Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Superposition principle. Exercises page 137
Problem number: 552.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + 4y' = x + e^{-4x}}$$

17.2.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 4, C = 0, f(x) = x + e^{-4x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+4y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=1, B=4, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x}+4\lambda\, e^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2+4\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=4, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{-4}{(2)\,(1)}\pm\frac{1}{(2)\,(1)}\sqrt{4^2-(4)\,(1)\,(0)}\\&=-2\pm 2\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1&=-2+2\\\lambda_2&=-2-2\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1&=0\\\lambda_2&=-4\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y&=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}\\y&=c_1e^{(0)x}+c_2e^{(-4)x}\end{aligned}$$

Or

$$y = c_1 + c_2 e^{-4x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + c_2 e^{-4x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x + e^{-4x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-4x}\}, \{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-4x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{-4x}\}, \{x, x^2\}]$$

Since e^{-4x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\, e^{-4x}\}, \{x, x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\, e^{-4x} + A_2 x + A_3 x^2$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 e^{-4x} + 2A_3 + 4A_2 + 8A_3 x = x + e^{-4x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{4}, A_2 = -\frac{1}{16}, A_3 = \frac{1}{8}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\,e^{-4x}}{4} - \frac{x}{16} + \frac{x^2}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + c_2 e^{-4x}\right) + \left(-\frac{x\,e^{-4x}}{4} - \frac{x}{16} + \frac{x^2}{8}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + c_2 e^{-4x} - \frac{x\,e^{-4x}}{4} - \frac{x}{16} + \frac{x^2}{8} \tag{1}$$

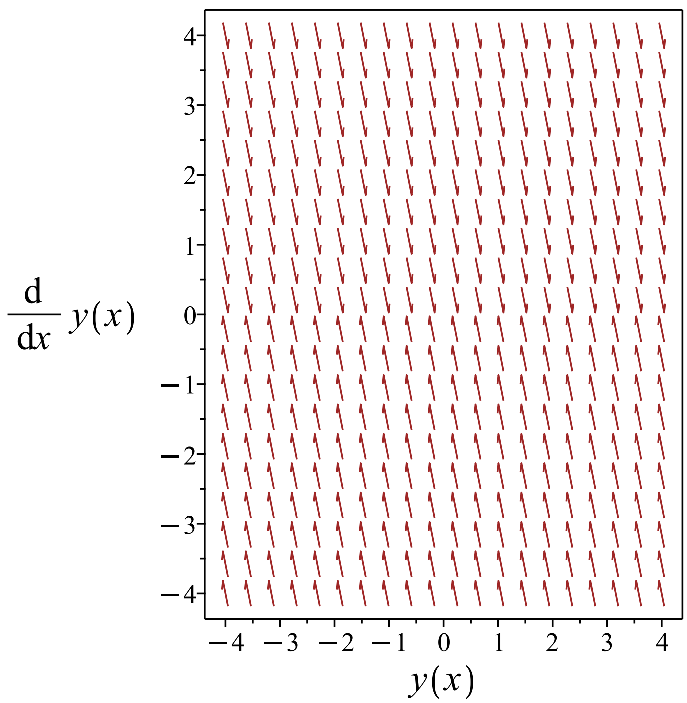

Figure 633: Slope field plot

Verification of solutions

$$y = c_1 + c_2 e^{-4x} - \frac{x\,e^{-4x}}{4} - \frac{x}{16} + \frac{x^2}{8}$$

Verified OK.

17.2.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(y'' + 4y'\right) dx = \int \left(x + e^{-4x}\right) dx$$
$$4y + y' = \frac{x^2}{2} - \frac{e^{-4x}}{4} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 4$$
$$q(x) = \frac{x^2}{2} - \frac{e^{-4x}}{4} + c_1$$

Hence the ode is

$$4y + y' = \frac{x^2}{2} - \frac{e^{-4x}}{4} + c_1$$

The integrating factor μ is

$$\mu = e^{\int 4dx}$$
$$= e^{4x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{x^2}{2} - \frac{e^{-4x}}{4} + c_1\right)$$
$$\frac{d}{dx}\left(e^{4x}y\right) = \left(e^{4x}\right)\left(\frac{x^2}{2} - \frac{e^{-4x}}{4} + c_1\right)$$
$$d\left(e^{4x}y\right) = \left(-\frac{1}{4} + \frac{(2x^2 + 4c_1)\,e^{4x}}{4}\right) dx$$

Integrating gives

$$e^{4x}y = \int -\frac{1}{4} + \frac{(2x^2 + 4c_1)\,e^{4x}}{4}\, dx$$
$$e^{4x}y = -\frac{x}{4} + \frac{x^2 e^{4x}}{8} - \frac{e^{4x}x}{16} + \frac{e^{4x}}{64} + \frac{e^{4x}c_1}{4} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{4x}$ results in

$$y = e^{-4x}\left(-\frac{x}{4} + \frac{x^2 e^{4x}}{8} - \frac{e^{4x} x}{16} + \frac{e^{4x}}{64} + \frac{e^{4x} c_1}{4}\right) + c_2 e^{-4x}$$

which simplifies to

$$y = \frac{1}{64} + \frac{(-x + 4c_2)\, e^{-4x}}{4} + \frac{x^2}{8} - \frac{x}{16} + \frac{c_1}{4}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{64} + \frac{(-x + 4c_2)\, e^{-4x}}{4} + \frac{x^2}{8} - \frac{x}{16} + \frac{c_1}{4} \tag{1}$$

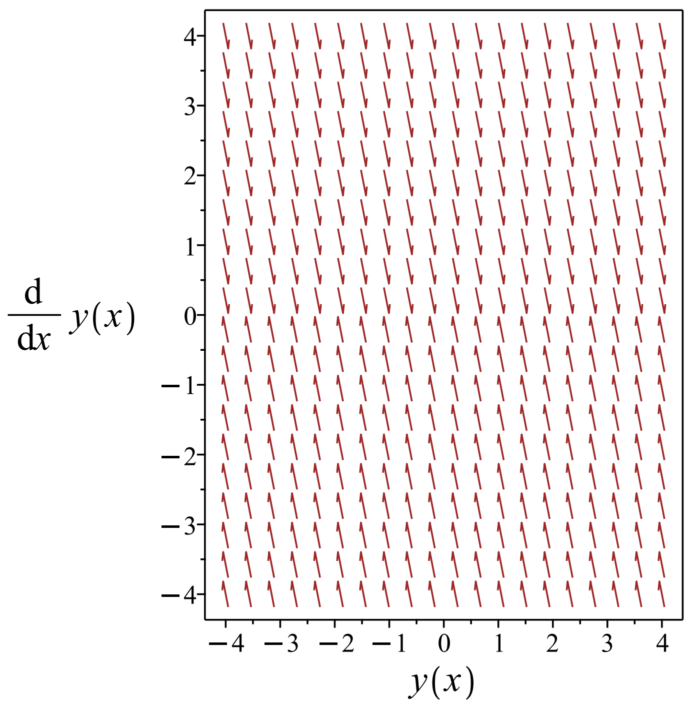

Figure 634: Slope field plot

Verification of solutions

$$y = \frac{1}{64} + \frac{(-x + 4c_2)\, e^{-4x}}{4} + \frac{x^2}{8} - \frac{x}{16} + \frac{c_1}{4}$$

Verified OK.

17.2.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + 4p(x) - x - e^{-4x} = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= 4 \\ q(x) &= x + e^{-4x} \end{aligned}$$

Hence the ode is

$$p'(x) + 4p(x) = x + e^{-4x}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 4dx} \\ &= e^{4x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu)\left(x + e^{-4x}\right) \\ \frac{d}{dx}\left(e^{4x} p\right) &= \left(e^{4x}\right)\left(x + e^{-4x}\right) \\ d\left(e^{4x} p\right) &= \left(e^{4x} x + 1\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{4x} p &= \int e^{4x} x + 1 \, dx \\ e^{4x} p &= x + \frac{e^{4x} x}{4} - \frac{e^{4x}}{16} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{4x}$ results in

$$p(x) = \mathrm{e}^{-4x}\left(x + \frac{\mathrm{e}^{4x}x}{4} - \frac{\mathrm{e}^{4x}}{16}\right) + c_1\mathrm{e}^{-4x}$$

which simplifies to

$$p(x) = -\frac{1}{16} + (x + c_1)\,\mathrm{e}^{-4x} + \frac{x}{4}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -\frac{1}{16} + (x + c_1)\,\mathrm{e}^{-4x} + \frac{x}{4}$$

Integrating both sides gives

$$\begin{aligned} y &= \int x\,\mathrm{e}^{-4x} + \frac{x}{4} - \frac{1}{16} + c_1\mathrm{e}^{-4x}\,\mathrm{d}x \\ &= \frac{x^2}{8} - \frac{x}{16} - \frac{x\,\mathrm{e}^{-4x}}{4} - \frac{\mathrm{e}^{-4x}}{16} - \frac{c_1\mathrm{e}^{-4x}}{4} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2}{8} - \frac{x}{16} - \frac{x\,\mathrm{e}^{-4x}}{4} - \frac{\mathrm{e}^{-4x}}{16} - \frac{c_1\mathrm{e}^{-4x}}{4} + c_2 \tag{1}$$

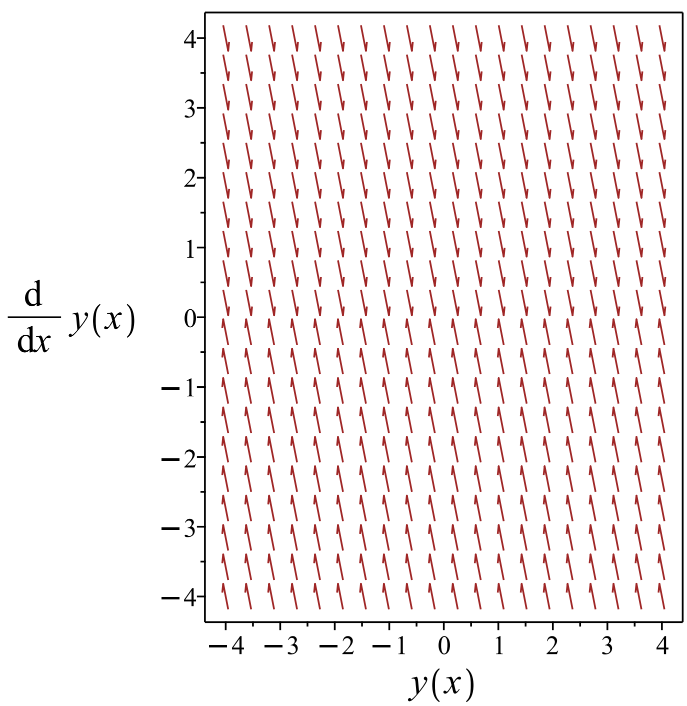

Figure 635: Slope field plot

Verification of solutions

$$y = \frac{x^2}{8} - \frac{x}{16} - \frac{x\,\mathrm{e}^{-4x}}{4} - \frac{\mathrm{e}^{-4x}}{16} - \frac{c_1 \mathrm{e}^{-4x}}{4} + c_2$$

Verified OK.

17.2.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + 4y' = x + \mathrm{e}^{-4x}$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 4y')\, dx = \int \left(x + \mathrm{e}^{-4x}\right) dx$$

$$4y + y' = \frac{x^2}{2} - \frac{\mathrm{e}^{-4x}}{4} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 4$$
$$q(x) = \frac{x^2}{2} - \frac{\mathrm{e}^{-4x}}{4} + c_1$$

Hence the ode is

$$4y + y' = \frac{x^2}{2} - \frac{\mathrm{e}^{-4x}}{4} + c_1$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int 4dx}$$
$$= \mathrm{e}^{4x}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\left(\frac{x^2}{2} - \frac{\mathrm{e}^{-4x}}{4} + c_1\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{4x} y\right) = \left(\mathrm{e}^{4x}\right)\left(\frac{x^2}{2} - \frac{\mathrm{e}^{-4x}}{4} + c_1\right)$$
$$\mathrm{d}\left(\mathrm{e}^{4x} y\right) = \left(-\frac{1}{4} + \frac{(2x^2 + 4c_1)\,\mathrm{e}^{4x}}{4}\right) \mathrm{d}x$$

Integrating gives

$$e^{4x}y = \int -\frac{1}{4} + \frac{(2x^2 + 4c_1)\, e^{4x}}{4}\, dx$$

$$e^{4x}y = -\frac{x}{4} + \frac{x^2 e^{4x}}{8} - \frac{e^{4x}x}{16} + \frac{e^{4x}}{64} + \frac{e^{4x}c_1}{4} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{4x}$ results in

$$y = e^{-4x}\left(-\frac{x}{4} + \frac{x^2 e^{4x}}{8} - \frac{e^{4x}x}{16} + \frac{e^{4x}}{64} + \frac{e^{4x}c_1}{4}\right) + c_2 e^{-4x}$$

which simplifies to

$$y = \frac{1}{64} + \frac{(-x + 4c_2)\, e^{-4x}}{4} + \frac{x^2}{8} - \frac{x}{16} + \frac{c_1}{4}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{64} + \frac{(-x + 4c_2)\, e^{-4x}}{4} + \frac{x^2}{8} - \frac{x}{16} + \frac{c_1}{4} \tag{1}$$

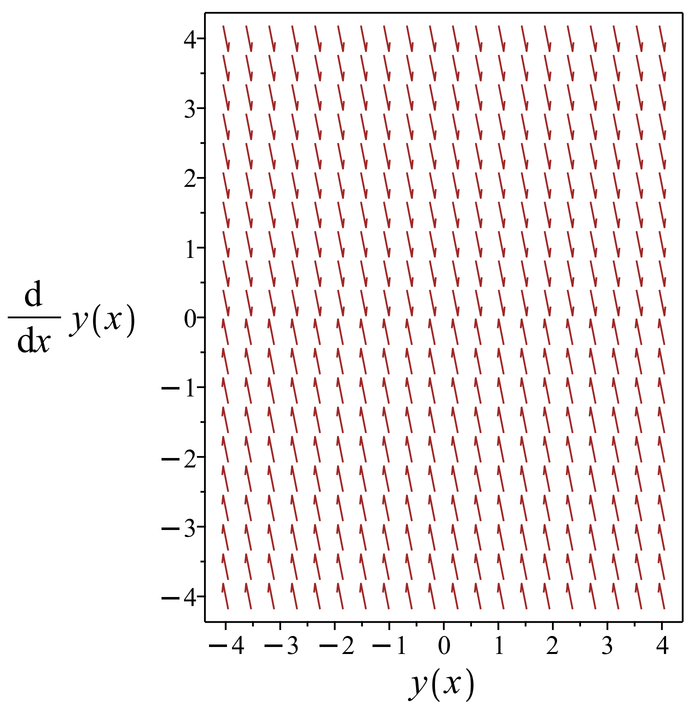

Figure 636: Slope field plot

Verification of solutions

$$y = \frac{1}{64} + \frac{(-x + 4c_2)\,e^{-4x}}{4} + \frac{x^2}{8} - \frac{x}{16} + \frac{c_1}{4}$$

Verified OK.

17.2.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 500: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-2x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4}{1}\,dx} \\
&= z_1 e^{-2x} \\
&= z_1 \left(\mathrm{e}^{-2x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-4x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-4x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\mathrm{e}^{4x}}{4}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-4x}\right) + c_2\left(\mathrm{e}^{-4x}\left(\frac{\mathrm{e}^{4x}}{4}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-4x} + \frac{c_2}{4}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \mathrm{e}^{-4x}$$
$$y_2 = \frac{1}{4}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-4x} & \frac{1}{4} \\ \frac{d}{dx}(\mathrm{e}^{-4x}) & \frac{d}{dx}\left(\frac{1}{4}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-4x} & \frac{1}{4} \\ -4\,e^{-4x} & 0 \end{vmatrix}$$

Therefore

$$W = \left(e^{-4x}\right)(0) - \left(\frac{1}{4}\right)\left(-4\,e^{-4x}\right)$$

Which simplifies to

$$W = e^{-4x}$$

Which simplifies to

$$W = e^{-4x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x}{4} + \frac{e^{-4x}}{4}}{e^{-4x}}\,dx$$

Which simplifies to

$$u_1 = -\int \left(\frac{e^{4x}x}{4} + \frac{1}{4}\right) dx$$

Hence

$$u_1 = -\frac{x}{4} - \frac{e^{4x}x}{16} + \frac{e^{4x}}{64}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{-4x}\left(x + e^{-4x}\right)}{e^{-4x}}\,dx$$

Which simplifies to

$$u_2 = \int \left(x + e^{-4x}\right) dx$$

Hence

$$u_2 = \frac{x^2}{2} - \frac{e^{-4x}}{4}$$

Which simplifies to

$$
\begin{aligned}
u_1 &= \frac{(-4x+1)\,\mathrm{e}^{4x}}{64} - \frac{x}{4} \\
u_2 &= \frac{x^2}{2} - \frac{\mathrm{e}^{-4x}}{4}
\end{aligned}
$$

Therefore the particular solution, from equation (1) is

$$
y_p(x) = \left(\frac{(-4x+1)\,\mathrm{e}^{4x}}{64} - \frac{x}{4}\right)\mathrm{e}^{-4x} + \frac{x^2}{8} - \frac{\mathrm{e}^{-4x}}{16}
$$

Which simplifies to

$$
y_p(x) = \frac{1}{64} + \frac{(-4x-1)\,\mathrm{e}^{-4x}}{16} + \frac{x^2}{8} - \frac{x}{16}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1\mathrm{e}^{-4x} + \frac{c_2}{4}\right) + \left(\frac{1}{64} + \frac{(-4x-1)\,\mathrm{e}^{-4x}}{16} + \frac{x^2}{8} - \frac{x}{16}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1\mathrm{e}^{-4x} + \frac{c_2}{4} + \frac{1}{64} + \frac{(-4x-1)\,\mathrm{e}^{-4x}}{16} + \frac{x^2}{8} - \frac{x}{16} \tag{1}
$$

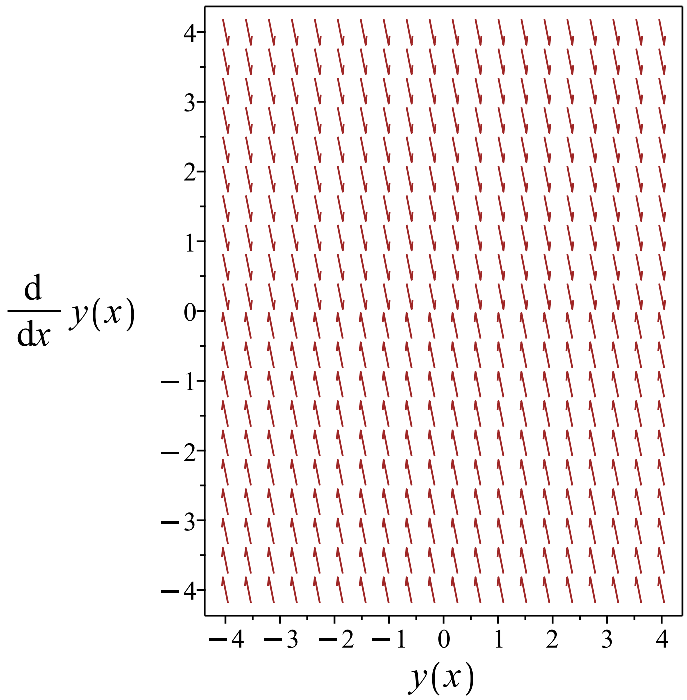

Figure 637: Slope field plot

Verification of solutions

$$y = c_1 e^{-4x} + \frac{c_2}{4} + \frac{1}{64} + \frac{(-4x-1)\, e^{-4x}}{16} + \frac{x^2}{8} - \frac{x}{16}$$

Verified OK.

17.2.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 4 \\ r(x) &= 0 \\ s(x) &= x + e^{-4x} \end{aligned}$$

Hence

$$p''(x) = 0$$
$$q'(x) = 0$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\; dx$$

Substituting the above values for p, q, r, s gives

$$4y + y' = \int x + \mathrm{e}^{-4x}\, dx$$

We now have a first order ode to solve which is

$$4y + y' = \frac{x^2}{2} - \frac{\mathrm{e}^{-4x}}{4} + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 4$$
$$q(x) = \frac{x^2}{2} - \frac{\mathrm{e}^{-4x}}{4} + c_1$$

Hence the ode is

$$4y + y' = \frac{x^2}{2} - \frac{\mathrm{e}^{-4x}}{4} + c_1$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int 4dx}$$
$$= \mathrm{e}^{4x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{x^2}{2} - \frac{e^{-4x}}{4} + c_1\right)$$
$$\frac{d}{dx}(e^{4x}y) = (e^{4x})\left(\frac{x^2}{2} - \frac{e^{-4x}}{4} + c_1\right)$$
$$d(e^{4x}y) = \left(-\frac{1}{4} + \frac{(2x^2 + 4c_1)\,e^{4x}}{4}\right) dx$$

Integrating gives

$$e^{4x}y = \int -\frac{1}{4} + \frac{(2x^2 + 4c_1)\,e^{4x}}{4}\,dx$$
$$e^{4x}y = -\frac{x}{4} + \frac{x^2e^{4x}}{8} - \frac{e^{4x}x}{16} + \frac{e^{4x}}{64} + \frac{e^{4x}c_1}{4} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{4x}$ results in

$$y = e^{-4x}\left(-\frac{x}{4} + \frac{x^2e^{4x}}{8} - \frac{e^{4x}x}{16} + \frac{e^{4x}}{64} + \frac{e^{4x}c_1}{4}\right) + c_2e^{-4x}$$

which simplifies to

$$y = \frac{1}{64} + \frac{(-x + 4c_2)\,e^{-4x}}{4} + \frac{x^2}{8} - \frac{x}{16} + \frac{c_1}{4}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{64} + \frac{(-x + 4c_2)\,e^{-4x}}{4} + \frac{x^2}{8} - \frac{x}{16} + \frac{c_1}{4} \tag{1}$$

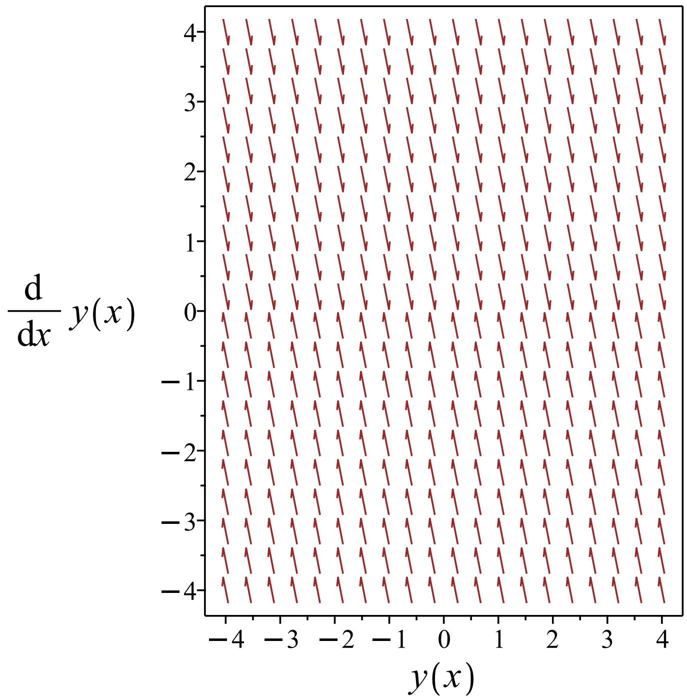

Figure 638: Slope field plot

Verification of solutions

$$y = \frac{1}{64} + \frac{(-x + 4c_2)\,e^{-4x}}{4} + \frac{x^2}{8} - \frac{x}{16} + \frac{c_1}{4}$$

Verified OK.

17.2.7 Maple step by step solution

Let's solve

$y'' + 4y' = x + e^{-4x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4r = 0$

- Factor the characteristic polynomial

  $r(r + 4) = 0$

- Roots of the characteristic polynomial

$r = (-4, 0)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-4x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-4x} + c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x + \mathrm{e}^{-4x}\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $$W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-4x} & 1 \\ -4\,\mathrm{e}^{-4x} & 0 \end{bmatrix}$$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 4\,\mathrm{e}^{-4x}$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\mathrm{e}^{-4x}\left(\int (\mathrm{e}^{4x} x + 1) dx\right)}{4} + \frac{\left(\int (x + \mathrm{e}^{-4x}) dx\right)}{4}$

- ○ Compute integrals

  $y_p(x) = \frac{1}{64} + \frac{(-4x-1)\mathrm{e}^{-4x}}{16} + \frac{x^2}{8} - \frac{x}{16}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-4x} + c_2 + \frac{1}{64} + \frac{(-4x-1)\mathrm{e}^{-4x}}{16} + \frac{x^2}{8} - \frac{x}{16}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - y = x + \sin(x)}$$

17.3.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = -1, f(x) = x + \sin(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)} \\ &= \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +1 \\ \lambda_2 &= -1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 \\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(1)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$y = \mathrm{e}^x c_1 + \mathrm{e}^{-x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^x c_1 + \mathrm{e}^{-x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x + \sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}, \{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_2 x + A_1 + A_3 \cos(x) + A_4 \sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_3 \cos(x) - 2A_4 \sin(x) - A_2 x - A_1 = x + \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = -1, A_3 = 0, A_4 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -x - \frac{\sin(x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x c_1 + e^{-x} c_2) + \left(-x - \frac{\sin(x)}{2}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = e^{x} c_1 + e^{-x} c_2 - x - \frac{\sin(x)}{2} \tag{1}$$

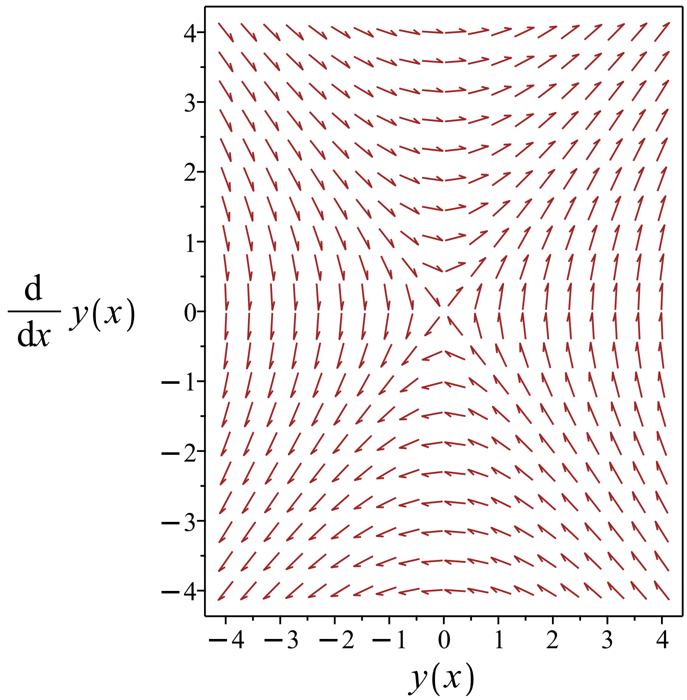

Figure 639: Slope field plot

Verification of solutions

$$y = e^{x} c_1 + e^{-x} c_2 - x - \frac{\sin(x)}{2}$$

Verified OK.

17.3.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 0 \\
C &= -1
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{1}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 1 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 502: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \mathrm{e}^{-x} \end{aligned}$$

Which simplifies to

$$y_1 = e^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= e^{-x} \int \frac{1}{e^{-2x}}\, dx \\ &= e^{-x} \left(\frac{e^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(e^{-x}\right) + c_2 \left(e^{-x} \left(\frac{e^{2x}}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{-x} + \frac{e^{x} c_2}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x+\sin (x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\},\{\cos (x), \sin (x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\mathrm{e}^{x}}{2}, \mathrm{e}^{-x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_{p}=A_{2} x+A_{1}+A_{3} \cos (x)+A_{4} \sin (x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2 A_{3} \cos (x)-2 A_{4} \sin (x)-A_{2} x-A_{1}=x+\sin (x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_{1}=0, A_{2}=-1, A_{3}=0, A_{4}=-\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_{p}=-x-\frac{\sin (x)}{2}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_{h}+y_{p} \\
&= \left(c_{1} \mathrm{e}^{-x}+\frac{\mathrm{e}^{x} c_{2}}{2}\right)+\left(-x-\frac{\sin (x)}{2}\right)
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-x} + \frac{e^x c_2}{2} - x - \frac{\sin(x)}{2} \tag{1}$$

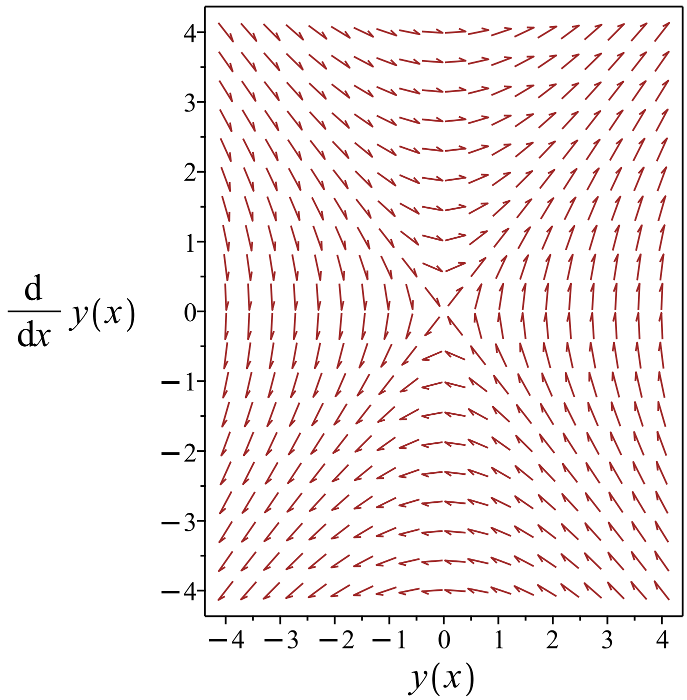

Figure 640: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + \frac{e^x c_2}{2} - x - \frac{\sin(x)}{2}$$

Verified OK.

17.3.3 Maple step by step solution

Let's solve

$y'' - y = x + \sin(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 - 1 = 0$

- Factor the characteristic polynomial

  $(r-1)(r+1) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-x} + c_2 e^{x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = x + \sin(x)\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x} & e^{x} \\ -e^{-x} & e^{x} \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{e^{-x}\left(\int e^{x}(x+\sin(x))dx\right)}{2} + \frac{e^{x}\left(\int e^{-x}(x+\sin(x))dx\right)}{2}$

- ○ Compute integrals

  $y_p(x) = -x - \frac{\sin(x)}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-x} + c_2 e^{x} - x - \frac{\sin(x)}{2}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 2y' + 2y = (1 + \sin(x))\,e^{x}}$$

17.4.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 2, f(x) = (1 + \sin(x))\,e^{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda\, e^{\lambda x} + 2\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-2^2 - (4)\,(1)\,(2)} \\ &= 1 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 1 + i \\ \lambda_2 &= 1 - i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 + i \\ \lambda_2 &= 1 - i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 1$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{x}(c_1 \cos(x) + c_2 \sin(x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$(1+\sin(x))\,e^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{x}\},\{e^{x}\cos(x)\,,e^{x}\sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}\cos(x)\,,e^{x}\sin(x)\}$$

Since $e^{x}\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{x}\},\{x\,e^{x}\cos(x)\,,x\,e^{x}\sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^{x} + A_2 x\,e^{x}\cos(x) + A_3 x\,e^{x}\sin(x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 e^{x} - 2A_2 e^{x}\sin(x) + 2A_3 e^{x}\cos(x) = (1+\sin(x))\,e^{x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 1, A_2 = -\frac{1}{2}, A_3 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = e^{x} - \frac{x\,e^{x}\cos(x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^{x}(c_1\cos(x) + c_2\sin(x))) + \left(e^{x} - \frac{x\,e^{x}\cos(x)}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^x(c_1 \cos(x) + c_2 \sin(x)) + e^x - \frac{x e^x \cos(x)}{2} \tag{1}$$

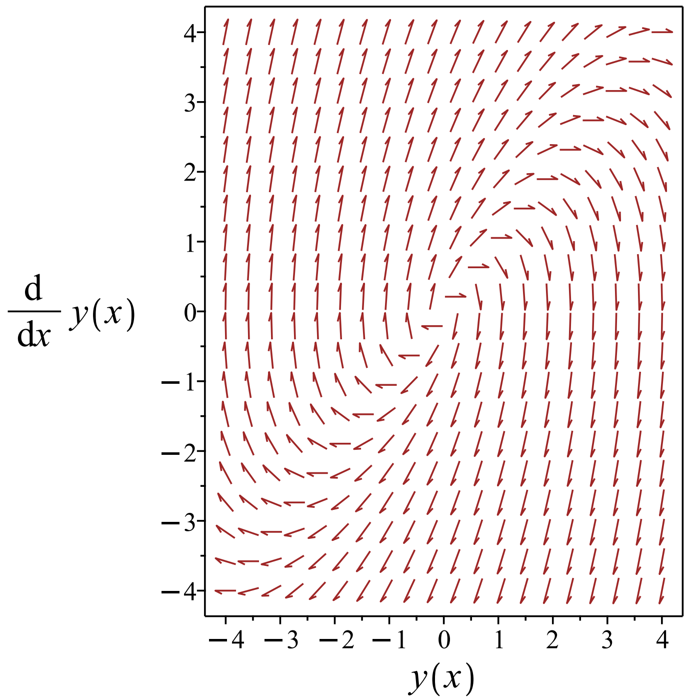

Figure 641: Slope field plot

Verification of solutions

$$y = e^x(c_1 \cos(x) + c_2 \sin(x)) + e^x - \frac{x e^x \cos(x)}{2}$$

Verified OK.

17.4.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= -2 \\
C &= 2
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-1}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -1 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = -z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 504: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\
&= z_1 e^{x} \\
&= z_1 (\mathrm{e}^{x})
\end{aligned}
$$

Which simplifies to

$$y_1 = e^x \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\, dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(e^x \cos(x)) + c_2(e^x \cos(x)(\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = e^x \cos(x)\, c_1 + e^x \sin(x)\, c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$(1 + \sin(x))\, e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}, \{e^x \cos(x), e^x \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x \cos(x), e^x \sin(x)\}$$

Since $e^x \cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^x\}, \{x e^x \cos(x), x e^x \sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^x + A_2 x e^x \cos(x) + A_3 x e^x \sin(x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 e^x - 2A_2 e^x \sin(x) + 2A_3 e^x \cos(x) = (1 + \sin(x)) e^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 1, A_2 = -\frac{1}{2}, A_3 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = e^x - \frac{x e^x \cos(x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x \cos(x) c_1 + e^x \sin(x) c_2) + \left(e^x - \frac{x e^x \cos(x)}{2}\right) \end{aligned}$$

Which simplifies to

$$y = e^x (c_1 \cos(x) + c_2 \sin(x)) + e^x - \frac{x e^x \cos(x)}{2}$$

Summary

The solution(s) found are the following

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x)) + e^{x} - \frac{x e^{x} \cos(x)}{2} \tag{1}$$

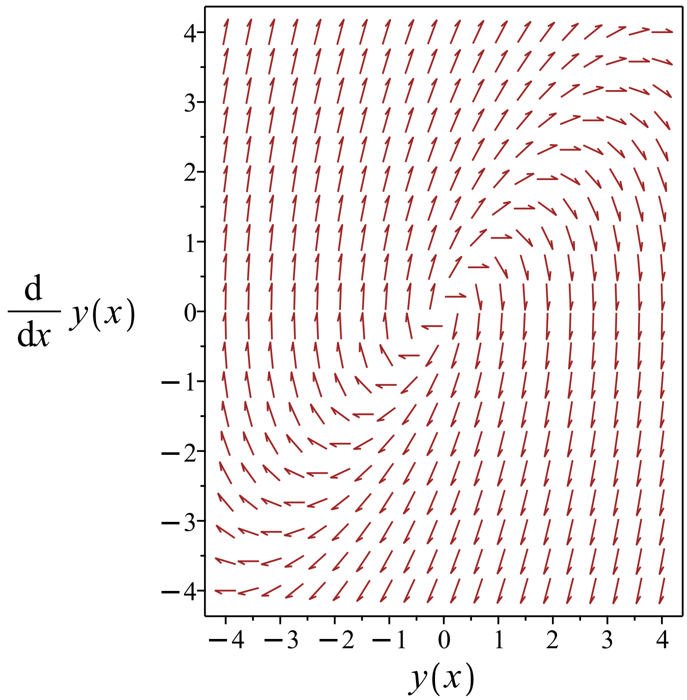

Figure 642: Slope field plot

Verification of solutions

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x)) + e^{x} - \frac{x e^{x} \cos(x)}{2}$$

Verified OK.

17.4.3 Maple step by step solution

Let's solve

$y'' - 2y' + 2y = (1 + \sin(x)) e^{x}$

- Highest derivative means the order of the ODE is 2

y''

- Characteristic polynomial of homogeneous ODE

$r^2 - 2r + 2 = 0$

- Use quadratic formula to solve for r

$r = \frac{2 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

$r = (1 - \mathrm{I}, 1 + \mathrm{I})$

- 1st solution of the homogeneous ODE

$y_1(x) = \mathrm{e}^x \cos(x)$

- 2nd solution of the homogeneous ODE

$y_2(x) = \mathrm{e}^x \sin(x)$

- General solution of the ODE

$y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

$y = \mathrm{e}^x \cos(x)\, c_1 + \mathrm{e}^x \sin(x)\, c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = (1 + \sin(x))\, \mathrm{e}^x\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^x \cos(x) & \mathrm{e}^x \sin(x) \\ \mathrm{e}^x \cos(x) - \mathrm{e}^x \sin(x) & \mathrm{e}^x \sin(x) + \mathrm{e}^x \cos(x) \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = \mathrm{e}^{2x}$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = \mathrm{e}^x\left(-\cos(x)\left(\int \left(\sin(x)^2 + \sin(x)\right) dx\right) + \sin(x)\left(\int \cos(x)\,(1 + \sin(x))\, dx\right)\right)$

- ○ Compute integrals

  $y_p(x) = \frac{(\sin(x) + 2 - \cos(x) x)\, \mathrm{e}^x}{2}$

- Substitute particular solution into general solution to ODE

$y = \mathrm{e}^x \cos(x)\, c_1 + \mathrm{e}^x \sin(x)\, c_2 + \frac{(\sin(x) + 2 - \cos(x) x)\, \mathrm{e}^x}{2}$

Problem number: 555.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' - y'' = 1 + e^x}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - y'' = 0$$

The characteristic equation is

$$\lambda^3 - \lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_2 x + c_1 + e^x c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = x$$
$$y_3 = e^x$$

Now the particular solution to the given ODE is found

$$y''' - y'' = 1 + e^x$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1 + e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, e^x\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}, \{e^x\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2\}, \{e^x\}]$$

Since e^x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2\}, \{x\, e^x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 + A_2 x\, e^x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_2 e^x - 2A_1 = 1 + e^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{2}, A_2 = 1\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x^2}{2} + x\,\mathrm{e}^x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 x + c_1 + \mathrm{e}^x c_3) + \left(-\frac{x^2}{2} + x\,\mathrm{e}^x\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_2 x + c_1 + \mathrm{e}^x c_3 - \frac{x^2}{2} + x\,\mathrm{e}^x \tag{1}$$

Verification of solutions

$$y = c_2 x + c_1 + \mathrm{e}^x c_3 - \frac{x^2}{2} + x\,\mathrm{e}^x$$

Verified OK.

Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Superposition principle. Exercises page 137
Problem number: 556.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' + 4y' = e^{2x} + \sin(2x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + 4y' = 0$$

The characteristic equation is

$$\lambda^3 + 4\lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 2i$$
$$\lambda_3 = -2i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + e^{2ix} c_2 + e^{-2ix} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = e^{2ix}$$
$$y_3 = e^{-2ix}$$

Now the particular solution to the given ODE is found

$$y''' + 4y' = e^{2x} + \sin(2x)$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)} \, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} 1 & e^{2ix} & e^{-2ix} \\ 0 & 2i e^{2ix} & -2i e^{-2ix} \\ 0 & -4 e^{2ix} & -4 e^{-2ix} \end{bmatrix}$$

$$|W| = -16i e^{2ix} e^{-2ix}$$

The determinant simplifies to

$$|W| = -16i$$

Now we determine W_i for each U_i.

$$\begin{aligned} W_1(x) &= \det \begin{bmatrix} e^{2ix} & e^{-2ix} \\ 2ie^{2ix} & -2ie^{-2ix} \end{bmatrix} \\ &= -4i \end{aligned}$$

$$\begin{aligned} W_2(x) &= \det \begin{bmatrix} 1 & e^{-2ix} \\ 0 & -2ie^{-2ix} \end{bmatrix} \\ &= -2ie^{-2ix} \end{aligned}$$

$$\begin{aligned} W_3(x) &= \det \begin{bmatrix} 1 & e^{2ix} \\ 0 & 2ie^{2ix} \end{bmatrix} \\ &= 2ie^{2ix} \end{aligned}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned} U_1 &= (-1)^{3-1} \int \frac{F(x)W_1(x)}{aW(x)}\, dx \\ &= (-1)^2 \int \frac{\left(e^{2x} + \sin(2x)\right)(-4i)}{(1)(-16i)}\, dx \\ &= \int \frac{-4i(e^{2x} + \sin(2x))}{-16i}\, dx \\ &= \int \left(\frac{e^{2x}}{4} + \frac{\sin(2x)}{4}\right) dx \\ &= \frac{e^{2x}}{8} - \frac{\cos(2x)}{8} \end{aligned}$$

$$
\begin{aligned}
U_2 &= (-1)^{3-2} \int \frac{F(x) W_2(x)}{a W(x)} \, dx \\
&= (-1)^1 \int \frac{\left(\mathrm{e}^{2x} + \sin(2x)\right)\left(-2i\mathrm{e}^{-2ix}\right)}{(1)(-16i)} \, dx \\
&= -\int \frac{-2i\left(\mathrm{e}^{2x} + \sin(2x)\right) \mathrm{e}^{-2ix}}{-16i} \, dx \\
&= -\int \left(\frac{\left(\mathrm{e}^{2x} + \sin(2x)\right) \mathrm{e}^{-2ix}}{8}\right) dx \\
&= -\frac{\mathrm{e}^{(2-2i)x}}{32} - \frac{i\mathrm{e}^{(2-2i)x}}{32} + \frac{ix}{16} + \frac{\mathrm{e}^{-4ix}}{64}
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{3-3} \int \frac{F(x) W_3(x)}{a W(x)} \, dx \\
&= (-1)^0 \int \frac{\left(\mathrm{e}^{2x} + \sin(2x)\right)\left(2i\mathrm{e}^{2ix}\right)}{(1)(-16i)} \, dx \\
&= \int \frac{2i\left(\mathrm{e}^{2x} + \sin(2x)\right) \mathrm{e}^{2ix}}{-16i} \, dx \\
&= \int \left(-\frac{\left(\mathrm{e}^{2x} + \sin(2x)\right) \mathrm{e}^{2ix}}{8}\right) dx \\
&= -\frac{ix}{16} + \frac{\mathrm{e}^{4ix}}{64} - \frac{\mathrm{e}^{(2+2i)x}}{32} + \frac{i\mathrm{e}^{(2+2i)x}}{32}
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Hence

$$
\begin{aligned}
y_p = {} & \left(\frac{\mathrm{e}^{2x}}{8} - \frac{\cos(2x)}{8}\right) \\
& + \left(-\frac{\mathrm{e}^{(2-2i)x}}{32} - \frac{i\mathrm{e}^{(2-2i)x}}{32} + \frac{ix}{16} + \frac{\mathrm{e}^{-4ix}}{64}\right)\left(\mathrm{e}^{2ix}\right) \\
& + \left(-\frac{ix}{16} + \frac{\mathrm{e}^{4ix}}{64} - \frac{\mathrm{e}^{(2+2i)x}}{32} + \frac{i\mathrm{e}^{(2+2i)x}}{32}\right)\left(\mathrm{e}^{-2ix}\right)
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = \frac{\mathrm{e}^{2x}}{16} - \frac{3\cos(2x)}{32} - \frac{x\sin(2x)}{8}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 + \mathrm{e}^{2ix} c_2 + \mathrm{e}^{-2ix} c_3\right) + \left(\frac{\mathrm{e}^{2x}}{16} - \frac{3\cos(2x)}{32} - \frac{x\sin(2x)}{8}\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$y = c_1 + e^{2ix} c_2 + e^{-2ix} c_3 + \frac{e^{2x}}{16} - \frac{3\cos(2x)}{32} - \frac{x \sin(2x)}{8} \tag{1}$$

Verification of solutions

$$y = c_1 + e^{2ix} c_2 + e^{-2ix} c_3 + \frac{e^{2x}}{16} - \frac{3\cos(2x)}{32} - \frac{x \sin(2x)}{8}$$

Verified OK.

17.6.1 Maple step by step solution

Let's solve

$y''' + 4y' = e^{2x} + \sin(2x)$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - ◦ Define new variable $y_1(x)$

    $y_1(x) = y$
  - ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$
  - ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$
  - ◦ Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = e^{2x} + \sin(2x) - 4y_2(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = e^{2x} + \sin(2x) - 4y_2(x)]$

- Define vector

  $$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -4 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ e^{2x} + \sin(2x) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ e^{2x} + \sin(2x) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -4 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[-2\,\mathrm{I}, \begin{bmatrix} -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right], \left[2\,\mathrm{I}, \begin{bmatrix} -\frac{1}{4} \\ -\frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-2\,\mathrm{I}, \begin{bmatrix} -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-2\,\mathrm{I}x}\cdot\begin{bmatrix} -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(2x) - \mathrm{I}\sin(2x))\cdot\begin{bmatrix} -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\frac{\cos(2x)}{4} + \frac{\mathrm{I}\sin(2x)}{4} \\ \frac{\mathrm{I}}{2}(\cos(2x) - \mathrm{I}\sin(2x)) \\ \cos(2x) - \mathrm{I}\sin(2x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = \begin{bmatrix} -\frac{\cos(2x)}{4} \\ \frac{\sin(2x)}{2} \\ \cos(2x) \end{bmatrix}, \vec{y}_3(x) = \begin{bmatrix} \frac{\sin(2x)}{4} \\ \frac{\cos(2x)}{2} \\ -\sin(2x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \vec{y}_p(x)$$

□ Fundamental matrix

 ◦ Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} 1 & -\frac{\cos(2x)}{4} & \frac{\sin(2x)}{4} \\ 0 & \frac{\sin(2x)}{2} & \frac{\cos(2x)}{2} \\ 0 & \cos(2x) & -\sin(2x) \end{bmatrix}$$

 ◦ The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} 1 & -\frac{\cos(2x)}{4} & \frac{\sin(2x)}{4} \\ 0 & \frac{\sin(2x)}{2} & \frac{\cos(2x)}{2} \\ 0 & \cos(2x) & -\sin(2x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & -\frac{1}{4} & 0 \\ 0 & 0 & \frac{1}{2} \\ 0 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} 1 & \frac{\sin(2x)}{2} & \frac{1}{4} - \frac{\cos(2x)}{4} \\ 0 & \cos(2x) & \frac{\sin(2x)}{2} \\ 0 & -2\sin(2x) & \cos(2x) \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(x)$ and solve for $\overrightarrow{v}(x)$

$\overrightarrow{y}_p(x) = \Phi(x) \cdot \overrightarrow{v}(x)$

- Take the derivative of the particular solution

$\overrightarrow{y}'_p(x) = \Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

$\Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

- Cancel like terms

$\Phi(x) \cdot \overrightarrow{v}'(x) = \overrightarrow{f}(x)$

- Multiply by the inverse of the fundamental matrix

$\overrightarrow{v}'(x) = \frac{1}{\Phi(x)} \cdot \overrightarrow{f}(x)$

- Integrate to solve for $\overrightarrow{v}(x)$

$\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$

- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

$$\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \left[\begin{array}{c} \frac{(-2x-1)\sin(2x)}{16} - \frac{\cos(2x)}{16} + \frac{e^{2x}}{16} \\ \frac{\cos(2x)(-2x-1)}{8} + \frac{e^{2x}}{8} \\ \frac{(1+2x)\sin(2x)}{4} - \frac{\cos(2x)}{4} + \frac{e^{2x}}{4} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \left[\begin{array}{c} \frac{(-2x-1)\sin(2x)}{16} - \frac{\cos(2x)}{16} + \frac{e^{2x}}{16} \\ \frac{\cos(2x)(-2x-1)}{8} + \frac{e^{2x}}{8} \\ \frac{(1+2x)\sin(2x)}{4} - \frac{\cos(2x)}{4} + \frac{e^{2x}}{4} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = \frac{(4c_3-2x-1)\sin(2x)}{16} + \frac{(-4c_2-1)\cos(2x)}{16} + c_1 + \frac{e^{2x}}{16}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 4y = \sin(x)\sin(2x)}$$

17.7.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 4, f(x) = \sin(x)\sin(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 4\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(4)}\\ &= \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2i\\ \lambda_2 &= -2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2i\\ \lambda_2 &= -2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(2x) + c_2 \sin(2x))$$

Or

$$y = c_1 \cos(2x) + c_2 \sin(2x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(2x) + c_2 \sin(2x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)\sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}, \{\cos(3x), \sin(3x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(2x), \sin(2x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x) + A_3 \cos(3x) + A_4 \sin(3x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_1 \cos(x) + 3A_2 \sin(x) - 5A_3 \cos(3x) - 5A_4 \sin(3x) = \sin(x)\sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{6}, A_2 = 0, A_3 = \frac{1}{10}, A_4 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\cos(x)}{6} + \frac{\cos(3x)}{10}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(2x) + c_2 \sin(2x)) + \left(\frac{\cos(x)}{6} + \frac{\cos(3x)}{10}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(2x) + c_2 \sin(2x) + \frac{\cos(x)}{6} + \frac{\cos(3x)}{10} \tag{1}$$

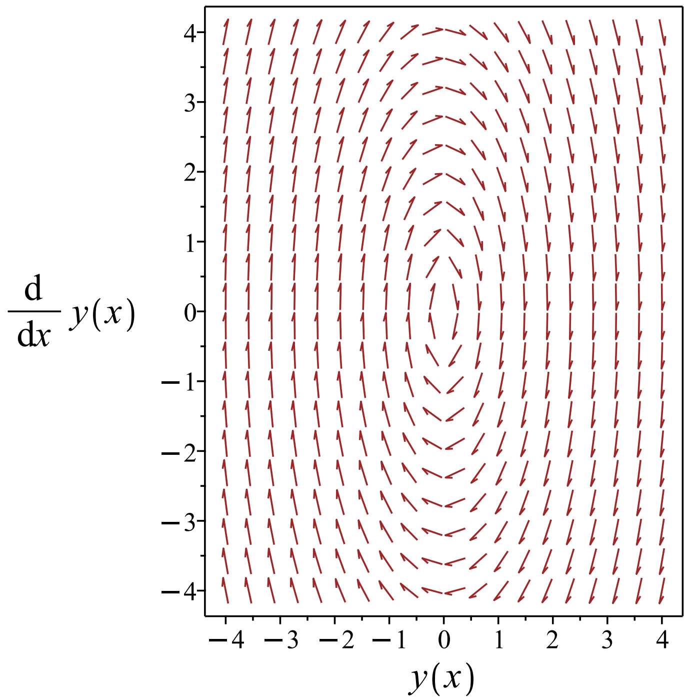

Figure 643: Slope field plot

Verification of solutions

$$y = c_1 \cos(2x) + c_2 \sin(2x) + \frac{\cos(x)}{6} + \frac{\cos(3x)}{10}$$

Verified OK.

17.7.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 507: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(2x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \cos(2x) \int \frac{1}{\cos(2x)^2}\, dx \\
&= \cos(2x) \left(\frac{\tan(2x)}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(2x)) + c_2\left(\cos(2x)\left(\frac{\tan(2x)}{2}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)\sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}, \{\cos(3x), \sin(3x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sin(2x)}{2}, \cos(2x)\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\cos(x) + A_2\sin(x) + A_3\cos(3x) + A_4\sin(3x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_1\cos(x) + 3A_2\sin(x) - 5A_3\cos(3x) - 5A_4\sin(3x) = \sin(x)\sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{6}, A_2 = 0, A_3 = \frac{1}{10}, A_4 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\cos(x)}{6} + \frac{\cos(3x)}{10}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\cos(2x) + \frac{c_2\sin(2x)}{2}\right) + \left(\frac{\cos(x)}{6} + \frac{\cos(3x)}{10}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2} + \frac{\cos(x)}{6} + \frac{\cos(3x)}{10} \tag{1}$$

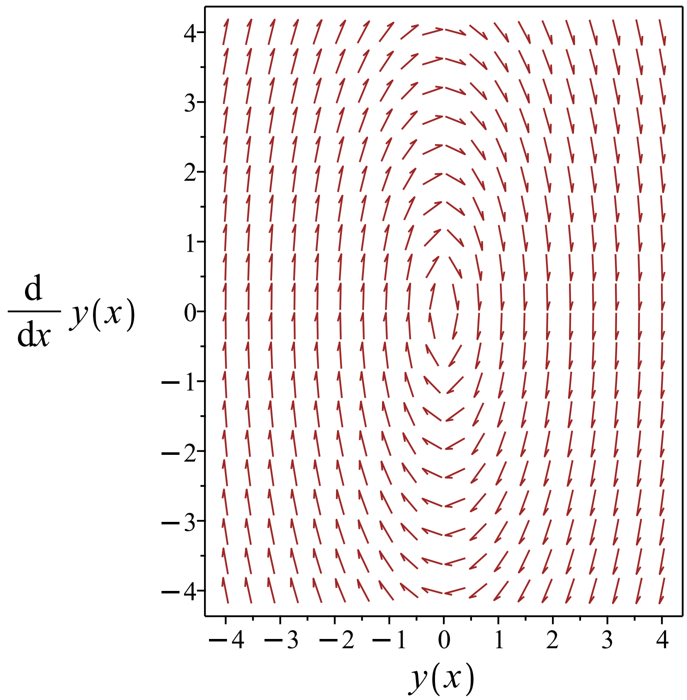

Figure 644: Slope field plot

Verification of solutions

$$y = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2} + \frac{\cos(x)}{6} + \frac{\cos(3x)}{10}$$

Verified OK.

17.7.3 Maple step by step solution

Let's solve

$y'' + 4y = \sin(x)\sin(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2+4=0$

- Use quadratic formula to solve for r

$r=\frac{0\pm(\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

$r=(-2\,\mathrm{I},2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

$y_1(x)=\cos(2x)$

- 2nd solution of the homogeneous ODE

$y_2(x)=\sin(2x)$

- General solution of the ODE

$y=c_1y_1(x)+c_2y_2(x)+y_p(x)$

- Substitute in solutions of the homogeneous ODE

$y=c_1\cos(2x)+c_2\sin(2x)+y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x)=-y_1(x)\left(\int\frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right)+y_2(x)\left(\int\frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right),f(x)=\sin(x)\sin(2x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x),y_2(x))=\begin{bmatrix}\cos(2x) & \sin(2x)\\ -2\sin(2x) & 2\cos(2x)\end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x),y_2(x))=2$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x)=-\frac{\cos(2x)\left(\int\sin(2x)^2\sin(x)dx\right)}{2}+\frac{\sin(2x)\left(\int(-\cos(5x)+\cos(3x))dx\right)}{8}$

  - Compute integrals

    $y_p(x)=\frac{2\cos(x)^3}{5}-\frac{2\cos(x)}{15}$

- Substitute particular solution into general solution to ODE

$y=c_1\cos(2x)+c_2\sin(2x)+\frac{2\cos(x)^3}{5}-\frac{2\cos(x)}{15}$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' - 4y' = 2\cos(4x)^2}$$

17.8.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 0, f(x) = 1 + \cos(8x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''-4y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=1, B=-4, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x}-4\lambda\, \mathrm{e}^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2-4\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=-4, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{4}{(2)(1)}\pm\frac{1}{(2)(1)}\sqrt{-4^2-(4)(1)(0)}\\&=2\pm 2\end{aligned}$$

Hence

$$\lambda_1=2+2$$
$$\lambda_2=2-2$$

Which simplifies to

$$\lambda_1=4$$
$$\lambda_2=0$$

Since roots are real and distinct, then the solution is

$$y=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}$$
$$y=c_1e^{(4)x}+c_2e^{(0)x}$$

Or

$$y = e^{4x}c_1 + c_2$$

Therefore the homogeneous solution y_h is

$$y_h = e^{4x}c_1 + c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1 + \cos(8x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{\cos(8x), \sin(8x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{4x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}, \{\cos(8x), \sin(8x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x + A_2 \cos(8x) + A_3 \sin(8x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-64A_2 \cos(8x) - 64A_3 \sin(8x) - 4A_1 + 32A_2 \sin(8x) - 32A_3 \cos(8x) = 1 + \cos(8x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{4}, A_2 = -\frac{1}{80}, A_3 = -\frac{1}{160}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^{4x}c_1 + c_2) + \left(-\frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{4x}c_1 + c_2 - \frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160} \tag{1}$$

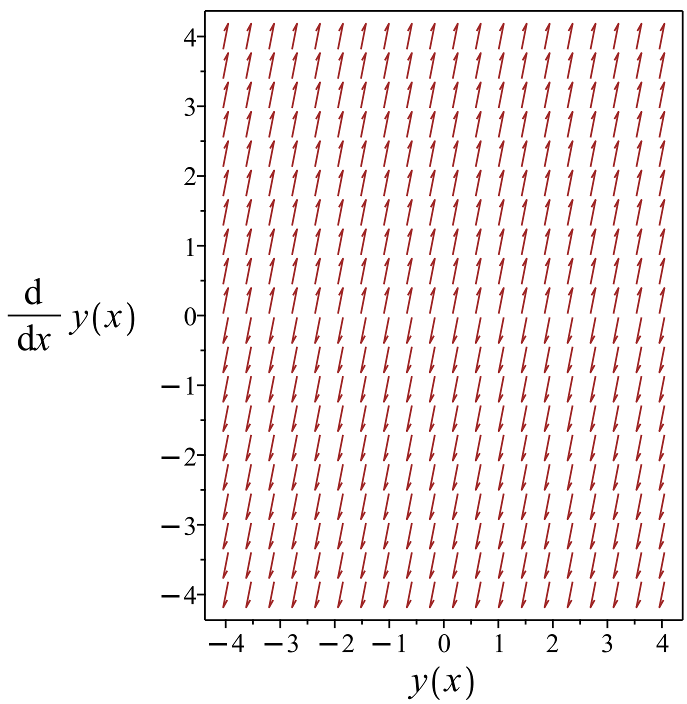

Figure 645: Slope field plot

Verification of solutions

$$y = e^{4x}c_1 + c_2 - \frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160}$$

Verified OK.

17.8.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$
\begin{aligned}
\int (y''-4y')\,dx &= \int (1+\cos(8x))\,dx \\
-4y+y' &= x+\frac{\sin(8x)}{8}+c_1
\end{aligned}
$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
y'+p(x)y = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -4 \\
q(x) &= x+\frac{\sin(8x)}{8}+c_1
\end{aligned}
$$

Hence the ode is

$$
-4y+y' = x+\frac{\sin(8x)}{8}+c_1
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int(-4)dx} \\
&= \mathrm{e}^{-4x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(x+\frac{\sin(8x)}{8}+c_1\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{-4x}y\right) &= \left(\mathrm{e}^{-4x}\right)\left(x+\frac{\sin(8x)}{8}+c_1\right) \\
\mathrm{d}\left(\mathrm{e}^{-4x}y\right) &= \left(\frac{(\sin(8x)+8c_1+8x)\,\mathrm{e}^{-4x}}{8}\right)\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{-4x}y &= \int \frac{(\sin(8x)+8c_1+8x)\,\mathrm{e}^{-4x}}{8}\,\mathrm{d}x \\
\mathrm{e}^{-4x}y &= -\frac{\mathrm{e}^{-4x}\cos(8x)}{80}-\frac{\mathrm{e}^{-4x}\sin(8x)}{160}-\frac{\mathrm{e}^{-4x}\cos(2x)}{20}-\frac{\mathrm{e}^{-4x}\sin(2x)}{10}-\frac{\mathrm{e}^{-4x}(-4\sin(2x)-2\cos(2x))}{40}-
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-4x}$ results in

$$y = \mathrm{e}^{4x}\left(-\frac{\mathrm{e}^{-4x}\cos(8x)}{80} - \frac{\mathrm{e}^{-4x}\sin(8x)}{160} - \frac{\mathrm{e}^{-4x}\cos(2x)}{20} - \frac{\mathrm{e}^{-4x}\sin(2x)}{10} - \frac{\mathrm{e}^{-4x}(-4\sin(2x) - 2\cos(2x))}{40} \right.$$

which simplifies to

$$y = -\frac{1}{16} + c_2\mathrm{e}^{4x} - \frac{c_1}{4} - \frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160}$$

Summary

The solution(s) found are the following

$$y = -\frac{1}{16} + c_2\mathrm{e}^{4x} - \frac{c_1}{4} - \frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160} \tag{1}$$

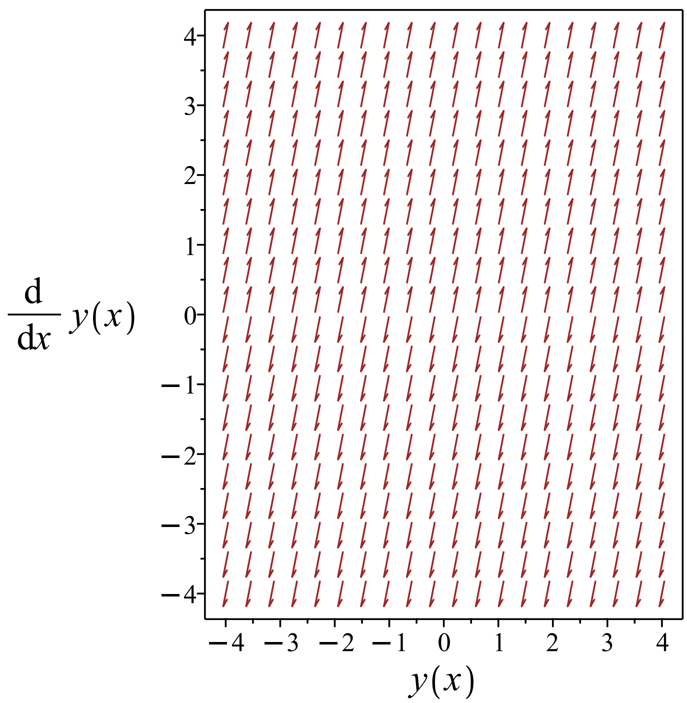

Figure 646: Slope field plot

Verification of solutions

$$y = -\frac{1}{16} + c_2\mathrm{e}^{4x} - \frac{c_1}{4} - \frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160}$$

Verified OK.

17.8.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - 4p(x) - 1 - \cos(8x) = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -4 \\ q(x) &= 1 + \cos(8x) \end{aligned}$$

Hence the ode is

$$p'(x) - 4p(x) = 1 + \cos(8x)$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-4)dx} \\ &= e^{-4x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu)(1 + \cos(8x)) \\ \frac{d}{dx}\left(e^{-4x} p\right) &= \left(e^{-4x}\right)(1 + \cos(8x)) \\ d\left(e^{-4x} p\right) &= \left((1 + \cos(8x))\, e^{-4x}\right) dx \end{aligned}$$

Integrating gives

$$e^{-4x} p = \int (1 + \cos(8x))\, e^{-4x}\, dx$$

$$e^{-4x} p = -\frac{3\, e^{-4x}}{10} + \frac{8(-4\cos(x) + 8\sin(x))\, e^{-4x} \cos(x)^7}{5} - \frac{16(-4\cos(x) + 6\sin(x))\, e^{-4x} \cos(x)^5}{5} + 2(-$$

Dividing both sides by the integrating factor $\mu = e^{-4x}$ results in

$$p(x) = e^{4x}\left(-\frac{3\,e^{-4x}}{10} + \frac{8(-4\cos(x) + 8\sin(x))\,e^{-4x}\cos(x)^7}{5} - \frac{16(-4\cos(x) + 6\sin(x))\,e^{-4x}\cos(x)^5}{5} + 2\right.$$

which simplifies to

$$p(x) = \frac{\sin(8x)}{10} - \frac{\cos(8x)}{20} - \frac{1}{4} + e^{4x}c_1$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{\sin(8x)}{10} - \frac{\cos(8x)}{20} - \frac{1}{4} + e^{4x}c_1$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{\sin(8x)}{10} - \frac{\cos(8x)}{20} - \frac{1}{4} + e^{4x}c_1\, dx \\ &= -\frac{x}{4} + \frac{e^{4x}c_1}{4} - \frac{\sin(8x)}{160} - \frac{\cos(8x)}{80} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{x}{4} + \frac{e^{4x}c_1}{4} - \frac{\sin(8x)}{160} - \frac{\cos(8x)}{80} + c_2 \tag{1}$$

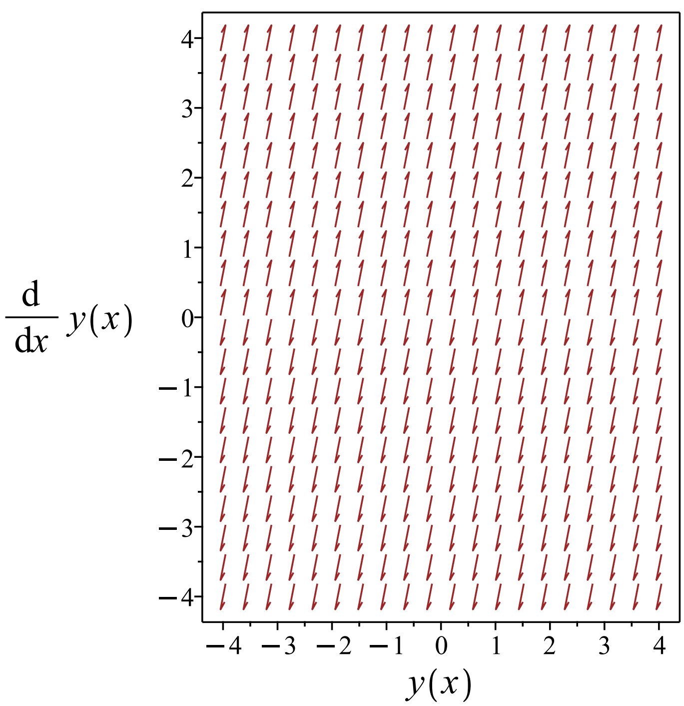

Figure 647: Slope field plot

Verification of solutions

$$y = -\frac{x}{4} + \frac{e^{4x} c_1}{4} - \frac{\sin(8x)}{160} - \frac{\cos(8x)}{80} + c_2$$

Verified OK.

17.8.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' - 4y' = 1 + \cos(8x)$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - 4y')\, dx = \int (1 + \cos(8x))\, dx$$
$$-4y + y' = x + \frac{\sin(8x)}{8} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -4$$
$$q(x) = x + \frac{\sin(8x)}{8} + c_1$$

Hence the ode is

$$-4y + y' = x + \frac{\sin(8x)}{8} + c_1$$

The integrating factor μ is

$$\mu = e^{\int(-4)dx}$$
$$= e^{-4x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(x + \frac{\sin(8x)}{8} + c_1\right)$$
$$\frac{d}{dx}(e^{-4x} y) = (e^{-4x})\left(x + \frac{\sin(8x)}{8} + c_1\right)$$
$$d(e^{-4x} y) = \left(\frac{(\sin(8x) + 8c_1 + 8x)\, e^{-4x}}{8}\right) dx$$

Integrating gives

$$e^{-4x}y = \int \frac{(\sin(8x) + 8c_1 + 8x)\,e^{-4x}}{8}\,dx$$

$$e^{-4x}y = -\frac{e^{-4x}\cos(8x)}{80} - \frac{e^{-4x}\sin(8x)}{160} - \frac{e^{-4x}\cos(2x)}{20} - \frac{e^{-4x}\sin(2x)}{10} - \frac{e^{-4x}(-4\sin(2x) - 2\cos(2x))}{40} -$$

Dividing both sides by the integrating factor $\mu = e^{-4x}$ results in

$$y = e^{4x}\left(-\frac{e^{-4x}\cos(8x)}{80} - \frac{e^{-4x}\sin(8x)}{160} - \frac{e^{-4x}\cos(2x)}{20} - \frac{e^{-4x}\sin(2x)}{10} - \frac{e^{-4x}(-4\sin(2x) - 2\cos(2x))}{40} -\right.$$

which simplifies to

$$y = -\frac{1}{16} + c_2 e^{4x} - \frac{c_1}{4} - \frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160}$$

Summary

The solution(s) found are the following

$$y = -\frac{1}{16} + c_2 e^{4x} - \frac{c_1}{4} - \frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160} \tag{1}$$

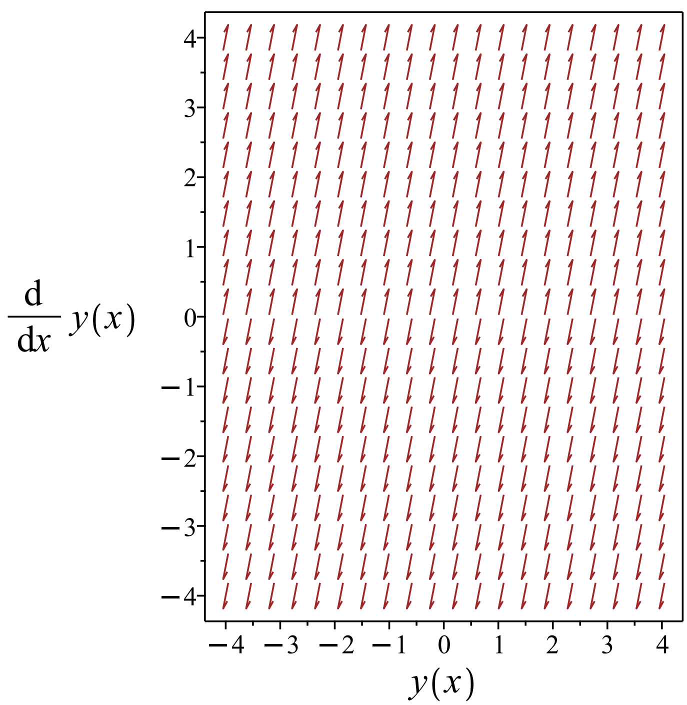

Figure 648: Slope field plot

Verification of solutions

$$y = -\frac{1}{16} + c_2 e^{4x} - \frac{c_1}{4} - \frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160}$$

Verified OK.

17.8.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 509: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-2x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx} \\
&= z_1 e^{2x} \\
&= z_1 \left(\mathrm{e}^{2x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = 1
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{4x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\mathrm{e}^{4x}}{4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2\left(1\left(\frac{\mathrm{e}^{4x}}{4}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 4y' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 + \frac{c_2 e^{4x}}{4}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1 + \cos(8x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{\cos(8x), \sin(8x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{1, \frac{e^{4x}}{4}\right\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}, \{\cos(8x), \sin(8x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x + A_2 \cos(8x) + A_3 \sin(8x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-64A_2 \cos(8x) - 64A_3 \sin(8x) - 4A_1 + 32A_2 \sin(8x) - 32A_3 \cos(8x) = 1 + \cos(8x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{4}, A_2 = -\frac{1}{80}, A_3 = -\frac{1}{160}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 + \frac{c_2 e^{4x}}{4}\right) + \left(-\frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 + \frac{c_2 e^{4x}}{4} - \frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160} \tag{1}
$$

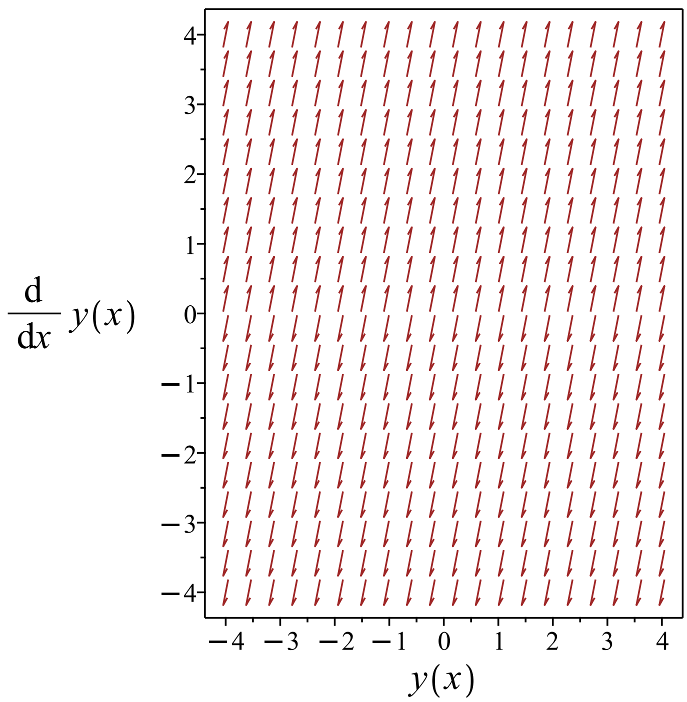

Figure 649: Slope field plot

Verification of solutions

$$
y = c_1 + \frac{c_2 e^{4x}}{4} - \frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160}
$$

Verified OK.

17.8.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= -4 \\ r(x) &= 0 \\ s(x) &= 1 + \cos(8x) \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\;dx$$

Substituting the above values for p, q, r, s gives

$$-4y + y' = \int 1 + \cos(8x)\;dx$$

We now have a first order ode to solve which is

$$-4y + y' = x + \frac{\sin(8x)}{8} + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -4 \\ q(x) &= x + \frac{\sin(8x)}{8} + c_1 \end{aligned}$$

Hence the ode is

$$-4y + y' = x + \frac{\sin(8x)}{8} + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int(-4)dx} \\ &= e^{-4x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(x + \frac{\sin(8x)}{8} + c_1\right) \\ \frac{d}{dx}\left(e^{-4x} y\right) &= \left(e^{-4x}\right)\left(x + \frac{\sin(8x)}{8} + c_1\right) \\ d\left(e^{-4x} y\right) &= \left(\frac{(\sin(8x) + 8c_1 + 8x)\, e^{-4x}}{8}\right) dx \end{aligned}$$

Integrating gives

$$e^{-4x} y = \int \frac{(\sin(8x) + 8c_1 + 8x)\, e^{-4x}}{8}\, dx$$

$$e^{-4x} y = -\frac{e^{-4x}\cos(8x)}{80} - \frac{e^{-4x}\sin(8x)}{160} - \frac{e^{-4x}\cos(2x)}{20} - \frac{e^{-4x}\sin(2x)}{10} - \frac{e^{-4x}(-4\sin(2x) - 2\cos(2x))}{40} -$$

Dividing both sides by the integrating factor $\mu = e^{-4x}$ results in

$$y = e^{4x}\left(-\frac{e^{-4x}\cos(8x)}{80} - \frac{e^{-4x}\sin(8x)}{160} - \frac{e^{-4x}\cos(2x)}{20} - \frac{e^{-4x}\sin(2x)}{10} - \frac{e^{-4x}(-4\sin(2x) - 2\cos(2x))}{40} -\right.$$

which simplifies to

$$y = -\frac{1}{16} + c_2 e^{4x} - \frac{c_1}{4} - \frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160}$$

Summary
The solution(s) found are the following

$$y = -\frac{1}{16} + c_2 e^{4x} - \frac{c_1}{4} - \frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160} \tag{1}$$

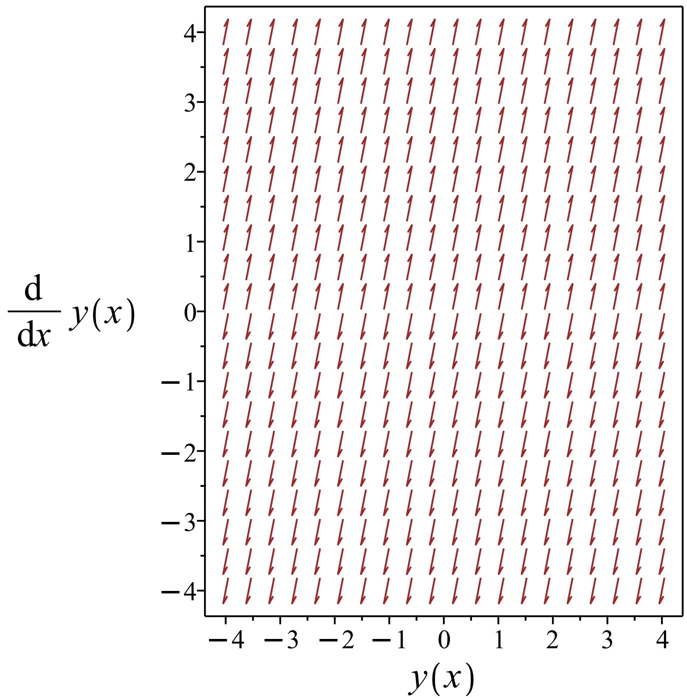

Figure 650: Slope field plot

Verification of solutions

$$y = -\frac{1}{16} + c_2 e^{4x} - \frac{c_1}{4} - \frac{x}{4} - \frac{\cos(8x)}{80} - \frac{\sin(8x)}{160}$$

Verified OK.

