmatrix}$$

• Plug particular solution back into general solution

$$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \left[\begin{array}{c} \frac{t^2}{2} - \frac{3\,e^{2t}}{4} + \frac{3t}{2} + \frac{3}{4} \\ -\frac{t^2}{2} + \frac{9\,e^{2t}}{4} - 6\,e^t + \frac{3t}{2} + \frac{15}{4} \end{array}\right]$$

- Substitute in vector of dependent variables

$$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} \frac{(-4c_2-9)e^{2t}}{12} + \frac{t^2}{2} + \frac{3t}{2} + \frac{3}{4} \\ \frac{15}{4} + \frac{(4c_2+9)e^{2t}}{4} + (c_1-6)\,e^t - \frac{t^2}{2} + \frac{3t}{2} \end{array}\right]$$

- Solution to the system of ODEs

$$\left\{x(t) = \frac{(-4c_2-9)e^{2t}}{12} + \frac{t^2}{2} + \frac{3t}{2} + \frac{3}{4}, y(t) = \frac{15}{4} + \frac{(4c_2+9)e^{2t}}{4} + (c_1-6)\,e^t - \frac{t^2}{2} + \frac{3t}{2}\right\}$$

✓ Solution by Maple

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 7, Systems of linear differential equations. Section 7.1. Exercises page 277
Problem number: 17.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 3x(t) - t + 1 \\
y'(t) &= -5x(t) + y(t) + 2t - 1
\end{aligned}
$$

16.17.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 3 & 0 \\ -5 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 1-t \\ 2t-1 \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} e^{3t} & 0 \\ -\frac{5\,e^{3t}}{2} + \frac{5\,e^{t}}{2} & e^{t} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} e^{3t} & 0 \\ -\frac{5\,e^{3t}}{2} + \frac{5\,e^{t}}{2} & e^{t} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} e^{3t} c_1 \\ \left(-\frac{5\,e^{3t}}{2} + \frac{5\,e^{t}}{2}\right) c_1 + e^{t} c_2 \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\,dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} e^{-3t} & 0 \\ \frac{5\,e^{-3t}\left(e^{2t}-1\right)}{2} & e^{-t} \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} e^{3t} & 0 \\ -\frac{5\,e^{3t}}{2} + \frac{5\,e^{t}}{2} & e^{t} \end{bmatrix} \int \begin{bmatrix} e^{-3t} & 0 \\ \frac{5\,e^{-3t}\left(e^{2t}-1\right)}{2} & e^{-t} \end{bmatrix} \begin{bmatrix} 1-t \\ 2t-1 \end{bmatrix} dt \\ &= \begin{bmatrix} e^{3t} & 0 \\ -\frac{5\,e^{3t}}{2} + \frac{5\,e^{t}}{2} & e^{t} \end{bmatrix} \begin{bmatrix} \frac{e^{-3t}(-2+3t)}{9} \\ \frac{5(2-3t)e^{-3t}}{18} + \frac{e^{-t}(-2+t)}{2} \end{bmatrix} \\ &= \begin{bmatrix} -\frac{2}{9} + \frac{t}{3} \\ -\frac{4}{9} - \frac{t}{3} \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$\begin{aligned} \vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\ &= \begin{bmatrix} e^{3t} c_1 - \frac{2}{9} + \frac{t}{3} \\ -\frac{4}{9} - \frac{5\,e^{3t} c_1}{2} + \frac{e^{t}(5c_1+2c_2)}{2} - \frac{t}{3} \end{bmatrix} \end{aligned}$$

16.17.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 3 & 0 \\ -5 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 1-t \\ 2t-1 \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 3 & 0 \\ -5 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 3-\lambda & 0 \\ -5 & 1-\lambda \end{bmatrix}\right) = 0$$

Since the matrix A is triangular matrix, then the determinant is the product of the elements along the diagonal. Therefore the above becomes

$$(3-\lambda)(1-\lambda) = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 3$$
$$\lambda_2 = 1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue
3	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & 0 \\ -5 & 1 \end{bmatrix} - (1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 2 & 0 \\ -5 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2 & 0 & 0 \\ -5 & 0 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{5R_1}{2} \Longrightarrow \left[\begin{array}{cc|c} 2 & 0 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & 0 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 0\}$

Hence the solution is

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = t\begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & 0 \\ -5 & 1 \end{bmatrix} - (3) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 0 & 0 \\ -5 & -2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 0 & 0 & 0 \\ -5 & -2 & 0 \end{array}\right]$$

Since the current pivot $A(1, 1)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 1 and row 2 gives

$$\left[\begin{array}{cc|c} -5 & -2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -5 & -2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{2t}{5}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{2t}{5} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{2t}{5} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{2t}{5} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{2}{5} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{2t}{5} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{2}{5} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{2t}{5} \\ t \end{bmatrix} = \begin{bmatrix} -2 \\ 5 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
3	1	1	No	$\begin{bmatrix} -\frac{2}{5} \\ 1 \end{bmatrix}$
1	1	1	No	$\begin{bmatrix} 0 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 3 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{3t} \\ &= \begin{bmatrix} -\frac{2}{5} \\ 1 \end{bmatrix} e^{3t} \end{aligned}$$

Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_2(t) &= \vec{v}_2 e^{t} \\ &= \begin{bmatrix} 0 \\ 1 \end{bmatrix} e^{t} \end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\frac{2\,\mathrm{e}^{3t}}{5} \\ \mathrm{e}^{3t} \end{bmatrix} + c_2 \begin{bmatrix} 0 \\ \mathrm{e}^{t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -\frac{2\,\mathrm{e}^{3t}}{5} & 0 \\ \mathrm{e}^{3t} & \mathrm{e}^{t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1}\vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{5\,\mathrm{e}^{-3t}}{2} & 0 \\ \frac{5\,\mathrm{e}^{-t}}{2} & \mathrm{e}^{-t} \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} -\frac{2\,\mathrm{e}^{3t}}{5} & 0 \\ \mathrm{e}^{3t} & \mathrm{e}^{t} \end{bmatrix} \int \begin{bmatrix} -\frac{5\,\mathrm{e}^{-3t}}{2} & 0 \\ \frac{5\,\mathrm{e}^{-t}}{2} & \mathrm{e}^{-t} \end{bmatrix} \begin{bmatrix} 1-t \\ 2t-1 \end{bmatrix} dt \\
&= \begin{bmatrix} -\frac{2\,\mathrm{e}^{3t}}{5} & 0 \\ \mathrm{e}^{3t} & \mathrm{e}^{t} \end{bmatrix} \int \begin{bmatrix} \frac{5\,\mathrm{e}^{-3t}(t-1)}{2} \\ -\frac{\mathrm{e}^{-t}(-3+t)}{2} \end{bmatrix} dt \\
&= \begin{bmatrix} -\frac{2\,\mathrm{e}^{3t}}{5} & 0 \\ \mathrm{e}^{3t} & \mathrm{e}^{t} \end{bmatrix} \begin{bmatrix} -\frac{5\,\mathrm{e}^{-3t}(-2+3t)}{18} \\ \frac{\mathrm{e}^{-t}(-2+t)}{2} \end{bmatrix} \\
&= \begin{bmatrix} -\frac{2}{9} + \frac{t}{3} \\ -\frac{4}{9} - \frac{t}{3} \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{2c_1 e^{3t}}{5} \\ c_1 e^{3t} \end{bmatrix} + \begin{bmatrix} 0 \\ c_2 e^{t} \end{bmatrix} + \begin{bmatrix} -\frac{2}{9} + \frac{t}{3} \\ -\frac{4}{9} - \frac{t}{3} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{2c_1 e^{3t}}{5} - \frac{2}{9} + \frac{t}{3} \\ c_1 e^{3t} + c_2 e^{t} - \frac{4}{9} - \frac{t}{3} \end{bmatrix}$$

16.17.3 Maple step by step solution

Let's solve

$[x'(t) = 3x(t) - t + 1, y'(t) = -5x(t) + y(t) + 2t - 1]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 3 & 0 \\ -5 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 1-t \\ 2t-1 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 3 & 0 \\ -5 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 1-t \\ 2t-1 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} 1-t \\ 2t-1 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 3 & 0 \\ -5 & 1 \end{bmatrix}$$

- Rewrite the system as

  $\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t) + \overrightarrow{f}$
- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

  $$\left[\left[1, \left[\begin{array}{c} 0 \\ 1 \end{array}\right]\right], \left[3, \left[\begin{array}{c} -\frac{2}{5} \\ 1 \end{array}\right]\right]\right]$$
- Consider eigenpair

  $$\left[1, \left[\begin{array}{c} 0 \\ 1 \end{array}\right]\right]$$
- Solution to homogeneous system from eigenpair

  $$\overrightarrow{x}_1 = \mathrm{e}^t \cdot \left[\begin{array}{c} 0 \\ 1 \end{array}\right]$$
- Consider eigenpair

  $$\left[3, \left[\begin{array}{c} -\frac{2}{5} \\ 1 \end{array}\right]\right]$$
- Solution to homogeneous system from eigenpair

  $$\overrightarrow{x}_2 = \mathrm{e}^{3t} \cdot \left[\begin{array}{c} -\frac{2}{5} \\ 1 \end{array}\right]$$
- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{x}_p($

  $\overrightarrow{x}(t) = c_1 \overrightarrow{x}_1 + c_2 \overrightarrow{x}_2 + \overrightarrow{x}_p(t)$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

  $$\phi(t) = \left[\begin{array}{cc} 0 & -\frac{2\,\mathrm{e}^{3t}}{5} \\ \mathrm{e}^t & \mathrm{e}^{3t} \end{array}\right]$$
- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

  $\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$
- Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} 0 & -\frac{2\,e^{3t}}{5} \\ e^t & e^{3t} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 0 & -\frac{2}{5} \\ 1 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} e^{3t} & 0 \\ -\frac{5\,e^{3t}}{2} + \frac{5\,e^t}{2} & e^t \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

$$\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$$

- Take the derivative of the particular solution

$$\vec{x}_p'(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$$

- Substitute particular solution and its derivative into the system of ODEs

$$\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$$A \cdot \Phi(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$$

- Cancel like terms

$$\Phi(t) \cdot \vec{v}'(t) = \vec{f}(t)$$

- Multiply by the inverse of the fundamental matrix

$$\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$$

- Integrate to solve for $\vec{v}(t)$

$$\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\,ds$$

- Plug $\vec{v}(t)$ into the equation for the particular solution

$$\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\,ds\right)$$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{x}_p(t) = \begin{bmatrix} \frac{2\,e^{3t}}{9} - \frac{2}{9} + \frac{t}{3} \\ -\frac{5\,e^{3t}}{9} - \frac{4}{9} - \frac{t}{3} + e^t \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{x}(t) = c_1 \vec{x}_1 + c_2 \vec{x}_2 + \begin{bmatrix} \frac{2\,e^{3t}}{9} - \frac{2}{9} + \frac{t}{3} \\ -\frac{5\,e^{3t}}{9} - \frac{4}{9} - \frac{t}{3} + e^t \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{2}{9} + \frac{2(5-9c_2)e^{3t}}{45} + \frac{t}{3} \\ c_1 e^t + c_2 e^{3t} - \frac{5\,e^{3t}}{9} - \frac{4}{9} - \frac{t}{3} + e^t \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = -\frac{2}{9} + \frac{2(5-9c_2)e^{3t}}{45} + \frac{t}{3}, y(t) = c_1 e^t + c_2 e^{3t} - \frac{5\,e^{3t}}{9} - \frac{4}{9} - \frac{t}{3} + e^t\right\}$$

✓ Solution by Maple

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = 3x(t) + 4y(t)$$
$$y'(t) = 2x(t) + y(t)$$

With initial conditions

$$[x(0) = 1, y(0) = 2]$$

17.1.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 3 & 4 \\ 2 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{e^{-t}}{3} + \frac{2\,e^{5t}}{3} & \frac{2\,e^{5t}}{3} - \frac{2\,e^{-t}}{3} \\ \frac{e^{5t}}{3} - \frac{e^{-t}}{3} & \frac{2\,e^{-t}}{3} + \frac{e^{5t}}{3} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{x}_0 \\
&= \begin{bmatrix} \frac{e^{-t}}{3}+\frac{2\,e^{5t}}{3} & \frac{2\,e^{5t}}{3}-\frac{2\,e^{-t}}{3} \\ \frac{e^{5t}}{3}-\frac{e^{-t}}{3} & \frac{2\,e^{-t}}{3}+\frac{e^{5t}}{3} \end{bmatrix} \begin{bmatrix} 1 \\ 2 \end{bmatrix} \\
&= \begin{bmatrix} -e^{-t}+2\,e^{5t} \\ e^{5t}+e^{-t} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

17.1.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 3 & 4 \\ 2 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 3 & 4 \\ 2 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 3-\lambda & 4 \\ 2 & 1-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 4\lambda - 5 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -1$$
$$\lambda_2 = 5$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
5	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & 4 \\ 2 & 1 \end{bmatrix} - (-1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 4 & 4 \\ 2 & 2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 4 & 4 & 0 \\ 2 & 2 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{2} \Longrightarrow \left[\begin{array}{cc|c} 4 & 4 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 4 & 4 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 5$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & 4 \\ 2 & 1 \end{bmatrix} - (5) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -2 & 4 \\ 2 & -4 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -2 & 4 & 0 \\ 2 & -4 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} -2 & 4 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & 4 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 2t\}$

Hence the solution is

$$\begin{bmatrix} 2t \\ t \end{bmatrix} = \begin{bmatrix} 2t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 2t \\ t \end{bmatrix} = t \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 2t \\ t \end{bmatrix} = \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-1	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$
5	1	1	No	$\begin{bmatrix} 2 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{-t} \\ &= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{-t} \end{aligned}$$

Since eigenvalue 5 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{5t}\\ &= \begin{bmatrix} 2 \\ 1 \end{bmatrix} e^{5t}\end{aligned}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\mathrm{e}^{-t} \\ \mathrm{e}^{-t} \end{bmatrix} + c_2 \begin{bmatrix} 2\,\mathrm{e}^{5t} \\ \mathrm{e}^{5t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -c_1\mathrm{e}^{-t} + 2c_2\mathrm{e}^{5t} \\ c_1\mathrm{e}^{-t} + c_2\mathrm{e}^{5t} \end{bmatrix}$$

Since initial conditions are given, the solution above needs to be updated by solving for the constants of integrations using the given initial conditions

$$\begin{bmatrix} x(0) = 1 \\ y(0) = 2 \end{bmatrix} \tag{1}$$

Substituting initial conditions into the above solution at $t = 0$ gives

$$\begin{bmatrix} 1 \\ 2 \end{bmatrix} = \begin{bmatrix} -c_1 + 2c_2 \\ c_1 + c_2 \end{bmatrix}$$

Solving for the constants of integrations gives

$$\begin{bmatrix} c_1 = 1 \\ c_2 = 1 \end{bmatrix}$$

Substituting these constants back in original solution in Eq. (1) gives

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\mathrm{e}^{-t} + 2\,\mathrm{e}^{5t} \\ \mathrm{e}^{5t} + \mathrm{e}^{-t} \end{bmatrix}$$

The following is the phase plot of the system.

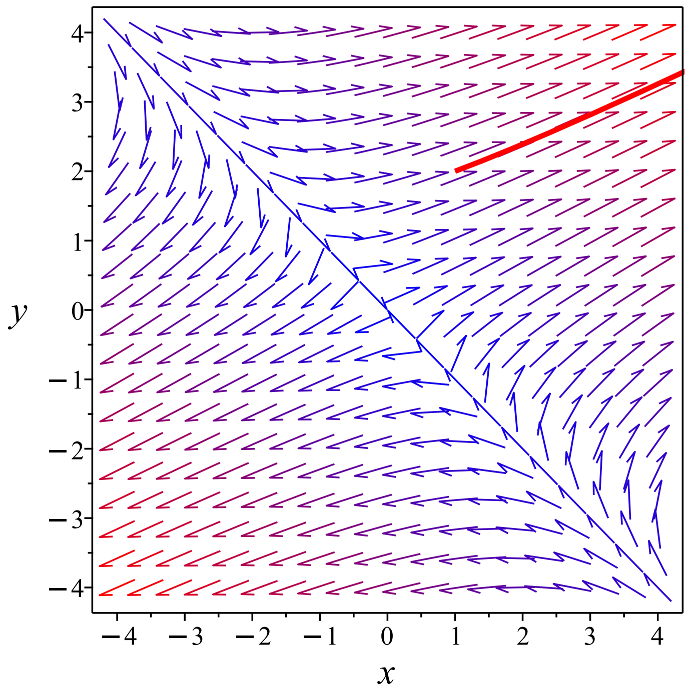

Figure 560: Phase plot

Problem number: 2.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 5x(t) + 3y(t) \\
y'(t) &= 4x(t) + y(t)
\end{aligned}
$$

With initial conditions

$$[x(0) = 0, y(0) = 8]$$

17.2.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 5 & 3 \\ 4 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{e^{-t}}{4} + \frac{3\,e^{7t}}{4} & \frac{3\,e^{7t}}{8} - \frac{3\,e^{-t}}{8} \\ \frac{e^{7t}}{2} - \frac{e^{-t}}{2} & \frac{3\,e^{-t}}{4} + \frac{e^{7t}}{4} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{x}_0 \\
&= \begin{bmatrix} \frac{e^{-t}}{4} + \frac{3\,e^{7t}}{4} & \frac{3\,e^{7t}}{8} - \frac{3\,e^{-t}}{8} \\ \frac{e^{7t}}{2} - \frac{e^{-t}}{2} & \frac{3\,e^{-t}}{4} + \frac{e^{7t}}{4} \end{bmatrix} \begin{bmatrix} 0 \\ 8 \end{bmatrix} \\
&= \begin{bmatrix} 3\,e^{7t} - 3\,e^{-t} \\ 6\,e^{-t} + 2\,e^{7t} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

17.2.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 5 & 3 \\ 4 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 5 & 3 \\ 4 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 5-\lambda & 3 \\ 4 & 1-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 6\lambda - 7 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -1$$
$$\lambda_2 = 7$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
7	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 5 & 3 \\ 4 & 1 \end{bmatrix} - (-1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 6 & 3 \\ 4 & 2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 6 & 3 & 0 \\ 4 & 2 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{2R_1}{3} \Longrightarrow \left[\begin{array}{cc|c} 6 & 3 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 6 & 3 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 2 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 7$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 5 & 3 \\ 4 & 1 \end{bmatrix} - (7) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -2 & 3 \\ 4 & -6 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -2 & 3 & 0 \\ 4 & -6 & 0 \end{array}\right]$$

$$R_2 = R_2 + 2R_1 \Longrightarrow \left[\begin{array}{cc|c} -2 & 3 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & 3 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{3t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{3t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{3t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{3t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{3}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{3t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{3}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{3t}{2} \\ t \end{bmatrix} = \begin{bmatrix} 3 \\ 2 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-1	1	1	No	$\begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix}$
7	1	1	No	$\begin{bmatrix} \frac{3}{2} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -1 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^{-t} \\
&= \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix} e^{-t}
\end{aligned}
$$

Since eigenvalue 7 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_2(t) &= \vec{v}_2 e^{7t} \\
&= \begin{bmatrix} \frac{3}{2} \\ 1 \end{bmatrix} e^{7t}
\end{aligned}
$$

Therefore the final solution is

$$
\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)
$$

Which is written as

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\frac{\mathrm{e}^{-t}}{2} \\ \mathrm{e}^{-t} \end{bmatrix} + c_2 \begin{bmatrix} \frac{3\,\mathrm{e}^{7t}}{2} \\ \mathrm{e}^{7t} \end{bmatrix}
$$

Which becomes

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{c_1 \mathrm{e}^{-t}}{2} + \frac{3 c_2 \mathrm{e}^{7t}}{2} \\ c_1 \mathrm{e}^{-t} + c_2 \mathrm{e}^{7t} \end{bmatrix}
$$

Since initial conditions are given, the solution above needs to be updated by solving for the constants of integrations using the given initial conditions

$$
\begin{bmatrix} x(0) = 0 \\ y(0) = 8 \end{bmatrix} \tag{1}
$$

Substituting initial conditions into the above solution at $t = 0$ gives

$$
\begin{bmatrix} 0 \\ 8 \end{bmatrix} = \begin{bmatrix} -\frac{c_1}{2} + \frac{3c_2}{2} \\ c_1 + c_2 \end{bmatrix}
$$

Solving for the constants of integrations gives

$$\left[\begin{array}{c} c_1 = 6 \\ c_2 = 2 \end{array}\right]$$

Substituting these constants back in original solution in Eq. (1) gives

$$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} 3\,e^{7t} - 3\,e^{-t} \\ 6\,e^{-t} + 2\,e^{7t} \end{array}\right]$$

The following is the phase plot of the system.