17.8.7 Maple step by step solution

Let's solve

$y'' - 4y' = 1 + \cos(8x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 - 4r = 0$

- Factor the characteristic polynomial

  $r(r-4) = 0$

- Roots of the characteristic polynomial

  $r = (0, 4)$

- 1st solution of the homogeneous ODE

  $y_1(x) = 1$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{4x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 e^{4x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 1 + \cos(8x)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & e^{4x} \\ 0 & 4\,e^{4x} \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 4\,e^{4x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\left(\int (1+\cos(8x))dx\right)}{4} + \frac{e^{4x}\left(\int (1+\cos(8x))e^{-4x}dx\right)}{4}$

  ◦ Compute integrals

  $y_p(x) = -\frac{\sin(8x)}{160} - \frac{\cos(8x)}{80} - \frac{1}{16} - \frac{x}{4}$

- Substitute particular solution into general solution to ODE

  $y = c_1 + c_2 e^{4x} - \frac{\sin(8x)}{160} - \frac{\cos(8x)}{80} - \frac{1}{16} - \frac{x}{4}$

```

$$\boxed{y'' - y' - 2y = 4x - 2\,e^{x}}$$

17.9.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -1, C = -2, f(x) = 4x - 2\,e^{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' - 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -1, C = -2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - \lambda e^{\lambda x} - 2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \lambda - 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -1, C = -2$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{1}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-1^2 - (4)(1)(-2)} \\
&= \frac{1}{2} \pm \frac{3}{2}
\end{aligned}$$

Hence

$$\lambda_1 = \frac{1}{2} + \frac{3}{2}$$

$$\lambda_2 = \frac{1}{2} - \frac{3}{2}$$

Which simplifies to

$$\lambda_1 = 2$$

$$\lambda_2 = -1$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$

$$y = c_1 e^{(2)x} + c_2 e^{(-1)x}$$

Or

$$y = e^{2x} c_1 + e^{-x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = e^{2x} c_1 + e^{-x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4x - 2\,\mathrm{e}^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{x}\}, \{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-x}, \mathrm{e}^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\mathrm{e}^{x} + A_2 + A_3 x$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1\mathrm{e}^{x} - A_3 - 2A_2 - 2A_3 x = 4x - 2\,\mathrm{e}^{x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = 1, A_3 = -2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \mathrm{e}^{x} + 1 - 2x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{2x}c_1 + \mathrm{e}^{-x}c_2\right) + \left(\mathrm{e}^{x} + 1 - 2x\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{2x}c_1 + \mathrm{e}^{-x}c_2 + \mathrm{e}^{x} + 1 - 2x \tag{1}$$

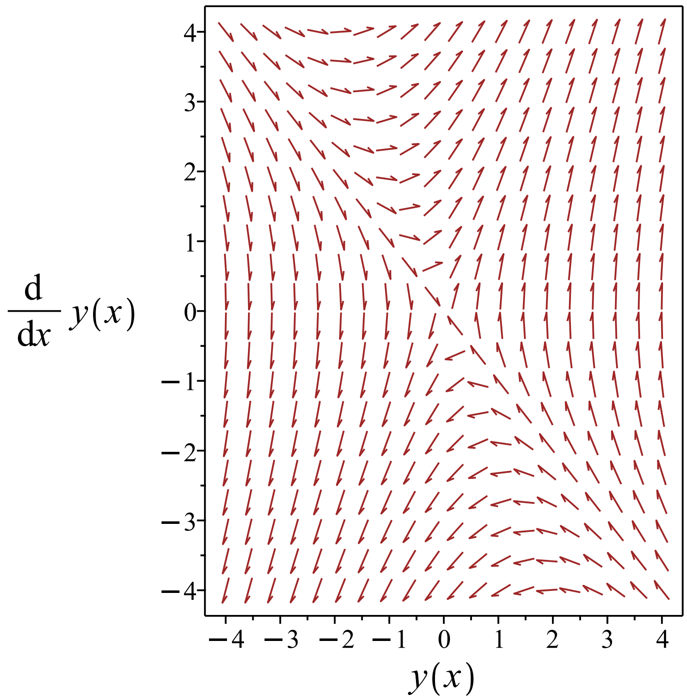

Figure 651: Slope field plot

Verification of solutions

$$y = e^{2x}c_1 + e^{-x}c_2 + e^x + 1 - 2x$$

Verified OK.

17.9.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -1 \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 511: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - 0\\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{-1}{1}\,dx}\\ &= z_1 e^{\frac{x}{2}}\\ &= z_1\left(\mathrm{e}^{\frac{x}{2}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{1}\,dx}}{(y_1)^2}\,dx\\ &= y_1 \int \frac{e^{x}}{(y_1)^2}\,dx\\ &= y_1\left(\frac{\mathrm{e}^{3x}}{3}\right)\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{3x}}{3}\right)\right)\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' - 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-x} + \frac{\mathrm{e}^{2x} c_2}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4x - 2\,\mathrm{e}^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{x}\}, \{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\mathrm{e}^{2x}}{3}, \mathrm{e}^{-x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \mathrm{e}^{x} + A_2 + A_3 x$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 e^x - A_3 - 2A_2 - 2A_3 x = 4x - 2\,e^x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = 1, A_3 = -2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = e^x + 1 - 2x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + \frac{e^{2x} c_2}{3}\right) + (e^x + 1 - 2x) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-x} + \frac{e^{2x} c_2}{3} + e^x + 1 - 2x \tag{1}$$

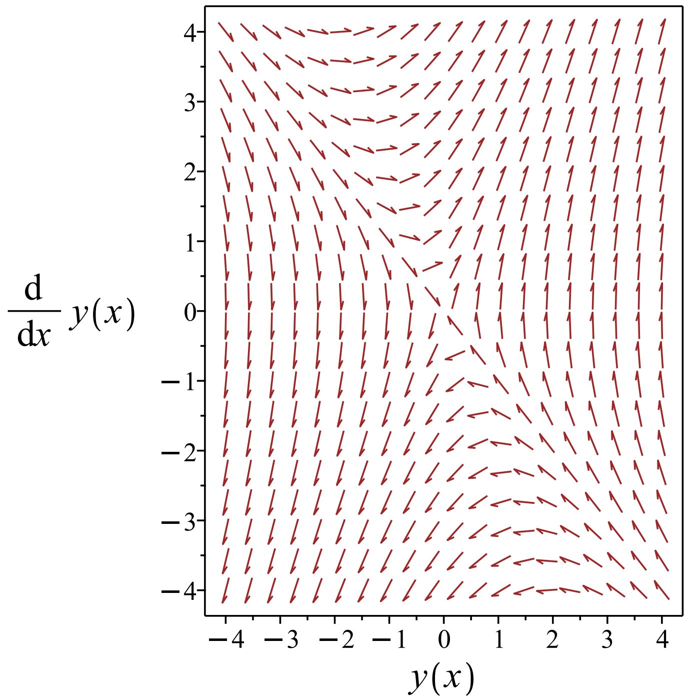

Figure 652: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + \frac{e^{2x} c_2}{3} + e^x + 1 - 2x$$

Verified OK.

17.9.3 Maple step by step solution

Let's solve

$y'' - y' - 2y = 4x - 2\,e^x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - r - 2 = 0$

- Factor the characteristic polynomial

  $(r + 1)(r - 2) = 0$

- Roots of the characteristic polynomial

$r = (-1, 2)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x}$
- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{2x}$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-x} + e^{2x} c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))} dx\right), f(x) = 4x - 2\,e^{x}\right]$
- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x} & e^{2x} \\ -e^{-x} & 2\,e^{2x} \end{bmatrix}$
- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 3\,e^{x}$
- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = \frac{2\,e^{-x}\left(\int (-2x+e^{x}) e^{x} dx\right)}{3} - \frac{2\,e^{2x}\left(\int (-2x+e^{x}) e^{-2x} dx\right)}{3}$
- ○ Compute integrals

  $y_p(x) = e^{x} + 1 - 2x$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-x} + e^{2x} c_2 + e^{x} + 1 - 2x$

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' - 3y' = 18x - 10\cos(x)}$$

17.10.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -3, C = 0, f(x) = 18x - 10\cos(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 3y' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -3, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 3\lambda\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 3\lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -3, C = 0$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{3}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-3^2 - (4)\,(1)\,(0)} \\
&= \frac{3}{2} \pm \frac{3}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
\lambda_1 &= \frac{3}{2} + \frac{3}{2} \\
\lambda_2 &= \frac{3}{2} - \frac{3}{2}
\end{aligned}$$

Which simplifies to

$$\begin{aligned}
\lambda_1 &= 3 \\
\lambda_2 &= 0
\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}
y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\
y &= c_1 e^{(3)x} + c_2 e^{(0)x}
\end{aligned}$$

Or

$$y = c_1 e^{3x} + c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{3x} + c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$18x - 10\cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}, \{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{3x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x, x^2\}, \{\cos(x), \sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_2 x^2 + A_1 x + A_3 \cos(x) + A_4 \sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_2 - A_3 \cos(x) - A_4 \sin(x) - 6A_2 x - 3A_1 + 3A_3 \sin(x) - 3A_4 \cos(x) = 18x - 10\cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2, A_2 = -3, A_3 = 1, A_4 = 3]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -3x^2 - 2x + \cos(x) + 3\sin(x)$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 e^{3x} + c_2\right) + \left(-3x^2 - 2x + \cos(x) + 3\sin(x)\right)
\end{aligned}
$$

<u>Summary</u>
The solution(s) found are the following

$$
y = c_1 e^{3x} + c_2 - 3x^2 - 2x + \cos(x) + 3\sin(x) \tag{1}
$$

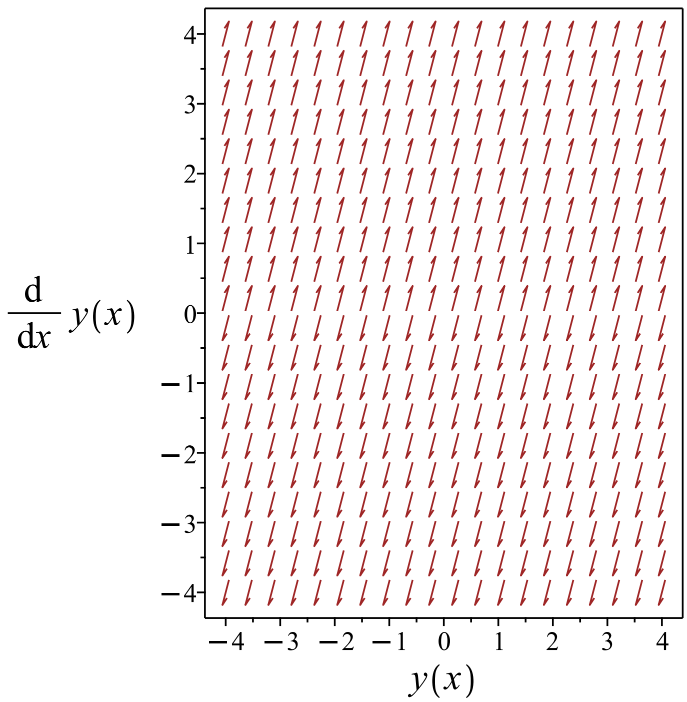

Figure 653: Slope field plot

<u>Verification of solutions</u>

$$
y = c_1 e^{3x} + c_2 - 3x^2 - 2x + \cos(x) + 3\sin(x)
$$

Verified OK.

17.10.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - 3y')\, dx = \int (18x - 10\cos(x))\, dx$$

$$-3y + y' = 9x^2 - 10\sin(x) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -3 \\ q(x) &= 9x^2 - 10\sin(x) + c_1 \end{aligned}$$

Hence the ode is

$$-3y + y' = 9x^2 - 10\sin(x) + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-3)dx} \\ &= e^{-3x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(9x^2 - 10\sin(x) + c_1\right) \\ \frac{d}{dx}\left(e^{-3x} y\right) &= \left(e^{-3x}\right)\left(9x^2 - 10\sin(x) + c_1\right) \\ d\left(e^{-3x} y\right) &= \left(\left(9x^2 - 10\sin(x) + c_1\right) e^{-3x}\right)\, dx \end{aligned}$$

Integrating gives

$$e^{-3x} y = \int \left(9x^2 - 10\sin(x) + c_1\right) e^{-3x}\, dx$$

$$e^{-3x} y = -3x^2 e^{-3x} - 2x\, e^{-3x} - \frac{2\, e^{-3x}}{3} + e^{-3x}\cos(x) + 3\, e^{-3x}\sin(x) - \frac{c_1 e^{-3x}}{3} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{-3x}$ results in

$$y = e^{3x}\left(-3x^2 e^{-3x} - 2x\, e^{-3x} - \frac{2\, e^{-3x}}{3} + e^{-3x}\cos(x) + 3\, e^{-3x}\sin(x) - \frac{c_1 e^{-3x}}{3}\right) + c_2 e^{3x}$$

which simplifies to

$$y = -\frac{2}{3} + c_2 e^{3x} - 3x^2 - \frac{c_1}{3} - 2x + \cos(x) + 3\sin(x)$$

Summary

The solution(s) found are the following

$$y = -\frac{2}{3} + c_2 e^{3x} - 3x^2 - \frac{c_1}{3} - 2x + \cos(x) + 3\sin(x) \tag{1}$$

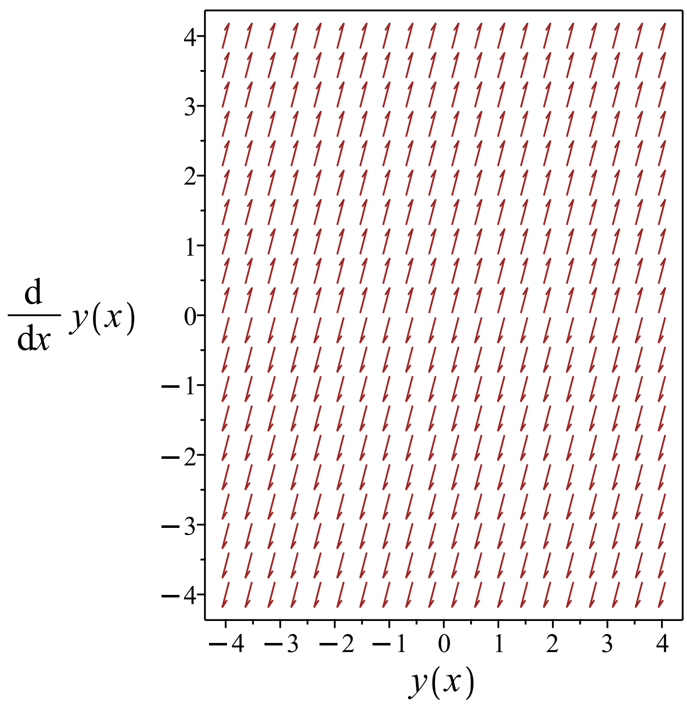

Figure 654: Slope field plot

Verification of solutions

$$y = -\frac{2}{3} + c_2 e^{3x} - 3x^2 - \frac{c_1}{3} - 2x + \cos(x) + 3\sin(x)$$

Verified OK.

17.10.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - 3p(x) - 18x + 10\cos(x) = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -3 \\ q(x) &= 18x - 10\cos(x) \end{aligned}$$

Hence the ode is

$$p'(x) - 3p(x) = 18x - 10\cos(x)$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-3)dx} \\ &= e^{-3x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu)\,(18x - 10\cos(x)) \\ \frac{d}{dx}\left(e^{-3x}p\right) &= \left(e^{-3x}\right)(18x - 10\cos(x)) \\ d\left(e^{-3x}p\right) &= \left((18x - 10\cos(x))\,e^{-3x}\right)\,dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{-3x}p &= \int (18x - 10\cos(x))\,e^{-3x}\,dx \\ e^{-3x}p &= -6x\,e^{-3x} - 2\,e^{-3x} + 3\,e^{-3x}\cos(x) - e^{-3x}\sin(x) + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-3x}$ results in

$$p(x) = e^{3x}\left(-6x\,e^{-3x} - 2\,e^{-3x} + 3\,e^{-3x}\cos(x) - e^{-3x}\sin(x)\right) + c_1 e^{3x}$$

which simplifies to

$$p(x) = c_1 e^{3x} - 6x - \sin(x) + 3\cos(x) - 2$$

Since $p = y'$ then the new first order ode to solve is

$$y' = c_1 e^{3x} - 6x - \sin(x) + 3\cos(x) - 2$$

Integrating both sides gives

$$\begin{aligned} y &= \int c_1 e^{3x} - 6x - \sin(x) + 3\cos(x) - 2\,dx \\ &= -2x + \frac{c_1 e^{3x}}{3} - 3x^2 + 3\sin(x) + \cos(x) + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -2x + \frac{c_1 e^{3x}}{3} - 3x^2 + 3\sin(x) + \cos(x) + c_2 \tag{1}$$

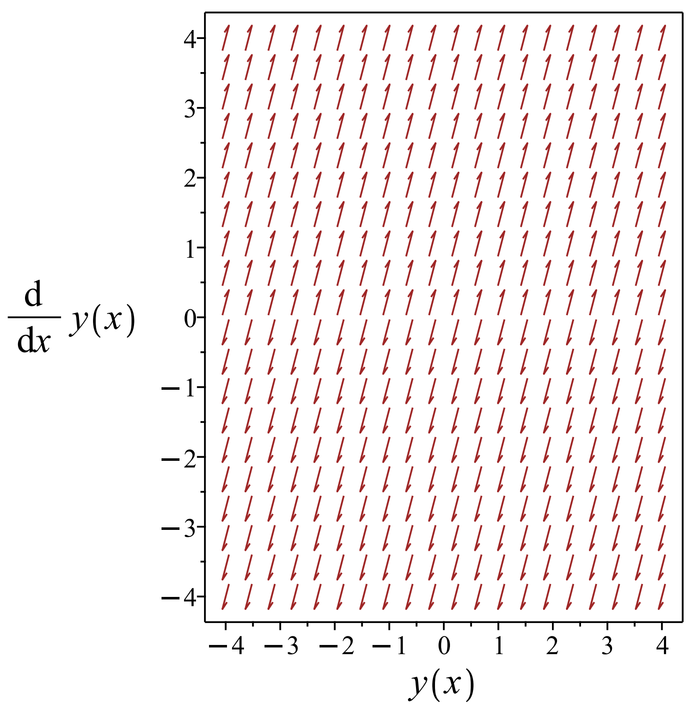

Figure 655: Slope field plot

Verification of solutions

$$y = -2x + \frac{c_1 e^{3x}}{3} - 3x^2 + 3\sin(x) + \cos(x) + c_2$$

Verified OK.

17.10.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' - 3y' = 18x - 10\cos(x)$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - 3y')\, dx = \int (18x - 10\cos(x))\, dx$$
$$-3y + y' = 9x^2 - 10\sin(x) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -3 \\ q(x) &= 9x^2 - 10\sin(x) + c_1 \end{aligned}$$

Hence the ode is

$$-3y + y' = 9x^2 - 10\sin(x) + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-3)dx} \\ &= e^{-3x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(9x^2 - 10\sin(x) + c_1\right) \\ \frac{d}{dx}\left(e^{-3x} y\right) &= \left(e^{-3x}\right)\left(9x^2 - 10\sin(x) + c_1\right) \\ d\left(e^{-3x} y\right) &= \left(\left(9x^2 - 10\sin(x) + c_1\right) e^{-3x}\right)\, dx \end{aligned}$$

Integrating gives

$$e^{-3x}y = \int \left(9x^2 - 10\sin(x) + c_1\right) e^{-3x}\, dx$$

$$e^{-3x}y = -3x^2 e^{-3x} - 2x\, e^{-3x} - \frac{2\, e^{-3x}}{3} + e^{-3x}\cos(x) + 3\, e^{-3x}\sin(x) - \frac{c_1 e^{-3x}}{3} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{-3x}$ results in

$$y = e^{3x}\left(-3x^2 e^{-3x} - 2x\, e^{-3x} - \frac{2\, e^{-3x}}{3} + e^{-3x}\cos(x) + 3\, e^{-3x}\sin(x) - \frac{c_1 e^{-3x}}{3}\right) + c_2 e^{3x}$$

which simplifies to

$$y = -\frac{2}{3} + c_2 e^{3x} - 3x^2 - \frac{c_1}{3} - 2x + \cos(x) + 3\sin(x)$$

Summary
The solution(s) found are the following

$$y = -\frac{2}{3} + c_2 e^{3x} - 3x^2 - \frac{c_1}{3} - 2x + \cos(x) + 3\sin(x) \tag{1}$$

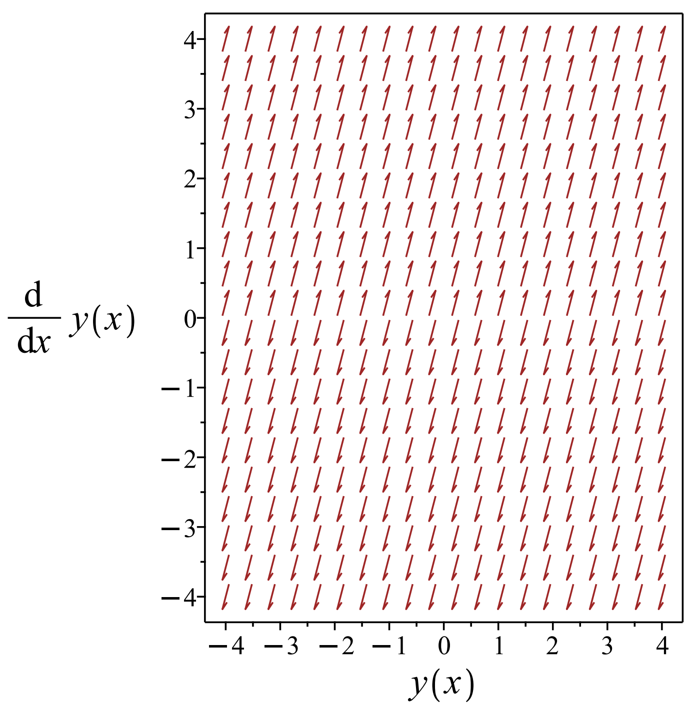

Figure 656: Slope field plot

Verification of solutions

$$y = -\frac{2}{3} + c_2 e^{3x} - 3x^2 - \frac{c_1}{3} - 2x + \cos(x) + 3\sin(x)$$

Verified OK.

17.10.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 3y' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -3 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 513: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-3}{1}\,dx} \\ &= z_1 e^{\frac{3x}{2}} \\ &= z_1 \left(\mathrm{e}^{\frac{3x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-3}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{3x}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{\mathrm{e}^{3x}}{3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(1) + c_2\left(1\left(\frac{\mathrm{e}^{3x}}{3}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 3y' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 + \frac{c_2 \mathrm{e}^{3x}}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$18x - 10 \cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}, \{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{1, \frac{\mathrm{e}^{3x}}{3}\right\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x, x^2\}, \{\cos(x), \sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_2 x^2 + A_1 x + A_3 \cos(x) + A_4 \sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_2 - A_3 \cos(x) - A_4 \sin(x) - 6A_2 x - 3A_1 + 3A_3 \sin(x) - 3A_4 \cos(x) = 18x - 10 \cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2, A_2 = -3, A_3 = 1, A_4 = 3]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -3x^2 - 2x + \cos(x) + 3\sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + \frac{c_2 e^{3x}}{3}\right) + \left(-3x^2 - 2x + \cos(x) + 3\sin(x)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + \frac{c_2 e^{3x}}{3} - 3x^2 - 2x + \cos(x) + 3\sin(x) \tag{1}$$

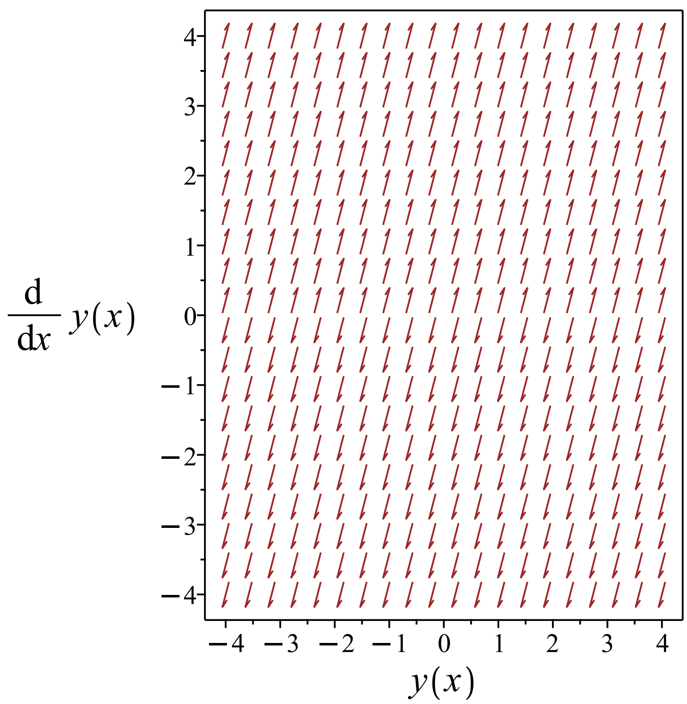

Figure 657: Slope field plot

Verification of solutions

$$y = c_1 + \frac{c_2 e^{3x}}{3} - 3x^2 - 2x + \cos(x) + 3\sin(x)$$

Verified OK.

17.10.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= -3 \\ r(x) &= 0 \\ s(x) &= 18x - 10\cos(x) \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\, y' + (q(x) - p'(x))\, y\right)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$-3y + y' = \int 18x - 10\cos(x)\, dx$$

We now have a first order ode to solve which is

$$-3y + y' = 9x^2 - 10\sin(x) + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -3 \\ q(x) &= 9x^2 - 10\sin(x) + c_1 \end{aligned}$$

Hence the ode is

$$-3y + y' = 9x^2 - 10\sin(x) + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-3)dx} \\ &= e^{-3x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(9x^2 - 10\sin(x) + c_1\right) \\ \frac{d}{dx}\left(e^{-3x}y\right) &= \left(e^{-3x}\right)\left(9x^2 - 10\sin(x) + c_1\right) \\ d\left(e^{-3x}y\right) &= \left(\left(9x^2 - 10\sin(x) + c_1\right)e^{-3x}\right)\,dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{-3x}y &= \int \left(9x^2 - 10\sin(x) + c_1\right)e^{-3x}\,dx \\ e^{-3x}y &= -3x^2e^{-3x} - 2x\,e^{-3x} - \frac{2\,e^{-3x}}{3} + e^{-3x}\cos(x) + 3\,e^{-3x}\sin(x) - \frac{c_1e^{-3x}}{3} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-3x}$ results in

$$y = e^{3x}\left(-3x^2e^{-3x} - 2x\,e^{-3x} - \frac{2\,e^{-3x}}{3} + e^{-3x}\cos(x) + 3\,e^{-3x}\sin(x) - \frac{c_1e^{-3x}}{3}\right) + c_2e^{3x}$$

which simplifies to

$$y = -\frac{2}{3} + c_2e^{3x} - 3x^2 - \frac{c_1}{3} - 2x + \cos(x) + 3\sin(x)$$

Summary

The solution(s) found are the following

$$y = -\frac{2}{3} + c_2e^{3x} - 3x^2 - \frac{c_1}{3} - 2x + \cos(x) + 3\sin(x) \tag{1}$$

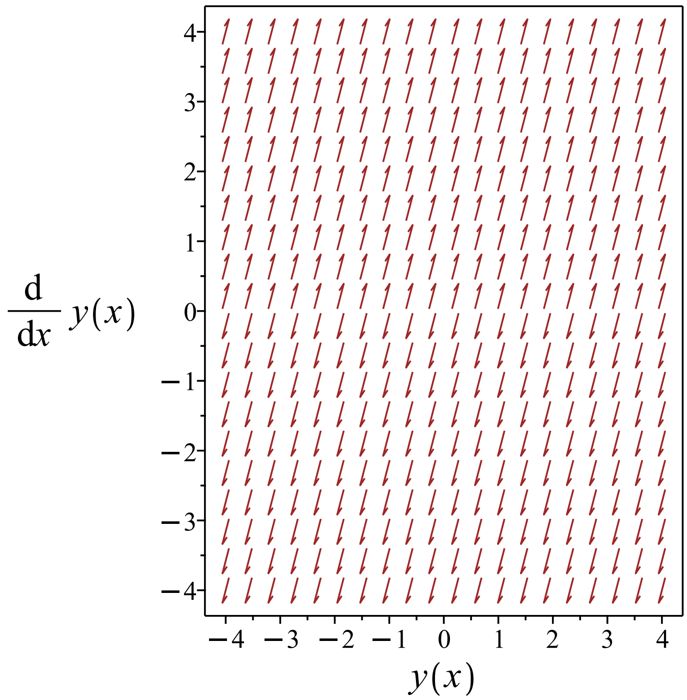

Figure 658: Slope field plot

Verification of solutions

$$y = -\frac{2}{3} + c_2 e^{3x} - 3x^2 - \frac{c_1}{3} - 2x + \cos(x) + 3\sin(x)$$

Verified OK.

17.10.7 Maple step by step solution

Let's solve

$y'' - 3y' = 18x - 10\cos(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 3r = 0$

- Factor the characteristic polynomial

  $r(r - 3) = 0$

- Roots of the characteristic polynomial

$r = (0, 3)$

- 1st solution of the homogeneous ODE

  $y_1(x) = 1$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 e^{3x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))} dx\right), f(x) = 18x - 10\cos(x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & e^{3x} \\ 0 & 3\,e^{3x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 3\,e^{3x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\frac{2\left(\int (9x-5\cos(x)) dx\right)}{3} - \frac{2\,e^{3x}\left(\int (-9x+5\cos(x))e^{-3x} dx\right)}{3}$

  - Compute integrals

    $y_p(x) = -3x^2 + 3\sin(x) - 2x - \frac{2}{3} + \cos(x)$

- Substitute particular solution into general solution to ODE

  $y = c_1 + c_2 e^{3x} - 3x^2 + 3\sin(x) - 2x - \frac{2}{3} + \cos(x)$

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' - 2y' + y = 2 + e^{x} \sin(x)}$$

17.11.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 1, f(x) = 2 + e^{x} \sin(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda\, e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-2)^2 - (4)(1)(1)} \\ &= 1\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -1$. Therefore the solution is

$$y = c_1 e^x + c_2 x\, e^x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = e^x c_1 + x\, e^x c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2 + e^x \sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{e^x \cos(x), e^x \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^x, e^x\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 + A_2 e^x \cos(x) + A_3 e^x \sin(x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_2 e^x \cos(x) - A_3 e^x \sin(x) + A_1 = 2 + e^x \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2, A_2 = 0, A_3 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2 - e^x \sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x c_1 + x e^x c_2) + (2 - e^x \sin(x)) \end{aligned}$$

Which simplifies to

$$y = e^x (c_2 x + c_1) + 2 - e^x \sin(x)$$

Summary

The solution(s) found are the following

$$y = e^x (c_2 x + c_1) + 2 - e^x \sin(x) \tag{1}$$

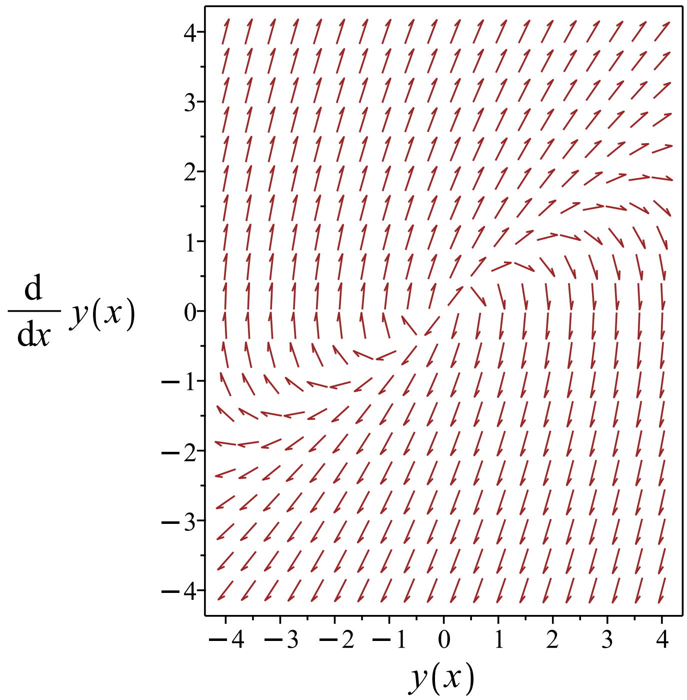

Figure 659: Slope field plot

Verification of solutions

$$y = e^x(c_2x + c_1) + 2 - e^x \sin(x)$$

Verified OK.

17.11.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{(p(x)^2 + p'(x))\,y}{2} = f(x)$$

Where $p(x) = -2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int -2\,dx} \\ &= e^{-x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= \mathrm{e}^{-x}(2+\mathrm{e}^{x}\sin(x)) \\
(\mathrm{e}^{-x}y)'' &= \mathrm{e}^{-x}(2+\mathrm{e}^{x}\sin(x))
\end{aligned}
$$

Integrating once gives

$$
(\mathrm{e}^{-x}y)' = -2\,\mathrm{e}^{-x}-\cos(x)+c_1
$$

Integrating again gives

$$
(\mathrm{e}^{-x}y) = c_1x-\sin(x)+2\,\mathrm{e}^{-x}+c_2
$$

Hence the solution is

$$
y = \frac{c_1x-\sin(x)+2\,\mathrm{e}^{-x}+c_2}{\mathrm{e}^{-x}}
$$

Or

$$
y = c_1x\,\mathrm{e}^{x}+\mathrm{e}^{x}c_2-\mathrm{e}^{x}\sin(x)+2
$$

Summary

The solution(s) found are the following

$$
y = c_1x\,\mathrm{e}^{x}+\mathrm{e}^{x}c_2-\mathrm{e}^{x}\sin(x)+2 \tag{1}
$$

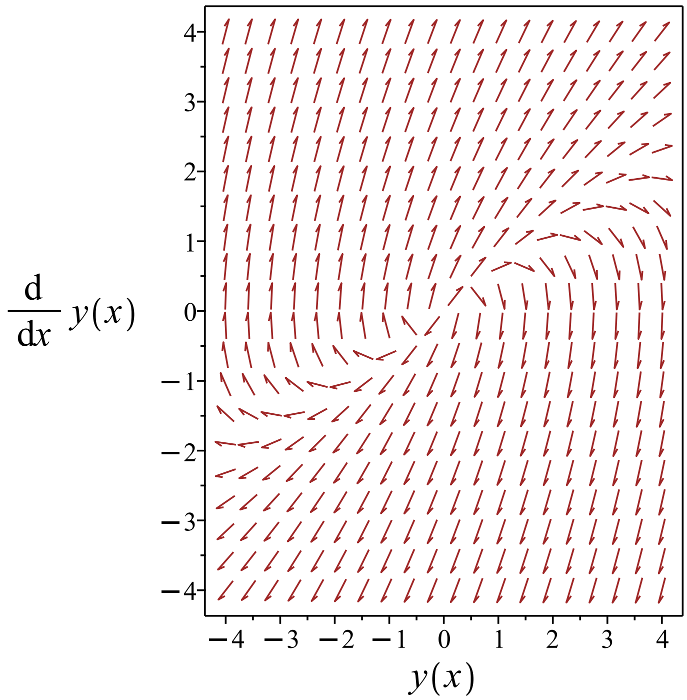

Figure 660: Slope field plot

Verification of solutions

$$y = c_1 x\,\mathrm{e}^{x} + \mathrm{e}^{x} c_2 - \mathrm{e}^{x} \sin(x) + 2$$

Verified OK.

17.11.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 515: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\
&= z_1 e^{x} \\
&= z_1(\mathrm{e}^{x})
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2(\mathrm{e}^x(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^x c_1 + x\,\mathrm{e}^x c_2
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
2 + \mathrm{e}^x \sin(x)
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{1\}, \{\mathrm{e}^x \cos(x), \mathrm{e}^x \sin(x)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{x\,\mathrm{e}^x, \mathrm{e}^x\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 + A_2 \mathrm{e}^x \cos(x) + A_3 \mathrm{e}^x \sin(x)
$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
-A_2 \mathrm{e}^x \cos(x) - A_3 \mathrm{e}^x \sin(x) + A_1 = 2 + \mathrm{e}^x \sin(x)
$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2, A_2 = 0, A_3 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2 - e^x \sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x c_1 + x\, e^x c_2) + (2 - e^x \sin(x)) \end{aligned}$$

Which simplifies to

$$y = e^x (c_2 x + c_1) + 2 - e^x \sin(x)$$

Summary
The solution(s) found are the following

$$y = e^x (c_2 x + c_1) + 2 - e^x \sin(x) \tag{1}$$

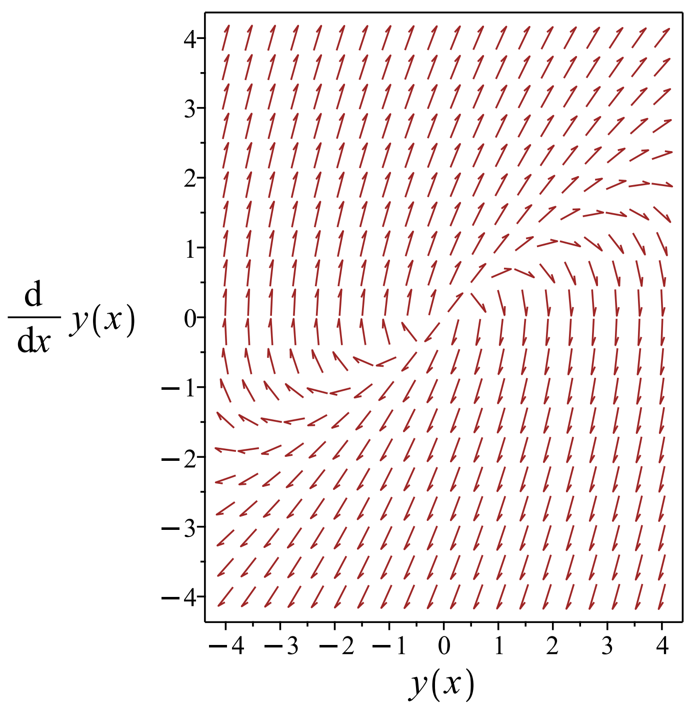

Figure 661: Slope field plot

Verification of solutions

$$y = e^x(c_2x + c_1) + 2 - e^x \sin(x)$$

Verified OK.

17.11.4 Maple step by step solution

Let's solve

$y'' - 2y' + y = 2 + e^x \sin(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 1 = 0$

- Factor the characteristic polynomial

  $(r-1)^2 = 0$

- Root of the characteristic polynomial

  $r = 1$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^x$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^x$

- General solution of the ODE

  $y = c_1y_1(x) + c_2y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^x c_1 + x\,e^x c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 2 + e^x \sin(x)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^x & x\,e^x \\ e^x & x\,e^x + e^x \end{bmatrix}$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{2x}$
- Substitute functions into equation for $y_p(x)$

  $y_p(x) = e^x\left(-\left(\int x(2\,e^{-x} + \sin(x))\,dx\right) + x\left(\int (2\,e^{-x} + \sin(x))\,dx\right)\right)$
- Compute integrals

  $y_p(x) = 2 - e^x \sin(x)$

- Substitute particular solution into general solution to ODE

  $y = x\,e^x c_2 - e^x \sin(x) + e^x c_1 + 2$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 2y' + 2y = (5x + 4)\,\mathrm{e}^{x} + \mathrm{e}^{-x}}$$

17.12.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 2, f(x) = (5x + 4)\,\mathrm{e}^{x} + \mathrm{e}^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda e^{\lambda x} + 2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{2^2 - (4)(1)(2)} \\ &= -1 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -1 + i \\ \lambda_2 &= -1 - i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 + i \\ \lambda_2 &= -1 - i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -1$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-x}(c_1 \cos(x) + c_2 \sin(x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$(5x+4)\,\mathrm{e}^{x}+\mathrm{e}^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{-x}\},\{x\,\mathrm{e}^{x},\mathrm{e}^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-x}\cos(x),\mathrm{e}^{-x}\sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\mathrm{e}^{-x}+A_2x\,\mathrm{e}^{x}+A_3\mathrm{e}^{x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1\mathrm{e}^{-x}+4A_2\mathrm{e}^{x}+5A_2x\,\mathrm{e}^{x}+5A_3\mathrm{e}^{x}=(5x+4)\,\mathrm{e}^{x}+\mathrm{e}^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = 1, A_3 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \mathrm{e}^{-x}+x\,\mathrm{e}^{x}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\ &= \left(\mathrm{e}^{-x}(c_1\cos(x)+c_2\sin(x))\right)+\left(\mathrm{e}^{-x}+x\,\mathrm{e}^{x}\right)\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-x}(c_1\cos(x)+c_2\sin(x))+\mathrm{e}^{-x}+x\,\mathrm{e}^{x} \tag{1}$$

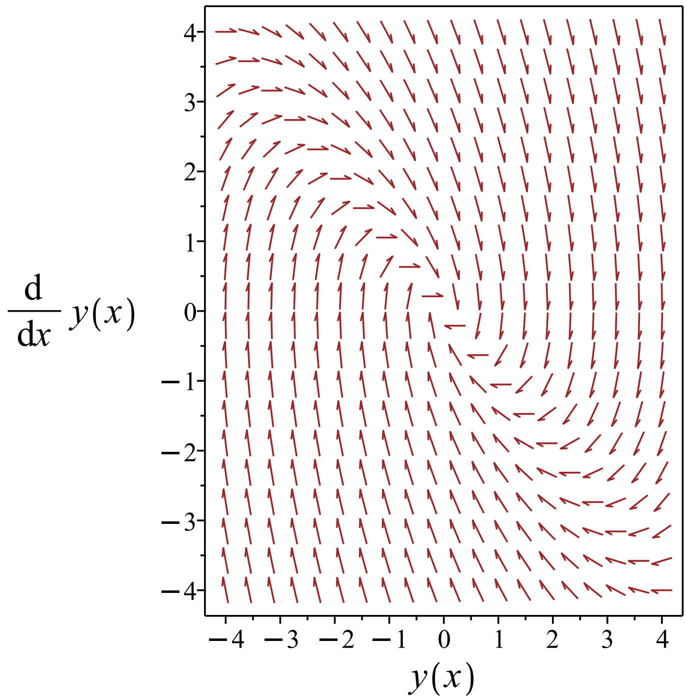

Figure 662: Slope field plot

Verification of solutions

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x)) + e^{-x} + x e^{x}$$

Verified OK.

17.12.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 517: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - 0\\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\, dx}\\ &= z_1 e^{-x}\\ &= z_1\left(\mathrm{e}^{-x}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}\cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\, dx}}{(y_1)^2}\, dx\\ &= y_1 \int \frac{e^{-2x}}{(y_1)^2}\, dx\\ &= y_1(\tan(x))\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x} \cos\left(x\right)\right) + c_2 \left(\mathrm{e}^{-x} \cos\left(x\right) \left(\tan\left(x\right)\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 2y' + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^{-x} \cos\left(x\right) c_1 + \mathrm{e}^{-x} \sin\left(x\right) c_2
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
(5x + 4)\,\mathrm{e}^{x} + \mathrm{e}^{-x}
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\mathrm{e}^{-x}\}, \{x\,\mathrm{e}^{x}, \mathrm{e}^{x}\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{\mathrm{e}^{-x} \cos\left(x\right), \mathrm{e}^{-x} \sin\left(x\right)\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 \mathrm{e}^{-x} + A_2 x\,\mathrm{e}^{x} + A_3 \mathrm{e}^{x}
$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
A_1 \mathrm{e}^{-x} + 4A_2 \mathrm{e}^{x} + 5A_2 x\,\mathrm{e}^{x} + 5A_3 \mathrm{e}^{x} = (5x + 4)\,\mathrm{e}^{x} + \mathrm{e}^{-x}
$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = 1, A_3 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = e^{-x} + x\,e^{x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-x}\cos(x)\,c_1 + e^{-x}\sin(x)\,c_2\right) + \left(e^{-x} + x\,e^{x}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-x}(c_1\cos(x) + c_2\sin(x)) + e^{-x} + x\,e^{x}$$

Summary
The solution(s) found are the following

$$y = e^{-x}(c_1\cos(x) + c_2\sin(x)) + e^{-x} + x\,e^{x} \tag{1}$$

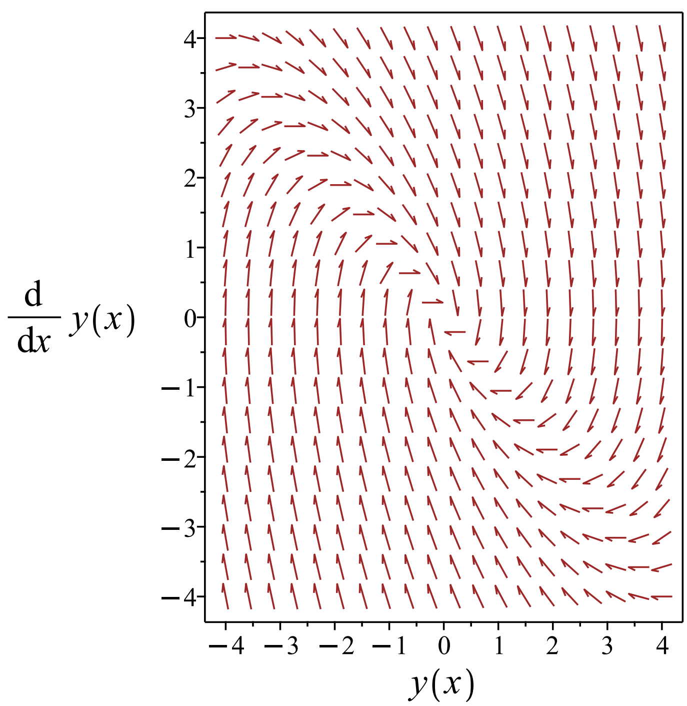

Figure 663: Slope field plot

Verification of solutions

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x)) + e^{-x} + x e^x$$

Verified OK.

17.12.3 Maple step by step solution

Let's solve

$y'' + 2y' + 2y = (5x + 4) e^x + e^{-x}$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = 5x e^x - 2y' - 2y + 4 e^x + e^{-x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + 2y' + 2y = 5x e^x + 4 e^x + e^{-x}$

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r + 2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-2) \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-1 - I, -1 + I)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x} \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-x} \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{-x} \cos(x) c_1 + e^{-x} \sin(x) c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

$$\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 5x\,\mathrm{e}^{x} + 4\,\mathrm{e}^{x} + \mathrm{e}^{-x}\right]$$

- Wronskian of solutions of the homogeneous equation

  $$W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-x}\cos(x) & \mathrm{e}^{-x}\sin(x) \\ -\mathrm{e}^{-x}\cos(x) - \mathrm{e}^{-x}\sin(x) & -\mathrm{e}^{-x}\sin(x) + \mathrm{e}^{-x}\cos(x) \end{bmatrix}$$

- Compute Wronskian

  $$W(y_1(x), y_2(x)) = \mathrm{e}^{-2x}$$

- Substitute functions into equation for $y_p(x)$

  $$y_p(x) = -\mathrm{e}^{-x}\left(\cos(x)\left(\int ((5x+4)\sin(x)\,\mathrm{e}^{2x} + \sin(x))\,dx\right) - \sin(x)\left(\int ((5x+4)\cos(x)\,\mathrm{e}^{2x} + \mathrm{co}\right.\right.$$

- Compute integrals

  $$y_p(x) = \mathrm{e}^{-x} + x\,\mathrm{e}^{x}$$

- Substitute particular solution into general solution to ODE

  $$y = \mathrm{e}^{-x}\cos(x)\,c_1 + \mathrm{e}^{-x}\sin(x)\,c_2 + x\,\mathrm{e}^{x} + \mathrm{e}^{-x}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 2y' + 5y = 4\,\mathrm{e}^{-x} + 17\sin(2x)}$$

17.13.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 5, f(x) = 4\,\mathrm{e}^{-x} + 17\sin(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda\, e^{\lambda x} + 5\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{2^2 - (4)\,(1)\,(5)}\\ &= -1 \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -1 + 2i\\ \lambda_2 &= -1 - 2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 + 2i\\ \lambda_2 &= -1 - 2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -1$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4\,\mathrm{e}^{-x}+17\sin\left(2x\right)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{-x}\},\{\cos\left(2x\right),\sin\left(2x\right)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-x}\cos\left(2x\right),\mathrm{e}^{-x}\sin\left(2x\right)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\mathrm{e}^{-x}+A_2\cos\left(2x\right)+A_3\sin\left(2x\right)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1\mathrm{e}^{-x}+A_2\cos\left(2x\right)+A_3\sin\left(2x\right)-4A_2\sin\left(2x\right)+4A_3\cos\left(2x\right)=4\,\mathrm{e}^{-x}+17\sin\left(2x\right)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = -4, A_3 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \mathrm{e}^{-x}-4\cos\left(2x\right)+\sin\left(2x\right)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{-x}(c_1\cos\left(2x\right)+c_2\sin\left(2x\right))\right)+\left(\mathrm{e}^{-x}-4\cos\left(2x\right)+\sin\left(2x\right)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-x}(c_1\cos\left(2x\right)+c_2\sin\left(2x\right))+\mathrm{e}^{-x}-4\cos\left(2x\right)+\sin\left(2x\right) \tag{1}$$

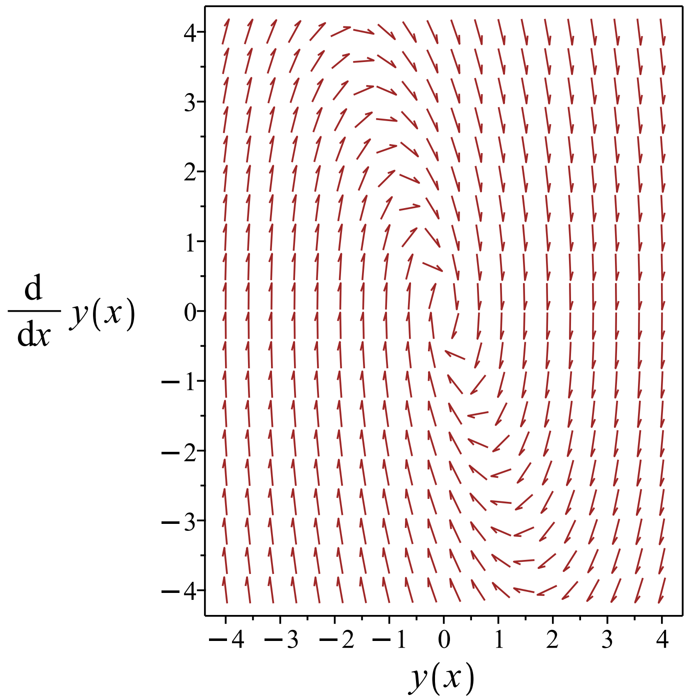

Figure 664: Slope field plot

Verification of solutions

$$y = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x)) + e^{-x} - 4\cos(2x) + \sin(2x)$$

Verified OK.

17.13.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 519: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\ &= z_1 e^{-x} \\ &= z_1 \left(\mathrm{e}^{-x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}\cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-2x}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{\tan(2x)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned}y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-x} \cos(2x)\right) + c_2 \left(\mathrm{e}^{-x} \cos(2x) \left(\frac{\tan(2x)}{2}\right)\right)\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 5y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \mathrm{e}^{-x} \cos(2x)\, c_1 + \frac{\mathrm{e}^{-x} \sin(2x)\, c_2}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4\,\mathrm{e}^{-x} + 17 \sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{-x}\}, \{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\mathrm{e}^{-x} \cos(2x), \frac{\mathrm{e}^{-x} \sin(2x)}{2}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \mathrm{e}^{-x} + A_2 \cos(2x) + A_3 \sin(2x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1 e^{-x} + A_2 \cos(2x) + A_3 \sin(2x) - 4A_2 \sin(2x) + 4A_3 \cos(2x) = 4\,e^{-x} + 17\sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = -4, A_3 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = e^{-x} - 4\cos(2x) + \sin(2x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-x} \cos(2x)\, c_1 + \frac{e^{-x} \sin(2x)\, c_2}{2}\right) + \left(e^{-x} - 4\cos(2x) + \sin(2x)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{-x} \cos(2x)\, c_1 + \frac{e^{-x} \sin(2x)\, c_2}{2} + e^{-x} - 4\cos(2x) + \sin(2x) \tag{1}$$

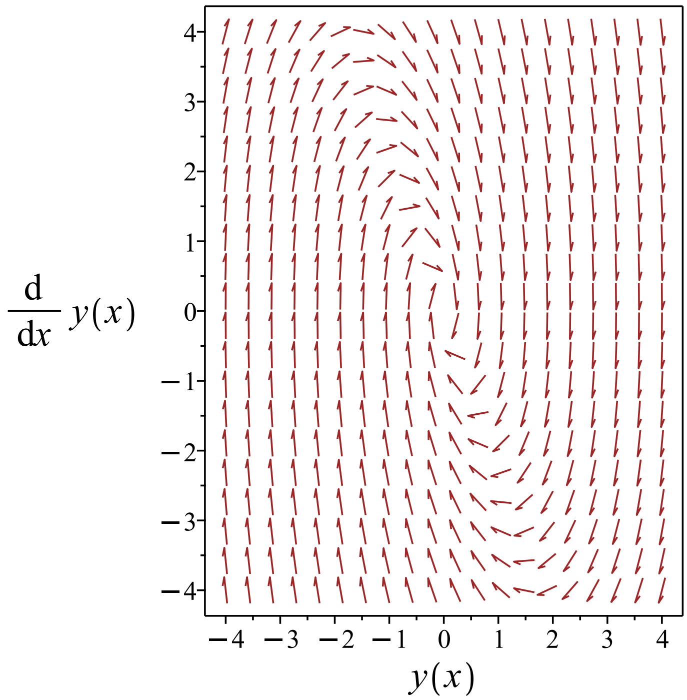

Figure 665: Slope field plot

Verification of solutions

$$y = e^{-x}\cos(2x)\,c_1 + \frac{e^{-x}\sin(2x)\,c_2}{2} + e^{-x} - 4\cos(2x) + \sin(2x)$$

Verified OK.

17.13.3 Maple step by step solution

Let's solve

$y'' + 2y' + 5y = 4\,e^{-x} + 17\sin(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r + 5 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-2)\pm(\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

$r = (-1-2\mathrm{I}, -1+2\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-x}\cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-x}\sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \mathrm{e}^{-x}\cos(2x)\, c_1 + \mathrm{e}^{-x}\sin(2x)\, c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 4\,\mathrm{e}^{-x} + 17\sin(2x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-x}\cos(2x) & \mathrm{e}^{-x}\sin(2x) \\ -\mathrm{e}^{-x}\cos(2x) - 2\,\mathrm{e}^{-x}\sin(2x) & -\mathrm{e}^{-x}\sin(2x) + 2\,\mathrm{e}^{-x}\cos(2x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2\,\mathrm{e}^{-2x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = \frac{\mathrm{e}^{-x}\left(-\cos(2x)\left(\int\left(17\sin(2x)^2\mathrm{e}^{x} + 4\sin(2x)\right)dx\right) + \sin(2x)\left(\int \cos(2x)(17\,\mathrm{e}^{x}\sin(2x)+4)dx\right)\right)}{2}$

  - Compute integrals

    $y_p(x) = \mathrm{e}^{-x} - 4\cos(2x) + \sin(2x)$

- Substitute particular solution into general solution to ODE

  $y = \mathrm{e}^{-x}\sin(2x)\, c_2 + \mathrm{e}^{-x}\cos(2x)\, c_1 + \mathrm{e}^{-x} + \sin(2x) - 4\cos(2x)$

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{2y'' - 3y' - 2y = 5\,\mathrm{e}^{x} \cosh(x)}$$

17.14.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 2, B = -3, C = -2, f(x) = 5\,\mathrm{e}^{x} \cosh(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$2y'' - 3y' - 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A=2, B=-3, C=-2$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$2\lambda^2 \mathrm{e}^{\lambda x} - 3\lambda\,\mathrm{e}^{\lambda x} - 2\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$2\lambda^2 - 3\lambda - 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A=2, B=-3, C=-2$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{3}{(2)\,(2)} \pm \frac{1}{(2)\,(2)}\sqrt{-3^2 - (4)\,(2)\,(-2)} \\
&= \frac{3}{4} \pm \frac{5}{4}
\end{aligned}$$

Hence

$$\begin{aligned}
\lambda_1 &= \frac{3}{4} + \frac{5}{4} \\
\lambda_2 &= \frac{3}{4} - \frac{5}{4}
\end{aligned}$$

Which simplifies to

$$\begin{aligned}
\lambda_1 &= 2 \\
\lambda_2 &= -\frac{1}{2}
\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}
y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\
y &= c_1 e^{(2)x} + c_2 e^{\left(-\frac{1}{2}\right)x}
\end{aligned}$$

Or

$$y = \mathrm{e}^{2x} c_1 + c_2 \mathrm{e}^{-\frac{x}{2}}$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{2x} c_1 + c_2 \mathrm{e}^{-\frac{x}{2}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^{2x}$$
$$y_2 = e^{-\frac{x}{2}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{2x} & e^{-\frac{x}{2}} \\ \frac{d}{dx}\left(e^{2x}\right) & \frac{d}{dx}\left(e^{-\frac{x}{2}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{2x} & e^{-\frac{x}{2}} \\ 2\,e^{2x} & -\frac{e^{-\frac{x}{2}}}{2} \end{vmatrix}$$

Therefore

$$W = \left(e^{2x}\right)\left(-\frac{e^{-\frac{x}{2}}}{2}\right) - \left(e^{-\frac{x}{2}}\right)\left(2\,e^{2x}\right)$$

Which simplifies to

$$W = -\frac{5\,e^{2x} e^{-\frac{x}{2}}}{2}$$

Which simplifies to

$$W = -\frac{5\,\mathrm{e}^{\frac{3x}{2}}}{2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{5\,\mathrm{e}^{-\frac{x}{2}}\mathrm{e}^{x}\cosh\left(x\right)}{-5\,\mathrm{e}^{\frac{3x}{2}}}dx$$

Which simplifies to

$$u_1 = -\int -\cosh\left(x\right)\mathrm{e}^{-x}dx$$

Hence

$$u_1 = \frac{x}{2}+\frac{\sinh\left(2x\right)}{4}-\frac{\cosh\left(2x\right)}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{5\,\mathrm{e}^{2x}\mathrm{e}^{x}\cosh\left(x\right)}{-5\,\mathrm{e}^{\frac{3x}{2}}}dx$$

Which simplifies to

$$u_2 = \int -\cosh\left(x\right)\mathrm{e}^{\frac{3x}{2}}dx$$

Hence

$$u_2 = -\sinh\left(\frac{x}{2}\right)-\frac{\sinh\left(\frac{5x}{2}\right)}{5}-\cosh\left(\frac{x}{2}\right)-\frac{\cosh\left(\frac{5x}{2}\right)}{5}$$

Therefore the particular solution, from equation (1) is

$$\begin{aligned} y_p(x) &= \left(\frac{x}{2}+\frac{\sinh\left(2x\right)}{4}-\frac{\cosh\left(2x\right)}{4}\right)\mathrm{e}^{2x} \\ &\quad+\left(-\sinh\left(\frac{x}{2}\right)-\frac{\sinh\left(\frac{5x}{2}\right)}{5}-\cosh\left(\frac{x}{2}\right)-\frac{\cosh\left(\frac{5x}{2}\right)}{5}\right)\mathrm{e}^{-\frac{x}{2}} \end{aligned}$$

Which simplifies to

$$y_p(x) = -\frac{5}{4}+\frac{\left(-\sinh\left(\frac{5x}{2}\right)-\cosh\left(\frac{5x}{2}\right)\right)\mathrm{e}^{-\frac{x}{2}}}{5}+\frac{x\,\mathrm{e}^{2x}}{2}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(e^{2x} c_1 + c_2 e^{-\frac{x}{2}}\right) + \left(-\frac{5}{4} + \frac{\left(-\sinh\left(\frac{5x}{2}\right) - \cosh\left(\frac{5x}{2}\right)\right) e^{-\frac{x}{2}}}{5} + \frac{x\, e^{2x}}{2}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = e^{2x} c_1 + c_2 e^{-\frac{x}{2}} - \frac{5}{4} + \frac{\left(-\sinh\left(\frac{5x}{2}\right) - \cosh\left(\frac{5x}{2}\right)\right) e^{-\frac{x}{2}}}{5} + \frac{x\, e^{2x}}{2} \tag{1}
$$

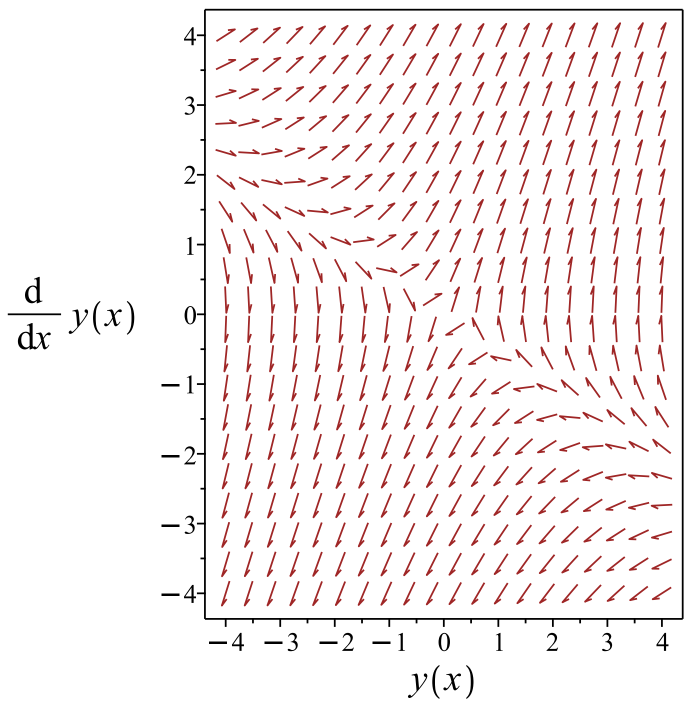

Figure 666: Slope field plot

Verification of solutions

$$
y = e^{2x} c_1 + c_2 e^{-\frac{x}{2}} - \frac{5}{4} + \frac{\left(-\sinh\left(\frac{5x}{2}\right) - \cosh\left(\frac{5x}{2}\right)\right) e^{-\frac{x}{2}}}{5} + \frac{x\, e^{2x}}{2}
$$

Verified OK.

17.14.2 Solving using Kovacic algorithm

Writing the ode as

$$2y'' - 3y' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2 \\ B &= -3 \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{25}{16} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 25 \\ t &= 16 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{25z(x)}{16} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 521: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{25}{16}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-\frac{5x}{4}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3}{2}\,dx}
\end{aligned}
$$

$$= z_1 e^{\frac{3x}{4}}$$
$$= z_1 \left(\mathrm{e}^{\frac{3x}{4}}\right)$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{-3}{2}\, dx}}{(y_1)^2}\, dx$$
$$= y_1 \int \frac{e^{\frac{3x}{2}}}{(y_1)^2}\, dx$$
$$= y_1 \left(\frac{2\,\mathrm{e}^{\frac{5x}{2}}}{5}\right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1\left(\mathrm{e}^{-\frac{x}{2}}\right) + c_2\left(\mathrm{e}^{-\frac{x}{2}}\left(\frac{2\,\mathrm{e}^{\frac{5x}{2}}}{5}\right)\right)$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$2y'' - 3y' - 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-\frac{x}{2}} + \frac{2\,\mathrm{e}^{2x} c_2}{5}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \mathrm{e}^{-\frac{x}{2}}$$
$$y_2 = \frac{2\,\mathrm{e}^{2x}}{5}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-\frac{x}{2}} & \frac{2\,\mathrm{e}^{2x}}{5} \\ \frac{d}{dx}\left(\mathrm{e}^{-\frac{x}{2}}\right) & \frac{d}{dx}\left(\frac{2\,\mathrm{e}^{2x}}{5}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{-\frac{x}{2}} & \frac{2\,\mathrm{e}^{2x}}{5} \\ -\frac{\mathrm{e}^{-\frac{x}{2}}}{2} & \frac{4\,\mathrm{e}^{2x}}{5} \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{-\frac{x}{2}}\right)\left(\frac{4\,\mathrm{e}^{2x}}{5}\right) - \left(\frac{2\,\mathrm{e}^{2x}}{5}\right)\left(-\frac{\mathrm{e}^{-\frac{x}{2}}}{2}\right)$$

Which simplifies to

$$W = \mathrm{e}^{2x}\mathrm{e}^{-\frac{x}{2}}$$

Which simplifies to

$$W = \mathrm{e}^{\frac{3x}{2}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2\,\mathrm{e}^{2x}\mathrm{e}^{x}\cosh(x)}{2\,\mathrm{e}^{\frac{3x}{2}}}\,dx$$

Which simplifies to

$$u_1 = -\int \cosh(x)\,\mathrm{e}^{\frac{3x}{2}}\,dx$$

Hence

$$u_1 = -\sinh\left(\frac{x}{2}\right) - \frac{\sinh\left(\frac{5x}{2}\right)}{5} - \cosh\left(\frac{x}{2}\right) - \frac{\cosh\left(\frac{5x}{2}\right)}{5}$$

And Eq. (3) becomes

$$u_2 = \int \frac{5\,\mathrm{e}^{-\frac{x}{2}}\mathrm{e}^{x}\cosh(x)}{2\,\mathrm{e}^{\frac{3x}{2}}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{5\cosh(x)\,\mathrm{e}^{-x}}{2}\,dx$$

Hence

$$u_2 = \frac{5x}{4} + \frac{5\sinh(2x)}{8} - \frac{5\cosh(2x)}{8}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\sinh\left(\frac{x}{2}\right) - \frac{\sinh\left(\frac{5x}{2}\right)}{5} - \cosh\left(\frac{x}{2}\right) - \frac{\cosh\left(\frac{5x}{2}\right)}{5}\right) e^{-\frac{x}{2}} + \frac{2\left(\frac{5x}{4} + \frac{5\sinh(2x)}{8} - \frac{5\cosh(2x)}{8}\right) e^{2x}}{5}$$

Which simplifies to

$$y_p(x) = -\frac{5}{4} + \frac{\left(-\sinh\left(\frac{5x}{2}\right) - \cosh\left(\frac{5x}{2}\right)\right) e^{-\frac{x}{2}}}{5} + \frac{x\,e^{2x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-\frac{x}{2}} + \frac{2\,e^{2x} c_2}{5}\right) + \left(-\frac{5}{4} + \frac{\left(-\sinh\left(\frac{5x}{2}\right) - \cosh\left(\frac{5x}{2}\right)\right) e^{-\frac{x}{2}}}{5} + \frac{x\,e^{2x}}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-\frac{x}{2}} + \frac{2\,e^{2x} c_2}{5} - \frac{5}{4} + \frac{\left(-\sinh\left(\frac{5x}{2}\right) - \cosh\left(\frac{5x}{2}\right)\right) e^{-\frac{x}{2}}}{5} + \frac{x\,e^{2x}}{2} \tag{1}$$

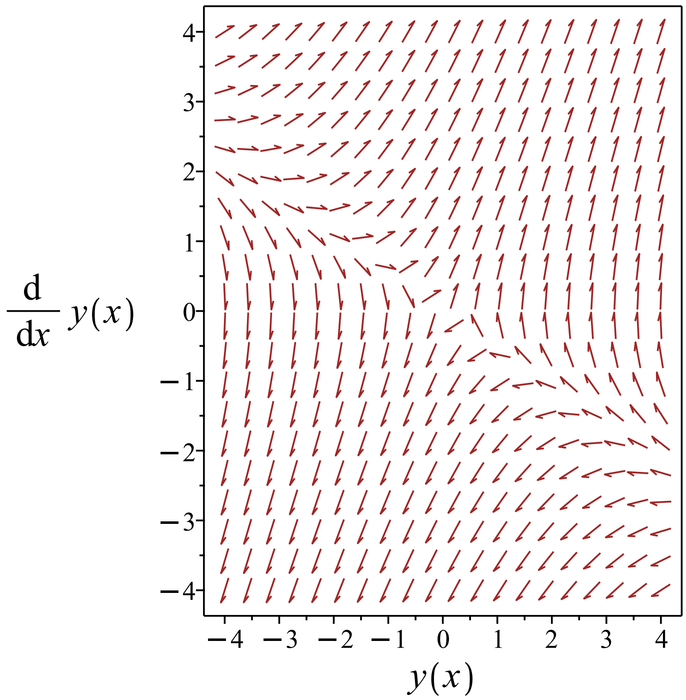

Figure 667: Slope field plot

Verification of solutions

$$y = c_1 e^{-\frac{x}{2}} + \frac{2\,e^{2x} c_2}{5} - \frac{5}{4} + \frac{\left(-\sinh\left(\frac{5x}{2}\right) - \cosh\left(\frac{5x}{2}\right)\right) e^{-\frac{x}{2}}}{5} + \frac{x\,e^{2x}}{2}$$

Verified OK.

17.14.3 Maple step by step solution

Let's solve

$2y'' - 3y' - 2y = 5\,e^{x} \cosh(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{3y'}{2} + y + \frac{5\,e^{x}\cosh(x)}{2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{3y'}{2} - y = \frac{5\,e^{x}\cosh(x)}{2}$

- Characteristic polynomial of homogeneous ODE

$r^2 - \frac{3}{2}r - 1 = 0$

- Factor the characteristic polynomial

  $\frac{(2r+1)(r-2)}{2} = 0$

- Roots of the characteristic polynomial

  $r = \left(2, -\frac{1}{2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-\frac{x}{2}}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{2x} c_1 + c_2 e^{-\frac{x}{2}} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \frac{5\, e^{x} \cosh(x)}{2}\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{2x} & e^{-\frac{x}{2}} \\ 2\, e^{2x} & -\frac{e^{-\frac{x}{2}}}{2} \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = -\frac{5\, e^{\frac{3x}{2}}}{2}$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = e^{2x}\left(\int \cosh(x)\, e^{-x} dx\right) - e^{-\frac{x}{2}}\left(\int \cosh(x)\, e^{\frac{3x}{2}} dx\right)$

- ○ Compute integrals

  $y_p(x) = -\frac{5}{4} + \frac{\left(-\sinh\left(\frac{5x}{2}\right) - \cosh\left(\frac{5x}{2}\right)\right) e^{-\frac{x}{2}}}{5} + \frac{x\, e^{2x}}{2}$

- Substitute particular solution into general solution to ODE

  $y = e^{2x} c_1 + c_2 e^{-\frac{x}{2}} - \frac{5}{4} + \frac{\left(-\sinh\left(\frac{5x}{2}\right) - \cosh\left(\frac{5x}{2}\right)\right) e^{-\frac{x}{2}}}{5} + \frac{x\, e^{2x}}{2}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 4y = x \sin(x)^2}$$

17.15.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 4, f(x) = x \sin(x)^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 4\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(4)} \\ &= \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2i \\ \lambda_2 &= -2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2i \\ \lambda_2 &= -2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos{(2x)} + c_2 \sin{(2x)})$$

Or

$$y = c_1 \cos(2x) + c_2 \sin(2x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(2x) + c_2 \sin(2x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x \sin(x)^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}, \{x \cos(2x), x \sin(2x), \cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(2x), \sin(2x)\}$$

Since $\cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{1, x\}, \{x \cos(2x), x \sin(2x), \cos(2x) x^2, \sin(2x) x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_2 x + A_1 + A_3 x \cos(2x) + A_4 x \sin(2x) + A_5 \cos(2x) x^2 + A_6 \sin(2x) x^2$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_3 \sin(2x) + 4A_4 \cos(2x) - 8A_5 \sin(2x) x + 2A_5 \cos(2x) + 8A_6 \cos(2x) x + 2A_6 \sin(2x) + 4A_2 x + 4A_1 = x \sin(x)^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{8}, A_3 = -\frac{1}{32}, A_4 = 0, A_5 = 0, A_6 = -\frac{1}{16}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x}{8} - \frac{x\cos(2x)}{32} - \frac{\sin(2x)\,x^2}{16}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(2x) + c_2\sin(2x)) + \left(\frac{x}{8} - \frac{x\cos(2x)}{32} - \frac{\sin(2x)\,x^2}{16}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\cos(2x) + c_2\sin(2x) + \frac{x}{8} - \frac{x\cos(2x)}{32} - \frac{\sin(2x)\,x^2}{16} \tag{1}$$

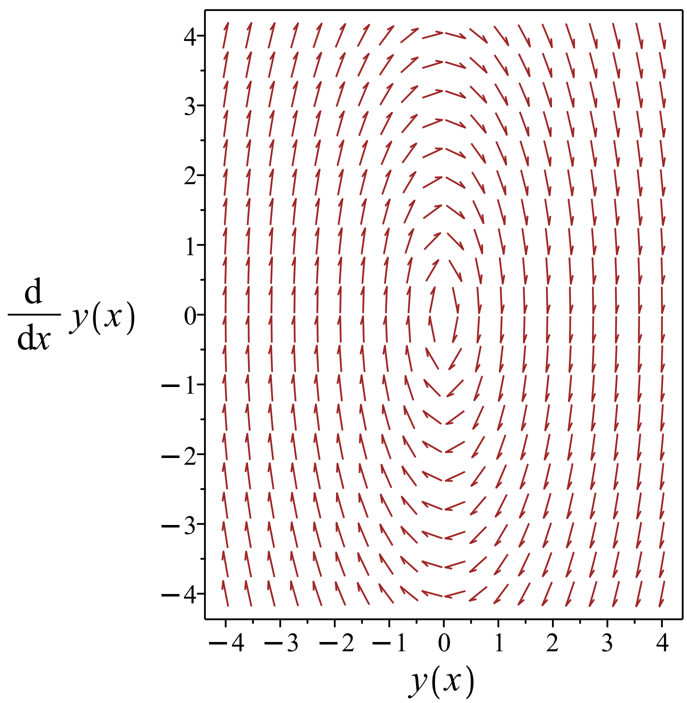

Figure 668: Slope field plot

Verification of solutions

$$y = c_1\cos(2x) + c_2\sin(2x) + \frac{x}{8} - \frac{x\cos(2x)}{32} - \frac{\sin(2x)\,x^2}{16}$$

Verified OK.

17.15.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 523: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(2x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(2x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \cos(2x) \int \frac{1}{\cos(2x)^2}\, dx \\ &= \cos(2x) \left(\frac{\tan(2x)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(2x)) + c_2\left(\cos(2x)\left(\frac{\tan(2x)}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x \sin(x)^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}, \{x \cos(2x), x \sin(2x), \cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sin(2x)}{2}, \cos(2x)\right\}$$

Since $\cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{1, x\}, \{x \cos(2x), x \sin(2x), \cos(2x) x^2, \sin(2x) x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_2 x + A_1 + A_3 x \cos(2x) + A_4 x \sin(2x) + A_5 \cos(2x) x^2 + A_6 \sin(2x) x^2$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_3 \sin(2x) + 4A_4 \cos(2x) - 8A_5 \sin(2x) x + 2A_5 \cos(2x) + 8A_6 \cos(2x) x + 2A_6 \sin(2x) + 4A_2 x + 4A_1 = x \sin(x)^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{8}, A_3 = -\frac{1}{32}, A_4 = 0, A_5 = 0, A_6 = -\frac{1}{16}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x}{8} - \frac{x\cos(2x)}{32} - \frac{\sin(2x)\,x^2}{16}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\cos(2x) + \frac{c_2\sin(2x)}{2}\right) + \left(\frac{x}{8} - \frac{x\cos(2x)}{32} - \frac{\sin(2x)\,x^2}{16}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\cos(2x) + \frac{c_2\sin(2x)}{2} + \frac{x}{8} - \frac{x\cos(2x)}{32} - \frac{\sin(2x)\,x^2}{16} \tag{1}$$

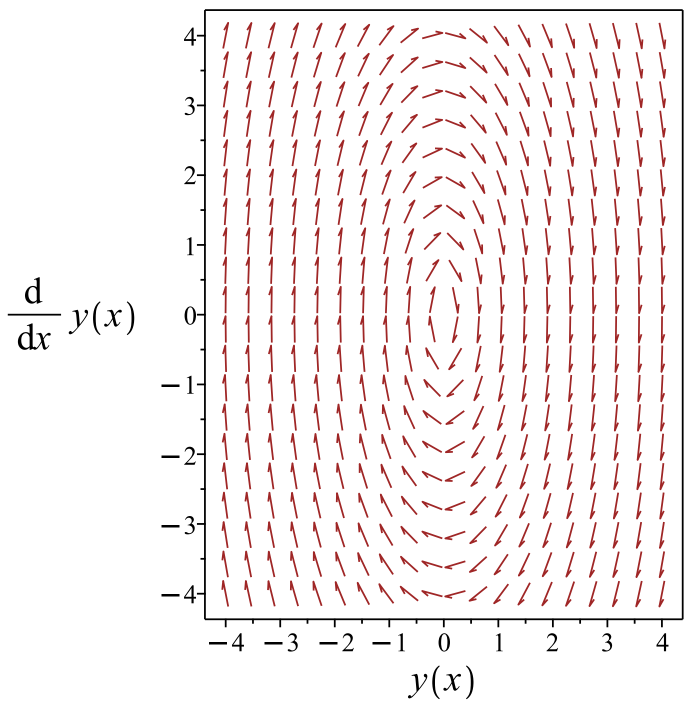

Figure 669: Slope field plot

Verification of solutions

$$y = c_1\cos(2x) + \frac{c_2\sin(2x)}{2} + \frac{x}{8} - \frac{x\cos(2x)}{32} - \frac{\sin(2x)\,x^2}{16}$$

Verified OK.

17.15.3 Maple step by step solution

Let's solve

$y'' + 4y = x \sin(x)^2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r = (-2\,\mathrm{I}, 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(2x) + c_2 \sin(2x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x \sin(x)^2\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(2x) & \sin(2x) \\ -2\sin(2x) & 2\cos(2x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2$

  - Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{\cos(2x)\left(\int \sin(2x)x\sin(x)^2dx\right)}{2} + \frac{\sin(2x)\left(\int \cos(2x)x\sin(x)^2dx\right)}{2}$$

- Compute integrals

$$y_p(x) = -\frac{\sin(2x)x^2}{16} + \frac{\sin(2x)}{128} - \frac{x\cos(2x)}{32} + \frac{x}{8}$$

- Substitute particular solution into general solution to ODE

$$y = c_1\cos(2x) + c_2\sin(2x) - \frac{\sin(2x)x^2}{16} + \frac{\sin(2x)}{128} - \frac{x\cos(2x)}{32} + \frac{x}{8}$$

Problem number: 566.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'''' + 2y''' + 2y'' + 2y' + y = x\,e^{x} + \frac{\cos(x)}{2}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 2y''' + 2y'' + 2y' + y = 0$$

The characteristic equation is

$$\lambda^4 + 2\lambda^3 + 2\lambda^2 + 2\lambda + 1 = 0$$

The roots of the above equation are

$$\lambda_1 = i$$
$$\lambda_2 = -i$$
$$\lambda_3 = -1$$
$$\lambda_4 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 \mathrm{e}^{-x} + c_2 x \,\mathrm{e}^{-x} + \mathrm{e}^{ix} c_3 + \mathrm{e}^{-ix} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= \mathrm{e}^{-x} \\ y_2 &= x \,\mathrm{e}^{-x} \\ y_3 &= \mathrm{e}^{ix} \\ y_4 &= \mathrm{e}^{-ix} \end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' + 2y''' + 2y'' + 2y' + y = x \,\mathrm{e}^{x} + \frac{\cos(x)}{2}$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)} \, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 & y_4 \\ y_1' & y_2' & y_3' & y_4' \\ y_1'' & y_2'' & y_3'' & y_4'' \\ y_1''' & y_2''' & y_3''' & y_4''' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} e^{-x} & x\,e^{-x} & e^{ix} & e^{-ix} \\ -e^{-x} & e^{-x}(1-x) & ie^{ix} & -ie^{-ix} \\ e^{-x} & e^{-x}(x-2) & -e^{ix} & -e^{-ix} \\ -e^{-x} & e^{-x}(3-x) & -ie^{ix} & ie^{-ix} \end{bmatrix}$$
$$|W| = -8ie^{-2x}e^{-ix}e^{ix}$$

The determinant simplifies to

$$|W| = -8ie^{-2x}$$

Now we determine W_i for each U_i.

$$W_1(x) = \det \begin{bmatrix} x\,e^{-x} & e^{ix} & e^{-ix} \\ e^{-x}(1-x) & ie^{ix} & -ie^{-ix} \\ e^{-x}(x-2) & -e^{ix} & -e^{-ix} \end{bmatrix}$$
$$= -4ie^{-x}(x-1)$$

$$W_2(x) = \det \begin{bmatrix} e^{-x} & e^{ix} & e^{-ix} \\ -e^{-x} & ie^{ix} & -ie^{-ix} \\ e^{-x} & -e^{ix} & -e^{-ix} \end{bmatrix}$$
$$= -4ie^{-x}$$

$$W_3(x) = \det \begin{bmatrix} e^{-x} & x\,e^{-x} & e^{-ix} \\ -e^{-x} & e^{-x}(1-x) & -ie^{-ix} \\ e^{-x} & e^{-x}(x-2) & -e^{-ix} \end{bmatrix}$$
$$= -2ie^{(-2-i)x}$$

$$W_4(x) = \det \begin{bmatrix} e^{-x} & x\,e^{-x} & e^{ix} \\ -e^{-x} & e^{-x}(1-x) & ie^{ix} \\ e^{-x} & e^{-x}(x-2) & -e^{ix} \end{bmatrix}$$
$$= 2ie^{(-2+i)x}$$

Now we are ready to evaluate each $U_i(x)$.

$$
\begin{aligned}
U_1 &= (-1)^{4-1} \int \frac{F(x)W_1(x)}{aW(x)}\, dx \\
&= (-1)^3 \int \frac{\left(x\,\mathrm{e}^x + \frac{\cos(x)}{2}\right)\left(-4i\mathrm{e}^{-x}(x-1)\right)}{(1)\left(-8i\mathrm{e}^{-2x}\right)}\, dx \\
&= -\int \frac{-4i\left(x\,\mathrm{e}^x + \frac{\cos(x)}{2}\right)\mathrm{e}^{-x}(x-1)}{-8i\mathrm{e}^{-2x}}\, dx \\
&= -\int \left(\frac{(x-1)\left(2x\,\mathrm{e}^x + \cos(x)\right)\mathrm{e}^x}{4}\right) dx \\
&= -\frac{x^2\mathrm{e}^{2x}}{4} + \frac{x\,\mathrm{e}^{2x}}{2} - \frac{\mathrm{e}^{2x}}{4} - \frac{x\,\mathrm{e}^x\cos(x)}{8} + \frac{\left(-\frac{x}{2}+\frac{1}{2}\right)\mathrm{e}^x\sin(x)}{4} + \frac{\mathrm{e}^x\cos(x)}{8} + \frac{\mathrm{e}^x\sin(x)}{8} \\
&= -\frac{x^2\mathrm{e}^{2x}}{4} + \frac{x\,\mathrm{e}^{2x}}{2} - \frac{\mathrm{e}^{2x}}{4} - \frac{x\,\mathrm{e}^x\cos(x)}{8} + \frac{\left(-\frac{x}{2}+\frac{1}{2}\right)\mathrm{e}^x\sin(x)}{4} + \frac{\mathrm{e}^x\cos(x)}{8} + \frac{\mathrm{e}^x\sin(x)}{8}
\end{aligned}
$$

$$
\begin{aligned}
U_2 &= (-1)^{4-2} \int \frac{F(x)W_2(x)}{aW(x)}\, dx \\
&= (-1)^2 \int \frac{\left(x\,\mathrm{e}^x + \frac{\cos(x)}{2}\right)\left(-4i\mathrm{e}^{-x}\right)}{(1)\left(-8i\mathrm{e}^{-2x}\right)}\, dx \\
&= \int \frac{-4i\left(x\,\mathrm{e}^x + \frac{\cos(x)}{2}\right)\mathrm{e}^{-x}}{-8i\mathrm{e}^{-2x}}\, dx \\
&= \int \left(\frac{x\,\mathrm{e}^{2x}}{2} + \frac{\mathrm{e}^x\cos(x)}{4}\right) dx \\
&= \frac{\mathrm{e}^x\cos(x)}{8} + \frac{\mathrm{e}^x\sin(x)}{8} + \frac{x\,\mathrm{e}^{2x}}{4} - \frac{\mathrm{e}^{2x}}{8} \\
&= \frac{\mathrm{e}^x\cos(x)}{8} + \frac{\mathrm{e}^x\sin(x)}{8} + \frac{x\,\mathrm{e}^{2x}}{4} - \frac{\mathrm{e}^{2x}}{8}
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{4-3} \int \frac{F(x) W_3(x)}{a W(x)}\, dx \\
&= (-1)^{1} \int \frac{\left(x\,\mathrm{e}^{x} + \frac{\cos(x)}{2}\right) \left(-2i \mathrm{e}^{(-2-i)x}\right)}{(1)\left(-8i \mathrm{e}^{-2x}\right)}\, dx \\
&= -\int \frac{-2i\left(x\,\mathrm{e}^{x} + \frac{\cos(x)}{2}\right) \mathrm{e}^{(-2-i)x}}{-8i \mathrm{e}^{-2x}}\, dx \\
&= -\int \left(\frac{(2x\,\mathrm{e}^{x} + \cos(x))\, \mathrm{e}^{-ix}}{8}\right) dx \\
&= -\left(\int \frac{(2x\,\mathrm{e}^{x} + \cos(x))\, \mathrm{e}^{-ix}}{8} dx\right)
\end{aligned}
$$

$$
\begin{aligned}
U_4 &= (-1)^{4-4} \int \frac{F(x) W_4(x)}{a W(x)}\, dx \\
&= (-1)^{0} \int \frac{\left(x\,\mathrm{e}^{x} + \frac{\cos(x)}{2}\right) \left(2i \mathrm{e}^{(-2+i)x}\right)}{(1)\left(-8i \mathrm{e}^{-2x}\right)}\, dx \\
&= \int \frac{2i\left(x\,\mathrm{e}^{x} + \frac{\cos(x)}{2}\right) \mathrm{e}^{(-2+i)x}}{-8i \mathrm{e}^{-2x}}\, dx \\
&= \int \left(-\frac{(2x\,\mathrm{e}^{x} + \cos(x))\, \mathrm{e}^{ix}}{8}\right) dx \\
&= -\frac{x}{16} + \frac{i \mathrm{e}^{2ix}}{32} + \left(-\frac{1}{16} + \frac{i}{16}\right)(2x - 1 + i)\, \mathrm{e}^{(1+i)x} \\
&= -\frac{x}{16} + \frac{i \mathrm{e}^{2ix}}{32} + \left(-\frac{1}{16} + \frac{i}{16}\right)(2x - 1 + i)\, \mathrm{e}^{(1+i)x}
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3 + U_4 y_4
$$

Hence

$$
\begin{aligned}
y_p = &\left(-\frac{x^2 \mathrm{e}^{2x}}{4} + \frac{x\,\mathrm{e}^{2x}}{2} - \frac{\mathrm{e}^{2x}}{4} - \frac{x\,\mathrm{e}^{x} \cos(x)}{8} + \frac{\left(-\frac{x}{2} + \frac{1}{2}\right) \mathrm{e}^{x} \sin(x)}{4} + \frac{\mathrm{e}^{x} \cos(x)}{8} + \frac{\mathrm{e}^{x} \sin(x)}{8}\right) \left(\mathrm{e}^{-x}\right) \\
&+ \left(\frac{\mathrm{e}^{x} \cos(x)}{8} + \frac{\mathrm{e}^{x} \sin(x)}{8} + \frac{x\,\mathrm{e}^{2x}}{4} - \frac{\mathrm{e}^{2x}}{8}\right) \left(x\,\mathrm{e}^{-x}\right) \\
&+ \left(-\left(\int \frac{(2x\,\mathrm{e}^{x} + \cos(x))\, \mathrm{e}^{-ix}}{8} dx\right)\right) \left(\mathrm{e}^{ix}\right) \\
&+ \left(-\frac{x}{16} + \frac{i \mathrm{e}^{2ix}}{32} + \left(-\frac{1}{16} + \frac{i}{16}\right)(2x - 1 + i)\, \mathrm{e}^{(1+i)x}\right) \left(\mathrm{e}^{-ix}\right)
\end{aligned}
$$

Therefore the particular solution is

$$y_p = \frac{x\,\mathrm{e}^{x}}{8}-\frac{i\sin\left(x\right)x}{16}-\frac{\cos\left(x\right)x}{16}+\frac{3\sin\left(x\right)}{16}+\frac{i\mathrm{e}^{ix}}{32}-\frac{x\,\mathrm{e}^{-ix}}{16}-\frac{\mathrm{e}^{x}}{4}+\frac{\cos\left(x\right)}{8}$$

Which simplifies to

$$y_p = \frac{\left(4+i-4x\right)\cos\left(x\right)}{32}+\frac{\left(x-2\right)\mathrm{e}^{x}}{8}+\frac{5\sin\left(x\right)}{32}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-x}+c_2 x\,\mathrm{e}^{-x}+\mathrm{e}^{ix}c_3+\mathrm{e}^{-ix}c_4\right)+\left(\frac{\left(4+i-4x\right)\cos\left(x\right)}{32}+\frac{\left(x-2\right)\mathrm{e}^{x}}{8}+\frac{5\sin\left(x\right)}{32}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{-ix}c_4+\mathrm{e}^{ix}c_3+\mathrm{e}^{-x}\left(c_2x+c_1\right)+\frac{\left(4+i-4x\right)\cos\left(x\right)}{32}+\frac{\left(x-2\right)\mathrm{e}^{x}}{8}+\frac{5\sin\left(x\right)}{32}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-ix}c_4+\mathrm{e}^{ix}c_3+\mathrm{e}^{-x}\left(c_2x+c_1\right)+\frac{\left(4+i-4x\right)\cos\left(x\right)}{32}+\frac{\left(x-2\right)\mathrm{e}^{x}}{8}+\frac{5\sin\left(x\right)}{32} \quad (1)$$

Verification of solutions

$$y = \mathrm{e}^{-ix}c_4+\mathrm{e}^{ix}c_3+\mathrm{e}^{-x}\left(c_2x+c_1\right)+\frac{\left(4+i-4x\right)\cos\left(x\right)}{32}+\frac{\left(x-2\right)\mathrm{e}^{x}}{8}+\frac{5\sin\left(x\right)}{32}$$

Verified OK.

17.16.1 Maple step by step solution

Let's solve

$y'''' + 2y''' + 2y'' + 2y' + y = x\,\mathrm{e}^{x} + \frac{\cos(x)}{2}$

- Highest derivative means the order of the ODE is 4

  y''''

□ Convert linear ODE into a system of first order ODEs

  ○ Define new variable $y_1(x)$

$y_1(x) = y$

- Define new variable $y_2(x)$

  $y_2(x) = y'$

- Define new variable $y_3(x)$

  $y_3(x) = y''$

- Define new variable $y_4(x)$

  $y_4(x) = y'''$

- Isolate for $y_4'(x)$ using original ODE

  $y_4'(x) = x\,e^x + \frac{\cos(x)}{2} - 2y_4(x) - 2y_3(x) - 2y_2(x) - y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $\left[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = x\,e^x + \frac{\cos(x)}{2} - 2y_4(x) - 2y_3(x) - 2y_2(x) -\right.$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & -2 & -2 & -2 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ x\,e^x + \frac{\cos(x)}{2} \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 0 \\ x\,e^x + \frac{\cos(x)}{2} \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & -2 & -2 & -2 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{y}'(x) = A \cdot \overrightarrow{y}(x) + \overrightarrow{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[-1, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} \mathrm{I} \\ -1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right]$$

- First solution from eigenvalue -1

$$\overrightarrow{y}_1(x) = \mathrm{e}^{-x} \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\overrightarrow{p}$ is to be solved for, $\lambda = -1$ is the eigenvalue, a

$$\overrightarrow{y}_2(x) = \mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Note that the x multiplying $\overrightarrow{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\overrightarrow{y}_2(x)$ into the homogeneous system

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda x}\overrightarrow{v} = \left(\mathrm{e}^{\lambda x}A\right) \cdot \left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Use the fact that $\overrightarrow{v}$ is an eigenvector of A

$$\lambda\, \mathrm{e}^{\lambda x} \left(x \vec{v} + \vec{p}\right) + \mathrm{e}^{\lambda x} \vec{v} = \mathrm{e}^{\lambda x} \left(\lambda x \vec{v} + A \cdot \vec{p}\right)$$

- Simplify equation

$$\lambda \vec{p} + \vec{v} = A \cdot \vec{p}$$

- Make use of the identity matrix I

$$(\lambda \cdot I) \cdot \vec{p} + \vec{v} = A \cdot \vec{p}$$

- Condition $\vec{p}$ must meet for $\vec{y}_2(x)$ to be a solution to the homogeneous system

$$(A - \lambda \cdot I) \cdot \vec{p} = \vec{v}$$

- Choose $\vec{p}$ to use in the second solution to the homogeneous system from eigenvalue -1

$$\left(\begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & -2 & -2 & -2 \end{bmatrix} - (-1) \cdot \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}\right) \cdot \vec{p} = \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}$$

- Choice of $\vec{p}$

$$\vec{p} = \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue -1

$$\vec{y}_2(x) = \mathrm{e}^{-x} \cdot \left(x \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right)$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-Ix} \cdot \begin{bmatrix} -I \\ -1 \\ I \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$(\cos(x) - I\sin(x)) \cdot \begin{bmatrix} -I \\ -1 \\ I \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -I(\cos(x) - I\sin(x)) \\ -\cos(x) + I\sin(x) \\ I(\cos(x) - I\sin(x)) \\ \cos(x) - I\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \begin{bmatrix} -\sin(x) \\ -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_4(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1(x) + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \vec{y}_p(x)$

☐ Fundamental matrix

  - Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} -e^{-x} & e^{-x}(-x-1) & -\sin(x) & -\cos(x) \\ e^{-x} & x\,e^{-x} & -\cos(x) & \sin(x) \\ -e^{-x} & -x\,e^{-x} & \sin(x) & \cos(x) \\ e^{-x} & x\,e^{-x} & \cos(x) & -\sin(x) \end{bmatrix}$$

  - The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} -\mathrm{e}^{-x} & \mathrm{e}^{-x}(-x-1) & -\sin(x) & -\cos(x) \\ \mathrm{e}^{-x} & x\,\mathrm{e}^{-x} & -\cos(x) & \sin(x) \\ -\mathrm{e}^{-x} & -x\,\mathrm{e}^{-x} & \sin(x) & \cos(x) \\ \mathrm{e}^{-x} & x\,\mathrm{e}^{-x} & \cos(x) & -\sin(x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -1 & -1 & 0 & -1 \\ 1 & 0 & -1 & 0 \\ -1 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} (x+1)\,\mathrm{e}^{-x} & x\,\mathrm{e}^{-x} - \frac{\cos(x)}{2} + \frac{\mathrm{e}^{-x}}{2} + \frac{\sin(x)}{2} & x\,\mathrm{e}^{-x} - \cos(x) + \mathrm{e}^{-x} & x\,\mathrm{e}^{-x} - \frac{\cos(x)}{2} + \frac{\mathrm{e}^{-}}{2} \\ -x\,\mathrm{e}^{-x} & \frac{\mathrm{e}^{-x}}{2} - x\,\mathrm{e}^{-x} + \frac{\cos(x)}{2} + \frac{\sin(x)}{2} & -x\,\mathrm{e}^{-x} + \sin(x) & \frac{\mathrm{e}^{-x}}{2} - x\,\mathrm{e}^{-x} - \frac{\cos(}{2} \\ x\,\mathrm{e}^{-x} & -\frac{\mathrm{e}^{-x}}{2} + x\,\mathrm{e}^{-x} - \frac{\sin(x)}{2} + \frac{\cos(x)}{2} & x\,\mathrm{e}^{-x} + \cos(x) & -\frac{\mathrm{e}^{-x}}{2} + x\,\mathrm{e}^{-x} + \frac{\sin(}{2} \\ -x\,\mathrm{e}^{-x} & \frac{\mathrm{e}^{-x}}{2} - x\,\mathrm{e}^{-x} - \frac{\cos(x)}{2} - \frac{\sin(x)}{2} & -x\,\mathrm{e}^{-x} - \sin(x) & \frac{\mathrm{e}^{-x}}{2} - x\,\mathrm{e}^{-x} + \frac{\cos(}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(x)$ and solve for $\overrightarrow{v}(x)$

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \overrightarrow{v}(x)$

- Take the derivative of the particular solution

  $\overrightarrow{y}'_p(x) = \Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \overrightarrow{v}'(x) = \overrightarrow{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\overrightarrow{v}'(x) = \frac{1}{\Phi(x)} \cdot \overrightarrow{f}(x)$

- Integrate to solve for $\overrightarrow{v}(x)$

$$\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$$

- Plug $\vec{v}(x)$ into the equation for the particular solution

$$\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \left[\begin{array}{c} \frac{e^{-x}}{4}+\frac{(-x-1)\cos(x)}{8}+\frac{(-x+4)\sin(x)}{8}-\frac{e^{x}}{8} \\ -\frac{e^{-x}}{4}+\frac{(3-x)\cos(x)}{8}+\frac{\sin(x)x}{8}-\frac{e^{x}}{8} \\ \frac{e^{-x}}{4}+\frac{(x+1)\cos(x)}{8}+\frac{(4x-3)e^{x}}{8}+\frac{\sin(x)x}{8} \\ -\frac{e^{-x}}{4}+\frac{\cos(x)(x-1)}{8}+\frac{(-x-2)\sin(x)}{8}+\frac{3\,e^{x}}{8} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1(x) + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \left[\begin{array}{c} \frac{e^{-x}}{4}+\frac{(-x-1)\cos(x)}{8}+\frac{(-x+4)\sin(x)}{8}-\frac{e^{x}}{8} \\ -\frac{e^{-x}}{4}+\frac{(3-x)\cos(x)}{8}+\frac{\sin(x)x}{8}-\frac{e^{x}}{8} \\ \frac{e^{-x}}{4}+\frac{(x+1)\cos(x)}{8}+\frac{(4x-3)e^{x}}{8}+\frac{\sin(x)x}{8} \\ -\frac{e^{-x}}{4}+\frac{\cos(x)(x-1)}{8}+\frac{(-x-2)\sin(x)}{8}+\frac{3\,e^{x}}{8} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = \frac{(-8c_2x-8c_1-8c_2+2)e^{-x}}{8} + \frac{(-x-8c_4-1)\cos(x)}{8} + \frac{(-x-8c_3+4)\sin(x)}{8} - \frac{e^{x}}{8}$$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + y' = \cos(x)^2 + e^x + x^2}$$

17.17.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = 0, f(x) = \cos(x)^2 + e^x + x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=1, B=1, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x}+\lambda e^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2+\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=1, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{-1}{(2)(1)}\pm\frac{1}{(2)(1)}\sqrt{1^2-(4)(1)(0)}\\&=-\frac{1}{2}\pm\frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1&=-\frac{1}{2}+\frac{1}{2}\\\lambda_2&=-\frac{1}{2}-\frac{1}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1&=0\\\lambda_2&=-1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y&=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}\\y&=c_1e^{(0)x}+c_2e^{(-1)x}\end{aligned}$$

Or

$$y = c_1 + e^{-x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + e^{-x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(x)^2 + e^x + x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}, \{\cos(2x), \sin(2x)\}, \{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^x\}, \{\cos(2x), \sin(2x)\}, \{x, x^2, x^3\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^x + A_2 \cos(2x) + A_3 \sin(2x) + A_4 x + A_5 x^2 + A_6 x^3$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^x - 4A_2 \cos(2x) - 4A_3 \sin(2x) + 2A_5 + 6A_6 x - 2A_2 \sin(2x) \\ + 2A_3 \cos(2x) + A_4 + 2A_5 x + 3A_6 x^2 = \cos(x)^2 + e^x + x^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = -\frac{1}{10}, A_3 = \frac{1}{20}, A_4 = \frac{5}{2}, A_5 = -1, A_6 = \frac{1}{3}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x}{2} - \frac{\cos(2x)}{10} + \frac{\sin(2x)}{20} + \frac{5x}{2} - x^2 + \frac{x^3}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 + e^{-x} c_2) + \left(\frac{e^x}{2} - \frac{\cos(2x)}{10} + \frac{\sin(2x)}{20} + \frac{5x}{2} - x^2 + \frac{x^3}{3}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + e^{-x} c_2 + \frac{e^x}{2} - \frac{\cos(2x)}{10} + \frac{\sin(2x)}{20} + \frac{5x}{2} - x^2 + \frac{x^3}{3} \tag{1}$$

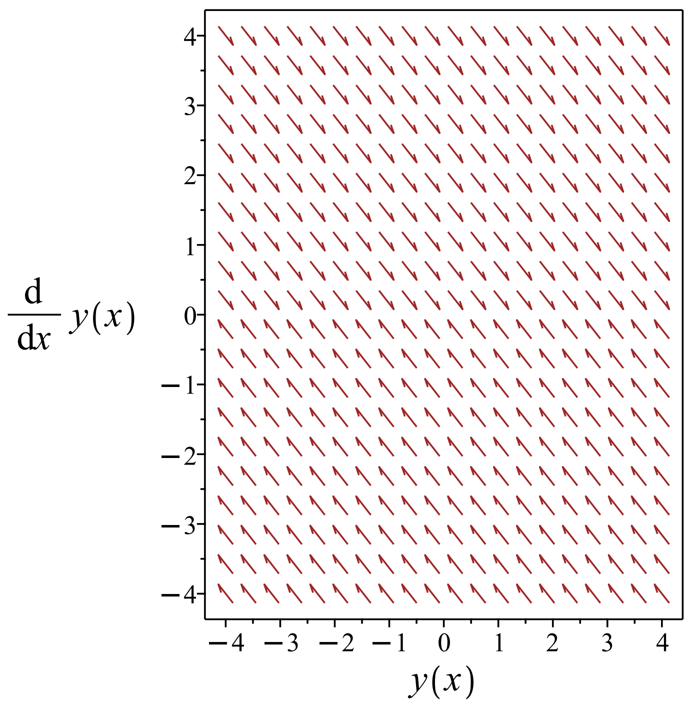

Figure 670: Slope field plot

Verification of solutions

$$y = c_1 + e^{-x} c_2 + \frac{e^x}{2} - \frac{\cos(2x)}{10} + \frac{\sin(2x)}{20} + \frac{5x}{2} - x^2 + \frac{x^3}{3}$$

Verified OK.

17.17.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + y')\, dx = \int \left(\cos(x)^2 + e^x + x^2\right) dx$$

$$y' + y = \frac{x^3}{3} + \frac{\sin(x)\cos(x)}{2} + \frac{x}{2} + e^x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 1 \\ q(x) &= \frac{x^3}{3} + \frac{\sin(2x)}{4} + \frac{x}{2} + e^x + c_1 \end{aligned}$$

Hence the ode is

$$y' + y = \frac{x^3}{3} + \frac{\sin(2x)}{4} + \frac{x}{2} + e^x + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 1 dx} \\ &= e^x \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(\frac{x^3}{3} + \frac{\sin(2x)}{4} + \frac{x}{2} + e^x + c_1\right) \\ \frac{d}{dx}(e^x y) &= (e^x)\left(\frac{x^3}{3} + \frac{\sin(2x)}{4} + \frac{x}{2} + e^x + c_1\right) \\ d(e^x y) &= \left(\frac{(4x^3 + 12\,e^x + 3\sin(2x) + 12c_1 + 6x)\,e^x}{12}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^x y &= \int \frac{(4x^3 + 12\,e^x + 3\sin(2x) + 12c_1 + 6x)\,e^x}{12}\, dx \\ e^x y &= \frac{x^3 e^x}{3} - e^x x^2 + \frac{5x\,e^x}{2} - \frac{5\,e^x}{2} + \frac{e^{2x}}{2} + \frac{e^x(\sin(2x) - 2\cos(2x))}{20} + e^x c_1 + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{x}$ results in

$$y = \mathrm{e}^{-x}\left(\frac{x^{3}\mathrm{e}^{x}}{3} - \mathrm{e}^{x} x^{2} + \frac{5x\,\mathrm{e}^{x}}{2} - \frac{5\,\mathrm{e}^{x}}{2} + \frac{\mathrm{e}^{2x}}{2} + \frac{\mathrm{e}^{x}(\sin(2x) - 2\cos(2x))}{20} + \mathrm{e}^{x} c_1\right) + \mathrm{e}^{-x} c_2$$

which simplifies to

$$y = \frac{x^{3}}{3} - x^{2} + \frac{\mathrm{e}^{x}}{2} + c_1 + \frac{5x}{2} + \frac{\sin(2x)}{20} - \frac{\cos(2x)}{10} - \frac{5}{2} + \mathrm{e}^{-x} c_2$$

<u>Summary</u>
The solution(s) found are the following

$$y = \frac{x^{3}}{3} - x^{2} + \frac{\mathrm{e}^{x}}{2} + c_1 + \frac{5x}{2} + \frac{\sin(2x)}{20} - \frac{\cos(2x)}{10} - \frac{5}{2} + \mathrm{e}^{-x} c_2 \tag{1}$$

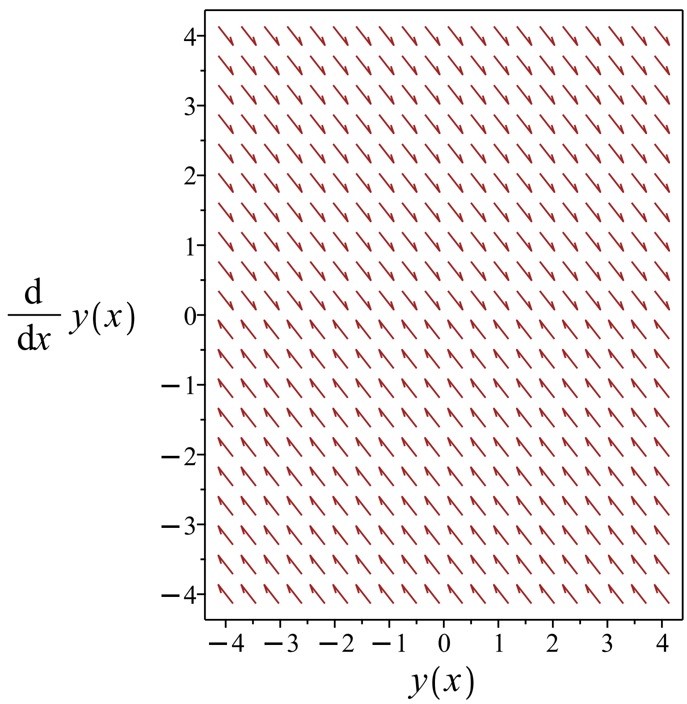

Figure 671: Slope field plot

<u>Verification of solutions</u>

$$y = \frac{x^{3}}{3} - x^{2} + \frac{\mathrm{e}^{x}}{2} + c_1 + \frac{5x}{2} + \frac{\sin(2x)}{20} - \frac{\cos(2x)}{10} - \frac{5}{2} + \mathrm{e}^{-x} c_2$$

Verified OK.

17.17.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + p(x) - \cos(x)^2 - e^x - x^2 = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= 1 \\ q(x) &= \cos(x)^2 + e^x + x^2 \end{aligned}$$

Hence the ode is

$$p'(x) + p(x) = \cos(x)^2 + e^x + x^2$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 1dx} \\ &= e^x \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu)\left(\cos(x)^2 + e^x + x^2\right) \\ \frac{d}{dx}(e^x p) &= (e^x)\left(\cos(x)^2 + e^x + x^2\right) \\ d(e^x p) &= \left(\left(\cos(x)^2 + e^x + x^2\right) e^x\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^x p &= \int \left(\cos(x)^2 + e^x + x^2\right) e^x \, dx \\ e^x p &= \frac{(\cos(x) + 2\sin(x)) e^x \cos(x)}{5} + \frac{12 e^x}{5} + \frac{e^{2x}}{2} + e^x x^2 - 2x e^x + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{x}$ results in

$$p(x) = e^{-x}\left(\frac{(\cos(x) + 2\sin(x))\, e^{x} \cos(x)}{5} + \frac{12\, e^{x}}{5} + \frac{e^{2x}}{2} + e^{x} x^{2} - 2x\, e^{x}\right) + c_1 e^{-x}$$

which simplifies to

$$p(x) = x^{2} + \frac{e^{x}}{2} - 2x + \frac{\sin(2x)}{5} + \frac{\cos(2x)}{10} + \frac{5}{2} + c_1 e^{-x}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = x^{2} + \frac{e^{x}}{2} - 2x + \frac{\sin(2x)}{5} + \frac{\cos(2x)}{10} + \frac{5}{2} + c_1 e^{-x}$$

Integrating both sides gives

$$\begin{aligned} y &= \int x^{2} + \frac{e^{x}}{2} - 2x + \frac{\sin(2x)}{5} + \frac{\cos(2x)}{10} + \frac{5}{2} + c_1 e^{-x}\, dx \\ &= -x^{2} + \frac{5x}{2} + \frac{x^{3}}{3} - c_1 e^{-x} + \frac{e^{x}}{2} - \frac{\cos(2x)}{10} + \frac{\sin(2x)}{20} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -x^{2} + \frac{5x}{2} + \frac{x^{3}}{3} - c_1 e^{-x} + \frac{e^{x}}{2} - \frac{\cos(2x)}{10} + \frac{\sin(2x)}{20} + c_2 \tag{1}$$

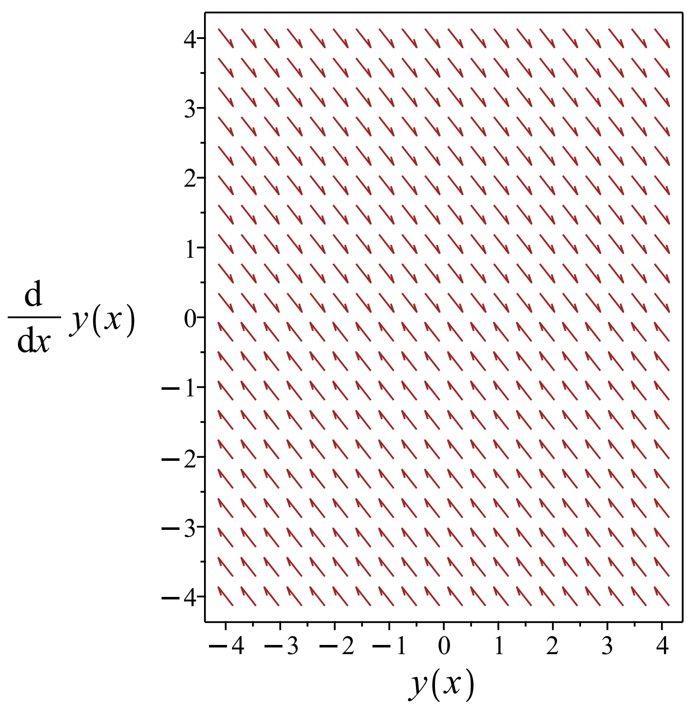

Figure 672: Slope field plot

Verification of solutions

$$y = -x^2 + \frac{5x}{2} + \frac{x^3}{3} - c_1 \mathrm{e}^{-x} + \frac{\mathrm{e}^x}{2} - \frac{\cos(2x)}{10} + \frac{\sin(2x)}{20} + c_2$$

Verified OK.

17.17.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + y' = \cos(x)^2 + \mathrm{e}^x + x^2$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + y')\, dx = \int (\cos(x)^2 + \mathrm{e}^x + x^2)\, dx$$

$$y' + y = \frac{x^3}{3} + \frac{\sin(x)\cos(x)}{2} + \frac{x}{2} + \mathrm{e}^x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 1$$
$$q(x) = \frac{x^3}{3} + \frac{\sin(2x)}{4} + \frac{x}{2} + \mathrm{e}^x + c_1$$

Hence the ode is

$$y' + y = \frac{x^3}{3} + \frac{\sin(2x)}{4} + \frac{x}{2} + \mathrm{e}^x + c_1$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int 1 dx}$$
$$= \mathrm{e}^x$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\left(\frac{x^3}{3} + \frac{\sin(2x)}{4} + \frac{x}{2} + \mathrm{e}^x + c_1\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}(\mathrm{e}^x y) = (\mathrm{e}^x)\left(\frac{x^3}{3} + \frac{\sin(2x)}{4} + \frac{x}{2} + \mathrm{e}^x + c_1\right)$$
$$\mathrm{d}(\mathrm{e}^x y) = \left(\frac{(4x^3 + 12\,\mathrm{e}^x + 3\sin(2x) + 12c_1 + 6x)\,\mathrm{e}^x}{12}\right) \mathrm{d}x$$

Integrating gives

$$e^x y = \int \frac{(4x^3 + 12\,e^x + 3\sin(2x) + 12c_1 + 6x)\,e^x}{12}\,dx$$

$$e^x y = \frac{x^3 e^x}{3} - e^x x^2 + \frac{5x\,e^x}{2} - \frac{5\,e^x}{2} + \frac{e^{2x}}{2} + \frac{e^x(\sin(2x) - 2\cos(2x))}{20} + e^x c_1 + c_2$$

Dividing both sides by the integrating factor $\mu = e^x$ results in

$$y = e^{-x}\left(\frac{x^3 e^x}{3} - e^x x^2 + \frac{5x\,e^x}{2} - \frac{5\,e^x}{2} + \frac{e^{2x}}{2} + \frac{e^x(\sin(2x) - 2\cos(2x))}{20} + e^x c_1\right) + e^{-x} c_2$$

which simplifies to

$$y = \frac{x^3}{3} - x^2 + \frac{e^x}{2} + c_1 + \frac{5x}{2} + \frac{\sin(2x)}{20} - \frac{\cos(2x)}{10} - \frac{5}{2} + e^{-x} c_2$$

Summary

The solution(s) found are the following

$$y = \frac{x^3}{3} - x^2 + \frac{e^x}{2} + c_1 + \frac{5x}{2} + \frac{\sin(2x)}{20} - \frac{\cos(2x)}{10} - \frac{5}{2} + e^{-x} c_2 \tag{1}$$

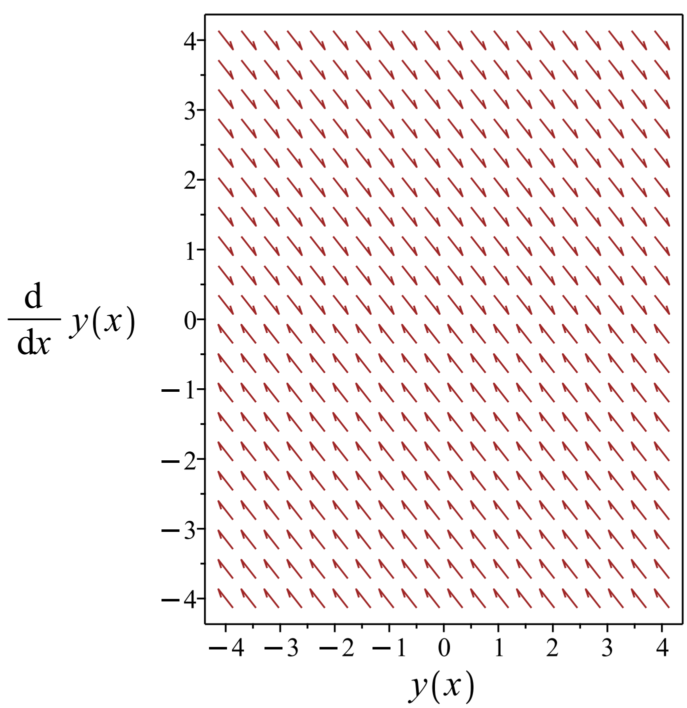

Figure 673: Slope field plot

Verification of solutions

$$
y = \frac{x^3}{3} - x^2 + \frac{e^x}{2} + c_1 + \frac{5x}{2} + \frac{\sin(2x)}{20} - \frac{\cos(2x)}{10} - \frac{5}{2} + e^{-x} c_2
$$

Verified OK.

17.17.5 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{align*}
y'' + y' &= 0 \tag{1} \\
Ay'' + By' + Cy &= 0 \tag{2}
\end{align*}
$$

Comparing (1) and (2) shows that

$$
\begin{align*}
A &= 1 \\
B &= 1 \tag{3} \\
C &= 0
\end{align*}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{align*}
r &= \frac{s}{t} \tag{5} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{align*}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{1}{4} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{align*}
s &= 1 \\
t &= 4
\end{align*}
$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 526: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = e^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\,dx} \\
&= z_1 e^{-\frac{x}{2}} \\
&= z_1\left(e^{-\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = e^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x}}{(y_1)^2}\,dx \\
&= y_1(e^x)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(e^{-x}\right) + c_2\left(e^{-x}(e^x)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{-x} + c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(x)^2 + e^x + x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}, \{\cos(2x), \sin(2x)\}, \{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^x\}, \{\cos(2x), \sin(2x)\}, \{x, x^2, x^3\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^x + A_2 \cos(2x) + A_3 \sin(2x) + A_4 x + A_5 x^2 + A_6 x^3$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{gathered}2A_1 e^x - 4A_2 \cos(2x) - 4A_3 \sin(2x) + 2A_5 + 6A_6 x - 2A_2 \sin(2x) \\ + 2A_3 \cos(2x) + A_4 + 2A_5 x + 3A_6 x^2 = \cos(x)^2 + e^x + x^2\end{gathered}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = -\frac{1}{10}, A_3 = \frac{1}{20}, A_4 = \frac{5}{2}, A_5 = -1, A_6 = \frac{1}{3}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x}{2} - \frac{\cos(2x)}{10} + \frac{\sin(2x)}{20} + \frac{5x}{2} - x^2 + \frac{x^3}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 e^{-x} + c_2) + \left(\frac{e^x}{2} - \frac{\cos(2x)}{10} + \frac{\sin(2x)}{20} + \frac{5x}{2} - x^2 + \frac{x^3}{3}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 + \frac{e^x}{2} - \frac{\cos(2x)}{10} + \frac{\sin(2x)}{20} + \frac{5x}{2} - x^2 + \frac{x^3}{3} \tag{1}$$

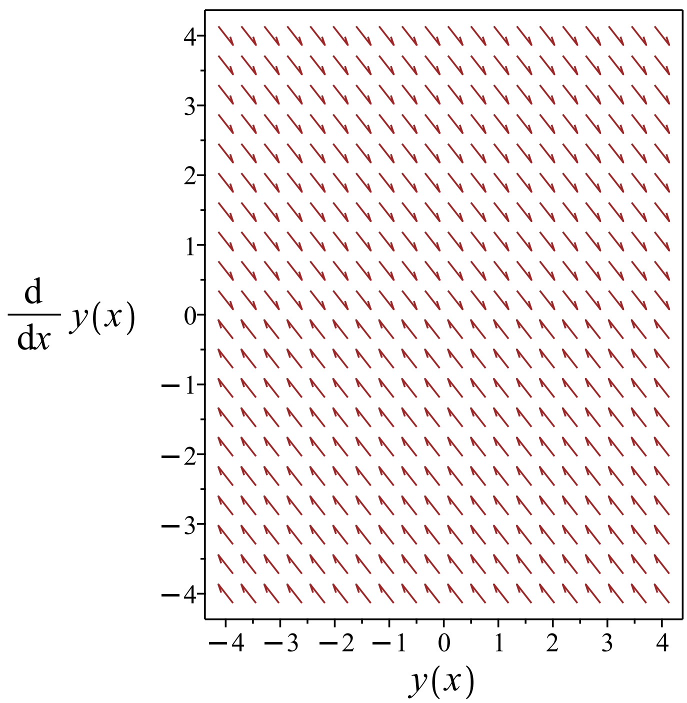

Figure 674: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + c_2 + \frac{e^x}{2} - \frac{\cos(2x)}{10} + \frac{\sin(2x)}{20} + \frac{5x}{2} - x^2 + \frac{x^3}{3}$$

Verified OK.

17.17.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 1 \\ r(x) &= 0 \\ s(x) &= \cos(x)^2 + e^x + x^2 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\, y' + (q(x) - p'(x))\, y\right)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$y' + y = \int \cos(x)^2 + e^x + x^2\, dx$$

We now have a first order ode to solve which is

$$y' + y = \frac{x^3}{3} + \frac{\sin(x)\cos(x)}{2} + \frac{x}{2} + e^x + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= 1\\ q(x) &= \frac{x^3}{3} + \frac{\sin(2x)}{4} + \frac{x}{2} + e^x + c_1\end{aligned}$$

Hence the ode is

$$y' + y = \frac{x^3}{3} + \frac{\sin(2x)}{4} + \frac{x}{2} + e^x + c_1$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int 1 dx}\\ &= e^x\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{x^3}{3} + \frac{\sin(2x)}{4} + \frac{x}{2} + e^x + c_1\right)\\ \frac{d}{dx}(e^x y) &= (e^x)\left(\frac{x^3}{3} + \frac{\sin(2x)}{4} + \frac{x}{2} + e^x + c_1\right)\\ d(e^x y) &= \left(\frac{(4x^3 + 12e^x + 3\sin(2x) + 12c_1 + 6x)e^x}{12}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^x y &= \int \frac{(4x^3 + 12e^x + 3\sin(2x) + 12c_1 + 6x)e^x}{12} dx\\ e^x y &= \frac{x^3 e^x}{3} - e^x x^2 + \frac{5x e^x}{2} - \frac{5e^x}{2} + \frac{e^{2x}}{2} + \frac{e^x(\sin(2x) - 2\cos(2x))}{20} + e^x c_1 + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^x$ results in

$$y = e^{-x}\left(\frac{x^3 e^x}{3} - e^x x^2 + \frac{5x e^x}{2} - \frac{5e^x}{2} + \frac{e^{2x}}{2} + \frac{e^x(\sin(2x) - 2\cos(2x))}{20} + e^x c_1\right) + e^{-x} c_2$$

which simplifies to

$$y = \frac{x^3}{3} - x^2 + \frac{e^x}{2} + c_1 + \frac{5x}{2} + \frac{\sin(2x)}{20} - \frac{\cos(2x)}{10} - \frac{5}{2} + e^{-x} c_2$$

Summary

The solution(s) found are the following

$$y = \frac{x^3}{3} - x^2 + \frac{e^x}{2} + c_1 + \frac{5x}{2} + \frac{\sin(2x)}{20} - \frac{\cos(2x)}{10} - \frac{5}{2} + e^{-x} c_2 \tag{1}$$

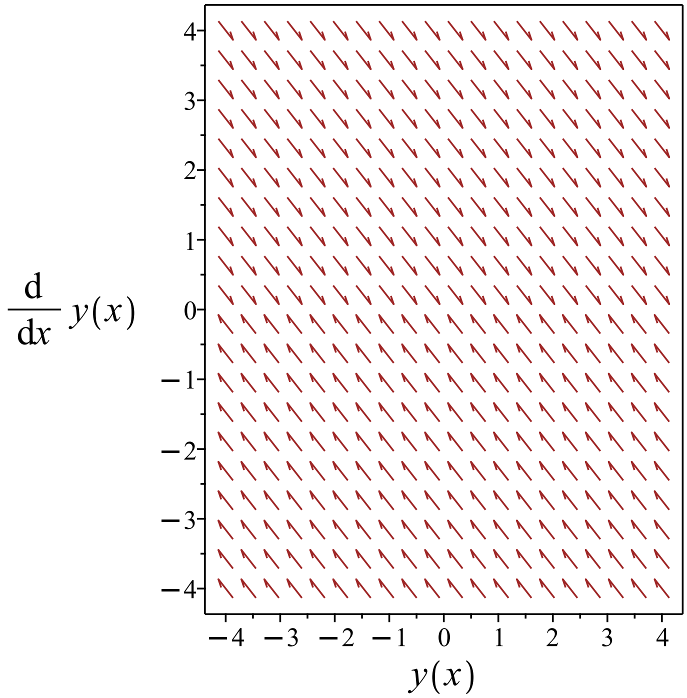

Figure 675: Slope field plot

Verification of solutions

$$y = \frac{x^3}{3} - x^2 + \frac{e^x}{2} + c_1 + \frac{5x}{2} + \frac{\sin(2x)}{20} - \frac{\cos(2x)}{10} - \frac{5}{2} + e^{-x} c_2$$

Verified OK.

17.17.7 Maple step by step solution

Let's solve

$y'' + y' = \cos(x)^2 + e^x + x^2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 + r = 0$

- Factor the characteristic polynomial

  $r(r+1) = 0$
- Roots of the characteristic polynomial

  $r = (-1, 0)$
- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-x}$
- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \cos(x)^2 + \mathrm{e}^x + x^2\right]$
- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-x} & 1 \\ -\mathrm{e}^{-x} & 0 \end{bmatrix}$
- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = \mathrm{e}^{-x}$
- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\mathrm{e}^{-x}\left(\int \left(\cos(x)^2 + \mathrm{e}^x + x^2\right) \mathrm{e}^x dx\right) + \int \left(\cos(x)^2 + \mathrm{e}^x + x^2\right) dx$
- ○ Compute integrals

  $y_p(x) = -\frac{5}{2} - \frac{\cos(2x)}{10} + \frac{\sin(2x)}{20} - x^2 + \frac{5x}{2} + \frac{\mathrm{e}^x}{2} + \frac{x^3}{3}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 - \frac{5}{2} - \frac{\cos(2x)}{10} + \frac{\sin(2x)}{20} - x^2 + \frac{5x}{2} + \frac{\mathrm{e}^x}{2} + \frac{x^3}{3}$

Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Superposition principle. Exercises page 137
Problem number: 568.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_y]]
```