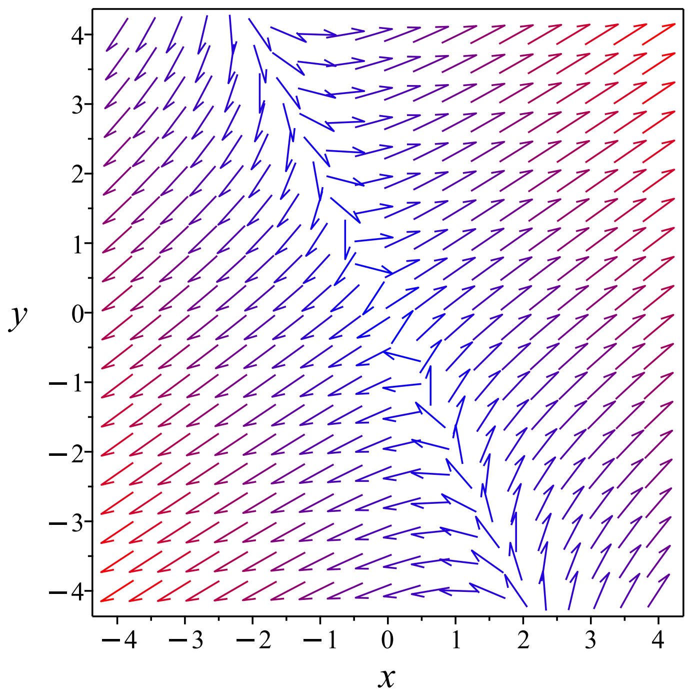

Figure 561: Phase plot

The following are plots of each solution.

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 7, Systems of linear differential equations. Section 7.3. Exercises page 299
Problem number: 3.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 5x(t) + 2y(t) + 5t \\
y'(t) &= 3x(t) + 4y(t) + 17t
\end{aligned}
$$

17.3.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 5 & 2 \\ 3 & 4 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 5t \\ 17t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{2\,e^{2t}}{5} + \frac{3\,e^{7t}}{5} & \frac{2\,e^{7t}}{5} - \frac{2\,e^{2t}}{5} \\ \frac{3\,e^{7t}}{5} - \frac{3\,e^{2t}}{5} & \frac{3\,e^{2t}}{5} + \frac{2\,e^{7t}}{5} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} \frac{2\,e^{2t}}{5} + \frac{3\,e^{7t}}{5} & \frac{2\,e^{7t}}{5} - \frac{2\,e^{2t}}{5} \\ \frac{3\,e^{7t}}{5} - \frac{3\,e^{2t}}{5} & \frac{3\,e^{2t}}{5} + \frac{2\,e^{7t}}{5} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} \left(\frac{2\,e^{2t}}{5} + \frac{3\,e^{7t}}{5}\right) c_1 + \left(\frac{2\,e^{7t}}{5} - \frac{2\,e^{2t}}{5}\right) c_2 \\ \left(\frac{3\,e^{7t}}{5} - \frac{3\,e^{2t}}{5}\right) c_1 + \left(\frac{3\,e^{2t}}{5} + \frac{2\,e^{7t}}{5}\right) c_2 \end{bmatrix} \\ &= \begin{bmatrix} \frac{(2c_1-2c_2)e^{2t}}{5} + \frac{3\,e^{7t}\left(c_1+\frac{2c_2}{3}\right)}{5} \\ \frac{(-3c_1+3c_2)e^{2t}}{5} + \frac{3\,e^{7t}\left(c_1+\frac{2c_2}{3}\right)}{5} \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} \frac{e^{-7t}(2\,e^{5t}+3)}{5} & -\frac{2\,e^{-7t}(e^{5t}-1)}{5} \\ -\frac{3\,e^{-7t}(e^{5t}-1)}{5} & \frac{e^{-7t}(3\,e^{5t}+2)}{5} \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} \frac{2\,e^{2t}}{5} + \frac{3\,e^{7t}}{5} & \frac{2\,e^{7t}}{5} - \frac{2\,e^{2t}}{5} \\ \frac{3\,e^{7t}}{5} - \frac{3\,e^{2t}}{5} & \frac{3\,e^{2t}}{5} + \frac{2\,e^{7t}}{5} \end{bmatrix} \int \begin{bmatrix} \frac{e^{-7t}(2\,e^{5t}+3)}{5} & -\frac{2\,e^{-7t}(e^{5t}-1)}{5} \\ -\frac{3\,e^{-7t}(e^{5t}-1)}{5} & \frac{e^{-7t}(3\,e^{5t}+2)}{5} \end{bmatrix} \begin{bmatrix} 5t \\ 17t \end{bmatrix} dt \\ &= \begin{bmatrix} \frac{2\,e^{2t}}{5} + \frac{3\,e^{7t}}{5} & \frac{2\,e^{7t}}{5} - \frac{2\,e^{2t}}{5} \\ \frac{3\,e^{7t}}{5} - \frac{3\,e^{2t}}{5} & \frac{3\,e^{2t}}{5} + \frac{2\,e^{7t}}{5} \end{bmatrix} \begin{bmatrix} \frac{(-7t-1)e^{-7t}}{5} + \frac{6(2t+1)e^{-2t}}{5} \\ \frac{(-7t-1)e^{-7t}}{5} + \frac{9(-2t-1)e^{-2t}}{5} \end{bmatrix} \\ &= \begin{bmatrix} 1+t \\ -5t-2 \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$= \begin{bmatrix} \frac{(2c_1-2c_2)e^{2t}}{5} + \frac{e^{7t}(3c_1+2c_2)}{5} + t + 1 \\ \frac{(-3c_1+3c_2)e^{2t}}{5} + \frac{e^{7t}(3c_1+2c_2)}{5} - 5t - 2 \end{bmatrix}$$

17.3.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 5 & 2 \\ 3 & 4 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 5t \\ 17t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 5 & 2 \\ 3 & 4 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 5-\lambda & 2 \\ 3 & 4-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 9\lambda + 14 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 2$$
$$\lambda_2 = 7$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
2	1	real eigenvalue
7	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 5 & 2 \\ 3 & 4 \end{bmatrix} - (2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 3 & 2 \\ 3 & 2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 3 & 2 & 0 \\ 3 & 2 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 3 & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 3 & 2 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{2t}{3}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{2t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{2t}{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{2t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{2}{3} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{2t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{2}{3} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{2t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -2 \\ 3 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 7$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 5 & 2 \\ 3 & 4 \end{bmatrix} - (7) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -2 & 2 \\ 3 & -3 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -2 & 2 & 0 \\ 3 & -3 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{3R_1}{2} \Longrightarrow \left[\begin{array}{cc|c} -2 & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & 2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
2	1	1	No	$\begin{bmatrix} -\frac{2}{3} \\ 1 \end{bmatrix}$
7	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 2 is real and distinct then the

corresponding eigenvector solution is

$$\vec{x}_1(t) = \vec{v}_1 e^{2t}$$
$$= \begin{bmatrix} -\frac{2}{3} \\ 1 \end{bmatrix} e^{2t}$$

Since eigenvalue 7 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{7t}$$
$$= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{7t}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\frac{2\,e^{2t}}{3} \\ e^{2t} \end{bmatrix} + c_2 \begin{bmatrix} e^{7t} \\ e^{7t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -\frac{2\,e^{2t}}{3} & e^{7t} \\ e^{2t} & e^{7t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{3\,e^{-2t}}{5} & \frac{3\,e^{-2t}}{5} \\ \frac{3\,e^{-7t}}{5} & \frac{2\,e^{-7t}}{5} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} -\frac{2\,e^{2t}}{3} & e^{7t} \\ e^{2t} & e^{7t} \end{bmatrix} \int \begin{bmatrix} -\frac{3\,e^{-2t}}{5} & \frac{3\,e^{-2t}}{5} \\ \frac{3\,e^{-7t}}{5} & \frac{2\,e^{-7t}}{5} \end{bmatrix} \begin{bmatrix} 5t \\ 17t \end{bmatrix} dt$$
$$= \begin{bmatrix} -\frac{2\,e^{2t}}{3} & e^{7t} \\ e^{2t} & e^{7t} \end{bmatrix} \int \begin{bmatrix} \frac{36t\,e^{-2t}}{5} \\ \frac{49\,e^{-7t}t}{5} \end{bmatrix} dt$$
$$= \begin{bmatrix} -\frac{2\,e^{2t}}{3} & e^{7t} \\ e^{2t} & e^{7t} \end{bmatrix} \begin{bmatrix} -\frac{9(2t+1)e^{-2t}}{5} \\ -\frac{(7t+1)e^{-7t}}{5} \end{bmatrix}$$
$$= \begin{bmatrix} 1+t \\ -5t-2 \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{2c_1e^{2t}}{3} \\ c_1e^{2t} \end{bmatrix} + \begin{bmatrix} c_2e^{7t} \\ c_2e^{7t} \end{bmatrix} + \begin{bmatrix} 1+t \\ -5t-2 \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{2c_1e^{2t}}{3} + c_2e^{7t} + 1 + t \\ c_1e^{2t} + c_2e^{7t} - 5t - 2 \end{bmatrix}$$

17.3.3 Maple step by step solution

Let's solve

$[x'(t) = 5x(t) + 2y(t) + 5t, y'(t) = 3x(t) + 4y(t) + 17t]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 5 & 2 \\ 3 & 4 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 5t \\ 17t \end{bmatrix}$$

- System to solve

$$\overrightarrow{x}'(t) = \begin{bmatrix} 5 & 2 \\ 3 & 4 \end{bmatrix} \cdot \overrightarrow{x}(t) + \begin{bmatrix} 5t \\ 17t \end{bmatrix}$$

- Define the forcing function

$$\overrightarrow{f}(t) = \begin{bmatrix} 5t \\ 17t \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 5 & 2 \\ 3 & 4 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t) + \overrightarrow{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[2, \begin{bmatrix} -\frac{2}{3} \\ 1 \end{bmatrix}\right], \left[7, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} -\frac{2}{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{x}_1 = \mathrm{e}^{2t} \cdot \begin{bmatrix} -\frac{2}{3} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[7, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{x}_2 = \mathrm{e}^{7t} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{x}_p($

  $\overrightarrow{x}(t) = c_1\overrightarrow{x}_1 + c_2\overrightarrow{x}_2 + \overrightarrow{x}_p(t)$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

  $\phi(t) = \begin{bmatrix} -\frac{2\,e^{2t}}{3} & e^{7t} \\ e^{2t} & e^{7t} \end{bmatrix}$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

  $\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(t)$ and $\phi(0)$

  $\Phi(t) = \begin{bmatrix} -\frac{2\,e^{2t}}{3} & e^{7t} \\ e^{2t} & e^{7t} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -\frac{2}{3} & 1 \\ 1 & 1 \end{bmatrix}}$

- Evaluate and simplify to get the fundamental matrix

  $\Phi(t) = \begin{bmatrix} \frac{2\,e^{2t}}{5} + \frac{3\,e^{7t}}{5} & \frac{2\,e^{7t}}{5} - \frac{2\,e^{2t}}{5} \\ \frac{3\,e^{7t}}{5} - \frac{3\,e^{2t}}{5} & \frac{3\,e^{2t}}{5} + \frac{2\,e^{7t}}{5} \end{bmatrix}$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

  $\overrightarrow{x}_p(t) = \Phi(t) \cdot \overrightarrow{v}(t)$

- Take the derivative of the particular solution

  $\overrightarrow{x}_p'(t) = \Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- Cancel like terms

  $\Phi(t) \cdot \overrightarrow{v}'(t) = \overrightarrow{f}(t)$

- Multiply by the inverse of the fundamental matrix

$$\overrightarrow{v}'(t) = \frac{1}{\Phi(t)} \cdot \overrightarrow{f}(t)$$

- Integrate to solve for $\overrightarrow{v}(t)$

$$\overrightarrow{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$$

- Plug $\overrightarrow{v}(t)$ into the equation for the particular solution

$$\overrightarrow{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$$

- Plug in the fundamental matrix and the forcing function and compute

$$\overrightarrow{x}_p(t) = \left[\begin{array}{c} t+1-\frac{6\,\mathrm{e}^{2t}}{5}+\frac{\mathrm{e}^{7t}}{5} \\ \frac{\mathrm{e}^{7t}}{5}-5t-2+\frac{9\,\mathrm{e}^{2t}}{5} \end{array}\right]$$

- Plug particular solution back into general solution

$$\overrightarrow{x}(t) = c_1\overrightarrow{x}_1 + c_2\overrightarrow{x}_2 + \left[\begin{array}{c} t+1-\frac{6\,\mathrm{e}^{2t}}{5}+\frac{\mathrm{e}^{7t}}{5} \\ \frac{\mathrm{e}^{7t}}{5}-5t-2+\frac{9\,\mathrm{e}^{2t}}{5} \end{array}\right]$$

- Substitute in vector of dependent variables

$$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} \frac{(-10c_1-18)\mathrm{e}^{2t}}{15}+\frac{(15c_2+3)\mathrm{e}^{7t}}{15}+t+1 \\ \frac{(9+5c_1)\mathrm{e}^{2t}}{5}+\frac{(1+5c_2)\mathrm{e}^{7t}}{5}-5t-2 \end{array}\right]$$

- Solution to the system of ODEs

$$\left\{x(t) = \frac{(-10c_1-18)\mathrm{e}^{2t}}{15}+\frac{(15c_2+3)\mathrm{e}^{7t}}{15}+t+1, y(t) = \frac{(9+5c_1)\mathrm{e}^{2t}}{5}+\frac{(1+5c_2)\mathrm{e}^{7t}}{5}-5t-2\right\}$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 5x(t) - 2y(t) \\
y'(t) &= 4x(t) - y(t)
\end{aligned}
$$

18.1.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 5 & -2 \\ 4 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} -e^{t} + 2\,e^{3t} & -e^{3t} + e^{t} \\ 2\,e^{3t} - 2\,e^{t} & 2\,e^{t} - e^{3t} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} -\mathrm{e}^{t}+2\,\mathrm{e}^{3t} & -\mathrm{e}^{3t}+\mathrm{e}^{t} \\ 2\,\mathrm{e}^{3t}-2\,\mathrm{e}^{t} & 2\,\mathrm{e}^{t}-\mathrm{e}^{3t} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} (-\mathrm{e}^{t}+2\,\mathrm{e}^{3t})\,c_1+(-\mathrm{e}^{3t}+\mathrm{e}^{t})\,c_2 \\ (2\,\mathrm{e}^{3t}-2\,\mathrm{e}^{t})\,c_1+(2\,\mathrm{e}^{t}-\mathrm{e}^{3t})\,c_2 \end{bmatrix} \\
&= \begin{bmatrix} (2c_1-c_2)\,\mathrm{e}^{3t}-(c_1-c_2)\,\mathrm{e}^{t} \\ (2c_1-c_2)\,\mathrm{e}^{3t}-2(c_1-c_2)\,\mathrm{e}^{t} \end{bmatrix}
\end{aligned}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

18.1.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 5 & -2 \\ 4 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A-\lambda I\right)=0$$

Expanding gives

$$\det\left(\begin{bmatrix} 5 & -2 \\ 4 & -1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 5-\lambda & -2 \\ 4 & -1-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 4\lambda + 3 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 1$$
$$\lambda_2 = 3$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue
3	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 5 & -2 \\ 4 & -1 \end{bmatrix} - (1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 4 & -2 \\ 4 & -2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 4 & -2 & 0 \\ 4 & -2 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 4 & -2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 4 & -2 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 2 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 5 & -2 \\ 4 & -1 \end{bmatrix} - (3) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 2 & -2 \\ 4 & -4 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2 & -2 & 0 \\ 4 & -4 & 0 \end{array}\right]$$

$$R_2 = R_2 - 2R_1 \Longrightarrow \left[\begin{array}{cc|c} 2 & -2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & -2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
1	1	1	No	$\begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$
3	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^{t} \\ &= \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix} e^{t}\end{aligned}$$

Since eigenvalue 3 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{3t} \\ &= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{3t}\end{aligned}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \frac{e^{t}}{2} \\ e^{t} \end{bmatrix} + c_2 \begin{bmatrix} e^{3t} \\ e^{3t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{c_1 e^{t}}{2} + c_2 e^{3t} \\ c_1 e^{t} + c_2 e^{3t} \end{bmatrix}$$

The following is the phase plot of the system.