$$\boxed{y'''' + 4y''' = e^{x} + 3\sin(2x) + 1}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 4y''' = 0$$

The characteristic equation is

$$\lambda^4 + 4\lambda^3 = 0$$

The roots of the above equation are

$$\lambda_1 = -4$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$
$$\lambda_4 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_3x^2 + c_2x + c_1 + e^{-4x}c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= 1 \\ y_2 &= x \\ y_3 &= x^2 \\ y_4 &= e^{-4x} \end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' + 4y''' = e^x + 3\sin(2x) + 1$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x + 3\sin(2x) + 1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{e^x\}, \{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, x^2, e^{-4x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}, \{e^x\}, \{\cos(2x), \sin(2x)\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2\}, \{e^x\}, \{\cos(2x), \sin(2x)\}]$$

Since x^2 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^3\}, \{e^x\}, \{\cos(2x), \sin(2x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1x^3 + A_2\mathrm{e}^x + A_3\cos(2x) + A_4\sin(2x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&5A_2\mathrm{e}^x + 16A_3\cos(2x) + 16A_4\sin(2x) + 24A_1 + 32A_3\sin(2x) - 32A_4\cos(2x)\\&= \mathrm{e}^x + 3\sin(2x) + 1\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{24}, A_2 = \frac{1}{5}, A_3 = \frac{3}{40}, A_4 = \frac{3}{80}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^3}{24} + \frac{\mathrm{e}^x}{5} + \frac{3\cos(2x)}{40} + \frac{3\sin(2x)}{80}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\&= \left(c_3x^2 + c_2x + c_1 + \mathrm{e}^{-4x}c_4\right) + \left(\frac{x^3}{24} + \frac{\mathrm{e}^x}{5} + \frac{3\cos(2x)}{40} + \frac{3\sin(2x)}{80}\right)\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_3x^2 + c_2x + c_1 + \mathrm{e}^{-4x}c_4 + \frac{x^3}{24} + \frac{\mathrm{e}^x}{5} + \frac{3\cos(2x)}{40} + \frac{3\sin(2x)}{80} \tag{1}$$

Verification of solutions

$$y = c_3x^2 + c_2x + c_1 + \mathrm{e}^{-4x}c_4 + \frac{x^3}{24} + \frac{\mathrm{e}^x}{5} + \frac{3\cos(2x)}{40} + \frac{3\sin(2x)}{80}$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 2y' + 5y = 10\sin(x) + 17\sin(2x)}$$

17.19.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 5, f(x) = 10\sin(x) + 17\sin(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 2\lambda\, \mathrm{e}^{\lambda x} + 5\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-2^2 - (4)\,(1)\,(5)}\\ &= 1 \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 1 + 2i\\ \lambda_2 &= 1 - 2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 + 2i\\ \lambda_2 &= 1 - 2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 1$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{x}(c_1 \cos(2x) + c_2 \sin(2x))$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{x}(c_1 \cos(2x) + c_2 \sin(2x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$10\sin(x) + 17\sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}, \{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x \cos(2x), e^x \sin(2x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x) + A_3 \cos(2x) + A_4 \sin(2x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&4A_1 \cos(x) + 4A_2 \sin(x) + A_3 \cos(2x) + A_4 \sin(2x) + 2A_1 \sin(x)\\&- 2A_2 \cos(x) + 4A_3 \sin(2x) - 4A_4 \cos(2x) = 10\sin(x) + 17\sin(2x)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = 2, A_3 = 4, A_4 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \cos(x) + 2\sin(x) + 4\cos(2x) + \sin(2x)$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\&= (e^x(c_1 \cos(2x) + c_2 \sin(2x))) + (\cos(x) + 2\sin(x) + 4\cos(2x) + \sin(2x))\end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^x(c_1 \cos(2x) + c_2 \sin(2x)) + \cos(x) + 2\sin(x) + 4\cos(2x) + \sin(2x) \tag{1}$$

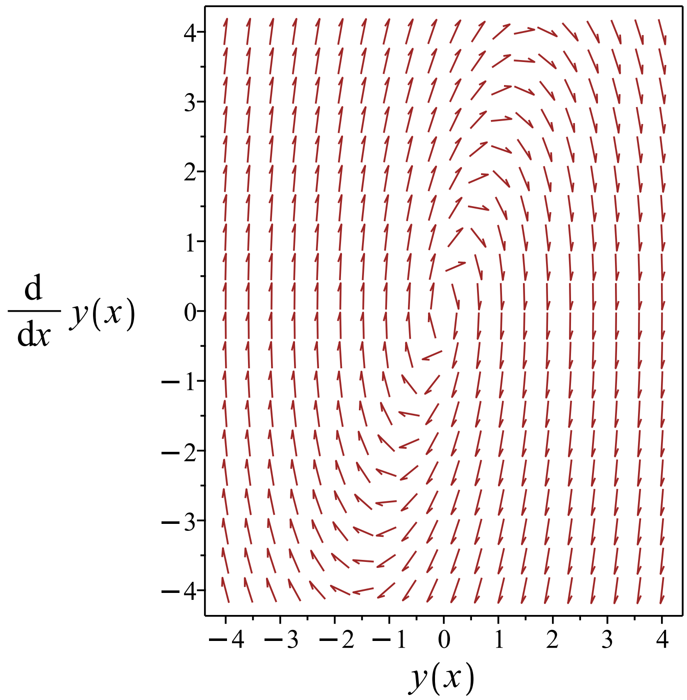

Figure 676: Slope field plot

Verification of solutions

$$y = e^{x}(c_1 \cos(2x) + c_2 \sin(2x)) + \cos(x) + 2\sin(x) + 4\cos(2x) + \sin(2x)$$

Verified OK.

17.19.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 528: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\ &= z_1 e^{x} \\ &= z_1(\mathrm{e}^{x}) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}\cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\tan(2x)}{2}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x \cos(2x)) + c_2\left(\mathrm{e}^x \cos(2x)\left(\frac{\tan(2x)}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' + 5y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^x \cos(2x)\, c_1 + \frac{\sin(2x)\, \mathrm{e}^x c_2}{2}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
10\sin(x) + 17\sin(2x)
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\cos(x), \sin(x)\}, \{\cos(2x), \sin(2x)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\mathrm{e}^x \cos(2x), \frac{\mathrm{e}^x \sin(2x)}{2}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 \cos(x) + A_2 \sin(x) + A_3 \cos(2x) + A_4 \sin(2x)
$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1 \cos(x) + 4A_2 \sin(x) + A_3 \cos(2x) + A_4 \sin(2x) + 2A_1 \sin(x) - 2A_2 \cos(x) + 4A_3 \sin(2x) - 4A_4 \cos(2x) = 10 \sin(x) + 17 \sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = 2, A_3 = 4, A_4 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \cos(x) + 2\sin(x) + 4\cos(2x) + \sin(2x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^x \cos(2x) c_1 + \frac{\sin(2x) e^x c_2}{2}\right) + (\cos(x) + 2\sin(x) + 4\cos(2x) + \sin(2x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^x \cos(2x) c_1 + \frac{\sin(2x) e^x c_2}{2} + \cos(x) + 2\sin(x) + 4\cos(2x) + \sin(2x) \tag{1}$$

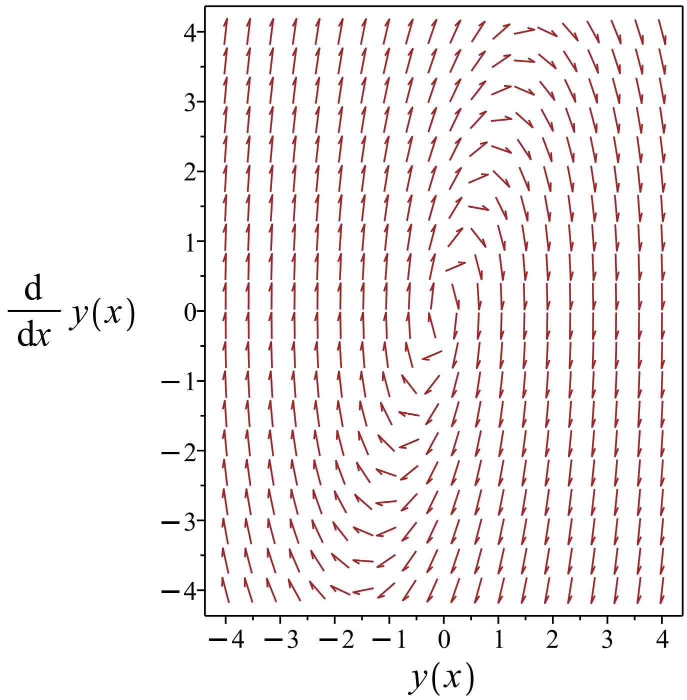

Figure 677: Slope field plot

Verification of solutions

$$y = e^{x} \cos(2x) c_1 + \frac{\sin(2x) e^{x} c_2}{2} + \cos(x) + 2\sin(x) + 4\cos(2x) + \sin(2x)$$

Verified OK.

17.19.3 Maple step by step solution

Let's solve

$y'' - 2y' + 5y = 10\sin(x) + 17\sin(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 5 = 0$

- Use quadratic formula to solve for r

  $r = \frac{2 \pm (\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

$r = (1-2\mathrm{I}, 1+2\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^x \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^x \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \mathrm{e}^x \cos(2x) c_1 + \sin(2x) \mathrm{e}^x c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))} dx\right), f(x) = 10\sin(x) + 17\sin(2x)\right.$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^x \cos(2x) & \mathrm{e}^x \sin(2x) \\ \mathrm{e}^x \cos(2x) - 2\,\mathrm{e}^x \sin(2x) & \mathrm{e}^x \sin(2x) + 2\,\mathrm{e}^x \cos(2x) \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2\,\mathrm{e}^{2x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = \mathrm{e}^x\left(-\cos(2x)\left(\int \sin(2x)(17\cos(x)+5)\sin(x)\,\mathrm{e}^{-x} dx\right) + \sin(2x)\left(\int \cos(2x)(17\cos(x)\right.\right.$

  ◦ Compute integrals

  $y_p(x) = 8\cos(x)^2 + (2\sin(x)+1)\cos(x) + 2\sin(x) - 4$

- Substitute particular solution into general solution to ODE

  $y = \mathrm{e}^x \cos(2x) c_1 + \sin(2x) \mathrm{e}^x c_2 + 8\cos(x)^2 + (2\sin(x)+1)\cos(x) + 2\sin(x) - 4$

Problem number: 570.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + y' = x^2 - e^{-x} + e^x}$$

17.20.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = 0, f(x) = x^2 - e^{-x} + e^x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=1, B=1, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x}+\lambda\,\mathrm{e}^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2+\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=1, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{-1}{(2)\,(1)}\pm\frac{1}{(2)\,(1)}\sqrt{1^2-(4)\,(1)\,(0)}\\&=-\frac{1}{2}\pm\frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1&=-\frac{1}{2}+\frac{1}{2}\\\lambda_2&=-\frac{1}{2}-\frac{1}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1&=0\\\lambda_2&=-1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y&=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}\\y&=c_1e^{(0)x}+c_2e^{(-1)x}\end{aligned}$$

Or

$$y = c_1 + e^{-x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + e^{-x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 - e^{-x} + e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}, \{e^{-x}\}, \{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^x\}, \{e^{-x}\}, \{x, x^2, x^3\}]$$

Since e^{-x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^x\}, \{x\, e^{-x}\}, \{x, x^2, x^3\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^x + A_2 x\, e^{-x} + A_3 x + A_4 x^2 + A_5 x^3$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^x - A_2 e^{-x} + 2A_4 + 6A_5 x + A_3 + 2A_4 x + 3A_5 x^2 = x^2 - e^{-x} + e^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = 1, A_3 = 2, A_4 = -1, A_5 = \frac{1}{3}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x}{2} + x\,e^{-x} + 2x - x^2 + \frac{x^3}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 + e^{-x}c_2) + \left(\frac{e^x}{2} + x\,e^{-x} + 2x - x^2 + \frac{x^3}{3}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + e^{-x}c_2 + \frac{e^x}{2} + x\,e^{-x} + 2x - x^2 + \frac{x^3}{3} \tag{1}$$

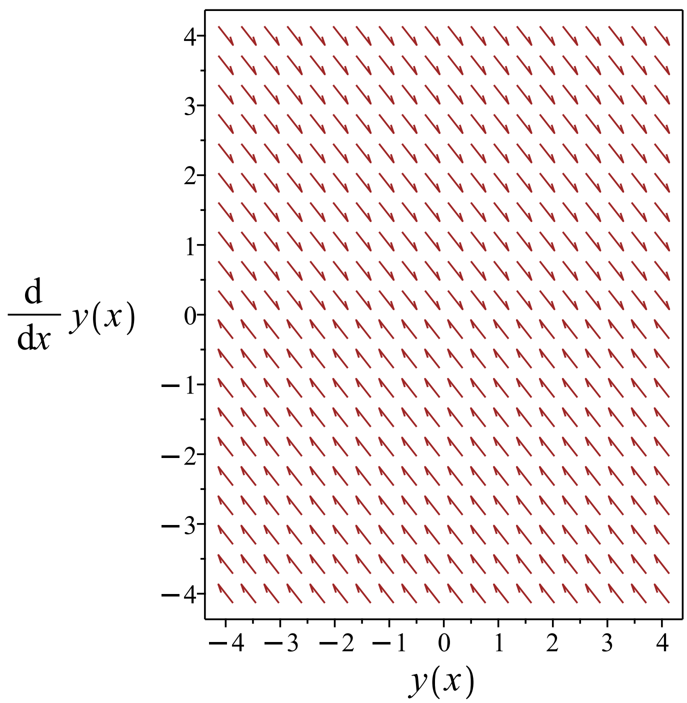

Figure 678: Slope field plot

Verification of solutions

$$y = c_1 + e^{-x}c_2 + \frac{e^x}{2} + x\,e^{-x} + 2x - x^2 + \frac{x^3}{3}$$

Verified OK.

17.20.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y''+y')\,dx = \int (x^2-\mathrm{e}^{-x}+\mathrm{e}^{x})\,dx$$

$$y'+y = \frac{x^3}{3}+\mathrm{e}^{-x}+\mathrm{e}^{x}+c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 1\\ q(x) &= \frac{x^3}{3}+\mathrm{e}^{-x}+\mathrm{e}^{x}+c_1 \end{aligned}$$

Hence the ode is

$$y'+y = \frac{x^3}{3}+\mathrm{e}^{-x}+\mathrm{e}^{x}+c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int 1dx}\\ &= \mathrm{e}^{x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{x^3}{3}+\mathrm{e}^{-x}+\mathrm{e}^{x}+c_1\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}(\mathrm{e}^{x} y) &= (\mathrm{e}^{x})\left(\frac{x^3}{3}+\mathrm{e}^{-x}+\mathrm{e}^{x}+c_1\right)\\ \mathrm{d}(\mathrm{e}^{x} y) &= \left(\mathrm{e}^{2x}+1+\frac{(x^3+3c_1)\,\mathrm{e}^{x}}{3}\right)\,\mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} \mathrm{e}^{x} y &= \int \mathrm{e}^{2x}+1+\frac{(x^3+3c_1)\,\mathrm{e}^{x}}{3}\,\mathrm{d}x\\ \mathrm{e}^{x} y &= x+\frac{x^3\mathrm{e}^{x}}{3}-\mathrm{e}^{x}x^2+2x\,\mathrm{e}^{x}-2\,\mathrm{e}^{x}+\mathrm{e}^{x}c_1+\frac{\mathrm{e}^{2x}}{2}+c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^x$ results in

$$y = e^{-x}\left(x + \frac{x^3 e^x}{3} - e^x x^2 + 2x\, e^x - 2\, e^x + e^x c_1 + \frac{e^{2x}}{2}\right) + e^{-x} c_2$$

which simplifies to

$$y = -2 + (x + c_2)\, e^{-x} + \frac{x^3}{3} - x^2 + 2x + c_1 + \frac{e^x}{2}$$

Summary

The solution(s) found are the following

$$y = -2 + (x + c_2)\, e^{-x} + \frac{x^3}{3} - x^2 + 2x + c_1 + \frac{e^x}{2} \tag{1}$$

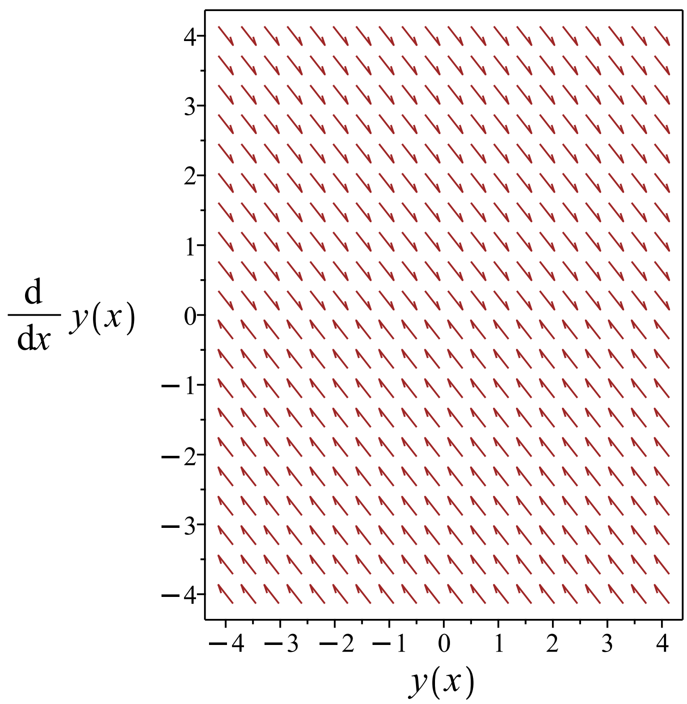

Figure 679: Slope field plot

Verification of solutions

$$y = -2 + (x + c_2)\, e^{-x} + \frac{x^3}{3} - x^2 + 2x + c_1 + \frac{e^x}{2}$$

Verified OK.

17.20.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + p(x) - x^2 + \mathrm{e}^{-x} - \mathrm{e}^x = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned}
p(x) &= 1 \\
q(x) &= x^2 - \mathrm{e}^{-x} + \mathrm{e}^x
\end{aligned}$$

Hence the ode is

$$p'(x) + p(x) = x^2 - \mathrm{e}^{-x} + \mathrm{e}^x$$

The integrating factor μ is

$$\begin{aligned}
\mu &= \mathrm{e}^{\int 1dx} \\
&= \mathrm{e}^x
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu p) &= (\mu)\left(x^2 - \mathrm{e}^{-x} + \mathrm{e}^x\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}(p\,\mathrm{e}^x) &= (\mathrm{e}^x)\left(x^2 - \mathrm{e}^{-x} + \mathrm{e}^x\right) \\
\mathrm{d}(p\,\mathrm{e}^x) &= \left(\mathrm{e}^x x^2 + \mathrm{e}^{2x} - 1\right)\,\mathrm{d}x
\end{aligned}$$

Integrating gives

$$\begin{aligned}
p\,\mathrm{e}^x &= \int \mathrm{e}^x x^2 + \mathrm{e}^{2x} - 1\,\mathrm{d}x \\
p\,\mathrm{e}^x &= -x + \mathrm{e}^x x^2 - 2x\,\mathrm{e}^x + 2\,\mathrm{e}^x + \frac{\mathrm{e}^{2x}}{2} + c_1
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^x$ results in

$$p(x) = e^{-x}\left(-x + e^x x^2 - 2x\,e^x + 2\,e^x + \frac{e^{2x}}{2}\right) + c_1 e^{-x}$$

which simplifies to

$$p(x) = 2 + (-x + c_1)\,e^{-x} + x^2 - 2x + \frac{e^x}{2}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = 2 + (-x + c_1)\,e^{-x} + x^2 - 2x + \frac{e^x}{2}$$

Integrating both sides gives

$$\begin{aligned} y &= \int -x\,e^{-x} + x^2 - 2x + 2 + \frac{e^x}{2} + c_1 e^{-x}\,dx \\ &= -x^2 + 2x + \frac{x^3}{3} - c_1 e^{-x} + x\,e^{-x} + e^{-x} + \frac{e^x}{2} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -x^2 + 2x + \frac{x^3}{3} - c_1 e^{-x} + x\,e^{-x} + e^{-x} + \frac{e^x}{2} + c_2 \tag{1}$$

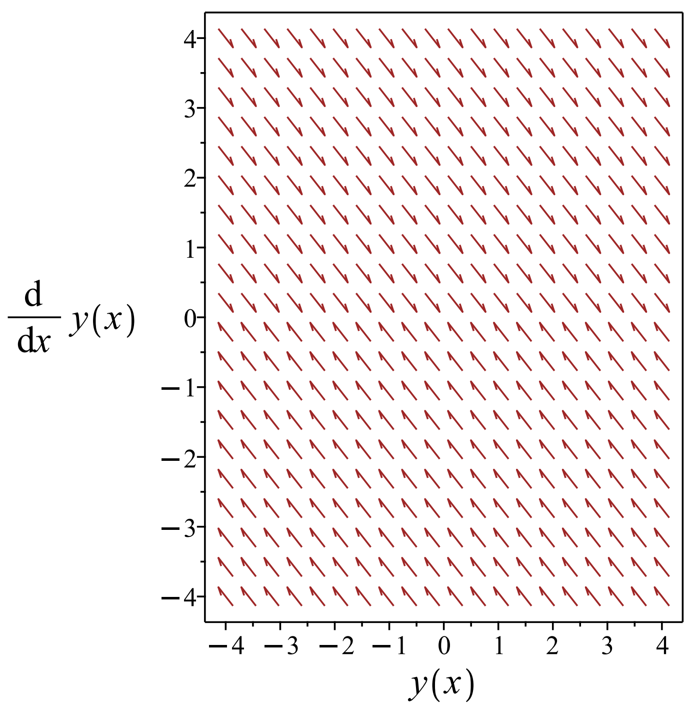

Figure 680: Slope field plot

Verification of solutions

$$y = -x^2 + 2x + \frac{x^3}{3} - c_1 e^{-x} + x\,e^{-x} + e^{-x} + \frac{e^x}{2} + c_2$$

Verified OK.

17.20.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + y' = x^2 - e^{-x} + e^x$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + y')\,dx = \int (x^2 - e^{-x} + e^x)\,dx$$
$$y' + y = \frac{x^3}{3} + e^{-x} + e^x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 1$$
$$q(x) = \frac{x^3}{3} + e^{-x} + e^x + c_1$$

Hence the ode is

$$y' + y = \frac{x^3}{3} + e^{-x} + e^x + c_1$$

The integrating factor μ is

$$\mu = e^{\int 1 dx}$$
$$= e^x$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{x^3}{3} + e^{-x} + e^x + c_1\right)$$
$$\frac{d}{dx}(e^x y) = (e^x)\left(\frac{x^3}{3} + e^{-x} + e^x + c_1\right)$$
$$d(e^x y) = \left(e^{2x} + 1 + \frac{(x^3 + 3c_1)\,e^x}{3}\right)\,dx$$

Integrating gives

$$e^{x}y = \int e^{2x} + 1 + \frac{(x^3 + 3c_1)e^{x}}{3}\, dx$$

$$e^{x}y = x + \frac{x^3 e^{x}}{3} - e^{x}x^2 + 2x\,e^{x} - 2\,e^{x} + e^{x}c_1 + \frac{e^{2x}}{2} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{x}$ results in

$$y = e^{-x}\left(x + \frac{x^3 e^{x}}{3} - e^{x}x^2 + 2x\,e^{x} - 2\,e^{x} + e^{x}c_1 + \frac{e^{2x}}{2}\right) + e^{-x}c_2$$

which simplifies to

$$y = -2 + (x + c_2)\,e^{-x} + \frac{x^3}{3} - x^2 + 2x + c_1 + \frac{e^{x}}{2}$$

Summary

The solution(s) found are the following

$$y = -2 + (x + c_2)\,e^{-x} + \frac{x^3}{3} - x^2 + 2x + c_1 + \frac{e^{x}}{2} \tag{1}$$

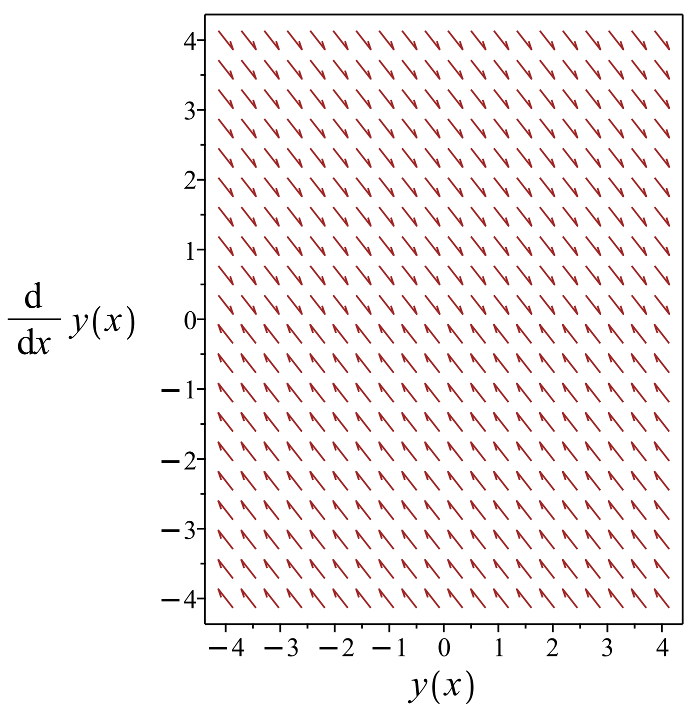

Figure 681: Slope field plot

Verification of solutions

$$y = -2 + (x + c_2)\,\mathrm{e}^{-x} + \frac{x^3}{3} - x^2 + 2x + c_1 + \frac{\mathrm{e}^x}{2}$$

Verified OK.

17.20.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 1 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 530: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\,dx} \\
&= z_1 e^{-\frac{x}{2}} \\
&= z_1\left(\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x}}{(y_1)^2}\,dx \\
&= y_1(\mathrm{e}^{x})
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-x}\right) + c_2\left(\mathrm{e}^{-x}(\mathrm{e}^{x})\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+y'=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{-x} + c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 - e^{-x} + e^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{x}\}, \{e^{-x}\}, \{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-x}\}$$

Since e^{-x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{x}\}, \{x\,e^{-x}\}, \{1, x, x^2\}]$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{x}\}, \{x\,e^{-x}\}, \{x, x^2, x^3\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^{x} + A_2 x\,e^{-x} + A_3 x + A_4 x^2 + A_5 x^3$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{x} - A_2 e^{-x} + 2A_4 + 6A_5 x + A_3 + 2A_4 x + 3A_5 x^2 = x^2 - e^{-x} + e^{x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = 1, A_3 = 2, A_4 = -1, A_5 = \frac{1}{3}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x}{2} + x\,e^{-x} + 2x - x^2 + \frac{x^3}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 e^{-x} + c_2) + \left(\frac{e^x}{2} + x\,e^{-x} + 2x - x^2 + \frac{x^3}{3}\right) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 + \frac{e^x}{2} + x\,e^{-x} + 2x - x^2 + \frac{x^3}{3} \tag{1}$$

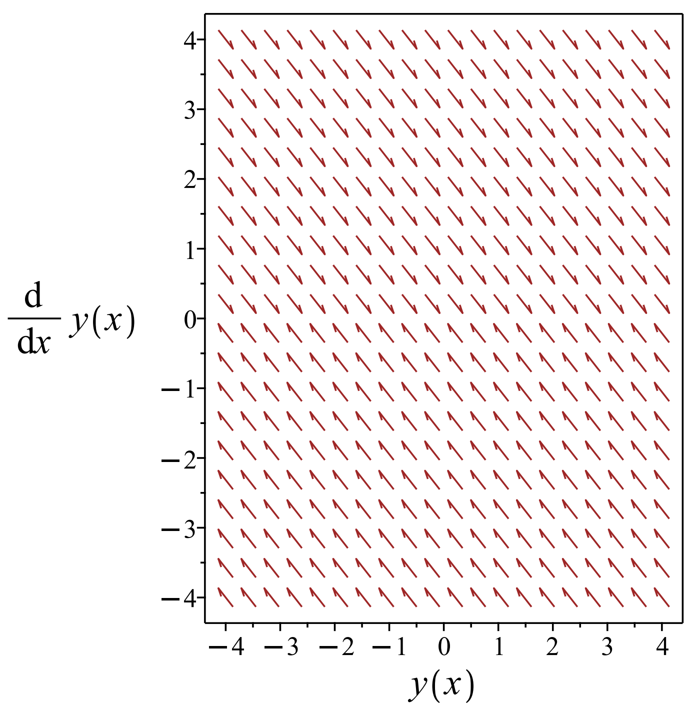

Figure 682: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + c_2 + \frac{e^x}{2} + x e^{-x} + 2x - x^2 + \frac{x^3}{3}$$

Verified OK.

17.20.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x) y'' + q(x) y' + r(x) y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 1 \\ r(x) &= 0 \\ s(x) &= x^2 - e^{-x} + e^x \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x) y' + (q(x) - p'(x)) y)' = s(x)$$

Integrating gives

$$p(x) y' + (q(x) - p'(x)) y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$y' + y = \int x^2 - e^{-x} + e^x \, dx$$

We now have a first order ode to solve which is

$$y' + y = \frac{x^3}{3} + e^{-x} + e^x + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 1 \\ q(x) &= \frac{x^3}{3} + e^{-x} + e^x + c_1 \end{aligned}$$

Hence the ode is

$$y' + y = \frac{x^3}{3} + e^{-x} + e^x + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 1dx} \\ &= e^x \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(\frac{x^3}{3} + e^{-x} + e^x + c_1\right) \\ \frac{d}{dx}(e^x y) &= (e^x)\left(\frac{x^3}{3} + e^{-x} + e^x + c_1\right) \\ d(e^x y) &= \left(e^{2x} + 1 + \frac{(x^3 + 3c_1)\, e^x}{3}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^x y &= \int e^{2x} + 1 + \frac{(x^3 + 3c_1)\, e^x}{3}\, dx \\ e^x y &= x + \frac{x^3 e^x}{3} - e^x x^2 + 2x\, e^x - 2\, e^x + e^x c_1 + \frac{e^{2x}}{2} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^x$ results in

$$y = e^{-x}\left(x + \frac{x^3 e^x}{3} - e^x x^2 + 2x\, e^x - 2\, e^x + e^x c_1 + \frac{e^{2x}}{2}\right) + e^{-x} c_2$$

which simplifies to

$$y = -2 + (x + c_2)\,e^{-x} + \frac{x^3}{3} - x^2 + 2x + c_1 + \frac{e^x}{2}$$

Summary
The solution(s) found are the following

$$y = -2 + (x + c_2)\,e^{-x} + \frac{x^3}{3} - x^2 + 2x + c_1 + \frac{e^x}{2} \tag{1}$$

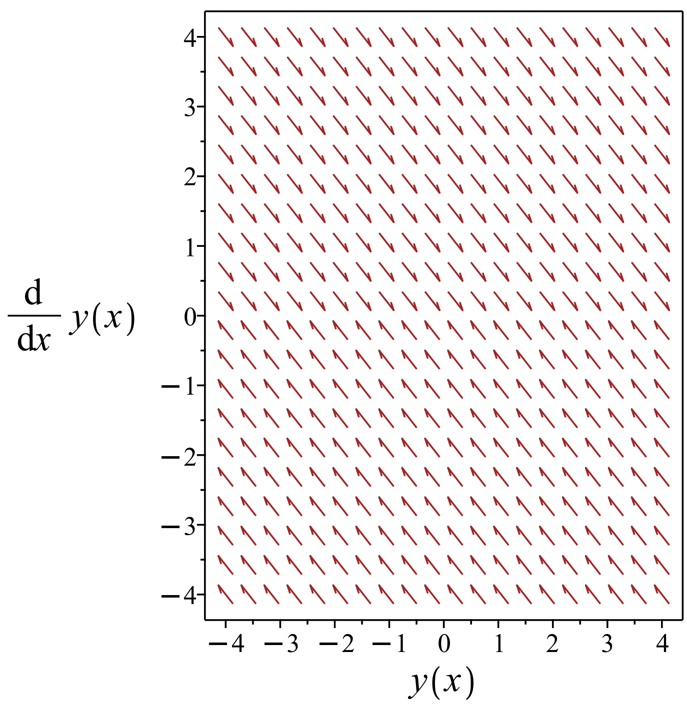

Figure 683: Slope field plot

Verification of solutions

$$y = -2 + (x + c_2)\,e^{-x} + \frac{x^3}{3} - x^2 + 2x + c_1 + \frac{e^x}{2}$$

Verified OK.

17.20.7 Maple step by step solution

Let's solve

$y'' + y' = x^2 - e^{-x} + e^{x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + r = 0$

- Factor the characteristic polynomial

  $r(r + 1) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 0)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-x} + c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x^2 - e^{-x} + e^{x}\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x} & 1 \\ -e^{-x} & 0 \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{-x}$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -e^{-x}\left(\int (e^{x} x^2 + e^{2x} - 1) dx\right) + \int (x^2 - e^{-x} + e^{x}) dx$

- Compute integrals

  $y_p(x) = x\,e^{-x} - x^2 + 2x - 2 + \frac{e^x}{2} + \frac{x^3}{3} + e^{-x}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-x} + c_2 + x\,e^{-x} - x^2 + 2x - 2 + \frac{e^x}{2} + \frac{x^3}{3} + e^{-x}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''-2y'-3y=2x+\mathrm{e}^{-x}-2\,\mathrm{e}^{3x}}$$

17.21.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=1, B=-2, C=-3, f(x)=2x+\mathrm{e}^{-x}-2\,\mathrm{e}^{3x}$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''-2y'-3y=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A = 1, B = -2, C = -3$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 2\lambda\, \mathrm{e}^{\lambda x} - 3\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda - 3 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = -3$ into the above gives

$$\begin{aligned} \lambda_{1,2} &= \frac{2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-2^2 - (4)\,(1)\,(-3)} \\ &= 1 \pm 2 \end{aligned}$$

Hence

$$\begin{aligned} \lambda_1 &= 1 + 2 \\ \lambda_2 &= 1 - 2 \end{aligned}$$

Which simplifies to

$$\begin{aligned} \lambda_1 &= 3 \\ \lambda_2 &= -1 \end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned} y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(3)x} + c_2 e^{(-1)x} \end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{3x} + \mathrm{e}^{-x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{3x} + \mathrm{e}^{-x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2x + e^{-x} - 2\,e^{3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-x}\}, \{e^{3x}\}, \{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-x}, e^{3x}\}$$

Since e^{3x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{-x}\}, \{e^{3x}x\}, \{1, x\}]$$

Since e^{-x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{-x}\}, \{e^{3x}x\}, \{1, x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^{-x} + A_2 e^{3x} x + A_3 + A_4 x$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 e^{-x} + 4A_2 e^{3x} - 2A_4 - 3A_3 - 3A_4 x = 2x + e^{-x} - 2\,e^{3x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{4}, A_2 = -\frac{1}{2}, A_3 = \frac{4}{9}, A_4 = -\frac{2}{3}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\,e^{-x}}{4} - \frac{e^{3x}x}{2} + \frac{4}{9} - \frac{2x}{3}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 e^{3x} + e^{-x} c_2\right) + \left(-\frac{x\, e^{-x}}{4} - \frac{e^{3x} x}{2} + \frac{4}{9} - \frac{2x}{3}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^{3x} + e^{-x} c_2 - \frac{x\, e^{-x}}{4} - \frac{e^{3x} x}{2} + \frac{4}{9} - \frac{2x}{3} \tag{1}
$$

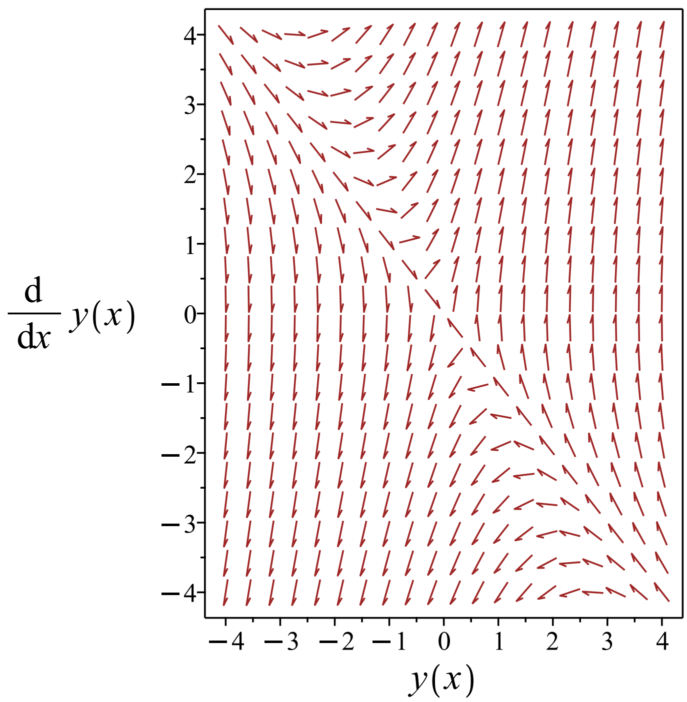

Figure 684: Slope field plot

Verification of solutions

$$
y = c_1 e^{3x} + e^{-x} c_2 - \frac{x\, e^{-x}}{4} - \frac{e^{3x} x}{2} + \frac{4}{9} - \frac{2x}{3}
$$

Verified OK.

17.21.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' - 3y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= -3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 532: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-2x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-2}{1} \, dx}
\end{aligned}$$

$$= z_1 e^x$$
$$= z_1 (\mathrm{e}^x)$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\, dx \\ &= y_1 \left(\frac{\mathrm{e}^{4x}}{4}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 (\mathrm{e}^{-x}) + c_2 \left(\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{4x}}{4}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' - 3y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{3x}}{4}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^{-x}$$
$$y_2 = \frac{e^{3x}}{4}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-x} & \frac{e^{3x}}{4} \\ \frac{d}{dx}\left(e^{-x}\right) & \frac{d}{dx}\left(\frac{e^{3x}}{4}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-x} & \frac{e^{3x}}{4} \\ -e^{-x} & \frac{3\,e^{3x}}{4} \end{vmatrix}$$

Therefore

$$W = \left(e^{-x}\right)\left(\frac{3\,e^{3x}}{4}\right) - \left(\frac{e^{3x}}{4}\right)\left(-e^{-x}\right)$$

Which simplifies to

$$W = e^{-x} e^{3x}$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{e^{3x}(2x+e^{-x}-2e^{3x})}{4}}{e^{2x}} dx$$

Which simplifies to

$$u_1 = -\int \left(-\frac{e^{4x}}{2} + \frac{x e^{x}}{2} + \frac{1}{4}\right) dx$$

Hence

$$u_1 = -\frac{x}{4} - \frac{x e^{x}}{2} + \frac{e^{x}}{2} + \frac{e^{4x}}{8}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{-x}(2x + e^{-x} - 2e^{3x})}{e^{2x}} dx$$

Which simplifies to

$$u_2 = \int \left(2x e^{x} - 2e^{4x} + 1\right) e^{-4x} dx$$

Hence

$$u_2 = -2x - \frac{e^{-4x}}{4} - \frac{2x e^{-3x}}{3} - \frac{2e^{-3x}}{9}$$

Which simplifies to

$$u_1 = \frac{e^{4x}}{8} + \frac{(-4x+4)e^{x}}{8} - \frac{x}{4}$$
$$u_2 = \frac{2(-1-3x)e^{-3x}}{9} - 2x - \frac{e^{-4x}}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{e^{4x}}{8} + \frac{(-4x+4)e^{x}}{8} - \frac{x}{4}\right)e^{-x} + \frac{\left(\frac{2(-1-3x)e^{-3x}}{9} - 2x - \frac{e^{-4x}}{4}\right)e^{3x}}{4}$$

Which simplifies to

$$y_p(x) = \frac{4}{9} + \frac{(-4x-1)\,\mathrm{e}^{-x}}{16} + \frac{(1-4x)\,\mathrm{e}^{3x}}{8} - \frac{2x}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{3x}}{4}\right) + \left(\frac{4}{9} + \frac{(-4x-1)\,\mathrm{e}^{-x}}{16} + \frac{(1-4x)\,\mathrm{e}^{3x}}{8} - \frac{2x}{3}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{3x}}{4} + \frac{4}{9} + \frac{(-4x-1)\,\mathrm{e}^{-x}}{16} + \frac{(1-4x)\,\mathrm{e}^{3x}}{8} - \frac{2x}{3} \tag{1}$$

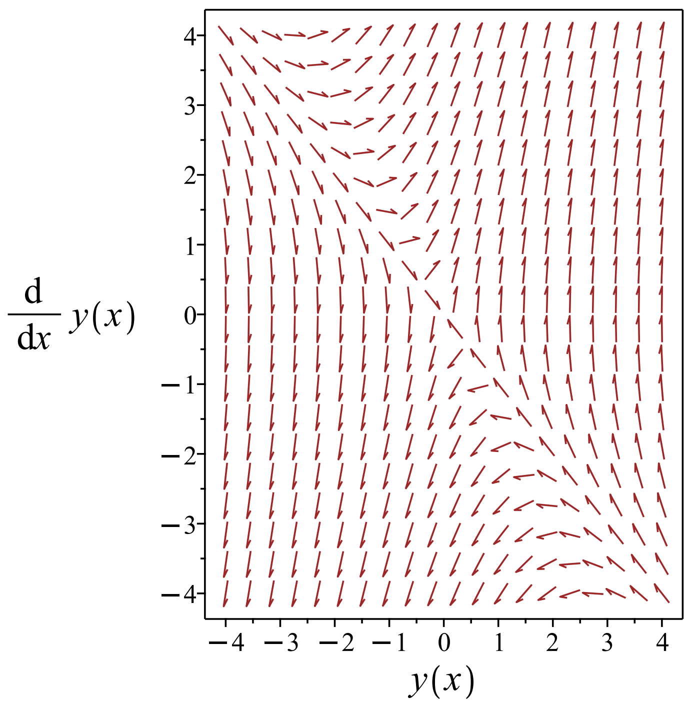

Figure 685: Slope field plot

Verification of solutions

$$y = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{3x}}{4} + \frac{4}{9} + \frac{(-4x-1)\,\mathrm{e}^{-x}}{16} + \frac{(1-4x)\,\mathrm{e}^{3x}}{8} - \frac{2x}{3}$$

Verified OK.

17.21.3 Maple step by step solution

Let's solve

$y'' - 2y' - 3y = 2x + e^{-x} - 2\,e^{3x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r - 3 = 0$

- Factor the characteristic polynomial

  $(r+1)(r-3) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 3)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-x} + c_2 e^{3x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ∘ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 2x + e^{-x} - 2\,e^{3x}\right]$

- ∘ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x} & e^{3x} \\ -e^{-x} & 3\,e^{3x} \end{bmatrix}$

- ∘ Compute Wronskian

  $W(y_1(x), y_2(x)) = 4\,e^{2x}$

- ∘ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{e^{-x}\left(\int (2x e^x - 2e^{4x} + 1)\,dx\right)}{4} + \frac{e^{3x}\left(\int (2x e^x - 2e^{4x} + 1)e^{-4x}\,dx\right)}{4}$$

- Compute integrals

$$y_p(x) = \frac{4}{9} + \frac{(-4x-1)e^{-x}}{16} + \frac{(1-4x)e^{3x}}{8} - \frac{2x}{3}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 e^{-x} + c_2 e^{3x} + \frac{4}{9} + \frac{(-4x-1)e^{-x}}{16} + \frac{(1-4x)e^{3x}}{8} - \frac{2x}{3}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 4y = e^{x} + 4\sin(2x) + 2\cos(x)^{2} - 1}$$

17.22.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 4, f(x) = e^{x} + \cos(2x) + 4\sin(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(4)}\\ &= \pm 2i\end{aligned}$$

Hence

$$\lambda_1 = +2i$$
$$\lambda_2 = -2i$$

Which simplifies to

$$\lambda_1 = 2i$$
$$\lambda_2 = -2i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(2x) + c_2 \sin(2x))$$

Or

$$y = c_1 \cos(2x) + c_2 \sin(2x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(2x) + c_2 \sin(2x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x + \cos(2x) + 4\sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}, \{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(2x), \sin(2x)\}$$

Since $\cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^x\}, \{x\cos(2x), x\sin(2x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^x + A_2 x \cos(2x) + A_3 x \sin(2x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$5A_1 e^x - 4A_2 \sin(2x) + 4A_3 \cos(2x) = e^x + \cos(2x) + 4\sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{5}, A_2 = -1, A_3 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x}{5} - x\cos(2x) + \frac{x\sin(2x)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(2x) + c_2\sin(2x)) + \left(\frac{e^x}{5} - x\cos(2x) + \frac{x\sin(2x)}{4}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1\cos(2x) + c_2\sin(2x) + \frac{e^x}{5} - x\cos(2x) + \frac{x\sin(2x)}{4} \tag{1}$$

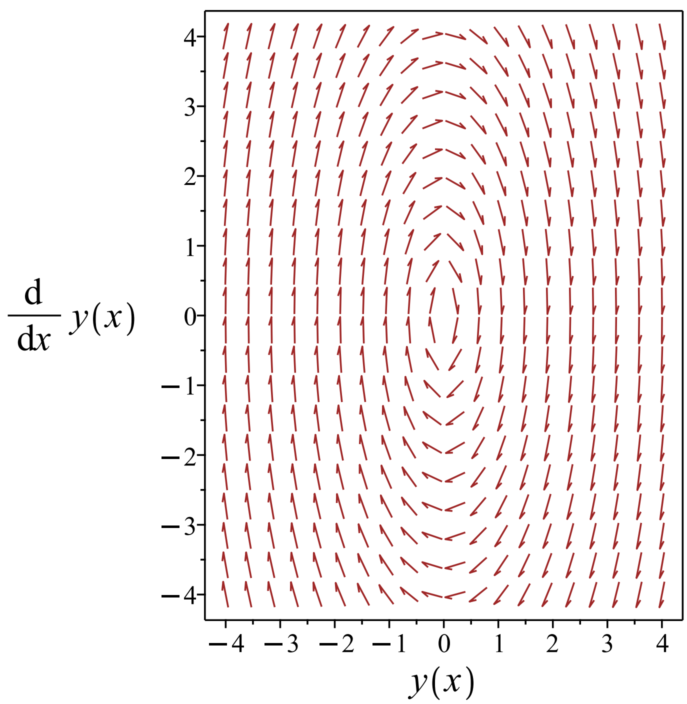

Figure 686: Slope field plot

Verification of solutions

$$y = c_1\cos(2x) + c_2\sin(2x) + \frac{e^x}{5} - x\cos(2x) + \frac{x\sin(2x)}{4}$$

Verified OK.

17.22.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 534: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(2x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B=0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(2x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B=0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(2x) \int \frac{1}{\cos(2x)^2}\,dx \\ &= \cos(2x)\left(\frac{\tan(2x)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(2x)) + c_2\left(\cos(2x)\left(\frac{\tan(2x)}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x + \cos(2x) + 4\sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}, \{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sin(2x)}{2}, \cos(2x)\right\}$$

Since $\cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^x\}, \{x\cos(2x), x\sin(2x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^x + A_2 x\cos(2x) + A_3 x\sin(2x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$5A_1 e^x - 4A_2 \sin(2x) + 4A_3 \cos(2x) = e^x + \cos(2x) + 4\sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{5}, A_2 = -1, A_3 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x}{5} - x\cos(2x) + \frac{x\sin(2x)}{4}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2}\right) + \left(\frac{e^x}{5} - x \cos(2x) + \frac{x \sin(2x)}{4}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2} + \frac{e^x}{5} - x \cos(2x) + \frac{x \sin(2x)}{4} \tag{1}
$$

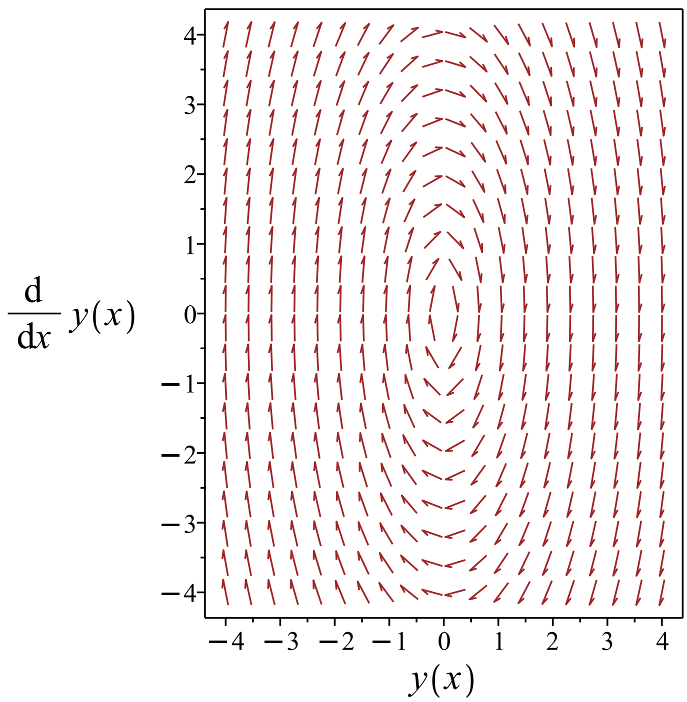

Figure 687: Slope field plot

Verification of solutions

$$
y = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2} + \frac{e^x}{5} - x \cos(2x) + \frac{x \sin(2x)}{4}
$$

Verified OK.