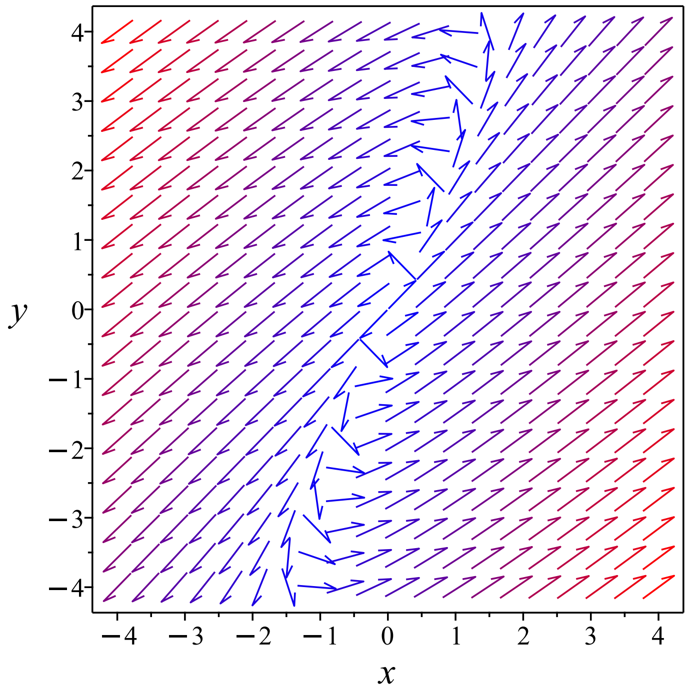

Figure 562: Phase plot

18.1.3 Maple step by step solution

Let's solve

$[x'(t) = 5x(t) - 2y(t), y'(t) = 4x(t) - y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 5 & -2 \\ 4 & -1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 5 & -2 \\ 4 & -1 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 5 & -2 \\ 4 & -1 \end{bmatrix}$$

- Rewrite the system as

  $\vec{x}'(t) = A \cdot \vec{x}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

  $$\left[\left[1, \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

  $$\left[1, \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

  $$\vec{x}_1 = e^t \cdot \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

  $$\left[3, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

  $$\vec{x}_2 = e^{3t} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

  $\vec{x} = c_1 \vec{x}_1 + c_2 \vec{x}_2$

- Substitute solutions into the general solution

  $$\vec{x} = c_1 e^t \cdot \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix} + c_2 e^{3t} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{c_1 e^t}{2} + c_2 e^{3t} \\ c_1 e^t + c_2 e^{3t} \end{bmatrix}$$

- Solution to the system of ODEs

  $$\left\{x(t) = \frac{c_1 e^t}{2} + c_2 e^{3t}, y(t) = c_1 e^t + c_2 e^{3t}\right\}$$

✓ Solution by Maple

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = 5x(t) - y(t)$$
$$y'(t) = 3x(t) + y(t)$$

18.2.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 5 & -1 \\ 3 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} -\frac{e^{2t}}{2} + \frac{3\,e^{4t}}{2} & -\frac{e^{4t}}{2} + \frac{e^{2t}}{2} \\ \frac{3\,e^{4t}}{2} - \frac{3\,e^{2t}}{2} & \frac{3\,e^{2t}}{2} - \frac{e^{4t}}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} -\frac{e^{2t}}{2}+\frac{3\,e^{4t}}{2} & -\frac{e^{4t}}{2}+\frac{e^{2t}}{2} \\ \frac{3\,e^{4t}}{2}-\frac{3\,e^{2t}}{2} & \frac{3\,e^{2t}}{2}-\frac{e^{4t}}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(-\frac{e^{2t}}{2}+\frac{3\,e^{4t}}{2}\right)c_1+\left(-\frac{e^{4t}}{2}+\frac{e^{2t}}{2}\right)c_2 \\ \left(\frac{3\,e^{4t}}{2}-\frac{3\,e^{2t}}{2}\right)c_1+\left(\frac{3\,e^{2t}}{2}-\frac{e^{4t}}{2}\right)c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(c_2-c_1)e^{2t}}{2}+\frac{3\,e^{4t}\left(-\frac{c_2}{3}+c_1\right)}{2} \\ \frac{(-3c_1+3c_2)e^{2t}}{2}+\frac{3\,e^{4t}\left(-\frac{c_2}{3}+c_1\right)}{2} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

18.2.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 5 & -1 \\ 3 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A-\lambda I\right)=0$$

Expanding gives

$$\det\left(\begin{bmatrix} 5 & -1 \\ 3 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 5-\lambda & -1 \\ 3 & 1-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 6\lambda + 8 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 2$$
$$\lambda_2 = 4$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
2	1	real eigenvalue
4	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 5 & -1 \\ 3 & 1 \end{bmatrix} - (2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 3 & -1 \\ 3 & -1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 3 & -1 & 0 \\ 3 & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 3 & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 3 & -1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{t}{3}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 3 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 4$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 5 & -1 \\ 3 & 1 \end{bmatrix} - (4) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 1 & -1 \\ 3 & -3 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 & -1 & 0 \\ 3 & -3 & 0 \end{array}\right]$$

$$R_2 = R_2 - 3R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & -1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
2	1	1	No	$\begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}$
4	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 2 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^{2t} \\ &= \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix} e^{2t}\end{aligned}$$

Since eigenvalue 4 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{4t} \\ &= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{4t}\end{aligned}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \frac{e^{2t}}{3} \\ e^{2t} \end{bmatrix} + c_2 \begin{bmatrix} e^{4t} \\ e^{4t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{c_1 e^{2t}}{3} + c_2 e^{4t} \\ c_1 e^{2t} + c_2 e^{4t} \end{bmatrix}$$

The following is the phase plot of the system.

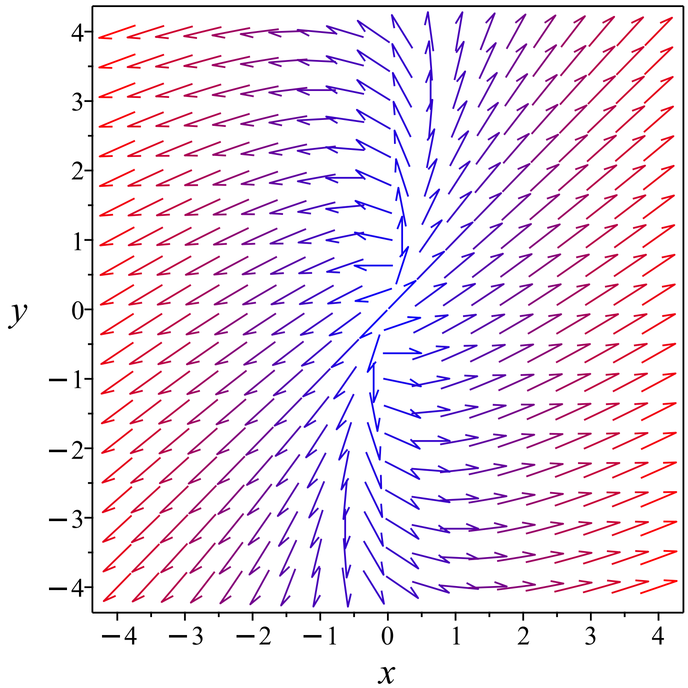

Figure 563: Phase plot

18.2.3 Maple step by step solution

Let's solve

$[x'(t) = 5x(t) - y(t), y'(t) = 3x(t) + y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 5 & -1 \\ 3 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 5 & -1 \\ 3 & 1 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 5 & -1 \\ 3 & 1 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[2, \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}\right], \left[4, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= -2x(t) + 7y(t) \\
y'(t) &= 3x(t) + 2y(t)
\end{aligned}
$$

With initial conditions

$$
[x(0) = 9, y(0) = -1]
$$

18.3.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -2 & 7 \\ 3 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

For the above matrix A, the matrix exponential can be found to be

$$
e^{At} = \begin{bmatrix} \frac{7\,\mathrm{e}^{-5t}}{10} + \frac{3\,\mathrm{e}^{5t}}{10} & \frac{7\,\mathrm{e}^{5t}}{10} - \frac{7\,\mathrm{e}^{-5t}}{10} \\ \frac{3\,\mathrm{e}^{5t}}{10} - \frac{3\,\mathrm{e}^{-5t}}{10} & \frac{3\,\mathrm{e}^{-5t}}{10} + \frac{7\,\mathrm{e}^{5t}}{10} \end{bmatrix}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{x}_0 \\
&= \begin{bmatrix} \frac{7\,e^{-5t}}{10} + \frac{3\,e^{5t}}{10} & \frac{7\,e^{5t}}{10} - \frac{7\,e^{-5t}}{10} \\ \frac{3\,e^{5t}}{10} - \frac{3\,e^{-5t}}{10} & \frac{3\,e^{-5t}}{10} + \frac{7\,e^{5t}}{10} \end{bmatrix} \begin{bmatrix} 9 \\ -1 \end{bmatrix} \\
&= \begin{bmatrix} 7\,e^{-5t} + 2\,e^{5t} \\ 2\,e^{5t} - 3\,e^{-5t} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

18.3.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -2 & 7 \\ 3 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$
\det(A - \lambda I) = 0
$$

Expanding gives

$$
\det\left(\begin{bmatrix} -2 & 7 \\ 3 & 2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0
$$

Therefore

$$
\det\left(\begin{bmatrix} -2-\lambda & 7 \\ 3 & 2-\lambda \end{bmatrix}\right) = 0
$$

Which gives the characteristic equation

$$
\lambda^2 - 25 = 0
$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 5$$
$$\lambda_2 = -5$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-5	1	real eigenvalue
5	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -5$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -2 & 7 \\ 3 & 2 \end{bmatrix} - (-5)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 3 & 7 \\ 3 & 7 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 3 & 7 & 0 \\ 3 & 7 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 3 & 7 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 3 & 7 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{7t}{3}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{7t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{7t}{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{7t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{7}{3} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{7t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{7}{3} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{7t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -7 \\ 3 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 5$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -2 & 7 \\ 3 & 2 \end{bmatrix} - (5) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -7 & 7 \\ 3 & -3 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -7 & 7 & 0 \\ 3 & -3 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{3R_1}{7} \Longrightarrow \left[\begin{array}{cc|c} -7 & 7 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -7 & 7 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
5	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$
-5	1	1	No	$\begin{bmatrix} -\frac{7}{3} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 5 is real and distinct then the

corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^{5t} \\ &= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{5t}\end{aligned}$$

Since eigenvalue -5 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{-5t} \\ &= \begin{bmatrix} -\frac{7}{3} \\ 1 \end{bmatrix} e^{-5t}\end{aligned}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} e^{5t} \\ e^{5t} \end{bmatrix} + c_2 \begin{bmatrix} -\frac{7\,e^{-5t}}{3} \\ e^{-5t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 e^{5t} - \frac{7 c_2 e^{-5t}}{3} \\ c_1 e^{5t} + c_2 e^{-5t} \end{bmatrix}$$

Since initial conditions are given, the solution above needs to be updated by solving for the constants of integrations using the given initial conditions

$$\begin{bmatrix} x(0) = 9 \\ y(0) = -1 \end{bmatrix} \tag{1}$$

Substituting initial conditions into the above solution at $t = 0$ gives

$$\begin{bmatrix} 9 \\ -1 \end{bmatrix} = \begin{bmatrix} c_1 - \frac{7c_2}{3} \\ c_1 + c_2 \end{bmatrix}$$

Solving for the constants of integrations gives

$$\begin{bmatrix} c_1 = 2 \\ c_2 = -3 \end{bmatrix}$$

Substituting these constants back in original solution in Eq. (1) gives

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} 7\,e^{-5t} + 2\,e^{5t} \\ 2\,e^{5t} - 3\,e^{-5t} \end{bmatrix}$$

The following is the phase plot of the system.

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 7, Systems of linear differential equations. Section 7.4. Exercises page 309
Problem number: 24.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = -2x(t) + y(t)$$
$$y'(t) = 7x(t) + 4y(t)$$

With initial conditions

$$[x(0) = 6, y(0) = 2]$$

18.4.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -2 & 1 \\ 7 & 4 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{(e^{8t}+7)e^{-3t}}{8} & \frac{(e^{8t}-1)e^{-3t}}{8} \\ \frac{7(e^{8t}-1)e^{-3t}}{8} & \frac{(7e^{8t}+1)e^{-3t}}{8} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{x}_0 \\
&= \begin{bmatrix} \frac{(e^{8t}+7)e^{-3t}}{8} & \frac{(e^{8t}-1)e^{-3t}}{8} \\ \frac{7(e^{8t}-1)e^{-3t}}{8} & \frac{(7e^{8t}+1)e^{-3t}}{8} \end{bmatrix} \begin{bmatrix} 6 \\ 2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{3(e^{8t}+7)e^{-3t}}{4} + \frac{(e^{8t}-1)e^{-3t}}{4} \\ \frac{21(e^{8t}-1)e^{-3t}}{4} + \frac{(7e^{8t}+1)e^{-3t}}{4} \end{bmatrix} \\
&= \begin{bmatrix} (e^{8t}+5)\,e^{-3t} \\ (7\,e^{8t}-5)\,e^{-3t} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

18.4.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -2 & 1 \\ 7 & 4 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} -2 & 1 \\ 7 & 4 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -2-\lambda & 1 \\ 7 & 4-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 2\lambda - 15 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 5$$
$$\lambda_2 = -3$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-3	1	real eigenvalue
5	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -2 & 1 \\ 7 & 4 \end{bmatrix} - (-3)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 1 & 1 \\ 7 & 7 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 & 1 & 0 \\ 7 & 7 & 0 \end{array}\right]$$

$$R_2 = R_2 - 7R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 5$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -2 & 1 \\ 7 & 4 \end{bmatrix} - (5) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -7 & 1 \\ 7 & -1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -7 & 1 & 0 \\ 7 & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} -7 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -7 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{t}{7}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{t}{7} \\ t \end{bmatrix} = \begin{bmatrix} \frac{t}{7} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{t}{7} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{7} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{t}{7} \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{7} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{t}{7} \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 7 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
5	1	1	No	$\begin{bmatrix} \frac{1}{7} \\ 1 \end{bmatrix}$
-3	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 5 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^{5t}\\ &= \begin{bmatrix} \frac{1}{7} \\ 1 \end{bmatrix} e^{5t}\end{aligned}$$

Since eigenvalue -3 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{-3t}\\ &= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{-3t}\end{aligned}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \frac{e^{5t}}{7} \\ e^{5t} \end{bmatrix} + c_2 \begin{bmatrix} -e^{-3t} \\ e^{-3t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{(c_1 e^{8t} - 7c_2) e^{-3t}}{7} \\ (c_1 e^{8t} + c_2) e^{-3t} \end{bmatrix}$$

Since initial conditions are given, the solution above needs to be updated by solving for the constants of integrations using the given initial conditions

$$\begin{bmatrix} x(0) = 6 \\ y(0) = 2 \end{bmatrix} \tag{1}$$

Substituting initial conditions into the above solution at $t = 0$ gives

$$\begin{bmatrix} 6 \\ 2 \end{bmatrix} = \begin{bmatrix} \frac{c_1}{7} - c_2 \\ c_1 + c_2 \end{bmatrix}$$

Solving for the constants of integrations gives

$$\begin{bmatrix} c_1 = 7 \\ c_2 = -5 \end{bmatrix}$$

Substituting these constants back in original solution in Eq. (1) gives

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{(7\,\mathrm{e}^{8t}+35)\,\mathrm{e}^{-3t}}{7} \\ (7\,\mathrm{e}^{8t}-5)\,\mathrm{e}^{-3t} \end{bmatrix}$$

The following is the phase plot of the system.

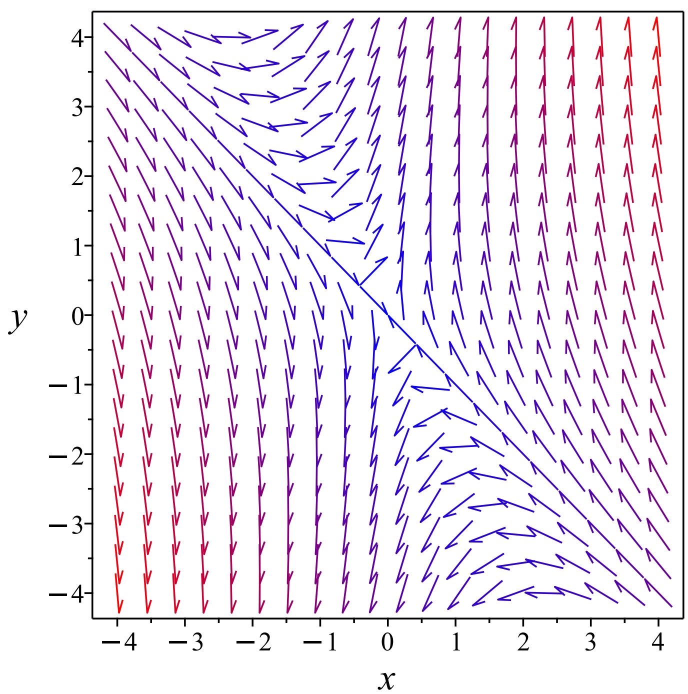

Figure 565: Phase plot

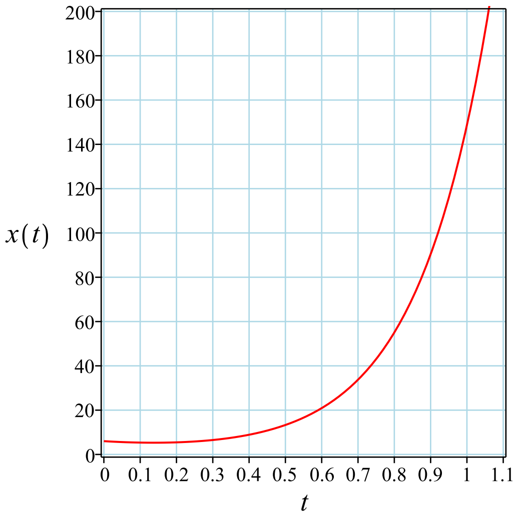
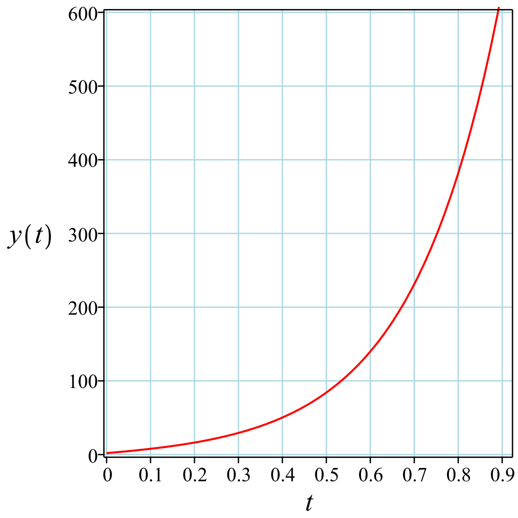
The following are plots of each solution.