17.22.3 Maple step by step solution

Let's solve

$y'' + 4y = e^x + \cos(2x) + 4\sin(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r = (-2\,\mathrm{I}, 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(2x) + c_2 \sin(2x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = e^x + \cos(2x) + 4\sin(2\right.$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(2x) & \sin(2x) \\ -2\sin(2x) & 2\cos(2x) \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2$

- ○ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{\cos(2x)\left(\int \sin(2x)\left(e^x+\cos(2x)+4\sin(2x)\right)dx\right)}{2} + \frac{\sin(2x)\left(\int \cos(2x)\left(e^x+\cos(2x)+4\sin(2x)\right)dx\right)}{2}$$

- Compute integrals

$$y_p(x) = -2\cos(x)^2 x + \frac{\sin(x)(2+x)\cos(x)}{2} + x + \frac{e^x}{5}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 \cos(2x) + c_2 \sin(2x) - 2\cos(x)^2 x + \frac{\sin(x)(2+x)\cos(x)}{2} + x + \frac{e^x}{5}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 3y' + 2y = 6x\,\mathrm{e}^{-x}\left(1 - \mathrm{e}^{-x}\right)}$$

17.23.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 3, C = 2, f(x) = -6x\,\mathrm{e}^{-x}(\mathrm{e}^{-x} - 1)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 3y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 3, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 3\lambda\, e^{\lambda x} + 2\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 3\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 3, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-3}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{3^2 - (4)\,(1)\,(2)} \\ &= -\frac{3}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{3}{2} + \frac{1}{2} \\ \lambda_2 &= -\frac{3}{2} - \frac{1}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 \\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(-1)x} + c_2 e^{(-2)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{-x} + \mathrm{e}^{-2x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{-x} + \mathrm{e}^{-2x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$-6x\,\mathrm{e}^{-x}(\mathrm{e}^{-x} - 1)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,\mathrm{e}^{-2x}, \mathrm{e}^{-2x}\}, \{x\,\mathrm{e}^{-x}, \mathrm{e}^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-2x}, \mathrm{e}^{-x}\}$$

Since e^{-x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,\mathrm{e}^{-2x}, \mathrm{e}^{-2x}\}, \{x\,\mathrm{e}^{-x}, \mathrm{e}^{-x} x^2\}]$$

Since e^{-2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,\mathrm{e}^{-2x}, \mathrm{e}^{-2x} x^2\}, \{x\,\mathrm{e}^{-x}, \mathrm{e}^{-x} x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,\mathrm{e}^{-2x} + A_2 \mathrm{e}^{-2x} x^2 + A_3 x\,\mathrm{e}^{-x} + A_4 \mathrm{e}^{-x} x^2$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 \mathrm{e}^{-2x} - 2A_2 \mathrm{e}^{-2x} x + 2A_2 \mathrm{e}^{-2x} + A_3 \mathrm{e}^{-x} + 2A_4 \mathrm{e}^{-x} x + 2A_4 \mathrm{e}^{-x} = -6x\,\mathrm{e}^{-x}(\mathrm{e}^{-x} - 1)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 6, A_2 = 3, A_3 = -6, A_4 = 3]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 6x\,\mathrm{e}^{-2x} + 3\,\mathrm{e}^{-2x} x^2 - 6x\,\mathrm{e}^{-x} + 3\,\mathrm{e}^{-x} x^2$$

Therefore the general solution is

$$y = y_h + y_p$$
$$= \left(c_1 e^{-x} + e^{-2x} c_2\right) + \left(6x\, e^{-2x} + 3\, e^{-2x} x^2 - 6x\, e^{-x} + 3\, e^{-x} x^2\right)$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + e^{-2x} c_2 + 6x\, e^{-2x} + 3\, e^{-2x} x^2 - 6x\, e^{-x} + 3\, e^{-x} x^2 \quad (1)$$

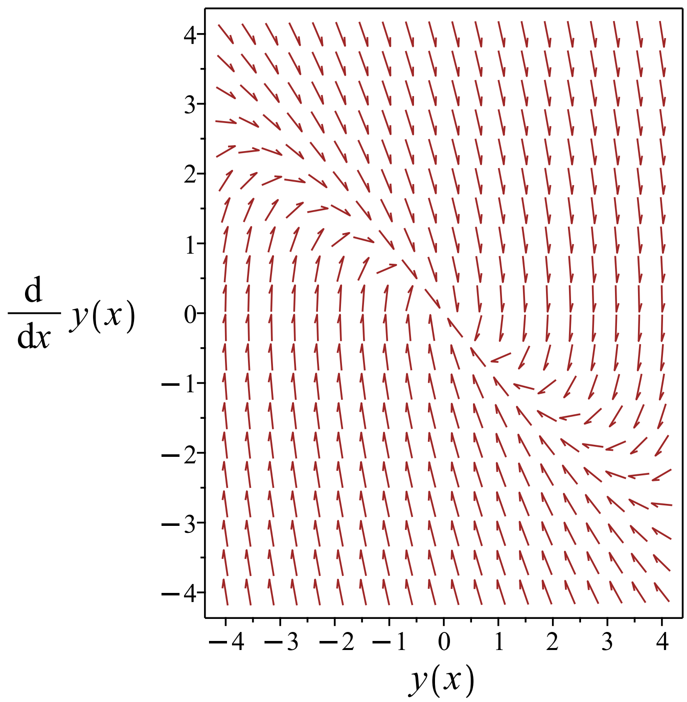

Figure 688: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + e^{-2x} c_2 + 6x\, e^{-2x} + 3\, e^{-2x} x^2 - 6x\, e^{-x} + 3\, e^{-x} x^2$$

Verified OK.

17.23.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 3y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 3 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 536: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = e^{-\frac{x}{2}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3}{1}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{-\frac{3x}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{3x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-3x}}{(y_1)^2}\, dx \\
&= y_1(\mathrm{e}^x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-2x}\right) + c_2\left(\mathrm{e}^{-2x}(\mathrm{e}^x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 3y' + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-2x} + \mathrm{e}^{-x} c_2
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$-6x\,\mathrm{e}^{-x}\left(\mathrm{e}^{-x}-1\right)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,\mathrm{e}^{-2x}, \mathrm{e}^{-2x}\}, \{x\,\mathrm{e}^{-x}, \mathrm{e}^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-2x}, \mathrm{e}^{-x}\}$$

Since e^{-2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,\mathrm{e}^{-2x}, \mathrm{e}^{-2x}x^2\}, \{x\,\mathrm{e}^{-x}, \mathrm{e}^{-x}\}]$$

Since e^{-x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,\mathrm{e}^{-2x}, \mathrm{e}^{-2x}x^2\}, \{x\,\mathrm{e}^{-x}, \mathrm{e}^{-x}x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,\mathrm{e}^{-2x} + A_2\mathrm{e}^{-2x}x^2 + A_3 x\,\mathrm{e}^{-x} + A_4\mathrm{e}^{-x}x^2$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1\mathrm{e}^{-2x} - 2A_2\mathrm{e}^{-2x}x + 2A_2\mathrm{e}^{-2x} + A_3\mathrm{e}^{-x} + 2A_4\mathrm{e}^{-x}x + 2A_4\mathrm{e}^{-x} = -6x\,\mathrm{e}^{-x}\left(\mathrm{e}^{-x}-1\right)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 6, A_2 = 3, A_3 = -6, A_4 = 3]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 6x\,\mathrm{e}^{-2x} + 3\,\mathrm{e}^{-2x}x^2 - 6x\,\mathrm{e}^{-x} + 3\,\mathrm{e}^{-x}x^2$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \mathrm{e}^{-2x} + \mathrm{e}^{-x} c_2\right) + \left(6x\,\mathrm{e}^{-2x} + 3\,\mathrm{e}^{-2x} x^2 - 6x\,\mathrm{e}^{-x} + 3\,\mathrm{e}^{-x} x^2\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-2x} + \mathrm{e}^{-x} c_2 + 6x\,\mathrm{e}^{-2x} + 3\,\mathrm{e}^{-2x} x^2 - 6x\,\mathrm{e}^{-x} + 3\,\mathrm{e}^{-x} x^2 \tag{1}
$$

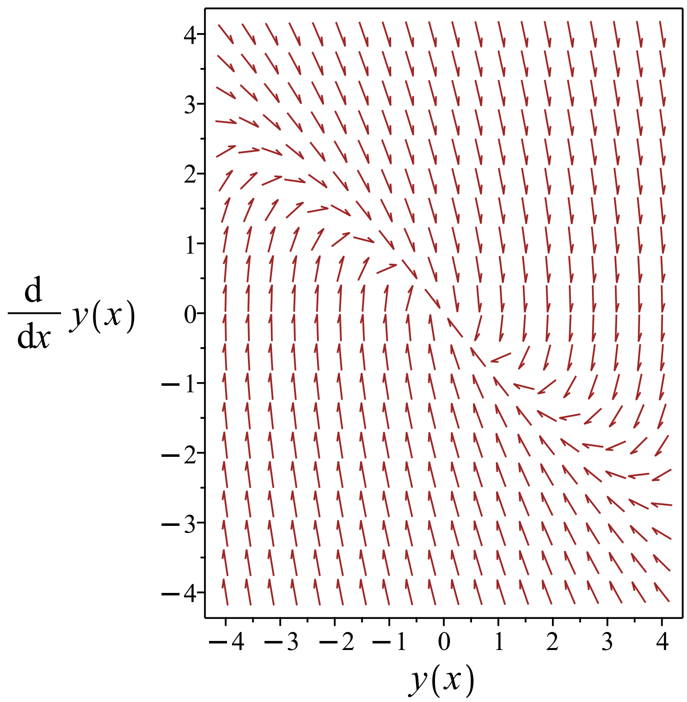

Figure 689: Slope field plot

Verification of solutions

$$
y = c_1 \mathrm{e}^{-2x} + \mathrm{e}^{-x} c_2 + 6x\,\mathrm{e}^{-2x} + 3\,\mathrm{e}^{-2x} x^2 - 6x\,\mathrm{e}^{-x} + 3\,\mathrm{e}^{-x} x^2
$$

Verified OK.

17.23.3 Maple step by step solution

Let's solve

$y'' + 3y' + 2y = -6x\,\mathrm{e}^{-x}(\mathrm{e}^{-x} - 1)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 3r + 2 = 0$

- Factor the characteristic polynomial

  $(r+2)(r+1) = 0$

- Roots of the characteristic polynomial

  $r = (-2, -1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1\mathrm{e}^{-2x} + \mathrm{e}^{-x}c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = -6x\,\mathrm{e}^{-x}(\mathrm{e}^{-x} - 1)\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-2x} & \mathrm{e}^{-x} \\ -2\,\mathrm{e}^{-2x} & -\mathrm{e}^{-x} \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = \mathrm{e}^{-3x}$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -6\,\mathrm{e}^{-2x}\left(\int x(-1 + \mathrm{e}^{x})\,dx\right) - 6\,\mathrm{e}^{-x}\left(\int (\mathrm{e}^{-x} - 1)\,x dx\right)$

- Compute integrals

  $y_p(x) = (3x^2+6x+6)\,e^{-2x} + 3\,e^{-x}(x^2-2x+2)$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-2x} + e^{-x} c_2 + (3x^2+6x+6)\,e^{-2x} + 3\,e^{-x}(x^2-2x+2)$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = \cos(2x)^2 + \sin\left(\frac{x}{2}\right)^2}$$

17.24.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = \frac{\cos(4x)}{2} + 1 - \frac{\cos(x)}{2}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)}\\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i\\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i\\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\frac{\cos(4x)}{2} + 1 - \frac{\cos(x)}{2}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{\cos(x), \sin(x)\}, \{\cos(4x), \sin(4x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{1\}, \{\cos(x)\, x, \sin(x)\, x\}, \{\cos(4x), \sin(4x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 + A_2 \cos(x)\, x + A_3 \sin(x)\, x + A_4 \cos(4x) + A_5 \sin(4x)$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_2 \sin(x) + 2A_3 \cos(x) - 15A_4 \cos(4x) - 15A_5 \sin(4x) + A_1 = \frac{\cos(4x)}{2} + 1 - \frac{\cos(x)}{2}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 1, A_2 = 0, A_3 = -\frac{1}{4}, A_4 = -\frac{1}{30}, A_5 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 1 - \frac{\sin(x)\, x}{4} - \frac{\cos(4x)}{30}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + \left(1 - \frac{\sin(x)\, x}{4} - \frac{\cos(4x)}{30}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) + 1 - \frac{\sin(x)\, x}{4} - \frac{\cos(4x)}{30} \tag{1}$$

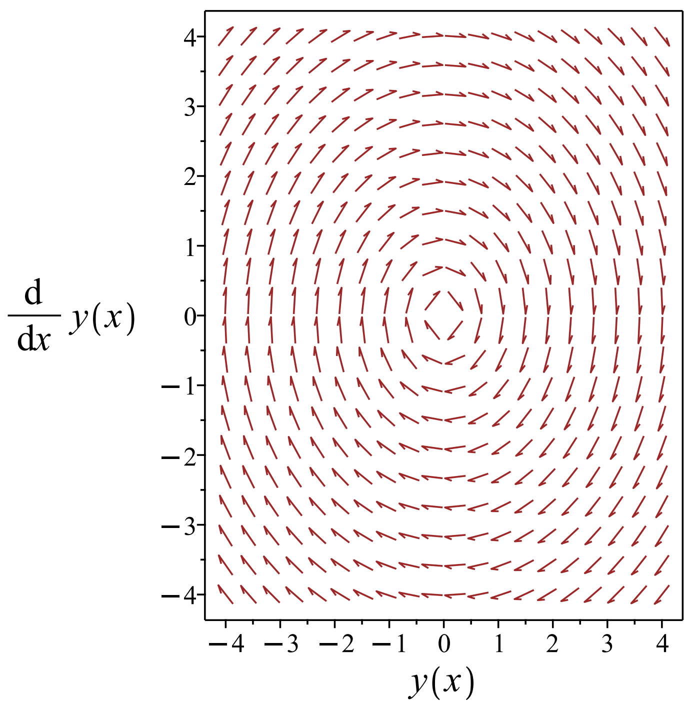

Figure 690: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + 1 - \frac{\sin(x)\, x}{4} - \frac{\cos(4x)}{30}$$

Verified OK.

17.24.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 538: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \cos(x)
\end{aligned}
$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\
&= \cos(x)\,(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4\cos(x)^4 - 4\cos(x)^2 + \frac{3}{2} - \frac{\cos(x)}{2}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{\cos(x), \sin(x)\}, \{\cos(2x), \sin(2x)\}, \{\cos(4x), \sin(4x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{1\}, \{\cos(x)x, \sin(x)x\}, \{\cos(2x), \sin(2x)\}, \{\cos(4x), \sin(4x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 + A_2\cos(x)x + A_3\sin(x)x + A_4\cos(2x) + A_5\sin(2x) + A_6\cos(4x) + A_7\sin(4x)$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6, A_7\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-2A_2\sin(x) + 2A_3\cos(x) - 3A_4\cos(2x) - 3A_5\sin(2x)\\&- 15A_6\cos(4x) - 15A_7\sin(4x) + A_1 = \frac{\cos(4x)}{2} + 1 - \frac{\cos(x)}{2}\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 1, A_2 = 0, A_3 = -\frac{1}{4}, A_4 = 0, A_5 = 0, A_6 = -\frac{1}{30}, A_7 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 1 - \frac{\sin(x)x}{4} - \frac{\cos(4x)}{30}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + \left(1 - \frac{\sin(x)\, x}{4} - \frac{\cos(4x)}{30}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(x) + c_2 \sin(x) + 1 - \frac{\sin(x)\, x}{4} - \frac{\cos(4x)}{30} \tag{1}
$$

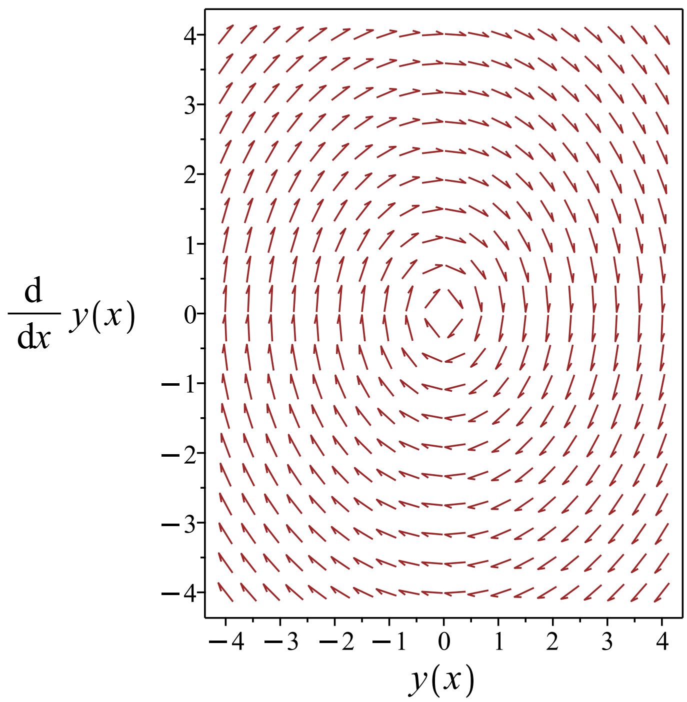

Figure 691: Slope field plot

Verification of solutions

$$
y = c_1 \cos(x) + c_2 \sin(x) + 1 - \frac{\sin(x)\, x}{4} - \frac{\cos(4x)}{30}
$$

Verified OK.

17.24.3 Maple step by step solution

Let's solve

$y'' + y = \frac{\cos(4x)}{2} + 1 - \frac{\cos(x)}{2}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \frac{\cos(4x)}{2} + 1 - \frac{\cos(x)}{2}\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 1$

- ○ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{\cos(x)\left(\int \sin(x)(\cos(4x)+2-\cos(x))dx\right)}{2} + \frac{\sin(x)\left(\int \left(8\cos(x)^5-8\cos(x)^3-\cos(x)^2+3\cos(x)\right)dx\right)}{2}$$

- Compute integrals

$$y_p(x) = -\frac{4\cos(x)^4}{15} + \frac{4\cos(x)^2}{15} - \frac{\sin(x)x}{4} - \frac{\cos(x)}{8} + \frac{29}{30}$$

- Substitute particular solution into general solution to ODE

$$y = c_1\cos(x) + c_2\sin(x) - \frac{4\cos(x)^4}{15} + \frac{4\cos(x)^2}{15} - \frac{\sin(x)x}{4} - \frac{\cos(x)}{8} + \frac{29}{30}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 4y' + 5y = 1 + 8\cos(x) + e^{2x}}$$

17.25.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 5, f(x) = 1 + 8\cos(x) + e^{2x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 4\lambda\, \mathrm{e}^{\lambda x} + 5\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-4^2 - (4)\,(1)\,(5)}\\ &= 2 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 2 + i\\ \lambda_2 &= 2 - i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2 + i\\ \lambda_2 &= 2 - i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 2$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x))$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{2x}(c_1 \cos(x) + c_2 \sin(x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1+8\cos(x)+e^{2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\},\{e^{2x}\},\{\cos(x),\sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{2x}\cos(x),e^{2x}\sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 + A_2 e^{2x} + A_3\cos(x) + A_4\sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_2 e^{2x} + 4A_3\cos(x) + 4A_4\sin(x) + 4A_3\sin(x) - 4A_4\cos(x) + 5A_1 = 1 + 8\cos(x) + e^{2x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1=\frac{1}{5}, A_2=1, A_3=1, A_4=-1\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{5} + e^{2x} + \cos(x) - \sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{2x}(c_1\cos(x) + c_2\sin(x))\right) + \left(\frac{1}{5} + e^{2x} + \cos(x) - \sin(x)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{1}{5} + e^{2x} + \cos(x) - \sin(x) \tag{1}$$

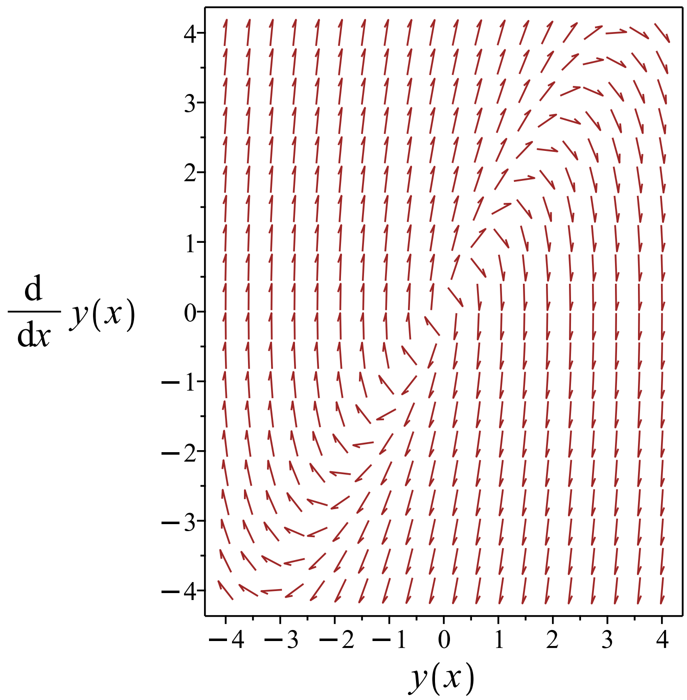

Figure 692: Slope field plot

Verification of solutions

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{1}{5} + e^{2x} + \cos(x) - \sin(x)$$

Verified OK.

17.25.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A &= 1\\ B &= -4\\ C &= 5\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r &= \frac{s}{t}\\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s &= -1\\ t &= 1\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 540: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx} \\ &= z_1 e^{2x} \\ &= z_1\left(e^{2x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^{2x} \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{4x}}{(y_1)^2} \, dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(e^{2x} \cos(x)\right) + c_2 \left(e^{2x} \cos(x) (\tan(x))\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 5y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \cos(x) e^{2x} c_1 + e^{2x} \sin(x) c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1 + 8 \cos(x) + e^{2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{e^{2x}\}, \{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{2x}\cos(x), e^{2x}\sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 + A_2 e^{2x} + A_3 \cos(x) + A_4 \sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_2 e^{2x} + 4A_3 \cos(x) + 4A_4 \sin(x) + 4A_3 \sin(x) - 4A_4 \cos(x) + 5A_1 = 1 + 8\cos(x) + e^{2x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{5}, A_2 = 1, A_3 = 1, A_4 = -1\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{5} + e^{2x} + \cos(x) - \sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\cos(x) e^{2x} c_1 + e^{2x} \sin(x) c_2\right) + \left(\frac{1}{5} + e^{2x} + \cos(x) - \sin(x)\right) \end{aligned}$$

Which simplifies to

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{1}{5} + e^{2x} + \cos(x) - \sin(x)$$

Summary

The solution(s) found are the following

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{1}{5} + e^{2x} + \cos(x) - \sin(x) \tag{1}$$

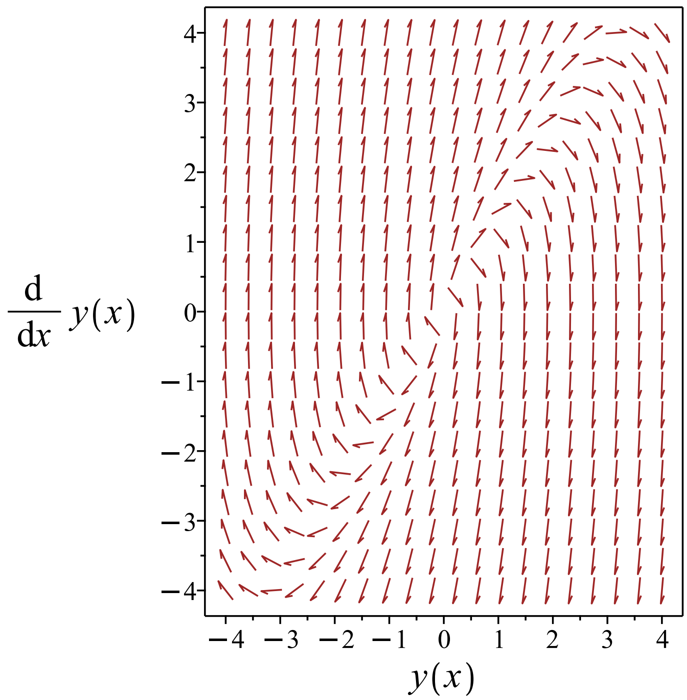

Figure 693: Slope field plot

Verification of solutions

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{1}{5} + e^{2x} + \cos(x) - \sin(x)$$

Verified OK.

17.25.3 Maple step by step solution

Let's solve

$y'' - 4y' + 5y = 1 + 8\cos(x) + e^{2x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 - 4r + 5 = 0$

- Use quadratic formula to solve for r

  $r = \frac{4 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (2 - \mathrm{I}, 2 + \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{2x} \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{2x} \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \cos(x)\,\mathrm{e}^{2x} c_1 + \mathrm{e}^{2x} \sin(x)\, c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 1 + 8\cos(x) + \mathrm{e}^{2x}\right]$

  ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{2x} \cos(x) & \mathrm{e}^{2x} \sin(x) \\ 2\,\mathrm{e}^{2x} \cos(x) - \mathrm{e}^{2x} \sin(x) & 2\,\mathrm{e}^{2x} \sin(x) + \mathrm{e}^{2x} \cos(x) \end{bmatrix}$

  ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = \mathrm{e}^{4x}$

  ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\mathrm{e}^{2x} \left(\cos(x) \left(\int \sin(x) \left(\mathrm{e}^{-2x} + 8\,\mathrm{e}^{-2x} \cos(x) + 1\right) dx\right) - \sin(x) \left(\int \left(\left(8\cos(x)^2 + \cos(x)\right)\right.\right.\right.$

  ○ Compute integrals

  $y_p(x) = \frac{1}{5} + \mathrm{e}^{2x} + \cos(x) - \sin(x)$

- Substitute particular solution into general solution to ODE

  $y = \cos(x)\,\mathrm{e}^{2x} c_1 + \mathrm{e}^{2x} \sin(x)\, c_2 + \cos(x) + \mathrm{e}^{2x} - \sin(x) + \frac{1}{5}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 2y' + 2y = e^{x} \sin\left(\frac{x}{2}\right)^{2}}$$

17.26.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 2, f(x) = e^{x} \sin\left(\frac{x}{2}\right)^{2}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda\, e^{\lambda x} + 2\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-2^2 - (4)(1)(2)} \\ &= 1 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 1 + i \\ \lambda_2 &= 1 - i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 + i \\ \lambda_2 &= 1 - i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 1$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^x (c_1 \cos(x) + c_2 \sin(x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x \sin\left(\frac{x}{2}\right)^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}, \{e^x \cos(x), e^x \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x \cos(x), e^x \sin(x)\}$$

Since $e^x \cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^x\}, \{x\, e^x \cos(x), x\, e^x \sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^x + A_2 x\, e^x \cos(x) + A_3 x\, e^x \sin(x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 e^x - 2A_2 e^x \sin(x) + 2A_3 e^x \cos(x) = e^x \sin\left(\frac{x}{2}\right)^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = 0, A_3 = -\frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x}{2} - \frac{x\, e^x \sin(x)}{4}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(e^x (c_1 \cos(x) + c_2 \sin(x))\right) + \left(\frac{e^x}{2} - \frac{x\, e^x \sin(x)}{4}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = e^x (c_1 \cos(x) + c_2 \sin(x)) + \frac{e^x}{2} - \frac{x\, e^x \sin(x)}{4} \tag{1}
$$

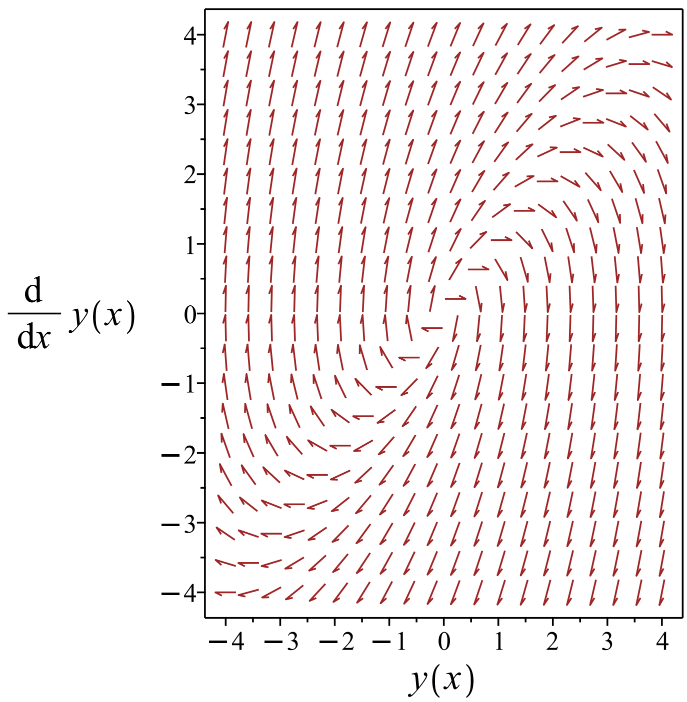

Figure 694: Slope field plot

Verification of solutions

$$
y = e^x (c_1 \cos(x) + c_2 \sin(x)) + \frac{e^x}{2} - \frac{x\, e^x \sin(x)}{4}
$$

Verified OK.

17.26.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 542: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx}
\end{aligned}$$

$$
\begin{aligned}
&= z_1 e^x \\
&= z_1(\mathrm{e}^x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^x \cos(x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{2x}}{(y_1)^2}\, dx \\
&= y_1(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x \cos(x)) + c_2(\mathrm{e}^x \cos(x)(\tan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^x \cos(x)\, c_1 + c_2 \mathrm{e}^x \sin(x)
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x \sin\left(\frac{x}{2}\right)^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}, \{e^x \cos(x), e^x \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x \cos(x), e^x \sin(x)\}$$

Since $e^x \cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^x\}, \{x\, e^x \cos(x), x\, e^x \sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^x + A_2 x\, e^x \cos(x) + A_3 x\, e^x \sin(x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 e^x - 2A_2 e^x \sin(x) + 2A_3 e^x \cos(x) = e^x \sin\left(\frac{x}{2}\right)^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = 0, A_3 = -\frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x}{2} - \frac{x\, e^x \sin(x)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x \cos(x)\, c_1 + c_2 e^x \sin(x)) + \left(\frac{e^x}{2} - \frac{x\, e^x \sin(x)}{4}\right) \end{aligned}$$

Which simplifies to

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{e^{x}}{2} - \frac{x\,e^{x} \sin(x)}{4}$$

Summary

The solution(s) found are the following

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{e^{x}}{2} - \frac{x\,e^{x} \sin(x)}{4} \tag{1}$$

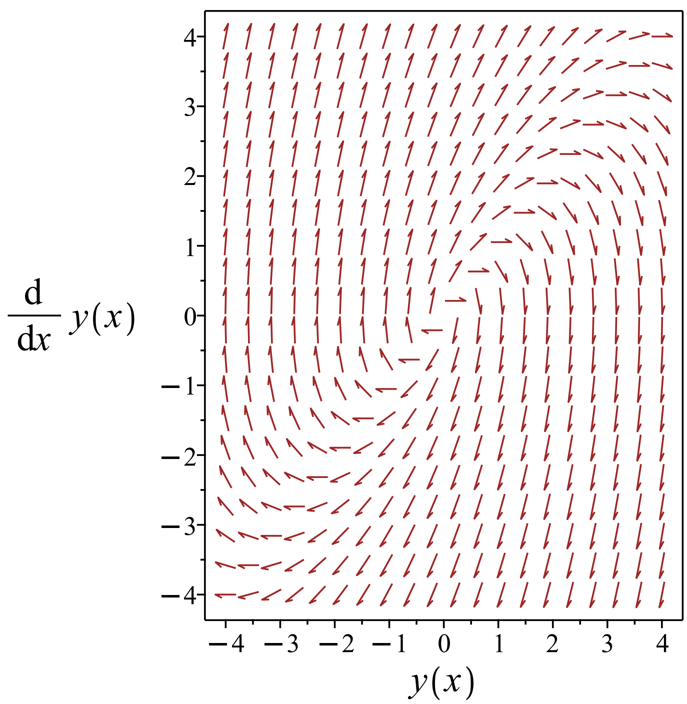

Figure 695: Slope field plot

Verification of solutions

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{e^{x}}{2} - \frac{x\,e^{x} \sin(x)}{4}$$

Verified OK.

17.26.3 Maple step by step solution

Let's solve

$y'' - 2y' + 2y = e^x \sin\left(\frac{x}{2}\right)^2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{2 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (1 - \mathrm{I}, 1 + \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^x \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^x \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^x \cos(x) c_1 + c_2 e^x \sin(x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = e^x \sin\left(\frac{x}{2}\right)^2\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^x \cos(x) & e^x \sin(x) \\ e^x \cos(x) - e^x \sin(x) & e^x \sin(x) + e^x \cos(x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = e^{2x}$

  - Substitute functions into equation for $y_p(x)$

$$y_p(x) = -e^x \left(\cos(x) \left(\int \sin(x) \sin\left(\frac{x}{2}\right)^2 dx\right) - \sin(x) \left(\int \cos(x) \sin\left(\frac{x}{2}\right)^2 dx\right)\right)$$

- Compute integrals

$$y_p(x) = -\frac{\left(\sin(x) x + \frac{\cos(x)}{2} - 2\right) e^x}{4}$$

- Substitute particular solution into general solution to ODE

$$y = e^x \cos(x) c_1 + c_2 e^x \sin(x) - \frac{\left(\sin(x) x + \frac{\cos(x)}{2} - 2\right) e^x}{4}$$

Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Superposition principle. Exercises page 137
Problem number: 577.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' - 3y' = 1 + e^{x} + \cos(x) + \sin(x)}$$

17.27.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -3, C = 0, f(x) = 1 + e^{x} + \cos(x) + \sin(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''-3y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=1, B=-3, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x}-3\lambda\, \mathrm{e}^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2-3\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=-3, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{3}{(2)(1)}\pm\frac{1}{(2)(1)}\sqrt{-3^2-(4)(1)(0)}\\&=\frac{3}{2}\pm\frac{3}{2}\end{aligned}$$

Hence

$$\lambda_1=\frac{3}{2}+\frac{3}{2}$$
$$\lambda_2=\frac{3}{2}-\frac{3}{2}$$

Which simplifies to

$$\lambda_1=3$$
$$\lambda_2=0$$

Since roots are real and distinct, then the solution is

$$y=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}$$
$$y=c_1e^{(3)x}+c_2e^{(0)x}$$

Or

$$y = c_1 e^{3x} + c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{3x} + c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1 + e^x + \cos(x) + \sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{e^x\}, \{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{3x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}, \{e^x\}, \{\cos(x), \sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x + A_2 e^x + A_3 \cos(x) + A_4 \sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned} &-2A_2 e^x - A_3 \cos(x) - A_4 \sin(x) - 3A_1 + 3A_3 \sin(x) - 3A_4 \cos(x) \\ &= 1 + e^x + \cos(x) + \sin(x) \end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{3}, A_2 = -\frac{1}{2}, A_3 = \frac{1}{5}, A_4 = -\frac{2}{5}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x}{3} - \frac{e^x}{2} + \frac{\cos(x)}{5} - \frac{2\sin(x)}{5}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 e^{3x} + c_2) + \left(-\frac{x}{3} - \frac{e^x}{2} + \frac{\cos(x)}{5} - \frac{2\sin(x)}{5}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{3x} + c_2 - \frac{x}{3} - \frac{e^x}{2} + \frac{\cos(x)}{5} - \frac{2\sin(x)}{5} \tag{1}$$

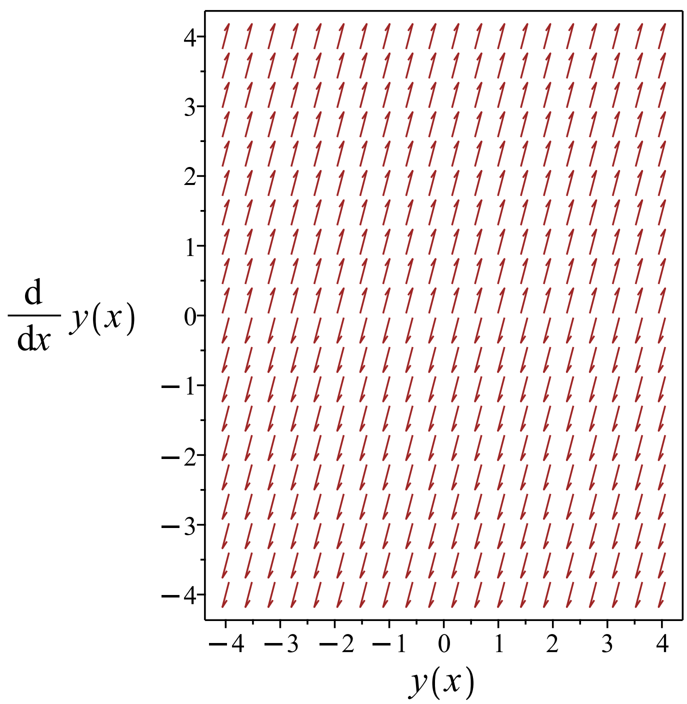

Figure 696: Slope field plot

Verification of solutions

$$y = c_1 e^{3x} + c_2 - \frac{x}{3} - \frac{e^x}{2} + \frac{\cos(x)}{5} - \frac{2\sin(x)}{5}$$

Verified OK.

17.27.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - 3y')\, dx = \int (1 + e^x + \cos(x) + \sin(x))\, dx$$

$$-3y + y' = x + \sin(x) + e^x - \cos(x) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -3 \\ q(x) &= x + \sin(x) + e^x - \cos(x) + c_1 \end{aligned}$$

Hence the ode is

$$-3y + y' = x + \sin(x) + e^x - \cos(x) + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-3)dx} \\ &= e^{-3x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\,(x + \sin(x) + e^x - \cos(x) + c_1) \\ \frac{d}{dx}\left(e^{-3x} y\right) &= \left(e^{-3x}\right)(x + \sin(x) + e^x - \cos(x) + c_1) \\ d\left(e^{-3x} y\right) &= \left((x + \sin(x) + e^x - \cos(x) + c_1)\, e^{-3x}\right)\, dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{-3x} y &= \int (x + \sin(x) + e^x - \cos(x) + c_1)\, e^{-3x}\, dx \\ e^{-3x} y &= -\frac{x\, e^{-3x}}{3} - \frac{e^{-3x}}{9} + \frac{e^{-3x}\cos(x)}{5} - \frac{2\, e^{-3x}\sin(x)}{5} - \frac{e^{-2x}}{2} - \frac{c_1 e^{-3x}}{3} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-3x}$ results in

$$y = e^{3x}\left(-\frac{x\, e^{-3x}}{3} - \frac{e^{-3x}}{9} + \frac{e^{-3x}\cos(x)}{5} - \frac{2\, e^{-3x}\sin(x)}{5} - \frac{e^{-2x}}{2} - \frac{c_1 e^{-3x}}{3}\right) + c_2 e^{3x}$$

which simplifies to

$$y = -\frac{1}{9} + c_2 e^{3x} - \frac{e^x}{2} - \frac{c_1}{3} - \frac{x}{3} + \frac{\cos(x)}{5} - \frac{2\sin(x)}{5}$$

Summary

The solution(s) found are the following

$$y = -\frac{1}{9} + c_2 e^{3x} - \frac{e^x}{2} - \frac{c_1}{3} - \frac{x}{3} + \frac{\cos(x)}{5} - \frac{2\sin(x)}{5} \tag{1}$$

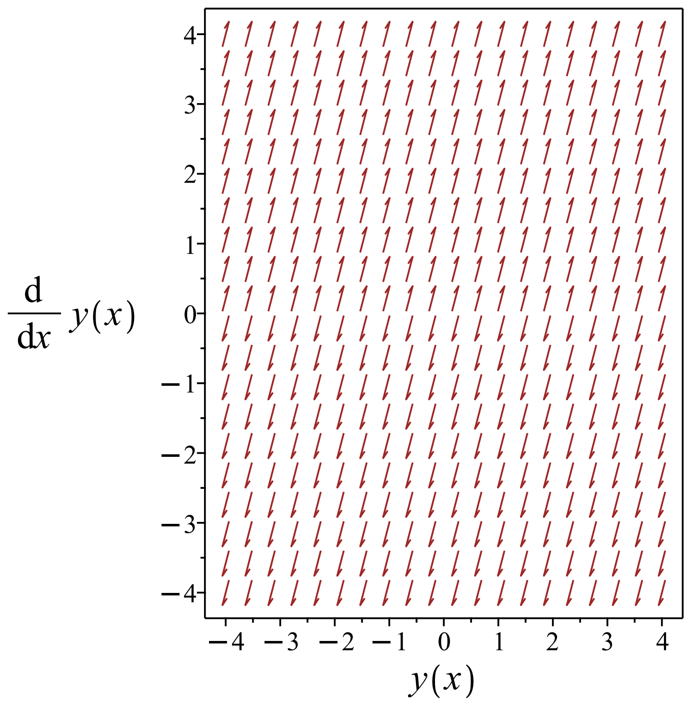

Figure 697: Slope field plot

Verification of solutions

$$y = -\frac{1}{9} + c_2 e^{3x} - \frac{e^x}{2} - \frac{c_1}{3} - \frac{x}{3} + \frac{\cos(x)}{5} - \frac{2\sin(x)}{5}$$

Verified OK.

17.27.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - 3p(x) - 1 - e^{x} - \cos(x) - \sin(x) = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned}
p(x) &= -3 \\
q(x) &= 1 + e^{x} + \cos(x) + \sin(x)
\end{aligned}$$

Hence the ode is

$$p'(x) - 3p(x) = 1 + e^{x} + \cos(x) + \sin(x)$$

The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int (-3)dx} \\
&= e^{-3x}
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dx}(\mu p) &= (\mu)\left(1 + e^{x} + \cos(x) + \sin(x)\right) \\
\frac{d}{dx}\left(e^{-3x} p\right) &= \left(e^{-3x}\right)\left(1 + e^{x} + \cos(x) + \sin(x)\right) \\
d\left(e^{-3x} p\right) &= \left(\left(1 + e^{x} + \cos(x) + \sin(x)\right) e^{-3x}\right) dx
\end{aligned}$$

Integrating gives

$$\begin{aligned}
e^{-3x} p &= \int \left(1 + e^{x} + \cos(x) + \sin(x)\right) e^{-3x} \, dx \\
e^{-3x} p &= -\frac{e^{-3x}}{3} - \frac{e^{-2x}}{2} - \frac{2 e^{-3x} \cos(x)}{5} - \frac{e^{-3x} \sin(x)}{5} + c_1
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-3x}$ results in

$$p(x) = \mathrm{e}^{3x}\left(-\frac{\mathrm{e}^{-3x}}{3} - \frac{\mathrm{e}^{-2x}}{2} - \frac{2\,\mathrm{e}^{-3x}\cos(x)}{5} - \frac{\mathrm{e}^{-3x}\sin(x)}{5}\right) + c_1\mathrm{e}^{3x}$$

which simplifies to

$$p(x) = c_1\mathrm{e}^{3x} - \frac{2\cos(x)}{5} - \frac{\sin(x)}{5} - \frac{1}{3} - \frac{\mathrm{e}^{x}}{2}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = c_1\mathrm{e}^{3x} - \frac{2\cos(x)}{5} - \frac{\sin(x)}{5} - \frac{1}{3} - \frac{\mathrm{e}^{x}}{2}$$

Integrating both sides gives

$$\begin{aligned} y &= \int c_1\mathrm{e}^{3x} - \frac{2\cos(x)}{5} - \frac{\sin(x)}{5} - \frac{1}{3} - \frac{\mathrm{e}^{x}}{2}\,\mathrm{d}x \\ &= -\frac{x}{3} + \frac{c_1\mathrm{e}^{3x}}{3} - \frac{2\sin(x)}{5} - \frac{\mathrm{e}^{x}}{2} + \frac{\cos(x)}{5} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{x}{3} + \frac{c_1\mathrm{e}^{3x}}{3} - \frac{2\sin(x)}{5} - \frac{\mathrm{e}^{x}}{2} + \frac{\cos(x)}{5} + c_2 \tag{1}$$

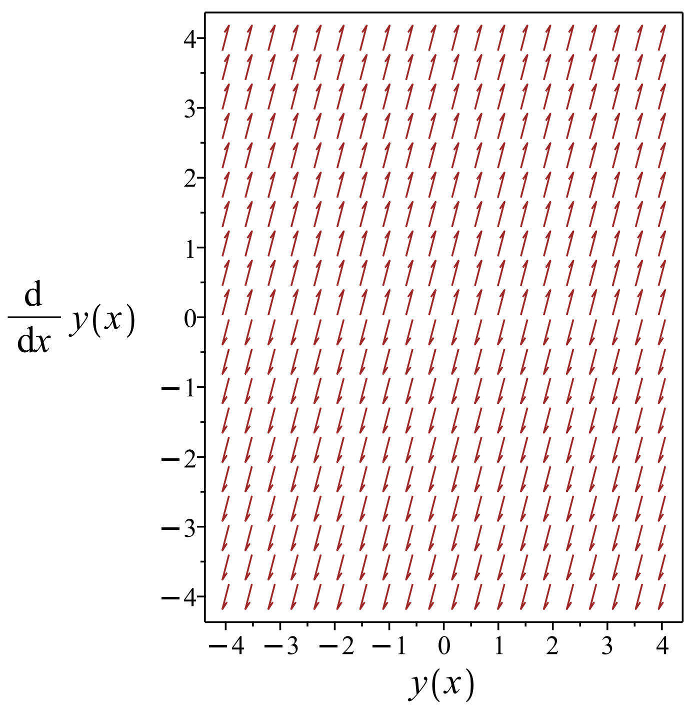

Figure 698: Slope field plot

Verification of solutions

$$y = -\frac{x}{3} + \frac{c_1 e^{3x}}{3} - \frac{2\sin(x)}{5} - \frac{e^x}{2} + \frac{\cos(x)}{5} + c_2$$

Verified OK.

17.27.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' - 3y' = 1 + e^x + \cos(x) + \sin(x)$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - 3y')\, dx = \int (1 + e^x + \cos(x) + \sin(x))\, dx$$

$$-3y + y' = x + \sin(x) + e^x - \cos(x) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -3 \\ q(x) &= x + \sin(x) + e^x - \cos(x) + c_1 \end{aligned}$$

Hence the ode is

$$-3y + y' = x + \sin(x) + e^x - \cos(x) + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-3)dx} \\ &= e^{-3x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)(x + \sin(x) + e^x - \cos(x) + c_1) \\ \frac{d}{dx}\left(e^{-3x} y\right) &= \left(e^{-3x}\right)(x + \sin(x) + e^x - \cos(x) + c_1) \\ d\left(e^{-3x} y\right) &= \left((x + \sin(x) + e^x - \cos(x) + c_1)\, e^{-3x}\right)\, dx \end{aligned}$$

Integrating gives

$$e^{-3x}y = \int \left(x+\sin(x)+e^{x}-\cos(x)+c_1\right)e^{-3x}\,dx$$
$$e^{-3x}y = -\frac{x\,e^{-3x}}{3}-\frac{e^{-3x}}{9}+\frac{e^{-3x}\cos(x)}{5}-\frac{2\,e^{-3x}\sin(x)}{5}-\frac{e^{-2x}}{2}-\frac{c_1e^{-3x}}{3}+c_2$$

Dividing both sides by the integrating factor $\mu = e^{-3x}$ results in

$$y = e^{3x}\left(-\frac{x\,e^{-3x}}{3}-\frac{e^{-3x}}{9}+\frac{e^{-3x}\cos(x)}{5}-\frac{2\,e^{-3x}\sin(x)}{5}-\frac{e^{-2x}}{2}-\frac{c_1e^{-3x}}{3}\right)+c_2e^{3x}$$

which simplifies to

$$y = -\frac{1}{9}+c_2e^{3x}-\frac{e^{x}}{2}-\frac{c_1}{3}-\frac{x}{3}+\frac{\cos(x)}{5}-\frac{2\sin(x)}{5}$$

Summary

The solution(s) found are the following

$$y = -\frac{1}{9}+c_2e^{3x}-\frac{e^{x}}{2}-\frac{c_1}{3}-\frac{x}{3}+\frac{\cos(x)}{5}-\frac{2\sin(x)}{5} \tag{1}$$

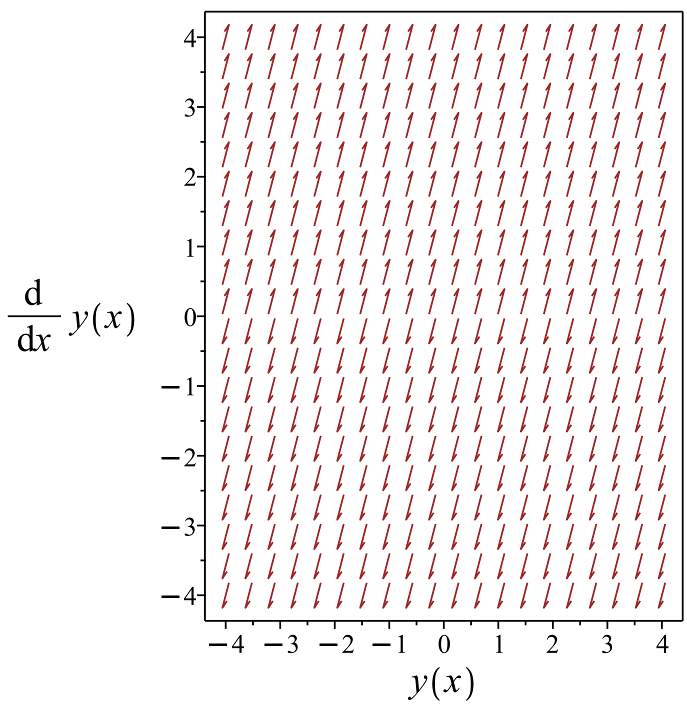

Figure 699: Slope field plot

Verification of solutions

$$y = -\frac{1}{9} + c_2 e^{3x} - \frac{e^x}{2} - \frac{c_1}{3} - \frac{x}{3} + \frac{\cos(x)}{5} - \frac{2\sin(x)}{5}$$

Verified OK.

17.27.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 3y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -3 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 544: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-3}{1}\,dx} \\ &= z_1 e^{\frac{3x}{2}} \\ &= z_1\left(\mathrm{e}^{\frac{3x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-3}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{3x}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\mathrm{e}^{3x}}{3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(1) + c_2\left(1\left(\frac{\mathrm{e}^{3x}}{3}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''-3y'=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h=c_1+\frac{c_2 e^{3x}}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1+e^x+\cos(x)+\sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\},\{e^x\},\{\cos(x),\sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{1,\frac{e^{3x}}{3}\right\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\},\{e^x\},\{\cos(x),\sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p=A_1x+A_2e^x+A_3\cos(x)+A_4\sin(x)$$

The unknowns $\{A_1,A_2,A_3,A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_2e^x-A_3\cos(x)-A_4\sin(x)-3A_1+3A_3\sin(x)-3A_4\cos(x) \\ =1+e^x+\cos(x)+\sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{3}, A_2 = -\frac{1}{2}, A_3 = \frac{1}{5}, A_4 = -\frac{2}{5}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x}{3} - \frac{e^x}{2} + \frac{\cos(x)}{5} - \frac{2\sin(x)}{5}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + \frac{c_2 e^{3x}}{3}\right) + \left(-\frac{x}{3} - \frac{e^x}{2} + \frac{\cos(x)}{5} - \frac{2\sin(x)}{5}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + \frac{c_2 e^{3x}}{3} - \frac{x}{3} - \frac{e^x}{2} + \frac{\cos(x)}{5} - \frac{2\sin(x)}{5} \tag{1}$$

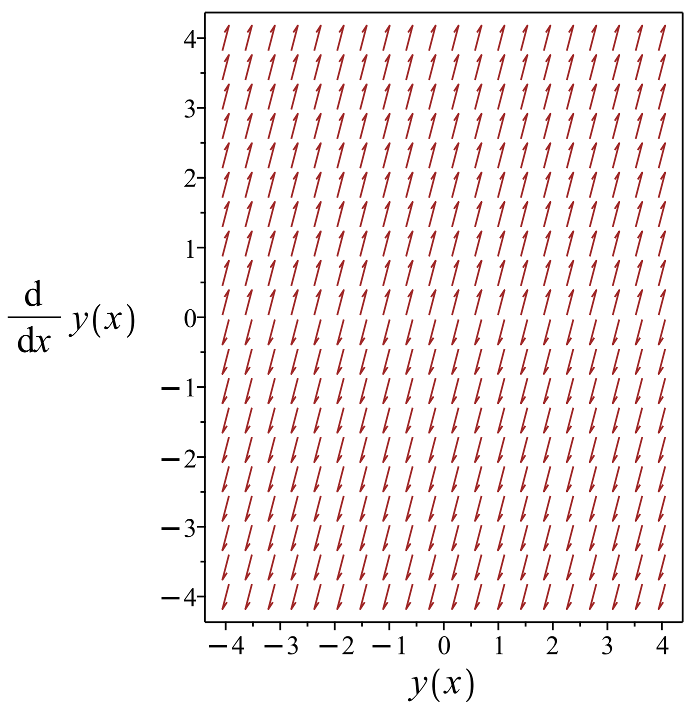

Figure 700: Slope field plot

Verification of solutions

$$y = c_1 + \frac{c_2 e^{3x}}{3} - \frac{x}{3} - \frac{e^x}{2} + \frac{\cos(x)}{5} - \frac{2\sin(x)}{5}$$

Verified OK.

17.27.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= -3 \\ r(x) &= 0 \\ s(x) &= 1 + e^x + \cos(x) + \sin(x) \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y' + (q(x) - p'(x))\,y\right)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$-3y + y' = \int 1 + e^x + \cos(x) + \sin(x)\,dx$$

We now have a first order ode to solve which is

$$-3y + y' = x + \sin(x) + e^x - \cos(x) + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}
p(x) &= -3 \\
q(x) &= x + \sin(x) + e^x - \cos(x) + c_1
\end{aligned}$$

Hence the ode is

$$-3y + y' = x + \sin(x) + e^x - \cos(x) + c_1$$

The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int (-3) dx} \\
&= e^{-3x}
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)(x + \sin(x) + e^x - \cos(x) + c_1) \\
\frac{d}{dx}(e^{-3x} y) &= (e^{-3x})(x + \sin(x) + e^x - \cos(x) + c_1) \\
d(e^{-3x} y) &= ((x + \sin(x) + e^x - \cos(x) + c_1) e^{-3x})\, dx
\end{aligned}$$

Integrating gives

$$\begin{aligned}
e^{-3x} y &= \int (x + \sin(x) + e^x - \cos(x) + c_1) e^{-3x}\, dx \\
e^{-3x} y &= -\frac{x\, e^{-3x}}{3} - \frac{e^{-3x}}{9} + \frac{e^{-3x} \cos(x)}{5} - \frac{2\, e^{-3x} \sin(x)}{5} - \frac{e^{-2x}}{2} - \frac{c_1 e^{-3x}}{3} + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-3x}$ results in

$$y = e^{3x} \left(-\frac{x\, e^{-3x}}{3} - \frac{e^{-3x}}{9} + \frac{e^{-3x} \cos(x)}{5} - \frac{2\, e^{-3x} \sin(x)}{5} - \frac{e^{-2x}}{2} - \frac{c_1 e^{-3x}}{3} \right) + c_2 e^{3x}$$

which simplifies to

$$y = -\frac{1}{9} + c_2 e^{3x} - \frac{e^x}{2} - \frac{c_1}{3} - \frac{x}{3} + \frac{\cos(x)}{5} - \frac{2\sin(x)}{5}$$

Summary

The solution(s) found are the following

$$y = -\frac{1}{9} + c_2 e^{3x} - \frac{e^x}{2} - \frac{c_1}{3} - \frac{x}{3} + \frac{\cos(x)}{5} - \frac{2\sin(x)}{5} \tag{1}$$

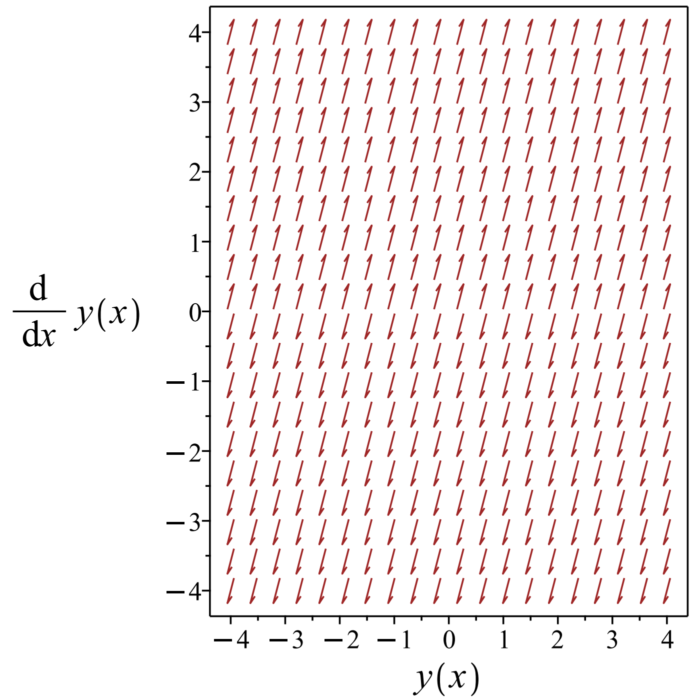

Figure 701: Slope field plot

Verification of solutions

$$y = -\frac{1}{9} + c_2 e^{3x} - \frac{e^x}{2} - \frac{c_1}{3} - \frac{x}{3} + \frac{\cos(x)}{5} - \frac{2\sin(x)}{5}$$

Verified OK.

17.27.7 Maple step by step solution

Let's solve

$y'' - 3y' = 1 + e^x + \cos(x) + \sin(x)$

- Highest derivative means the order of the ODE is 2

y''

- Characteristic polynomial of homogeneous ODE

$r^2 - 3r = 0$

- Factor the characteristic polynomial

  $r(r-3) = 0$

- Roots of the characteristic polynomial

  $r = (0, 3)$

- 1st solution of the homogeneous ODE

  $y_1(x) = 1$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 e^{3x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 1 + e^x + \cos(x) + \sin(\right.$

  ◦ Wronskian of solutions of the homogeneous equation

  $$W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & e^{3x} \\ 0 & 3 e^{3x} \end{bmatrix}$$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 3 e^{3x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\left(\int (1+e^x+\cos(x)+\sin(x))dx\right)}{3} + \frac{e^{3x}\left(\int (1+e^x+\cos(x)+\sin(x))e^{-3x}dx\right)}{3}$

  ◦ Compute integrals

  $y_p(x) = -\frac{x}{3} - \frac{2\sin(x)}{5} - \frac{e^x}{2} + \frac{\cos(x)}{5} - \frac{1}{9}$

- Substitute particular solution into general solution to ODE

  $y = c_1 + c_2 e^{3x} - \frac{x}{3} - \frac{2\sin(x)}{5} - \frac{e^x}{2} + \frac{\cos(x)}{5} - \frac{1}{9}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 2y' + 5y = e^{x}\left(1 - 2\sin\left(x\right)^{2}\right) + 10x + 1}$$

17.28.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 5, f(x) = e^{x}\cos\left(2x\right) + 10x + 1$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda \, e^{\lambda x} + 5 \, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 5$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-2^2 - (4)(1)(5)} \\
&= 1 \pm 2i
\end{aligned}$$

Hence

$$\lambda_1 = 1 + 2i$$
$$\lambda_2 = 1 - 2i$$

Which simplifies to

$$\lambda_1 = 1 + 2i$$
$$\lambda_2 = 1 - 2i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 1$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{x}(c_1 \cos(2x) + c_2 \sin(2x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{x}(c_1 \cos(2x) + c_2 \sin(2x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{x} \cos(2x) + 10x + 1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}, \{e^{x} \cos(2x), e^{x} \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x} \cos(2x), e^{x} \sin(2x)\}$$

Since $e^{x} \cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{1, x\}, \{x\, e^{x} \cos(2x), x\, e^{x} \sin(2x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_2 x + A_1 + A_3 x\, e^{x} \cos(2x) + A_4 x\, e^{x} \sin(2x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_3 e^{x} \sin(2x) + 4A_4 e^{x} \cos(2x) - 2A_2 + 5A_2 x + 5A_1 = e^{x} \cos(2x) + 10x + 1$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 1, A_2 = 2, A_3 = 0, A_4 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2x + 1 + \frac{x\, e^{x} \sin(2x)}{4}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(e^x (c_1 \cos(2x) + c_2 \sin(2x))\right) + \left(2x + 1 + \frac{x\,e^x \sin(2x)}{4}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = e^x (c_1 \cos(2x) + c_2 \sin(2x)) + 2x + 1 + \frac{x\,e^x \sin(2x)}{4} \tag{1}
$$

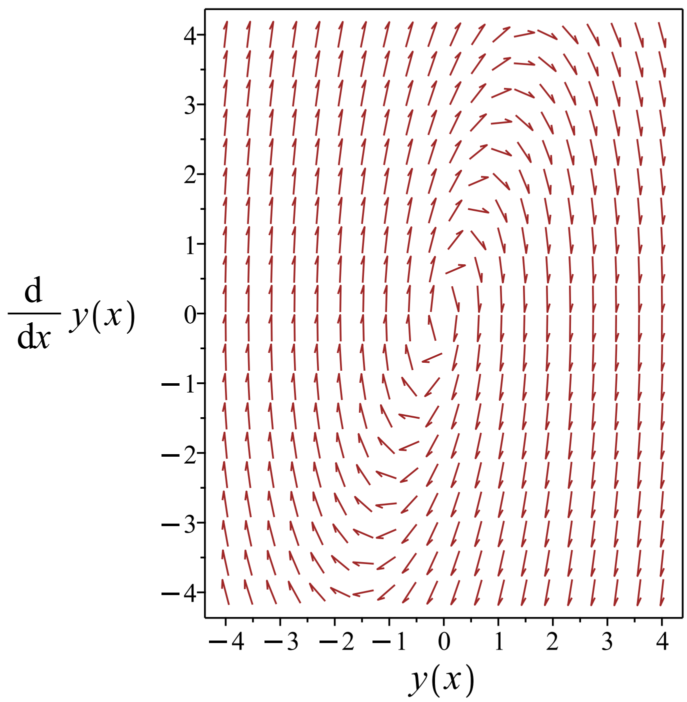

Figure 702: Slope field plot

Verification of solutions

$$
y = e^x (c_1 \cos(2x) + c_2 \sin(2x)) + 2x + 1 + \frac{x\,e^x \sin(2x)}{4}
$$

Verified OK.

17.28.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 546: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \end{aligned}$$

$$
\begin{aligned}
&= z_1 e^x \\
&= z_1(\mathrm{e}^x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^x \cos(2x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{2x}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\tan(2x)}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x \cos(2x)) + c_2\left(\mathrm{e}^x \cos(2x) \left(\frac{\tan(2x)}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' + 5y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^x \cos(2x)\, c_1 + \frac{\sin(2x)\, \mathrm{e}^x c_2}{2}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{x} \cos(2x) + 10x + 1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}, \{e^{x} \cos(2x), e^{x} \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^{x} \cos(2x), \frac{e^{x} \sin(2x)}{2}\right\}$$

Since $e^{x} \cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{1, x\}, \{x\, e^{x} \cos(2x), x\, e^{x} \sin(2x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_2 x + A_1 + A_3 x\, e^{x} \cos(2x) + A_4 x\, e^{x} \sin(2x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_3 e^{x} \sin(2x) + 4A_4 e^{x} \cos(2x) - 2A_2 + 5A_2 x + 5A_1 = e^{x} \cos(2x) + 10x + 1$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 1, A_2 = 2, A_3 = 0, A_4 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2x + 1 + \frac{x\, e^{x} \sin(2x)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{x} \cos(2x)\, c_1 + \frac{\sin(2x)\, e^{x} c_2}{2}\right) + \left(2x + 1 + \frac{x\, e^{x} \sin(2x)}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{x} \cos(2x) c_1 + \frac{\sin(2x) e^{x} c_2}{2} + 2x + 1 + \frac{x e^{x} \sin(2x)}{4} \tag{1}$$

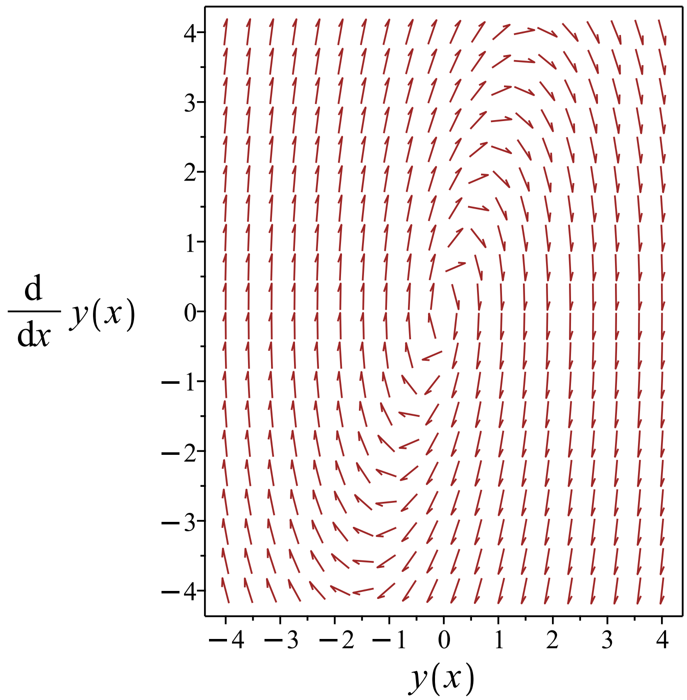

Figure 703: Slope field plot

Verification of solutions

$$y = e^{x} \cos(2x) c_1 + \frac{\sin(2x) e^{x} c_2}{2} + 2x + 1 + \frac{x e^{x} \sin(2x)}{4}$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 4y' + 4y = 4x + \sin(x) + \sin(2x)}$$

17.29.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 4, f(x) = 4x + \sin(x) + \sin(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 4\lambda\, e^{\lambda x} + 4\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{(-4)^2 - (4)\,(1)\,(4)}\\ &= 2\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -2$. Therefore the solution is

$$y = c_1 e^{2x} + c_2 x\, e^{2x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = e^{2x} c_1 + c_2 x\, e^{2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4x + \sin(x) + \sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}, \{\cos(x), \sin(x)\}, \{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{2x}, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_2 x + A_1 + A_3 \cos(x) + A_4 \sin(x) + A_5 \cos(2x) + A_6 \sin(2x)$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&3A_3 \cos(x) + 3A_4 \sin(x) - 4A_2 + 4A_3 \sin(x) - 4A_4 \cos(x)\\&+ 8A_5 \sin(2x) - 8A_6 \cos(2x) + 4A_2 x + 4A_1 = 4x + \sin(x) + \sin(2x)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 1, A_2 = 1, A_3 = \frac{4}{25}, A_4 = \frac{3}{25}, A_5 = \frac{1}{8}, A_6 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x + 1 + \frac{4\cos(x)}{25} + \frac{3\sin(x)}{25} + \frac{\cos(2x)}{8}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\&= \left(e^{2x} c_1 + c_2 x\, e^{2x}\right) + \left(x + 1 + \frac{4\cos(x)}{25} + \frac{3\sin(x)}{25} + \frac{\cos(2x)}{8}\right)\end{aligned}$$

Which simplifies to

$$y = e^{2x}(c_2 x + c_1) + x + 1 + \frac{4\cos(x)}{25} + \frac{3\sin(x)}{25} + \frac{\cos(2x)}{8}$$

Summary

The solution(s) found are the following

$$y = e^{2x}(c_2 x + c_1) + x + 1 + \frac{4\cos(x)}{25} + \frac{3\sin(x)}{25} + \frac{\cos(2x)}{8} \tag{1}$$

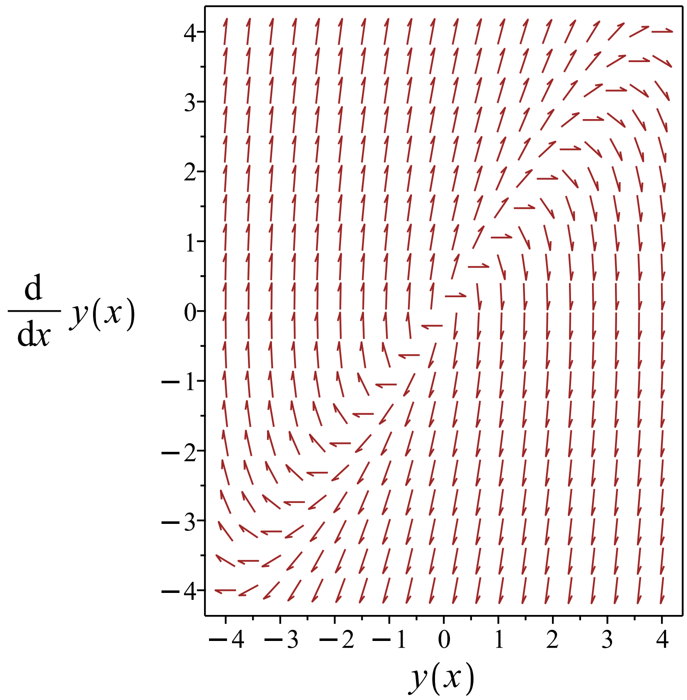

Figure 704: Slope field plot

Verification of solutions

$$y = e^{2x}(c_2x + c_1) + x + 1 + \frac{4\cos(x)}{25} + \frac{3\sin(x)}{25} + \frac{\cos(2x)}{8}$$

Verified OK.

17.29.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)$$

Where $p(x) = -4$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int -4\,dx} \\ &= e^{-2x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= e^{-2x}(4x + \sin(x) + \sin(2x)) \\
\left(e^{-2x}y\right)'' &= e^{-2x}(4x + \sin(x) + \sin(2x))
\end{aligned}
$$

Integrating once gives

$$
\left(e^{-2x}y\right)' = \frac{\left(-10\cos(x)^2 + (-10\sin(x) - 4)\cos(x) - 40x - 8\sin(x) - 15\right)e^{-2x}}{20} + c_1
$$

Integrating again gives

$$
\left(e^{-2x}y\right) = \frac{\left(50\cos(x)^2 + 200x + 32\cos(x) + 24\sin(x) + 175\right)e^{-2x}}{200} + c_1 x + c_2
$$

Hence the solution is

$$
y = \frac{\frac{\left(50\cos(x)^2+200x+32\cos(x)+24\sin(x)+175\right)e^{-2x}}{200} + c_1 x + c_2}{e^{-2x}}
$$

Or

$$
y = c_1 x\, e^{2x} + e^{2x} c_2 + \frac{\cos(x)^2}{4} + x + \frac{4\cos(x)}{25} + \frac{3\sin(x)}{25} + \frac{7}{8}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = c_1 x\, e^{2x} + e^{2x} c_2 + \frac{\cos(x)^2}{4} + x + \frac{4\cos(x)}{25} + \frac{3\sin(x)}{25} + \frac{7}{8} \tag{1}
$$

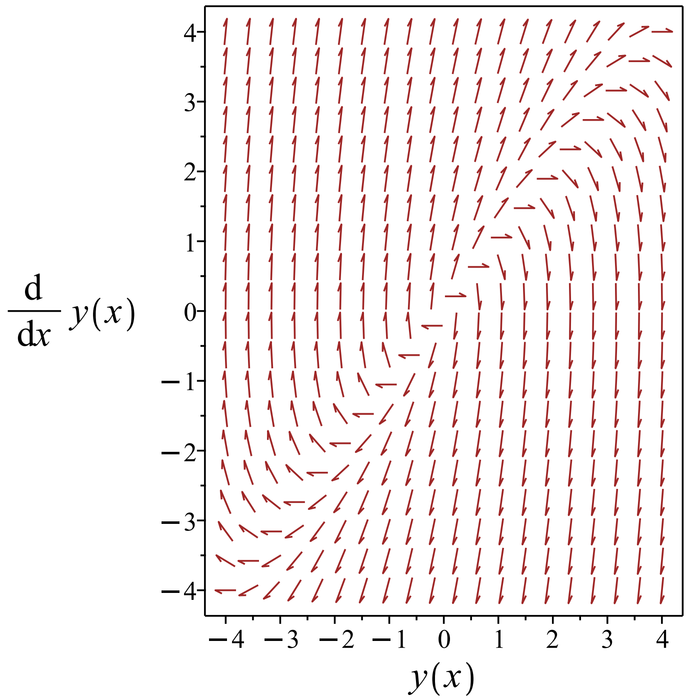

Figure 705: Slope field plot

Verification of solutions

$$y = c_1 x\,\mathrm{e}^{2x} + \mathrm{e}^{2x} c_2 + \frac{\cos(x)^2}{4} + x + \frac{4\cos(x)}{25} + \frac{3\sin(x)}{25} + \frac{7}{8}$$

Verified OK.

17.29.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 548: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx} \\ &= z_1 e^{2x} \\ &= z_1\left(\mathrm{e}^{2x}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{4x}}{(y_1)^2}\,dx \\ &= y_1(x)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{2x}\right) + c_2 \left(\mathrm{e}^{2x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 4y' + 4y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^{2x} c_1 + c_2 x\,\mathrm{e}^{2x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
4x + \sin(x) + \sin(2x)
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{1, x\}, \{\cos(x), \sin(x)\}, \{\cos(2x), \sin(2x)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{x\,\mathrm{e}^{2x}, \mathrm{e}^{2x}\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_2 x + A_1 + A_3 \cos(x) + A_4 \sin(x) + A_5 \cos(2x) + A_6 \sin(2x)
$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_3 \cos(x) + 3A_4 \sin(x) - 4A_2 + 4A_3 \sin(x) - 4A_4 \cos(x) \\ + 8A_5 \sin(2x) - 8A_6 \cos(2x) + 4A_2 x + 4A_1 = 4x + \sin(x) + \sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 1, A_2 = 1, A_3 = \frac{4}{25}, A_4 = \frac{3}{25}, A_5 = \frac{1}{8}, A_6 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x + 1 + \frac{4\cos(x)}{25} + \frac{3\sin(x)}{25} + \frac{\cos(2x)}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{2x} c_1 + c_2 x\, \mathrm{e}^{2x}\right) + \left(x + 1 + \frac{4\cos(x)}{25} + \frac{3\sin(x)}{25} + \frac{\cos(2x)}{8}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{2x}(c_2 x + c_1) + x + 1 + \frac{4\cos(x)}{25} + \frac{3\sin(x)}{25} + \frac{\cos(2x)}{8}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{2x}(c_2 x + c_1) + x + 1 + \frac{4\cos(x)}{25} + \frac{3\sin(x)}{25} + \frac{\cos(2x)}{8} \tag{1}$$

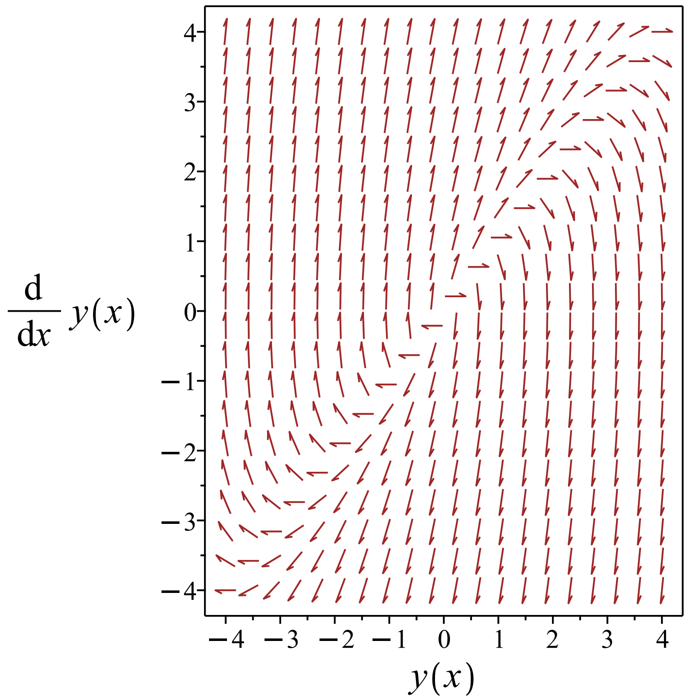

Figure 706: Slope field plot

Verification of solutions

$$y = e^{2x}(c_2x + c_1) + x + 1 + \frac{4\cos(x)}{25} + \frac{3\sin(x)}{25} + \frac{\cos(2x)}{8}$$

Verified OK.

17.29.4 Maple step by step solution

Let's solve

$y'' - 4y' + 4y = 4x + \sin(x) + \sin(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 4r + 4 = 0$

- Factor the characteristic polynomial

  $(r-2)^2 = 0$

- Root of the characteristic polynomial

$r = 2$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{2x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{2x} c_1 + c_2 x\,e^{2x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 4x + \sin(x) + \sin(2x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{2x} & x\,e^{2x} \\ 2\,e^{2x} & e^{2x} + 2x\,e^{2x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = e^{4x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = e^{2x}\left(-\left(\int (4x + \sin(x) + \sin(2x))\,x\,e^{-2x}dx\right) + x\left(\int e^{-2x}(4x + \sin(x) + \sin(2x))\,dx\right)\right)$

  - Compute integrals

    $y_p(x) = \frac{\cos(x)^2}{4} + x + \frac{4\cos(x)}{25} + \frac{3\sin(x)}{25} + \frac{7}{8}$

- Substitute particular solution into general solution to ODE

  $y = c_2 x\,e^{2x} + e^{2x} c_1 + \frac{3\sin(x)}{25} + \frac{4\cos(x)}{25} + \frac{\cos(x)^2}{4} + \frac{7}{8} + x$

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + 2y' + y = 1 + 2\cos(x) + \cos(2x) - \sin(2x)}$$

17.30.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 1, f(x) = 1 + 2\cos(x) + \cos(2x) - \sin(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 2\lambda\,\mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{(2)^2 - (4)\,(1)\,(1)}\\ &= -1\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 1$. Therefore the solution is

$$y = c_1 \mathrm{e}^{-x} + c_2 x\,\mathrm{e}^{-x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{-x} + c_2 x\,\mathrm{e}^{-x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1 + 2\cos(x) + \cos(2x) - \sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{\cos(x), \sin(x)\}, \{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\,\mathrm{e}^{-x}, \mathrm{e}^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 + A_2 \cos(x) + A_3 \sin(x) + A_4 \cos(2x) + A_5 \sin(2x)$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-3A_4 \cos(2x) - 3A_5 \sin(2x) - 2A_2 \sin(x) + 2A_3 \cos(x) - 4A_4 \sin(2x) \\ + 4A_5 \cos(2x) + A_1 = 1 + 2\cos(x) + \cos(2x) - \sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 1, A_2 = 0, A_3 = 1, A_4 = \frac{1}{25}, A_5 = \frac{7}{25}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 1 + \sin(x) + \frac{\cos(2x)}{25} + \frac{7\sin(2x)}{25}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2 x\, e^{-x}\right) + \left(1 + \sin(x) + \frac{\cos(2x)}{25} + \frac{7\sin(2x)}{25}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-x}(c_2 x + c_1) + 1 + \sin(x) + \frac{\cos(2x)}{25} + \frac{7\sin(2x)}{25}$$

Summary

The solution(s) found are the following

$$y = e^{-x}(c_2 x + c_1) + 1 + \sin(x) + \frac{\cos(2x)}{25} + \frac{7\sin(2x)}{25} \tag{1}$$

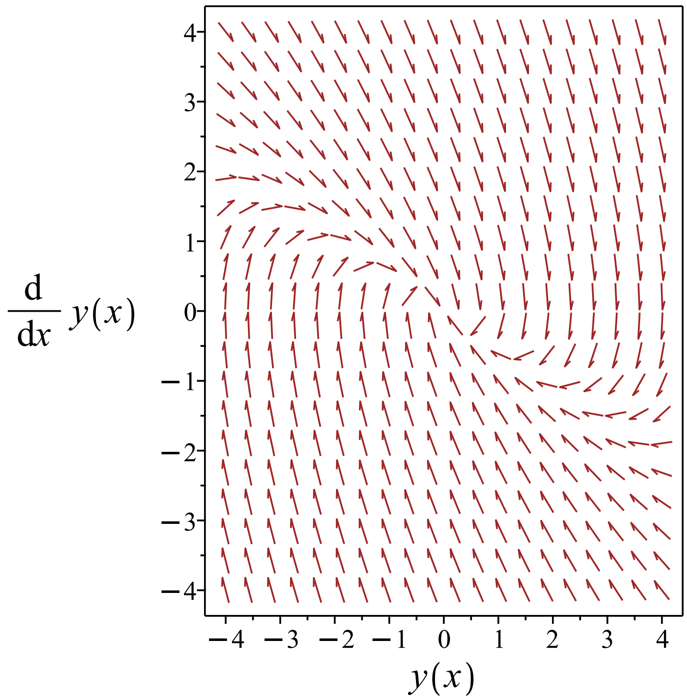

Figure 707: Slope field plot

Verification of solutions

$$y = e^{-x}(c_2x + c_1) + 1 + \sin(x) + \frac{\cos(2x)}{25} + \frac{7\sin(2x)}{25}$$

Verified OK.