✓ Solution by Maple

Time used: 0.015 (sec). Leaf size: 32

```

Problem number: 1.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"find eigenvalues and eigenvectors"**

Find the eigenvalues and associated eigenvectors of the matrix

$$\begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix}$$

The first step is to determine the characteristic polynomial of the matrix in order to find the eigenvalues of the matrix A. This is given by

$$\det(A - \lambda I) = 0$$
$$\det\left(\begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$
$$\det\begin{bmatrix} 1-\lambda & 2 \\ 3 & 2-\lambda \end{bmatrix} = 0$$
$$\lambda^2 - 3\lambda - 4 = 0$$

The eigenvalues are the roots of the above characteristic polynomial. Solving for the roots gives

$$\lambda_1 = 4$$
$$\lambda_2 = -1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
4	1	real eigenvalue

For each eigenvalue λ found above, we now find the corresponding eigenvector. Considering $\lambda = -1$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned}
A\boldsymbol{v} &= \lambda\boldsymbol{v} \\
A\boldsymbol{v} - \lambda\boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} - (-1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} - \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} 2 & 2 \\ 3 & 3 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix}
\end{aligned}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{cc|c} 2 & 2 & 0 \\ 3 & 3 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{3R_1}{2} \Longrightarrow \left[\begin{array}{cc|c} 2 & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & 2 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Considering $\lambda = 4$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned} A\boldsymbol{v} &= \lambda \boldsymbol{v} \\ A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\ (A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\ \left(\begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} - (4) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ \left(\begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} - \begin{bmatrix} 4 & 0 \\ 0 & 4 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ \begin{bmatrix} -3 & 2 \\ 3 & -2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \end{aligned}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{cc|c} -3 & 2 & 0 \\ 3 & -2 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} -3 & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -3 & 2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{2t}{3}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{2t}{3} \\ t \end{bmatrix} = \begin{bmatrix} \frac{2t}{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{2t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} \frac{2t}{3} \\ t \end{bmatrix} = \begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix}$$

Which can be normalized to

$$\begin{bmatrix} \frac{2t}{3} \\ t \end{bmatrix} = \begin{bmatrix} 2 \\ 3 \end{bmatrix}$$

The following table summarises the result found above.

λ	algebraic multiplicity	geometric multiplicity	defective eigenvalue?	associated eigenvectors
-1	1	2	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$
4	1	2	No	$\begin{bmatrix} 2 \\ 3 \end{bmatrix}$

Since the matrix is not defective, then it is diagonalizable. Let P the matrix whose columns are the eigenvectors found, and let D be diagonal matrix with the eigenvalues at its diagonal. Then we can write

$$A = PDP^{-1}$$

Where

$$D = \begin{bmatrix} -1 & 0 \\ 0 & 4 \end{bmatrix}$$

$$P = \begin{bmatrix} -1 & 2 \\ 1 & 3 \end{bmatrix}$$

Therefore

$$\begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} = \begin{bmatrix} -1 & 2 \\ 1 & 3 \end{bmatrix} \begin{bmatrix} -1 & 0 \\ 0 & 4 \end{bmatrix} \begin{bmatrix} -1 & 2 \\ 1 & 3 \end{bmatrix}^{-1}$$

The type(s) of ODE detected by this program : **"find eigenvalues and eigenvectors"**

Find the eigenvalues and associated eigenvectors of the matrix

$$\begin{bmatrix} 3 & 2 \\ 6 & -1 \end{bmatrix}$$

The first step is to determine the characteristic polynomial of the matrix in order to find the eigenvalues of the matrix A. This is given by

$$\det(A - \lambda I) = 0$$
$$\det\left(\begin{bmatrix} 3 & 2 \\ 6 & -1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$
$$\det \begin{bmatrix} 3-\lambda & 2 \\ 6 & -1-\lambda \end{bmatrix} = 0$$
$$\lambda^2 - 2\lambda - 15 = 0$$

The eigenvalues are the roots of the above characteristic polynomial. Solving for the roots gives

$$\lambda_1 = 5$$
$$\lambda_2 = -3$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-3	1	real eigenvalue
5	1	real eigenvalue

For each eigenvalue λ found above, we now find the corresponding eigenvector. Considering $\lambda = -3$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda \boldsymbol{v} \\
A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} 3 & 2 \\ 6 & -1 \end{bmatrix} - (-3) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} 3 & 2 \\ 6 & -1 \end{bmatrix} - \begin{bmatrix} -3 & 0 \\ 0 & -3 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} 6 & 2 \\ 6 & 2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{cc|c} 6 & 2 & 0 \\ 6 & 2 & 0 \end{array}\right]
$$

$$
R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 6 & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]
$$

Therefore the system in Echelon form is

$$
\begin{bmatrix} 6 & 2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}
$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{t}{3}\right\}$

Hence the solution is

$$
\begin{bmatrix} -\frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{t}{3} \\ t \end{bmatrix}
$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{3} \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} -\frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{3} \\ 1 \end{bmatrix}$$

Which can be normalized to

$$\begin{bmatrix} -\frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 3 \end{bmatrix}$$

Considering $\lambda = 5$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned} A\boldsymbol{v} &= \lambda \boldsymbol{v} \\ A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\ (A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\ \left(\begin{bmatrix} 3 & 2 \\ 6 & -1 \end{bmatrix} - (5) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ \left(\begin{bmatrix} 3 & 2 \\ 6 & -1 \end{bmatrix} - \begin{bmatrix} 5 & 0 \\ 0 & 5 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ \begin{bmatrix} -2 & 2 \\ 6 & -6 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \end{aligned}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{cc|c} -2 & 2 & 0 \\ 6 & -6 & 0 \end{array}\right]$$

$$R_2 = R_2 + 3R_1 \Longrightarrow \left[\begin{array}{cc|c} -2 & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & 2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table summarises the result found above.

λ	algebraic multiplicity	geometric multiplicity	defective eigenvalue?	associated eigenvectors
-3	1	2	No	$\begin{bmatrix} -1 \\ 3 \end{bmatrix}$
5	1	2	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$

Since the matrix is not defective, then it is diagonalizable. Let P the matrix whose columns are the eigenvectors found, and let D be diagonal matrix with the eigenvalues at its diagonal. Then we can write

$$A = PDP^{-1}$$

Where

$$D = \begin{bmatrix} -3 & 0 \\ 0 & 5 \end{bmatrix}$$

$$P = \begin{bmatrix} -1 & 1 \\ 3 & 1 \end{bmatrix}$$

Therefore

$$\begin{bmatrix} 3 & 2 \\ 6 & -1 \end{bmatrix} = \begin{bmatrix} -1 & 1 \\ 3 & 1 \end{bmatrix} \begin{bmatrix} -3 & 0 \\ 0 & 5 \end{bmatrix} \begin{bmatrix} -1 & 1 \\ 3 & 1 \end{bmatrix}^{-1}$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"find eigenvalues and eigenvectors"**

Find the eigenvalues and associated eigenvectors of the matrix

$$\begin{bmatrix} 3 & 1 \\ 12 & 2 \end{bmatrix}$$

The first step is to determine the characteristic polynomial of the matrix in order to find the eigenvalues of the matrix A. This is given by

$$\det(A - \lambda I) = 0$$
$$\det\left(\begin{bmatrix} 3 & 1 \\ 12 & 2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$
$$\det\begin{bmatrix} 3-\lambda & 1 \\ 12 & 2-\lambda \end{bmatrix} = 0$$
$$\lambda^2 - 5\lambda - 6 = 0$$

The eigenvalues are the roots of the above characteristic polynomial. Solving for the roots gives

$$\lambda_1 = 6$$
$$\lambda_2 = -1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
6	1	real eigenvalue

For each eigenvalue λ found above, we now find the corresponding eigenvector. Considering $\lambda = -1$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned} A\boldsymbol{v} &= \lambda \boldsymbol{v} \\ A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\ (A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\ \left(\begin{bmatrix} 3 & 1 \\ 12 & 2 \end{bmatrix} - (-1) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ \left(\begin{bmatrix} 3 & 1 \\ 12 & 2 \end{bmatrix} - \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ \begin{bmatrix} 4 & 1 \\ 12 & 3 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \end{aligned}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{cc|c} 4 & 1 & 0 \\ 12 & 3 & 0 \end{array}\right]$$

$$R_2 = R_2 - 3R_1 \Longrightarrow \left[\begin{array}{cc|c} 4 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 4 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -\frac{t}{4}\}$

Hence the solution is

$$\begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}$$

Which can be normalized to

$$\begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 4 \end{bmatrix}$$

Considering $\lambda = 6$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned} A\boldsymbol{v} &= \lambda\boldsymbol{v} \\ A\boldsymbol{v} - \lambda\boldsymbol{v} &= \boldsymbol{0} \\ (A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\ \left(\begin{bmatrix} 3 & 1 \\ 12 & 2 \end{bmatrix} - (6) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ \left(\begin{bmatrix} 3 & 1 \\ 12 & 2 \end{bmatrix} - \begin{bmatrix} 6 & 0 \\ 0 & 6 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ \begin{bmatrix} -3 & 1 \\ 12 & -4 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \end{aligned}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{cc|c} -3 & 1 & 0 \\ 12 & -4 & 0 \end{array}\right]$$

$$R_2 = R_2 + 4R_1 \Longrightarrow \left[\begin{array}{cc|c} -3 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -3 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{t}{3}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}$$

Which can be normalized to

$$\begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 3 \end{bmatrix}$$

The following table summarises the result found above.

λ	algebraic multiplicity	geometric multiplicity	defective eigenvalue?	associated eigenvectors
-1	1	2	No	$\begin{bmatrix} -1 \\ 4 \end{bmatrix}$
6	1	2	No	$\begin{bmatrix} 1 \\ 3 \end{bmatrix}$

Since the matrix is not defective, then it is diagonalizable. Let P the matrix whose columns are the eigenvectors found, and let D be diagonal matrix with the eigenvalues at its diagonal. Then we can write

$$A = PDP^{-1}$$

Where

$$D = \begin{bmatrix} -1 & 0 \\ 0 & 6 \end{bmatrix}$$

$$P = \begin{bmatrix} -1 & 1 \\ 4 & 3 \end{bmatrix}$$

Therefore

$$\begin{bmatrix} 3 & 1 \\ 12 & 2 \end{bmatrix} = \begin{bmatrix} -1 & 1 \\ 4 & 3 \end{bmatrix} \begin{bmatrix} -1 & 0 \\ 0 & 6 \end{bmatrix} \begin{bmatrix} -1 & 1 \\ 4 & 3 \end{bmatrix}^{-1}$$

Problem number: 4.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"find eigenvalues and eigenvectors"**

Find the eigenvalues and associated eigenvectors of the matrix

$$\begin{bmatrix} -2 & 7 \\ 3 & 2 \end{bmatrix}$$

The first step is to determine the characteristic polynomial of the matrix in order to find the eigenvalues of the matrix A. This is given by

$$\det(A - \lambda I) = 0$$

$$\det\left(\begin{bmatrix} -2 & 7 \\ 3 & 2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

$$\det\begin{bmatrix} -2-\lambda & 7 \\ 3 & 2-\lambda \end{bmatrix} = 0$$

$$\lambda^2 - 25 = 0$$

The eigenvalues are the roots of the above characteristic polynomial. Solving for the roots gives

$$\lambda_1 = 5$$
$$\lambda_2 = -5$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-5	1	real eigenvalue
5	1	real eigenvalue

For each eigenvalue λ found above, we now find the corresponding eigenvector. Considering $\lambda = -5$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda\boldsymbol{v} \\
A\boldsymbol{v} - \lambda\boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} -2 & 7 \\ 3 & 2 \end{bmatrix} - (-5)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} -2 & 7 \\ 3 & 2 \end{bmatrix} - \begin{bmatrix} -5 & 0 \\ 0 & -5 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} 3 & 7 \\ 3 & 7 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{cc|c} 3 & 7 & 0 \\ 3 & 7 & 0 \end{array}\right]
$$

$$
R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 3 & 7 & 0 \\ 0 & 0 & 0 \end{array}\right]
$$

Therefore the system in Echelon form is

$$
\begin{bmatrix} 3 & 7 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}
$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{7t}{3}\right\}$

Hence the solution is

$$
\begin{bmatrix} -\frac{7t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{7t}{3} \\ t \end{bmatrix}
$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{7t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{7}{3} \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} -\frac{7t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{7}{3} \\ 1 \end{bmatrix}$$

Which can be normalized to

$$\begin{bmatrix} -\frac{7t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -7 \\ 3 \end{bmatrix}$$

Considering $\lambda = 5$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned} A\boldsymbol{v} &= \lambda \boldsymbol{v} \\ A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\ (A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\ \left(\begin{bmatrix} -2 & 7 \\ 3 & 2 \end{bmatrix} - (5) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ \left(\begin{bmatrix} -2 & 7 \\ 3 & 2 \end{bmatrix} - \begin{bmatrix} 5 & 0 \\ 0 & 5 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ \begin{bmatrix} -7 & 7 \\ 3 & -3 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \end{aligned}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{cc|c} -7 & 7 & 0 \\ 3 & -3 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{3R_1}{7} \Longrightarrow \left[\begin{array}{cc|c} -7 & 7 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -7 & 7 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table summarises the result found above.

λ	algebraic multiplicity	geometric multiplicity	defective eigenvalue?	associated eigenvectors
-5	1	2	No	$\begin{bmatrix} -7 \\ 3 \end{bmatrix}$
5	1	2	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$

Since the matrix is not defective, then it is diagonalizable. Let P the matrix whose columns are the eigenvectors found, and let D be diagonal matrix with the eigenvalues at its diagonal. Then we can write

$$A = PDP^{-1}$$

Where

$$D = \begin{bmatrix} -5 & 0 \\ 0 & 5 \end{bmatrix}$$

$$P = \begin{bmatrix} -7 & 1 \\ 3 & 1 \end{bmatrix}$$

Therefore

$$\begin{bmatrix} -2 & 7 \\ 3 & 2 \end{bmatrix} = \begin{bmatrix} -7 & 1 \\ 3 & 1 \end{bmatrix} \begin{bmatrix} -5 & 0 \\ 0 & 5 \end{bmatrix} \begin{bmatrix} -7 & 1 \\ 3 & 1 \end{bmatrix}^{-1}$$

Problem number: 5.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"find eigenvalues and eigenvectors"**

Find the eigenvalues and associated eigenvectors of the matrix

$$\begin{bmatrix} 3 & 4 \\ 5 & 2 \end{bmatrix}$$

The first step is to determine the characteristic polynomial of the matrix in order to find the eigenvalues of the matrix A. This is given by

$$\det(A - \lambda I) = 0$$
$$\det\left(\begin{bmatrix} 3 & 4 \\ 5 & 2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$
$$\det \begin{bmatrix} 3-\lambda & 4 \\ 5 & 2-\lambda \end{bmatrix} = 0$$
$$\lambda^2 - 5\lambda - 14 = 0$$

The eigenvalues are the roots of the above characteristic polynomial. Solving for the roots gives

$$\lambda_1 = 7$$
$$\lambda_2 = -2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-2	1	real eigenvalue
7	1	real eigenvalue

For each eigenvalue λ found above, we now find the corresponding eigenvector. Considering $\lambda = -2$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda \boldsymbol{v} \\
A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} 3 & 4 \\ 5 & 2 \end{bmatrix} - (-2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} 3 & 4 \\ 5 & 2 \end{bmatrix} - \begin{bmatrix} -2 & 0 \\ 0 & -2 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} 5 & 4 \\ 5 & 4 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{cc|c} 5 & 4 & 0 \\ 5 & 4 & 0 \end{array}\right]
$$

$$
R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 5 & 4 & 0 \\ 0 & 0 & 0 \end{array}\right]
$$

Therefore the system in Echelon form is

$$
\begin{bmatrix} 5 & 4 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}
$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -\frac{4t}{5}\}$

Hence the solution is

$$
\begin{bmatrix} -\frac{4t}{5} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{4t}{5} \\ t \end{bmatrix}
$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{4t}{5} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{4}{5} \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} -\frac{4t}{5} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{4}{5} \\ 1 \end{bmatrix}$$

Which can be normalized to

$$\begin{bmatrix} -\frac{4t}{5} \\ t \end{bmatrix} = \begin{bmatrix} -4 \\ 5 \end{bmatrix}$$

Considering $\lambda = 7$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned} A\boldsymbol{v} &= \lambda \boldsymbol{v} \\ A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\ (A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\ \left(\begin{bmatrix} 3 & 4 \\ 5 & 2 \end{bmatrix} - (7) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ \left(\begin{bmatrix} 3 & 4 \\ 5 & 2 \end{bmatrix} - \begin{bmatrix} 7 & 0 \\ 0 & 7 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ \begin{bmatrix} -4 & 4 \\ 5 & -5 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \end{aligned}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{cc|c} -4 & 4 & 0 \\ 5 & -5 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{5R_1}{4} \Longrightarrow \left[\begin{array}{cc|c} -4 & 4 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -4 & 4 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table summarises the result found above.

λ	algebraic multiplicity	geometric multiplicity	defective eigenvalue?	associated eigenvectors
-2	1	2	No	$\begin{bmatrix} -4 \\ 5 \end{bmatrix}$
7	1	2	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$

Since the matrix is not defective, then it is diagonalizable. Let P the matrix whose columns are the eigenvectors found, and let D be diagonal matrix with the eigenvalues at its diagonal. Then we can write

$$A = PDP^{-1}$$

Where

$$D = \begin{bmatrix} -2 & 0 \\ 0 & 7 \end{bmatrix}$$

$$P = \begin{bmatrix} -4 & 1 \\ 5 & 1 \end{bmatrix}$$

Therefore

$$\begin{bmatrix} 3 & 4 \\ 5 & 2 \end{bmatrix} = \begin{bmatrix} -4 & 1 \\ 5 & 1 \end{bmatrix} \begin{bmatrix} -2 & 0 \\ 0 & 7 \end{bmatrix} \begin{bmatrix} -4 & 1 \\ 5 & 1 \end{bmatrix}^{-1}$$

Problem number: 6.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"find eigenvalues and eigenvectors"**

Find the eigenvalues and associated eigenvectors of the matrix

$$\begin{bmatrix} 3 & -5 \\ -4 & 2 \end{bmatrix}$$

The first step is to determine the characteristic polynomial of the matrix in order to find the eigenvalues of the matrix A. This is given by

$$\det(A - \lambda I) = 0$$

$$\det\left(\begin{bmatrix} 3 & -5 \\ -4 & 2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

$$\det\begin{bmatrix} 3-\lambda & -5 \\ -4 & 2-\lambda \end{bmatrix} = 0$$

$$\lambda^2 - 5\lambda - 14 = 0$$

The eigenvalues are the roots of the above characteristic polynomial. Solving for the roots gives

$$\lambda_1 = 7$$

$$\lambda_2 = -2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-2	1	real eigenvalue
7	1	real eigenvalue

For each eigenvalue λ found above, we now find the corresponding eigenvector. Considering $\lambda = -2$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda\boldsymbol{v} \\
A\boldsymbol{v} - \lambda\boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} 3 & -5 \\ -4 & 2 \end{bmatrix} - (-2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} 3 & -5 \\ -4 & 2 \end{bmatrix} - \begin{bmatrix} -2 & 0 \\ 0 & -2 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} 5 & -5 \\ -4 & 4 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{cc|c} 5 & -5 & 0 \\ -4 & 4 & 0 \end{array}\right]
$$

$$
R_2 = R_2 + \frac{4R_1}{5} \Longrightarrow \left[\begin{array}{cc|c} 5 & -5 & 0 \\ 0 & 0 & 0 \end{array}\right]
$$

Therefore the system in Echelon form is

$$
\begin{bmatrix} 5 & -5 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}
$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$
\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}
$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Considering $\lambda = 7$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned} A\boldsymbol{v} &= \lambda\boldsymbol{v} \\ A\boldsymbol{v} - \lambda\boldsymbol{v} &= \boldsymbol{0} \\ (A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\ \left(\begin{bmatrix} 3 & -5 \\ -4 & 2 \end{bmatrix} - (7)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ \left(\begin{bmatrix} 3 & -5 \\ -4 & 2 \end{bmatrix} - \begin{bmatrix} 7 & 0 \\ 0 & 7 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ \begin{bmatrix} -4 & -5 \\ -4 & -5 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \end{aligned}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{cc|c} -4 & -5 & 0 \\ -4 & -5 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} -4 & -5 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -4 & -5 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{5t}{4}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{5t}{4} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{5t}{4} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{5t}{4} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{5}{4} \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} -\frac{5t}{4} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{5}{4} \\ 1 \end{bmatrix}$$

Which can be normalized to

$$\begin{bmatrix} -\frac{5t}{4} \\ t \end{bmatrix} = \begin{bmatrix} -5 \\ 4 \end{bmatrix}$$

The following table summarises the result found above.

λ	algebraic multiplicity	geometric multiplicity	defective eigenvalue?	associated eigenvectors
-2	1	2	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$
7	1	2	No	$\begin{bmatrix} -5 \\ 4 \end{bmatrix}$

Since the matrix is not defective, then it is diagonalizable. Let P the matrix whose columns are the eigenvectors found, and let D be diagonal matrix with the eigenvalues at its diagonal. Then we can write

$$A = PDP^{-1}$$

Where

$$D = \begin{bmatrix} -2 & 0 \\ 0 & 7 \end{bmatrix}$$

$$P = \begin{bmatrix} 1 & -5 \\ 1 & 4 \end{bmatrix}$$

Therefore

$$\begin{bmatrix} 3 & -5 \\ -4 & 2 \end{bmatrix} = \begin{bmatrix} 1 & -5 \\ 1 & 4 \end{bmatrix} \begin{bmatrix} -2 & 0 \\ 0 & 7 \end{bmatrix} \begin{bmatrix} 1 & -5 \\ 1 & 4 \end{bmatrix}^{-1}$$

Problem number: 7.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"find eigenvalues and eigenvectors"**

Find the eigenvalues and associated eigenvectors of the matrix

$$\begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix}$$

The first step is to determine the characteristic polynomial of the matrix in order to find the eigenvalues of the matrix A. This is given by

$$\det(A - \lambda I) = 0$$

$$\det\left(\begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) = 0$$

$$\det \begin{bmatrix} 1-\lambda & 1 & -1 \\ 2 & 3-\lambda & -4 \\ 4 & 1 & -4-\lambda \end{bmatrix} = 0$$

$$-\lambda^3 + 7\lambda - 6 = 0$$

The eigenvalues are the roots of the above characteristic polynomial. Solving for the roots gives

$$\lambda_1 = 1$$
$$\lambda_2 = 2$$
$$\lambda_3 = -3$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue
-3	1	real eigenvalue
2	1	real eigenvalue

For each eigenvalue λ found above, we now find the corresponding eigenvector. Considering $\lambda = 1$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$A\boldsymbol{v} = \lambda \boldsymbol{v}$$
$$A\boldsymbol{v} - \lambda \boldsymbol{v} = \boldsymbol{0}$$
$$(A - \lambda I)\boldsymbol{v} = \boldsymbol{0}$$
$$\left(\begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$
$$\left(\begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} - \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 0 & 1 & -1 \\ 2 & 2 & -4 \\ 4 & 1 & -5 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{ccc|c} 0 & 1 & -1 & 0 \\ 2 & 2 & -4 & 0 \\ 4 & 1 & -5 & 0 \end{array}\right]$$

Since the current pivot $A(1,1)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 1 and row 2 gives

$$\left[\begin{array}{ccc|c} 2 & 2 & -4 & 0 \\ 0 & 1 & -1 & 0 \\ 4 & 1 & -5 & 0 \end{array}\right]$$

$$R_3 = R_3 - 2R_1 \Longrightarrow \left[\begin{array}{ccc|c} 2 & 2 & -4 & 0 \\ 0 & 1 & -1 & 0 \\ 0 & -3 & 3 & 0 \end{array}\right]$$

$$R_3 = R_3 + 3R_2 \Longrightarrow \left[\begin{array}{ccc|c} 2 & 2 & -4 & 0 \\ 0 & 1 & -1 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & 2 & -4 \\ 0 & 1 & -1 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t, v_2 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

Considering $\lambda = -3$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda \boldsymbol{v} \\
A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} - (-3) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} - \begin{bmatrix} -3 & 0 & 0 \\ 0 & -3 & 0 \\ 0 & 0 & -3 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} 4 & 1 & -1 \\ 2 & 6 & -4 \\ 4 & 1 & -1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{ccc|c} 4 & 1 & -1 & 0 \\ 2 & 6 & -4 & 0 \\ 4 & 1 & -1 & 0 \end{array}\right]
$$

$$
R_2 = R_2 - \frac{R_1}{2} \Longrightarrow \left[\begin{array}{ccc|c} 4 & 1 & -1 & 0 \\ 0 & \frac{11}{2} & -\frac{7}{2} & 0 \\ 4 & 1 & -1 & 0 \end{array}\right]
$$

$$
R_3 = R_3 - R_1 \Longrightarrow \left[\begin{array}{ccc|c} 4 & 1 & -1 & 0 \\ 0 & \frac{11}{2} & -\frac{7}{2} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]
$$

Therefore the system in Echelon form is

$$
\begin{bmatrix} 4 & 1 & -1 \\ 0 & \frac{11}{2} & -\frac{7}{2} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{t}{11}, v_2 = \frac{7t}{11}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{t}{11} \\ \frac{7t}{11} \\ t \end{bmatrix} = \begin{bmatrix} \frac{t}{11} \\ \frac{7t}{11} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{t}{11} \\ \frac{7t}{11} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{11} \\ \frac{7}{11} \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} \frac{t}{11} \\ \frac{7t}{11} \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{11} \\ \frac{7}{11} \\ 1 \end{bmatrix}$$

Which can be normalized to

$$\begin{bmatrix} \frac{t}{11} \\ \frac{7t}{11} \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 7 \\ 11 \end{bmatrix}$$

Considering $\lambda = 2$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda \boldsymbol{v} \\
A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} - (2) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} - \begin{bmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} -1 & 1 & -1 \\ 2 & 1 & -4 \\ 4 & 1 & -6 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{ccc|c} -1 & 1 & -1 & 0 \\ 2 & 1 & -4 & 0 \\ 4 & 1 & -6 & 0 \end{array}\right]
$$

$$
R_2 = R_2 + 2R_1 \Longrightarrow \left[\begin{array}{ccc|c} -1 & 1 & -1 & 0 \\ 0 & 3 & -6 & 0 \\ 4 & 1 & -6 & 0 \end{array}\right]
$$

$$
R_3 = R_3 + 4R_1 \Longrightarrow \left[\begin{array}{ccc|c} -1 & 1 & -1 & 0 \\ 0 & 3 & -6 & 0 \\ 0 & 5 & -10 & 0 \end{array}\right]
$$

$$
R_3 = R_3 - \frac{5R_2}{3} \Longrightarrow \left[\begin{array}{ccc|c} -1 & 1 & -1 & 0 \\ 0 & 3 & -6 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]
$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & 1 & -1 \\ 0 & 3 & -6 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t, v_2 = 2t\}$

Hence the solution is

$$\begin{bmatrix} t \\ 2t \\ t \end{bmatrix} = \begin{bmatrix} t \\ 2t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ 2t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} t \\ 2t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$$

The following table summarises the result found above.

λ	algebraic multiplicity	geometric multiplicity	defective eigenvalue?	associated eigenvectors
1	1	3	No	$\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$
-3	1	3	No	$\begin{bmatrix} 1 \\ 7 \\ 11 \end{bmatrix}$
2	1	3	No	$\begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$

Since the matrix is not defective, then it is diagonalizable. Let P the matrix whose columns are the eigenvectors found, and let D be diagonal matrix with the eigenvalues at its diagonal. Then we can write

$$A = PDP^{-1}$$

Where

$$D = \begin{bmatrix} 1 & 0 & 0 \\ 0 & -3 & 0 \\ 0 & 0 & 2 \end{bmatrix}$$

$$P = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 7 & 2 \\ 1 & 11 & 1 \end{bmatrix}$$

Therefore

$$\begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 7 & 2 \\ 1 & 11 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & -3 & 0 \\ 0 & 0 & 2 \end{bmatrix} \begin{bmatrix} 1 & 1 & 1 \\ 1 & 7 & 2 \\ 1 & 11 & 1 \end{bmatrix}^{-1}$$

The type(s) of ODE detected by this program : **"find eigenvalues and eigenvectors"**

Find the eigenvalues and associated eigenvectors of the matrix

$$\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix}$$

The first step is to determine the characteristic polynomial of the matrix in order to find the eigenvalues of the matrix A. This is given by

$$\det(A - \lambda I) = 0$$

$$\det\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) = 0$$

$$\det\begin{bmatrix} 1-\lambda & -1 & -1 \\ 1 & 3-\lambda & 1 \\ -3 & -6 & 6-\lambda \end{bmatrix} = 0$$

$$-\lambda^3 + 10\lambda^2 - 31\lambda + 30 = 0$$

The eigenvalues are the roots of the above characteristic polynomial. Solving for the roots gives

$$\lambda_1 = 5$$
$$\lambda_2 = 2$$
$$\lambda_3 = 3$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
2	1	real eigenvalue
3	1	real eigenvalue
5	1	real eigenvalue

For each eigenvalue λ found above, we now find the corresponding eigenvector. Considering $\lambda = 2$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda\boldsymbol{v} \\
A\boldsymbol{v} - \lambda\boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} - (2) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} - \begin{bmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} -1 & -1 & -1 \\ 1 & 1 & 1 \\ -3 & -6 & 4 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{ccc|c} -1 & -1 & -1 & 0 \\ 1 & 1 & 1 & 0 \\ -3 & -6 & 4 & 0 \end{array}\right]
$$

$$
R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{ccc|c} -1 & -1 & -1 & 0 \\ 0 & 0 & 0 & 0 \\ -3 & -6 & 4 & 0 \end{array}\right]
$$

$$
R_3 = R_3 - 3R_1 \implies \left[\begin{array}{ccc|c} -1 & -1 & -1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & -3 & 7 & 0 \end{array}\right]
$$

Since the current pivot $A(2,2)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 2 and row 3 gives

$$
\left[\begin{array}{ccc|c} -1 & -1 & -1 & 0 \\ 0 & -3 & 7 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]
$$

Therefore the system in Echelon form is

$$
\begin{bmatrix} -1 & -1 & -1 \\ 0 & -3 & 7 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{10t}{3}, v_2 = \frac{7t}{3}\right\}$

Hence the solution is

$$
\begin{bmatrix} -\frac{10t}{3} \\ \frac{7t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{10t}{3} \\ \frac{7t}{3} \\ t \end{bmatrix}
$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$
\begin{bmatrix} -\frac{10t}{3} \\ \frac{7t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{10}{3} \\ \frac{7}{3} \\ 1 \end{bmatrix}
$$

Or, by letting $t = 1$ then the eigenvector is

$$
\begin{bmatrix} -\frac{10t}{3} \\ \frac{7t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{10}{3} \\ \frac{7}{3} \\ 1 \end{bmatrix}
$$

Which can be normalized to

$$\begin{bmatrix} -\frac{10t}{3} \\ \frac{7t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -10 \\ 7 \\ 3 \end{bmatrix}$$

Considering $\lambda = 3$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned} A\boldsymbol{v} &= \lambda\boldsymbol{v} \\ A\boldsymbol{v} - \lambda\boldsymbol{v} &= \mathbf{0} \\ (A - \lambda I)\boldsymbol{v} &= \mathbf{0} \end{aligned}$$

$$\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} - (3) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} - \begin{bmatrix} 3 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 3 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -2 & -1 & -1 \\ 1 & 0 & 1 \\ -3 & -6 & 3 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{ccc|c} -2 & -1 & -1 & 0 \\ 1 & 0 & 1 & 0 \\ -3 & -6 & 3 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{2} \Longrightarrow \left[\begin{array}{ccc|c} -2 & -1 & -1 & 0 \\ 0 & -\frac{1}{2} & \frac{1}{2} & 0 \\ -3 & -6 & 3 & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{3R_1}{2} \Longrightarrow \left[\begin{array}{ccc|c} -2 & -1 & -1 & 0 \\ 0 & -\frac{1}{2} & \frac{1}{2} & 0 \\ 0 & -\frac{9}{2} & \frac{9}{2} & 0 \end{array}\right]$$

$$R_3 = R_3 - 9R_2 \Longrightarrow \left[\begin{array}{ccc|c} -2 & -1 & -1 & 0 \\ 0 & -\frac{1}{2} & \frac{1}{2} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & -1 & -1 \\ 0 & -\frac{1}{2} & \frac{1}{2} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t, v_2 = t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} -t \\ t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$$

Considering $\lambda = 5$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned}
A\boldsymbol{v} &= \lambda\boldsymbol{v} \\
A\boldsymbol{v} - \lambda\boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} - (5)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} - \begin{bmatrix} 5 & 0 & 0 \\ 0 & 5 & 0 \\ 0 & 0 & 5 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} -4 & -1 & -1 \\ 1 & -2 & 1 \\ -3 & -6 & 1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{ccc|c} -4 & -1 & -1 & 0 \\ 1 & -2 & 1 & 0 \\ -3 & -6 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{4} \Longrightarrow \left[\begin{array}{ccc|c} -4 & -1 & -1 & 0 \\ 0 & -\frac{9}{4} & \frac{3}{4} & 0 \\ -3 & -6 & 1 & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{3R_1}{4} \Longrightarrow \left[\begin{array}{ccc|c} -4 & -1 & -1 & 0 \\ 0 & -\frac{9}{4} & \frac{3}{4} & 0 \\ 0 & -\frac{21}{4} & \frac{7}{4} & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{7R_2}{3} \Longrightarrow \left[\begin{array}{ccc|c} -4 & -1 & -1 & 0 \\ 0 & -\frac{9}{4} & \frac{3}{4} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -4 & -1 & -1 \\ 0 & -\frac{9}{4} & \frac{3}{4} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{t}{3}, v_2 = \frac{t}{3}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{t}{3} \\ \frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{t}{3} \\ \frac{t}{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{t}{3} \\ \frac{t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{3} \\ \frac{1}{3} \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} -\frac{t}{3} \\ \frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{3} \\ \frac{1}{3} \\ 1 \end{bmatrix}$$

Which can be normalized to

$$\begin{bmatrix} -\frac{t}{3} \\ \frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \\ 3 \end{bmatrix}$$

The following table summarises the result found above.

λ	algebraic multiplicity	geometric multiplicity	defective eigenvalue?	associated eigenvectors
2	1	3	No	$\begin{bmatrix} -10 \\ 7 \\ 3 \end{bmatrix}$
3	1	3	No	$\begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$
5	1	3	No	$\begin{bmatrix} -1 \\ 1 \\ 3 \end{bmatrix}$

Since the matrix is not defective, then it is diagonalizable. Let P the matrix whose columns are the eigenvectors found, and let D be diagonal matrix with the eigenvalues at its diagonal. Then we can write

$$A = PDP^{-1}$$

Where

$$D = \begin{bmatrix} 2 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 5 \end{bmatrix}$$

$$P = \begin{bmatrix} -10 & -1 & -1 \\ 7 & 1 & 1 \\ 3 & 1 & 3 \end{bmatrix}$$

Therefore

$$\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} = \begin{bmatrix} -10 & -1 & -1 \\ 7 & 1 & 1 \\ 3 & 1 & 3 \end{bmatrix} \begin{bmatrix} 2 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 5 \end{bmatrix} \begin{bmatrix} -10 & -1 & -1 \\ 7 & 1 & 1 \\ 3 & 1 & 3 \end{bmatrix}^{-1}$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 7, Systems of linear differential equations. Section 7.5. Matrices and vectors. Exercises page 345
Problem number: 9.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"find eigenvalues and eigenvectors"**

Find the eigenvalues and associated eigenvectors of the matrix

$$\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & 1 & -1 \end{bmatrix}$$

The first step is to determine the characteristic polynomial of the matrix in order to find the eigenvalues of the matrix A. This is given by

$$\det(A - \lambda I) = 0$$

$$\det\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & 1 & -1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) = 0$$

$$\det\begin{bmatrix} 1-\lambda & -1 & -1 \\ 1 & 3-\lambda & 1 \\ -3 & 1 & -1-\lambda \end{bmatrix} = 0$$

$$-\lambda^3 + 3\lambda^2 + 4\lambda - 12 = 0$$

The eigenvalues are the roots of the above characteristic polynomial. Solving for the roots gives

$$\lambda_1 = 2$$
$$\lambda_2 = 3$$
$$\lambda_3 = -2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-2	1	real eigenvalue
2	1	real eigenvalue
3	1	real eigenvalue

For each eigenvalue λ found above, we now find the corresponding eigenvector. Considering $\lambda = -2$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda\boldsymbol{v} \\
A\boldsymbol{v} - \lambda\boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & 1 & -1 \end{bmatrix} - (-2)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & 1 & -1 \end{bmatrix} - \begin{bmatrix} -2 & 0 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & -2 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} 3 & -1 & -1 \\ 1 & 5 & 1 \\ -3 & 1 & 1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{ccc|c} 3 & -1 & -1 & 0 \\ 1 & 5 & 1 & 0 \\ -3 & 1 & 1 & 0 \end{array}\right]
$$

$$
R_2 = R_2 - \frac{R_1}{3} \Longrightarrow \left[\begin{array}{ccc|c} 3 & -1 & -1 & 0 \\ 0 & \frac{16}{3} & \frac{4}{3} & 0 \\ -3 & 1 & 1 & 0 \end{array}\right]
$$