17.30.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)$$

Where $p(x) = 2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int 2\,dx} \\ &= e^{x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= e^{x}(1 + 2\cos(x) + \cos(2x) - \sin(2x)) \\
(e^{x}y)'' &= e^{x}(1 + 2\cos(x) + \cos(2x) - \sin(2x))
\end{aligned}
$$

Integrating once gives

$$
(e^{x}y)' = \frac{\left(6\cos(x)^{2} + 2\sin(x)\cos(x) + 2 + 5\cos(x) + 5\sin(x)\right)e^{x}}{5} + c_1
$$

Integrating again gives

$$
(e^{x}y) = \frac{\left(2\cos(x)^{2} + 14\sin(x)\cos(x) + 25\sin(x) + 24\right)e^{x}}{25} + c_1x + c_2
$$

Hence the solution is

$$
y = \frac{\frac{\left(2\cos(x)^{2}+14\sin(x)\cos(x)+25\sin(x)+24\right)e^{x}}{25} + c_1x + c_2}{e^{x}}
$$

Or

$$
y = \frac{2\cos(x)^{2}}{25} + \frac{14\cos(x)\sin(x)}{25} + c_1x\,e^{-x} + \sin(x) + e^{-x}c_2 + \frac{24}{25}
$$

Summary

The solution(s) found are the following

$$
y = \frac{2\cos(x)^{2}}{25} + \frac{14\cos(x)\sin(x)}{25} + c_1x\,e^{-x} + \sin(x) + e^{-x}c_2 + \frac{24}{25} \tag{1}
$$

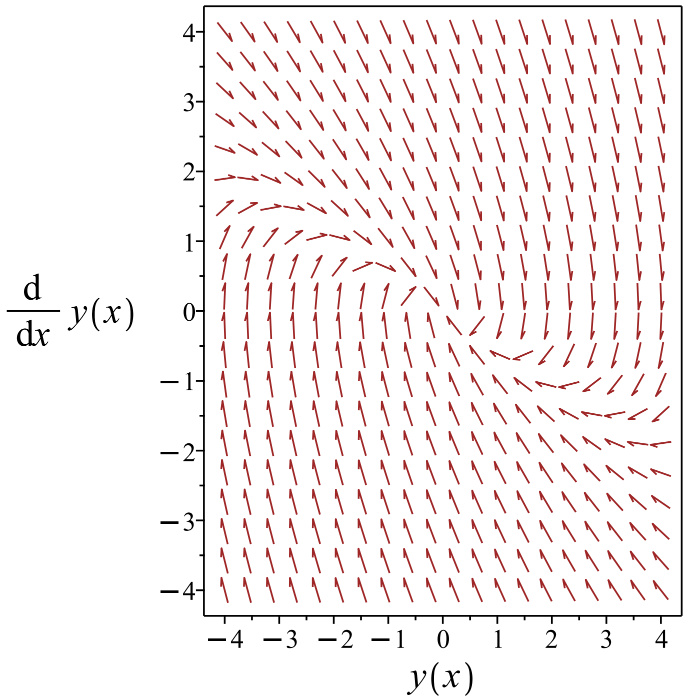

Figure 708: Slope field plot

Verification of solutions

$$y = \frac{2\cos(x)^2}{25} + \frac{14\cos(x)\sin(x)}{25} + c_1 x \,\mathrm{e}^{-x} + \sin(x) + \mathrm{e}^{-x} c_2 + \frac{24}{25}$$

Verified OK.

17.30.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 550: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\
&= z_1 e^{-x} \\
&= z_1 \left(\mathrm{e}^{-x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2x}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 2y' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-x} + c_2 x \,\mathrm{e}^{-x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
2\cos(x)\left(-\sin(x) + \cos(x) + 1\right)
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{1\}, \{\cos(x), \sin(x)\}, \{\cos(2x), \sin(2x)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{x \,\mathrm{e}^{-x}, \mathrm{e}^{-x}\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 + A_2 \cos(x) + A_3 \sin(x) + A_4 \cos(2x) + A_5 \sin(2x)
$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-3A_4 \cos(2x) - 3A_5 \sin(2x) - 2A_2 \sin(x) + 2A_3 \cos(x) - 4A_4 \sin(2x) \\ + 4A_5 \cos(2x) + A_1 = 1 + 2\cos(x) + \cos(2x) - \sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 1, A_2 = 0, A_3 = 1, A_4 = \frac{1}{25}, A_5 = \frac{7}{25}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 1 + \sin(x) + \frac{\cos(2x)}{25} + \frac{7\sin(2x)}{25}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + c_2 x\,\mathrm{e}^{-x}\right) + \left(1 + \sin(x) + \frac{\cos(2x)}{25} + \frac{7\sin(2x)}{25}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{-x}(c_2 x + c_1) + 1 + \sin(x) + \frac{\cos(2x)}{25} + \frac{7\sin(2x)}{25}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-x}(c_2 x + c_1) + 1 + \sin(x) + \frac{\cos(2x)}{25} + \frac{7\sin(2x)}{25} \tag{1}$$

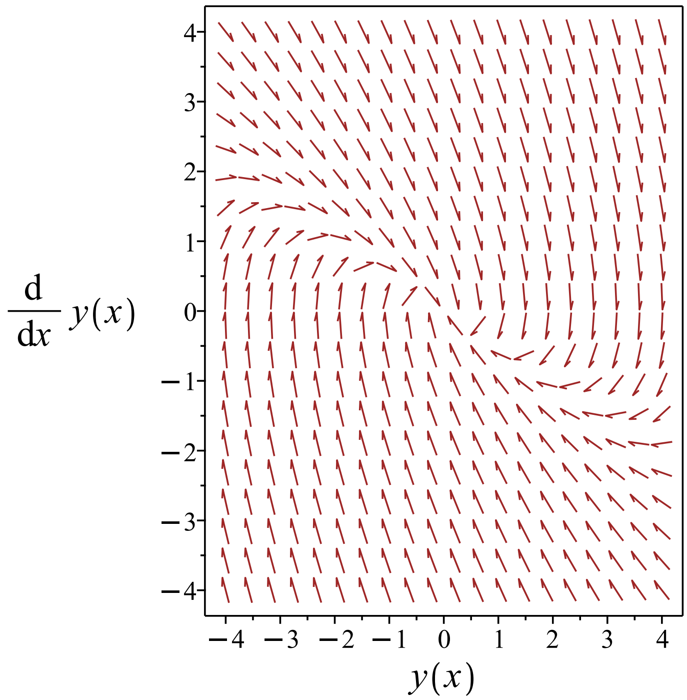

Figure 709: Slope field plot

Verification of solutions

$$y = e^{-x}(c_2x + c_1) + 1 + \sin(x) + \frac{\cos(2x)}{25} + \frac{7\sin(2x)}{25}$$

Verified OK.

17.30.4 Maple step by step solution

Let's solve

$y'' + 2y' + y = 1 + 2\cos(x) + \cos(2x) - \sin(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r + 1 = 0$

- Factor the characteristic polynomial

  $(r + 1)^2 = 0$

- Root of the characteristic polynomial

$r = -1$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,\mathrm{e}^{-x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 x\,\mathrm{e}^{-x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 1 + 2\cos(x) + \cos(2x\right.$

  - Wronskian of solutions of the homogeneous equation

    $$W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-x} & x\,\mathrm{e}^{-x} \\ -\mathrm{e}^{-x} & \mathrm{e}^{-x} - x\,\mathrm{e}^{-x} \end{bmatrix}$$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = \mathrm{e}^{-2x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = 2\,\mathrm{e}^{-x}\left(-\left(\int x\cos(x)(-\sin(x) + \cos(x) + 1)\,\mathrm{e}^{x}dx\right) + x\left(\int \cos(x)(-\sin(x) + \cos(x) + 1\right.\right.$

  - Compute integrals

    $y_p(x) = \frac{(14\cos(x)+25)\sin(x)}{25} + \frac{2\cos(x)^2}{25} + \frac{24}{25}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 x\,\mathrm{e}^{-x} + \frac{(14\cos(x)+25)\sin(x)}{25} + \frac{2\cos(x)^2}{25} + \frac{24}{25}$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y' + y = -1 + \sin(x) + x + x^2}$$

17.31.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = 1, f(x) = -1 + \sin(x) + x + x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 1, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + \lambda e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + \lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 1, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-1}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{1^2 - (4)(1)(1)}\\ &= -\frac{1}{2} \pm \frac{i\sqrt{3}}{2}\end{aligned}$$

Hence

$$\lambda_1 = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$$
$$\lambda_2 = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$$

Which simplifies to

$$\lambda_1 = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$$
$$\lambda_2 = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -\frac{1}{2}$ and $\beta = \frac{\sqrt{3}}{2}$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-\frac{x}{2}}\left(c_1 \cos\left(\frac{x\sqrt{3}}{2}\right) + c_2 \sin\left(\frac{x\sqrt{3}}{2}\right)\right)$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-\frac{x}{2}} \left(c_1 \cos\left(\frac{x\sqrt{3}}{2}\right) + c_2 \sin\left(\frac{x\sqrt{3}}{2}\right)\right)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$-1 + \sin(x) + x + x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}, \{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{ e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right), e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right) \right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x) + A_3 + A_4 x + A_5 x^2$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_5 - A_1 \sin(x) + A_2 \cos(x) + A_4 + 2A_5 x + A_3 + A_4 x + A_5 x^2 = -1 + \sin(x) + x + x^2$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1, A_2 = 0, A_3 = -2, A_4 = -1, A_5 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\cos(x) - 2 - x + x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-\frac{x}{2}} \left(c_1 \cos\left(\frac{x\sqrt{3}}{2}\right) + c_2 \sin\left(\frac{x\sqrt{3}}{2}\right)\right)\right) + \left(-\cos(x) - 2 - x + x^2\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{-\frac{x}{2}} \left(c_1 \cos \left(\frac{x\sqrt{3}}{2} \right) + c_2 \sin \left(\frac{x\sqrt{3}}{2} \right) \right) - \cos(x) - 2 - x + x^2 \tag{1}$$

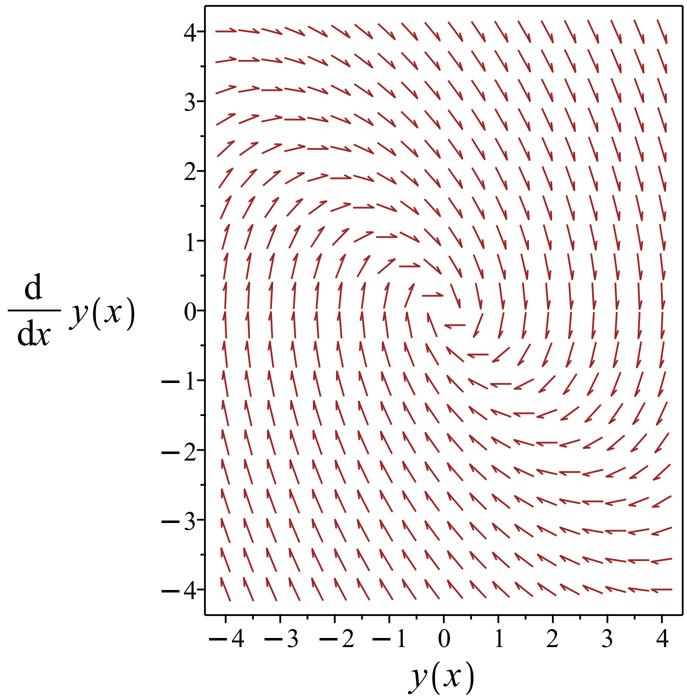

Figure 710: Slope field plot

Verification of solutions

$$y = e^{-\frac{x}{2}} \left(c_1 \cos \left(\frac{x\sqrt{3}}{2} \right) + c_2 \sin \left(\frac{x\sqrt{3}}{2} \right) \right) - \cos(x) - 2 - x + x^2$$

Verified OK.

17.31.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y' + y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 1 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -\frac{3z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 552: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -\frac{3}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos\left(\frac{x\sqrt{3}}{2}\right)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\,dx} \\
&= z_1 e^{-\frac{x}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{2\sqrt{3}\,\tan\left(\frac{x\sqrt{3}}{2}\right)}{3}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)\right) + c_2\left(\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)\left(\frac{2\sqrt{3}\,\tan\left(\frac{x\sqrt{3}}{2}\right)}{3}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \cos\left(\frac{x\sqrt{3}}{2}\right) \mathrm{e}^{-\frac{x}{2}} c_1 + \frac{2c_2 \mathrm{e}^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$-1 + \sin(x) + x + x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}, \{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right), \frac{2\,\mathrm{e}^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x) + A_3 + A_4 x + A_5 x^2$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_5 - A_1 \sin(x) + A_2 \cos(x) + A_4 + 2A_5 x + A_3 + A_4 x + A_5 x^2 = -1 + \sin(x) + x + x^2$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1, A_2 = 0, A_3 = -2, A_4 = -1, A_5 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\cos(x) - 2 - x + x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\cos\left(\frac{x\sqrt{3}}{2}\right) e^{-\frac{x}{2}} c_1 + \frac{2c_2 e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3}\right) + \left(-\cos(x) - 2 - x + x^2\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \cos\left(\frac{x\sqrt{3}}{2}\right) e^{-\frac{x}{2}} c_1 + \frac{2c_2 e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} - \cos(x) - 2 - x + x^2 \tag{1}$$

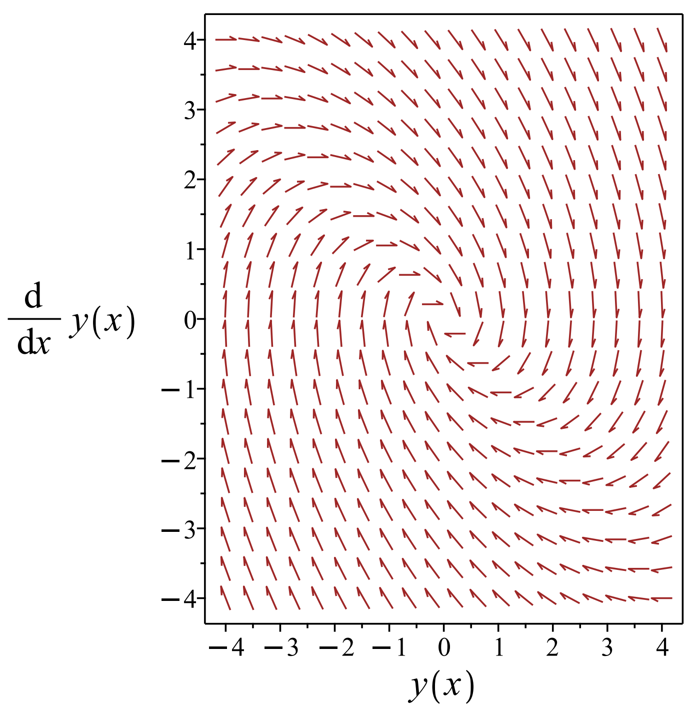

Figure 711: Slope field plot

Verification of solutions

$$y = \cos\left(\frac{x\sqrt{3}}{2}\right) \mathrm{e}^{-\frac{x}{2}} c_1 + \frac{2c_2 \mathrm{e}^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} - \cos(x) - 2 - x + x^2$$

Verified OK.

17.31.3 Maple step by step solution

Let's solve

$y'' + y' + y = -1 + \sin(x) + x + x^2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + r + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-1) \pm (\sqrt{-3})}{2}$

- Roots of the characteristic polynomial

  $r = \left(-\frac{1}{2} - \frac{\mathrm{I}\sqrt{3}}{2}, -\frac{1}{2} + \frac{\mathrm{I}\sqrt{3}}{2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \cos\left(\frac{x\sqrt{3}}{2}\right) \mathrm{e}^{-\frac{x}{2}} c_1 + \sin\left(\frac{x\sqrt{3}}{2}\right) \mathrm{e}^{-\frac{x}{2}} c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = -1 + \sin(x) + x + x^2\right]$

- ○ Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right) & e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right) \\ -\frac{e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{2} - \frac{e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} & -\frac{e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} \end{bmatrix}$$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = \frac{\sqrt{3}\, e^{-x}}{2}$

- Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{2 e^{-\frac{x}{2}} \sqrt{3} \left(\cos\left(\frac{x\sqrt{3}}{2}\right)\left(\int e^{\frac{x}{2}} (-1+\sin(x)+x+x^2) \sin\left(\frac{x\sqrt{3}}{2}\right)dx\right) - \sin\left(\frac{x\sqrt{3}}{2}\right)\left(\int e^{\frac{x}{2}} (-1+\sin(x)+x+x^2) \cos\left(\frac{x\sqrt{3}}{2}\right)dx\right)\right)}{3}$

- Compute integrals

  $y_p(x) = -\cos(x) - 2 - x + x^2$

- Substitute particular solution into general solution to ODE

  $y = \cos\left(\frac{x\sqrt{3}}{2}\right) e^{-\frac{x}{2}} c_1 + \sin\left(\frac{x\sqrt{3}}{2}\right) e^{-\frac{x}{2}} c_2 + x^2 - \cos(x) - x - 2$

Maple trace

```
`Methods for second order ODEs:

Problem number: 582.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 6y' + 9y = 18\,\mathrm{e}^{-3x} + 8\sin(x) + 6\cos(x)}$$

17.32.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 6, C = 9, f(x) = 18\,\mathrm{e}^{-3x} + 8\sin(x) + 6\cos(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 6y' + 9y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 6, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 6\lambda\, e^{\lambda x} + 9\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 6\lambda + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 6, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-6}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{(6)^2 - (4)\,(1)\,(9)}\\ &= -3\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 3$. Therefore the solution is

$$y = c_1 e^{-3x} + c_2 x\, e^{-3x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{-3x} + c_2 x\, e^{-3x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$18\, e^{-3x} + 8 \sin(x) + 6 \cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-3x}\}, \{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{-3x}, e^{-3x}\}$$

Since e^{-3x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{-3x}\}, \{\cos(x), \sin(x)\}]$$

Since $x\,e^{-3x}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2e^{-3x}\}, \{\cos(x), \sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1x^2e^{-3x} + A_2\cos(x) + A_3\sin(x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&2A_1e^{-3x} + 8A_2\cos(x) + 8A_3\sin(x) - 6A_2\sin(x) + 6A_3\cos(x)\\&= 18\,e^{-3x} + 8\sin(x) + 6\cos(x)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 9, A_2 = 0, A_3 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 9x^2e^{-3x} + \sin(x)$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\&= \left(c_1e^{-3x} + c_2x\,e^{-3x}\right) + \left(9x^2e^{-3x} + \sin(x)\right)\end{aligned}$$

Which simplifies to

$$y = e^{-3x}(c_2x + c_1) + 9x^2e^{-3x} + \sin(x)$$

Summary

The solution(s) found are the following

$$y = e^{-3x}(c_2x + c_1) + 9x^2e^{-3x} + \sin(x) \tag{1}$$

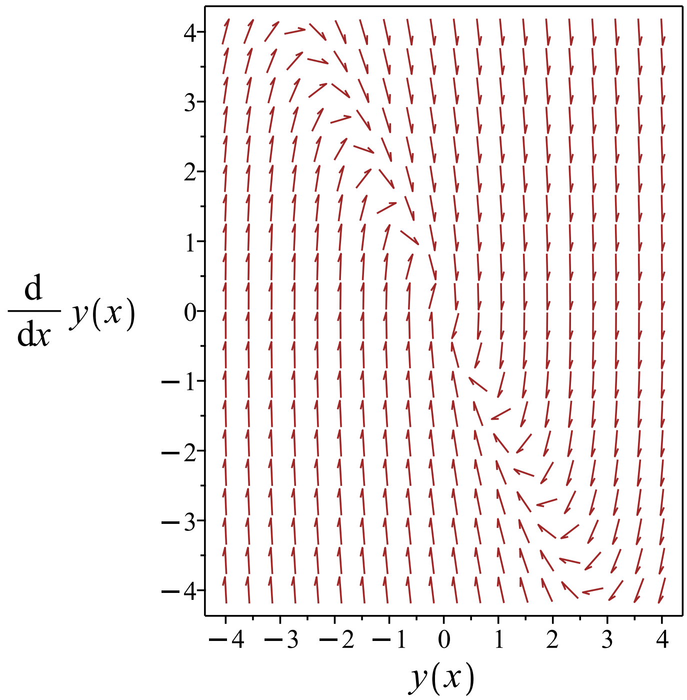

Figure 712: Slope field plot

Verification of solutions

$$y = e^{-3x}(c_2x + c_1) + 9x^2e^{-3x} + \sin(x)$$

Verified OK.

17.32.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{(p(x)^2 + p'(x))\,y}{2} = f(x)$$

Where $p(x) = 6$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int 6\,dx} \\ &= e^{3x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= e^{3x}\left(18\,e^{-3x} + 8\sin(x) + 6\cos(x)\right) \\
\left(e^{3x}y\right)'' &= e^{3x}\left(18\,e^{-3x} + 8\sin(x) + 6\cos(x)\right)
\end{aligned}
$$

Integrating once gives

$$
\left(e^{3x}y\right)' = 18x + (\cos(x) + 3\sin(x))\,e^{3x} + c_1
$$

Integrating again gives

$$
\left(e^{3x}y\right) = c_1x + e^{3x}\sin(x) + 9x^2 + c_2
$$

Hence the solution is

$$
y = \frac{c_1x + e^{3x}\sin(x) + 9x^2 + c_2}{e^{3x}}
$$

Or

$$
y = \sin(x) + c_1x\,e^{-3x} + 9x^2e^{-3x} + c_2e^{-3x}
$$

Summary

The solution(s) found are the following

$$
y = \sin(x) + c_1x\,e^{-3x} + 9x^2e^{-3x} + c_2e^{-3x} \tag{1}
$$

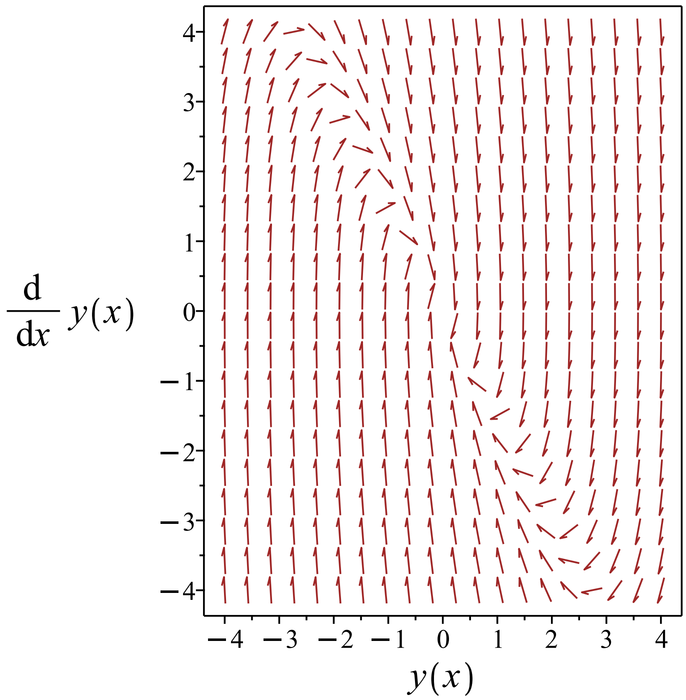

Figure 713: Slope field plot

Verification of solutions

$$y = \sin(x) + c_1 x\,\mathrm{e}^{-3x} + 9x^2\mathrm{e}^{-3x} + c_2\mathrm{e}^{-3x}$$

Verified OK.

17.32.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 6y' + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 6 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 554: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{6}{1}\,dx} \\ &= z_1 e^{-3x} \\ &= z_1 \left(\mathrm{e}^{-3x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{6}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-6x}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-3x}\right) + c_2\left(\mathrm{e}^{-3x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 6y' + 9y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-3x} + c_2 x\,\mathrm{e}^{-3x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
18\,\mathrm{e}^{-3x} + 8\sin(x) + 6\cos(x)
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\mathrm{e}^{-3x}\}, \{\cos(x), \sin(x)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{x\,\mathrm{e}^{-3x}, \mathrm{e}^{-3x}\}
$$

Since e^{-3x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$
[\{x\,\mathrm{e}^{-3x}\}, \{\cos(x), \sin(x)\}]
$$

Since $x\,\mathrm{e}^{-3x}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$
[\{x^2 \mathrm{e}^{-3x}\}, \{\cos(x), \sin(x)\}]
$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 e^{-3x} + A_2 \cos(x) + A_3 \sin(x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{-3x} + 8A_2 \cos(x) + 8A_3 \sin(x) - 6A_2 \sin(x) + 6A_3 \cos(x)$$
$$= 18\,e^{-3x} + 8\sin(x) + 6\cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 9, A_2 = 0, A_3 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 9x^2 e^{-3x} + \sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-3x} + c_2 x\, e^{-3x}\right) + \left(9x^2 e^{-3x} + \sin(x)\right) \end{aligned}$$

Which simplifies to

$$y = e^{-3x}(c_2 x + c_1) + 9x^2 e^{-3x} + \sin(x)$$

Summary

The solution(s) found are the following

$$y = e^{-3x}(c_2 x + c_1) + 9x^2 e^{-3x} + \sin(x) \tag{1}$$

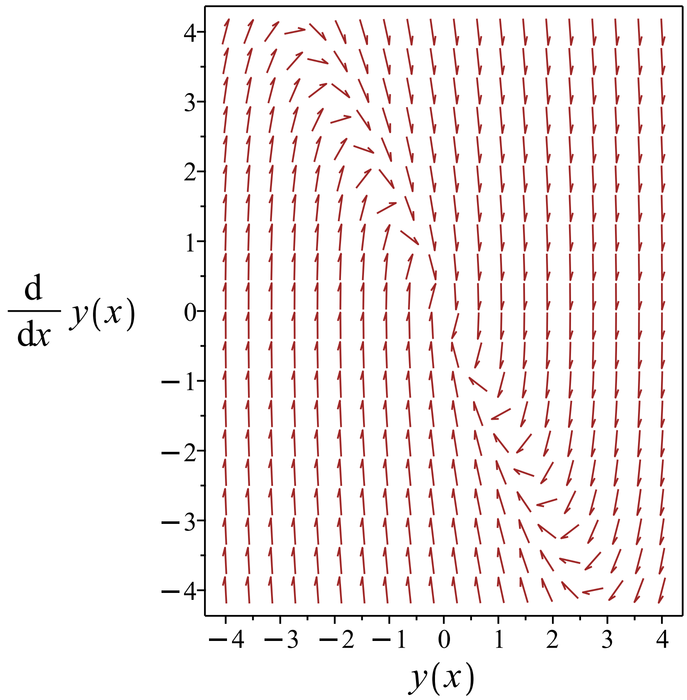

Figure 714: Slope field plot

Verification of solutions

$$y = e^{-3x}(c_2x + c_1) + 9x^2e^{-3x} + \sin(x)$$

Verified OK.

17.32.4 Maple step by step solution

Let's solve

$y'' + 6y' + 9y = 18\,e^{-3x} + 8\sin(x) + 6\cos(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 6r + 9 = 0$

- Factor the characteristic polynomial

  $(r+3)^2 = 0$

- Root of the characteristic polynomial

$r = -3$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-3x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\, e^{-3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-3x} + c_2 x\, e^{-3x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 18\, e^{-3x} + 8 \sin(x) + 6\right.$

  ◦ Wronskian of solutions of the homogeneous equation

  $$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-3x} & x\, e^{-3x} \\ -3\, e^{-3x} & e^{-3x} - 3x\, e^{-3x} \end{bmatrix}$$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{-6x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -2\, e^{-3x}\left(-x\left(\int (9 + (4 \sin(x) + 3 \cos(x))\, e^{3x})\, dx\right) + \int 3\left(3 + \left(\cos(x) + \frac{4 \sin(x)}{3}\right) e^{3x}\right) x d$

  ◦ Compute integrals

  $y_p(x) = 9x^2 e^{-3x} + \sin(x)$

- Substitute particular solution into general solution to ODE

  $y = c_2 x\, e^{-3x} + 9x^2 e^{-3x} + c_1 e^{-3x} + \sin(x)$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + 2y' = -1 + 3\sin(2x) + \cos(x)}$$

17.33.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 0, f(x) = -1 + 3\sin(2x) + \cos(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 2\lambda\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{2^2 - (4)\,(1)\,(0)}\\ &= -1 \pm 1\end{aligned}$$

Hence

$$\lambda_1 = -1 + 1$$
$$\lambda_2 = -1 - 1$$

Which simplifies to

$$\lambda_1 = 0$$
$$\lambda_2 = -2$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(0)x} + c_2 e^{(-2)x}$$

Or

$$y = c_1 + e^{-2x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + e^{-2x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$-1 + 3\sin(2x) + \cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{\cos(x), \sin(x)\}, \{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-2x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}, \{\cos(x), \sin(x)\}, \{\cos(2x), \sin(2x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x + A_2 \cos(x) + A_3 \sin(x) + A_4 \cos(2x) + A_5 \sin(2x)$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_2 \cos(x) - A_3 \sin(x) - 4A_4 \cos(2x) - 4A_5 \sin(2x) + 2A_1 - 2A_2 \sin(x) + 2A_3 \cos(x) - 4A_4 \sin(2x) + 4A_5 \cos(2x) = -1 + 3\sin(2x) + \cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{2}, A_2 = -\frac{1}{5}, A_3 = \frac{2}{5}, A_4 = -\frac{3}{8}, A_5 = -\frac{3}{8}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x}{2} - \frac{\cos(x)}{5} + \frac{2\sin(x)}{5} - \frac{3\cos(2x)}{8} - \frac{3\sin(2x)}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 + e^{-2x} c_2) + \left(-\frac{x}{2} - \frac{\cos(x)}{5} + \frac{2\sin(x)}{5} - \frac{3\cos(2x)}{8} - \frac{3\sin(2x)}{8}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + e^{-2x} c_2 - \frac{x}{2} - \frac{\cos(x)}{5} + \frac{2\sin(x)}{5} - \frac{3\cos(2x)}{8} - \frac{3\sin(2x)}{8} \tag{1}$$

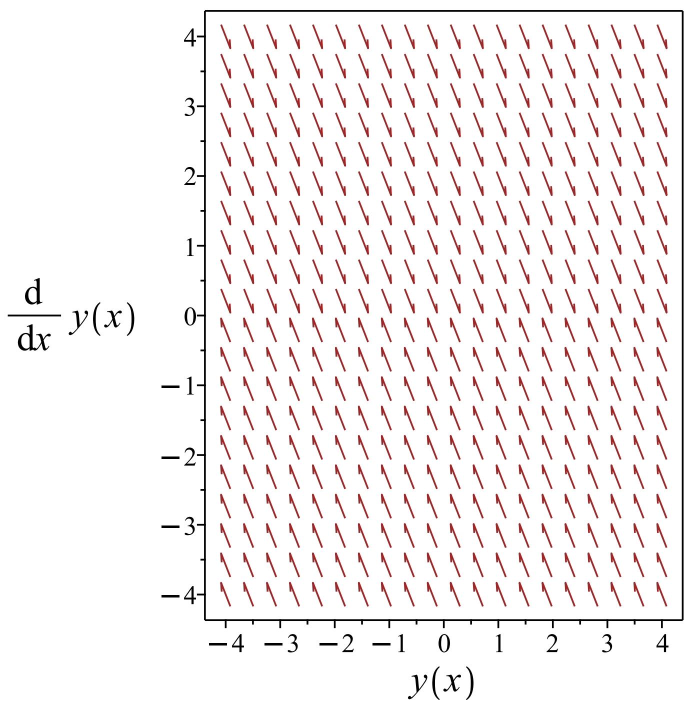

Figure 715: Slope field plot

Verification of solutions

$$y = c_1 + e^{-2x} c_2 - \frac{x}{2} - \frac{\cos(x)}{5} + \frac{2\sin(x)}{5} - \frac{3\cos(2x)}{8} - \frac{3\sin(2x)}{8}$$

Verified OK.

17.33.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 2y')\, dx = \int (-1 + 3\sin(2x) + \cos(x))\, dx$$

$$2y + y' = -x - \frac{3\cos(2x)}{2} + \sin(x) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 2$$
$$q(x) = -x - \frac{3\cos(2x)}{2} + \sin(x) + c_1$$

Hence the ode is

$$2y + y' = -x - \frac{3\cos(2x)}{2} + \sin(x) + c_1$$

The integrating factor μ is

$$\mu = e^{\int 2dx} = e^{2x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(-x - \frac{3\cos(2x)}{2} + \sin(x) + c_1\right)$$
$$\frac{d}{dx}(e^{2x} y) = (e^{2x})\left(-x - \frac{3\cos(2x)}{2} + \sin(x) + c_1\right)$$
$$d(e^{2x} y) = \left(\frac{(2\sin(x) - 3\cos(2x) + 2c_1 - 2x)\, e^{2x}}{2}\right) dx$$

Integrating gives

$$e^{2x} y = \int \frac{(2\sin(x) - 3\cos(2x) + 2c_1 - 2x)\, e^{2x}}{2}\, dx$$
$$e^{2x} y = -\frac{3(2\sin(x) + 2\cos(x))\, e^{2x}\cos(x)}{8} + \frac{5\, e^{2x}}{8} - \frac{e^{2x}\cos(x)}{5} + \frac{2\, e^{2x}\sin(x)}{5} - \frac{x\, e^{2x}}{2} + \frac{e^{2x} c_1}{2} + c_2$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{2x}$ results in

$$y = \mathrm{e}^{-2x}\left(-\frac{3(2\sin(x)+2\cos(x))\,\mathrm{e}^{2x}\cos(x)}{8} + \frac{5\,\mathrm{e}^{2x}}{8} - \frac{\mathrm{e}^{2x}\cos(x)}{5} + \frac{2\,\mathrm{e}^{2x}\sin(x)}{5} - \frac{x\,\mathrm{e}^{2x}}{2} + \frac{\mathrm{e}^{2x}c_1}{2}\right) + \mathrm{e}^{-2}$$

which simplifies to

$$y = -\frac{3\cos(x)\sin(x)}{4} - \frac{3\cos(x)^2}{4} + \frac{c_1}{2} - \frac{x}{2} + \frac{2\sin(x)}{5} - \frac{\cos(x)}{5} + \frac{5}{8} + \mathrm{e}^{-2x}c_2$$

Summary

The solution(s) found are the following

$$y = -\frac{3\cos(x)\sin(x)}{4} - \frac{3\cos(x)^2}{4} + \frac{c_1}{2} - \frac{x}{2} + \frac{2\sin(x)}{5} - \frac{\cos(x)}{5} + \frac{5}{8} + \mathrm{e}^{-2x}c_2 \quad (1)$$

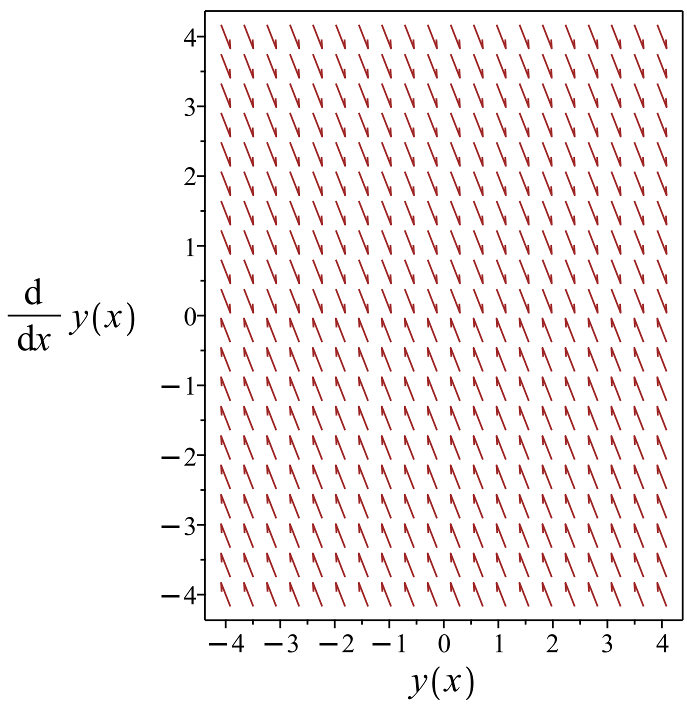

Figure 716: Slope field plot

Verification of solutions

$$y = -\frac{3\cos(x)\sin(x)}{4} - \frac{3\cos(x)^2}{4} + \frac{c_1}{2} - \frac{x}{2} + \frac{2\sin(x)}{5} - \frac{\cos(x)}{5} + \frac{5}{8} + \mathrm{e}^{-2x}c_2$$

Verified OK.

17.33.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + 2p(x) + 1 - 3\sin(2x) - \cos(x) = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= 2 \\ q(x) &= -1 + 3\sin(2x) + \cos(x) \end{aligned}$$

Hence the ode is

$$p'(x) + 2p(x) = -1 + 3\sin(2x) + \cos(x)$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 2dx} \\ &= e^{2x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu)(-1 + 3\sin(2x) + \cos(x)) \\ \frac{d}{dx}(e^{2x} p) &= (e^{2x})(-1 + 3\sin(2x) + \cos(x)) \\ d(e^{2x} p) &= ((-1 + 3\sin(2x) + \cos(x))e^{2x})\ dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{2x} p &= \int (-1 + 3\sin(2x) + \cos(x))e^{2x}\, dx \\ e^{2x} p &= -\frac{e^{2x}}{2} + \frac{3e^{2x}(2\sin(2x) - 2\cos(2x))}{8} + \frac{2e^{2x}\cos(x)}{5} + \frac{e^{2x}\sin(x)}{5} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$p(x) = e^{-2x}\left(-\frac{e^{2x}}{2} + \frac{3\,e^{2x}(2\sin(2x) - 2\cos(2x))}{8} + \frac{2\,e^{2x}\cos(x)}{5} + \frac{e^{2x}\sin(x)}{5}\right) + c_1 e^{-2x}$$

which simplifies to

$$p(x) = \frac{3\cos(x)\sin(x)}{2} - \frac{3\cos(x)^2}{2} + \frac{\sin(x)}{5} + \frac{2\cos(x)}{5} + \frac{1}{4} + c_1 e^{-2x}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{3\cos(x)\sin(x)}{2} - \frac{3\cos(x)^2}{2} + \frac{\sin(x)}{5} + \frac{2\cos(x)}{5} + \frac{1}{4} + c_1 e^{-2x}$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{3\cos(x)\sin(x)}{2} - \frac{3\cos(x)^2}{2} + \frac{\sin(x)}{5} + \frac{2\cos(x)}{5} + \frac{1}{4} + c_1 e^{-2x}\, dx \\ &= -\frac{x}{2} - \frac{3\cos(x)\sin(x)}{4} - \frac{c_1 e^{-2x}}{2} + \frac{3\sin(x)^2}{4} + \frac{2\sin(x)}{5} - \frac{\cos(x)}{5} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{x}{2} - \frac{3\cos(x)\sin(x)}{4} - \frac{c_1 e^{-2x}}{2} + \frac{3\sin(x)^2}{4} + \frac{2\sin(x)}{5} - \frac{\cos(x)}{5} + c_2 \tag{1}$$

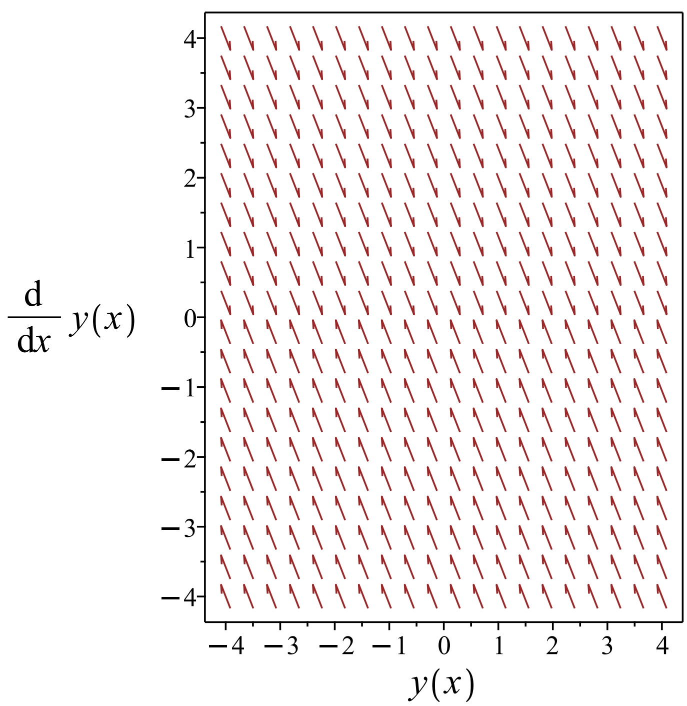

Figure 717: Slope field plot

Verification of solutions

$$y = -\frac{x}{2} - \frac{3\cos(x)\sin(x)}{4} - \frac{c_1 e^{-2x}}{2} + \frac{3\sin(x)^2}{4} + \frac{2\sin(x)}{5} - \frac{\cos(x)}{5} + c_2$$

Verified OK.

17.33.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + 2y' = -1 + 3\sin(2x) + \cos(x)$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 2y')\, dx = \int (-1 + 3\sin(2x) + \cos(x))\, dx$$

$$2y + y' = -x - \frac{3\cos(2x)}{2} + \sin(x) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 2$$
$$q(x) = -x - \frac{3\cos(2x)}{2} + \sin(x) + c_1$$

Hence the ode is

$$2y + y' = -x - \frac{3\cos(2x)}{2} + \sin(x) + c_1$$

The integrating factor μ is

$$\mu = e^{\int 2dx}$$
$$= e^{2x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(-x - \frac{3\cos(2x)}{2} + \sin(x) + c_1\right)$$
$$\frac{d}{dx}(e^{2x} y) = (e^{2x})\left(-x - \frac{3\cos(2x)}{2} + \sin(x) + c_1\right)$$
$$d(e^{2x} y) = \left(\frac{(2\sin(x) - 3\cos(2x) + 2c_1 - 2x)\, e^{2x}}{2}\right) dx$$

Integrating gives

$$e^{2x}y = \int \frac{(2\sin(x) - 3\cos(2x) + 2c_1 - 2x)\, e^{2x}}{2}\, dx$$

$$e^{2x}y = -\frac{3(2\sin(x) + 2\cos(x))\, e^{2x}\cos(x)}{8} + \frac{5\, e^{2x}}{8} - \frac{e^{2x}\cos(x)}{5} + \frac{2\, e^{2x}\sin(x)}{5} - \frac{x\, e^{2x}}{2} + \frac{e^{2x}c_1}{2} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$y = e^{-2x}\left(-\frac{3(2\sin(x) + 2\cos(x))\, e^{2x}\cos(x)}{8} + \frac{5\, e^{2x}}{8} - \frac{e^{2x}\cos(x)}{5} + \frac{2\, e^{2x}\sin(x)}{5} - \frac{x\, e^{2x}}{2} + \frac{e^{2x}c_1}{2}\right) + e^{-2}$$

which simplifies to

$$y = -\frac{3\cos(x)\sin(x)}{4} - \frac{3\cos(x)^2}{4} + \frac{c_1}{2} - \frac{x}{2} + \frac{2\sin(x)}{5} - \frac{\cos(x)}{5} + \frac{5}{8} + e^{-2x}c_2$$

Summary

The solution(s) found are the following

$$y = -\frac{3\cos(x)\sin(x)}{4} - \frac{3\cos(x)^2}{4} + \frac{c_1}{2} - \frac{x}{2} + \frac{2\sin(x)}{5} - \frac{\cos(x)}{5} + \frac{5}{8} + e^{-2x}c_2 \quad (1)$$

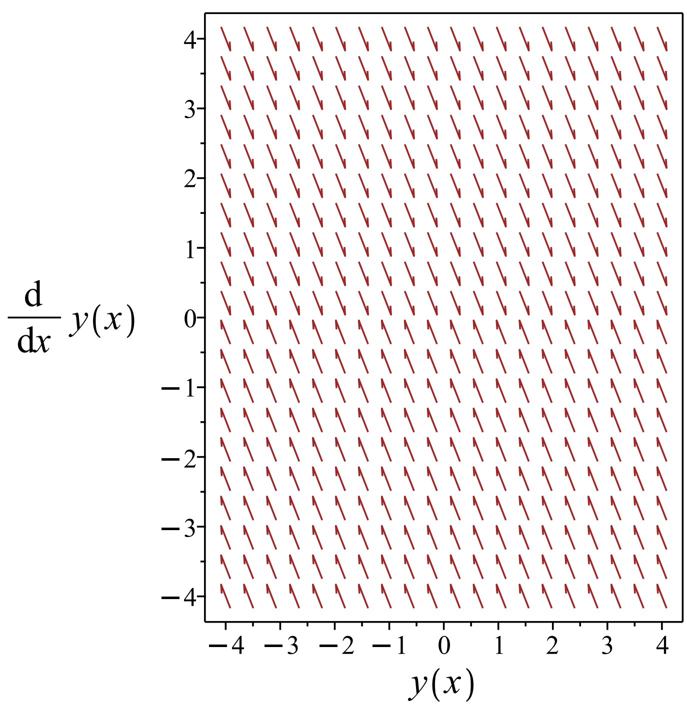

Figure 718: Slope field plot

Verification of solutions

$$y = -\frac{3\cos(x)\sin(x)}{4} - \frac{3\cos(x)^2}{4} + \frac{c_1}{2} - \frac{x}{2} + \frac{2\sin(x)}{5} - \frac{\cos(x)}{5} + \frac{5}{8} + \mathrm{e}^{-2x}c_2$$

Verified OK.

17.33.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 556: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\
&= z_1 e^{-x} \\
&= z_1 \left(\mathrm{e}^{-x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\mathrm{e}^{2x}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-2x}\right) + c_2\left(\mathrm{e}^{-2x}\left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{-2x} + \frac{c_2}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^{-2x}$$
$$y_2 = \frac{1}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-2x} & \frac{1}{2} \\ \frac{d}{dx}\left(e^{-2x}\right) & \frac{d}{dx}\left(\frac{1}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-2x} & \frac{1}{2} \\ -2\,e^{-2x} & 0 \end{vmatrix}$$

Therefore

$$W = \left(e^{-2x}\right)(0) - \left(\frac{1}{2}\right)\left(-2\,e^{-2x}\right)$$

Which simplifies to

$$W = e^{-2x}$$

Which simplifies to

$$W = e^{-2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{1}{2} + \frac{3\sin(2x)}{2} + \frac{\cos(x)}{2}}{e^{-2x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\left(-1 + 3\sin(2x) + \cos(x)\right)e^{2x}}{2}dx$$

Hence

$$u_1 = \frac{e^{2x}}{4} - \frac{3\,e^{2x}\left(2\sin(2x) - 2\cos(2x)\right)}{16} - \frac{e^{2x}\cos(x)}{5} - \frac{e^{2x}\sin(x)}{10}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{-2x}\left(-1 + 3\sin(2x) + \cos(x)\right)}{e^{-2x}}\,dx$$

Which simplifies to

$$u_2 = \int \left(-1 + 3\sin(2x) + \cos(x)\right)dx$$

Hence

$$u_2 = -x - \frac{3\cos(2x)}{2} + \sin(x)$$

Which simplifies to

$$u_1 = \frac{\left(30\cos(x)^2+(-30\sin(x)-8)\cos(x)-4\sin(x)-5\right)e^{2x}}{40}$$
$$u_2 = -x-\frac{3\cos(2x)}{2}+\sin(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\left(30\cos(x)^2+(-30\sin(x)-8)\cos(x)-4\sin(x)-5\right)e^{2x}e^{-2x}}{40} - \frac{x}{2}-\frac{3\cos(2x)}{4}+\frac{\sin(x)}{2}$$

Which simplifies to

$$y_p(x) = -\frac{3\cos(x)\sin(x)}{4}+\frac{2\sin(x)}{5}-\frac{3\cos(x)^2}{4}-\frac{\cos(x)}{5}+\frac{5}{8}-\frac{x}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h+y_p \\ &= \left(c_1e^{-2x}+\frac{c_2}{2}\right)+\left(-\frac{3\cos(x)\sin(x)}{4}+\frac{2\sin(x)}{5}-\frac{3\cos(x)^2}{4}-\frac{\cos(x)}{5}+\frac{5}{8}-\frac{x}{2}\right)\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1e^{-2x}+\frac{c_2}{2}-\frac{3\cos(x)\sin(x)}{4}+\frac{2\sin(x)}{5}-\frac{3\cos(x)^2}{4}-\frac{\cos(x)}{5}+\frac{5}{8}-\frac{x}{2} \quad (1)$$

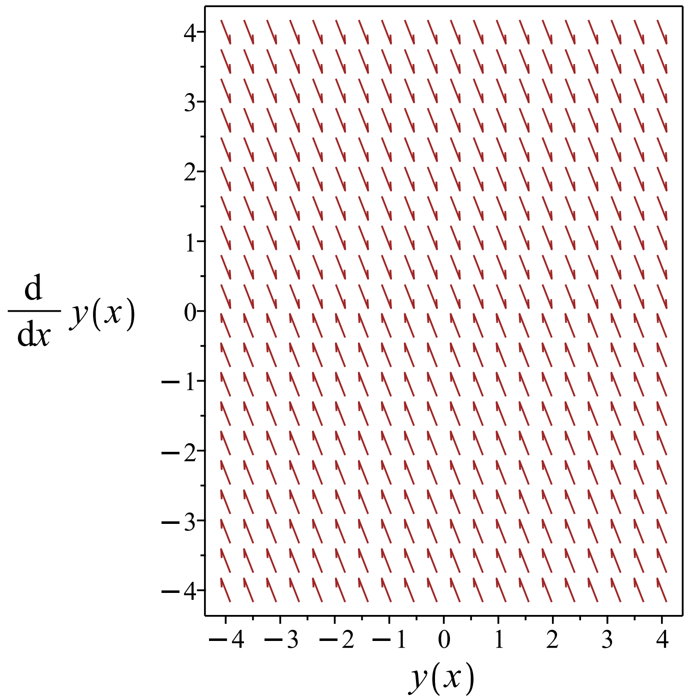

Figure 719: Slope field plot

Verification of solutions

$$y = c_1 e^{-2x} + \frac{c_2}{2} - \frac{3\cos(x)\sin(x)}{4} + \frac{2\sin(x)}{5} - \frac{3\cos(x)^2}{4} - \frac{\cos(x)}{5} + \frac{5}{8} - \frac{x}{2}$$

Verified OK.

17.33.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 2 \\ r(x) &= 0 \\ s(x) &= -1 + 3\sin(2x) + \cos(x) \end{aligned}$$

Hence

$$
\begin{aligned}
p''(x) &= 0 \\
q'(x) &= 0
\end{aligned}
$$

Therefore (1) becomes

$$
0 - (0) + (0) = 0
$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$
\left(p(x)\, y' + \left(q(x) - p'(x)\right) y\right)' = s(x)
$$

Integrating gives

$$
p(x)\, y' + \left(q(x) - p'(x)\right) y = \int s(x)\, dx
$$

Substituting the above values for p, q, r, s gives

$$
2y + y' = \int -1 + 3 \sin \left(2x\right) + \cos \left(x\right) dx
$$

We now have a first order ode to solve which is

$$
2y + y' = -x - \frac{3 \cos \left(2x\right)}{2} + \sin \left(x\right) + c_1
$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
y' + p(x)y = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= 2 \\
q(x) &= -x - \frac{3 \cos \left(2x\right)}{2} + \sin \left(x\right) + c_1
\end{aligned}
$$

Hence the ode is

$$
2y + y' = -x - \frac{3 \cos \left(2x\right)}{2} + \sin \left(x\right) + c_1
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int 2dx} \\
&= \mathrm{e}^{2x}
\end{aligned}
$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(-x - \frac{3\cos(2x)}{2} + \sin(x) + c_1\right)$$
$$\frac{d}{dx}(e^{2x} y) = (e^{2x})\left(-x - \frac{3\cos(2x)}{2} + \sin(x) + c_1\right)$$
$$d(e^{2x} y) = \left(\frac{(2\sin(x) - 3\cos(2x) + 2c_1 - 2x)\,e^{2x}}{2}\right) dx$$

Integrating gives

$$e^{2x} y = \int \frac{(2\sin(x) - 3\cos(2x) + 2c_1 - 2x)\,e^{2x}}{2}\, dx$$
$$e^{2x} y = -\frac{3(2\sin(x) + 2\cos(x))\,e^{2x}\cos(x)}{8} + \frac{5\,e^{2x}}{8} - \frac{e^{2x}\cos(x)}{5} + \frac{2\,e^{2x}\sin(x)}{5} - \frac{x\,e^{2x}}{2} + \frac{e^{2x} c_1}{2} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$y = e^{-2x}\left(-\frac{3(2\sin(x) + 2\cos(x))\,e^{2x}\cos(x)}{8} + \frac{5\,e^{2x}}{8} - \frac{e^{2x}\cos(x)}{5} + \frac{2\,e^{2x}\sin(x)}{5} - \frac{x\,e^{2x}}{2} + \frac{e^{2x} c_1}{2}\right) + e^{-2}$$

which simplifies to

$$y = -\frac{3\cos(x)\sin(x)}{4} - \frac{3\cos(x)^2}{4} + \frac{c_1}{2} - \frac{x}{2} + \frac{2\sin(x)}{5} - \frac{\cos(x)}{5} + \frac{5}{8} + e^{-2x} c_2$$

Summary

The solution(s) found are the following

$$y = -\frac{3\cos(x)\sin(x)}{4} - \frac{3\cos(x)^2}{4} + \frac{c_1}{2} - \frac{x}{2} + \frac{2\sin(x)}{5} - \frac{\cos(x)}{5} + \frac{5}{8} + e^{-2x} c_2 \quad (1)$$

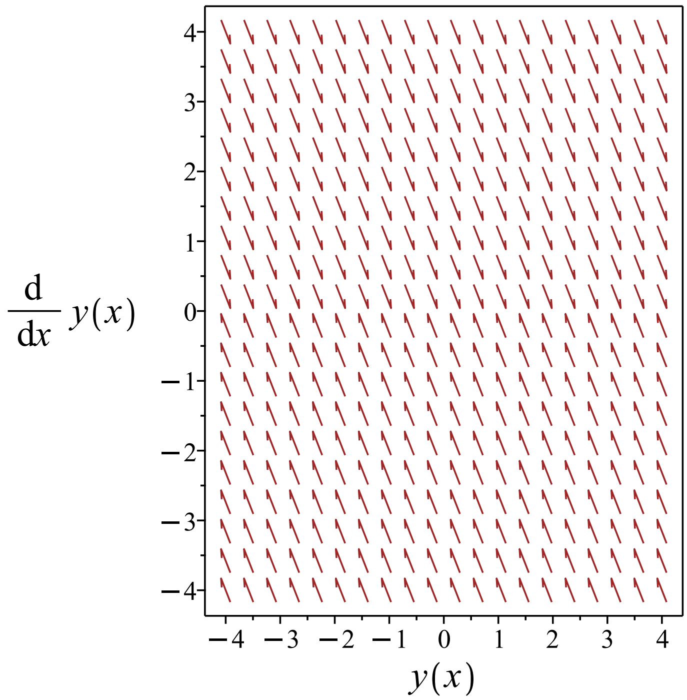

Figure 720: Slope field plot

Verification of solutions

$$y = -\frac{3\cos(x)\sin(x)}{4} - \frac{3\cos(x)^2}{4} + \frac{c_1}{2} - \frac{x}{2} + \frac{2\sin(x)}{5} - \frac{\cos(x)}{5} + \frac{5}{8} + e^{-2x}c_2$$

Verified OK.

17.33.7 Maple step by step solution

Let's solve

$y'' + 2y' = -1 + 3\sin(2x) + \cos(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r = 0$

- Factor the characteristic polynomial

  $r(r+2) = 0$

- Roots of the characteristic polynomial

$r = (-2, 0)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-2x} + c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = -1 + 3\sin(2x) + \cos(\right.$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-2x} & 1 \\ -2\,\mathrm{e}^{-2x} & 0 \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2\,\mathrm{e}^{-2x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\frac{\mathrm{e}^{-2x}\left(\int (-1+3\sin(2x)+\cos(x))\mathrm{e}^{2x} dx\right)}{2} + \frac{\left(\int (-1+3\sin(2x)+\cos(x)) dx\right)}{2}$

  - Compute integrals

    $y_p(x) = -\frac{3\cos(x)\sin(x)}{4} + \frac{2\sin(x)}{5} - \frac{3\cos(x)^2}{4} - \frac{\cos(x)}{5} + \frac{5}{8} - \frac{x}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-2x} + c_2 - \frac{3\cos(x)\sin(x)}{4} + \frac{2\sin(x)}{5} - \frac{3\cos(x)^2}{4} - \frac{\cos(x)}{5} + \frac{5}{8} - \frac{x}{2}$

Problem number: 584.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' - 2y'' + y' = 2x + e^x}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 2y'' + y' = 0$$

The characteristic equation is

$$\lambda^3 - 2\lambda^2 + \lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 1$$
$$\lambda_3 = 1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + c_2 e^x + x\,e^x c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= 1 \\
y_2 &= \mathrm{e}^x \\
y_3 &= x\,\mathrm{e}^x
\end{aligned}
$$

Now the particular solution to the given ODE is found

$$
y''' - 2y'' + y' = 2x + \mathrm{e}^x
$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
2x + \mathrm{e}^x
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\mathrm{e}^x\}, \{1, x\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{1, x\,\mathrm{e}^x, \mathrm{e}^x\}
$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$
[\{\mathrm{e}^x\}, \{x, x^2\}]
$$

Since e^x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$
[\{x\,\mathrm{e}^x\}, \{x, x^2\}]
$$

Since $x\,\mathrm{e}^x$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$
[\{\mathrm{e}^x x^2\}, \{x, x^2\}]
$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$
y_p = A_1 \mathrm{e}^x x^2 + A_2 x + A_3 x^2
$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
2A_1 \mathrm{e}^x - 4A_3 + A_2 + 2A_3 x = 2x + \mathrm{e}^x
$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = 4, A_3 = 1\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x x^2}{2} + 4x + x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 + c_2 e^x + x\, e^x c_3) + \left(\frac{e^x x^2}{2} + 4x + x^2\right) \end{aligned}$$

Which simplifies to

$$y = (c_3 x + c_2)\, e^x + c_1 + \frac{e^x x^2}{2} + 4x + x^2$$

Summary

The solution(s) found are the following

$$y = (c_3 x + c_2)\, e^x + c_1 + \frac{e^x x^2}{2} + 4x + x^2 \tag{1}$$

Verification of solutions

$$y = (c_3 x + c_2)\, e^x + c_1 + \frac{e^x x^2}{2} + 4x + x^2$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = 2\sin(x)\sin(2x)}$$

17.35.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = \cos(x) - \cos(3x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(x) - \cos(3x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}, \{\cos(3x), \sin(3x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{\cos(x)\, x, \sin(x)\, x\}, \{\cos(3x), \sin(3x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 \cos(x)\, x + A_2 \sin(x)\, x + A_3 \cos(3x) + A_4 \sin(3x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 \sin(x) + 2A_2 \cos(x) - 8A_3 \cos(3x) - 8A_4 \sin(3x) = \cos(x) - \cos(3x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{2}, A_3 = \frac{1}{8}, A_4 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\sin(x)\, x}{2} + \frac{\cos(3x)}{8}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + \left(\frac{\sin(x)\, x}{2} + \frac{\cos(3x)}{8}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(x) + c_2 \sin(x) + \frac{\sin(x)\, x}{2} + \frac{\cos(3x)}{8} \tag{1}
$$

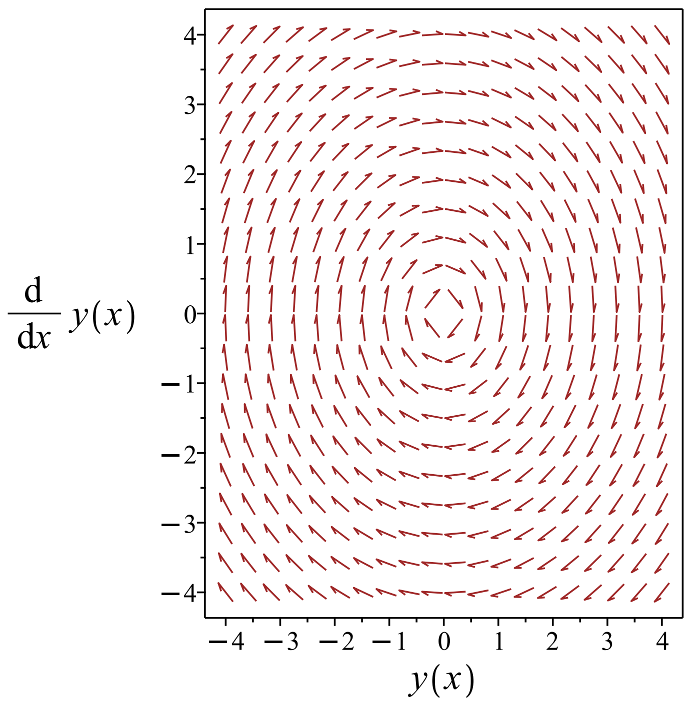

Figure 721: Slope field plot

Verification of solutions

$$
y = c_1 \cos(x) + c_2 \sin(x) + \frac{\sin(x)\, x}{2} + \frac{\cos(3x)}{8}
$$

Verified OK.

17.35.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 558: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A}\, dx}$$

Since $B=0$ then the above reduces to

$$\begin{aligned}y_1 &= z_1\\ &= \cos(x)\end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B=0$ then the above becomes

$$\begin{aligned}y_2 &= y_1 \int \frac{1}{y_1^2}\, dx\\ &= \cos(x) \int \frac{1}{\cos(x)^2}\, dx\\ &= \cos(x)\,(\tan(x))\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y &= c_1 y_1 + c_2 y_2\\ &= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x)))\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4\sin(x)^2\cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}, \{\cos(3x), \sin(3x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{\cos(x)x, \sin(x)x\}, \{\cos(3x), \sin(3x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1\cos(x)x + A_2\sin(x)x + A_3\cos(3x) + A_4\sin(3x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1\sin(x) + 2A_2\cos(x) - 8A_3\cos(3x) - 8A_4\sin(3x) = \cos(x) - \cos(3x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{2}, A_3 = \frac{1}{8}, A_4 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\sin(x)x}{2} + \frac{\cos(3x)}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + \left(\frac{\sin(x)x}{2} + \frac{\cos(3x)}{8}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{\sin(x) x}{2} + \frac{\cos(3x)}{8} \tag{1}$$

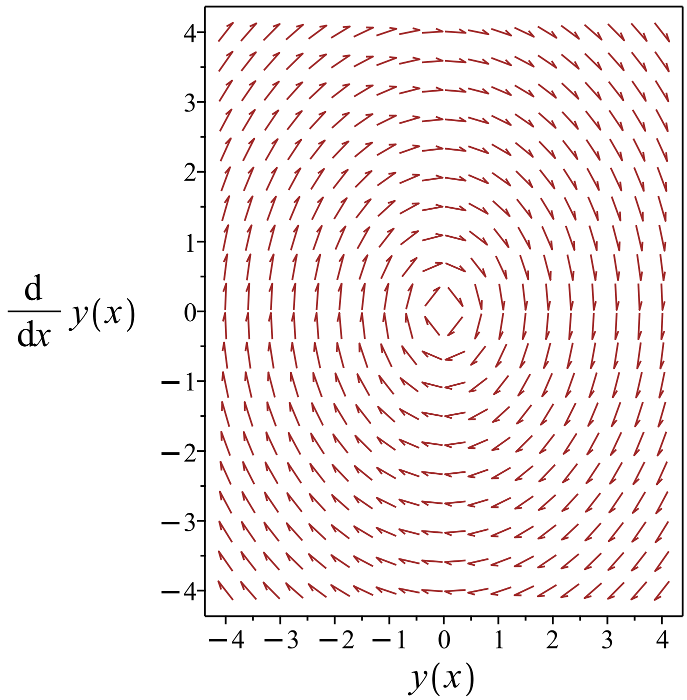

Figure 722: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{\sin(x) x}{2} + \frac{\cos(3x)}{8}$$

Verified OK.

17.35.3 Maple step by step solution

Let's solve

$y'' + y = \cos(x) - \cos(3x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \cos(x) - \cos(3x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \left[\begin{array}{cc} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{array}\right]$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -4\cos(x)\left(\int \sin(x)^3 \cos(x)\, dx\right) + \frac{\sin(x)\left(\int (1-\cos(4x)) dx\right)}{2}$

  - Compute integrals

    $y_p(x) = \frac{\sin(x)(-\cos(x)\sin(x)+x)}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + \frac{\sin(x)(-\cos(x)\sin(x)+x)}{2}$

Problem number: 586.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' - y'' - 2y' = 4x + 3\sin(x) + \cos(x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - y'' - 2y' = 0$$

The characteristic equation is

$$\lambda^3 - \lambda^2 - 2\lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 2$$
$$\lambda_3 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 + e^{2x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = 1$$
$$y_3 = e^{2x}$$

Now the particular solution to the given ODE is found

$$y''' - y'' - 2y' = 4x + 3\sin(x) + \cos(x)$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4x + 3\sin(x) + \cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}, \{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-x}, e^{2x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x, x^2\}, \{\cos(x), \sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_2 x^2 + A_1 x + A_3 \cos(x) + A_4 \sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_3 \sin(x) - 3A_4 \cos(x) - 2A_2 + A_3 \cos(x) + A_4 \sin(x) - 4A_2 x - 2A_1 = 4x + 3\sin(x) + \cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = -1, A_3 = 1, A_4 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -x^2 + x + \cos(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + c_2 + \mathrm{e}^{2x} c_3\right) + \left(-x^2 + x + \cos(x)\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-x} + c_2 + \mathrm{e}^{2x} c_3 - x^2 + x + \cos(x) \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-x} + c_2 + \mathrm{e}^{2x} c_3 - x^2 + x + \cos(x)$$

Verified OK.

17.36.1 Maple step by step solution

Let's solve

$y''' - y'' - 2y' = 4x + 3\sin(x) + \cos(x)$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  ○ Define new variable $y_1(x)$

    $y_1(x) = y$

  ○ Define new variable $y_2(x)$

    $y_2(x) = y'$

  ○ Define new variable $y_3(x)$

    $y_3(x) = y''$

- Isolate for $y_3'(x)$ using original ODE

  $y_3'(x) = 4x + 3\sin(x) + \cos(x) + y_3(x) + 2y_2(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 4x + 3\sin(x) + \cos(x) + y_3(x) + 2y_2(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 2 & 1 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 4x + 3\sin(x) + \cos(x) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 4x + 3\sin(x) + \cos(x) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 2 & 1 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = e^{-x} \cdot \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[0, \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]$$

- Consider eigenpair

$$\left[2, \left[\begin{array}{c} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = e^{2x} \cdot \left[\begin{array}{c} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$$\vec{y}(x) = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3 + \vec{y}_p(x)$$

□ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} e^{-x} & 1 & \frac{e^{2x}}{4} \\ -e^{-x} & 0 & \frac{e^{2x}}{2} \\ e^{-x} & 0 & e^{2x} \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

  $$\Phi(x) = \begin{bmatrix} e^{-x} & 1 & \frac{e^{2x}}{4} \\ -e^{-x} & 0 & \frac{e^{2x}}{2} \\ e^{-x} & 0 & e^{2x} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & 1 & \frac{1}{4} \\ -1 & 0 & \frac{1}{2} \\ 1 & 0 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

  $$\Phi(x) = \begin{bmatrix} 1 & -\frac{2e^{-x}}{3} + \frac{1}{2} + \frac{e^{2x}}{6} & \frac{e^{-x}}{3} - \frac{1}{2} + \frac{e^{2x}}{6} \\ 0 & \frac{2e^{-x}}{3} + \frac{e^{2x}}{3} & -\frac{e^{-x}}{3} + \frac{e^{2x}}{3} \\ 0 & -\frac{2e^{-x}}{3} + \frac{2e^{2x}}{3} & \frac{e^{-x}}{3} + \frac{2e^{2x}}{3} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\overrightarrow{v}(x)$

  $\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$

- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\overrightarrow{y}_p(x) = \left[\begin{array}{c} -x^2 + x + \cos(x) + \frac{e^{2x}}{3} - 3 + \frac{5\,e^{-x}}{3} \\ \frac{2\,e^{2x}}{3} - 2x - \sin(x) + 1 - \frac{5\,e^{-x}}{3} \\ \frac{4\,e^{2x}}{3} - \cos(x) - 2 + \frac{5\,e^{-x}}{3} \end{array}\right]$$

- Plug particular solution back into general solution

$$\overrightarrow{y}(x) = c_1 \overrightarrow{y}_1 + c_2 \overrightarrow{y}_2 + c_3 \overrightarrow{y}_3 + \left[\begin{array}{c} -x^2 + x + \cos(x) + \frac{e^{2x}}{3} - 3 + \frac{5\,e^{-x}}{3} \\ \frac{2\,e^{2x}}{3} - 2x - \sin(x) + 1 - \frac{5\,e^{-x}}{3} \\ \frac{4\,e^{2x}}{3} - \cos(x) - 2 + \frac{5\,e^{-x}}{3} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = \frac{(12c_1 + 20)e^{-x}}{12} + \frac{(3c_3 + 4)e^{2x}}{12} - x^2 + x + c_2 + \cos(x) - 3$$

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' - 4y' = x\,\mathrm{e}^{2x} + \sin(x) + x^2}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 4y' = 0$$

The characteristic equation is

$$\lambda^3 - 4\lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 2$$
$$\lambda_3 = -2$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + \mathrm{e}^{-2x} c_2 + \mathrm{e}^{2x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= 1 \\ y_2 &= \mathrm{e}^{-2x} \\ y_3 &= \mathrm{e}^{2x} \end{aligned}$$

Now the particular solution to the given ODE is found

$$y''' - 4y' = x\,\mathrm{e}^{2x} + \sin(x) + x^2$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)}\, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} 1 & \mathrm{e}^{-2x} & \mathrm{e}^{2x} \\ 0 & -2\,\mathrm{e}^{-2x} & 2\,\mathrm{e}^{2x} \\ 0 & 4\,\mathrm{e}^{-2x} & 4\,\mathrm{e}^{2x} \end{bmatrix}$$

$$|W| = -16\,\mathrm{e}^{2x} \mathrm{e}^{-2x}$$

The determinant simplifies to

$$|W| = -16$$

Now we determine W_i for each U_i.

$$W_1(x) = \det \begin{bmatrix} e^{-2x} & e^{2x} \\ -2\,e^{-2x} & 2\,e^{2x} \end{bmatrix}$$
$$= 4$$

$$W_2(x) = \det \begin{bmatrix} 1 & e^{2x} \\ 0 & 2\,e^{2x} \end{bmatrix}$$
$$= 2\,e^{2x}$$

$$W_3(x) = \det \begin{bmatrix} 1 & e^{-2x} \\ 0 & -2\,e^{-2x} \end{bmatrix}$$
$$= -2\,e^{-2x}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned} U_1 &= (-1)^{3-1} \int \frac{F(x)W_1(x)}{aW(x)}\,dx \\ &= (-1)^2 \int \frac{(x\,e^{2x} + \sin(x) + x^2)(4)}{(1)(-16)}\,dx \\ &= \int \frac{4x\,e^{2x} + 4\sin(x) + 4x^2}{-16}\,dx \\ &= \int \left(-\frac{x\,e^{2x}}{4} - \frac{\sin(x)}{4} - \frac{x^2}{4}\right)dx \\ &= -\frac{x^3}{12} - \frac{x\,e^{2x}}{8} + \frac{e^{2x}}{16} + \frac{\cos(x)}{4} \end{aligned}$$

$$\begin{aligned} U_2 &= (-1)^{3-2} \int \frac{F(x)W_2(x)}{aW(x)}\,dx \\ &= (-1)^1 \int \frac{(x\,e^{2x} + \sin(x) + x^2)(2\,e^{2x})}{(1)(-16)}\,dx \\ &= -\int \frac{2(x\,e^{2x} + \sin(x) + x^2)\,e^{2x}}{-16}\,dx \\ &= -\int \left(-\frac{(x\,e^{2x} + \sin(x) + x^2)\,e^{2x}}{8}\right)dx \\ &= \frac{e^{4x}x}{32} - \frac{e^{4x}}{128} - \frac{e^{2x}\cos(x)}{40} + \frac{e^{2x}\sin(x)}{20} + \frac{x^2 e^{2x}}{16} - \frac{x\,e^{2x}}{16} + \frac{e^{2x}}{32} \end{aligned}$$

$$
\begin{aligned}
U_3 &= (-1)^{3-3} \int \frac{F(x) W_3(x)}{a W(x)}\, dx \\
&= (-1)^{0} \int \frac{\left(x\,\mathrm{e}^{2x}+\sin\left(x\right)+x^{2}\right) \left(-2\,\mathrm{e}^{-2x}\right)}{\left(1\right) \left(-16\right)}\, dx \\
&= \int \frac{-2 (x\,\mathrm{e}^{2x}+\sin\left(x\right)+x^{2})\,\mathrm{e}^{-2x}}{-16}\, dx \\
&= \int \left(\frac{\left(x^{2}+\sin\left(x\right)\right) \mathrm{e}^{-2x}}{8}+\frac{x}{8}\right)\, dx \\
&= \frac{x^{2}}{16}-\frac{\mathrm{e}^{-2x} x^{2}}{16}-\frac{x\,\mathrm{e}^{-2x}}{16}-\frac{\mathrm{e}^{-2x}}{32}-\frac{\mathrm{e}^{-2x} \cos\left(x\right)}{40}-\frac{\mathrm{e}^{-2x} \sin\left(x\right)}{20} \\
&= \frac{x^{2}}{16}-\frac{\mathrm{e}^{-2x} x^{2}}{16}-\frac{x\,\mathrm{e}^{-2x}}{16}-\frac{\mathrm{e}^{-2x}}{32}-\frac{\mathrm{e}^{-2x} \cos\left(x\right)}{40}-\frac{\mathrm{e}^{-2x} \sin\left(x\right)}{20}
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Hence

$$
\begin{aligned}
y_p &= \left(-\frac{x^{3}}{12}-\frac{x\,\mathrm{e}^{2x}}{8}+\frac{\mathrm{e}^{2x}}{16}+\frac{\cos\left(x\right)}{4}\right) \\
&+ \left(\frac{\mathrm{e}^{4x} x}{32}-\frac{\mathrm{e}^{4x}}{128}-\frac{\mathrm{e}^{2x} \cos\left(x\right)}{40}+\frac{\mathrm{e}^{2x} \sin\left(x\right)}{20}+\frac{x^{2} \mathrm{e}^{2x}}{16}-\frac{x\,\mathrm{e}^{2x}}{16}+\frac{\mathrm{e}^{2x}}{32}\right) \left(\mathrm{e}^{-2x}\right) \\
&+ \left(\frac{x^{2}}{16}-\frac{\mathrm{e}^{-2x} x^{2}}{16}-\frac{x\,\mathrm{e}^{-2x}}{16}-\frac{\mathrm{e}^{-2x}}{32}-\frac{\mathrm{e}^{-2x} \cos\left(x\right)}{40}-\frac{\mathrm{e}^{-2x} \sin\left(x\right)}{20}\right) \left(\mathrm{e}^{2x}\right)
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = \frac{\left(8 x^{2}-12 x+7\right) \mathrm{e}^{2x}}{128}-\frac{x^{3}}{12}-\frac{x}{8}+\frac{\cos\left(x\right)}{5}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1+\mathrm{e}^{-2x} c_2+\mathrm{e}^{2x} c_3\right) + \left(\frac{\left(8 x^{2}-12 x+7\right) \mathrm{e}^{2x}}{128}-\frac{x^{3}}{12}-\frac{x}{8}+\frac{\cos\left(x\right)}{5}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1+\mathrm{e}^{-2x} c_2+\mathrm{e}^{2x} c_3+\frac{\left(8 x^{2}-12 x+7\right) \mathrm{e}^{2x}}{128}-\frac{x^{3}}{12}-\frac{x}{8}+\frac{\cos\left(x\right)}{5} \tag{1}
$$

Verification of solutions

$$y = c_1 + e^{-2x}c_2 + e^{2x}c_3 + \frac{(8x^2 - 12x + 7)\,e^{2x}}{128} - \frac{x^3}{12} - \frac{x}{8} + \frac{\cos(x)}{5}$$

Verified OK.

Problem number: 588.
ODE order: 5.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_y]]
```

$$\boxed{y^{(5)} - y'''' = x\,\mathrm{e}^{x} - 1}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y^{(5)} - y'''' = 0$$

The characteristic equation is

$$\lambda^5 - \lambda^4 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$
$$\lambda_4 = 0$$
$$\lambda_5 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_4x^3 + c_3x^2 + c_2x + c_1 + e^x c_5$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= 1 \\ y_2 &= x \\ y_3 &= x^2 \\ y_4 &= x^3 \\ y_5 &= e^x \end{aligned}$$

Now the particular solution to the given ODE is found

$$y^{(5)} - y'''' = x e^x - 1$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x e^x - 1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{x e^x, e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, x^2, x^3, e^x\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}, \{x e^x, e^x\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2\}, \{x e^x, e^x\}]$$

Since x^2 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^3\}, \{x e^x, e^x\}]$$

Since x^3 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^4\}, \{x e^x, e^x\}]$$

Since e^{x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^4\}, \{x\,\mathrm{e}^{x}, \mathrm{e}^{x}x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1x^4 + A_2x\,\mathrm{e}^{x} + A_3\mathrm{e}^{x}x^2$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_2\mathrm{e}^{x} + 2A_3\mathrm{e}^{x}x + 8A_3\mathrm{e}^{x} - 24A_1 = x\,\mathrm{e}^{x} - 1$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{24}, A_2 = -4, A_3 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^4}{24} - 4x\,\mathrm{e}^{x} + \frac{\mathrm{e}^{x}x^2}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_4x^3 + c_3x^2 + c_2x + c_1 + \mathrm{e}^{x}c_5\right) + \left(\frac{x^4}{24} - 4x\,\mathrm{e}^{x} + \frac{\mathrm{e}^{x}x^2}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_4x^3 + c_3x^2 + c_2x + c_1 + \mathrm{e}^{x}c_5 + \frac{x^4}{24} - 4x\,\mathrm{e}^{x} + \frac{\mathrm{e}^{x}x^2}{2} \tag{1}$$

Verification of solutions

$$y = c_4x^3 + c_3x^2 + c_2x + c_1 + \mathrm{e}^{x}c_5 + \frac{x^4}{24} - 4x\,\mathrm{e}^{x} + \frac{\mathrm{e}^{x}x^2}{2}$$

Verified OK.

$$\boxed{y^{(5)} - y''' = x + 2\,\mathrm{e}^{-x}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y^{(5)} - y''' = 0$$

The characteristic equation is

$$\lambda^5 - \lambda^3 = 0$$

The roots of the above equation are

$$\begin{aligned}\lambda_1 &= 0\\ \lambda_2 &= 0\\ \lambda_3 &= 0\\ \lambda_4 &= 1\\ \lambda_5 &= -1\end{aligned}$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 + c_3 x + c_4 x^2 + e^x c_5$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= e^{-x} \\ y_2 &= 1 \\ y_3 &= x \\ y_4 &= x^2 \\ y_5 &= e^x \end{aligned}$$

Now the particular solution to the given ODE is found

$$y^{(5)} - y''' = x + 2\,e^{-x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x + 2\,e^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-x}\}, \{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, x^2, e^x, e^{-x}\}$$

Since e^{-x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{-x}\}, \{1, x\}]$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{-x}\}, \{x, x^2\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{-x}\}, \{x^2, x^3\}]$$

Since x^2 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{-x}\}, \{x^3, x^4\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,\mathrm{e}^{-x} + A_2 x^3 + A_3 x^4$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 \mathrm{e}^{-x} - 6A_2 - 24A_3 x = x + 2\,\mathrm{e}^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 1, A_2 = 0, A_3 = -\frac{1}{24}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x\,\mathrm{e}^{-x} - \frac{x^4}{24}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + c_2 + c_3 x + c_4 x^2 + \mathrm{e}^{x} c_5\right) + \left(x\,\mathrm{e}^{-x} - \frac{x^4}{24}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-x} + c_2 + c_3 x + c_4 x^2 + \mathrm{e}^{x} c_5 + x\,\mathrm{e}^{-x} - \frac{x^4}{24} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-x} + c_2 + c_3 x + c_4 x^2 + \mathrm{e}^{x} c_5 + x\,\mathrm{e}^{-x} - \frac{x^4}{24}$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y'' + y = 2 - 2x}$$

With initial conditions

$$[y(0) = 2, y'(0) = -2]$$

18.1.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= 1 \\ F &= 2 - 2x \end{aligned}$$

Hence the ode is

$$y'' + y = 2 - 2x$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 2 - 2x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

18.1.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = 2 - 2x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x + 1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_2x + A_1$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_2x + A_1 = 2 - 2x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2, A_2 = -2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2 - 2x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + (2 - 2x) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(x) + c_2 \sin(x) + 2 - 2x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = c_1 + 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 \sin(x) + c_2 \cos(x) - 2$$

substituting $y' = -2$ and $x = 0$ in the above gives

$$-2 = -2 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

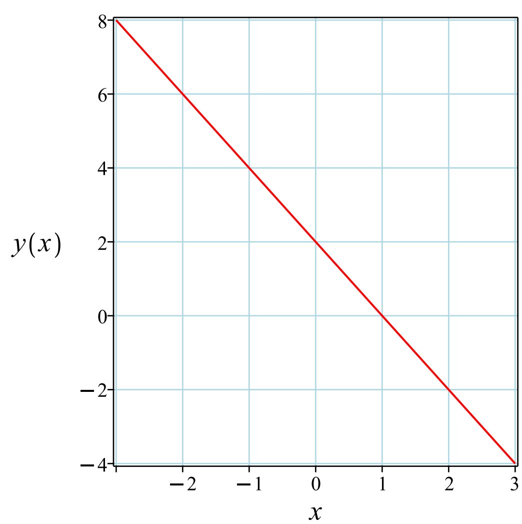
Substituting these values back in above solution results in

$$y = 2 - 2x$$

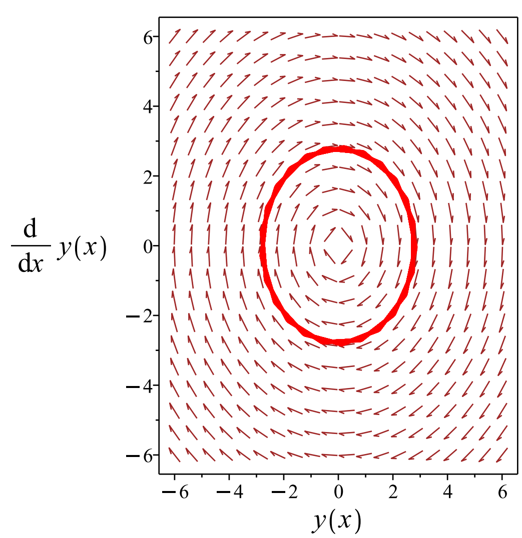
Summary

The solution(s) found are the following

$$y = 2 - 2x \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 2 - 2x$$

Verified OK.

18.1.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 562: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B=0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \cos(x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \cos(x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Since $B=0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\
&= \cos(x) \int \frac{1}{\cos(x)^2}\,dx \\
&= \cos(x)\,(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
y'' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \cos(x) + c_2 \sin(x)
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x + 1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_2 x + A_1$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_2 x + A_1 = 2 - 2x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2, A_2 = -2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2 - 2x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + (2 - 2x) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(x) + c_2 \sin(x) + 2 - 2x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = c_1 + 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 \sin(x) + c_2 \cos(x) - 2$$

substituting $y' = -2$ and $x = 0$ in the above gives

$$-2 = -2 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

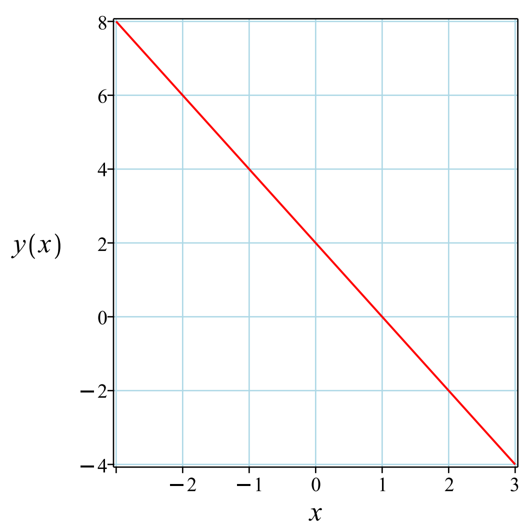
Substituting these values back in above solution results in

$$y = 2 - 2x$$

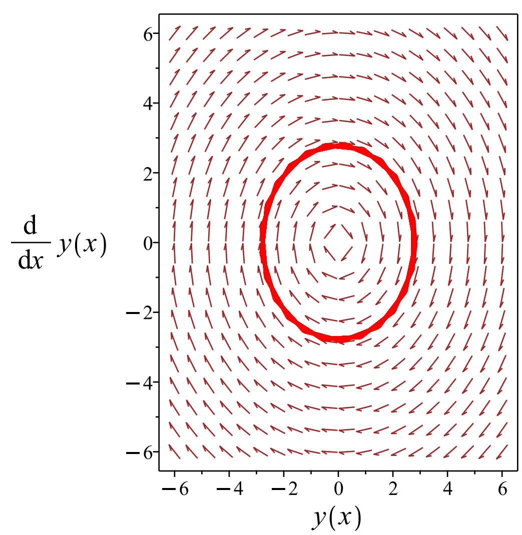
Summary

The solution(s) found are the following

$$y = 2 - 2x \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 2 - 2x$$

Verified OK.