$$R_3 = R_3 + R_1 \implies \left[\begin{array}{ccc|c} 3 & -1 & -1 & 0 \\ 0 & \frac{16}{3} & \frac{4}{3} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 3 & -1 & -1 \\ 0 & \frac{16}{3} & \frac{4}{3} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{t}{4}, v_2 = -\frac{t}{4}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{t}{4} \\ -\frac{t}{4} \\ t \end{bmatrix} = \begin{bmatrix} \frac{t}{4} \\ -\frac{t}{4} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{t}{4} \\ -\frac{t}{4} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{4} \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} \frac{t}{4} \\ -\frac{t}{4} \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{4} \\ 1 \end{bmatrix}$$

Which can be normalized to

$$\begin{bmatrix} \frac{t}{4} \\ -\frac{t}{4} \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ -1 \\ 4 \end{bmatrix}$$

Considering $\lambda = 2$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda \boldsymbol{v} \\
A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & 1 & -1 \end{bmatrix} - (2) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & 1 & -1 \end{bmatrix} - \begin{bmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} -1 & -1 & -1 \\ 1 & 1 & 1 \\ -3 & 1 & -3 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{ccc|c} -1 & -1 & -1 & 0 \\ 1 & 1 & 1 & 0 \\ -3 & 1 & -3 & 0 \end{array}\right]
$$

$$
R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{ccc|c} -1 & -1 & -1 & 0 \\ 0 & 0 & 0 & 0 \\ -3 & 1 & -3 & 0 \end{array}\right]
$$

$$
R_3 = R_3 - 3R_1 \Longrightarrow \left[\begin{array}{ccc|c} -1 & -1 & -1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 4 & 0 & 0 \end{array}\right]
$$

Since the current pivot $A(2,2)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 2 and row 3 gives

$$
\left[\begin{array}{ccc|c} -1 & -1 & -1 & 0 \\ 0 & 4 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]
$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & -1 & -1 \\ 0 & 4 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t, v_2 = 0\}$

Hence the solution is

$$\begin{bmatrix} -t \\ 0 \\ t \end{bmatrix} = \begin{bmatrix} -t \\ 0 \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ 0 \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} -t \\ 0 \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$$

Considering $\lambda = 3$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda\boldsymbol{v} \\
A\boldsymbol{v} - \lambda\boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & 1 & -1 \end{bmatrix} - (3)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & 1 & -1 \end{bmatrix} - \begin{bmatrix} 3 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 3 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} -2 & -1 & -1 \\ 1 & 0 & 1 \\ -3 & 1 & -4 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{ccc|c} -2 & -1 & -1 & 0 \\ 1 & 0 & 1 & 0 \\ -3 & 1 & -4 & 0 \end{array}\right]
$$

$$
R_2 = R_2 + \frac{R_1}{2} \implies \left[\begin{array}{ccc|c} -2 & -1 & -1 & 0 \\ 0 & -\frac{1}{2} & \frac{1}{2} & 0 \\ -3 & 1 & -4 & 0 \end{array}\right]
$$

$$
R_3 = R_3 - \frac{3R_1}{2} \implies \left[\begin{array}{ccc|c} -2 & -1 & -1 & 0 \\ 0 & -\frac{1}{2} & \frac{1}{2} & 0 \\ 0 & \frac{5}{2} & -\frac{5}{2} & 0 \end{array}\right]
$$

$$
R_3 = R_3 + 5R_2 \implies \left[\begin{array}{ccc|c} -2 & -1 & -1 & 0 \\ 0 & -\frac{1}{2} & \frac{1}{2} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]
$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & -1 & -1 \\ 0 & -\frac{1}{2} & \frac{1}{2} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t, v_2 = t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} -t \\ t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$$

The following table summarises the result found above.

λ	algebraic multiplicity	geometric multiplicity	defective eigenvalue?	associated eigenvectors
-2	1	3	No	$\begin{bmatrix} 1 \\ -1 \\ 4 \end{bmatrix}$
2	1	3	No	$\begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$
3	1	3	No	$\begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$

Since the matrix is not defective, then it is diagonalizable. Let P the matrix whose columns are the eigenvectors found, and let D be diagonal matrix with the eigenvalues at its diagonal. Then we can write

$$A = PDP^{-1}$$

Where

$$D = \begin{bmatrix} -2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix}$$

$$P = \begin{bmatrix} 1 & -1 & -1 \\ -1 & 0 & 1 \\ 4 & 1 & 1 \end{bmatrix}$$

Therefore

$$\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & 1 & -1 \end{bmatrix} = \begin{bmatrix} 1 & -1 & -1 \\ -1 & 0 & 1 \\ 4 & 1 & 1 \end{bmatrix} \begin{bmatrix} -2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix} \begin{bmatrix} 1 & -1 & -1 \\ -1 & 0 & 1 \\ 4 & 1 & 1 \end{bmatrix}^{-1}$$

Problem number: 10.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"find eigenvalues and eigenvectors"**

Find the eigenvalues and associated eigenvectors of the matrix

$$\begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix}$$

The first step is to determine the characteristic polynomial of the matrix in order to find the eigenvalues of the matrix A. This is given by

$$\det(A - \lambda I) = 0$$

$$\det\left(\begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) = 0$$

$$\det \begin{bmatrix} 1-\lambda & 1 & 0 \\ 1 & -\lambda & 1 \\ 0 & 1 & 1-\lambda \end{bmatrix} = 0$$

$$-\lambda^3 + 2\lambda^2 + \lambda - 2 = 0$$

The eigenvalues are the roots of the above characteristic polynomial. Solving for the roots gives

$$\lambda_1 = 1$$
$$\lambda_2 = 2$$
$$\lambda_3 = -1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
1	1	real eigenvalue
2	1	real eigenvalue

For each eigenvalue λ found above, we now find the corresponding eigenvector. Considering $\lambda = -1$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda \boldsymbol{v} \\
A\boldsymbol{v} - \lambda \boldsymbol{v} &= \mathbf{0} \\
(A - \lambda I)\boldsymbol{v} &= \mathbf{0} \\
\left(\begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix} - (-1) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix} - \begin{bmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} 2 & 1 & 0 \\ 1 & 1 & 1 \\ 0 & 1 & 2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{ccc|c} 2 & 1 & 0 & 0 \\ 1 & 1 & 1 & 0 \\ 0 & 1 & 2 & 0 \end{array}\right]
$$

$$
R_2 = R_2 - \frac{R_1}{2} \Longrightarrow \left[\begin{array}{ccc|c} 2 & 1 & 0 & 0 \\ 0 & \frac{1}{2} & 1 & 0 \\ 0 & 1 & 2 & 0 \end{array}\right]
$$

$$R_3 = R_3 - 2R_2 \Longrightarrow \left[\begin{array}{ccc|c} 2 & 1 & 0 & 0 \\ 0 & \frac{1}{2} & 1 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & 1 & 0 \\ 0 & \frac{1}{2} & 1 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t, v_2 = -2t\}$

Hence the solution is

$$\begin{bmatrix} t \\ -2t \\ t \end{bmatrix} = \begin{bmatrix} t \\ -2t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ -2t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ -2 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} t \\ -2t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ -2 \\ 1 \end{bmatrix}$$

Considering $\lambda = 1$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda \boldsymbol{v} \\
A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix} - \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} 0 & 1 & 0 \\ 1 & -1 & 1 \\ 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{ccc|c} 0 & 1 & 0 & 0 \\ 1 & -1 & 1 & 0 \\ 0 & 1 & 0 & 0 \end{array}\right]
$$

Since the current pivot $A(1,1)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 1 and row 2 gives

$$
\left[\begin{array}{ccc|c} 1 & -1 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{array}\right]
$$

$$
R_3 = R_3 - R_2 \Longrightarrow \left[\begin{array}{ccc|c} 1 & -1 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]
$$

Therefore the system in Echelon form is

$$
\begin{bmatrix} 1 & -1 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t, v_2 = 0\}$

Hence the solution is

$$\begin{bmatrix} -t \\ 0 \\ t \end{bmatrix} = \begin{bmatrix} -t \\ 0 \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ 0 \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} -t \\ 0 \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$$

Considering $\lambda = 2$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned} A\boldsymbol{v} &= \lambda \boldsymbol{v} \\ A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\ (A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \end{aligned}$$

$$\left(\begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix} - (2) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\left(\begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix} - \begin{bmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -1 & 1 & 0 \\ 1 & -2 & 1 \\ 0 & 1 & -1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{ccc|c} -1 & 1 & 0 & 0 \\ 1 & -2 & 1 & 0 \\ 0 & 1 & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{ccc|c} -1 & 1 & 0 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & 1 & -1 & 0 \end{array}\right]$$

$$R_3 = R_3 + R_2 \Longrightarrow \left[\begin{array}{ccc|c} -1 & 1 & 0 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & 1 & 0 \\ 0 & -1 & 1 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t, v_2 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

The following table summarises the result found above.

λ	algebraic multiplicity	geometric multiplicity	defective eigenvalue?	associated eigenvectors
-1	1	3	No	$\begin{bmatrix} 1 \\ -2 \\ 1 \end{bmatrix}$
1	1	3	No	$\begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$
2	1	3	No	$\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$

Since the matrix is not defective, then it is diagonalizable. Let P the matrix whose columns are the eigenvectors found, and let D be diagonal matrix with the eigenvalues at its diagonal. Then we can write

$$A = PDP^{-1}$$

Where

$$D = \begin{bmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 2 \end{bmatrix}$$

$$P = \begin{bmatrix} 1 & -1 & 1 \\ -2 & 0 & 1 \\ 1 & 1 & 1 \end{bmatrix}$$

Therefore

$$\begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix} = \begin{bmatrix} 1 & -1 & 1 \\ -2 & 0 & 1 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 2 \end{bmatrix} \begin{bmatrix} 1 & -1 & 1 \\ -2 & 0 & 1 \\ 1 & 1 & 1 \end{bmatrix}^{-1}$$

Problem number: 11.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"find eigenvalues and eigenvectors"**

Find the eigenvalues and associated eigenvectors of the matrix

$$\begin{bmatrix} 1 & 3 & -6 \\ 0 & 2 & 2 \\ 0 & -1 & 5 \end{bmatrix}$$

The first step is to determine the characteristic polynomial of the matrix in order to find the eigenvalues of the matrix A. This is given by

$$\det(A - \lambda I) = 0$$

$$\det\left(\begin{bmatrix} 1 & 3 & -6 \\ 0 & 2 & 2 \\ 0 & -1 & 5 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) = 0$$

$$\det\begin{bmatrix} 1-\lambda & 3 & -6 \\ 0 & 2-\lambda & 2 \\ 0 & -1 & 5-\lambda \end{bmatrix} = 0$$

$$-(-1+\lambda)\left(\lambda^2 - 7\lambda + 12\right) = 0$$

The eigenvalues are the roots of the above characteristic polynomial. Solving for the roots gives

$$\lambda_1 = 1$$
$$\lambda_2 = 4$$
$$\lambda_3 = 3$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue
3	1	real eigenvalue
4	1	real eigenvalue

For each eigenvalue λ found above, we now find the corresponding eigenvector. Considering $\lambda = 1$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda\boldsymbol{v} \\
A\boldsymbol{v} - \lambda\boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} 1 & 3 & -6 \\ 0 & 2 & 2 \\ 0 & -1 & 5 \end{bmatrix} - (1)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} 1 & 3 & -6 \\ 0 & 2 & 2 \\ 0 & -1 & 5 \end{bmatrix} - \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} 0 & 3 & -6 \\ 0 & 1 & 2 \\ 0 & -1 & 4 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{ccc|c} 0 & 3 & -6 & 0 \\ 0 & 1 & 2 & 0 \\ 0 & -1 & 4 & 0 \end{array}\right]
$$

$$
R_2 = R_2 - \frac{R_1}{3} \Longrightarrow \left[\begin{array}{ccc|c} 0 & 3 & -6 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & -1 & 4 & 0 \end{array}\right]
$$

$$R_3 = R_3 + \frac{R_1}{3} \Longrightarrow \left[\begin{array}{ccc|c} 0 & 3 & -6 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & 2 & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{R_2}{2} \Longrightarrow \left[\begin{array}{ccc|c} 0 & 3 & -6 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 0 & 3 & -6 \\ 0 & 0 & 4 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_1\}$ and the leading variables are $\{v_2, v_3\}$. Let $v_1 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_2 = 0, v_3 = 0\}$

Hence the solution is

$$\begin{bmatrix} t \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} t \\ 0 \\ 0 \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ 0 \\ 0 \end{bmatrix} = t \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} t \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

Considering $\lambda = 3$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda \boldsymbol{v} \\
A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} 1 & 3 & -6 \\ 0 & 2 & 2 \\ 0 & -1 & 5 \end{bmatrix} - (3) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} 1 & 3 & -6 \\ 0 & 2 & 2 \\ 0 & -1 & 5 \end{bmatrix} - \begin{bmatrix} 3 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 3 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} -2 & 3 & -6 \\ 0 & -1 & 2 \\ 0 & -1 & 2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{ccc|c} -2 & 3 & -6 & 0 \\ 0 & -1 & 2 & 0 \\ 0 & -1 & 2 & 0 \end{array}\right]
$$

$$
R_3 = R_3 - R_2 \Longrightarrow \left[\begin{array}{ccc|c} -2 & 3 & -6 & 0 \\ 0 & -1 & 2 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]
$$

Therefore the system in Echelon form is

$$
\begin{bmatrix} -2 & 3 & -6 \\ 0 & -1 & 2 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 0, v_2 = 2t\}$

Hence the solution is

$$\begin{bmatrix} 0 \\ 2t \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 2t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 0 \\ 2t \\ t \end{bmatrix} = t \begin{bmatrix} 0 \\ 2 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} 0 \\ 2t \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 2 \\ 1 \end{bmatrix}$$

Considering $\lambda = 4$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned} A\boldsymbol{v} &= \lambda\boldsymbol{v} \\ A\boldsymbol{v} - \lambda\boldsymbol{v} &= \mathbf{0} \\ (A - \lambda I)\boldsymbol{v} &= \mathbf{0} \\ \left(\begin{bmatrix} 1 & 3 & -6 \\ 0 & 2 & 2 \\ 0 & -1 & 5 \end{bmatrix} - (4) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\ \left(\begin{bmatrix} 1 & 3 & -6 \\ 0 & 2 & 2 \\ 0 & -1 & 5 \end{bmatrix} - \begin{bmatrix} 4 & 0 & 0 \\ 0 & 4 & 0 \\ 0 & 0 & 4 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\ \begin{bmatrix} -3 & 3 & -6 \\ 0 & -2 & 2 \\ 0 & -1 & 1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \end{aligned}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{ccc|c} -3 & 3 & -6 & 0 \\ 0 & -2 & 2 & 0 \\ 0 & -1 & 1 & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{R_2}{2} \Longrightarrow \left[\begin{array}{ccc|c} -3 & 3 & -6 & 0 \\ 0 & -2 & 2 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -3 & 3 & -6 \\ 0 & -2 & 2 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t, v_2 = t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} -t \\ t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$$

The following table summarises the result found above.

λ	algebraic multiplicity	geometric multiplicity	defective eigenvalue?	associated eigenvectors
1	1	3	No	$\begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$
3	1	3	No	$\begin{bmatrix} 0 \\ 2 \\ 1 \end{bmatrix}$
4	1	3	No	$\begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$

Since the matrix is not defective, then it is diagonalizable. Let P the matrix whose columns are the eigenvectors found, and let D be diagonal matrix with the eigenvalues at its diagonal. Then we can write

$$A = PDP^{-1}$$

Where

$$D = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 4 \end{bmatrix}$$

$$P = \begin{bmatrix} 1 & 0 & -1 \\ 0 & 2 & 1 \\ 0 & 1 & 1 \end{bmatrix}$$

Therefore

$$\begin{bmatrix} 1 & 3 & -6 \\ 0 & 2 & 2 \\ 0 & -1 & 5 \end{bmatrix} = \begin{bmatrix} 1 & 0 & -1 \\ 0 & 2 & 1 \\ 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 4 \end{bmatrix} \begin{bmatrix} 1 & 0 & -1 \\ 0 & 2 & 1 \\ 0 & 1 & 1 \end{bmatrix}^{-1}$$

The type(s) of ODE detected by this program : **"find eigenvalues and eigenvectors"**

Find the eigenvalues and associated eigenvectors of the matrix

$$\begin{bmatrix} -5 & -12 & 6 \\ 1 & 5 & -1 \\ -7 & -10 & 8 \end{bmatrix}$$

The first step is to determine the characteristic polynomial of the matrix in order to find the eigenvalues of the matrix A. This is given by

$$\det(A - \lambda I) = 0$$

$$\det\left(\begin{bmatrix} -5 & -12 & 6 \\ 1 & 5 & -1 \\ -7 & -10 & 8 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) = 0$$

$$\det\begin{bmatrix} -5-\lambda & -12 & 6 \\ 1 & 5-\lambda & -1 \\ -7 & -10 & 8-\lambda \end{bmatrix} = 0$$

$$-\lambda^3 + 8\lambda^2 - 19\lambda + 12 = 0$$

The eigenvalues are the roots of the above characteristic polynomial. Solving for the roots gives

$$\lambda_1 = 1$$
$$\lambda_2 = 3$$
$$\lambda_3 = 4$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue
3	1	real eigenvalue
4	1	real eigenvalue

For each eigenvalue λ found above, we now find the corresponding eigenvector. Considering $\lambda = 1$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda \boldsymbol{v} \\
A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} -5 & -12 & 6 \\ 1 & 5 & -1 \\ -7 & -10 & 8 \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} -5 & -12 & 6 \\ 1 & 5 & -1 \\ -7 & -10 & 8 \end{bmatrix} - \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} -6 & -12 & 6 \\ 1 & 4 & -1 \\ -7 & -10 & 7 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{ccc|c} -6 & -12 & 6 & 0 \\ 1 & 4 & -1 & 0 \\ -7 & -10 & 7 & 0 \end{array}\right]
$$

$$
R_2 = R_2 + \frac{R_1}{6} \Longrightarrow \left[\begin{array}{ccc|c} -6 & -12 & 6 & 0 \\ 0 & 2 & 0 & 0 \\ -7 & -10 & 7 & 0 \end{array}\right]
$$

$$R_3 = R_3 - \frac{7R_1}{6} \Longrightarrow \left[\begin{array}{ccc|c} -6 & -12 & 6 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 4 & 0 & 0 \end{array}\right]$$

$$R_3 = R_3 - 2R_2 \Longrightarrow \left[\begin{array}{ccc|c} -6 & -12 & 6 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -6 & -12 & 6 \\ 0 & 2 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t, v_2 = 0\}$

Hence the solution is

$$\begin{bmatrix} t \\ 0 \\ t \end{bmatrix} = \begin{bmatrix} t \\ 0 \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ 0 \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} t \\ 0 \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$$

Considering $\lambda = 3$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned} A\boldsymbol{v} &= \lambda\boldsymbol{v} \\ A\boldsymbol{v} - \lambda\boldsymbol{v} &= \boldsymbol{0} \\ (A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \end{aligned}$$

$$\left(\begin{bmatrix} -5 & -12 & 6 \\ 1 & 5 & -1 \\ -7 & -10 & 8 \end{bmatrix} - (3)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\left(\begin{bmatrix} -5 & -12 & 6 \\ 1 & 5 & -1 \\ -7 & -10 & 8 \end{bmatrix} - \begin{bmatrix} 3 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 3 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -8 & -12 & 6 \\ 1 & 2 & -1 \\ -7 & -10 & 5 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{ccc|c} -8 & -12 & 6 & 0 \\ 1 & 2 & -1 & 0 \\ -7 & -10 & 5 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{8} \Longrightarrow \left[\begin{array}{ccc|c} -8 & -12 & 6 & 0 \\ 0 & \frac{1}{2} & -\frac{1}{4} & 0 \\ -7 & -10 & 5 & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{7R_1}{8} \Longrightarrow \left[\begin{array}{ccc|c} -8 & -12 & 6 & 0 \\ 0 & \frac{1}{2} & -\frac{1}{4} & 0 \\ 0 & \frac{1}{2} & -\frac{1}{4} & 0 \end{array}\right]$$

$$R_3 = R_3 - R_2 \Longrightarrow \left[\begin{array}{ccc|c} -8 & -12 & 6 & 0 \\ 0 & \frac{1}{2} & -\frac{1}{4} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -8 & -12 & 6 \\ 0 & \frac{1}{2} & -\frac{1}{4} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = 0, v_2 = \frac{t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} 0 \\ \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ \frac{t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 0 \\ \frac{t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} 0 \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} 0 \\ \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

Which can be normalized to

$$\begin{bmatrix} 0 \\ \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \\ 2 \end{bmatrix}$$

Considering $\lambda = 4$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned} A\boldsymbol{v} &= \lambda \boldsymbol{v} \\ A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\ (A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \end{aligned}$$

$$\left(\begin{bmatrix} -5 & -12 & 6 \\ 1 & 5 & -1 \\ -7 & -10 & 8 \end{bmatrix} - (4) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\left(\begin{bmatrix} -5 & -12 & 6 \\ 1 & 5 & -1 \\ -7 & -10 & 8 \end{bmatrix} - \begin{bmatrix} 4 & 0 & 0 \\ 0 & 4 & 0 \\ 0 & 0 & 4 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -9 & -12 & 6 \\ 1 & 1 & -1 \\ -7 & -10 & 4 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{ccc|c} -9 & -12 & 6 & 0 \\ 1 & 1 & -1 & 0 \\ -7 & -10 & 4 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{9} \Longrightarrow \left[\begin{array}{ccc|c} -9 & -12 & 6 & 0 \\ 0 & -\frac{1}{3} & -\frac{1}{3} & 0 \\ -7 & -10 & 4 & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{7R_1}{9} \Longrightarrow \left[\begin{array}{ccc|c} -9 & -12 & 6 & 0 \\ 0 & -\frac{1}{3} & -\frac{1}{3} & 0 \\ 0 & -\frac{2}{3} & -\frac{2}{3} & 0 \end{array}\right]$$

$$R_3 = R_3 - 2R_2 \Longrightarrow \left[\begin{array}{ccc|c} -9 & -12 & 6 & 0 \\ 0 & -\frac{1}{3} & -\frac{1}{3} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -9 & -12 & 6 \\ 0 & -\frac{1}{3} & -\frac{1}{3} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 2t, v_2 = -t\}$

Hence the solution is

$$\begin{bmatrix} 2t \\ -t \\ t \end{bmatrix} = \begin{bmatrix} 2t \\ -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 2t \\ -t \\ t \end{bmatrix} = t \begin{bmatrix} 2 \\ -1 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} 2t \\ -t \\ t \end{bmatrix} = \begin{bmatrix} 2 \\ -1 \\ 1 \end{bmatrix}$$

The following table summarises the result found above.

λ	algebraic multiplicity	geometric multiplicity	defective eigenvalue?	associated eigenvectors
1	1	3	No	$\begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$
3	1	3	No	$\begin{bmatrix} 0 \\ 1 \\ 2 \end{bmatrix}$
4	1	3	No	$\begin{bmatrix} 2 \\ -1 \\ 1 \end{bmatrix}$

Since the matrix is not defective, then it is diagonalizable. Let P the matrix whose columns are the eigenvectors found, and let D be diagonal matrix with the eigenvalues at its diagonal. Then we can write

$$A = PDP^{-1}$$

Where

$$D = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 4 \end{bmatrix}$$

$$P = \begin{bmatrix} 1 & 0 & 2 \\ 0 & 1 & -1 \\ 1 & 2 & 1 \end{bmatrix}$$

Therefore

$$\begin{bmatrix} -5 & -12 & 6 \\ 1 & 5 & -1 \\ -7 & -10 & 8 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 2 \\ 0 & 1 & -1 \\ 1 & 2 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 4 \end{bmatrix} \begin{bmatrix} 1 & 0 & 2 \\ 0 & 1 & -1 \\ 1 & 2 & 1 \end{bmatrix}^{-1}$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"find eigenvalues and eigenvectors"**

Find the eigenvalues and associated eigenvectors of the matrix

$$\begin{bmatrix} -2 & 5 & 5 \\ -1 & 4 & 5 \\ 3 & -3 & 2 \end{bmatrix}$$

The first step is to determine the characteristic polynomial of the matrix in order to find the eigenvalues of the matrix A. This is given by

$$\det(A - \lambda I) = 0$$

$$\det\left(\begin{bmatrix} -2 & 5 & 5 \\ -1 & 4 & 5 \\ 3 & -3 & 2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) = 0$$

$$\det \begin{bmatrix} -2-\lambda & 5 & 5 \\ -1 & 4-\lambda & 5 \\ 3 & -3 & 2-\lambda \end{bmatrix} = 0$$

$$-\lambda^3 + 4\lambda^2 - \lambda - 6 = 0$$

The eigenvalues are the roots of the above characteristic polynomial. Solving for the roots gives

$$\lambda_1 = 2$$
$$\lambda_2 = 3$$
$$\lambda_3 = -1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
2	1	real eigenvalue
3	1	real eigenvalue

For each eigenvalue λ found above, we now find the corresponding eigenvector. Considering $\lambda = -1$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda\boldsymbol{v} \\
A\boldsymbol{v} - \lambda\boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} -2 & 5 & 5 \\ -1 & 4 & 5 \\ 3 & -3 & 2 \end{bmatrix} - (-1)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} -2 & 5 & 5 \\ -1 & 4 & 5 \\ 3 & -3 & 2 \end{bmatrix} - \begin{bmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} -1 & 5 & 5 \\ -1 & 5 & 5 \\ 3 & -3 & 3 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{ccc|c} -1 & 5 & 5 & 0 \\ -1 & 5 & 5 & 0 \\ 3 & -3 & 3 & 0 \end{array}\right]
$$

$$
R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{ccc|c} -1 & 5 & 5 & 0 \\ 0 & 0 & 0 & 0 \\ 3 & -3 & 3 & 0 \end{array}\right]
$$

$$R_3 = R_3 + 3R_1 \Longrightarrow \left[\begin{array}{ccc|c} -1 & 5 & 5 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 12 & 18 & 0 \end{array}\right]$$

Since the current pivot $A(2,2)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 2 and row 3 gives

$$\left[\begin{array}{ccc|c} -1 & 5 & 5 & 0 \\ 0 & 12 & 18 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & 5 & 5 \\ 0 & 12 & 18 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{5t}{2}, v_2 = -\frac{3t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{5t}{2} \\ -\frac{3t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{5t}{2} \\ -\frac{3t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{5t}{2} \\ -\frac{3t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{5}{2} \\ -\frac{3}{2} \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} -\frac{5t}{2} \\ -\frac{3t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{5}{2} \\ -\frac{3}{2} \\ 1 \end{bmatrix}$$

Which can be normalized to

$$\begin{bmatrix} -\frac{5t}{2} \\ -\frac{3t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -5 \\ -3 \\ 2 \end{bmatrix}$$

Considering $\lambda = 2$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned} A\boldsymbol{v} &= \lambda\boldsymbol{v} \\ A\boldsymbol{v} - \lambda\boldsymbol{v} &= \boldsymbol{0} \\ (A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \end{aligned}$$

$$\left(\begin{bmatrix} -2 & 5 & 5 \\ -1 & 4 & 5 \\ 3 & -3 & 2 \end{bmatrix} - (2)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\left(\begin{bmatrix} -2 & 5 & 5 \\ -1 & 4 & 5 \\ 3 & -3 & 2 \end{bmatrix} - \begin{bmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -4 & 5 & 5 \\ -1 & 2 & 5 \\ 3 & -3 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{ccc|c} -4 & 5 & 5 & 0 \\ -1 & 2 & 5 & 0 \\ 3 & -3 & 0 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{4} \Longrightarrow \left[\begin{array}{ccc|c} -4 & 5 & 5 & 0 \\ 0 & \frac{3}{4} & \frac{15}{4} & 0 \\ 3 & -3 & 0 & 0 \end{array}\right]$$

$$R_3 = R_3 + \frac{3R_1}{4} \Longrightarrow \left[\begin{array}{ccc|c} -4 & 5 & 5 & 0 \\ 0 & \frac{3}{4} & \frac{15}{4} & 0 \\ 0 & \frac{3}{4} & \frac{15}{4} & 0 \end{array}\right]$$

$$R_3 = R_3 - R_2 \Longrightarrow \left[\begin{array}{ccc|c} -4 & 5 & 5 & 0 \\ 0 & \frac{3}{4} & \frac{15}{4} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -4 & 5 & 5 \\ 0 & \frac{3}{4} & \frac{15}{4} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -5t, v_2 = -5t\}$

Hence the solution is

$$\begin{bmatrix} -5t \\ -5t \\ t \end{bmatrix} = \begin{bmatrix} -5t \\ -5t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -5t \\ -5t \\ t \end{bmatrix} = t \begin{bmatrix} -5 \\ -5 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} -5t \\ -5t \\ t \end{bmatrix} = \begin{bmatrix} -5 \\ -5 \\ 1 \end{bmatrix}$$

Considering $\lambda = 3$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned}
A\boldsymbol{v} &= \lambda\boldsymbol{v} \\
A\boldsymbol{v} - \lambda\boldsymbol{v} &= \mathbf{0} \\
(A - \lambda I)\boldsymbol{v} &= \mathbf{0} \\
\left(\begin{bmatrix} -2 & 5 & 5 \\ -1 & 4 & 5 \\ 3 & -3 & 2 \end{bmatrix} - (3) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} -2 & 5 & 5 \\ -1 & 4 & 5 \\ 3 & -3 & 2 \end{bmatrix} - \begin{bmatrix} 3 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 3 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} -5 & 5 & 5 \\ -1 & 1 & 5 \\ 3 & -3 & -1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{ccc|c} -5 & 5 & 5 & 0 \\ -1 & 1 & 5 & 0 \\ 3 & -3 & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{5} \Longrightarrow \left[\begin{array}{ccc|c} -5 & 5 & 5 & 0 \\ 0 & 0 & 4 & 0 \\ 3 & -3 & -1 & 0 \end{array}\right]$$

$$R_3 = R_3 + \frac{3R_1}{5} \Longrightarrow \left[\begin{array}{ccc|c} -5 & 5 & 5 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & 2 & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{R_2}{2} \Longrightarrow \left[\begin{array}{ccc|c} -5 & 5 & 5 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -5 & 5 & 5 \\ 0 & 0 & 4 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1, v_3\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t, v_3 = 0\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \\ 0 \end{bmatrix} = \begin{bmatrix} t \\ t \\ 0 \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \\ 0 \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} t \\ t \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$$

The following table summarises the result found above.

λ	algebraic multiplicity	geometric multiplicity	defective eigenvalue?	associated eigenvectors
-1	1	3	No	$\begin{bmatrix} -5 \\ -3 \\ 2 \end{bmatrix}$
2	1	3	No	$\begin{bmatrix} -5 \\ -5 \\ 1 \end{bmatrix}$
3	1	3	No	$\begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$

Since the matrix is not defective, then it is diagonalizable. Let P the matrix whose columns are the eigenvectors found, and let D be diagonal matrix with the eigenvalues at its diagonal. Then we can write

$$A = PDP^{-1}$$

Where

$$D = \begin{bmatrix} -1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix}$$

$$P = \begin{bmatrix} -5 & -5 & 1 \\ -3 & -5 & 1 \\ 2 & 1 & 0 \end{bmatrix}$$

Therefore

$$\begin{bmatrix} -2 & 5 & 5 \\ -1 & 4 & 5 \\ 3 & -3 & 2 \end{bmatrix} = \begin{bmatrix} -5 & -5 & 1 \\ -3 & -5 & 1 \\ 2 & 1 & 0 \end{bmatrix} \begin{bmatrix} -1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix} \begin{bmatrix} -5 & -5 & 1 \\ -3 & -5 & 1 \\ 2 & 1 & 0 \end{bmatrix}^{-1}$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"find eigenvalues and eigenvectors"**

Find the eigenvalues and associated eigenvectors of the matrix

$$\begin{bmatrix} -2 & 6 & -18 \\ 12 & -23 & 66 \\ 5 & -10 & 29 \end{bmatrix}$$

The first step is to determine the characteristic polynomial of the matrix in order to find the eigenvalues of the matrix A. This is given by

$$\det(A - \lambda I) = 0$$

$$\det\left(\begin{bmatrix} -2 & 6 & -18 \\ 12 & -23 & 66 \\ 5 & -10 & 29 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) = 0$$

$$\det\begin{bmatrix} -2-\lambda & 6 & -18 \\ 12 & -23-\lambda & 66 \\ 5 & -10 & 29-\lambda \end{bmatrix} = 0$$

$$-\lambda^3 + 4\lambda^2 + \lambda - 4 = 0$$

The eigenvalues are the roots of the above characteristic polynomial. Solving for the roots gives

$$\lambda_1 = 1$$
$$\lambda_2 = 4$$
$$\lambda_3 = -1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
1	1	real eigenvalue
4	1	real eigenvalue

For each eigenvalue λ found above, we now find the corresponding eigenvector. Considering $\lambda = -1$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$\begin{aligned}
A\boldsymbol{v} &= \lambda \boldsymbol{v} \\
A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} -2 & 6 & -18 \\ 12 & -23 & 66 \\ 5 & -10 & 29 \end{bmatrix} - (-1) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} -2 & 6 & -18 \\ 12 & -23 & 66 \\ 5 & -10 & 29 \end{bmatrix} - \begin{bmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} -1 & 6 & -18 \\ 12 & -22 & 66 \\ 5 & -10 & 30 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$\left[\begin{array}{ccc|c} -1 & 6 & -18 & 0 \\ 12 & -22 & 66 & 0 \\ 5 & -10 & 30 & 0 \end{array}\right]$$

$$R_2 = R_2 + 12R_1 \Longrightarrow \left[\begin{array}{ccc|c} -1 & 6 & -18 & 0 \\ 0 & 50 & -150 & 0 \\ 5 & -10 & 30 & 0 \end{array}\right]$$

$$R_3 = R_3 + 5R_1 \Longrightarrow \left[\begin{array}{ccc|c} -1 & 6 & -18 & 0 \\ 0 & 50 & -150 & 0 \\ 0 & 20 & -60 & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{2R_2}{5} \Longrightarrow \left[\begin{array}{ccc|c} -1 & 6 & -18 & 0 \\ 0 & 50 & -150 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & 6 & -18 \\ 0 & 50 & -150 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 0, v_2 = 3t\}$

Hence the solution is

$$\begin{bmatrix} 0 \\ 3t \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 3t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 0 \\ 3t \\ t \end{bmatrix} = t \begin{bmatrix} 0 \\ 3 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} 0 \\ 3t \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 3 \\ 1 \end{bmatrix}$$

Considering $\lambda = 1$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda \boldsymbol{v} \\
A\boldsymbol{v} - \lambda \boldsymbol{v} &= \mathbf{0} \\
(A - \lambda I)\boldsymbol{v} &= \mathbf{0} \\
\left(\begin{bmatrix} -2 & 6 & -18 \\ 12 & -23 & 66 \\ 5 & -10 & 29 \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} -2 & 6 & -18 \\ 12 & -23 & 66 \\ 5 & -10 & 29 \end{bmatrix} - \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} -3 & 6 & -18 \\ 12 & -24 & 66 \\ 5 & -10 & 28 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{ccc|c} -3 & 6 & -18 & 0 \\ 12 & -24 & 66 & 0 \\ 5 & -10 & 28 & 0 \end{array}\right]
$$

$$
R_2 = R_2 + 4R_1 \Longrightarrow \left[\begin{array}{ccc|c} -3 & 6 & -18 & 0 \\ 0 & 0 & -6 & 0 \\ 5 & -10 & 28 & 0 \end{array}\right]
$$

$$
R_3 = R_3 + \frac{5R_1}{3} \Longrightarrow \left[\begin{array}{ccc|c} -3 & 6 & -18 & 0 \\ 0 & 0 & -6 & 0 \\ 0 & 0 & -2 & 0 \end{array}\right]
$$

$$
R_3 = R_3 - \frac{R_2}{3} \Longrightarrow \left[\begin{array}{ccc|c} -3 & 6 & -18 & 0 \\ 0 & 0 & -6 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]
$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -3 & 6 & -18 \\ 0 & 0 & -6 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1, v_3\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 2t, v_3 = 0\}$

Hence the solution is

$$\begin{bmatrix} 2t \\ t \\ 0 \end{bmatrix} = \begin{bmatrix} 2t \\ t \\ 0 \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 2t \\ t \\ 0 \end{bmatrix} = t \begin{bmatrix} 2 \\ 1 \\ 0 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} 2t \\ t \\ 0 \end{bmatrix} = \begin{bmatrix} 2 \\ 1 \\ 0 \end{bmatrix}$$

Considering $\lambda = 4$

We need now to determine the eigenvector $\boldsymbol{v}$ where

$$
\begin{aligned}
A\boldsymbol{v} &= \lambda \boldsymbol{v} \\
A\boldsymbol{v} - \lambda \boldsymbol{v} &= \boldsymbol{0} \\
(A - \lambda I)\boldsymbol{v} &= \boldsymbol{0} \\
\left(\begin{bmatrix} -2 & 6 & -18 \\ 12 & -23 & 66 \\ 5 & -10 & 29 \end{bmatrix} - (4) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\left(\begin{bmatrix} -2 & 6 & -18 \\ 12 & -23 & 66 \\ 5 & -10 & 29 \end{bmatrix} - \begin{bmatrix} 4 & 0 & 0 \\ 0 & 4 & 0 \\ 0 & 0 & 4 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} -6 & 6 & -18 \\ 12 & -27 & 66 \\ 5 & -10 & 25 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

We will now do Gaussian elimination in order to solve for the eigenvector. The augmented matrix is

$$
\left[\begin{array}{ccc|c} -6 & 6 & -18 & 0 \\ 12 & -27 & 66 & 0 \\ 5 & -10 & 25 & 0 \end{array}\right]
$$

$$
R_2 = R_2 + 2R_1 \Longrightarrow \left[\begin{array}{ccc|c} -6 & 6 & -18 & 0 \\ 0 & -15 & 30 & 0 \\ 5 & -10 & 25 & 0 \end{array}\right]
$$

$$
R_3 = R_3 + \frac{5R_1}{6} \Longrightarrow \left[\begin{array}{ccc|c} -6 & 6 & -18 & 0 \\ 0 & -15 & 30 & 0 \\ 0 & -5 & 10 & 0 \end{array}\right]
$$

$$
R_3 = R_3 - \frac{R_2}{3} \Longrightarrow \left[\begin{array}{ccc|c} -6 & 6 & -18 & 0 \\ 0 & -15 & 30 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]
$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -6 & 6 & -18 \\ 0 & -15 & 30 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t, v_2 = 2t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ 2t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ 2t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ 2t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 2 \\ 1 \end{bmatrix}$$

Or, by letting $t = 1$ then the eigenvector is

$$\begin{bmatrix} -t \\ 2t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 2 \\ 1 \end{bmatrix}$$

The following table summarises the result found above.

λ	algebraic multiplicity	geometric multiplicity	defective eigenvalue?	associated eigenvectors
-1	1	3	No	$\begin{bmatrix} 0 \\ 3 \\ 1 \end{bmatrix}$
1	1	3	No	$\begin{bmatrix} 2 \\ 1 \\ 0 \end{bmatrix}$
4	1	3	No	$\begin{bmatrix} -1 \\ 2 \\ 1 \end{bmatrix}$

Since the matrix is not defective, then it is diagonalizable. Let P the matrix whose columns are the eigenvectors found, and let D be diagonal matrix with the eigenvalues at its diagonal. Then we can write

$$A = PDP^{-1}$$

Where

$$D = \begin{bmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 4 \end{bmatrix}$$

$$P = \begin{bmatrix} 0 & 2 & -1 \\ 3 & 1 & 2 \\ 1 & 0 & 1 \end{bmatrix}$$

Therefore

$$\begin{bmatrix} -2 & 6 & -18 \\ 12 & -23 & 66 \\ 5 & -10 & 29 \end{bmatrix} = \begin{bmatrix} 0 & 2 & -1 \\ 3 & 1 & 2 \\ 1 & 0 & 1 \end{bmatrix} \begin{bmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 4 \end{bmatrix} \begin{bmatrix} 0 & 2 & -1 \\ 3 & 1 & 2 \\ 1 & 0 & 1 \end{bmatrix}^{-1}$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 7, Systems of linear differential equations. Section 7.7. Exercises page 375
Problem number: 1.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= x(t) + y(t) - z(t) \\
y'(t) &= 2x(t) + 3y(t) - 4z(t) \\
z'(t) &= 4x(t) + y(t) - 4z(t)
\end{aligned}
$$

20.1.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{(-4\,\mathrm{e}^{5t}+15\,\mathrm{e}^{4t}-1)\mathrm{e}^{-3t}}{10} & \mathrm{e}^{2t}-\mathrm{e}^{t} & \frac{(-6\,\mathrm{e}^{5t}+5\,\mathrm{e}^{4t}+1)\mathrm{e}^{-3t}}{10} \\ \frac{(-8\,\mathrm{e}^{5t}+15\,\mathrm{e}^{4t}-7)\mathrm{e}^{-3t}}{10} & -\mathrm{e}^{t}+2\,\mathrm{e}^{2t} & \frac{(-12\,\mathrm{e}^{5t}+5\,\mathrm{e}^{4t}+7)\mathrm{e}^{-3t}}{10} \\ \frac{(-4\,\mathrm{e}^{5t}+15\,\mathrm{e}^{4t}-11)\mathrm{e}^{-3t}}{10} & \mathrm{e}^{2t}-\mathrm{e}^{t} & \frac{(-6\,\mathrm{e}^{5t}+5\,\mathrm{e}^{4t}+11)\mathrm{e}^{-3t}}{10} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = e^{At}\vec{c}$$