18.1.4 Maple step by step solution

Let's solve

$\left[y'' + y = 2 - 2x, y(0) = 2, y'\Big|_{\{x=0\}} = -2\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 2 - 2x\right]$

- ○ Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = 1$
- Substitute functions into equation for $y_p(x)$

  $y_p(x) = 2\cos(x)\left(\int(x-1)\sin(x)\,dx\right) - 2\sin(x)\left(\int\cos(x)(x-1)\,dx\right)$
- Compute integrals

  $y_p(x) = 2 - 2x$

- Substitute particular solution into general solution to ODE

  $y = c_1\cos(x) + c_2\sin(x) + 2 - 2x$

☐ Check validity of solution $y = c_1\cos(x) + c_2\sin(x) + 2 - 2x$

- Use initial condition $y(0) = 2$

  $2 = c_1 + 2$
- Compute derivative of the solution

  $y' = -c_1\sin(x) + c_2\cos(x) - 2$
- Use the initial condition $y'\Big|_{\{x=0\}} = -2$

  $-2 = -2 + c_2$
- Solve for c_1 and c_2

  $\{c_1 = 0, c_2 = 0\}$
- Substitute constant values into general solution and simplify

  $y = 2 - 2x$

- Solution to the IVP

  $y = 2 - 2x$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 6y' + 9y = 9x^2 - 12x + 2}$$

With initial conditions

$$[y(0) = 1, y'(0) = 3]$$

18.2.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -6 \\ q(x) &= 9 \\ F &= 9x^2 - 12x + 2 \end{aligned}$$

Hence the ode is

$$y'' - 6y' + 9y = 9x^2 - 12x + 2$$

The domain of $p(x) = -6$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 9$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 9x^2 - 12x + 2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

18.2.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -6, C = 9, f(x) = 9x^2 - 12x + 2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 6y' + 9y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -6, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 6\lambda e^{\lambda x} + 9 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 6\lambda + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -6, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{6}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-6)^2 - (4)(1)(9)} \\ &= 3\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -3$. Therefore the solution is

$$y = c_1 e^{3x} + c_2 e^{3x} x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{3x} + c_2 x\, e^{3x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 + x + 1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{3x} x, e^{3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_3x^2 + A_2x + A_1$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$9A_3x^2 + 9A_2x - 12xA_3 + 9A_1 - 6A_2 + 2A_3 = 9x^2 - 12x + 2$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 0, A_3 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{3x} + c_2 x\, e^{3x}\right) + \left(x^2\right) \end{aligned}$$

Which simplifies to

$$y = e^{3x}(c_2x + c_1) + x^2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{3x}(c_2x + c_1) + x^2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 3\,\mathrm{e}^{3x}(c_2x + c_1) + c_2\mathrm{e}^{3x} + 2x$$

substituting $y' = 3$ and $x = 0$ in the above gives

$$3 = 3c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

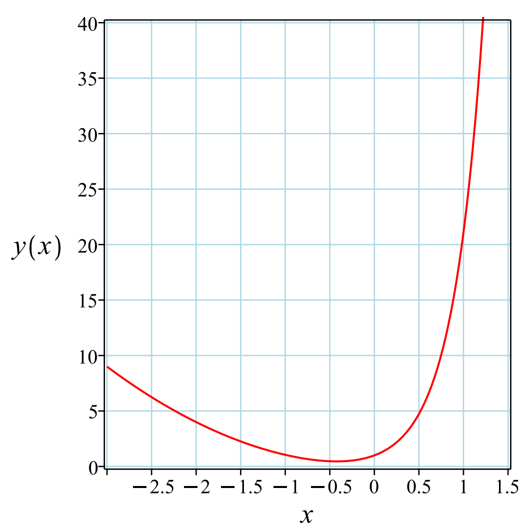
$$c_1 = 1$$
$$c_2 = 0$$

Substituting these values back in above solution results in

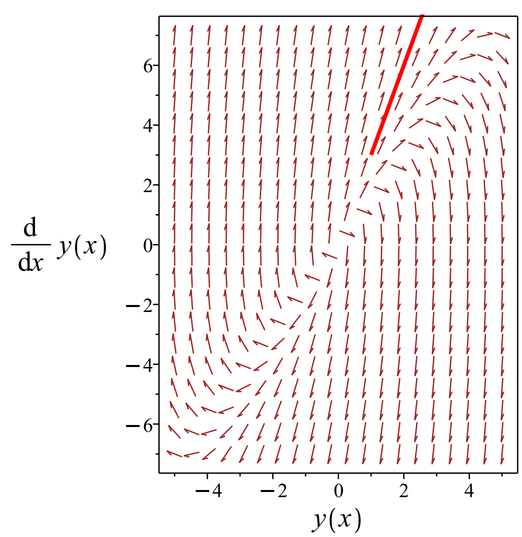
$$y = x^2 + \mathrm{e}^{3x}$$

Summary
The solution(s) found are the following

$$y = x^2 + \mathrm{e}^{3x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = x^2 + \mathrm{e}^{3x}$$

Verified OK.

18.2.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^{2}+p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -6$. Therefore, there is an integrating factor given by

$$\begin{aligned}
M(x) &= e^{\frac{1}{2}\int p\,dx} \\
&= e^{\int -6\,dx} \\
&= \mathrm{e}^{-3x}
\end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned}
(M(x)y)'' &= \mathrm{e}^{-3x}\left(9x^{2}-12x+2\right) \\
\left(\mathrm{e}^{-3x}y\right)'' &= \mathrm{e}^{-3x}\left(9x^{2}-12x+2\right)
\end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{-3x}y\right)' = \left(-3x^{2}+2x\right)\mathrm{e}^{-3x}+c_1$$

Integrating again gives

$$\left(\mathrm{e}^{-3x}y\right) = x\left(x\,\mathrm{e}^{-3x}+c_1\right)+c_2$$

Hence the solution is

$$y = \frac{x\left(x\,\mathrm{e}^{-3x}+c_1\right)+c_2}{\mathrm{e}^{-3x}}$$

Or

$$y = c_1 x\,\mathrm{e}^{3x} + c_2\mathrm{e}^{3x} + x^{2}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 x\,\mathrm{e}^{3x} + c_2\mathrm{e}^{3x} + x^{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 e^{3x} + 3c_1 x\, e^{3x} + 3c_2 e^{3x} + 2x$$

substituting $y' = 3$ and $x = 0$ in the above gives

$$3 = c_1 + 3c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

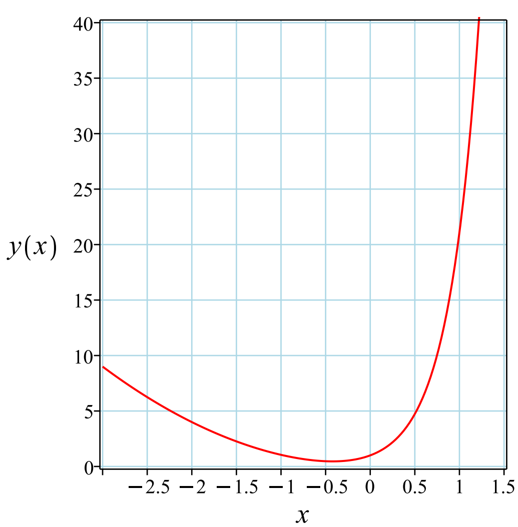
$$c_1 = 0$$
$$c_2 = 1$$

Substituting these values back in above solution results in

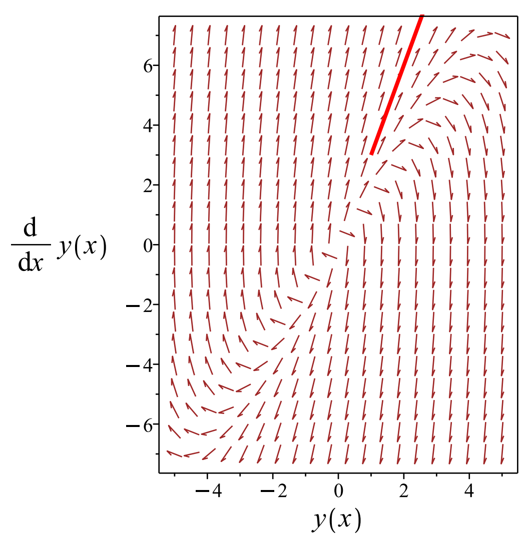
$$y = x^2 + e^{3x}$$

Summary
The solution(s) found are the following

$$y = x^2 + e^{3x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = x^2 + e^{3x}$$

Verified OK.

18.2.4 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 6y' + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -6 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 564: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-6}{1} \, dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{3x} \\
&= z_1\left(\mathrm{e}^{3x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{3x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-6}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{6x}}{(y_1)^2}\, dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{3x}\right) + c_2\left(\mathrm{e}^{3x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 6y' + 9y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{3x} + c_2 x\, \mathrm{e}^{3x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 + x + 1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{3x}x, e^{3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_3 x^2 + A_2 x + A_1$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$9A_3x^2 + 9A_2x - 12xA_3 + 9A_1 - 6A_2 + 2A_3 = 9x^2 - 12x + 2$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 0, A_3 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{3x} + c_2 x\, e^{3x}\right) + \left(x^2\right) \end{aligned}$$

Which simplifies to

$$y = e^{3x}(c_2 x + c_1) + x^2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{3x}(c_2x + c_1) + x^2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 3\,e^{3x}(c_2x + c_1) + c_2e^{3x} + 2x$$

substituting $y' = 3$ and $x = 0$ in the above gives

$$3 = 3c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = 0$$

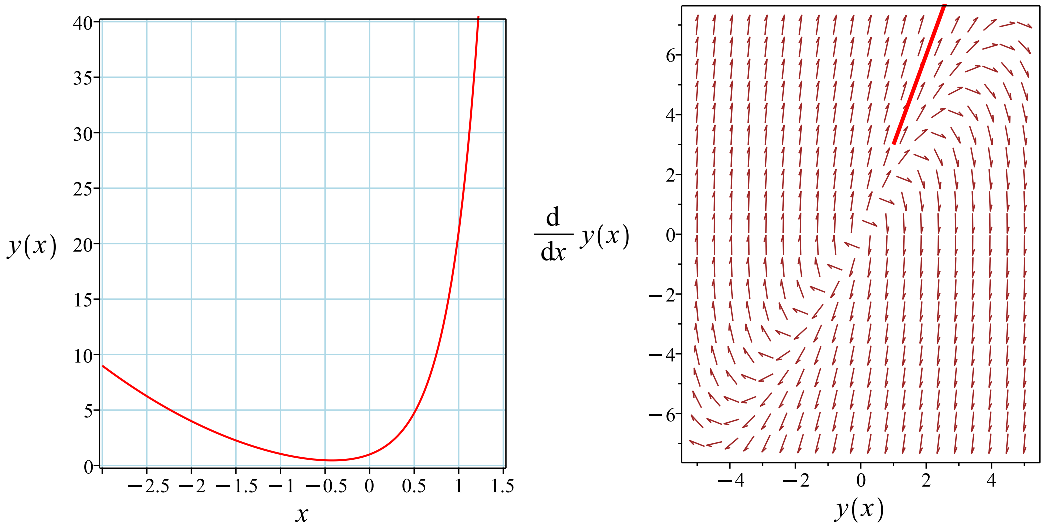
Substituting these values back in above solution results in

$$y = x^2 + e^{3x}$$

Summary

The solution(s) found are the following

$$y = x^2 + e^{3x} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = x^2 + e^{3x}$$

Verified OK.

18.2.5 Maple step by step solution

Let's solve

$$\left[y'' - 6y' + 9y = 9x^2 - 12x + 2, y(0) = 1, y'\Big|_{\{x=0\}} = 3\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 6r + 9 = 0$

- Factor the characteristic polynomial

  $(r - 3)^2 = 0$

- Root of the characteristic polynomial

  $r = 3$

- 1st solution of the homogeneous ODE

$y_1(x) = e^{3x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = e^{3x}x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{3x} + c_2 x\, e^{3x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))} dx\right), f(x) = 9x^2 - 12x + 2\right]$

- Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{3x} & e^{3x}x \\ 3\,e^{3x} & 3\,e^{3x}x + e^{3x} \end{bmatrix}$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{6x}$

- Substitute functions into equation for $y_p(x)$

  $y_p(x) = e^{3x}\left(-\left(\int x\, e^{-3x}(9x^2 - 12x + 2)\, dx\right) + \left(\int e^{-3x}(9x^2 - 12x + 2)\, dx\right) x\right)$

- Compute integrals

  $y_p(x) = x^2$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{3x} + c_2 x\, e^{3x} + x^2$

☐ Check validity of solution $y = c_1 e^{3x} + c_2 x e^{3x} + x^2$

- Use initial condition $y(0) = 1$

  $1 = c_1$

- Compute derivative of the solution

  $y' = 3c_1 e^{3x} + c_2 e^{3x} + 3c_2 x\, e^{3x} + 2x$

- Use the initial condition $y'\Big|_{\{x=0\}} = 3$

  $3 = 3c_1 + c_2$

- Solve for c_1 and c_2

  $\{c_1 = 1, c_2 = 0\}$

- Substitute constant values into general solution and simplify

  $y = x^2 + e^{3x}$

- Solution to the IVP

  $y = x^2 + e^{3x}$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Initial value problem. Exercises page 140
Problem number: 592.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + 9y = 36\,\mathrm{e}^{3x}}$$

With initial conditions

$$[y(0) = 2, y'(0) = 6]$$

18.3.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= 9 \\ F &= 36\,\mathrm{e}^{3x} \end{aligned}$$

Hence the ode is

$$y'' + 9y = 36\,e^{3x}$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 9$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 36\,e^{3x}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

18.3.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 9, f(x) = 36\,e^{3x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 9y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 9\,e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(9)} \\ &= \pm 3i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +3i \\ \lambda_2 &= -3i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 3i \\ \lambda_2 &= -3i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 3$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(3x) + c_2 \sin(3x))$$

Or

$$y = c_1 \cos(3x) + c_2 \sin(3x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(3x) + c_2 \sin(3x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$36\,\mathrm{e}^{3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{3x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(3x), \sin(3x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{3x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$18 A_1 e^{3x} = 36 e^{3x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2 e^{3x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(3x) + c_2 \sin(3x)) + (2 e^{3x}) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(3x) + c_2 \sin(3x) + 2 e^{3x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = c_1 + 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -3c_1 \sin(3x) + 3c_2 \cos(3x) + 6\,e^{3x}$$

substituting $y' = 6$ and $x = 0$ in the above gives

$$6 = 6 + 3c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

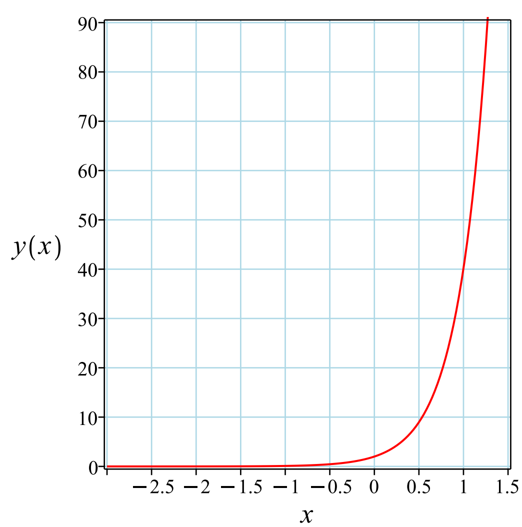
Substituting these values back in above solution results in

$$y = 2\,e^{3x}$$

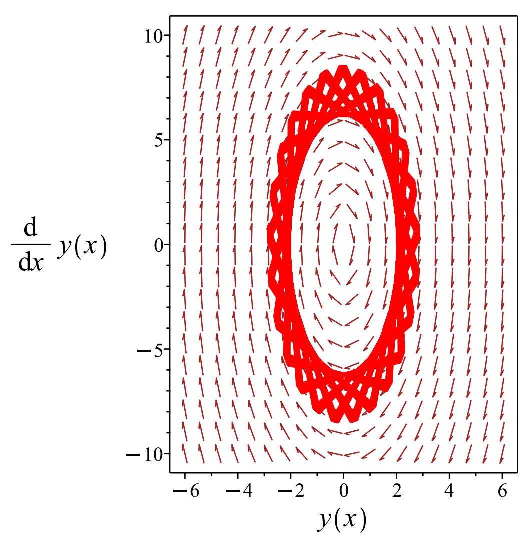
Summary

The solution(s) found are the following

$$y = 2\,e^{3x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 2\,e^{3x}$$

Verified OK.

18.3.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 9y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-9}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -9 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -9z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 566: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -9$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(3x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \cos(3x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \cos(3x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \cos(3x) \int \frac{1}{\cos(3x)^2}\, dx \\
&= \cos(3x) \left(\frac{\tan(3x)}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(3x)) + c_2\left(\cos(3x)\left(\frac{\tan(3x)}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 9y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$36\,\mathrm{e}^{3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{3x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sin(3x)}{3}, \cos(3x)\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \mathrm{e}^{3x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$18A_1 \mathrm{e}^{3x} = 36\,\mathrm{e}^{3x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2\,\mathrm{e}^{3x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3}\right) + \left(2\,\mathrm{e}^{3x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3} + 2\,e^{3x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = c_1 + 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -3c_1 \sin(3x) + c_2 \cos(3x) + 6\,e^{3x}$$

substituting $y' = 6$ and $x = 0$ in the above gives

$$6 = 6 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

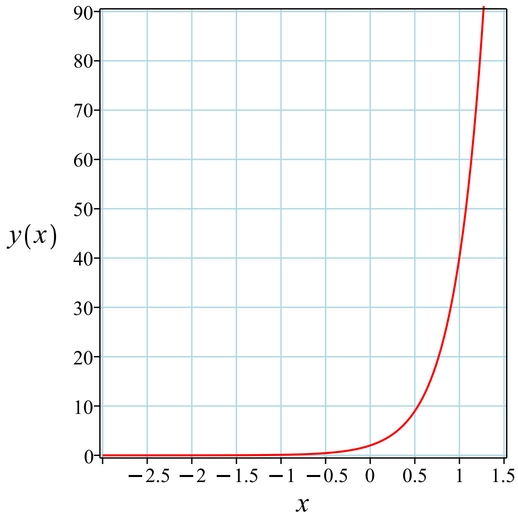
Substituting these values back in above solution results in

$$y = 2\,e^{3x}$$

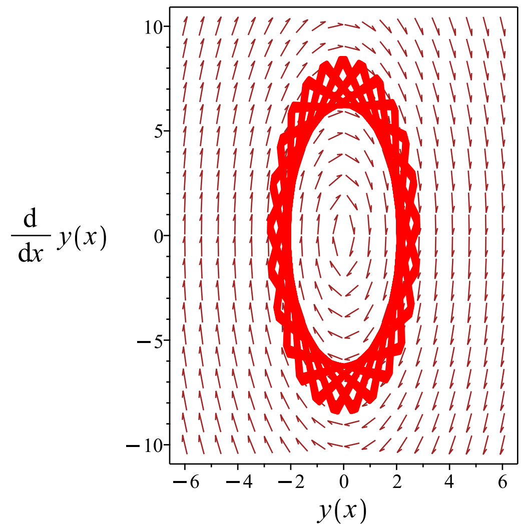
Summary

The solution(s) found are the following

$$y = 2\,e^{3x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 2\,\mathrm{e}^{3x}$$

Verified OK.

18.3.4 Maple step by step solution

Let's solve

$$\left[y'' + 9y = 36\,\mathrm{e}^{3x}, y(0) = 2, y'\Big|_{\{x=0\}} = 6\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 9 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-36})}{2}$

- Roots of the characteristic polynomial

  $r = (-3\,\mathrm{I}, 3\,\mathrm{I})$

- 1st solution of the homogeneous ODE

$y_1(x) = \cos(3x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(3x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(3x) + c_2 \sin(3x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 36\,\mathrm{e}^{3x}\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(3x) & \sin(3x) \\ -3\sin(3x) & 3\cos(3x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 3$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -12\cos(3x)\left(\int \sin(3x)\,\mathrm{e}^{3x}dx\right) + 12\sin(3x)\left(\int \cos(3x)\,\mathrm{e}^{3x}dx\right)$

  - Compute integrals

    $y_p(x) = 2\,\mathrm{e}^{3x}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(3x) + c_2 \sin(3x) + 2\,\mathrm{e}^{3x}$

☐ Check validity of solution $y = c_1 \cos(3x) + c_2 \sin(3x) + 2\mathrm{e}^{3x}$

  - Use initial condition $y(0) = 2$

    $2 = c_1 + 2$

  - Compute derivative of the solution

    $y' = -3c_1 \sin(3x) + 3c_2 \cos(3x) + 6\,\mathrm{e}^{3x}$

  - Use the initial condition $y'\Big|_{\{x=0\}} = 6$

    $6 = 6 + 3c_2$

- Solve for c_1 and c_2

  $\{c_1 = 0, c_2 = 0\}$

- Substitute constant values into general solution and simplify

  $y = 2\,e^{3x}$

- Solution to the IVP

  $y = 2\,e^{3x}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 4y' + 4y = 2\,e^{2x}}$$

With initial conditions

$$[y(0) = 0, y'(0) = 0]$$

18.4.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -4 \\ q(x) &= 4 \\ F &= 2\,e^{2x} \end{aligned}$$

Hence the ode is

$$y'' - 4y' + 4y = 2\,e^{2x}$$

The domain of $p(x) = -4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 2\,e^{2x}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

18.4.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 4, f(x) = 2\,e^{2x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 4\lambda e^{\lambda x} + 4 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-4)^2 - (4)(1)(4)} \\ &= 2\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -2$. Therefore the solution is

$$y = c_1 e^{2x} + c_2 x e^{2x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = e^{2x} c_1 + c_2 x e^{2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2 e^{2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x e^{2x}, e^{2x}\}$$

Since e^{2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,\mathrm{e}^{2x}\}]$$

Since $x\,\mathrm{e}^{2x}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2\mathrm{e}^{2x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 \mathrm{e}^{2x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1\mathrm{e}^{2x} = 2\,\mathrm{e}^{2x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x^2\mathrm{e}^{2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{2x}c_1 + c_2 x\,\mathrm{e}^{2x}\right) + \left(x^2\mathrm{e}^{2x}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{2x}(c_2 x + c_1) + x^2\mathrm{e}^{2x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \mathrm{e}^{2x}(c_2 x + c_1) + x^2\mathrm{e}^{2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2\,\mathrm{e}^{2x}(c_2 x + c_1) + \mathrm{e}^{2x} c_2 + 2x\,\mathrm{e}^{2x} + 2x^2 \mathrm{e}^{2x}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = 2c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

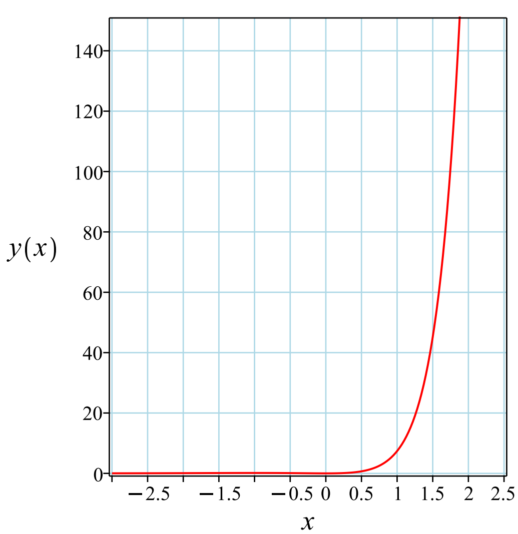
Substituting these values back in above solution results in

$$y = x^2 \mathrm{e}^{2x}$$

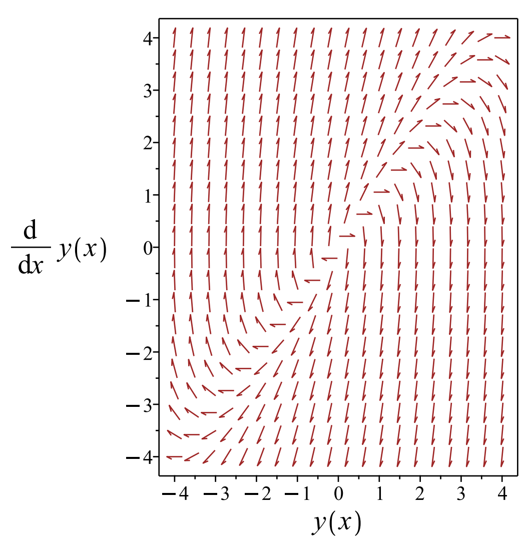
Summary

The solution(s) found are the following

$$y = x^2 \mathrm{e}^{2x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = x^2 e^{2x}$$

Verified OK.

18.4.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -4$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int -4\, dx} \\ &= e^{-2x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= 2\, e^{2x} e^{-2x} \\ \left(e^{-2x} y\right)'' &= 2\, e^{2x} e^{-2x} \end{aligned}$$

Integrating once gives

$$\left(e^{-2x} y\right)' = 2x + c_1$$

Integrating again gives

$$\left(e^{-2x} y\right) = x(x + c_1) + c_2$$

Hence the solution is

$$y = \frac{x(x + c_1) + c_2}{e^{-2x}}$$

Or

$$y = c_1 x\, e^{2x} + x^2 e^{2x} + e^{2x} c_2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 x\, e^{2x} + x^2 e^{2x} + e^{2x} c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = e^{2x} c_1 + 2c_1 x\, e^{2x} + 2x\, e^{2x} + 2x^2 e^{2x} + 2\, e^{2x} c_2$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = c_1 + 2c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

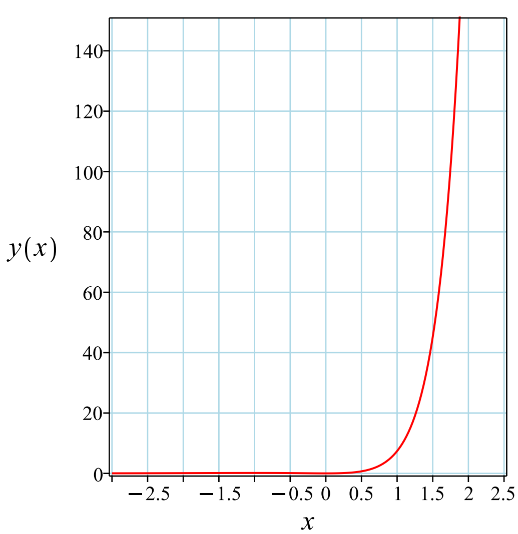
$$c_1 = 0$$
$$c_2 = 0$$

Substituting these values back in above solution results in

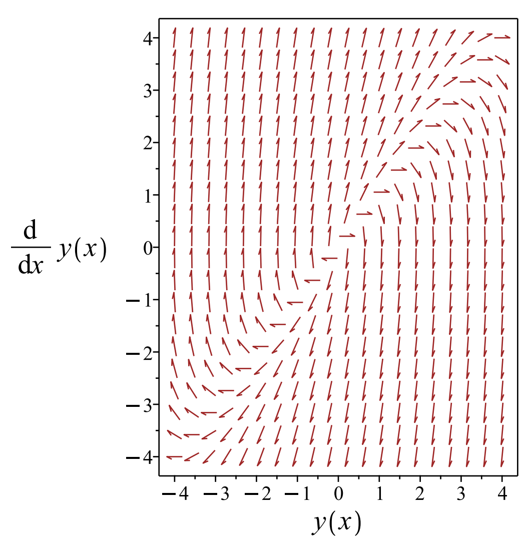
$$y = x^2 e^{2x}$$

Summary
The solution(s) found are the following

$$y = x^2 e^{2x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = x^2 e^{2x}$$

Verified OK.

18.4.4 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 568: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx} \\
&= z_1 e^{2x} \\
&= z_1\left(\mathrm{e}^{2x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{4x}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{2x}\right) + c_2\left(\mathrm{e}^{2x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
y'' - 4y' + 4y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = e^{2x} c_1 + c_2 x\, e^{2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2\, e^{2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{2x}, e^{2x}\}$$

Since e^{2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\, e^{2x}\}]$$

Since $x\, e^{2x}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 e^{2x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 e^{2x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2 A_1 e^{2x} = 2\, e^{2x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x^2 e^{2x}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(e^{2x} c_1 + c_2 x\, e^{2x}\right) + \left(x^2 e^{2x}\right)
\end{aligned}
$$

Which simplifies to

$$
y = e^{2x} (c_2 x + c_1) + x^2 e^{2x}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = e^{2x} (c_2 x + c_1) + x^2 e^{2x} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$
0 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = 2\, e^{2x} (c_2 x + c_1) + e^{2x} c_2 + 2x\, e^{2x} + 2x^2 e^{2x}
$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$
0 = 2c_1 + c_2 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 0 \\
c_2 &= 0
\end{aligned}
$$

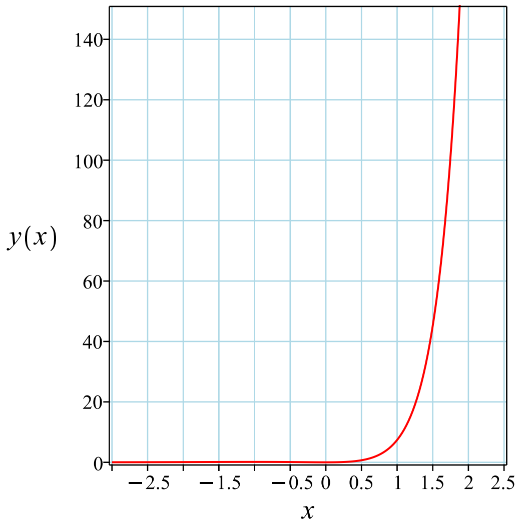
Substituting these values back in above solution results in

$$
y = x^2 e^{2x}
$$

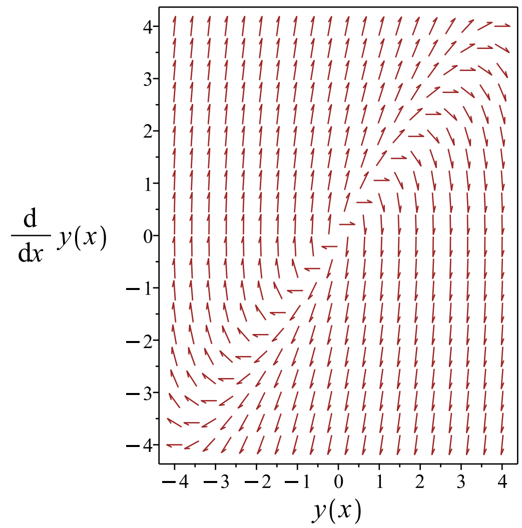
Summary

The solution(s) found are the following

$$
y = x^2 e^{2x} \tag{1}
$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = x^2 e^{2x}$$

Verified OK.

18.4.5 Maple step by step solution

Let's solve

$\left[y'' - 4y' + 4y = 2\,e^{2x}, y(0) = 0, y'\Big|_{\{x=0\}} = 0\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 4r + 4 = 0$

- Factor the characteristic polynomial

  $(r-2)^2 = 0$

- Root of the characteristic polynomial

  $r = 2$

- 1st solution of the homogeneous ODE

$y_1(x) = e^{2x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^{2x}$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = e^{2x} c_1 + c_2 x\,e^{2x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 2\,e^{2x}\right]$
- Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{2x} & x\,e^{2x} \\ 2\,e^{2x} & e^{2x} + 2x\,e^{2x} \end{bmatrix}$
- Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{4x}$
- Substitute functions into equation for $y_p(x)$

  $y_p(x) = -2\,e^{2x}\left(\int x dx - \left(\int 1 dx\right) x\right)$
- Compute integrals

  $y_p(x) = x^2 e^{2x}$

- Substitute particular solution into general solution to ODE

  $y = e^{2x} c_1 + c_2 x\,e^{2x} + x^2 e^{2x}$

☐ Check validity of solution $y = e^{2x} c_1 + c_2 x e^{2x} + x^2 e^{2x}$

- Use initial condition $y(0) = 0$

  $0 = c_1$
- Compute derivative of the solution

  $y' = 2\,e^{2x} c_1 + e^{2x} c_2 + 2c_2 x\,e^{2x} + 2x\,e^{2x} + 2x^2 e^{2x}$
- Use the initial condition $y'\Big|_{\{x=0\}} = 0$

  $0 = 2c_1 + c_2$

- Solve for c_1 and c_2

  $\{c_1 = 0, c_2 = 0\}$

- Substitute constant values into general solution and simplify

  $y = x^2 e^{2x}$

- Solution to the IVP

  $y = x^2 e^{2x}$

Problem number: 594.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' - 5y' + 6y = (12x - 7)\,\mathrm{e}^{-x}}$$

With initial conditions

$$[y(0) = 0, y'(0) = 0]$$

18.5.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -5 \\ q(x) &= 6 \\ F &= (12x - 7)\,\mathrm{e}^{-x} \end{aligned}$$

Hence the ode is

$$y'' - 5y' + 6y = (12x - 7)\,e^{-x}$$

The domain of $p(x) = -5$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 6$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = (12x - 7)\,e^{-x}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

18.5.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -5, C = 6, f(x) = (12x - 7)\,e^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 5y' + 6y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -5, C = 6$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 5\lambda\, e^{\lambda x} + 6\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 5\lambda + 6 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -5, C = 6$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{5}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-5^2 - (4)\,(1)\,(6)} \\ &= \frac{5}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\lambda_1 = \frac{5}{2} + \frac{1}{2}$$

$$\lambda_2 = \frac{5}{2} - \frac{1}{2}$$

Which simplifies to

$$\lambda_1 = 3$$

$$\lambda_2 = 2$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$

$$y = c_1 e^{(3)x} + c_2 e^{(2)x}$$

Or

$$y = c_1 \mathrm{e}^{3x} + \mathrm{e}^{2x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{3x} + \mathrm{e}^{2x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$(12x - 7)\,\mathrm{e}^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^{-x}, e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{2x}, e^{3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,e^{-x} + A_2 e^{-x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-7A_1 e^{-x} + 12A_1 x\,e^{-x} + 12A_2 e^{-x} = (12x - 7)\,e^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x\,e^{-x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{3x} + e^{2x} c_2\right) + \left(x\,e^{-x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{3x} + e^{2x} c_2 + x\,e^{-x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 3c_1 e^{3x} + 2\,e^{2x} c_2 + e^{-x} - x\,e^{-x}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = 3c_1 + 2c_2 + 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

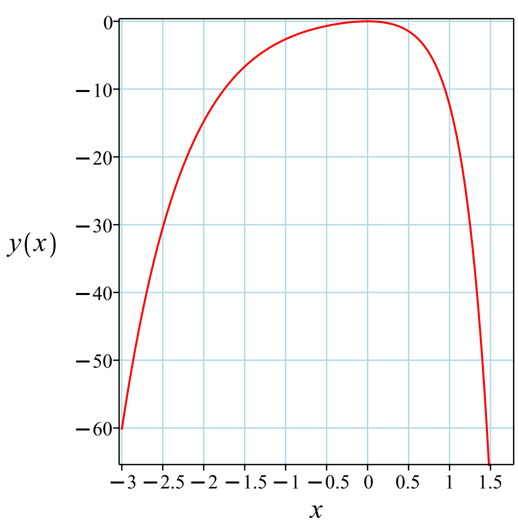
$$c_1 = -1$$
$$c_2 = 1$$

Substituting these values back in above solution results in

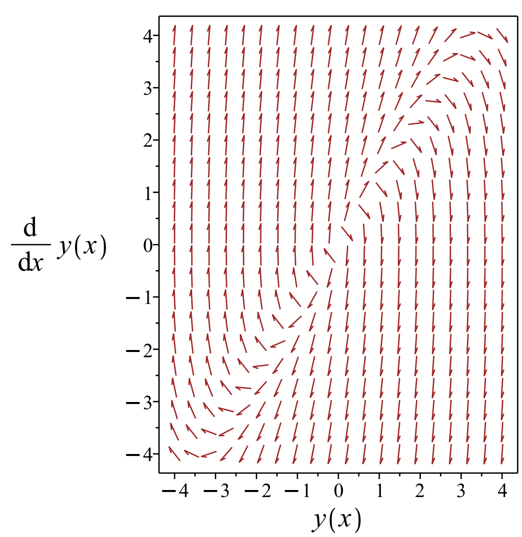
$$y = x\,e^{-x} - e^{3x} + e^{2x}$$

Summary
The solution(s) found are the following

$$y = x\,e^{-x} - e^{3x} + e^{2x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = x\,e^{-x} - e^{3x} + e^{2x}$$

Verified OK.

18.5.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 5y' + 6y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -5 \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 570: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-5}{1}\,dx} \end{aligned}$$

$$
\begin{aligned}
&= z_1 e^{\frac{5x}{2}} \\
&= z_1 \left(\mathrm{e}^{\frac{5x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-5}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{5x}}{(y_1)^2}\, dx \\
&= y_1(\mathrm{e}^{x})
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{2x}\right) + c_2\left(\mathrm{e}^{2x}(\mathrm{e}^{x})\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 5y' + 6y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^{2x} c_1 + c_2 \mathrm{e}^{3x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$(12x - 7)\,e^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^{-x}, e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{2x}, e^{3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,e^{-x} + A_2 e^{-x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-7A_1 e^{-x} + 12A_1 x\,e^{-x} + 12A_2 e^{-x} = (12x - 7)\,e^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x\,e^{-x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{2x} c_1 + c_2 e^{3x}\right) + \left(x\,e^{-x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{2x} c_1 + c_2 e^{3x} + x\,e^{-x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2\,e^{2x} c_1 + 3 c_2 e^{3x} + e^{-x} - x\,e^{-x}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = 2c_1 + 3c_2 + 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

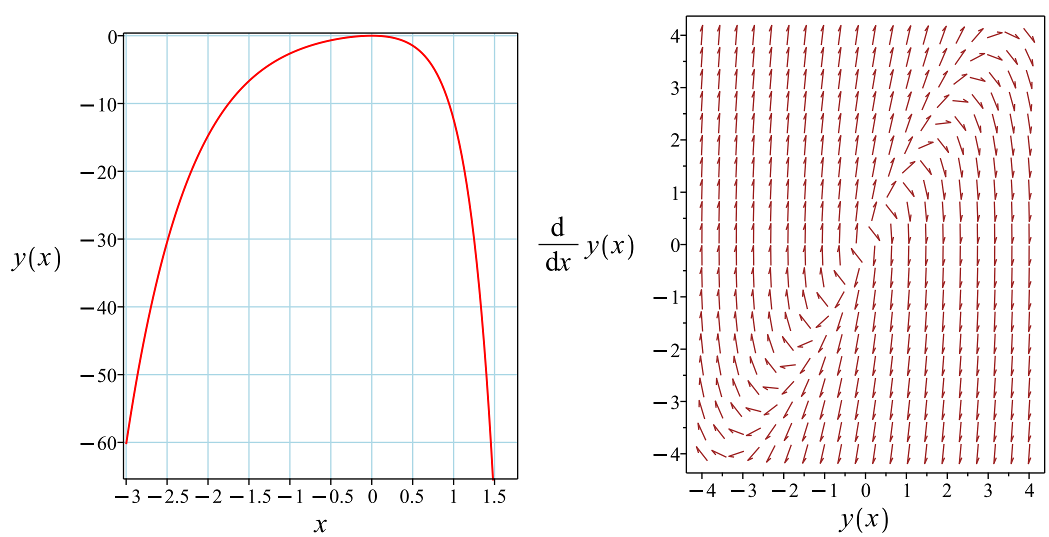
$$c_1 = 1$$
$$c_2 = -1$$

Substituting these values back in above solution results in

$$y = x\,e^{-x} - e^{3x} + e^{2x}$$

<u>Summary</u>
The solution(s) found are the following

$$y = x\,e^{-x} - e^{3x} + e^{2x} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = x\,e^{-x} - e^{3x} + e^{2x}$$

Verified OK.

18.5.4 Maple step by step solution

Let's solve

$$\left[y'' - 5y' + 6y = (12x - 7)\,e^{-x}, y(0) = 0, y'\Big|_{\{x=0\}} = 0\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 5r + 6 = 0$

- Factor the characteristic polynomial

  $(r - 2)\,(r - 3) = 0$

- Roots of the characteristic polynomial

  $r = (2, 3)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{2x} c_1 + c_2 e^{3x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $$\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = (12x - 7)\,e^{-x}\right]$$

  - Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{2x} & e^{3x} \\ 2\,e^{2x} & 3\,e^{3x} \end{bmatrix}$$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{5x}$

- Substitute functions into equation for $y_p(x)$

  $y_p(x) = -e^{2x}\left(\int (12x-7)\,e^{-3x}dx\right) + e^{3x}\left(\int (12x-7)\,e^{-4x}dx\right)$

- Compute integrals

  $y_p(x) = x\,e^{-x}$

- Substitute particular solution into general solution to ODE

  $y = e^{2x}c_1 + c_2e^{3x} + x\,e^{-x}$

☐ Check validity of solution $y = e^{2x}c_1 + c_2e^{3x} + xe^{-x}$

- Use initial condition $y(0) = 0$

  $0 = c_1 + c_2$

- Compute derivative of the solution

  $y' = 2\,e^{2x}c_1 + 3c_2e^{3x} + e^{-x} - x\,e^{-x}$

- Use the initial condition $y'\Big|_{\{x=0\}} = 0$

  $0 = 2c_1 + 3c_2 + 1$

- Solve for c_1 and c_2

  $\{c_1 = 1, c_2 = -1\}$

- Substitute constant values into general solution and simplify

  $y = x\,e^{-x} - e^{3x} + e^{2x}$

- Solution to the IVP

  $y = x\,e^{-x} - e^{3x} + e^{2x}$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + y' = e^{-x}}$$

With initial conditions

$$[y(0) = 1, y'(0) = -1]$$

18.6.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 0 \\ F &= \mathrm{e}^{-x} \end{aligned}$$

Hence the ode is

$$y'' + y' = \mathrm{e}^{-x}$$

The domain of $p(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $F = \mathrm{e}^{-x}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

18.6.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = 0, f(x) = \mathrm{e}^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 1, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + \lambda e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + \lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 1, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-1}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{1^2 - (4)(1)(0)}\\ &= -\frac{1}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{1}{2} + \frac{1}{2}\\ \lambda_2 &= -\frac{1}{2} - \frac{1}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 0\\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(0)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$y = c_1 + e^{-x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + e^{-x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-x}\}$$

Since e^{-x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\, e^{-x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\, e^{-x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 e^{-x} = e^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -x\, e^{-x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + e^{-x} c_2\right) + \left(-x\, e^{-x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 + e^{-x} c_2 - x\,e^{-x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -e^{-x} c_2 - e^{-x} + x\,e^{-x}$$

substituting $y' = -1$ and $x = 0$ in the above gives

$$-1 = -c_2 - 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 1 \\ c_2 &= 0 \end{aligned}$$

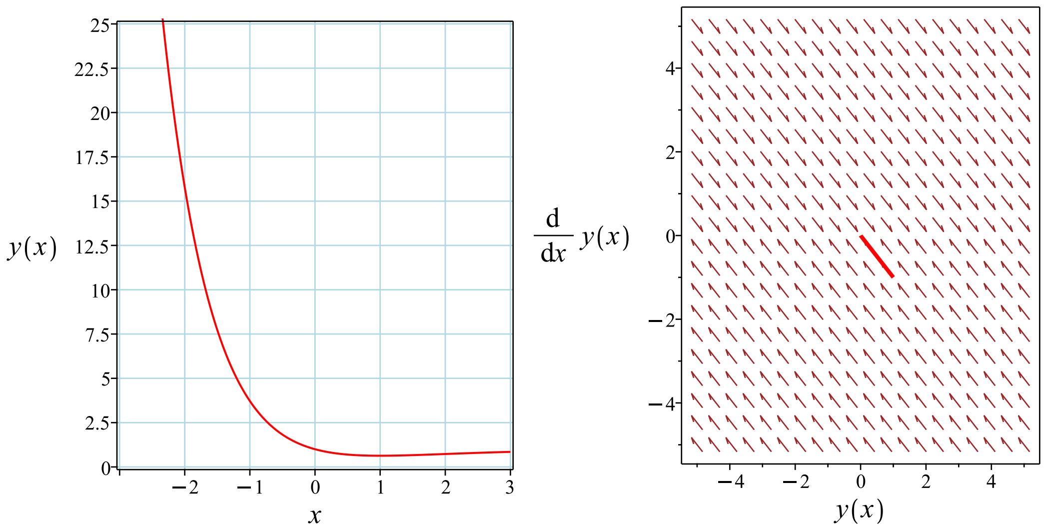
Substituting these values back in above solution results in

$$y = 1 - x\,e^{-x}$$

Summary

The solution(s) found are the following

$$y = 1 - x\,e^{-x} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = 1 - x\,\mathrm{e}^{-x}$$

Verified OK.

18.6.3 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + y')\,dx = \int \mathrm{e}^{-x} dx$$
$$y' + y = -\mathrm{e}^{-x} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 1$$
$$q(x) = -\mathrm{e}^{-x} + c_1$$

Hence the ode is

$$y' + y = -\mathrm{e}^{-x} + c_1$$

The integrating factor μ is

$$\mu = e^{\int 1dx}$$
$$= e^x$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(-e^{-x} + c_1\right)$$
$$\frac{d}{dx}(e^x y) = (e^x)\left(-e^{-x} + c_1\right)$$
$$d(e^x y) = (e^x c_1 - 1)\, dx$$

Integrating gives

$$e^x y = \int e^x c_1 - 1\, dx$$
$$e^x y = -x + e^x c_1 + c_2$$

Dividing both sides by the integrating factor $\mu = e^x$ results in

$$y = e^{-x}(-x + e^x c_1) + e^{-x} c_2$$

which simplifies to

$$y = (-x + c_2)\, e^{-x} + c_1$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = (-x + c_2)\, e^{-x} + c_1 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -e^{-x} - (-x + c_2)\, e^{-x}$$

substituting $y' = -1$ and $x = 0$ in the above gives

$$-1 = -c_2 - 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = 0$$

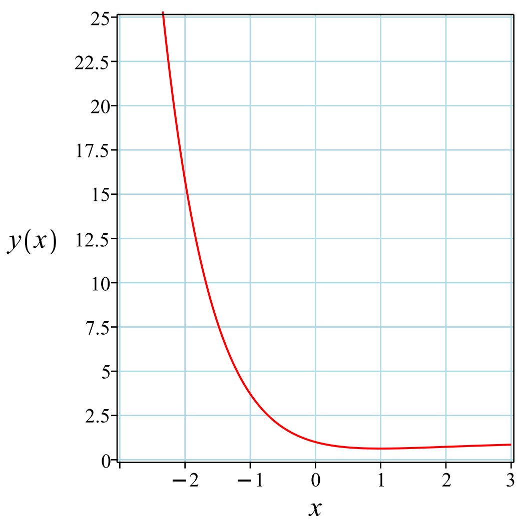
Substituting these values back in above solution results in

$$y = 1 - x\,\mathrm{e}^{-x}$$

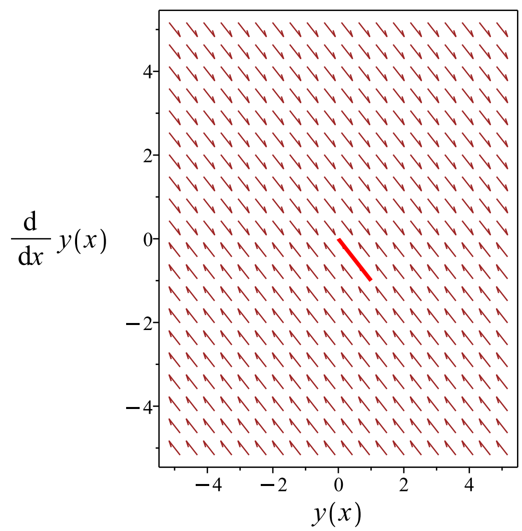
Summary

The solution(s) found are the following

$$y = 1 - x\,\mathrm{e}^{-x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 1 - x\,\mathrm{e}^{-x}$$

Verified OK.

18.6.4 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + p(x) - e^{-x} = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int 1dx} \\ &= e^{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu p) &= (\mu)\left(e^{-x}\right) \\ \frac{d}{dx}(e^{x} p) &= (e^{x})\left(e^{-x}\right) \\ d(e^{x} p) &= dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{x} p &= \int dx \\ e^{x} p &= x + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{x}$ results in

$$p(x) = x\, e^{-x} + c_1 e^{-x}$$

which simplifies to

$$p(x) = (x + c_1)\, e^{-x}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $p = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = c_1$$

$$c_1 = -1$$

Substituting c_1 found above in the general solution gives

$$p(x) = e^{-x}(x - 1)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = e^{-x}(x - 1)$$

Integrating both sides gives

$$\begin{aligned}
y &= \int e^{-x}(x - 1)\, dx \\
&= -x\, e^{-x} + c_2
\end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_2$$

$$c_2 = 1$$

Substituting c_2 found above in the general solution gives

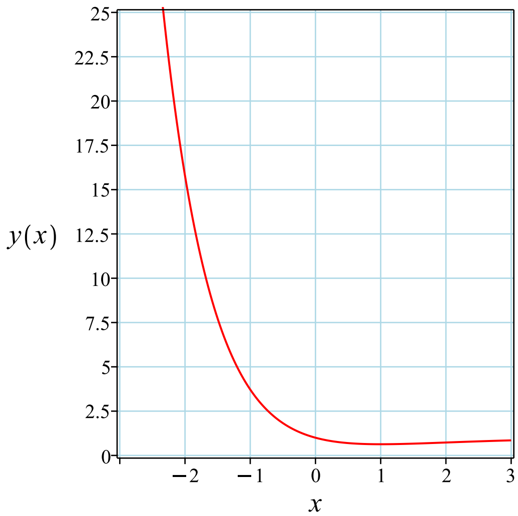
$$y = 1 - x\, e^{-x}$$

Initial conditions are used to solve for the constants of integration.

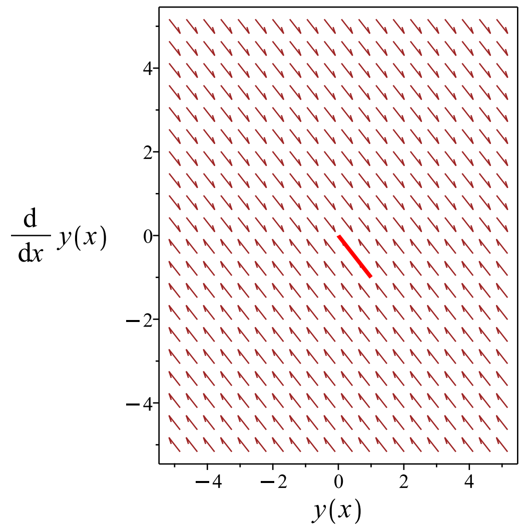
Summary

The solution(s) found are the following

$$y = 1 - x\, e^{-x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = 1 - x\,\mathrm{e}^{-x}$$

Verified OK.

18.6.5 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + y' = \mathrm{e}^{-x}$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + y')\,dx = \int \mathrm{e}^{-x} dx$$
$$y' + y = -\mathrm{e}^{-x} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 1$$
$$q(x) = -\mathrm{e}^{-x} + c_1$$

Hence the ode is

$$y' + y = -e^{-x} + c_1$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int 1dx}\\ &= e^{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(-e^{-x} + c_1\right)\\ \frac{d}{dx}(e^{x} y) &= (e^{x})\left(-e^{-x} + c_1\right)\\ d(e^{x} y) &= (e^{x} c_1 - 1)\ dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{x} y &= \int e^{x} c_1 - 1\, dx\\ e^{x} y &= -x + e^{x} c_1 + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{x}$ results in

$$y = e^{-x}(-x + e^{x} c_1) + e^{-x} c_2$$

which simplifies to

$$y = (-x + c_2)\, e^{-x} + c_1$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = (-x + c_2)\, e^{-x} + c_1 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -e^{-x} - (-x + c_2)\, e^{-x}$$

substituting $y' = -1$ and $x = 0$ in the above gives

$$-1 = -c_2 - 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = 0$$

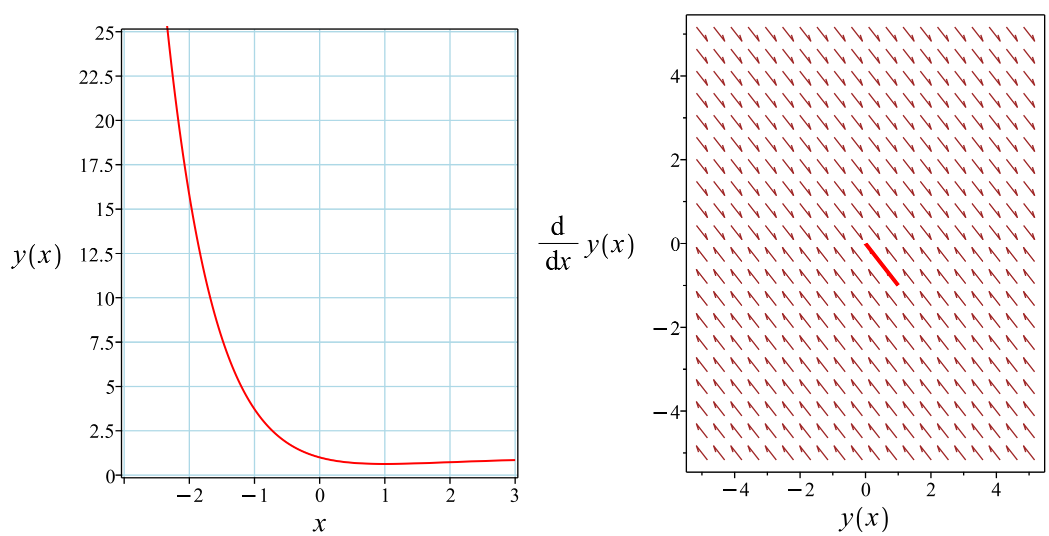
Substituting these values back in above solution results in

$$y = 1 - x\,\mathrm{e}^{-x}$$

Summary

The solution(s) found are the following

$$y = 1 - x\,\mathrm{e}^{-x} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = 1 - x\,\mathrm{e}^{-x}$$

Verified OK.

18.6.6 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 1 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 572: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-\frac{x}{2}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\, dx}
\end{aligned}
$$

$$= z_1 e^{-\frac{x}{2}}$$
$$= z_1 \left(e^{-\frac{x}{2}}\right)$$

Which simplifies to

$$y_1 = e^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{1}{1}\, dx}}{(y_1)^2}\, dx$$
$$= y_1 \int \frac{e^{-x}}{(y_1)^2}\, dx$$
$$= y_1(e^x)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(e^{-x}\right) + c_2 \left(e^{-x}(e^x)\right)$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{-x} + c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-x}\}$$

Since e^{-x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{-x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^{-x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 e^{-x} = e^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -x\,e^{-x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2\right) + \left(-x\,e^{-x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{-x} + c_2 - x\, e^{-x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 e^{-x} - e^{-x} + x\, e^{-x}$$

substituting $y' = -1$ and $x = 0$ in the above gives

$$-1 = -c_1 - 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

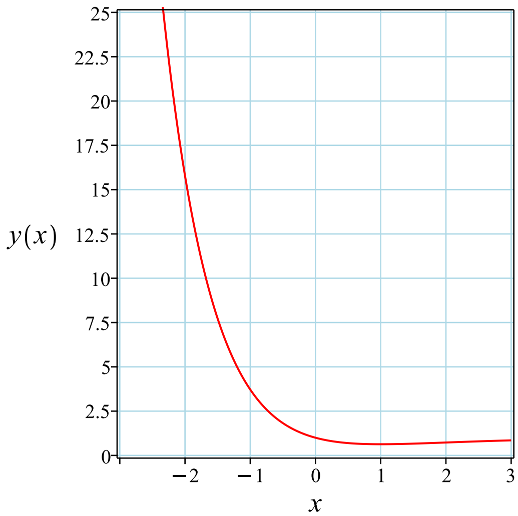
$$c_1 = 0$$
$$c_2 = 1$$

Substituting these values back in above solution results in

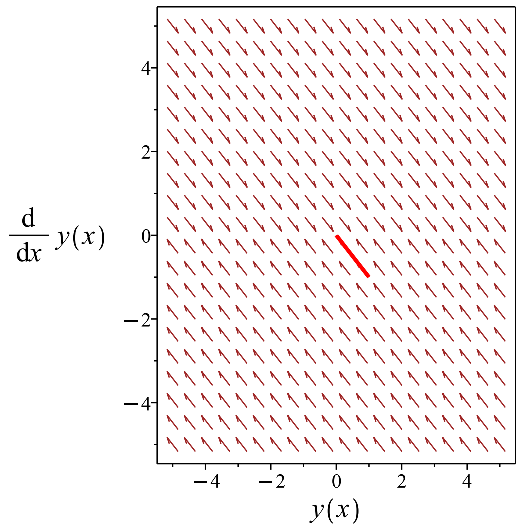
$$y = 1 - x\, e^{-x}$$

Summary
The solution(s) found are the following

$$y = 1 - x\, e^{-x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 1 - x\,\mathrm{e}^{-x}$$

Verified OK.

18.6.7 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 1 \\ r(x) &= 0 \\ s(x) &= \mathrm{e}^{-x} \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0-(0)+(0)=0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y'+\left(q(x)-p'(x)\right)y\right)'=s(x)$$

Integrating gives

$$p(x)\,y'+\left(q(x)-p'(x)\right)y=\int s(x)\;dx$$

Substituting the above values for p, q, r, s gives

$$y'+y=\int \mathrm{e}^{-x}\;dx$$

We now have a first order ode to solve which is

$$y'+y=-\mathrm{e}^{-x}+c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$\begin{aligned}p(x)&=1\\ q(x)&=-\mathrm{e}^{-x}+c_1\end{aligned}$$

Hence the ode is

$$y'+y=-\mathrm{e}^{-x}+c_1$$

The integrating factor μ is

$$\begin{aligned}\mu&=\mathrm{e}^{\int 1dx}\\ &=\mathrm{e}^{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y)&=(\mu)\left(-\mathrm{e}^{-x}+c_1\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}(\mathrm{e}^{x}y)&=(\mathrm{e}^{x})\left(-\mathrm{e}^{-x}+c_1\right)\\ \mathrm{d}(\mathrm{e}^{x}y)&=(\mathrm{e}^{x}c_1-1)\;\mathrm{d}x\end{aligned}$$

Integrating gives

$$
\begin{aligned}
e^{x} y &= \int e^{x} c_1 - 1 \,dx \\
e^{x} y &= -x + e^{x} c_1 + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{x}$ results in

$$
y = e^{-x}(-x + e^{x} c_1) + e^{-x} c_2
$$

which simplifies to

$$
y = (-x + c_2)\, e^{-x} + c_1
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = (-x + c_2)\, e^{-x} + c_1 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$
1 = c_1 + c_2 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -e^{-x} - (-x + c_2)\, e^{-x}
$$

substituting $y' = -1$ and $x = 0$ in the above gives

$$
-1 = -c_2 - 1 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

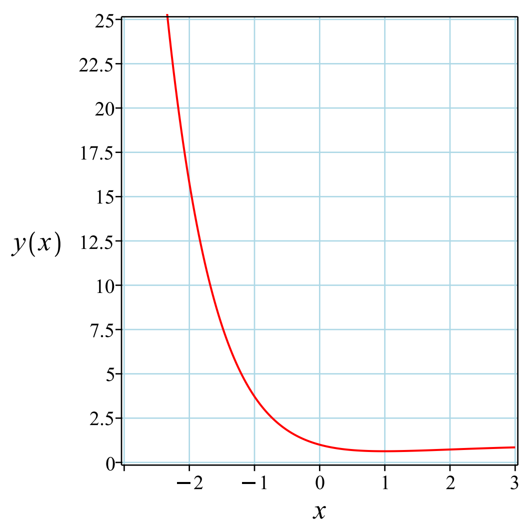
$$
\begin{aligned}
c_1 &= 1 \\
c_2 &= 0
\end{aligned}
$$

Substituting these values back in above solution results in

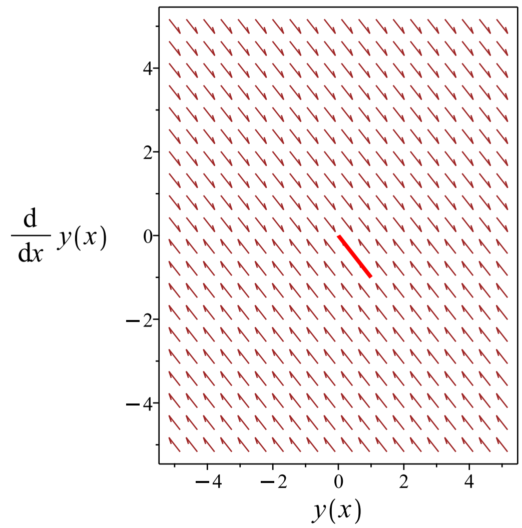
$$
y = 1 - x\, e^{-x}
$$

Summary
The solution(s) found are the following

$$
y = 1 - x\, e^{-x} \tag{1}
$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = 1 - x\,\mathrm{e}^{-x}$$

Verified OK.

18.6.8 Maple step by step solution

Let's solve

$$\left[y'' + y' = \mathrm{e}^{-x}, y(0) = 1, y'\Big|_{\{x=0\}} = -1\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + r = 0$

- Factor the characteristic polynomial

  $r(r+1) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 0)$

- 1st solution of the homogeneous ODE

$y_1(x) = \mathrm{e}^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x) \left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \mathrm{e}^{-x}\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-x} & 1 \\ -\mathrm{e}^{-x} & 0 \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = \mathrm{e}^{-x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\mathrm{e}^{-x}\left(\int 1dx\right) + \int \mathrm{e}^{-x}dx$

  - Compute integrals

    $y_p(x) = \mathrm{e}^{-x}(-x-1)$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 + \mathrm{e}^{-x}(-x-1)$

□ Check validity of solution $y = c_1 \mathrm{e}^{-x} + c_2 + \mathrm{e}^{-x}(-x-1)$

  - Use initial condition $y(0) = 1$

    $1 = -1 + c_1 + c_2$

  - Compute derivative of the solution

    $y' = -c_1 \mathrm{e}^{-x} - \mathrm{e}^{-x}(-x-1) - \mathrm{e}^{-x}$

  - Use the initial condition $y'\Big|_{\{x=0\}} = -1$

    $-1 = -c_1$

- Solve for c_1 and c_2

  $\{c_1 = 1, c_2 = 1\}$

- Substitute constant values into general solution and simplify

  $y = 1 - x\,\mathrm{e}^{-x}$

- Solution to the IVP

  $y = 1 - x\,\mathrm{e}^{-x}$

Problem number: 596.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 6y' + 9y = 10 \sin(x)}$$

With initial conditions

$$[y(0) = 0, y'(0) = 0]$$

18.7.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 6 \\ q(x) &= 9 \\ F &= 10\sin(x) \end{aligned}$$

Hence the ode is

$$y'' + 6y' + 9y = 10\sin(x)$$

The domain of $p(x) = 6$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 9$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 10\sin(x)$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

18.7.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 6, C = 9, f(x) = 10\sin(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 6y' + 9y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 6, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 6\lambda e^{\lambda x} + 9 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 6\lambda + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 6, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-6}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(6)^2 - (4)(1)(9)} \\ &= -3\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 3$. Therefore the solution is

$$y = c_1 e^{-3x} + c_2 x e^{-3x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{-3x} + c_2 x e^{-3x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$10 \sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x e^{-3x}, e^{-3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$8A_1 \cos(x) + 8A_2 \sin(x) - 6A_1 \sin(x) + 6A_2 \cos(x) = 10 \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{3}{5}, A_2 = \frac{4}{5}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-3x} + c_2 x\, e^{-3x}\right) + \left(-\frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-3x}(c_2 x + c_1) - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{-3x}(c_2 x + c_1) - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = -\frac{3}{5} + c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -3\,\mathrm{e}^{-3x}(c_2x + c_1) + c_2\mathrm{e}^{-3x} + \frac{3\sin(x)}{5} + \frac{4\cos(x)}{5}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = \frac{4}{5} - 3c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{3}{5}$$
$$c_2 = 1$$

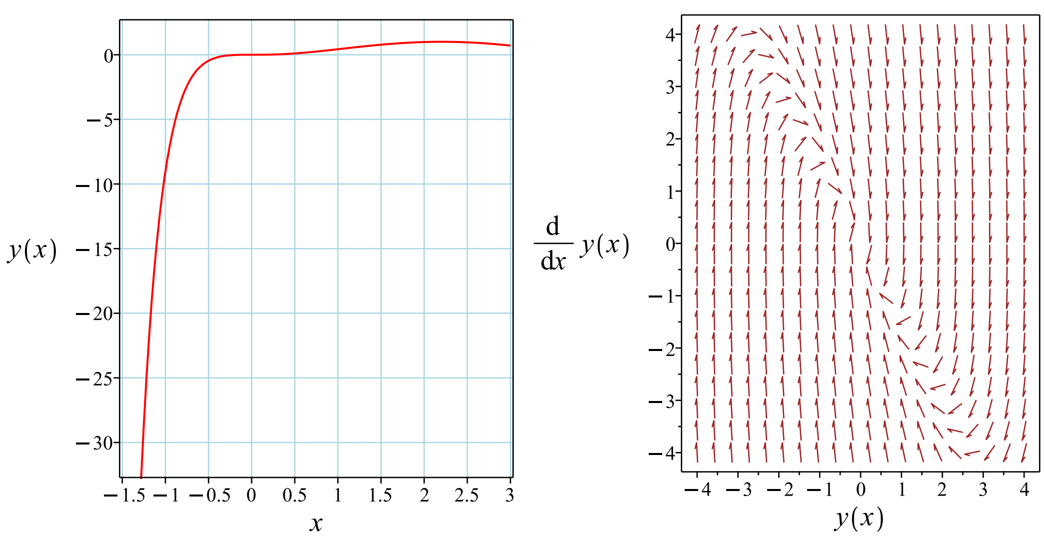
Substituting these values back in above solution results in

$$y = x\,\mathrm{e}^{-3x} + \frac{3\,\mathrm{e}^{-3x}}{5} - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}$$

Summary

The solution(s) found are the following

$$y = x\,\mathrm{e}^{-3x} + \frac{3\,\mathrm{e}^{-3x}}{5} - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = x\,\mathrm{e}^{-3x} + \frac{3\,\mathrm{e}^{-3x}}{5} - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}$$

Verified OK.

18.7.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = 6$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int 6\, dx} \\ &= \mathrm{e}^{3x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= 10\,\mathrm{e}^{3x} \sin(x) \\ \left(\mathrm{e}^{3x} y\right)'' &= 10\,\mathrm{e}^{3x} \sin(x) \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{3x} y\right)' = -(\cos(x) - 3\sin(x))\,\mathrm{e}^{3x} + c_1$$

Integrating again gives

$$\left(\mathrm{e}^{3x} y\right) = \frac{(-3\cos(x) + 4\sin(x))\,\mathrm{e}^{3x}}{5} + c_1 x + c_2$$

Hence the solution is

$$y = \frac{\frac{(-3\cos(x)+4\sin(x))\mathrm{e}^{3x}}{5} + c_1 x + c_2}{\mathrm{e}^{3x}}$$

Or

$$y = -\frac{3\cos(x)}{5} + \frac{4\sin(x)}{5} + c_1 x\,\mathrm{e}^{-3x} + c_2 \mathrm{e}^{-3x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{3\cos(x)}{5} + \frac{4\sin(x)}{5} + c_1 x\,\mathrm{e}^{-3x} + c_2 \mathrm{e}^{-3x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = -\frac{3}{5} + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{3\sin(x)}{5} + \frac{4\cos(x)}{5} + c_1 \mathrm{e}^{-3x} - 3c_1 x\,\mathrm{e}^{-3x} - 3c_2 \mathrm{e}^{-3x}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = \frac{4}{5} + c_1 - 3c_2 \tag{2A}$$

Equations $\{1\mathrm{A},2\mathrm{A}\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = \frac{3}{5}$$

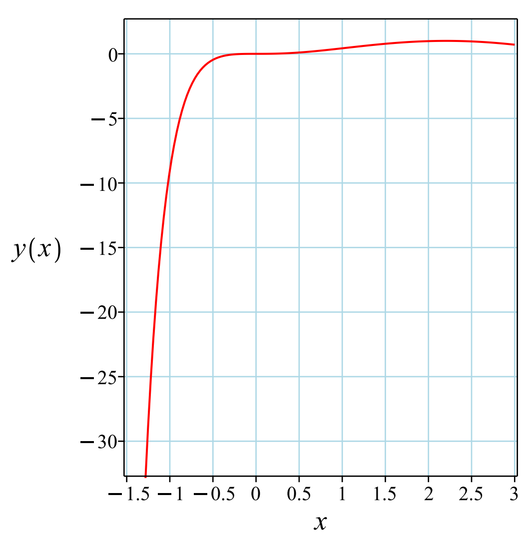
Substituting these values back in above solution results in

$$y = x\,\mathrm{e}^{-3x} + \frac{3\,\mathrm{e}^{-3x}}{5} - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}$$

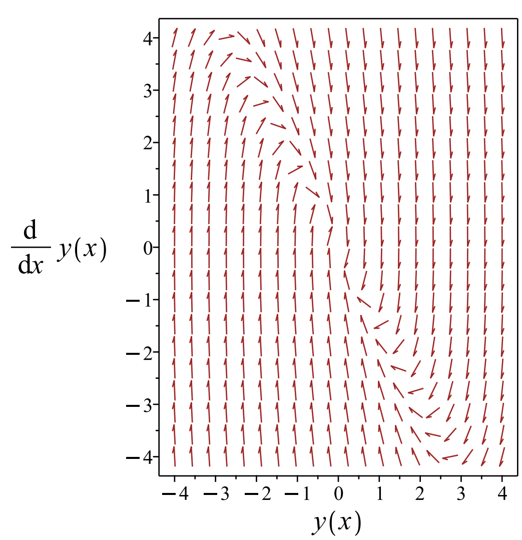
Summary

The solution(s) found are the following

$$y = x\,\mathrm{e}^{-3x} + \frac{3\,\mathrm{e}^{-3x}}{5} - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = x\,\mathrm{e}^{-3x} + \frac{3\,\mathrm{e}^{-3x}}{5} - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}$$

Verified OK.

18.7.4 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 6y' + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 6 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 574: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{6}{1}\,dx} \\
&= z_1 e^{-3x} \\
&= z_1 \left(\mathrm{e}^{-3x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-3x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{6}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-6x}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-3x}\right) + c_2\left(\mathrm{e}^{-3x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 6y' + 9y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-3x} + c_2 x \,\mathrm{e}^{-3x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$10 \sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x \,\mathrm{e}^{-3x}, \mathrm{e}^{-3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$8A_1 \cos(x) + 8A_2 \sin(x) - 6A_1 \sin(x) + 6A_2 \cos(x) = 10 \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{3}{5}, A_2 = \frac{4}{5}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-3x} + c_2 x \,\mathrm{e}^{-3x}\right) + \left(-\frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-3x}(c_2x + c_1) - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{-3x}(c_2x + c_1) - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = -\frac{3}{5} + c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -3\,e^{-3x}(c_2x + c_1) + c_2e^{-3x} + \frac{3\sin(x)}{5} + \frac{4\cos(x)}{5}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = \frac{4}{5} - 3c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{3}{5}$$
$$c_2 = 1$$

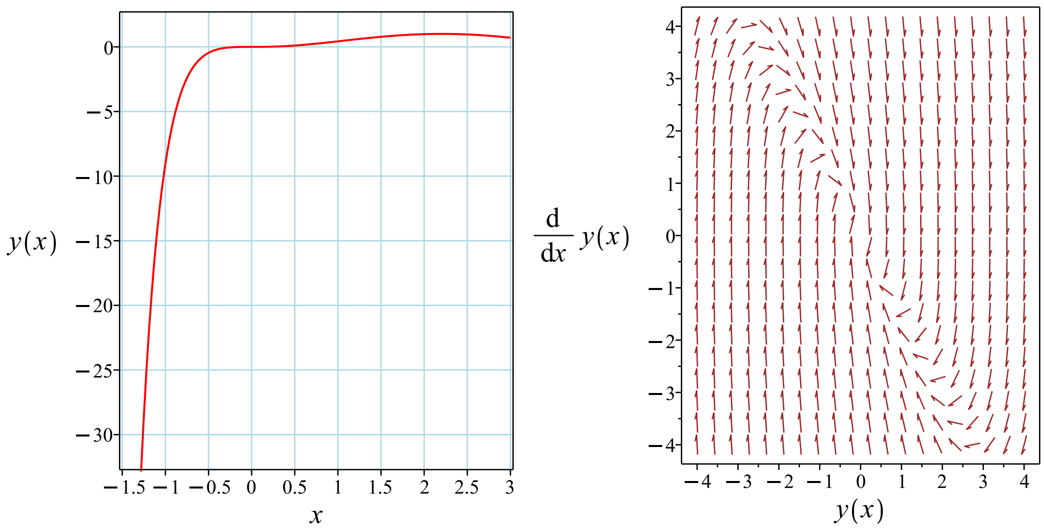
Substituting these values back in above solution results in

$$y = x\,e^{-3x} + \frac{3\,e^{-3x}}{5} - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}$$

Summary

The solution(s) found are the following

$$y = x\,e^{-3x} + \frac{3\,e^{-3x}}{5} - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5} \tag{1}$$



(a) Solution plot (b) Slope field plot

<u>Verification of solutions</u>

$$y = x\,\mathrm{e}^{-3x} + \frac{3\,\mathrm{e}^{-3x}}{5} - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}$$

Verified OK.

18.7.5 Maple step by step solution

Let's solve

$$\left[y'' + 6y' + 9y = 10\sin(x),\, y(0) = 0,\, y'\Big|_{\{x=0\}} = 0\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 6r + 9 = 0$

- Factor the characteristic polynomial

  $(r+3)^2 = 0$

- Root of the characteristic polynomial

  $r = -3$

- 1st solution of the homogeneous ODE

$y_1(x) = \mathrm{e}^{-3x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,\mathrm{e}^{-3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-3x} + c_2 x\,\mathrm{e}^{-3x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 10\sin(x)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-3x} & x\,\mathrm{e}^{-3x} \\ -3\,\mathrm{e}^{-3x} & \mathrm{e}^{-3x} - 3x\,\mathrm{e}^{-3x} \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = \mathrm{e}^{-6x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = 10\,\mathrm{e}^{-3x}\left(-\left(\int \sin(x)\,x\,\mathrm{e}^{3x}dx\right) + x\left(\int \mathrm{e}^{3x}\sin(x)\,dx\right)\right)$

  ◦ Compute integrals

  $y_p(x) = -\frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-3x} + c_2 x\,\mathrm{e}^{-3x} - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}$

☐ Check validity of solution $y = c_1 \mathrm{e}^{-3x} + c_2 x \mathrm{e}^{-3x} - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}$

  ◦ Use initial condition $y(0) = 0$

  $0 = -\frac{3}{5} + c_1$

  ◦ Compute derivative of the solution

  $y' = -3c_1 \mathrm{e}^{-3x} + c_2 \mathrm{e}^{-3x} - 3c_2 x\,\mathrm{e}^{-3x} + \frac{3\sin(x)}{5} + \frac{4\cos(x)}{5}$

  ◦ Use the initial condition $y'\Big|_{\{x=0\}} = 0$

  $0 = \frac{4}{5} - 3c_1 + c_2$

- Solve for c_1 and c_2

  $\{c_1 = \frac{3}{5}, c_2 = 1\}$

- Substitute constant values into general solution and simplify

  $y = x\,\mathrm{e}^{-3x} + \frac{3\,\mathrm{e}^{-3x}}{5} - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}$

- Solution to the IVP

  $y = x\,\mathrm{e}^{-3x} + \frac{3\,\mathrm{e}^{-3x}}{5} - \frac{3\cos(x)}{5} + \frac{4\sin(x)}{5}$

Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Initial value problem. Exercises page 140
Problem number: 597.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + y = 2\cos(x)}$$

With initial conditions

$$[y(0) = 1, y'(0) = 0]$$

18.8.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= 1 \\ F &= 2\cos(x) \end{aligned}$$

Hence the ode is

$$y'' + y = 2\cos(x)$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 2\cos(x)$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

18.8.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = 2\cos(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)}\\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i\\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i\\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2\cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{\cos(x)\,x, \sin(x)\,x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1\cos(x)\,x + A_2\sin(x)\,x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1\sin(x) + 2A_2\cos(x) = 2\cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \sin(x)\,x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + (\sin(x)\,x) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1\cos(x) + c_2\sin(x) + \sin(x)\,x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 \sin(x) + c_2 \cos(x) + \cos(x)\, x + \sin(x)$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

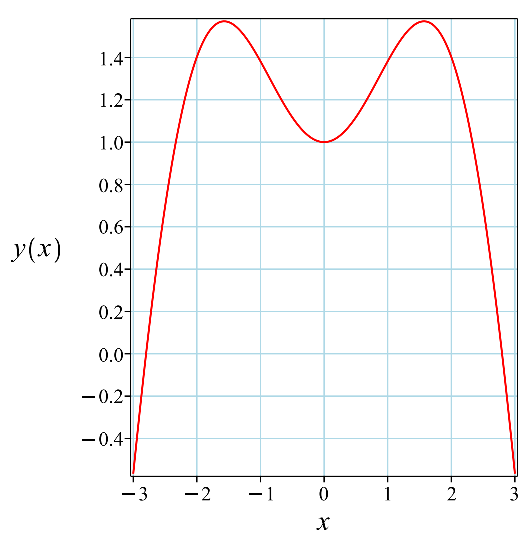
$$c_1 = 1$$
$$c_2 = 0$$

Substituting these values back in above solution results in

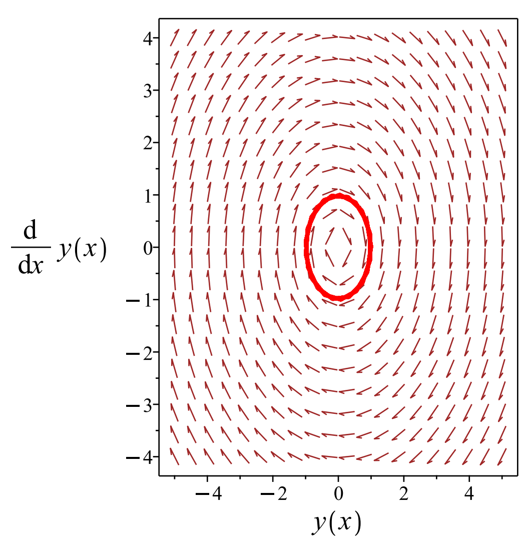
$$y = \sin(x)\, x + \cos(x)$$

Summary
The solution(s) found are the following

$$y = \sin(x)\, x + \cos(x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \sin(x)\, x + \cos(x)$$

Verified OK.

18.8.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 576: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\,dx \\ &= \cos(x)\,(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2\cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{\cos(x)\, x, \sin(x)\, x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 \cos(x)\, x + A_2 \sin(x)\, x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 \sin(x) + 2A_2 \cos(x) = 2\cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \sin(x)\, x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + (\sin(x)\, x) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(x) + c_2 \sin(x) + \sin(x) x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 \sin(x) + c_2 \cos(x) + \cos(x) x + \sin(x)$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

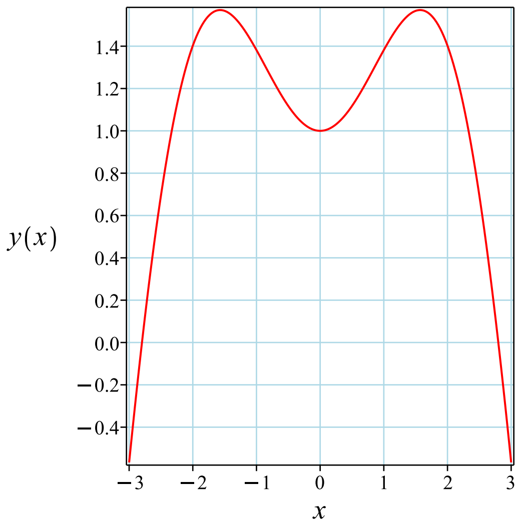
$$\begin{aligned} c_1 &= 1 \\ c_2 &= 0 \end{aligned}$$

Substituting these values back in above solution results in

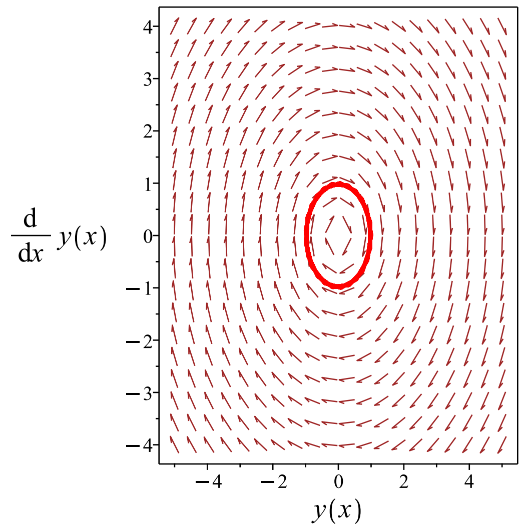
$$y = \sin(x) x + \cos(x)$$

Summary
The solution(s) found are the following

$$y = \sin(x) x + \cos(x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \sin(x)\,x + \cos(x)$$

Verified OK.

18.8.4 Maple step by step solution

Let's solve

$\left[y'' + y = 2\cos(x), y(0) = 1, y'\Big|_{\{x=0\}} = 0\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

$y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 2\cos(x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\cos(x)\left(\int \sin(2x)\, dx\right) + 2\sin(x)\left(\int \cos(x)^2\, dx\right)$

  - Compute integrals

    $y_p(x) = \frac{\cos(x)}{2} + \sin(x)\, x$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + \frac{\cos(x)}{2} + \sin(x)\, x$

☐ Check validity of solution $y = c_1 \cos(x) + c_2 \sin(x) + \frac{\cos(x)}{2} + \sin(x)\, x$

  - Use initial condition $y(0) = 1$

    $1 = c_1 + \frac{1}{2}$

  - Compute derivative of the solution

    $y' = -c_1 \sin(x) + c_2 \cos(x) + \frac{\sin(x)}{2} + \cos(x)\, x$

  - Use the initial condition $y'\Big|_{\{x=0\}} = 0$

    $0 = c_2$

- Solve for c_1 and c_2

  $\{c_1 = \frac{1}{2}, c_2 = 0\}$
- Substitute constant values into general solution and simplify

  $y = \sin(x)\, x + \cos(x)$

- Solution to the IVP

  $y = \sin(x)\, x + \cos(x)$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + 4y = \sin(x)}$$

With initial conditions

$$[y(0) = 1, y'(0) = 1]$$

18.9.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= 4 \\ F &= \sin(x) \end{aligned}$$

Hence the ode is

$$y'' + 4y = \sin(x)$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = \sin(x)$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

18.9.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 4, f(x) = \sin(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(4)} \\ &= \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2i \\ \lambda_2 &= -2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2i \\ \lambda_2 &= -2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(2x) + c_2 \sin(2x))$$

Or

$$y = c_1 \cos(2x) + c_2 \sin(2x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(2x) + c_2 \sin(2x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(2x), \sin(2x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_1 \cos(x) + 3A_2 \sin(x) = \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{3}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\sin(x)}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(2x) + c_2 \sin(2x)) + \left(\frac{\sin(x)}{3}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(2x) + c_2 \sin(2x) + \frac{\sin(x)}{3} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -2c_1 \sin(2x) + 2c_2 \cos(2x) + \frac{\cos(x)}{3}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = \frac{1}{3} + 2c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = \frac{1}{3}$$

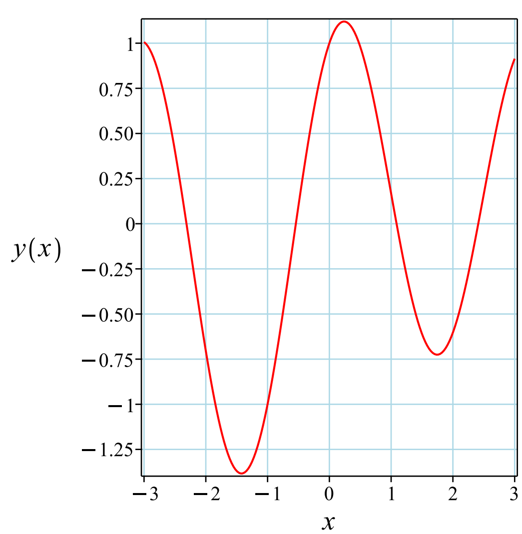
Substituting these values back in above solution results in

$$y = \cos(2x) + \frac{\sin(2x)}{3} + \frac{\sin(x)}{3}$$

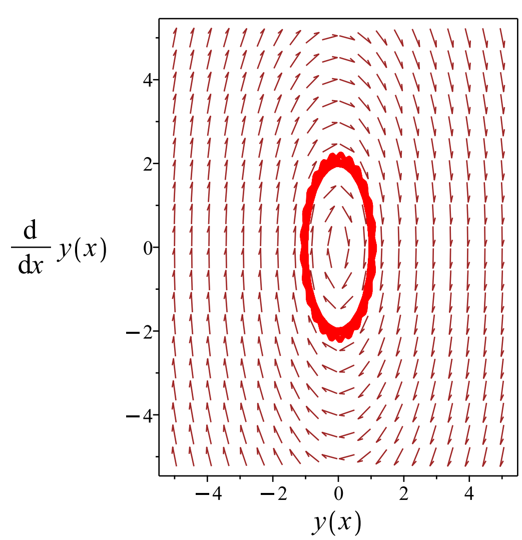
Summary

The solution(s) found are the following

$$y = \cos(2x) + \frac{\sin(2x)}{3} + \frac{\sin(x)}{3} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \cos(2x) + \frac{\sin(2x)}{3} + \frac{\sin(x)}{3}$$

Verified OK.

18.9.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 578: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(2x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(2x) \int \frac{1}{\cos(2x)^2}\,dx \\ &= \cos(2x)\left(\frac{\tan(2x)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(2x)) + c_2\left(\cos(2x)\left(\frac{\tan(2x)}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+4y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1\cos(2x)+\frac{c_2\sin(2x)}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x),\sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sin(2x)}{2},\cos(2x)\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\cos(x)+A_2\sin(x)$$

The unknowns $\{A_1,A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_1\cos(x)+3A_2\sin(x)=\sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1=0,A_2=\frac{1}{3}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p=\frac{\sin(x)}{3}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2}\right) + \left(\frac{\sin(x)}{3}\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2} + \frac{\sin(x)}{3} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$
1 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -2c_1 \sin(2x) + c_2 \cos(2x) + \frac{\cos(x)}{3}
$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$
1 = \frac{1}{3} + c_2 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 1 \\
c_2 &= \frac{2}{3}
\end{aligned}
$$

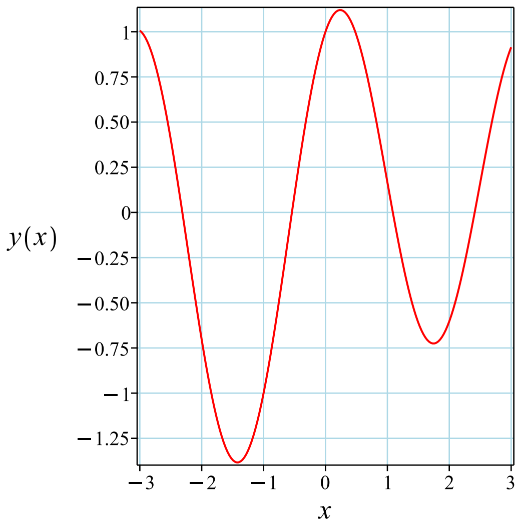
Substituting these values back in above solution results in

$$
y = \cos(2x) + \frac{\sin(2x)}{3} + \frac{\sin(x)}{3}
$$

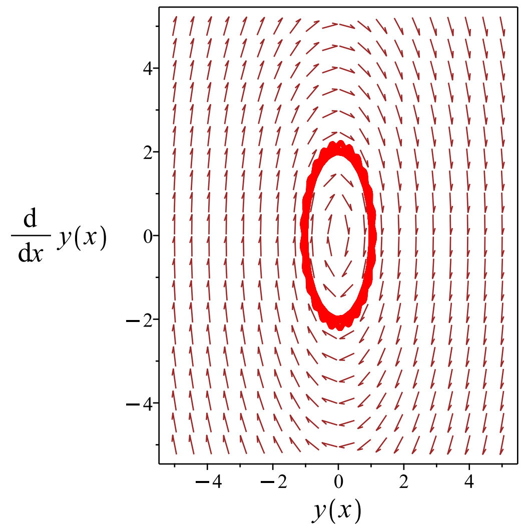
Summary

The solution(s) found are the following

$$
y = \cos(2x) + \frac{\sin(2x)}{3} + \frac{\sin(x)}{3} \tag{1}
$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \cos(2x) + \frac{\sin(2x)}{3} + \frac{\sin(x)}{3}$$

Verified OK.

18.9.4 Maple step by step solution

Let's solve

$$\left[y'' + 4y = \sin(x), y(0) = 1, y'\Big|_{\{x=0\}} = 1\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r = (-2\,\mathrm{I}, 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

$y_1(x) = \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(2x)$

- General solution of the ODE

  $y = c_1y_1(x) + c_2y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1\cos(2x) + c_2\sin(2x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \sin(x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(2x) & \sin(2x) \\ -2\sin(2x) & 2\cos(2x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\cos(2x)\left(\int \sin(x)^2\cos(x)\,dx\right) + \frac{\sin(2x)\left(\int(\sin(3x)-\sin(x))dx\right)}{4}$

  - Compute integrals

    $y_p(x) = \frac{\sin(x)}{3}$

- Substitute particular solution into general solution to ODE

  $y = c_1\cos(2x) + c_2\sin(2x) + \frac{\sin(x)}{3}$

☐ Check validity of solution $y = c_1\cos(2x) + c_2\sin(2x) + \frac{\sin(x)}{3}$

  - Use initial condition $y(0) = 1$

    $1 = c_1$

  - Compute derivative of the solution

    $y' = -2c_1\sin(2x) + 2c_2\cos(2x) + \frac{\cos(x)}{3}$

  - Use the initial condition $y'\Big|_{\{x=0\}} = 1$

    $1 = \frac{1}{3} + 2c_2$

- Solve for c_1 and c_2

  $\{c_1 = 1, c_2 = \frac{1}{3}\}$

- Substitute constant values into general solution and simplify

  $y = \cos(2x) + \frac{\sin(2x)}{3} + \frac{\sin(x)}{3}$

- Solution to the IVP

  $y = \cos(2x) + \frac{\sin(2x)}{3} + \frac{\sin(x)}{3}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + y = 4\cos(x)\, x}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1]$$

18.10.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= 1 \\ F &= 4\cos(x)\, x \end{aligned}$$

Hence the ode is

$$y'' + y = 4\cos(x)\, x$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 4\cos(x)\, x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

18.10.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = 4\cos(x)\, x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4\cos(x)\, x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x)\, x, \sin(x)\, x, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2\cos(x), x^2\sin(x), \cos(x)\, x, \sin(x)\, x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1x^2\cos(x) + A_2x^2\sin(x) + A_3\cos(x)\, x + A_4\sin(x)\, x$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&2A_1\cos(x) - 4A_1x\sin(x) + 2A_2\sin(x) + 4A_2x\cos(x) - 2A_3\sin(x) + 2A_4\cos(x)\\&= 4\cos(x)\, x\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 1, A_3 = 1, A_4 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x^2\sin(x) + \cos(x)\, x$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\&= (c_1\cos(x) + c_2\sin(x)) + (x^2\sin(x) + \cos(x)\, x)\end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(x) + c_2 \sin(x) + x^2 \sin(x) + \cos(x) x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 \sin(x) + c_2 \cos(x) + \sin(x) x + x^2 \cos(x) + \cos(x)$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = 1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 0 \\ c_2 &= 0 \end{aligned}$$

Substituting these values back in above solution results in

$$y = x^2 \sin(x) + \cos(x) x$$

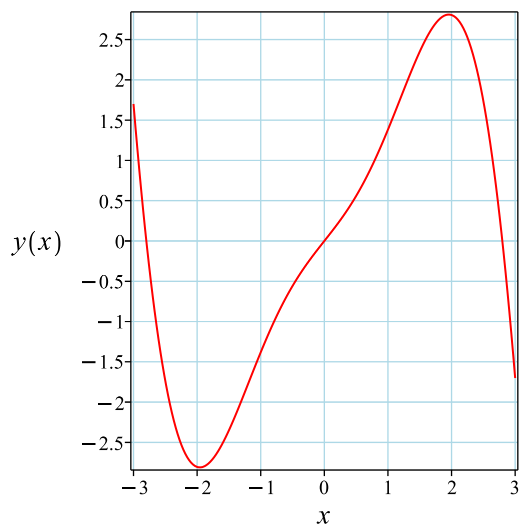
Which simplifies to

$$y = x(\sin(x) x + \cos(x))$$

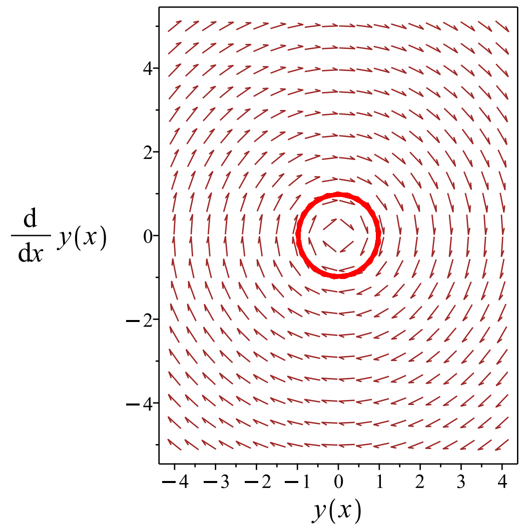
Summary

The solution(s) found are the following

$$y = x(\sin(x) x + \cos(x)) \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = x(\sin(x)\, x + \cos(x))$$

Verified OK.

18.10.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 580: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\,dx \\ &= \cos(x)\,(\tan(x)) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1(\cos(x)) + c_2(\cos(x)(\tan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \cos(x) + c_2 \sin(x)
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
4\cos(x)\, x
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\cos(x)\, x, \sin(x)\, x, \cos(x), \sin(x)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{\cos(x), \sin(x)\}
$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$
[\{x^2\cos(x), x^2\sin(x), \cos(x)\, x, \sin(x)\, x\}]
$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$
y_p = A_1x^2\cos(x) + A_2x^2\sin(x) + A_3\cos(x)\, x + A_4\sin(x)\, x
$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1\cos(x) - 4A_1x\sin(x) + 2A_2\sin(x) + 4A_2x\cos(x) - 2A_3\sin(x) + 2A_4\cos(x) = 4\cos(x)x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 1, A_3 = 1, A_4 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x^2\sin(x) + \cos(x)x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + (x^2\sin(x) + \cos(x)x) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1\cos(x) + c_2\sin(x) + x^2\sin(x) + \cos(x)x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1\sin(x) + c_2\cos(x) + \sin(x)x + x^2\cos(x) + \cos(x)$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = 1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 0 \\ c_2 &= 0 \end{aligned}$$

Substituting these values back in above solution results in

$$y = x^2 \sin(x) + \cos(x) x$$

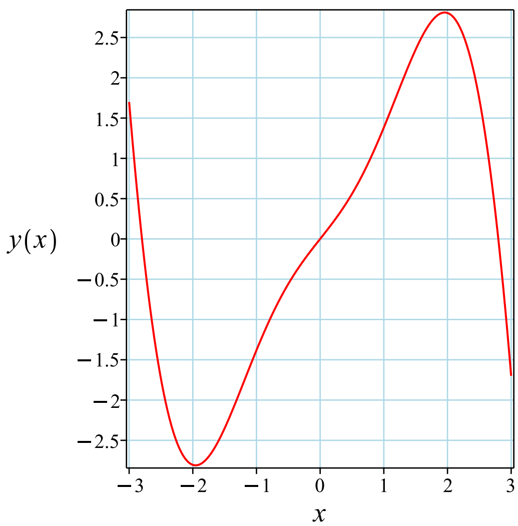
Which simplifies to

$$y = x(\sin(x) x + \cos(x))$$

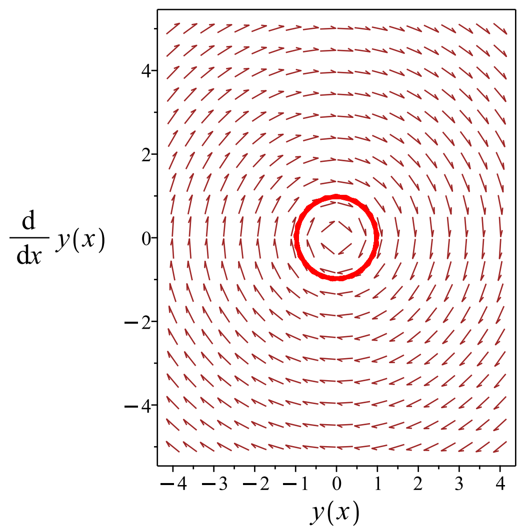
Summary

The solution(s) found are the following

$$y = x(\sin(x) x + \cos(x)) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = x(\sin(x) x + \cos(x))$$

Verified OK.

  $y_1(x)=\cos\left(x\right)$

- 2nd solution of the homogeneous ODE

  $y_2(x)=\sin\left(x\right)$

- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)+y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y=c_1\cos\left(x\right)+c_2\sin\left(x\right)+y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x)=-y_1(x)\left(\int\frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right)+y_2(x)\left(\int\frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x)=4\cos\left(x\right)x\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x))=\begin{bmatrix}\cos\left(x\right) & \sin\left(x\right)\\ -\sin\left(x\right) & \cos\left(x\right)\end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x))=1$

- ○ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -2\cos(x)\left(\int x\sin(2x)\,dx\right) + 4\sin(x)\left(\int \cos(x)^2 x dx\right)$$

- ◦ Compute integrals

$$y_p(x) = x^2 \sin(x) + \cos(x) x - \sin(x)$$

- Substitute particular solution into general solution to ODE

$$y = c_1 \cos(x) + c_2 \sin(x) + x^2 \sin(x) + \cos(x) x - \sin(x)$$

☐ Check validity of solution $y = c_1 \cos(x) + c_2 \sin(x) + x^2 \sin(x) + \cos(x) x - \sin(x)$

- ◦ Use initial condition $y(0) = 0$

$$0 = c_1$$

- ◦ Compute derivative of the solution

$$y' = -c_1 \sin(x) + c_2 \cos(x) + \sin(x) x + x^2 \cos(x)$$

- ◦ Use the initial condition $y'\Big|_{\{x=0\}} = 1$

$$1 = c_2$$

- ◦ Solve for c_1 and c_2

$$\{c_1 = 0, c_2 = 1\}$$

- ◦ Substitute constant values into general solution and simplify

$$y = x(\sin(x) x + \cos(x))$$

- Solution to the IVP

$$y = x(\sin(x) x + \cos(x))$$

Problem number: 600.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' - 4y' + 5y = 2\,\mathrm{e}^{x} x^{2}}$$

With initial conditions

$$[y(0) = 2, y'(0) = 3]$$

18.11.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -4 \\ q(x) &= 5 \\ F &= 2\,\mathrm{e}^{x} x^{2} \end{aligned}$$

Hence the ode is

$$y'' - 4y' + 5y = 2\,\mathrm{e}^{x}x^{2}$$

The domain of $p(x) = -4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 5$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 2\,\mathrm{e}^{x}x^{2}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

18.11.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 5, f(x) = 2\,\mathrm{e}^{x}x^{2}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 4\lambda\,\mathrm{e}^{\lambda x} + 5\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-4^2 - (4)(1)(5)} \\ &= 2 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 2 + i \\ \lambda_2 &= 2 - i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2 + i \\ \lambda_2 &= 2 - i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 2$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{2x}(c_1 \cos(x) + c_2 \sin(x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2\, e^x x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^{x}, e^{x}x^{2}, e^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{2x}\cos(x), e^{2x}\sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,e^{x} + A_2 e^{x} x^{2} + A_3 e^{x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 e^{x} + 2A_1 x\,e^{x} + 2A_2 e^{x} x^{2} - 4A_2 e^{x} x + 2A_2 e^{x} + 2A_3 e^{x} = 2\,e^{x} x^{2}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2, A_2 = 1, A_3 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2x\,e^{x} + e^{x} x^{2} + e^{x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{2x}(c_1\cos(x) + c_2\sin(x))\right) + \left(2x\,e^{x} + e^{x} x^{2} + e^{x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{2x}(c_1\cos(x) + c_2\sin(x)) + 2x\,e^{x} + e^{x} x^{2} + e^{x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = c_1 + 1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2\,\mathrm{e}^{2x}(c_1 \cos(x) + c_2 \sin(x)) + \mathrm{e}^{2x}(-c_1 \sin(x) + c_2 \cos(x)) + 4x\,\mathrm{e}^{x} + 3\,\mathrm{e}^{x} + \mathrm{e}^{x} x^2$$

substituting $y' = 3$ and $x = 0$ in the above gives

$$3 = 2c_1 + c_2 + 3 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = -2$$

Substituting these values back in above solution results in

$$y = \mathrm{e}^{x} x^2 + 2x\,\mathrm{e}^{x} + \mathrm{e}^{2x} \cos(x) - 2\,\mathrm{e}^{2x} \sin(x) + \mathrm{e}^{x}$$

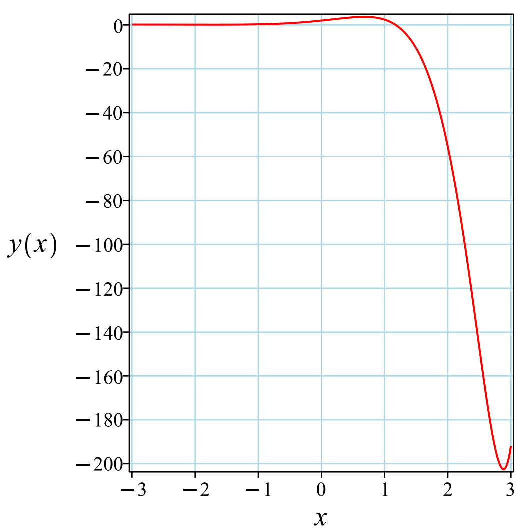
Which simplifies to

$$y = (\cos(x) - 2\sin(x))\,\mathrm{e}^{2x} + \mathrm{e}^{x}(x+1)^2$$

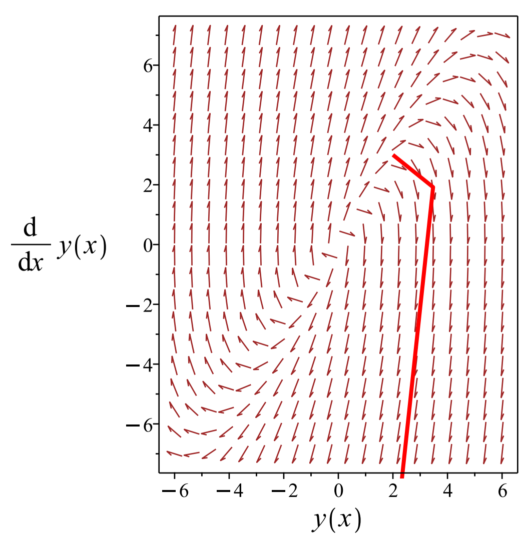
Summary

The solution(s) found are the following

$$y = (\cos(x) - 2\sin(x))\,\mathrm{e}^{2x} + \mathrm{e}^{x}(x+1)^2 \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = (\cos(x) - 2\sin(x))\,e^{2x} + e^{x}(x+1)^{2}$$

Verified OK.

18.11.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 582: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx} \\
&= z_1 e^{2x} \\
&= z_1 \left(\mathrm{e}^{2x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{2x} \cos(x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{4x}}{(y_1)^2}\,dx \\
&= y_1(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{2x} \cos(x)\right) + c_2 \left(\mathrm{e}^{2x} \cos(x)(\tan(x))\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 4y' + 5y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \cos(x)\, e^{2x} c_1 + e^{2x} \sin(x)\, c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2\, e^{x} x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\, e^{x}, e^{x} x^2, e^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{2x} \cos(x)\, , e^{2x} \sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\, e^{x} + A_2 e^{x} x^2 + A_3 e^{x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 e^{x} + 2A_1 x\, e^{x} + 2A_2 e^{x} x^2 - 4A_2 e^{x} x + 2A_2 e^{x} + 2A_3 e^{x} = 2\, e^{x} x^2$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2, A_2 = 1, A_3 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2x\, e^{x} + e^{x} x^2 + e^{x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\cos(x)\, e^{2x} c_1 + e^{2x} \sin(x)\, c_2\right) + \left(2x\, e^{x} + e^{x} x^2 + e^{x}\right) \end{aligned}$$

Which simplifies to

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x)) + 2x e^x + e^x x^2 + e^x$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x)) + 2x e^x + e^x x^2 + e^x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$2 = c_1 + 1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2 e^{2x}(c_1 \cos(x) + c_2 \sin(x)) + e^{2x}(-c_1 \sin(x) + c_2 \cos(x)) + 4x e^x + 3 e^x + e^x x^2$$

substituting $y' = 3$ and $x = 0$ in the above gives

$$3 = 2c_1 + c_2 + 3 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = -2$$

Substituting these values back in above solution results in

$$y = e^x x^2 + 2x e^x + e^{2x} \cos(x) - 2 e^{2x} \sin(x) + e^x$$

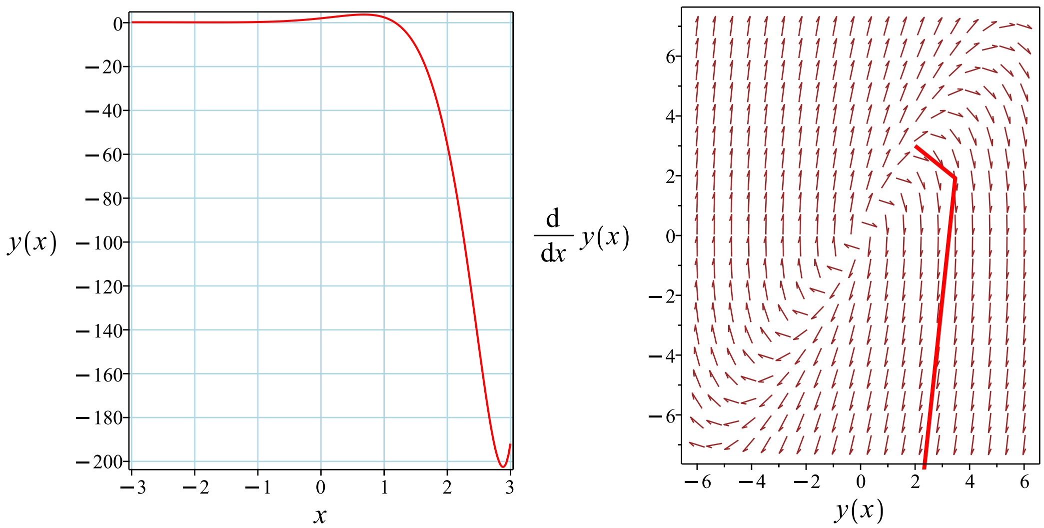
Which simplifies to

$$y = (\cos(x) - 2\sin(x)) e^{2x} + e^x (x+1)^2$$

Summary

The solution(s) found are the following

$$y = (\cos(x) - 2\sin(x)) e^{2x} + e^x (x+1)^2 \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = (\cos(x) - 2\sin(x))\,e^{2x} + e^{x}(x+1)^2$$

Verified OK.

18.11.4 Maple step by step solution

Let's solve

$$\left[y'' - 4y' + 5y = 2\,e^{x}x^2, y(0) = 2, y'\Big|_{\{x=0\}} = 3\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 4r + 5 = 0$

- Use quadratic formula to solve for r

  $r = \frac{4 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (2 - I, 2 + I)$

- 1st solution of the homogeneous ODE

$y_1(x) = e^{2x} \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{2x} \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \cos(x) e^{2x} c_1 + e^{2x} \sin(x) c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 2 e^x x^2\right]$

  ◦ Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{2x} \cos(x) & e^{2x} \sin(x) \\ 2 e^{2x} \cos(x) - e^{2x} \sin(x) & 2 e^{2x} \sin(x) + e^{2x} \cos(x) \end{bmatrix}$

  ◦ Compute Wronskian

    $W(y_1(x), y_2(x)) = e^{4x}$

  ◦ Substitute functions into equation for $y_p(x)$

    $y_p(x) = -2 e^{2x} \left(\cos(x) \left(\int x^2 \sin(x) e^{-x} dx\right) - \sin(x) \left(\int x^2 e^{-x} \cos(x) dx\right)\right)$

  ◦ Compute integrals

    $y_p(x) = e^x (x+1)^2$

- Substitute particular solution into general solution to ODE

  $y = \cos(x) e^{2x} c_1 + e^{2x} \sin(x) c_2 + e^x (x+1)^2$

☐ Check validity of solution $y = \cos(x) e^{2x} c_1 + e^{2x} \sin(x) c_2 + e^x (x+1)^2$

  ◦ Use initial condition $y(0) = 2$

    $2 = c_1 + 1$

  ◦ Compute derivative of the solution

    $y' = -\sin(x) e^{2x} c_1 + 2\cos(x) e^{2x} c_1 + 2 e^{2x} \sin(x) c_2 + e^{2x} \cos(x) c_2 + e^x (x+1)^2 + 2 e^x (x+1)$

  ◦ Use the initial condition $y'\Big|_{\{x=0\}} = 3$

    $3 = 2c_1 + c_2 + 3$

- Solve for c_1 and c_2

  $\{c_1 = 1, c_2 = -2\}$

- Substitute constant values into general solution and simplify

  $y = (\cos(x) - 2\sin(x))\,e^{2x} + e^{x}(x+1)^2$

- Solution to the IVP

  $y = (\cos(x) - 2\sin(x))\,e^{2x} + e^{x}(x+1)^2$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 6y' + 9y = 16\,\mathrm{e}^{-x} + 9x - 6}$$

With initial conditions

$$[y(0) = 1, y'(0) = 1]$$

18.12.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -6 \\ q(x) &= 9 \\ F &= 16\,e^{-x} + 9x - 6 \end{aligned}$$

Hence the ode is

$$y'' - 6y' + 9y = 16\,e^{-x} + 9x - 6$$

The domain of $p(x) = -6$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 9$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 16\,e^{-x} + 9x - 6$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

18.12.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -6, C = 9, f(x) = 16\,e^{-x} + 9x - 6$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 6y' + 9y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -6, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 6\lambda\, e^{\lambda x} + 9\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 6\lambda + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -6, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{6}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{(-6)^2 - (4)\,(1)\,(9)}\\ &= 3\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -3$. Therefore the solution is

$$y = c_1 e^{3x} + c_2 e^{3x} x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{3x} + c_2 x\, e^{3x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$16\, e^{-x} + 9x - 6$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-x}\}, \{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{3x} x, e^{3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{-x} + A_2 + A_3 x$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$16A_1 e^{-x} - 6A_3 + 9A_2 + 9A_3 x = 16\,e^{-x} + 9x - 6$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = 0, A_3 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = e^{-x} + x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{3x} + c_2 x\, e^{3x}\right) + \left(e^{-x} + x\right) \end{aligned}$$

Which simplifies to

$$y = e^{3x}(c_2 x + c_1) + e^{-x} + x$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{3x}(c_2 x + c_1) + e^{-x} + x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 + 1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 3\,e^{3x}(c_2x + c_1) + c_2e^{3x} - e^{-x} + 1$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = 3c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 1$$

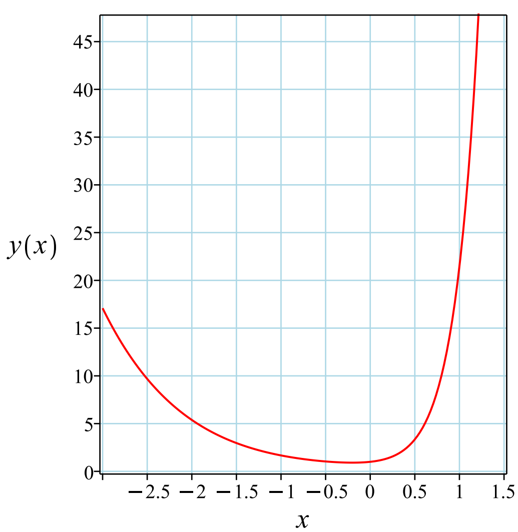
Substituting these values back in above solution results in

$$y = e^{3x}x + e^{-x} + x$$

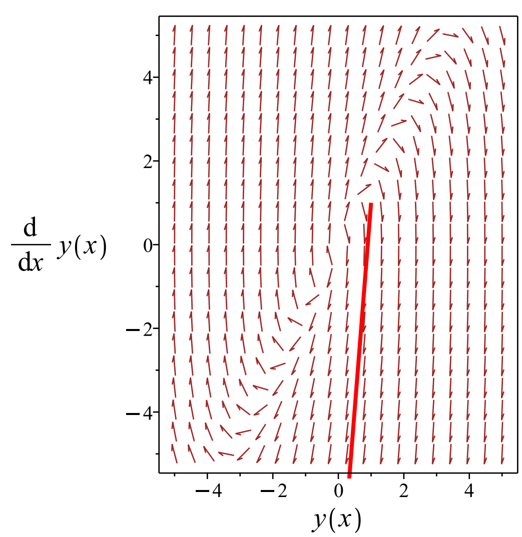
Summary

The solution(s) found are the following

$$y = e^{3x}x + e^{-x} + x \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^{3x}x + e^{-x} + x$$

Verified OK.

18.12.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -6$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int -6\, dx} \\ &= \mathrm{e}^{-3x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= \mathrm{e}^{-3x}\left(16\,\mathrm{e}^{-x} + 9x - 6\right) \\ \left(\mathrm{e}^{-3x} y\right)'' &= \mathrm{e}^{-3x}\left(16\,\mathrm{e}^{-x} + 9x - 6\right) \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{-3x} y\right)' = -4\,\mathrm{e}^{-4x} + \mathrm{e}^{-3x} - 3x\,\mathrm{e}^{-3x} + c_1$$

Integrating again gives

$$\left(\mathrm{e}^{-3x} y\right) = c_1 x + x\,\mathrm{e}^{-3x} + \mathrm{e}^{-4x} + c_2$$

Hence the solution is

$$y = \frac{c_1 x + x\,\mathrm{e}^{-3x} + \mathrm{e}^{-4x} + c_2}{\mathrm{e}^{-3x}}$$

Or

$$y = c_1 x\,\mathrm{e}^{3x} + c_2 \mathrm{e}^{3x} + x + \mathrm{e}^{-x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 x\,\mathrm{e}^{3x} + c_2 \mathrm{e}^{3x} + x + \mathrm{e}^{-x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = 1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 e^{3x} + 3c_1 x\, e^{3x} + 3c_2 e^{3x} + 1 - e^{-x}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = c_1 + 3c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

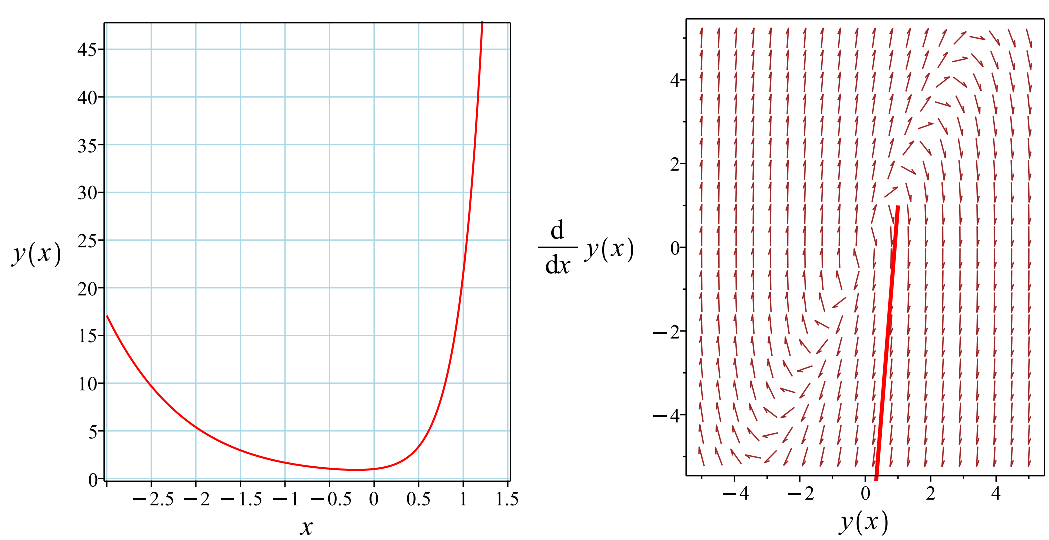
$$c_1 = 1$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = e^{3x} x + e^{-x} + x$$

Summary
The solution(s) found are the following

$$y = e^{3x} x + e^{-x} + x \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$
y = e^{3x}x + e^{-x} + x
$$

Verified OK.

18.12.4 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{align*}
y'' - 6y' + 9y &= 0 \tag{1} \\
Ay'' + By' + Cy &= 0 \tag{2}
\end{align*}
$$

Comparing (1) and (2) shows that

$$
\begin{align*}
A &= 1 \\
B &= -6 \tag{3} \\
C &= 9
\end{align*}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \tag{4}
$$

Where r is given by

$$
\begin{align*}
r &= \frac{s}{t} \tag{5} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{align*}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{0}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{align*}
s &= 0 \\
t &= 1
\end{align*}
$$

Therefore eq. (4) becomes

$$
z''(x) = 0 \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 584: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-6}{1}\,dx} \\
&= z_1 e^{3x} \\
&= z_1\left(\mathrm{e}^{3x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{3x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-6}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{6x}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{3x}\right) + c_2\left(\mathrm{e}^{3x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 6y' + 9y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 e^{3x} + c_2 x \,e^{3x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
16 \,e^{-x} + 9x - 6
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{e^{-x}\}, \{1, x\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{e^{3x} x, e^{3x}\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 e^{-x} + A_2 + A_3 x
$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
16 A_1 e^{-x} - 6 A_3 + 9 A_2 + 9 A_3 x = 16 \,e^{-x} + 9x - 6
$$

Solving for the unknowns by comparing coefficients results in

$$
[A_1 = 1, A_2 = 0, A_3 = 1]
$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$
y_p = e^{-x} + x
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 e^{3x} + c_2 x \,e^{3x}\right) + \left(e^{-x} + x\right)
\end{aligned}
$$

Which simplifies to

$$y = e^{3x}(c_2 x + c_1) + e^{-x} + x$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{3x}(c_2 x + c_1) + e^{-x} + x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 + 1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 3\,e^{3x}(c_2 x + c_1) + c_2 e^{3x} - e^{-x} + 1$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = 3c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 1$$

Substituting these values back in above solution results in

$$y = e^{3x}x + e^{-x} + x$$

Summary

The solution(s) found are the following

$$y = e^{3x}x + e^{-x} + x \tag{1}$$

18.12.5 Maple step by step solution

Let's solve

$$\left[y'' - 6y' + 9y = 16\,e^{-x} + 9x - 6, y(0) = 1, y'\Big|_{\{x=0\}} = 1\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 6r + 9 = 0$

- Factor the characteristic polynomial

  $(r-3)^2 = 0$

- Root of the characteristic polynomial

  $r = 3$

- 1st solution of the homogeneous ODE

$y_1(x) = e^{3x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = e^{3x}x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{3x} + c_2 x\, e^{3x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 16\, e^{-x} + 9x - 6\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{3x} & e^{3x}x \\ 3\, e^{3x} & 3\, e^{3x}x + e^{3x} \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{6x}$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = e^{3x}\left(-\left(\int (16\, e^{-x} + 9x - 6)\, x\, e^{-3x}dx\right) + \left(\int e^{-3x}(16\, e^{-x} + 9x - 6)\, dx\right) x\right)$

- ○ Compute integrals

  $y_p(x) = e^{-x} + x$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{3x} + c_2 x\, e^{3x} + e^{-x} + x$

☐ Check validity of solution $y = c_1 e^{3x} + c_2 x e^{3x} + e^{-x} + x$

- ○ Use initial condition $y(0) = 1$

  $1 = c_1 + 1$

- ○ Compute derivative of the solution

  $y' = 3c_1 e^{3x} + c_2 e^{3x} + 3c_2 x\, e^{3x} - e^{-x} + 1$

- ○ Use the initial condition $y'\Big|_{\{x=0\}} = 1$

  $1 = 3c_1 + c_2$

- Solve for c_1 and c_2

  $\{c_1 = 0, c_2 = 1\}$
- Substitute constant values into general solution and simplify

  $y = e^{3x}x + e^{-x} + x$

- Solution to the IVP

  $y = e^{3x}x + e^{-x} + x$

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' - y' = -5\,\mathrm{e}^{-x}(\sin(x) + \cos(x))}$$

With initial conditions

$$[y(0) = -4, y'(0) = 5]$$

18.13.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -1 \\ q(x) &= 0 \\ F &= -5\,\mathrm{e}^{-x}(\sin(x) + \cos(x)) \end{aligned}$$

Hence the ode is

$$y'' - y' = -5\,\mathrm{e}^{-x}(\sin(x) + \cos(x))$$

The domain of $p(x) = -1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $F = -5\,\mathrm{e}^{-x}(\sin(x) + \cos(x))$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

18.13.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -1, C = 0, f(x) = (-5\sin(x) - 5\cos(x))\,\mathrm{e}^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -1, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - \lambda \,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -1, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{1}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-1^2 - (4)\,(1)\,(0)}\\ &= \frac{1}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\lambda_1 = \frac{1}{2} + \frac{1}{2}$$

$$\lambda_2 = \frac{1}{2} - \frac{1}{2}$$

Which simplifies to

$$\lambda_1 = 1$$

$$\lambda_2 = 0$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$

$$y = c_1 e^{(1)x} + c_2 e^{(0)x}$$

Or

$$y = \mathrm{e}^{x} c_1 + c_2$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{x} c_1 + c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$-5\,e^{-x}(\sin(x)+\cos(x))$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-x}\cos(x), e^{-x}\sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{-x}\cos(x) + A_2 e^{-x}\sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&3A_1 e^{-x}\sin(x) - 3A_2 e^{-x}\cos(x) + A_1 e^{-x}\cos(x) + A_2 e^{-x}\sin(x)\\&= (-5\sin(x) - 5\cos(x))\,e^{-x}\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2, A_2 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2\,e^{-x}\cos(x) + e^{-x}\sin(x)$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\&= (e^{x}c_1 + c_2) + \left(-2\,e^{-x}\cos(x) + e^{-x}\sin(x)\right)\end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{x} c_1 + c_2 - 2\,e^{-x} \cos(x) + e^{-x} \sin(x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -4$ and $x = 0$ in the above gives

$$-4 = c_1 + c_2 - 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = e^{x} c_1 + 3\,e^{-x} \cos(x) + e^{-x} \sin(x)$$

substituting $y' = 5$ and $x = 0$ in the above gives

$$5 = c_1 + 3 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 2 \\ c_2 &= -4 \end{aligned}$$

Substituting these values back in above solution results in

$$y = e^{-x} \sin(x) - 2\,e^{-x} \cos(x) + 2\,e^{x} - 4$$

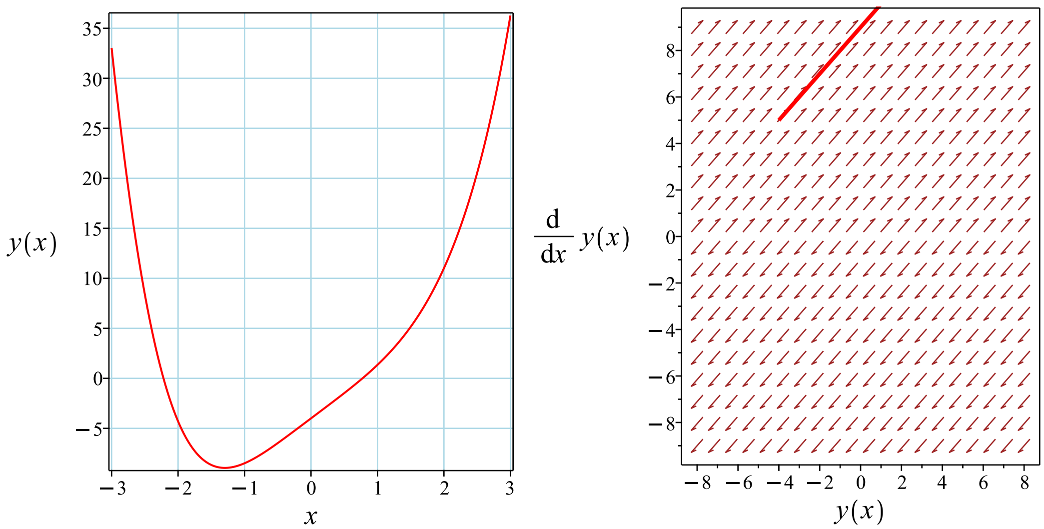
Which simplifies to

$$y = -4 + (\sin(x) - 2\cos(x))\,e^{-x} + 2\,e^{x}$$

<ins>Summary</ins>

The solution(s) found are the following

$$y = -4 + (\sin(x) - 2\cos(x))\,e^{-x} + 2\,e^{x} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = -4 + (\sin(x) - 2\cos(x))\,e^{-x} + 2\,e^{x}$$

Verified OK.

18.13.3 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - y')\,dx = \int (-5\sin(x) - 5\cos(x))\,e^{-x} dx$$

$$-y + y' = 5\,e^{-x}\cos(x) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -1$$
$$q(x) = 5\,e^{-x}\cos(x) + c_1$$

Hence the ode is

$$-y + y' = 5\,e^{-x}\cos(x) + c_1$$

The integrating factor μ is

$$\mu = e^{\int (-1)dx}$$
$$= e^{-x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(5\,e^{-x}\cos(x) + c_1\right)$$
$$\frac{d}{dx}\left(e^{-x} y\right) = \left(e^{-x}\right)\left(5\,e^{-x}\cos(x) + c_1\right)$$
$$d\left(e^{-x} y\right) = \left(\left(5\,e^{-x}\cos(x) + c_1\right)e^{-x}\right)\,dx$$

Integrating gives

$$e^{-x} y = \int \left(5\,e^{-x}\cos(x) + c_1\right)e^{-x}\,dx$$
$$e^{-x} y = -2\,e^{-2x}\cos(x) + e^{-2x}\sin(x) - c_1 e^{-x} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{-x}$ results in

$$y = e^{x}\left(-2\,e^{-2x}\cos(x) + e^{-2x}\sin(x) - c_1 e^{-x}\right) + c_2 e^{x}$$

which simplifies to

$$y = (\sin(x) - 2\cos(x))\,e^{-x} - c_1 + c_2 e^{x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = (\sin(x) - 2\cos(x))\,e^{-x} - c_1 + c_2 e^{x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -4$ and $x = 0$ in the above gives

$$-4 = c_2 - 2 - c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = (\cos(x) + 2\sin(x))\,e^{-x} - (\sin(x) - 2\cos(x))\,e^{-x} + c_2 e^{x}$$

substituting $y' = 5$ and $x = 0$ in the above gives

$$5 = c_2 + 3 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 4$$
$$c_2 = 2$$

Substituting these values back in above solution results in

$$y = e^{-x} \sin(x) - 2e^{-x} \cos(x) + 2e^{x} - 4$$

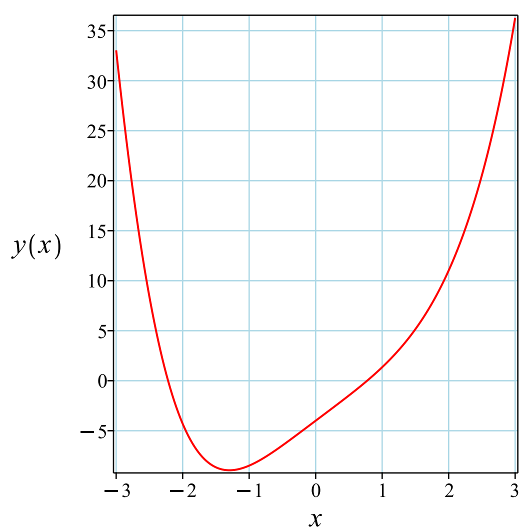
Which simplifies to

$$y = -4 + (\sin(x) - 2\cos(x)) e^{-x} + 2e^{x}$$

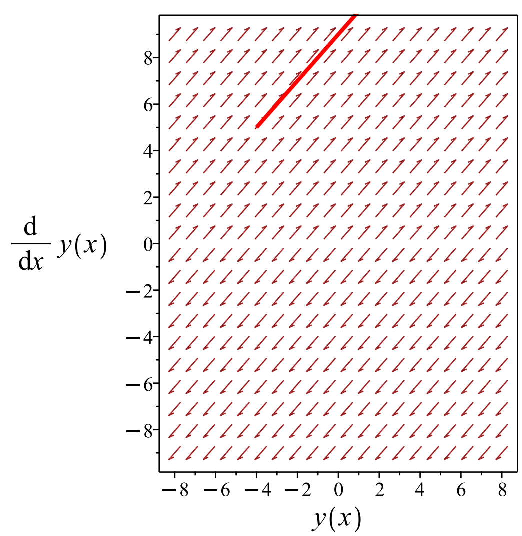
<u>Summary</u>

The solution(s) found are the following

$$y = -4 + (\sin(x) - 2\cos(x)) e^{-x} + 2e^{x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = -4 + (\sin(x) - 2\cos(x)) e^{-x} + 2e^{x}$$

Verified OK.

18.13.4 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - p(x) - (-5\sin(x) - 5\cos(x))\,\mathrm{e}^{-x} = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int (-1)dx} \\ &= \mathrm{e}^{-x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu p) &= (\mu)\left(-5\,\mathrm{e}^{-x}(\sin(x) + \cos(x))\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{-x}p\right) &= \left(\mathrm{e}^{-x}\right)\left(-5\,\mathrm{e}^{-x}(\sin(x) + \cos(x))\right) \\ \mathrm{d}\left(\mathrm{e}^{-x}p\right) &= \left(-5(\sin(x) + \cos(x))\,\mathrm{e}^{-2x}\right)\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\mathrm{e}^{-x}p &= \int -5(\sin(x) + \cos(x))\,\mathrm{e}^{-2x}\,\mathrm{d}x \\ \mathrm{e}^{-x}p &= 3\,\mathrm{e}^{-2x}\cos(x) + \mathrm{e}^{-2x}\sin(x) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-x}$ results in

$$p(x) = \mathrm{e}^{x}\left(3\,\mathrm{e}^{-2x}\cos(x) + \mathrm{e}^{-2x}\sin(x)\right) + \mathrm{e}^{x}c_1$$

which simplifies to

$$p(x) = \mathrm{e}^{-x}\left(\mathrm{e}^{2x}c_1 + \sin(x) + 3\cos(x)\right)$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $p = 5$ in the above solution gives an equation to solve for the constant of integration.

$$5 = c_1 + 3$$

$$c_1 = 2$$

Substituting c_1 found above in the general solution gives

$$p(x) = e^{-x}\left(\sin (x) + 3\cos (x) + 2\,e^{2x}\right)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = e^{-x}\left(\sin (x) + 3\cos (x) + 2\,e^{2x}\right)$$

Integrating both sides gives

$$\begin{aligned} y &= \int e^{-x}\left(\sin (x) + 3\cos (x) + 2\,e^{2x}\right) dx \\ &= e^{-x}\sin (x) - 2\,e^{-x}\cos (x) + 2\,e^{x} + c_2 \end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $y = -4$ in the above solution gives an equation to solve for the constant of integration.

$$-4 = c_2$$

$$c_2 = -4$$

Substituting c_2 found above in the general solution gives

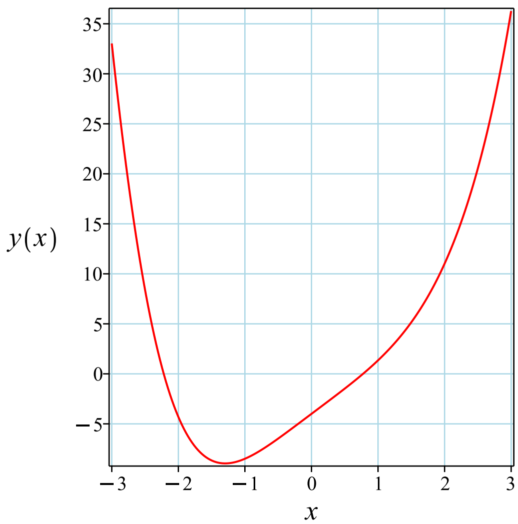
$$y = e^{-x}\sin (x) - 2\,e^{-x}\cos (x) + 2\,e^{x} - 4$$

Initial conditions are used to solve for the constants of integration.

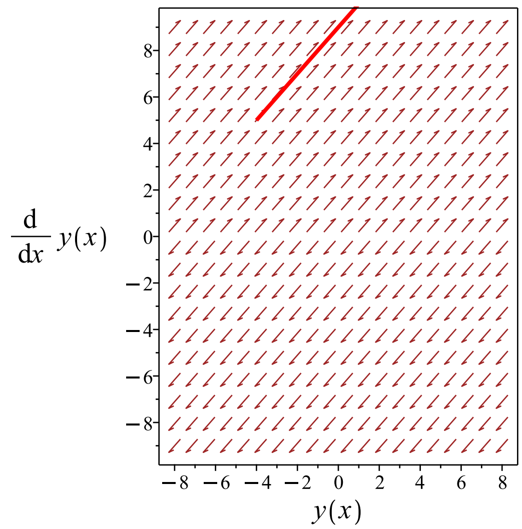
Summary

The solution(s) found are the following

$$y = e^{-x}\sin (x) - 2\,e^{-x}\cos (x) + 2\,e^{x} - 4 \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^{-x} \sin(x) - 2e^{-x} \cos(x) + 2e^{x} - 4$$

Verified OK.

18.13.5 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' - y' = (-5\sin(x) - 5\cos(x))\, e^{-x}$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - y')\, dx = \int (-5\sin(x) - 5\cos(x))\, e^{-x} dx$$

$$-y + y' = 5e^{-x} \cos(x) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -1$$
$$q(x) = 5e^{-x} \cos(x) + c_1$$

Hence the ode is

$$-y+y'=5\,\mathrm{e}^{-x}\cos\left(x\right)+c_1$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int(-1)dx}\\ &= \mathrm{e}^{-x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(5\,\mathrm{e}^{-x}\cos\left(x\right)+c_1\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{-x}y\right) &= \left(\mathrm{e}^{-x}\right)\left(5\,\mathrm{e}^{-x}\cos\left(x\right)+c_1\right)\\ \mathrm{d}\left(\mathrm{e}^{-x}y\right) &= \left(\left(5\,\mathrm{e}^{-x}\cos\left(x\right)+c_1\right)\mathrm{e}^{-x}\right)\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\mathrm{e}^{-x}y &= \int\left(5\,\mathrm{e}^{-x}\cos\left(x\right)+c_1\right)\mathrm{e}^{-x}\,\mathrm{d}x\\ \mathrm{e}^{-x}y &= -2\,\mathrm{e}^{-2x}\cos\left(x\right)+\mathrm{e}^{-2x}\sin\left(x\right)-c_1\mathrm{e}^{-x}+c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu=\mathrm{e}^{-x}$ results in

$$y=\mathrm{e}^{x}\left(-2\,\mathrm{e}^{-2x}\cos\left(x\right)+\mathrm{e}^{-2x}\sin\left(x\right)-c_1\mathrm{e}^{-x}\right)+c_2\mathrm{e}^{x}$$

which simplifies to

$$y=\left(\sin\left(x\right)-2\cos\left(x\right)\right)\mathrm{e}^{-x}-c_1+c_2\mathrm{e}^{x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y=\left(\sin\left(x\right)-2\cos\left(x\right)\right)\mathrm{e}^{-x}-c_1+c_2\mathrm{e}^{x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y=-4$ and $x=0$ in the above gives

$$-4=c_2-2-c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y'=\left(\cos\left(x\right)+2\sin\left(x\right)\right)\mathrm{e}^{-x}-\left(\sin\left(x\right)-2\cos\left(x\right)\right)\mathrm{e}^{-x}+c_2\mathrm{e}^{x}$$

substituting $y' = 5$ and $x = 0$ in the above gives

$$5 = c_2 + 3 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 4$$
$$c_2 = 2$$

Substituting these values back in above solution results in

$$y = e^{-x} \sin(x) - 2 e^{-x} \cos(x) + 2 e^{x} - 4$$

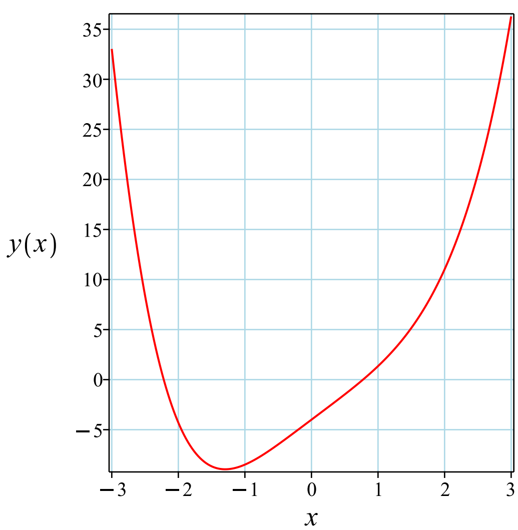
Which simplifies to

$$y = -4 + (\sin(x) - 2\cos(x)) e^{-x} + 2 e^{x}$$

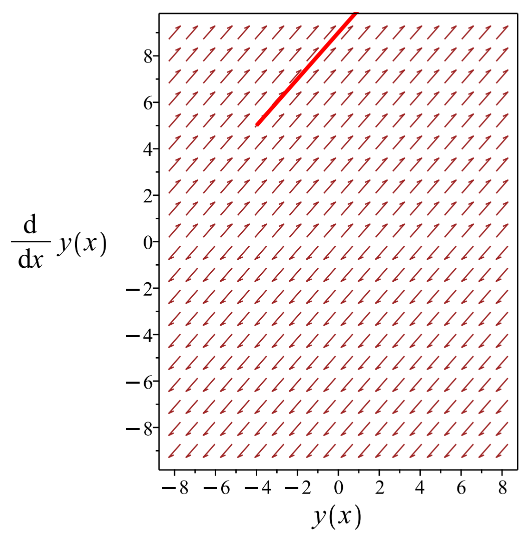
Summary

The solution(s) found are the following

$$y = -4 + (\sin(x) - 2\cos(x)) e^{-x} + 2 e^{x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -4 + (\sin(x) - 2\cos(x)) e^{-x} + 2 e^{x}$$

Verified OK.

18.13.6 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -1 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 586: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-\frac{x}{2}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-1}{1}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{\frac{x}{2}} \\
&= z_1 \left(\mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = 1
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{1}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{x}}{\left(y_1\right)^2}\, dx \\
&= y_1(\mathrm{e}^{x})
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2(1(\mathrm{e}^{x}))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - y' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 + c_2 \mathrm{e}^{x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$-5\,e^{-x}(\sin(x)+\cos(x))$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-x}\cos(x)\,, e^{-x}\sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{-x}\cos(x) + A_2 e^{-x}\sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&3A_1 e^{-x}\sin(x) - 3A_2 e^{-x}\cos(x) + A_1 e^{-x}\cos(x) + A_2 e^{-x}\sin(x)\\&= (-5\sin(x) - 5\cos(x))\,e^{-x}\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2, A_2 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2\,e^{-x}\cos(x) + e^{-x}\sin(x)$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\&= (c_1 + c_2 e^{x}) + \left(-2\,e^{-x}\cos(x) + e^{-x}\sin(x)\right)\end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 + c_2 e^x - 2\,e^{-x} \cos(x) + e^{-x} \sin(x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -4$ and $x = 0$ in the above gives

$$-4 = c_1 + c_2 - 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_2 e^x + 3\,e^{-x} \cos(x) + e^{-x} \sin(x)$$

substituting $y' = 5$ and $x = 0$ in the above gives

$$5 = c_2 + 3 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= -4 \\ c_2 &= 2 \end{aligned}$$

Substituting these values back in above solution results in

$$y = e^{-x} \sin(x) - 2\,e^{-x} \cos(x) + 2\,e^x - 4$$

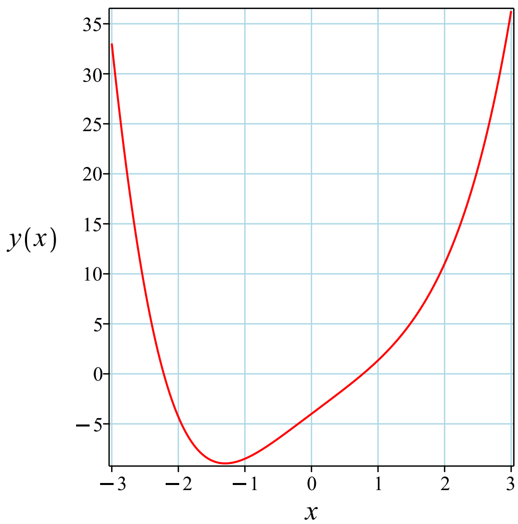
Which simplifies to

$$y = -4 + (\sin(x) - 2\cos(x))\,e^{-x} + 2\,e^x$$

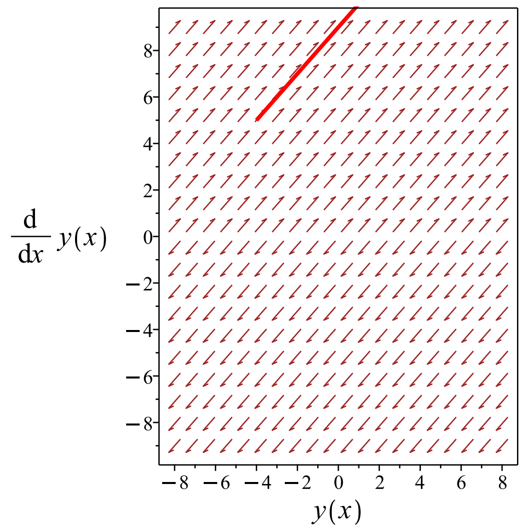
Summary

The solution(s) found are the following

$$y = -4 + (\sin(x) - 2\cos(x))\,e^{-x} + 2\,e^x \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = -4 + (\sin(x) - 2\cos(x))\,e^{-x} + 2\,e^{x}$$

Verified OK.

18.13.7 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= -1 \\ r(x) &= 0 \\ s(x) &= (-5\sin(x) - 5\cos(x))\,e^{-x} \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0-(0)+(0)=0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y'+\left(q(x)-p'(x)\right)y\right)'=s(x)$$

Integrating gives

$$p(x)\,y'+\left(q(x)-p'(x)\right)y=\int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$-y+y'=\int \left(-5\sin\left(x\right)-5\cos\left(x\right)\right){\mathrm e}^{-x}\,dx$$

We now have a first order ode to solve which is

$$-y+y'=5\,{\mathrm e}^{-x}\cos\left(x\right)+c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$\begin{aligned}p(x)&=-1\\ q(x)&=5\,{\mathrm e}^{-x}\cos\left(x\right)+c_1\end{aligned}$$

Hence the ode is

$$-y+y'=5\,{\mathrm e}^{-x}\cos\left(x\right)+c_1$$

The integrating factor μ is

$$\begin{aligned}\mu&={\mathrm e}^{\int(-1)dx}\\ &={\mathrm e}^{-x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm d}{\mathrm d x}(\mu y)&=(\mu)\left(5\,{\mathrm e}^{-x}\cos\left(x\right)+c_1\right)\\ \frac{\mathrm d}{\mathrm d x}\left({\mathrm e}^{-x}y\right)&=\left({\mathrm e}^{-x}\right)\left(5\,{\mathrm e}^{-x}\cos\left(x\right)+c_1\right)\\ \mathrm d\left({\mathrm e}^{-x}y\right)&=\left(\left(5\,{\mathrm e}^{-x}\cos\left(x\right)+c_1\right){\mathrm e}^{-x}\right)\,\mathrm d x\end{aligned}$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{-x} y &= \int \left(5\,\mathrm{e}^{-x} \cos\left(x\right)+c_1\right) \mathrm{e}^{-x}\,\mathrm{d}x \\
\mathrm{e}^{-x} y &= -2\,\mathrm{e}^{-2x} \cos\left(x\right)+\mathrm{e}^{-2x} \sin\left(x\right)-c_1 \mathrm{e}^{-x}+c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-x}$ results in

$$
y = \mathrm{e}^{x} \left(-2\,\mathrm{e}^{-2x} \cos\left(x\right)+\mathrm{e}^{-2x} \sin\left(x\right)-c_1 \mathrm{e}^{-x}\right)+c_2 \mathrm{e}^{x}
$$

which simplifies to

$$
y = \left(\sin\left(x\right)-2\cos\left(x\right)\right) \mathrm{e}^{-x}-c_1+c_2 \mathrm{e}^{x}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \left(\sin\left(x\right)-2\cos\left(x\right)\right) \mathrm{e}^{-x}-c_1+c_2 \mathrm{e}^{x} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -4$ and $x = 0$ in the above gives

$$
-4 = c_2-2-c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = \left(\cos\left(x\right)+2\sin\left(x\right)\right) \mathrm{e}^{-x}-\left(\sin\left(x\right)-2\cos\left(x\right)\right) \mathrm{e}^{-x}+c_2 \mathrm{e}^{x}
$$

substituting $y' = 5$ and $x = 0$ in the above gives

$$
5 = c_2+3 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 4 \\
c_2 &= 2
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \mathrm{e}^{-x} \sin\left(x\right)-2\,\mathrm{e}^{-x} \cos\left(x\right)+2\,\mathrm{e}^{x}-4
$$

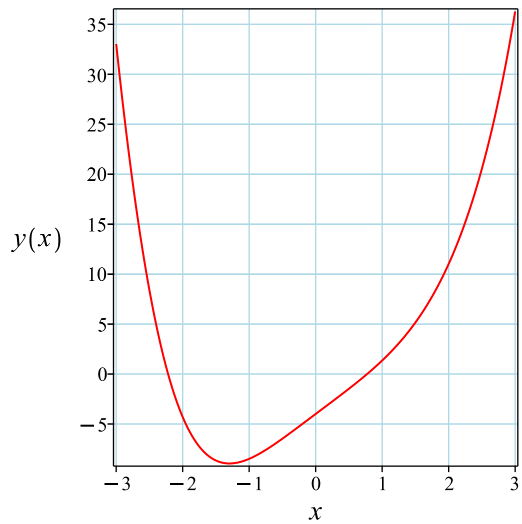
Which simplifies to

$$
y = -4+\left(\sin\left(x\right)-2\cos\left(x\right)\right) \mathrm{e}^{-x}+2\,\mathrm{e}^{x}
$$

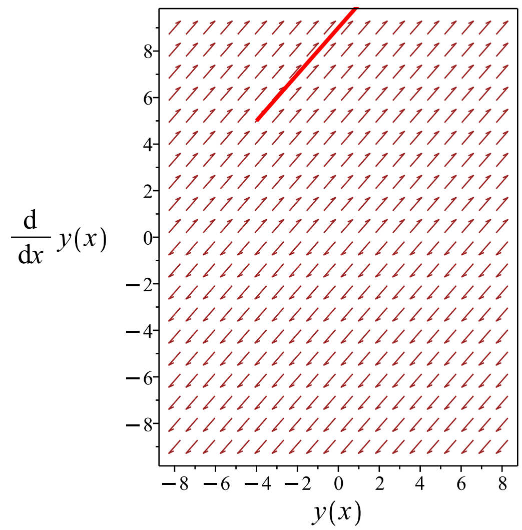
Summary

The solution(s) found are the following

$$y = -4 + (\sin(x) - 2\cos(x))\,e^{-x} + 2\,e^{x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -4 + (\sin(x) - 2\cos(x))\,e^{-x} + 2\,e^{x}$$

Verified OK.

18.13.8 Maple step by step solution

Let's solve

$$\left[y'' - y' = (-5\sin(x) - 5\cos(x))\,e^{-x}, y(0) = -4, y'\Big|_{\{x=0\}} = 5\right]$$

- Highest derivative means the order of the ODE is 2

$$y''$$

- Isolate 2nd derivative

$$y'' = -5\,e^{-x}\sin(x) - 5\,e^{-x}\cos(x) + y'$$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$$y'' - y' = -5\,e^{-x}(\sin(x) + \cos(x))$$

- Characteristic polynomial of homogeneous ODE

  $r^2 - r = 0$
- Factor the characteristic polynomial

  $r(r-1) = 0$
- Roots of the characteristic polynomial

  $r = (0, 1)$
- 1st solution of the homogeneous ODE

  $y_1(x) = 1$
- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^x$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 \mathrm{e}^x + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = -5\,\mathrm{e}^{-x}(\sin(x) + \cos(x\right.$
  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & \mathrm{e}^x \\ 0 & \mathrm{e}^x \end{bmatrix}$
  - Compute Wronskian

    $W(y_1(x), y_2(x)) = \mathrm{e}^x$
  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = 5\left(\int \mathrm{e}^{-x}(\sin(x) + \cos(x))\, dx\right) - 5\,\mathrm{e}^x\left(\int (\sin(x) + \cos(x))\, \mathrm{e}^{-2x} dx\right)$
  - Compute integrals

    $y_p(x) = (\sin(x) - 2\cos(x))\, \mathrm{e}^{-x}$
- Substitute particular solution into general solution to ODE

  $y = c_1 + c_2 \mathrm{e}^x + (\sin(x) - 2\cos(x))\, \mathrm{e}^{-x}$

☐ Check validity of solution $y = c_1 + c_2 \mathrm{e}^x + (\sin(x) - 2\cos(x))\, \mathrm{e}^{-x}$

- Use initial condition $y(0) = -4$

  $-4 = c_1 + c_2 - 2$
- Compute derivative of the solution

  $y' = (\cos(x) + 2\sin(x))\,\mathrm{e}^{-x} - (\sin(x) - 2\cos(x))\,\mathrm{e}^{-x} + c_2\mathrm{e}^{x}$
- Use the initial condition $y'\big|_{\{x=0\}} = 5$

  $5 = c_2 + 3$
- Solve for c_1 and c_2

  $\{c_1 = -4, c_2 = 2\}$
- Substitute constant values into general solution and simplify

  $y = -4 + (\sin(x) - 2\cos(x))\,\mathrm{e}^{-x} + 2\,\mathrm{e}^{x}$

- Solution to the IVP

  $y = -4 + (\sin(x) - 2\cos(x))\,\mathrm{e}^{-x} + 2\,\mathrm{e}^{x}$

Problem number: 603.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 2y' + 2y = 4\,\mathrm{e}^{x} \cos(x)}$$

With initial conditions

$$[y(\pi) = \pi\,\mathrm{e}^{\pi}, y'(\pi) = \mathrm{e}^{\pi}]$$

18.14.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -2 \\ q(x) &= 2 \\ F &= 4\,\mathrm{e}^{x} \cos(x) \end{aligned}$$

Hence the ode is

$$y'' - 2y' + 2y = 4\,e^{x} \cos(x)$$

The domain of $p(x) = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = \pi$ is inside this domain. The domain of $q(x) = 2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = \pi$ is also inside this domain. The domain of $F = 4\,e^{x} \cos(x)$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = \pi$ is also inside this domain. Hence solution exists and is unique.

18.14.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 2, f(x) = 4\,e^{x} \cos(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda\,e^{\lambda x} + 2\,e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-2^2 - (4)(1)(2)} \\ &= 1 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 1 + i \\ \lambda_2 &= 1 - i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 + i \\ \lambda_2 &= 1 - i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 1$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^x(c_1 \cos(x) + c_2 \sin(x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^x(c_1 \cos(x) + c_2 \sin(x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4\,e^x \cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x \cos(x), e^x \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x \cos(x), e^x \sin(x)\}$$

Since $e^x \cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x e^x \cos(x), x e^x \sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x e^x \cos(x) + A_2 x e^x \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 e^x \sin(x) + 2A_2 e^x \cos(x) = 4 e^x \cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2x e^x \sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x (c_1 \cos(x) + c_2 \sin(x))) + (2x e^x \sin(x)) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^x (c_1 \cos(x) + c_2 \sin(x)) + 2x e^x \sin(x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \pi\,\mathrm{e}^{\pi}$ and $x = \pi$ in the above gives

$$\pi\,\mathrm{e}^{\pi} = -c_1 \mathrm{e}^{\pi} \tag{1A}$$

Taking derivative of the solution gives

$$y' = \mathrm{e}^{x}(c_1 \cos(x) + c_2 \sin(x)) + \mathrm{e}^{x}(-c_1 \sin(x) + c_2 \cos(x)) + 2\,\mathrm{e}^{x} \sin(x) + 2x\,\mathrm{e}^{x} \sin(x) + 2x\,\mathrm{e}^{x} \cos(x)$$

substituting $y' = \mathrm{e}^{\pi}$ and $x = \pi$ in the above gives

$$\mathrm{e}^{\pi} = (-c_1 - c_2 - 2\pi)\,\mathrm{e}^{\pi} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -\pi$$
$$c_2 = -\pi - 1$$

Substituting these values back in above solution results in

$$y = -\mathrm{e}^{x} \cos(x)\,\pi - \mathrm{e}^{x} \sin(x)\,\pi + 2x\,\mathrm{e}^{x} \sin(x) - \mathrm{e}^{x} \sin(x)$$

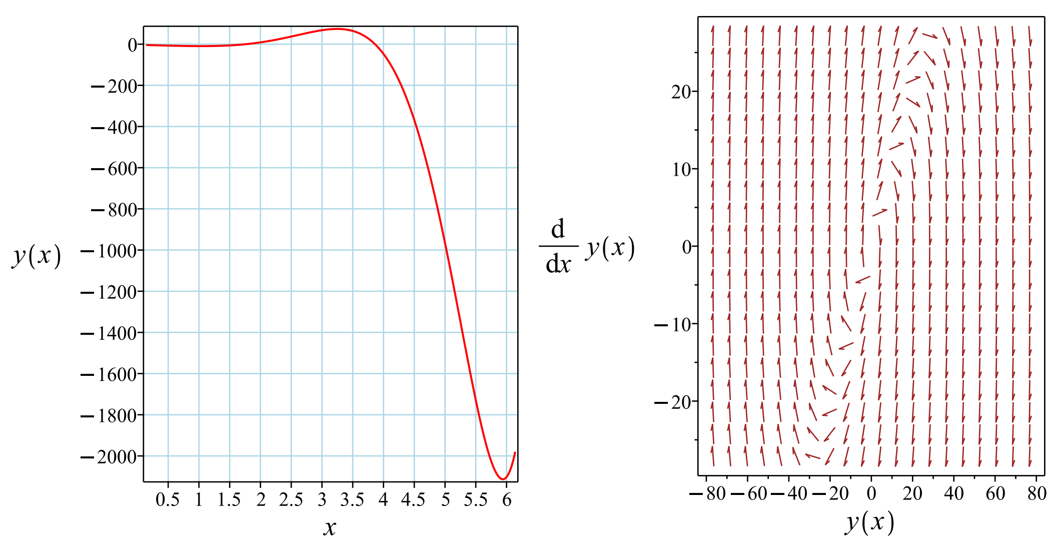
Which simplifies to

$$y = (2x - \pi - 1)\,\mathrm{e}^{x} \sin(x) - \mathrm{e}^{x} \cos(x)\,\pi$$

<u>Summary</u>

The solution(s) found are the following

$$y = (2x - \pi - 1)\,\mathrm{e}^{x} \sin(x) - \mathrm{e}^{x} \cos(x)\,\pi \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = (2x - \pi - 1)\,\mathrm{e}^{x} \sin(x) - \mathrm{e}^{x} \cos(x)\,\pi$$

Verified OK.

18.14.3 Solving using Kovacic algorithm

Writing the ode as

$$\begin{align*} y'' - 2y' + 2y &= 0 \tag{1} \\ Ay'' + By' + Cy &= 0 \tag{2} \end{align*}$$

Comparing (1) and (2) shows that

$$\begin{align*} A &= 1 \\ B &= -2 \tag{3} \\ C &= 2 \end{align*}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{align*} r &= \frac{s}{t} \tag{5} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{align*}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{align*} s &= -1 \\ t &= 1 \end{align*}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 588: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\
&= z_1 e^{x} \\
&= z_1(\mathrm{e}^{x})
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{x}\cos(x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\
&= y_1(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^{x}\cos(x)) + c_2(\mathrm{e}^{x}\cos(x)(\tan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^x \cos(x) + e^x \sin(x) c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4 e^x \cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x \cos(x), e^x \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x \cos(x), e^x \sin(x)\}$$

Since $e^x \cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x e^x \cos(x), x e^x \sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x e^x \cos(x) + A_2 x e^x \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 e^x \sin(x) + 2A_2 e^x \cos(x) = 4 e^x \cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2x e^x \sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 e^x \cos(x) + e^x \sin(x) c_2) + (2x e^x \sin(x)) \end{aligned}$$

Which simplifies to

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x)) + 2x\,e^{x} \sin(x)$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x)) + 2x\,e^{x} \sin(x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \pi\,e^{\pi}$ and $x = \pi$ in the above gives

$$\pi\,e^{\pi} = -c_1 e^{\pi} \tag{1A}$$

Taking derivative of the solution gives

$$y' = e^{x}(c_1 \cos(x) + c_2 \sin(x)) + e^{x}(-c_1 \sin(x) + c_2 \cos(x)) + 2\,e^{x} \sin(x) + 2x\,e^{x} \sin(x) + 2x\,e^{x} \cos(x)$$

substituting $y' = e^{\pi}$ and $x = \pi$ in the above gives

$$e^{\pi} = (-c_1 - c_2 - 2\pi)\,e^{\pi} \tag{2A}$$

Equations $\{1A,2A\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= -\pi \\ c_2 &= -\pi - 1 \end{aligned}$$

Substituting these values back in above solution results in

$$y = -e^{x} \cos(x)\,\pi - e^{x} \sin(x)\,\pi + 2x\,e^{x} \sin(x) - e^{x} \sin(x)$$

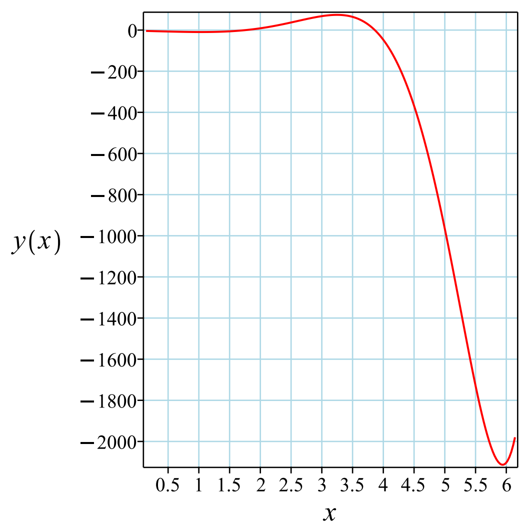
Which simplifies to

$$y = (2x - \pi - 1)\,e^{x} \sin(x) - e^{x} \cos(x)\,\pi$$

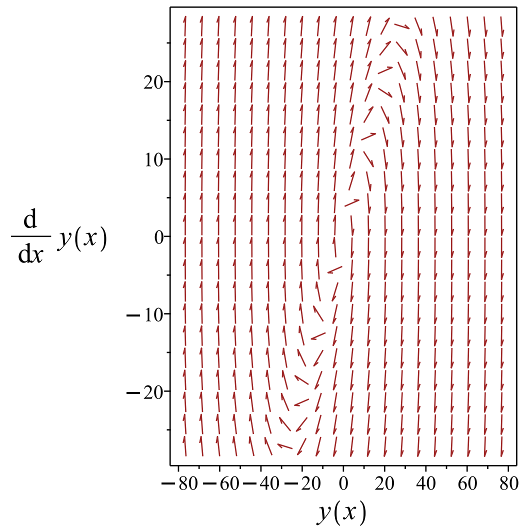
Summary

The solution(s) found are the following

$$y = (2x - \pi - 1)\,e^{x} \sin(x) - e^{x} \cos(x)\,\pi \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = (2x - \pi - 1)\, e^{x} \sin(x) - e^{x} \cos(x)\, \pi$$

Verified OK.

ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' - y' = -2x}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1, y''(0) = 2]$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - y' = 0$$

The characteristic equation is

$$\lambda^3 - \lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 1$$
$$\lambda_3 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 + e^x c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= e^{-x} \\ y_2 &= 1 \\ y_3 &= e^x \end{aligned}$$

Now the particular solution to the given ODE is found

$$y''' - y' = -2x$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^x, e^{-x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x, x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_2 x^2 + A_1 x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2xA_2 - A_1 = -2x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + c_2 + \mathrm{e}^x c_3\right) + \left(x^2\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{-x} + c_2 + \mathrm{e}^x c_3 + x^2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + c_2 + c_3 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 \mathrm{e}^{-x} + \mathrm{e}^x c_3 + 2x$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = -c_1 + c_3 \tag{2A}$$

Taking two derivatives of the solution gives

$$y'' = c_1 \mathrm{e}^{-x} + \mathrm{e}^x c_3 + 2$$

substituting $y'' = 2$ and $x = 0$ in the above gives

$$2 = c_1 + c_3 + 2 \tag{3A}$$

Equations {1A,2A,3A} are now solved for $\{c_1, c_2, c_3\}$. Solving for the constants gives

$$c_1 = -\frac{1}{2}$$
$$c_2 = 0$$
$$c_3 = \frac{1}{2}$$

Substituting these values back in above solution results in

$$y = -\frac{e^{-x}}{2} + \frac{e^{x}}{2} + x^2$$

Summary

The solution(s) found are the following

$$y = -\frac{e^{-x}}{2} + \frac{e^{x}}{2} + x^2 \tag{1}$$

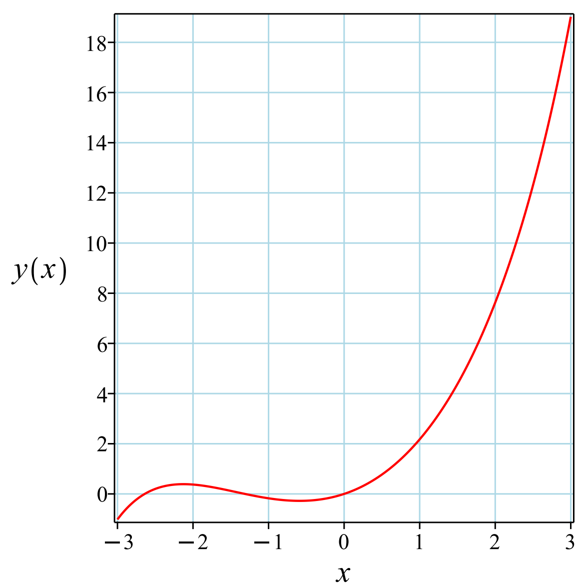

Figure 763: Solution plot

Verification of solutions

$$y = -\frac{e^{-x}}{2} + \frac{e^{x}}{2} + x^2$$

Verified OK.