$$= \begin{bmatrix} \frac{(-4\,\mathrm{e}^{5t}+15\,\mathrm{e}^{4t}-1)\mathrm{e}^{-3t}}{10} & \mathrm{e}^{2t}-\mathrm{e}^{t} & \frac{(-6\,\mathrm{e}^{5t}+5\,\mathrm{e}^{4t}+1)\mathrm{e}^{-3t}}{10} \\ \frac{(-8\,\mathrm{e}^{5t}+15\,\mathrm{e}^{4t}-7)\mathrm{e}^{-3t}}{10} & -\mathrm{e}^{t}+2\,\mathrm{e}^{2t} & \frac{(-12\,\mathrm{e}^{5t}+5\,\mathrm{e}^{4t}+7)\mathrm{e}^{-3t}}{10} \\ \frac{(-4\,\mathrm{e}^{5t}+15\,\mathrm{e}^{4t}-11)\mathrm{e}^{-3t}}{10} & \mathrm{e}^{2t}-\mathrm{e}^{t} & \frac{(-6\,\mathrm{e}^{5t}+5\,\mathrm{e}^{4t}+11)\mathrm{e}^{-3t}}{10} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ c_3 \end{bmatrix}$$

$$= \begin{bmatrix} \frac{(-4\,\mathrm{e}^{5t}+15\,\mathrm{e}^{4t}-1)\mathrm{e}^{-3t}c_1}{10} + (\mathrm{e}^{2t}-\mathrm{e}^{t})\,c_2 + \frac{(-6\,\mathrm{e}^{5t}+5\,\mathrm{e}^{4t}+1)\mathrm{e}^{-3t}c_3}{10} \\ \frac{(-8\,\mathrm{e}^{5t}+15\,\mathrm{e}^{4t}-7)\mathrm{e}^{-3t}c_1}{10} + (-\mathrm{e}^{t}+2\,\mathrm{e}^{2t})\,c_2 + \frac{(-12\,\mathrm{e}^{5t}+5\,\mathrm{e}^{4t}+7)\mathrm{e}^{-3t}c_3}{10} \\ \frac{(-4\,\mathrm{e}^{5t}+15\,\mathrm{e}^{4t}-11)\mathrm{e}^{-3t}c_1}{10} + (\mathrm{e}^{2t}-\mathrm{e}^{t})\,c_2 + \frac{(-6\,\mathrm{e}^{5t}+5\,\mathrm{e}^{4t}+11)\mathrm{e}^{-3t}c_3}{10} \end{bmatrix}$$

$$= \begin{bmatrix} \frac{3\left(\left(c_1-\frac{2c_2}{3}+\frac{c_3}{3}\right)\mathrm{e}^{4t}+\left(-\frac{4c_1}{15}+\frac{2c_2}{3}-\frac{2c_3}{5}\right)\mathrm{e}^{5t}-\frac{c_1}{15}+\frac{c_3}{15}\right)\mathrm{e}^{-3t}}{2} \\ \frac{3\left(\left(c_1-\frac{2c_2}{3}+\frac{c_3}{3}\right)\mathrm{e}^{4t}+\left(-\frac{8c_1}{15}+\frac{4c_2}{3}-\frac{4c_3}{5}\right)\mathrm{e}^{5t}-\frac{7c_1}{15}+\frac{7c_3}{15}\right)\mathrm{e}^{-3t}}{2} \\ \frac{3\,\mathrm{e}^{-3t}\left(\left(c_1-\frac{2c_2}{3}+\frac{c_3}{3}\right)\mathrm{e}^{4t}+\left(-\frac{4c_1}{15}+\frac{2c_2}{3}-\frac{2c_3}{5}\right)\mathrm{e}^{5t}-\frac{11c_1}{15}+\frac{11c_3}{15}\right)}{2} \end{bmatrix}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

20.1.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & 1 & -1 \\ 2 & 3-\lambda & -4 \\ 4 & 1 & -4-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^3 - 7\lambda + 6 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -3$$
$$\lambda_2 = 1$$
$$\lambda_3 = 2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue
-3	1	real eigenvalue
2	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} - (-3)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 4 & 1 & -1 \\ 2 & 6 & -4 \\ 4 & 1 & -1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 4 & 1 & -1 & 0 \\ 2 & 6 & -4 & 0 \\ 4 & 1 & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{2} \Longrightarrow \left[\begin{array}{ccc|c} 4 & 1 & -1 & 0 \\ 0 & \frac{11}{2} & -\frac{7}{2} & 0 \\ 4 & 1 & -1 & 0 \end{array}\right]$$

$$R_3 = R_3 - R_1 \Longrightarrow \left[\begin{array}{ccc|c} 4 & 1 & -1 & 0 \\ 0 & \frac{11}{2} & -\frac{7}{2} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 4 & 1 & -1 \\ 0 & \frac{11}{2} & -\frac{7}{2} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{t}{11}, v_2 = \frac{7t}{11}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{t}{11} \\ \frac{7t}{11} \\ t \end{bmatrix} = \begin{bmatrix} \frac{t}{11} \\ \frac{7t}{11} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{t}{11} \\ \frac{7t}{11} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{11} \\ \frac{7}{11} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{t}{11} \\ \frac{7t}{11} \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{11} \\ \frac{7}{11} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{t}{11} \\ \frac{7t}{11} \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 7 \\ 11 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 0 & 1 & -1 \\ 2 & 2 & -4 \\ 4 & 1 & -5 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 0 & 1 & -1 & 0 \\ 2 & 2 & -4 & 0 \\ 4 & 1 & -5 & 0 \end{array}\right]$$

Since the current pivot $A(1,1)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 1 and row 2 gives

$$\left[\begin{array}{ccc|c} 2 & 2 & -4 & 0 \\ 0 & 1 & -1 & 0 \\ 4 & 1 & -5 & 0 \end{array}\right]$$

$$R_3 = R_3 - 2R_1 \Longrightarrow \left[\begin{array}{ccc|c} 2 & 2 & -4 & 0 \\ 0 & 1 & -1 & 0 \\ 0 & -3 & 3 & 0 \end{array}\right]$$

$$R_3 = R_3 + 3R_2 \Longrightarrow \left[\begin{array}{ccc|c} 2 & 2 & -4 & 0 \\ 0 & 1 & -1 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & 2 & -4 \\ 0 & 1 & -1 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t, v_2 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_3 = 2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} - (2) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -1 & 1 & -1 \\ 2 & 1 & -4 \\ 4 & 1 & -6 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} -1 & 1 & -1 & 0 \\ 2 & 1 & -4 & 0 \\ 4 & 1 & -6 & 0 \end{array}\right]$$

$$R_2 = R_2 + 2R_1 \Longrightarrow \left[\begin{array}{ccc|c} -1 & 1 & -1 & 0 \\ 0 & 3 & -6 & 0 \\ 4 & 1 & -6 & 0 \end{array}\right]$$

$$R_3 = R_3 + 4R_1 \Longrightarrow \left[\begin{array}{ccc|c} -1 & 1 & -1 & 0 \\ 0 & 3 & -6 & 0 \\ 0 & 5 & -10 & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{5R_2}{3} \Longrightarrow \left[\begin{array}{ccc|c} -1 & 1 & -1 & 0 \\ 0 & 3 & -6 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & 1 & -1 \\ 0 & 3 & -6 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t, v_2 = 2t\}$

Hence the solution is

$$\begin{bmatrix} t \\ 2t \\ t \end{bmatrix} = \begin{bmatrix} t \\ 2t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ 2t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ 2t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-3	1	1	No	$\begin{bmatrix} \frac{1}{11} \\ \frac{7}{11} \\ 1 \end{bmatrix}$
1	1	1	No	$\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$
2	1	1	No	$\begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -3 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{-3t} \\ &= \begin{bmatrix} \frac{1}{11} \\ \frac{7}{11} \\ 1 \end{bmatrix} e^{-3t} \end{aligned}$$

Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_2(t) &= \vec{v}_2 e^{t} \\
&= \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} e^{t}
\end{aligned}
$$

Since eigenvalue 2 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_3(t) &= \vec{v}_3 e^{2t} \\
&= \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix} e^{2t}
\end{aligned}
$$

Therefore the final solution is

$$
\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + c_3\vec{x}_3(t)
$$

Which is written as

$$
\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = c_1 \begin{bmatrix} \frac{e^{-3t}}{11} \\ \frac{7\,e^{-3t}}{11} \\ e^{-3t} \end{bmatrix} + c_2 \begin{bmatrix} e^{t} \\ e^{t} \\ e^{t} \end{bmatrix} + c_3 \begin{bmatrix} e^{2t} \\ 2\,e^{2t} \\ e^{2t} \end{bmatrix}
$$

Which becomes

$$
\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} \frac{(11c_3 e^{5t} + 11c_2 e^{4t} + c_1)e^{-3t}}{11} \\ \frac{(22c_3 e^{5t} + 11c_2 e^{4t} + 7c_1)e^{-3t}}{11} \\ (c_3 e^{5t} + c_2 e^{4t} + c_1)\,e^{-3t} \end{bmatrix}
$$

20.1.3 Maple step by step solution

Let's solve

$[x'(t) = x(t) + y(t) - z(t)\,, y'(t) = 2x(t) + 3y(t) - 4z(t)\,, z'(t) = 4x(t) + y(t) - 4z(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & 1 & -1 \\ 2 & 3 & -4 \\ 4 & 1 & -4 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-3, \begin{bmatrix} \frac{1}{11} \\ \frac{7}{11} \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[2, \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-3, \begin{bmatrix} \frac{1}{11} \\ \frac{7}{11} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{x}_1 = e^{-3t} \cdot \begin{bmatrix} \frac{1}{11} \\ \frac{7}{11} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{x}_2 = e^{t} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 2, \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{x}_3 = e^{2t} \cdot \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\overrightarrow{x} = c_1 \overrightarrow{x}_1 + c_2 \overrightarrow{x}_2 + c_3 \overrightarrow{x}_3$$

- Substitute solutions into the general solution

$$\overrightarrow{x} = e^{-3t} c_1 \cdot \begin{bmatrix} \frac{1}{11} \\ \frac{7}{11} \\ 1 \end{bmatrix} + c_2 e^{t} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + c_3 e^{2t} \cdot \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} \frac{(11c_3 e^{5t}+11c_2 e^{4t}+c_1) e^{-3t}}{11} \\ \frac{(22c_3 e^{5t}+11c_2 e^{4t}+7c_1) e^{-3t}}{11} \\ (c_3 e^{5t} + c_2 e^{4t} + c_1) e^{-3t} \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = \frac{(11c_3 e^{5t}+11c_2 e^{4t}+c_1) e^{-3t}}{11}, y(t) = \frac{(22c_3 e^{5t}+11c_2 e^{4t}+7c_1) e^{-3t}}{11}, z(t) = (c_3 e^{5t} + c_2 e^{4t} + c_1) e^{-3t}\right\}$$

Book: Differential Equations by Shepley L. Ross. Third edition. John Willey. New Delhi. 2004.
Section: Chapter 7, Systems of linear differential equations. Section 7.7. Exercises page 375
Problem number: 2.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= x(t) - y(t) - z(t)\\
y'(t) &= x(t) + 3y(t) + z(t)\\
z'(t) &= -3x(t) - 6y(t) + 6z(t)
\end{aligned}
$$

20.2.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{10\,e^{2t}}{3} - 3\,e^{3t} + \frac{2\,e^{5t}}{3} & \frac{7\,e^{5t}}{6} - \frac{9\,e^{3t}}{2} + \frac{10\,e^{2t}}{3} & -\frac{e^{5t}}{2} + \frac{e^{3t}}{2} \\ 3\,e^{3t} - \frac{7\,e^{2t}}{3} - \frac{2\,e^{5t}}{3} & -\frac{7\,e^{2t}}{3} - \frac{7\,e^{5t}}{6} + \frac{9\,e^{3t}}{2} & \frac{e^{5t}}{2} - \frac{e^{3t}}{2} \\ 3\,e^{3t} - e^{2t} - 2\,e^{5t} & -\frac{7\,e^{5t}}{2} + \frac{9\,e^{3t}}{2} - e^{2t} & \frac{3\,e^{5t}}{2} - \frac{e^{3t}}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{10\,e^{2t}}{3} - 3\,e^{3t} + \frac{2\,e^{5t}}{3} & \frac{7\,e^{5t}}{6} - \frac{9\,e^{3t}}{2} + \frac{10\,e^{2t}}{3} & -\frac{e^{5t}}{2} + \frac{e^{3t}}{2} \\ 3\,e^{3t} - \frac{7\,e^{2t}}{3} - \frac{2\,e^{5t}}{3} & -\frac{7\,e^{2t}}{3} - \frac{7\,e^{5t}}{6} + \frac{9\,e^{3t}}{2} & \frac{e^{5t}}{2} - \frac{e^{3t}}{2} \\ 3\,e^{3t} - e^{2t} - 2\,e^{5t} & -\frac{7\,e^{5t}}{2} + \frac{9\,e^{3t}}{2} - e^{2t} & \frac{3\,e^{5t}}{2} - \frac{e^{3t}}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ c_3 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{10\,e^{2t}}{3} - 3\,e^{3t} + \frac{2\,e^{5t}}{3}\right) c_1 + \left(\frac{7\,e^{5t}}{6} - \frac{9\,e^{3t}}{2} + \frac{10\,e^{2t}}{3}\right) c_2 + \left(-\frac{e^{5t}}{2} + \frac{e^{3t}}{2}\right) c_3 \\ \left(3\,e^{3t} - \frac{7\,e^{2t}}{3} - \frac{2\,e^{5t}}{3}\right) c_1 + \left(-\frac{7\,e^{2t}}{3} - \frac{7\,e^{5t}}{6} + \frac{9\,e^{3t}}{2}\right) c_2 + \left(\frac{e^{5t}}{2} - \frac{e^{3t}}{2}\right) c_3 \\ \left(3\,e^{3t} - e^{2t} - 2\,e^{5t}\right) c_1 + \left(-\frac{7\,e^{5t}}{2} + \frac{9\,e^{3t}}{2} - e^{2t}\right) c_2 + \left(\frac{3\,e^{5t}}{2} - \frac{e^{3t}}{2}\right) c_3 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(-6c_1 - 9c_2 + c_3)e^{3t}}{2} + \frac{(4c_1 + 7c_2 - 3c_3)e^{5t}}{6} + \frac{10\,e^{2t}(c_1 + c_2)}{3} \\ \frac{(6c_1 + 9c_2 - c_3)e^{3t}}{2} + \frac{(-4c_1 - 7c_2 + 3c_3)e^{5t}}{6} - \frac{7\,e^{2t}(c_1 + c_2)}{3} \\ \frac{(6c_1 + 9c_2 - c_3)e^{3t}}{2} + \frac{(-4c_1 - 7c_2 + 3c_3)e^{5t}}{2} - e^{2t}(c_1 + c_2) \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

20.2.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & -1 & -1 \\ 1 & 3-\lambda & 1 \\ -3 & -6 & 6-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^3 - 10\lambda^2 + 31\lambda - 30 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 3$$
$$\lambda_2 = 5$$
$$\lambda_3 = 2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
2	1	real eigenvalue
3	1	real eigenvalue
5	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} - (2)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -1 & -1 & -1 \\ 1 & 1 & 1 \\ -3 & -6 & 4 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} -1 & -1 & -1 & 0 \\ 1 & 1 & 1 & 0 \\ -3 & -6 & 4 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \implies \left[\begin{array}{ccc|c} -1 & -1 & -1 & 0 \\ 0 & 0 & 0 & 0 \\ -3 & -6 & 4 & 0 \end{array}\right]$$

$$R_3 = R_3 - 3R_1 \implies \left[\begin{array}{ccc|c} -1 & -1 & -1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & -3 & 7 & 0 \end{array}\right]$$

Since the current pivot $A(2,2)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 2 and row 3 gives

$$\left[\begin{array}{ccc|c} -1 & -1 & -1 & 0 \\ 0 & -3 & 7 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & -1 & -1 \\ 0 & -3 & 7 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{10t}{3}, v_2 = \frac{7t}{3}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{10t}{3} \\ \frac{7t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{10t}{3} \\ \frac{7t}{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{10t}{3} \\ \frac{7t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{10}{3} \\ \frac{7}{3} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{10t}{3} \\ \frac{7t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{10}{3} \\ \frac{7}{3} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{10t}{3} \\ \frac{7t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -10 \\ 7 \\ 3 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} - (3) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -2 & -1 & -1 \\ 1 & 0 & 1 \\ -3 & -6 & 3 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} -2 & -1 & -1 & 0 \\ 1 & 0 & 1 & 0 \\ -3 & -6 & 3 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{2} \Longrightarrow \left[\begin{array}{ccc|c} -2 & -1 & -1 & 0 \\ 0 & -\frac{1}{2} & \frac{1}{2} & 0 \\ -3 & -6 & 3 & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{3R_1}{2} \Longrightarrow \left[\begin{array}{ccc|c} -2 & -1 & -1 & 0 \\ 0 & -\frac{1}{2} & \frac{1}{2} & 0 \\ 0 & -\frac{9}{2} & \frac{9}{2} & 0 \end{array}\right]$$

$$R_3 = R_3 - 9R_2 \Longrightarrow \left[\begin{array}{ccc|c} -2 & -1 & -1 & 0 \\ 0 & -\frac{1}{2} & \frac{1}{2} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & -1 & -1 \\ 0 & -\frac{1}{2} & \frac{1}{2} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t, v_2 = t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_3 = 5$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} - (5) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -4 & -1 & -1 \\ 1 & -2 & 1 \\ -3 & -6 & 1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} -4 & -1 & -1 & 0 \\ 1 & -2 & 1 & 0 \\ -3 & -6 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{4} \Longrightarrow \left[\begin{array}{ccc|c} -4 & -1 & -1 & 0 \\ 0 & -\frac{9}{4} & \frac{3}{4} & 0 \\ -3 & -6 & 1 & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{3R_1}{4} \Longrightarrow \left[\begin{array}{ccc|c} -4 & -1 & -1 & 0 \\ 0 & -\frac{9}{4} & \frac{3}{4} & 0 \\ 0 & -\frac{21}{4} & \frac{7}{4} & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{7R_2}{3} \Longrightarrow \left[\begin{array}{ccc|c} -4 & -1 & -1 & 0 \\ 0 & -\frac{9}{4} & \frac{3}{4} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -4 & -1 & -1 \\ 0 & -\frac{9}{4} & \frac{3}{4} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{t}{3}, v_2 = \frac{t}{3}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{t}{3} \\ \frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{t}{3} \\ \frac{t}{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{t}{3} \\ \frac{t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{3} \\ \frac{1}{3} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{t}{3} \\ \frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{3} \\ \frac{1}{3} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{t}{3} \\ \frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \\ 3 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
3	1	1	No	$\begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$
5	1	1	No	$\begin{bmatrix} -\frac{1}{3} \\ \frac{1}{3} \\ 1 \end{bmatrix}$
2	1	1	No	$\begin{bmatrix} -\frac{10}{3} \\ \frac{7}{3} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 3 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{3t} \\ &= \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix} e^{3t} \end{aligned}$$

Since eigenvalue 5 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_2(t) &= \vec{v}_2 e^{5t} \\ &= \begin{bmatrix} -\frac{1}{3} \\ \frac{1}{3} \\ 1 \end{bmatrix} e^{5t} \end{aligned}$$

Since eigenvalue 2 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_3(t) = \vec{v}_3 e^{2t}$$
$$= \begin{bmatrix} -\frac{10}{3} \\ \frac{7}{3} \\ 1 \end{bmatrix} e^{2t}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + c_3\vec{x}_3(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = c_1 \begin{bmatrix} -e^{3t} \\ e^{3t} \\ e^{3t} \end{bmatrix} + c_2 \begin{bmatrix} -\frac{e^{5t}}{3} \\ \frac{e^{5t}}{3} \\ e^{5t} \end{bmatrix} + c_3 \begin{bmatrix} -\frac{10\,e^{2t}}{3} \\ \frac{7\,e^{2t}}{3} \\ e^{2t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} -c_1 e^{3t} - \frac{c_2 e^{5t}}{3} - \frac{10 c_3 e^{2t}}{3} \\ c_1 e^{3t} + \frac{c_2 e^{5t}}{3} + \frac{7 c_3 e^{2t}}{3} \\ c_1 e^{3t} + c_2 e^{5t} + c_3 e^{2t} \end{bmatrix}$$

20.2.3 Maple step by step solution

Let's solve

$[x'(t) = x(t) - y(t) - z(t), y'(t) = x(t) + 3y(t) + z(t), z'(t) = -3x(t) - 6y(t) + 6z(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & -1 & -1 \\ 1 & 3 & 1 \\ -3 & -6 & 6 \end{bmatrix}$$

- Rewrite the system as

$\vec{x}'(t) = A \cdot \vec{x}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[2, \begin{bmatrix} -\frac{10}{3} \\ \frac{7}{3} \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}\right], \left[5, \begin{bmatrix} -\frac{1}{3} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} -\frac{10}{3} \\ \frac{7}{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = e^{2t} \cdot \begin{bmatrix} -\frac{10}{3} \\ \frac{7}{3} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[3, \left[\begin{array}{c} -1 \\ 1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \mathrm{e}^{3t} \cdot \left[\begin{array}{c} -1 \\ 1 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[5, \left[\begin{array}{c} -\frac{1}{3} \\ \frac{1}{3} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_3 = \mathrm{e}^{5t} \cdot \left[\begin{array}{c} -\frac{1}{3} \\ \frac{1}{3} \\ 1 \end{array}\right]$$

- General solution to the system of ODEs

$$\vec{x} = c_1 \vec{x}_1 + c_2 \vec{x}_2 + c_3 \vec{x}_3$$

- Substitute solutions into the general solution

$$\vec{x} = c_1 \mathrm{e}^{2t} \cdot \left[\begin{array}{c} -\frac{10}{3} \\ \frac{7}{3} \\ 1 \end{array}\right] + c_2 \mathrm{e}^{3t} \cdot \left[\begin{array}{c} -1 \\ 1 \\ 1 \end{array}\right] + c_3 \mathrm{e}^{5t} \cdot \left[\begin{array}{c} -\frac{1}{3} \\ \frac{1}{3} \\ 1 \end{array}\right]$$

- Substitute in vector of dependent variables

$$\left[\begin{array}{c} x(t) \\ y(t) \\ z(t) \end{array}\right] = \left[\begin{array}{c} -\frac{10 c_1 \mathrm{e}^{2t}}{3} - c_2 \mathrm{e}^{3t} - \frac{c_3 \mathrm{e}^{5t}}{3} \\ \frac{7 c_1 \mathrm{e}^{2t}}{3} + c_2 \mathrm{e}^{3t} + \frac{c_3 \mathrm{e}^{5t}}{3} \\ c_1 \mathrm{e}^{2t} + c_2 \mathrm{e}^{3t} + c_3 \mathrm{e}^{5t} \end{array}\right]$$

- Solution to the system of ODEs

$$\left\{x(t) = -\frac{10 c_1 \mathrm{e}^{2t}}{3} - c_2 \mathrm{e}^{3t} - \frac{c_3 \mathrm{e}^{5t}}{3}, y(t) = \frac{7 c_1 \mathrm{e}^{2t}}{3} + c_2 \mathrm{e}^{3t} + \frac{c_3 \mathrm{e}^{5t}}{3}, z(t) = c_1 \mathrm{e}^{2t} + c_2 \mathrm{e}^{3t} + c_3 \mathrm{e}^{5t}\right\}$$