18.15.1 Maple step by step solution

Let's solve

$$\left[y''' - y' = -2x, y(0) = 0, y'\Big|_{\{x=0\}} = 1, y''\Big|_{\{x=0\}} = 2\right]$$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(x)$

    $y_1(x) = y$

  - Define new variable $y_2(x)$

    $y_2(x) = y'$

  - Define new variable $y_3(x)$

    $y_3(x) = y''$

  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = -2x + y_2(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = -2x + y_2(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ -2x \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ -2x \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{y}'(x) = A \cdot \overrightarrow{y}(x) + \overrightarrow{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \mathrm{e}^{-x} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_2 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = e^x \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3 + \vec{y}_p(x)$$

☐ Fundamental matrix

  - Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} e^{-x} & 1 & e^x \\ -e^{-x} & 0 & e^x \\ e^{-x} & 0 & e^x \end{bmatrix}$$

  - The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$$

  - Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} e^{-x} & 1 & e^x \\ -e^{-x} & 0 & e^x \\ e^{-x} & 0 & e^x \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & 1 & 1 \\ -1 & 0 & 1 \\ 1 & 0 & 1 \end{bmatrix}}$$

  - Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} 1 & -\frac{e^{-x}}{2} + \frac{e^x}{2} & \frac{e^{-x}}{2} - 1 + \frac{e^x}{2} \\ 0 & \frac{e^x}{2} + \frac{e^{-x}}{2} & -\frac{e^{-x}}{2} + \frac{e^x}{2} \\ 0 & -\frac{e^{-x}}{2} + \frac{e^x}{2} & \frac{e^x}{2} + \frac{e^{-x}}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

  - Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

$\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\vec{y}_p(x) = \begin{bmatrix} x^2 - \mathrm{e}^{-x} + 2 - \mathrm{e}^{x} \\ 2x + \mathrm{e}^{-x} - \mathrm{e}^{x} \\ -\mathrm{e}^{-x} + 2 - \mathrm{e}^{x} \end{bmatrix}$$

- Plug particular solution back into general solution

  $$\vec{y}(x) = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3 + \begin{bmatrix} x^2 - \mathrm{e}^{-x} + 2 - \mathrm{e}^{x} \\ 2x + \mathrm{e}^{-x} - \mathrm{e}^{x} \\ -\mathrm{e}^{-x} + 2 - \mathrm{e}^{x} \end{bmatrix}$$

- First component of the vector is the solution to the ODE

  $y = (c_1 - 1)\,\mathrm{e}^{-x} + (c_3 - 1)\,\mathrm{e}^{x} + x^2 + c_2 + 2$

- Use the initial condition $y(0) = 0$

  $0 = c_1 + c_2 + c_3$

- Calculate the 1st derivative of the solution

  $y' = -(c_1 - 1)\,e^{-x} + (c_3 - 1)\,e^{x} + 2x$

- Use the initial condition $y'\Big|_{\{x=0\}} = 1$

  $1 = -c_1 + c_3$

- Calculate the 2nd derivative of the solution

  $y'' = (c_1 - 1)\,e^{-x} + 2 + (c_3 - 1)\,e^{x}$

- Use the initial condition $y''\Big|_{\{x=0\}} = 2$

  $2 = c_1 + c_3$

- Solve for the unknown coefficients

  $\left\{c_1 = \frac{1}{2}, c_2 = -2, c_3 = \frac{3}{2}\right\}$

- Solution to the IVP

  $y = -\frac{e^{-x}}{2} + \frac{e^{x}}{2} + x^2$

Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Initial value problem. Exercises page 140
Problem number: 605.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_high_order, _with_linear_symmetries]]`

$$\boxed{y'''' - y = 8\,\mathrm{e}^{x}}$$

With initial conditions

$$[y(0) = -1, y'(0) = 0, y''(0) = 1, y'''(0) = 0]$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - y = 0$$

The characteristic equation is

$$\lambda^4 - 1 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = -1$$
$$\lambda_3 = i$$
$$\lambda_4 = -i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 e^{x} + e^{ix} c_3 + e^{-ix} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = e^{x}$$
$$y_3 = e^{ix}$$
$$y_4 = e^{-ix}$$

Now the particular solution to the given ODE is found

$$y'''' - y = 8\,e^{x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8\,e^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{ix}, e^{-x}, e^{-ix}\}$$

Since e^{x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^{x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1 e^{x} = 8\,e^{x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2x\,e^x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2 e^x + e^{ix} c_3 + e^{-ix} c_4\right) + \left(2x\,e^x\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{-x} + c_2 e^x + e^{ix} c_3 + e^{-ix} c_4 + 2x\,e^x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -1$ and $x = 0$ in the above gives

$$-1 = c_1 + c_2 + c_3 + c_4 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 e^{-x} + c_2 e^x + i e^{ix} c_3 - i e^{-ix} c_4 + 2x\,e^x + 2\,e^x$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = c_3 i - c_4 i - c_1 + c_2 + 2 \tag{2A}$$

Taking two derivatives of the solution gives

$$y'' = c_1 e^{-x} + c_2 e^x - e^{ix} c_3 - e^{-ix} c_4 + 2x\,e^x + 4\,e^x$$

substituting $y'' = 1$ and $x = 0$ in the above gives

$$1 = c_1 + c_2 - c_3 - c_4 + 4 \tag{3A}$$

Taking three derivatives of the solution gives

$$y''' = -c_1 e^{-x} + c_2 e^x - i e^{ix} c_3 + i e^{-ix} c_4 + 2x\,e^x + 6\,e^x$$

substituting $y''' = 0$ and $x = 0$ in the above gives

$$0 = -c_3 i + c_4 i - c_1 + c_2 + 6 \tag{4A}$$

Equations {1A,2A,3A,4A} are now solved for $\{c_1, c_2, c_3, c_4\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 1 \\ c_2 &= -3 \\ c_3 &= \frac{1}{2} - i \\ c_4 &= \frac{1}{2} + i \end{aligned}$$

Substituting these values back in above solution results in

$$y = 2x\,e^{x} - 3\,e^{x} + e^{-x} + \cos(x) + 2\sin(x)$$

Which simplifies to

$$y = e^{-x} + (2x - 3)\,e^{x} + \cos(x) + 2\sin(x)$$

Summary

The solution(s) found are the following

$$y = e^{-x} + (2x - 3)\,e^{x} + \cos(x) + 2\sin(x) \tag{1}$$

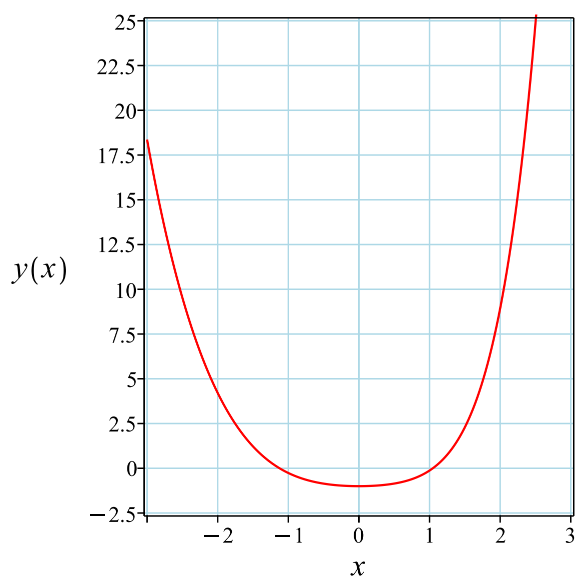

Figure 764: Solution plot

Verification of solutions

$$y = e^{-x} + (2x - 3)\, e^{x} + \cos(x) + 2\sin(x)$$

Verified OK.

18.16.1 Maple step by step solution

Let's solve

$$\left[y'''' - y = 8\, e^{x}, y(0) = -1, y'\Big|_{\{x=0\}} = 0, y''\Big|_{\{x=0\}} = 1, y'''\Big|_{\{x=0\}} = 0\right]$$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(x)$

    $y_1(x) = y$

  - Define new variable $y_2(x)$

    $y_2(x) = y'$

  - Define new variable $y_3(x)$

    $y_3(x) = y''$

  - Define new variable $y_4(x)$

    $y_4(x) = y'''$

  - Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = 8\, e^{x} + y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = 8\, e^{x} + y_1(x)]$

- Define vector

  $$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ 8\,\mathrm{e}^{x} \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 8\,\mathrm{e}^{x} \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} \mathrm{I} \\ -1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = e^{-x} \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-\mathrm{I}x} \cdot \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(x) - \mathrm{I}\sin(x)) \cdot \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ -\cos(x) + \mathrm{I}\sin(x) \\ \mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ \cos(x) - \mathrm{I}\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \begin{bmatrix} -\sin(x) \\ -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_4(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \vec{y}_p(x)$$

□ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} -\mathrm{e}^{-x} & \mathrm{e}^{x} & -\sin(x) & -\cos(x) \\ \mathrm{e}^{-x} & \mathrm{e}^{x} & -\cos(x) & \sin(x) \\ -\mathrm{e}^{-x} & \mathrm{e}^{x} & \sin(x) & \cos(x) \\ \mathrm{e}^{-x} & \mathrm{e}^{x} & \cos(x) & -\sin(x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} -e^{-x} & e^{x} & -\sin(x) & -\cos(x) \\ e^{-x} & e^{x} & -\cos(x) & \sin(x) \\ -e^{-x} & e^{x} & \sin(x) & \cos(x) \\ e^{-x} & e^{x} & \cos(x) & -\sin(x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -1 & 1 & 0 & -1 \\ 1 & 1 & -1 & 0 \\ -1 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} \frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\cos(x)}{2} & -\frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\sin(x)}{2} & \frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\cos(x)}{2} & -\frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\sin(x)}{2} \\ -\frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\sin(x)}{2} & \frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\cos(x)}{2} & -\frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\sin(x)}{2} & \frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\cos(x)}{2} \\ \frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\cos(x)}{2} & -\frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\sin(x)}{2} & \frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\cos(x)}{2} & -\frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\sin(x)}{2} \\ -\frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\sin(x)}{2} & \frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\cos(x)}{2} & -\frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\sin(x)}{2} & \frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\cos(x)}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$
- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$
- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$
- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$
- Plug $\vec{v}(x)$ into the equation for the particular solution

$$\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds \right)$$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \begin{bmatrix} e^{-x} + (2x-3)\, e^{x} + 2\cos(x) + 2\sin(x) \\ -e^{-x} + (2x-1)\, e^{x} + 2\cos(x) - 2\sin(x) \\ 2x\, e^{x} + e^{x} + e^{-x} - 2\cos(x) - 2\sin(x) \\ -e^{-x} + (2x+3)\, e^{x} - 2\cos(x) + 2\sin(x) \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3(x) + c_4 \vec{y}_4(x) + \begin{bmatrix} e^{-x} + (2x-3)\, e^{x} + 2\cos(x) + 2\sin(x) \\ -e^{-x} + (2x-1)\, e^{x} + 2\cos(x) - 2\sin(x) \\ 2x\, e^{x} + e^{x} + e^{-x} - 2\cos(x) - 2\sin(x) \\ -e^{-x} + (2x+3)\, e^{x} - 2\cos(x) + 2\sin(x) \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$y = (1-c_1)\, e^{-x} + (c_2 + 2x - 3)\, e^{x} + (-c_4 + 2)\cos(x) - \sin(x)(c_3 - 2)$

- Use the initial condition $y(0) = -1$

$-1 = -c_1 + c_2 - c_4$

- Calculate the 1st derivative of the solution

$y' = -(1-c_1)\, e^{-x} + 2\, e^{x} + (c_2 + 2x - 3)\, e^{x} - (-c_4 + 2)\sin(x) - (c_3 - 2)\cos(x)$

- Use the initial condition $y'\Big|_{\{x=0\}} = 0$

$0 = c_1 + c_2 - c_3$

- Calculate the 2nd derivative of the solution

$y'' = (1-c_1)\, e^{-x} + 4\, e^{x} + (c_2 + 2x - 3)\, e^{x} - (-c_4 + 2)\cos(x) + \sin(x)(c_3 - 2)$

- Use the initial condition $y''\Big|_{\{x=0\}} = 1$

$1 = -c_1 + c_2 + c_4$

- Calculate the 3rd derivative of the solution

$y''' = -(1-c_1)\, e^{-x} + 6\, e^{x} + (c_2 + 2x - 3)\, e^{x} + (-c_4 + 2)\sin(x) + (c_3 - 2)\cos(x)$

- Use the initial condition $y'''\Big|_{\{x=0\}} = 0$

$0 = c_1 + c_2 + c_3$

- Solve for the unknown coefficients

  $$\{c_1 = 0, c_2 = 0, c_3 = 0, c_4 = 1\}$$

- Solution to the IVP

  $$y = e^{-x} + (2x - 3) e^x + \cos(x) + 2\sin(x)$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _with_linear_symmetries]]
```

$$\boxed{y''' - y = 2x}$$

With initial conditions

$$[y(0) = 0, y'(0) = 0, y''(0) = 2]$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - y = 0$$

The characteristic equation is

$$\lambda^3 - 1 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$$
$$\lambda_3 = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + e^{\left(-\frac{1}{2} - \frac{i\sqrt{3}}{2}\right)x} c_2 + e^{\left(-\frac{1}{2} + \frac{i\sqrt{3}}{2}\right)x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^x$$
$$y_2 = e^{\left(-\frac{1}{2} - \frac{i\sqrt{3}}{2}\right)x}$$
$$y_3 = e^{\left(-\frac{1}{2} + \frac{i\sqrt{3}}{2}\right)x}$$

Now the particular solution to the given ODE is found

$$y''' - y = 2x$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^x, e^{\left(-\frac{1}{2} - \frac{i\sqrt{3}}{2}\right)x}, e^{\left(-\frac{1}{2} + \frac{i\sqrt{3}}{2}\right)x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_2 x + A_1$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_2x - A_1 = 2x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = -2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^x c_1 + \mathrm{e}^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_2 + \mathrm{e}^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_3\right) + (-2x) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \mathrm{e}^x c_1 + \mathrm{e}^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_2 + \mathrm{e}^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_3 - 2x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + c_2 + c_3 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \mathrm{e}^x c_1 + \left(-\frac{1}{2} - \frac{i\sqrt{3}}{2}\right) \mathrm{e}^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_2 + \left(-\frac{1}{2} + \frac{i\sqrt{3}}{2}\right) \mathrm{e}^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_3 - 2$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -2 + \frac{i(-c_2 + c_3)\sqrt{3}}{2} + c_1 - \frac{c_2}{2} - \frac{c_3}{2} \tag{2A}$$

Taking two derivatives of the solution gives

$$y'' = e^{x} c_1 + \left(-\frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2 e^{\left(-\frac{1}{2} - \frac{i\sqrt{3}}{2}\right)x} c_2 + \left(-\frac{1}{2} + \frac{i\sqrt{3}}{2}\right)^2 e^{\left(-\frac{1}{2} + \frac{i\sqrt{3}}{2}\right)x} c_3$$

substituting $y'' = 2$ and $x = 0$ in the above gives

$$2 = \frac{i(c_2 - c_3)\sqrt{3}}{2} + c_1 - \frac{c_2}{2} - \frac{c_3}{2} \tag{3A}$$

Equations {1A,2A,3A} are now solved for $\{c_1, c_2, c_3\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= \frac{4}{3} \\ c_2 &= -\frac{2}{3} \\ c_3 &= -\frac{2}{3} \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{4\,e^{x}}{3} - \frac{2\,e^{-\frac{(1+i\sqrt{3})x}{2}}}{3} - \frac{2\,e^{\frac{(-1+i\sqrt{3})x}{2}}}{3} - 2x$$

Summary

The solution(s) found are the following

$$y = \frac{4\,e^{x}}{3} - \frac{2\,e^{-\frac{(1+i\sqrt{3})x}{2}}}{3} - \frac{2\,e^{\frac{(-1+i\sqrt{3})x}{2}}}{3} - 2x \tag{1}$$

Verification of solutions

$$y = \frac{4\,e^{x}}{3} - \frac{2\,e^{-\frac{(1+i\sqrt{3})x}{2}}}{3} - \frac{2\,e^{\frac{(-1+i\sqrt{3})x}{2}}}{3} - 2x$$

Verified OK.

18.17.1 Maple step by step solution

Let's solve

$$\left[y''' - y = 2x, y(0) = 0, y'\Big|_{\{x=0\}} = 0, y''\Big|_{\{x=0\}} = 2\right]$$

- Highest derivative means the order of the ODE is 3

y'''

- ☐ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = 2x + y_1(x)$

    Convert linear ODE into a system of first order ODEs

    $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 2x + y_1(x)]$
- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 2x \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 2x \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \end{array}\right]\right], \left[-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}, \left[\begin{array}{c} \frac{1}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^{2}} \\ \frac{1}{-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{array}\right]\right], \left[-\frac{1}{2}+\frac{\mathrm{I}\sqrt{3}}{2}, \left[\begin{array}{c} \frac{1}{\left(-\frac{1}{2}+\frac{\mathrm{I}\sqrt{3}}{2}\right)^{2}} \\ \frac{1}{-\frac{1}{2}+\frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{x} \cdot \left[\begin{array}{c} 1 \\ 1 \\ 1 \end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}, \left[\begin{array}{c} \frac{1}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^{2}} \\ \frac{1}{-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$\mathrm{e}^{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)x} \cdot \left[\begin{array}{c} \frac{1}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^{2}} \\ \frac{1}{-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$e^{-\frac{x}{2}} \cdot \left(\cos\left(\frac{x\sqrt{3}}{2}\right) - \mathrm{I}\sin\left(\frac{x\sqrt{3}}{2}\right)\right) \cdot \left[\begin{array}{c} \frac{1}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^2} \\ \frac{1}{-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{array}\right]$$

- Simplify expression

$$e^{-\frac{x}{2}} \cdot \left[\begin{array}{c} \frac{\cos\left(\frac{x\sqrt{3}}{2}\right)-\mathrm{I}\sin\left(\frac{x\sqrt{3}}{2}\right)}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^2} \\ \frac{\cos\left(\frac{x\sqrt{3}}{2}\right)-\mathrm{I}\sin\left(\frac{x\sqrt{3}}{2}\right)}{-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}} \\ \cos\left(\frac{x\sqrt{3}}{2}\right) - \mathrm{I}\sin\left(\frac{x\sqrt{3}}{2}\right) \end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = e^{-\frac{x}{2}} \cdot \left[\begin{array}{c} -\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} - \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} \\ -\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} \\ \cos\left(\frac{x\sqrt{3}}{2}\right) \end{array}\right], \vec{y}_3(x) = e^{-\frac{x}{2}} \cdot \left[\begin{array}{c} -\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2} \\ \frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2} \\ -\sin\left(\frac{x\sqrt{3}}{2}\right) \end{array}\right]\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

  $\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \left[\begin{array}{ccc} e^{x} & e^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} - \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & e^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ e^{x} & e^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & e^{-\frac{x}{2}}\left(\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ e^{x} & e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right) & -e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right) \end{array}\right]$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} e^{x} & e^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} - \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & e^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ e^{x} & e^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & e^{-\frac{x}{2}}\left(\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ e^{x} & e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right) & -e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & -\frac{1}{2} & -\frac{\sqrt{3}}{2} \\ 1 & -\frac{1}{2} & \frac{\sqrt{3}}{2} \\ 1 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} \frac{e^{x}}{3} + \frac{2e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} & \frac{e^{x}}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} + \frac{e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} & \frac{e^{x}}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} \\ \frac{e^{x}}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} - \frac{e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} & \frac{e^{x}}{3} + \frac{2e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} & \frac{e^{x}}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} \\ \frac{e^{x}}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} + \frac{e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} & \frac{e^{x}}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} - \frac{e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} & \frac{e^{x}}{3} + \frac{2e}{} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \begin{bmatrix} \frac{2\,e^{x}}{3} - 2x + \frac{2\,e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} - \frac{2\,e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{3} \\ \frac{2\,e^{x}}{3} - 2 + \frac{4\,e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{3} \\ -\frac{2\,e^{-\frac{x}{2}}\left(-e^{\frac{3x}{2}} + \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3} + \cos\left(\frac{x\sqrt{3}}{2}\right)\right)}{3} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \begin{bmatrix} \frac{2\,e^{x}}{3} - 2x + \frac{2\,e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} - \frac{2\,e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{3} \\ \frac{2\,e^{x}}{3} - 2 + \frac{4\,e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{3} \\ -\frac{2\,e^{-\frac{x}{2}}\left(-e^{\frac{3x}{2}} + \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3} + \cos\left(\frac{x\sqrt{3}}{2}\right)\right)}{3} \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = -\frac{\left(c_3\sqrt{3}+c_2+\frac{4}{3}\right)e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{2} - \frac{\left(\left(c_2-\frac{4}{3}\right)\sqrt{3}-c_3\right)e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{(6c_1+4)e^{x}}{6} - 2x$$

- Use the initial condition $y(0) = 0$

$$0 = -\frac{c_3\sqrt{3}}{2} - \frac{c_2}{2} + c_1$$

- Calculate the 1st derivative of the solution

$$y' = \frac{\left(c_3\sqrt{3}+c_2+\frac{4}{3}\right)e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{4} + \frac{\left(c_3\sqrt{3}+c_2+\frac{4}{3}\right)e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{4} + \frac{\left(\left(c_2-\frac{4}{3}\right)\sqrt{3}-c_3\right)e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)}{4} - \frac{\left(\left(c_2-\frac{4}{3}\right)\sqrt{3}-\right.}{}$$

- Use the initial condition $y'\Big|_{\{x=0\}} = 0$

$$0 = \frac{c_3\sqrt{3}}{4} + \frac{c_2}{4} - 1 - \frac{\left(\left(c_2-\frac{4}{3}\right)\sqrt{3}-c_3\right)\sqrt{3}}{4} + c_1$$

- Calculate the 2nd derivative of the solution

$$y'' = \frac{\left(c_3\sqrt{3}+c_2+\frac{4}{3}\right)e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{4} - \frac{\left(c_3\sqrt{3}+c_2+\frac{4}{3}\right)e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{4} + \frac{\left(\left(c_2-\frac{4}{3}\right)\sqrt{3}-c_3\right)e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)}{4} + \frac{\left(\left(c_2-\frac{4}{3}\right)\sqrt{3}-\right.}{}$$

- Use the initial condition $y''\Big|_{\{x=0\}} = 2$

$$2 = \frac{c_3\sqrt{3}}{4} + \frac{c_2}{4} + 1 + \frac{\left(\left(c_2-\frac{4}{3}\right)\sqrt{3}-c_3\right)\sqrt{3}}{4} + c_1$$

- Solve for the unknown coefficients

$$\left\{c_1 = \frac{2}{3}, c_2 = \frac{4}{3}, c_3 = 0\right\}$$

- Solution to the IVP

$$y=-\frac{4\,\mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3}-2x+\frac{4\,\mathrm{e}^{x}}{3}$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_high_order, _with_linear_symmetries]]`

$$\boxed{y'''' - y = 8\,\mathrm{e}^{x}}$$

With initial conditions

$$[y(0) = 0, y'(0) = 2, y''(0) = 4, y'''(0) = 6]$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - y = 0$$

The characteristic equation is

$$\lambda^4 - 1 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = -1$$
$$\lambda_3 = i$$
$$\lambda_4 = -i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 e^{x} + e^{ix} c_3 + e^{-ix} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = e^{x}$$
$$y_3 = e^{ix}$$
$$y_4 = e^{-ix}$$

Now the particular solution to the given ODE is found

$$y'''' - y = 8\,e^{x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8\,e^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{ix}, e^{-x}, e^{-ix}\}$$

Since e^{x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^{x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1 e^{x} = 8\,e^{x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2x\,e^x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2 e^x + e^{ix} c_3 + e^{-ix} c_4\right) + (2x\,e^x) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{-x} + c_2 e^x + e^{ix} c_3 + e^{-ix} c_4 + 2x\,e^x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + c_2 + c_3 + c_4 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 e^{-x} + c_2 e^x + i e^{ix} c_3 - i e^{-ix} c_4 + 2x\,e^x + 2\,e^x$$

substituting $y' = 2$ and $x = 0$ in the above gives

$$2 = c_3 i - c_4 i - c_1 + c_2 + 2 \tag{2A}$$

Taking two derivatives of the solution gives

$$y'' = c_1 e^{-x} + c_2 e^x - e^{ix} c_3 - e^{-ix} c_4 + 2x\,e^x + 4\,e^x$$

substituting $y'' = 4$ and $x = 0$ in the above gives

$$4 = c_1 + c_2 - c_3 - c_4 + 4 \tag{3A}$$

Taking three derivatives of the solution gives

$$y''' = -c_1 e^{-x} + c_2 e^x - i e^{ix} c_3 + i e^{-ix} c_4 + 2x\,e^x + 6\,e^x$$

substituting $y''' = 6$ and $x = 0$ in the above gives

$$6 = -c_3 i + c_4 i - c_1 + c_2 + 6 \tag{4A}$$

Equations {1A,2A,3A,4A} are now solved for $\{c_1, c_2, c_3, c_4\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 0 \\ c_2 &= 0 \\ c_3 &= 0 \\ c_4 &= 0 \end{aligned}$$

Substituting these values back in above solution results in

$$y = 2x\,e^x$$

Summary

The solution(s) found are the following

$$y = 2x\,e^x \tag{1}$$

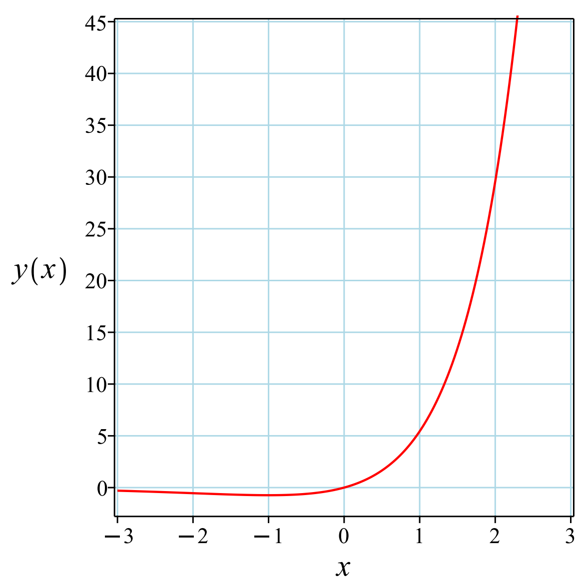

Figure 765: Solution plot

Verification of solutions

$$y = 2x\,e^x$$

Verified OK.

18.18.1 Maple step by step solution

Let's solve

$$\left[y'''' - y = 8\,\mathrm{e}^{x}, y(0) = 0, y'\Big|_{\{x=0\}} = 2, y''\Big|_{\{x=0\}} = 4, y'''\Big|_{\{x=0\}} = 6\right]$$

- Highest derivative means the order of the ODE is 4

  y''''

☐ Convert linear ODE into a system of first order ODEs

  ○ Define new variable $y_1(x)$

  $y_1(x) = y$

  ○ Define new variable $y_2(x)$

  $y_2(x) = y'$

  ○ Define new variable $y_3(x)$

  $y_3(x) = y''$

  ○ Define new variable $y_4(x)$

  $y_4(x) = y'''$

  ○ Isolate for $y_4'(x)$ using original ODE

  $y_4'(x) = 8\,\mathrm{e}^{x} + y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x)\,, y_3(x) = y_2'(x)\,, y_4(x) = y_3'(x)\,, y_4'(x) = 8\,\mathrm{e}^{x} + y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}\,'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ 8\,\mathrm{e}^{x} \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \left[\begin{array}{c} 0 \\ 0 \\ 0 \\ 8\,\mathrm{e}^{x} \end{array}\right]$$

- Define the coefficient matrix

$$A = \left[\begin{array}{cccc} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{array}\right]$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]\right], \left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array}\right]\right], \left[-\mathrm{I}, \left[\begin{array}{c} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{array}\right]\right], \left[\mathrm{I}, \left[\begin{array}{c} \mathrm{I} \\ -1 \\ -\mathrm{I} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{-x} \cdot \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c}1\\1\\1\\1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{x} \cdot \left[\begin{array}{c}1\\1\\1\\1\end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-I, \left[\begin{array}{c}-I\\-1\\I\\1\end{array}\right]\right]$$

- Solution from eigenpair

$$e^{-Ix} \cdot \left[\begin{array}{c}-I\\-1\\I\\1\end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(x) - I\sin(x)) \cdot \left[\begin{array}{c}-I\\-1\\I\\1\end{array}\right]$$

- Simplify expression

$$\begin{bmatrix} -\mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ -\cos(x) + \mathrm{I}\sin(x) \\ \mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ \cos(x) - \mathrm{I}\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \begin{bmatrix} -\sin(x) \\ -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_4(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} -\mathrm{e}^{-x} & \mathrm{e}^{x} & -\sin(x) & -\cos(x) \\ \mathrm{e}^{-x} & \mathrm{e}^{x} & -\cos(x) & \sin(x) \\ -\mathrm{e}^{-x} & \mathrm{e}^{x} & \sin(x) & \cos(x) \\ \mathrm{e}^{-x} & \mathrm{e}^{x} & \cos(x) & -\sin(x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} -\mathrm{e}^{-x} & \mathrm{e}^{x} & -\sin(x) & -\cos(x) \\ \mathrm{e}^{-x} & \mathrm{e}^{x} & -\cos(x) & \sin(x) \\ -\mathrm{e}^{-x} & \mathrm{e}^{x} & \sin(x) & \cos(x) \\ \mathrm{e}^{-x} & \mathrm{e}^{x} & \cos(x) & -\sin(x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -1 & 1 & 0 & -1 \\ 1 & 1 & -1 & 0 \\ -1 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x)=\begin{bmatrix} \frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\cos(x)}{2} & -\frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\sin(x)}{2} & \frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\cos(x)}{2} & -\frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\sin(x)}{2} \\ -\frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\sin(x)}{2} & \frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\cos(x)}{2} & -\frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\sin(x)}{2} & \frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\cos(x)}{2} \\ \frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\cos(x)}{2} & -\frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\sin(x)}{2} & \frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\cos(x)}{2} & -\frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\sin(x)}{2} \\ -\frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\sin(x)}{2} & \frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\cos(x)}{2} & -\frac{e^{-x}}{4}+\frac{e^{x}}{4}-\frac{\sin(x)}{2} & \frac{e^{-x}}{4}+\frac{e^{x}}{4}+\frac{\cos(x)}{2} \end{bmatrix}$$

- ☐ Find a particular solution of the system of ODEs using variation of parameters
  - Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

    $\vec{y}_p(x)=\Phi(x)\cdot\vec{v}(x)$
  - Take the derivative of the particular solution

    $\vec{y}_p{}'(x)=\Phi'(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}\,'(x)$
  - Substitute particular solution and its derivative into the system of ODEs

    $\Phi'(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}\,'(x)=A\cdot\Phi(x)\cdot\vec{v}(x)+\vec{f}(x)$
  - The fundamental matrix has columns that are solutions to the homogeneous system so its der

    $A\cdot\Phi(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}\,'(x)=A\cdot\Phi(x)\cdot\vec{v}(x)+\vec{f}(x)$
  - Cancel like terms

    $\Phi(x)\cdot\vec{v}\,'(x)=\vec{f}(x)$
  - Multiply by the inverse of the fundamental matrix

    $\vec{v}\,'(x)=\frac{1}{\Phi(x)}\cdot\vec{f}(x)$
  - Integrate to solve for $\vec{v}(x)$

    $\vec{v}(x)=\int_0^x\frac{1}{\Phi(s)}\cdot\vec{f}(s)\,ds$
  - Plug $\vec{v}(x)$ into the equation for the particular solution

    $\vec{y}_p(x)=\Phi(x)\cdot\left(\int_0^x\frac{1}{\Phi(s)}\cdot\vec{f}(s)\,ds\right)$
  - Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x)=\begin{bmatrix} e^{-x}+(2x-3)\,e^{x}+2\cos(x)+2\sin(x) \\ -e^{-x}+(2x-1)\,e^{x}+2\cos(x)-2\sin(x) \\ 2x\,e^{x}+e^{x}+e^{-x}-2\cos(x)-2\sin(x) \\ -e^{-x}+(2x+3)\,e^{x}-2\cos(x)+2\sin(x) \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3(x) + c_4 \vec{y}_4(x) + \begin{bmatrix} e^{-x} + (2x-3)\,e^{x} + 2\cos(x) + 2\sin(x) \\ -e^{-x} + (2x-1)\,e^{x} + 2\cos(x) - 2\sin(x) \\ 2x\,e^{x} + e^{x} + e^{-x} - 2\cos(x) - 2\sin(x) \\ -e^{-x} + (2x+3)\,e^{x} - 2\cos(x) + 2\sin(x) \end{bmatrix}$$

- First component of the vector is the solution to the ODE

  $y = (1-c_1)\,e^{-x} + (c_2 + 2x - 3)\,e^{x} + (-c_4 + 2)\cos(x) - \sin(x)(c_3 - 2)$

- Use the initial condition $y(0) = 0$

  $0 = -c_1 + c_2 - c_4$

- Calculate the 1st derivative of the solution

  $y' = -(1-c_1)\,e^{-x} + 2\,e^{x} + (c_2 + 2x - 3)\,e^{x} - (-c_4 + 2)\sin(x) - (c_3 - 2)\cos(x)$

- Use the initial condition $y'\Big|_{\{x=0\}} = 2$

  $2 = c_1 + c_2 - c_3$

- Calculate the 2nd derivative of the solution

  $y'' = (1-c_1)\,e^{-x} + 4\,e^{x} + (c_2 + 2x - 3)\,e^{x} - (-c_4 + 2)\cos(x) + \sin(x)(c_3 - 2)$

- Use the initial condition $y''\Big|_{\{x=0\}} = 4$

  $4 = -c_1 + c_2 + c_4$

- Calculate the 3rd derivative of the solution

  $y''' = -(1-c_1)\,e^{-x} + 6\,e^{x} + (c_2 + 2x - 3)\,e^{x} + (-c_4 + 2)\sin(x) + (c_3 - 2)\cos(x)$

- Use the initial condition $y'''\Big|_{\{x=0\}} = 6$

  $6 = c_1 + c_2 + c_3$

- Solve for the unknown coefficients

  $\{c_1 = 1, c_2 = 3, c_3 = 2, c_4 = 2\}$

- Solution to the IVP

  $y = 2x\,e^{x}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 4y' + 5y = \sin(x)}$$

18.19.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 5, f(x) = \sin(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A=1, B=-4, C=5$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 4\lambda\,\mathrm{e}^{\lambda x} + 5\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A=1, B=-4, C=5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-4^2 - (4)\,(1)\,(5)}\\ &= 2 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 2 + i\\ \lambda_2 &= 2 - i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2 + i\\ \lambda_2 &= 2 - i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 2$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x))$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{2x}(c_1 \cos(x) + c_2 \sin(x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{2x}\cos(x), e^{2x}\sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\cos(x) + A_2\sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1\cos(x) + 4A_2\sin(x) + 4A_1\sin(x) - 4A_2\cos(x) = \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{8}, A_2 = \frac{1}{8}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\cos(x)}{8} + \frac{\sin(x)}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{2x}(c_1\cos(x) + c_2\sin(x))\right) + \left(\frac{\cos(x)}{8} + \frac{\sin(x)}{8}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{2x}(c_1\cos(x) + c_2\sin(x)) + \frac{\cos(x)}{8} + \frac{\sin(x)}{8} \tag{1}$$

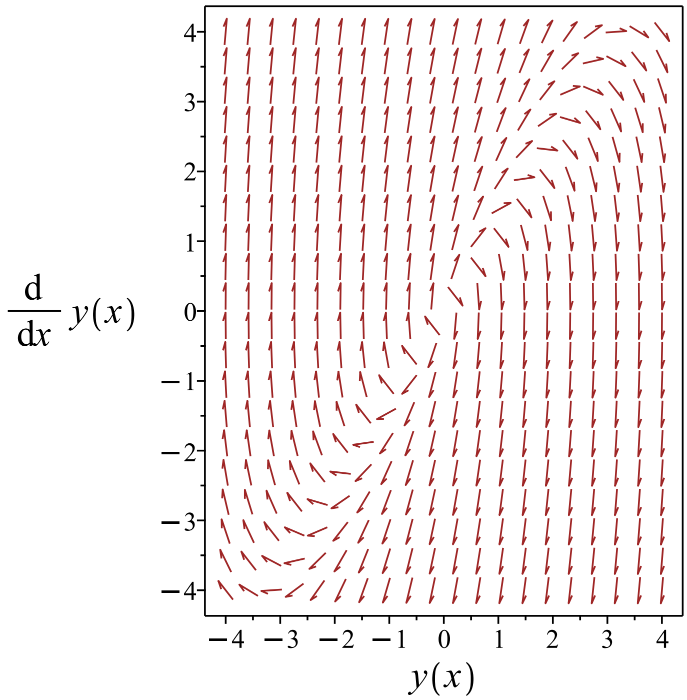

Figure 766: Slope field plot

Verification of solutions

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{\cos(x)}{8} + \frac{\sin(x)}{8}$$

Verified OK.

18.19.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 593: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - 0\\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx}\\ &= z_1 e^{2x}\\ &= z_1\left(\mathrm{e}^{2x}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2x}\cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\,dx}}{(y_1)^2}\,dx\\ &= y_1 \int \frac{e^{4x}}{(y_1)^2}\,dx\\ &= y_1(\tan(x))\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{2x} \cos\left(x\right)\right) + c_2 \left(\mathrm{e}^{2x} \cos\left(x\right) \left(\tan\left(x\right)\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 4y' + 5y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \cos\left(x\right) \mathrm{e}^{2x} c_1 + \mathrm{e}^{2x} \sin\left(x\right) c_2
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
\sin\left(x\right)
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\cos\left(x\right), \sin\left(x\right)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{\mathrm{e}^{2x} \cos\left(x\right), \mathrm{e}^{2x} \sin\left(x\right)\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 \cos\left(x\right) + A_2 \sin\left(x\right)
$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
4A_1 \cos\left(x\right) + 4A_2 \sin\left(x\right) + 4A_1 \sin\left(x\right) - 4A_2 \cos\left(x\right) = \sin\left(x\right)
$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{8}, A_2 = \frac{1}{8}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\cos(x)}{8} + \frac{\sin(x)}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\cos(x)\,\mathrm{e}^{2x} c_1 + \mathrm{e}^{2x}\sin(x)\, c_2\right) + \left(\frac{\cos(x)}{8} + \frac{\sin(x)}{8}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{2x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{\cos(x)}{8} + \frac{\sin(x)}{8}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{2x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{\cos(x)}{8} + \frac{\sin(x)}{8} \tag{1}$$

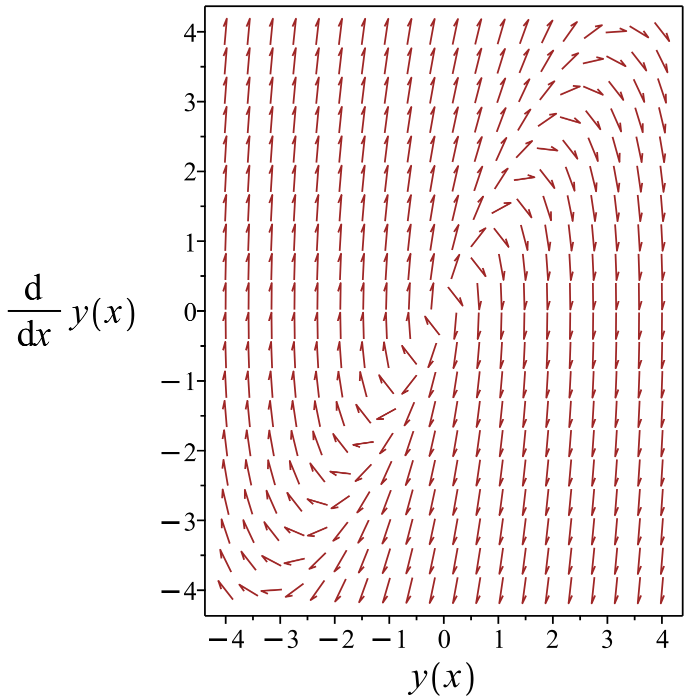

Figure 767: Slope field plot

Verification of solutions

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{\cos(x)}{8} + \frac{\sin(x)}{8}$$

Verified OK.

18.19.3 Maple step by step solution

Let's solve

$y'' - 4y' + 5y = \sin(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 4r + 5 = 0$

- Use quadratic formula to solve for r

  $r = \frac{4 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

$r = (2-\mathrm{I}, 2+\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{2x}\cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{2x}\sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \cos(x)\,\mathrm{e}^{2x} c_1 + \mathrm{e}^{2x}\sin(x)\, c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \sin(x)\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{2x}\cos(x) & \mathrm{e}^{2x}\sin(x) \\ 2\,\mathrm{e}^{2x}\cos(x) - \mathrm{e}^{2x}\sin(x) & 2\,\mathrm{e}^{2x}\sin(x) + \mathrm{e}^{2x}\cos(x) \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = \mathrm{e}^{4x}$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = \frac{\mathrm{e}^{2x}\left(\sin(x)\left(\int \mathrm{e}^{-2x}\sin(2x)dx\right) - 2\cos(x)\left(\int \sin(x)^2 \mathrm{e}^{-2x}dx\right)\right)}{2}$

- ○ Compute integrals

  $y_p(x) = \frac{\cos(x)}{8} + \frac{\sin(x)}{8}$

- Substitute particular solution into general solution to ODE

  $y = \mathrm{e}^{2x}\sin(x)\, c_2 + \cos(x)\,\mathrm{e}^{2x} c_1 + \frac{\sin(x)}{8} + \frac{\cos(x)}{8}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 2y' + 5y = 4\cos(2x) + \sin(2x)}$$

18.20.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 5, f(x) = 4\cos(2x) + \sin(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda\, e^{\lambda x} + 5\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{2^2 - (4)\,(1)\,(5)}\\ &= -1 \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -1 + 2i\\ \lambda_2 &= -1 - 2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 + 2i\\ \lambda_2 &= -1 - 2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -1$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4\cos(2x) + \sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-x}\cos(2x), e^{-x}\sin(2x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\cos(2x) + A_2\sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1\cos(2x) + A_2\sin(2x) - 4A_1\sin(2x) + 4A_2\cos(2x) = 4\cos(2x) + \sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \sin(2x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-x}(c_1\cos(2x) + c_2\sin(2x))\right) + (\sin(2x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{-x}(c_1\cos(2x) + c_2\sin(2x)) + \sin(2x) \tag{1}$$

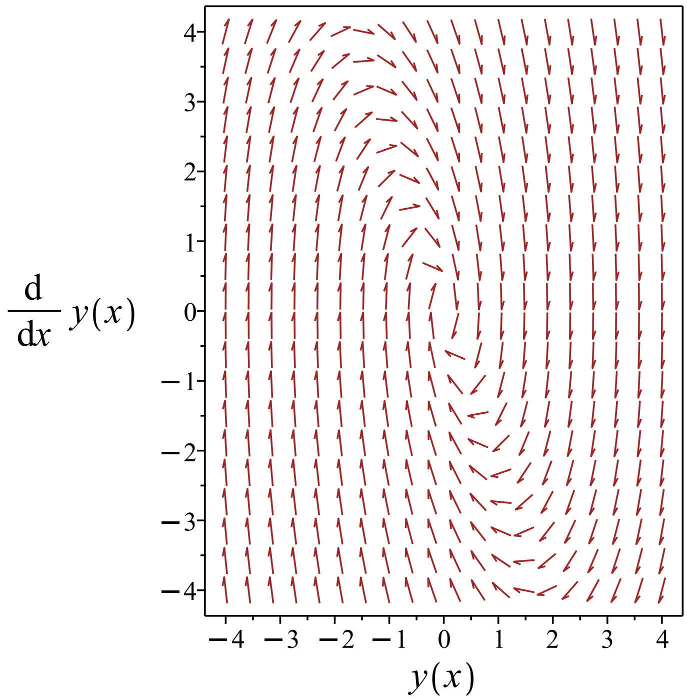

Figure 768: Slope field plot

Verification of solutions

$$y = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x)) + \sin(2x)$$

Verified OK.

18.20.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + 5y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 595: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(2x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\
&= z_1 e^{-x} \\
&= z_1 \left(\mathrm{e}^{-x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-x} \cos(2x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\tan(2x)}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x} \cos(2x)\right) + c_2 \left(\mathrm{e}^{-x} \cos(2x) \left(\frac{\tan(2x)}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 2y' + 5y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^{-x} \cos(2x)\, c_1 + \frac{\mathrm{e}^{-x} \sin(2x)\, c_2}{2}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
4\cos(2x) + \sin(2x)
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\cos(2x), \sin(2x)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\mathrm{e}^{-x} \cos(2x), \frac{\mathrm{e}^{-x} \sin(2x)}{2}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 \cos(2x) + A_2 \sin(2x)
$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 \cos(2x) + A_2 \sin(2x) - 4A_1 \sin(2x) + 4A_2 \cos(2x) = 4\cos(2x) + \sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \sin(2x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-x} \cos(2x) c_1 + \frac{e^{-x} \sin(2x) c_2}{2}\right) + (\sin(2x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{-x} \cos(2x) c_1 + \frac{e^{-x} \sin(2x) c_2}{2} + \sin(2x) \tag{1}$$

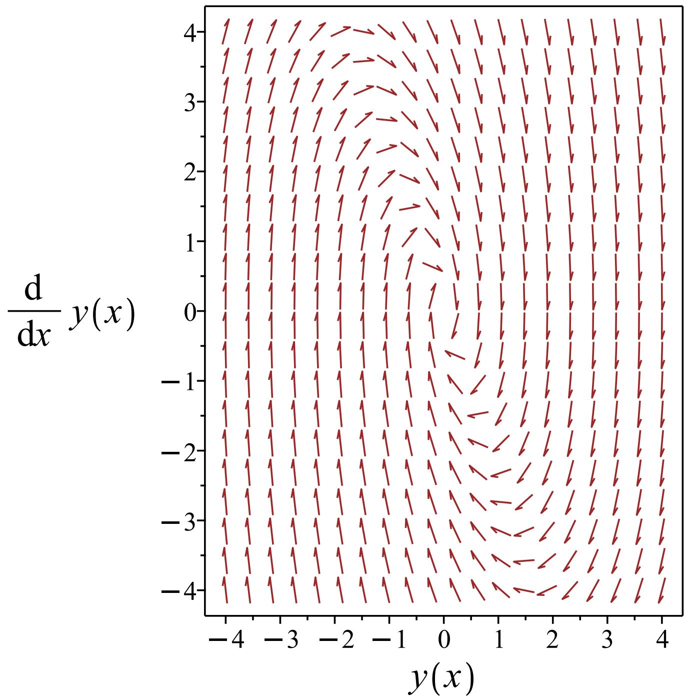

Figure 769: Slope field plot

Verification of solutions

$$y = e^{-x} \cos(2x) c_1 + \frac{e^{-x} \sin(2x) c_2}{2} + \sin(2x)$$

Verified OK.

18.20.3 Maple step by step solution

Let's solve

$y'' + 2y' + 5y = 4\cos(2x) + \sin(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r + 5 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-2)\pm(\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

$r = (-1-2\mathrm{I}, -1+2\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-x}\cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-x}\sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \mathrm{e}^{-x}\cos(2x)\, c_1 + \mathrm{e}^{-x}\sin(2x)\, c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))} dx\right), f(x) = 4\cos(2x) + \sin(2x)\right]$

- ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-x}\cos(2x) & \mathrm{e}^{-x}\sin(2x) \\ -\mathrm{e}^{-x}\cos(2x) - 2\,\mathrm{e}^{-x}\sin(2x) & -\mathrm{e}^{-x}\sin(2x) + 2\,\mathrm{e}^{-x}\cos(2x) \end{bmatrix}$

- ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2\,\mathrm{e}^{-2x}$

- ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = \frac{\mathrm{e}^{-x}\left(\cos(2x)\left(\int (\cos(4x)-1-4\sin(4x))\mathrm{e}^{x} dx\right)+\sin(2x)\left(\int (\sin(4x)+4\cos(4x)+4)\mathrm{e}^{x} dx\right)\right)}{4}$

- ◦ Compute integrals

  $y_p(x) = \sin(2x)$

- Substitute particular solution into general solution to ODE

  $y = \mathrm{e}^{-x}\sin(2x)\, c_2 + \mathrm{e}^{-x}\cos(2x)\, c_1 + \sin(2x)$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - y = 1}$$

18.21.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = -1, f(x) = 1$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)} \\ &= \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +1 \\ \lambda_2 &= -1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 \\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(1)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$y = e^x c_1 + e^{-x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = e^x c_1 + e^{-x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 = 1$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^x c_1 + e^{-x} c_2\right) + (-1) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = e^x c_1 + e^{-x} c_2 - 1 \tag{1}$$

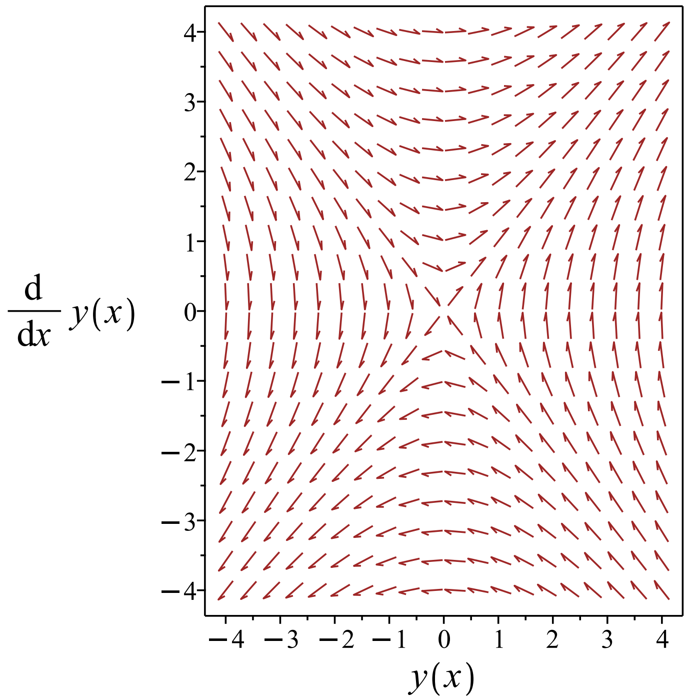

Figure 770: Slope field plot

Verification of solutions

$$y = e^{x}c_1 + e^{-x}c_2 - 1$$

Verified OK.

18.21.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' - yy' - y' = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' - yy' - y')\,dx = 0$$
$$\frac{y'^2}{2} - \frac{y^2}{2} - y = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{y^2 + 2y + 2c_1} \tag{1}$$
$$y' = -\sqrt{y^2 + 2y + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$
\begin{aligned}
\int \frac{1}{\sqrt{y^2+2c_1+2y}}dy &= \int dx \\
\ln\left(y+1+\sqrt{y^2+2c_1+2y}\right) &= x+c_2
\end{aligned}
$$

Raising both side to exponential gives

$$
y+1+\sqrt{y^2+2c_1+2y} = \mathrm{e}^{x+c_2}
$$

Which simplifies to

$$
y+1+\sqrt{y^2+2c_1+2y} = \mathrm{e}^{x} c_3
$$

Solving equation (2)

Integrating both sides gives

$$
\begin{aligned}
\int -\frac{1}{\sqrt{y^2+2c_1+2y}}dy &= \int dx \\
-\ln\left(y+1+\sqrt{y^2+2c_1+2y}\right) &= x+c_4
\end{aligned}
$$

Raising both side to exponential gives

$$
\frac{1}{y+1+\sqrt{y^2+2c_1+2y}} = \mathrm{e}^{x+c_4}
$$

Which simplifies to

$$
\frac{1}{y+1+\sqrt{y^2+2c_1+2y}} = \mathrm{e}^{x} c_5
$$

Summary

The solution(s) found are the following

$$
y = \frac{\left(\mathrm{e}^{2x} c_3^2 - 2\,\mathrm{e}^{x} c_3 - 2c_1 + 1\right)\mathrm{e}^{-x}}{2c_3} \tag{1}
$$

$$
y = -\frac{\left(2c_1 \mathrm{e}^{2x} c_5^2 - \mathrm{e}^{2x} c_5^2 + 2\,\mathrm{e}^{x} c_5 - 1\right)\mathrm{e}^{-x}}{2c_5} \tag{2}
$$

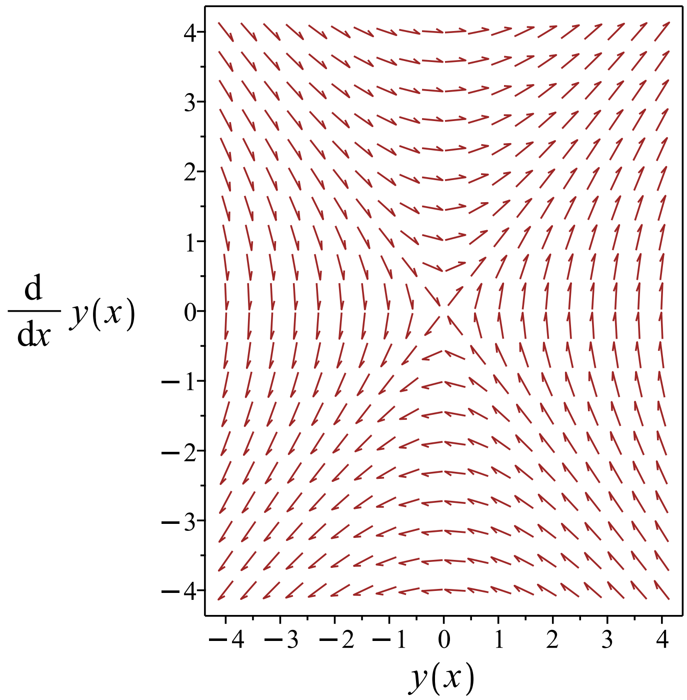

Figure 771: Slope field plot

Verification of solutions

$$y = \frac{(e^{2x}c_3^2 - 2\,e^x c_3 - 2c_1 + 1)\,e^{-x}}{2c_3}$$

Verified OK.

$$y = -\frac{(2c_1 e^{2x} c_5^2 - e^{2x} c_5^2 + 2\,e^x c_5 - 1)\,e^{-x}}{2c_5}$$

Verified OK.

18.21.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 597: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \mathrm{e}^{-x} \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \mathrm{e}^{-x} \int \frac{1}{\mathrm{e}^{-2x}}\, dx \\ &= \mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{x}}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{e^{x}}{2}, e^{-x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 = 1$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + \frac{c_2 e^{x}}{2}\right) + (-1) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + \frac{c_2 e^{x}}{2} - 1 \tag{1}$$

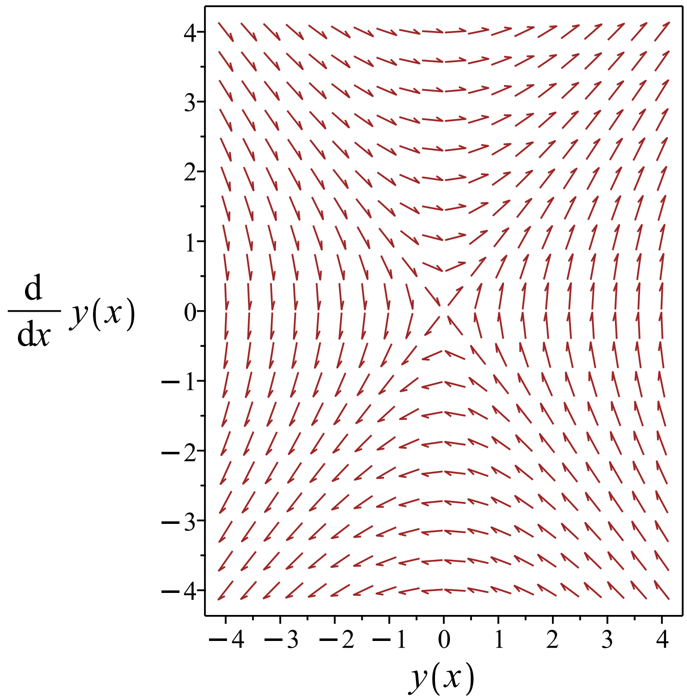

Figure 772: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + \frac{c_2 e^x}{2} - 1$$

Verified OK.

18.21.4 Maple step by step solution

Let's solve

$y'' - y = 1$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 1 = 0$

- Factor the characteristic polynomial

  $(r - 1)(r + 1) = 0$

- Roots of the characteristic polynomial

$r = (-1, 1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 1\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-x} & \mathrm{e}^{x} \\ -\mathrm{e}^{-x} & \mathrm{e}^{x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\frac{\mathrm{e}^{-x}\left(\int \mathrm{e}^{x} dx\right)}{2} + \frac{\mathrm{e}^{x}\left(\int \mathrm{e}^{-x} dx\right)}{2}$

  - Compute integrals

    $y_p(x) = -1$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} - 1$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - y = -2\cos(x)}$$

18.22.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = -1, f(x) = -2\cos(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)} \\ &= \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +1 \\ \lambda_2 &= -1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 \\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(1)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$y = \mathrm{e}^{x} c_1 + \mathrm{e}^{-x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{x} c_1 + \mathrm{e}^{-x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$-2\cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 \cos(x) - 2A_2 \sin(x) = -2\cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \cos(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{x} c_1 + e^{-x} c_2\right) + (\cos(x)) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = e^{x} c_1 + e^{-x} c_2 + \cos(x) \tag{1}$$

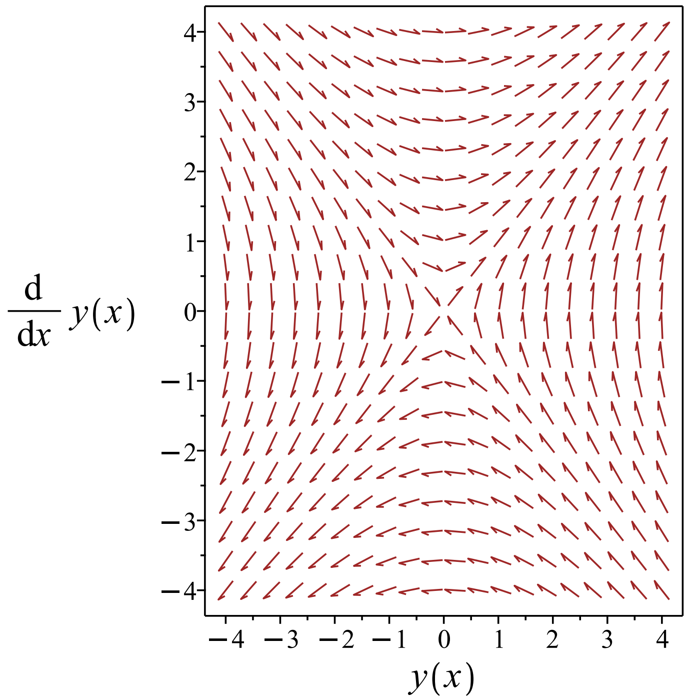

Figure 773: Slope field plot

Verification of solutions

$$y = e^x c_1 + e^{-x} c_2 + \cos(x)$$

Verified OK.

18.22.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 1$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 599: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \mathrm{e}^{-x} \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \mathrm{e}^{-x} \int \frac{1}{\mathrm{e}^{-2x}}\, dx \\ &= \mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{x}}{2}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
-2 \cos(x)
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\cos(x), \sin(x)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\frac{\mathrm{e}^{x}}{2}, \mathrm{e}^{-x}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 \cos(x) + A_2 \sin(x)
$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 \cos(x) - 2A_2 \sin(x) = -2\cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \cos(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{x}}{2}\right) + (\cos(x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{x}}{2} + \cos(x) \tag{1}$$

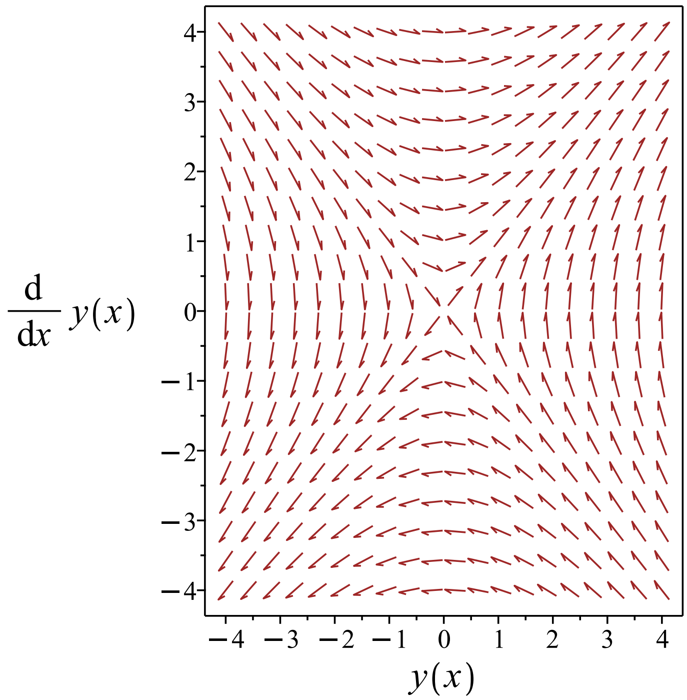

Figure 774: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + \frac{c_2 e^{x}}{2} + \cos(x)$$

Verified OK.

Problem number: 612.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

Unable to solve or complete the solution.

$$\boxed{y'' - 2y' + y = 4\,\mathrm{e}^{-x}}$$

With initial conditions

$$[y(\infty) = 0]$$

18.23.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned}p(x) &= -2\\ q(x) &= 1\\ F &= 4\,\mathrm{e}^{-x}\end{aligned}$$

Hence the ode is

$$y'' - 2y' + y = 4\,\mathrm{e}^{-x}$$

The domain of $p(x) = -2$ is

$$\{-\infty < x < \infty\}$$

But the point $x_0 = \infty$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

18.23.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 1, f(x) = 4\,\mathrm{e}^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 2\lambda\,\mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-2)^2 - (4)(1)(1)} \\ &= 1\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -1$. Therefore the solution is

$$y = c_1 \mathrm{e}^{x} + c_2 x\,\mathrm{e}^{x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{x} c_1 + x\,\mathrm{e}^{x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4\,\mathrm{e}^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\,\mathrm{e}^{x}, \mathrm{e}^{x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \mathrm{e}^{-x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1 \mathrm{e}^{-x} = 4\,\mathrm{e}^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \mathrm{e}^{-x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (\mathrm{e}^x c_1 + x\,\mathrm{e}^x c_2) + \left(\mathrm{e}^{-x}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^x (c_2 x + c_1) + \mathrm{e}^{-x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \mathrm{e}^x (c_2 x + c_1) + \mathrm{e}^{-x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = \infty$ in the above gives

$$0 = \operatorname{signum}(c_2)\,\infty \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

18.23.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int -2\,dx} \\ &= \mathrm{e}^{-x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= 4\,\mathrm{e}^{-2x} \\ \left(\mathrm{e}^{-x}y\right)'' &= 4\,\mathrm{e}^{-2x} \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{-x}y\right)' = -2\,\mathrm{e}^{-2x} + c_1$$

Integrating again gives

$$\left(\mathrm{e}^{-x}y\right) = c_1x + \mathrm{e}^{-2x} + c_2$$

Hence the solution is

$$y = \frac{c_1x + \mathrm{e}^{-2x} + c_2}{\mathrm{e}^{-x}}$$

Or

$$y = c_1x\,\mathrm{e}^{x} + c_2\mathrm{e}^{x} + \mathrm{e}^{-x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1x\,\mathrm{e}^{x} + c_2\mathrm{e}^{x} + \mathrm{e}^{-x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = \infty$ in the above gives

$$0 = \mathrm{signum}\,(c_1)\,\infty \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

<u>Verification of solutions</u> N/A

18.23.4 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 601: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx}
\end{aligned}$$

$$
\begin{aligned}
&= z_1 e^x \\
&= z_1(\mathrm{e}^x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^x
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{2x}}{(y_1)^2}\, dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2(\mathrm{e}^x(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^x c_1 + x\,\mathrm{e}^x c_2
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4\,\mathrm{e}^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\,\mathrm{e}^{x}, \mathrm{e}^{x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \mathrm{e}^{-x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1 \mathrm{e}^{-x} = 4\,\mathrm{e}^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \mathrm{e}^{-x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (\mathrm{e}^{x} c_1 + x\,\mathrm{e}^{x} c_2) + (\mathrm{e}^{-x}) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{x}(c_2 x + c_1) + \mathrm{e}^{-x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{x}(c_2 x + c_1) + e^{-x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = \infty$ in the above gives

$$0 = \text{signum}(c_2)\infty \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

18.23.5 Maple step by step solution

Let's solve

$[y'' - 2y' + y = 4\,e^{-x}, y(\infty) = 0]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 1 = 0$

- Factor the characteristic polynomial

  $(r-1)^2 = 0$

- Root of the characteristic polynomial

  $r = 1$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^{x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{x} c_1 + x\,e^{x} c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $$\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 4\,\mathrm{e}^{-x}\right]$$

- Wronskian of solutions of the homogeneous equation

  $$W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^x & x\,\mathrm{e}^x \\ \mathrm{e}^x & x\,\mathrm{e}^x + \mathrm{e}^x \end{bmatrix}$$

- Compute Wronskian

  $$W(y_1(x), y_2(x)) = \mathrm{e}^{2x}$$

- Substitute functions into equation for $y_p(x)$

  $$y_p(x) = -4\,\mathrm{e}^x\left(\int x\,\mathrm{e}^{-2x}dx - \left(\int \mathrm{e}^{-2x}dx\right)x\right)$$

- Compute integrals

  $$y_p(x) = \mathrm{e}^{-x}$$

- Substitute particular solution into general solution to ODE

  $$y = \mathrm{e}^x c_1 + x\,\mathrm{e}^x c_2 + \mathrm{e}^{-x}$$

Problem number: 613.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

Unable to solve or complete the solution.

$$\boxed{y'' + 4y' + 3y = 8\,\mathrm{e}^{x} + 9}$$

With initial conditions

$$[y(-\infty) = 3]$$

18.24.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 4 \\ q(x) &= 3 \\ F &= 8\,\mathrm{e}^{x} + 9 \end{aligned}$$

Hence the ode is

$$y'' + 4y' + 3y = 8\,\mathrm{e}^{x} + 9$$

The domain of $p(x) = 4$ is

$$\{-\infty < x < \infty\}$$

But the point $x_0 = -\infty$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

18.24.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 4, C = 3, f(x) = 8\,\mathrm{e}^{x} + 9$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 3y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 4, C = 3$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 4\lambda\,\mathrm{e}^{\lambda x} + 3\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4\lambda + 3 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 4, C = 3$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-4}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{4^2 - (4)(1)(3)} \\ &= -2 \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -2 + 1 \\ \lambda_2 &= -2 - 1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 \\ \lambda_2 &= -3\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(-1)x} + c_2 e^{(-3)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{-3x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{-3x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8\,\mathrm{e}^{x} + 9$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{\mathrm{e}^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-3x}, \mathrm{e}^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 + A_2 e^x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$8A_2 e^x + 3A_1 = 8\,e^x + 9$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 3, A_2 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3 + e^x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2 e^{-3x}\right) + \left(3 + e^x\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{-x} + c_2 e^{-3x} + 3 + e^x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = -\infty$ in the above gives

$$3 = \operatorname{signum}(c_2)\,\infty \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

18.24.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y' + 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4 \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 603: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-x}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{4}{1} \, dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{-2x} \\
&= z_1 \left(\mathrm{e}^{-2x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-3x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{\mathrm{e}^{-4x}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\mathrm{e}^{2x}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-3x}\right) + c_2 \left(\mathrm{e}^{-3x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 4y' + 3y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-3x} + \frac{\mathrm{e}^{-x} c_2}{2}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8\,\mathrm{e}^{x}+9$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\},\{\mathrm{e}^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\mathrm{e}^{-x}}{2},\mathrm{e}^{-3x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 + A_2\mathrm{e}^{x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$8A_2\mathrm{e}^{x} + 3A_1 = 8\,\mathrm{e}^{x}+9$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 3, A_2 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 3+\mathrm{e}^{x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-3x} + \frac{\mathrm{e}^{-x}c_2}{2}\right) + (3+\mathrm{e}^{x}) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{-3x} + \frac{e^{-x} c_2}{2} + 3 + e^{x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = -\infty$ in the above gives

$$3 = \operatorname{signum}(c_1)\,\infty \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

18.24.4 Maple step by step solution

Let's solve

$[y'' + 4y' + 3y = 8\,e^{x} + 9, y(-\infty) = 3]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4r + 3 = 0$

- Factor the characteristic polynomial

  $(r + 3)(r + 1) = 0$

- Roots of the characteristic polynomial

  $r = (-3, -1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-3x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-3x} + e^{-x} c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $$\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 8\,\mathrm{e}^x + 9\right]$$

- Wronskian of solutions of the homogeneous equation

  $$W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-3x} & \mathrm{e}^{-x} \\ -3\,\mathrm{e}^{-3x} & -\mathrm{e}^{-x} \end{bmatrix}$$

- Compute Wronskian

  $$W(y_1(x), y_2(x)) = 2\,\mathrm{e}^{-4x}$$

- Substitute functions into equation for $y_p(x)$

  $$y_p(x) = -\frac{\mathrm{e}^{-3x}\left(\int (8\,\mathrm{e}^x+9)\mathrm{e}^{3x}dx\right)}{2} + \frac{\mathrm{e}^{-x}\left(\int \left(8(\mathrm{e}^x)^2+9\,\mathrm{e}^x\right)dx\right)}{2}$$

- Compute integrals

  $$y_p(x) = 3 + \mathrm{e}^x$$

- Substitute particular solution into general solution to ODE

  $$y = c_1\mathrm{e}^{-3x} + \mathrm{e}^{-x}c_2 + 3 + \mathrm{e}^x$$

Problem number: 614.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

Unable to solve or complete the solution.

$$\boxed{y'' - y' - 5y = 1}$$

With initial conditions

$$\left[y(\infty) = -\frac{1}{5}\right]$$

18.25.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -1 \\ q(x) &= -5 \\ F &= 1 \end{aligned}$$

Hence the ode is

$$y'' - y' - 5y = 1$$

The domain of $p(x) = -1$ is

$$\{-\infty < x < \infty\}$$

But the point $x_0 = \infty$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

18.25.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -1, C = -5, f(x) = 1$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' - 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -1, C = -5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - \lambda \,\mathrm{e}^{\lambda x} - 5 \,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \lambda - 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -1, C = -5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{1}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-1^2 - (4)(1)(-5)} \\ &= \frac{1}{2} \pm \frac{\sqrt{21}}{2}\end{aligned}$$

Hence

$$\lambda_1 = \frac{1}{2} + \frac{\sqrt{21}}{2}$$
$$\lambda_2 = \frac{1}{2} - \frac{\sqrt{21}}{2}$$

Which simplifies to

$$\lambda_1 = \frac{1}{2} + \frac{\sqrt{21}}{2}$$
$$\lambda_2 = \frac{1}{2} - \frac{\sqrt{21}}{2}$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{\left(\frac{1}{2}+\frac{\sqrt{21}}{2}\right)x} + c_2 e^{\left(\frac{1}{2}-\frac{\sqrt{21}}{2}\right)x}$$

Or

$$y = c_1 \mathrm{e}^{\left(\frac{1}{2}+\frac{\sqrt{21}}{2}\right)x} + c_2 \mathrm{e}^{\left(\frac{1}{2}-\frac{\sqrt{21}}{2}\right)x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{\left(\frac{1}{2}+\frac{\sqrt{21}}{2}\right)x} + c_2 \mathrm{e}^{\left(\frac{1}{2}-\frac{\sqrt{21}}{2}\right)x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{ e^{\left(\frac{1}{2}-\frac{\sqrt{21}}{2}\right)x}, e^{\left(\frac{1}{2}+\frac{\sqrt{21}}{2}\right)x} \right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-5A_1 = 1$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{5}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{1}{5}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{\left(\frac{1}{2}+\frac{\sqrt{21}}{2}\right)x} + c_2 e^{\left(\frac{1}{2}-\frac{\sqrt{21}}{2}\right)x}\right) + \left(-\frac{1}{5}\right) \end{aligned}$$

Which simplifies to

$$y = c_1 e^{\frac{\left(1+\sqrt{21}\right)x}{2}} + c_2 e^{-\frac{\left(-1+\sqrt{21}\right)x}{2}} - \frac{1}{5}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{\frac{\left(1+\sqrt{21}\right)x}{2}} + c_2 \mathrm{e}^{-\frac{\left(-1+\sqrt{21}\right)x}{2}} - \frac{1}{5} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -\frac{1}{5}$ and $x = \infty$ in the above gives

$$-\frac{1}{5} = \mathrm{signum}\left(c_1\right) \infty \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

18.25.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y' - 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -1 \\ C &= -5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{21}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 21 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{21z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 605: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{21}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = e^{-\frac{x\sqrt{21}}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-1}{1}\,dx} \\
&= z_1 e^{\frac{x}{2}} \\
&= z_1 \left(e^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = e^{-\frac{\left(-1+\sqrt{21}\right)x}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\sqrt{21}\, e^{x\sqrt{21}}}{21}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{\left(-1+\sqrt{21}\right)x}{2}}\right) + c_2 \left(\mathrm{e}^{-\frac{\left(-1+\sqrt{21}\right)x}{2}} \left(\frac{\sqrt{21}\,\mathrm{e}^{x\sqrt{21}}}{21}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - y' - 5y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-\frac{\left(-1+\sqrt{21}\right)x}{2}} + \frac{c_2 \sqrt{21}\,\mathrm{e}^{\frac{\left(1+\sqrt{21}\right)x}{2}}}{21}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
1
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{1\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\frac{\sqrt{21}\,\mathrm{e}^{\frac{\left(1+\sqrt{21}\right)x}{2}}}{21}, \mathrm{e}^{-\frac{\left(-1+\sqrt{21}\right)x}{2}}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1
$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-5A_1 = 1$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{5}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{1}{5}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-\frac{\left(-1+\sqrt{21}\right)x}{2}} + \frac{c_2\sqrt{21}\,\mathrm{e}^{\frac{\left(1+\sqrt{21}\right)x}{2}}}{21}\right) + \left(-\frac{1}{5}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{-\frac{\left(-1+\sqrt{21}\right)x}{2}} + \frac{c_2\sqrt{21}\,\mathrm{e}^{\frac{\left(1+\sqrt{21}\right)x}{2}}}{21} - \frac{1}{5} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -\frac{1}{5}$ and $x = \infty$ in the above gives

$$-\frac{1}{5} = \operatorname{signum}(c_2)\,\infty \tag{1A}$$

Equations $\{1\text{A}\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

18.25.4 Maple step by step solution

Let's solve

$\left[y'' - y' - 5y = 1, y(\infty) = -\frac{1}{5}\right]$

- Highest derivative means the order of the ODE is 2

y''

- Characteristic polynomial of homogeneous ODE

$r^2 - r - 5 = 0$

- Use quadratic formula to solve for r

$r = \frac{1 \pm \left(\sqrt{21}\right)}{2}$

- Roots of the characteristic polynomial

$r = \left(\frac{1}{2} - \frac{\sqrt{21}}{2}, \frac{1}{2} + \frac{\sqrt{21}}{2}\right)$

- 1st solution of the homogeneous ODE

$y_1(x) = e^{\left(\frac{1}{2} - \frac{\sqrt{21}}{2}\right)x}$

- 2nd solution of the homogeneous ODE

$y_2(x) = e^{\left(\frac{1}{2} + \frac{\sqrt{21}}{2}\right)x}$

- General solution of the ODE

$y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

$y = c_1 e^{\left(\frac{1}{2} - \frac{\sqrt{21}}{2}\right)x} + c_2 e^{\left(\frac{1}{2} + \frac{\sqrt{21}}{2}\right)x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 1\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{\left(\frac{1}{2} - \frac{\sqrt{21}}{2}\right)x} & e^{\left(\frac{1}{2} + \frac{\sqrt{21}}{2}\right)x} \\ \left(\frac{1}{2} - \frac{\sqrt{21}}{2}\right) e^{\left(\frac{1}{2} - \frac{\sqrt{21}}{2}\right)x} & \left(\frac{1}{2} + \frac{\sqrt{21}}{2}\right) e^{\left(\frac{1}{2} + \frac{\sqrt{21}}{2}\right)x} \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = \sqrt{21}\, e^x$

- Substitute functions into equation for $y_p(x)$

$$y_p(x) = \frac{\sqrt{21}\left(-\mathrm{e}^{-\frac{(-1+\sqrt{21})x}{2}}\left(\int \mathrm{e}^{\frac{(-1+\sqrt{21})x}{2}}dx\right)+\mathrm{e}^{\frac{(1+\sqrt{21})x}{2}}\left(\int \mathrm{e}^{-\frac{(1+\sqrt{21})x}{2}}dx\right)\right)}{21}$$

- Compute integrals

$$y_p(x) = -\frac{1}{5}$$

- Substitute particular solution into general solution to ODE

$$y = c_1\mathrm{e}^{\left(\frac{1}{2}-\frac{\sqrt{21}}{2}\right)x} + c_2\mathrm{e}^{\left(\frac{1}{2}+\frac{\sqrt{21}}{2}\right)x} - \frac{1}{5}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

Unable to solve or complete the solution.

$$\boxed{y'' + 4y' + 4y = 2\,\mathrm{e}^{x}(\sin(x) + 7\cos(x))}$$

With initial conditions

$$[y(-\infty) = 0]$$

18.26.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 4 \\ q(x) &= 4 \\ F &= 2\,\mathrm{e}^{x}(\sin(x) + 7\cos(x)) \end{aligned}$$

Hence the ode is

$$y'' + 4y' + 4y = 2\,\mathrm{e}^{x}(\sin(x) + 7\cos(x))$$

The domain of $p(x) = 4$ is

$$\{-\infty < x < \infty\}$$

But the point $x_0 = -\infty$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

18.26.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 4, C = 4, f(x) = (2\sin(x) + 14\cos(x))\,\mathrm{e}^{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 4, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 4\lambda\,\mathrm{e}^{\lambda x} + 4\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4\lambda + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 4, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-4}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(4)^2 - (4)(1)(4)}\\ &= -2\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 2$. Therefore the solution is

$$y = c_1 \mathrm{e}^{-2x} + c_2 x\,\mathrm{e}^{-2x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{-2x} + c_2 x\,\mathrm{e}^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$(2\sin(x) + 14\cos(x))\,\mathrm{e}^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{x}\cos(x), \mathrm{e}^{x}\sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\,\mathrm{e}^{-2x}, \mathrm{e}^{-2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\mathrm{e}^{x}\cos(x) + A_2\mathrm{e}^{x}\sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-6A_1\mathrm{e}^{x}\sin(x)+6A_2\mathrm{e}^{x}\cos(x)+8A_1\mathrm{e}^{x}\cos(x)+8A_2\mathrm{e}^{x}\sin(x)=(2\sin(x)+14\cos(x))\,\mathrm{e}^{x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \mathrm{e}^{x}\sin(x) + \mathrm{e}^{x}\cos(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-2x} + c_2x\,\mathrm{e}^{-2x}\right) + \left(\mathrm{e}^{x}\sin(x) + \mathrm{e}^{x}\cos(x)\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{-2x}(c_2x + c_1) + \mathrm{e}^{x}\sin(x) + \mathrm{e}^{x}\cos(x)$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \mathrm{e}^{-2x}(c_2x + c_1) + \mathrm{e}^{x}\sin(x) + \mathrm{e}^{x}\cos(x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = -\infty$ in the above gives

$$0 = -\operatorname{signum}(c_2)\,\infty \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

18.26.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = 4$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2} \int p \, dx} \\ &= e^{\int 4 \, dx} \\ &= \mathrm{e}^{2x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x) y)'' &= \mathrm{e}^{2x} (2 \sin(x) + 14 \cos(x))\, \mathrm{e}^{x} \\ \left(\mathrm{e}^{2x} y\right)'' &= \mathrm{e}^{2x} (2 \sin(x) + 14 \cos(x))\, \mathrm{e}^{x} \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{2x} y\right)' = (2 \sin(x) + 4 \cos(x))\, \mathrm{e}^{3x} + c_1$$

Integrating again gives

$$\left(\mathrm{e}^{2x} y\right) = (\sin(x) + \cos(x))\, \mathrm{e}^{3x} + c_1 x + c_2$$

Hence the solution is

$$y = \frac{(\sin(x) + \cos(x))\, \mathrm{e}^{3x} + c_1 x + c_2}{\mathrm{e}^{2x}}$$

Or

$$y = \cos(x)\, \mathrm{e}^{x} + \mathrm{e}^{x} \sin(x) + c_1 x\, \mathrm{e}^{-2x} + \mathrm{e}^{-2x} c_2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \cos(x)\, \mathrm{e}^{x} + \mathrm{e}^{x} \sin(x) + c_1 x\, \mathrm{e}^{-2x} + \mathrm{e}^{-2x} c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = -\infty$ in the above gives

$$0 = -\operatorname{signum}(c_1)\infty \tag{1A}$$

Equations {1A} are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

18.26.4 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 0 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = 0 \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) e^{-\int \frac{B}{2A} dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 607: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4}{1}\,dx} \\ &= z_1 e^{-2x} \\ &= z_1\left(\mathrm{e}^{-2x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{4}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-4x}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-2x}\right) + c_2\left(\mathrm{e}^{-2x}(x)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+4y'+4y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{-2x} + c_2 x\, e^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2\, e^x(\sin(x)+7\cos(x))$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x)\, e^x, e^x \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{-2x}, e^{-2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x)\, e^x + A_2 e^x \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-6A_1 \sin(x)\, e^x + 6A_2 e^x \cos(x) + 8A_1 \cos(x)\, e^x + 8A_2 e^x \sin(x) = (2\sin(x)+14\cos(x))\, e^x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = e^x \sin(x) + \cos(x)\, e^x$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \mathrm{e}^{-2x} + c_2 x\,\mathrm{e}^{-2x}\right) + \left(\mathrm{e}^{x} \sin(x) + \cos(x)\,\mathrm{e}^{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y = \mathrm{e}^{-2x}(c_2 x + c_1) + \mathrm{e}^{x} \sin(x) + \cos(x)\,\mathrm{e}^{x}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \mathrm{e}^{-2x}(c_2 x + c_1) + \mathrm{e}^{x} \sin(x) + \cos(x)\,\mathrm{e}^{x} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = -\infty$ in the above gives

$$
0 = -\operatorname{signum}(c_2)\,\infty \tag{1A}
$$

Equations $\{1\mathrm{A}\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

18.26.5 Maple step by step solution

Let's solve

$[y'' + 4y' + 4y = (2\sin(x) + 14\cos(x))\,\mathrm{e}^{x}, y(-\infty) = 0]$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -4y + 2\,\mathrm{e}^{x} \sin(x) + 14\cos(x)\,\mathrm{e}^{x} - 4y'$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + 4y' + 4y = 2\,\mathrm{e}^{x}(\sin(x) + 7\cos(x))$

- Characteristic polynomial of homogeneous ODE

$r^2 + 4r + 4 = 0$

- Factor the characteristic polynomial

  $(r+2)^2 = 0$

- Root of the characteristic polynomial

  $r = -2$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-2x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,\mathrm{e}^{-2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-2x} + c_2 x\,\mathrm{e}^{-2x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 2\,\mathrm{e}^{x}(\sin(x) + 7\cos(x))\right.$

  ◦ Wronskian of solutions of the homogeneous equation

  $$W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-2x} & x\,\mathrm{e}^{-2x} \\ -2\,\mathrm{e}^{-2x} & \mathrm{e}^{-2x} - 2x\,\mathrm{e}^{-2x} \end{bmatrix}$$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = \mathrm{e}^{-4x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = 2\,\mathrm{e}^{-2x}\left(-\left(\int x(\sin(x) + 7\cos(x))\,\mathrm{e}^{3x} dx\right) + x\left(\int \mathrm{e}^{3x}(\sin(x) + 7\cos(x))\, dx\right)\right)$

  ◦ Compute integrals

  $y_p(x) = \mathrm{e}^{x}(\sin(x) + \cos(x))$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-2x} + c_2 x\,\mathrm{e}^{-2x} + \mathrm{e}^{x}(\sin(x) + \cos(x))$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

Unable to solve or complete the solution.

$$y'' - 5y' + 6y = 2\,\mathrm{e}^{-2x}(9\sin(2x) + 4\cos(2x))$$

With initial conditions

$$[y(\infty) = 0]$$

18.27.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -5 \\ q(x) &= 6 \\ F &= 2\,\mathrm{e}^{-2x}(9\sin(2x) + 4\cos(2x)) \end{aligned}$$

Hence the ode is

$$y'' - 5y' + 6y = 2\,\mathrm{e}^{-2x}(9\sin(2x) + 4\cos(2x))$$

The domain of $p(x) = -5$ is

$$\{-\infty < x < \infty\}$$

But the point $x_0 = \infty$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

18.27.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -5, C = 6, f(x) = (18\sin(2x) + 8\cos(2x))\,\mathrm{e}^{-2x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 5y' + 6y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -5, C = 6$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 5\lambda\,\mathrm{e}^{\lambda x} + 6\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 5\lambda + 6 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -5, C = 6$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{5}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-5^2 - (4)(1)(6)}\\ &= \frac{5}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= \frac{5}{2} + \frac{1}{2}\\ \lambda_2 &= \frac{5}{2} - \frac{1}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 3\\ \lambda_2 &= 2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(3)x} + c_2 e^{(2)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{3x} + \mathrm{e}^{2x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{3x} + \mathrm{e}^{2x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$(18 \sin(2x) + 8 \cos(2x))\, \mathrm{e}^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{-2x} \cos(2x), \mathrm{e}^{-2x} \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{2x}, \mathrm{e}^{3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{-2x} \cos(2x) + A_2 e^{-2x} \sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$18A_1 e^{-2x} \sin(2x) - 18A_2 e^{-2x} \cos(2x) + 16A_1 e^{-2x} \cos(2x) + 16A_2 e^{-2x} \sin(2x) \\ = (18 \sin(2x) + 8 \cos(2x)) e^{-2x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{113}{145}, A_2 = \frac{36}{145}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{113 e^{-2x} \cos(2x)}{145} + \frac{36 e^{-2x} \sin(2x)}{145}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 e^{3x} + e^{2x} c_2) + \left(\frac{113 e^{-2x} \cos(2x)}{145} + \frac{36 e^{-2x} \sin(2x)}{145}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{3x} + e^{2x} c_2 + \frac{113 e^{-2x} \cos(2x)}{145} + \frac{36 e^{-2x} \sin(2x)}{145} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = \infty$ in the above gives

$$0 = \operatorname{signum}(c_1) \infty \tag{1A}$$

Equations {1A} are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

18.27.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 5y' + 6y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -5 \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 609: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-\frac{x}{2}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-5}{1}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{\frac{5x}{2}} \\
&= z_1 \left(\mathrm{e}^{\frac{5x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-5}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{5x}}{(y_1)^2}\, dx \\
&= y_1(\mathrm{e}^{x})
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{2x}\right) + c_2 \left(\mathrm{e}^{2x}(\mathrm{e}^{x})\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 5y' + 6y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^{2x} c_1 + c_2 \mathrm{e}^{3x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2\,\mathrm{e}^{-2x}(9\sin(2x)+4\cos(2x))$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{-2x}\cos(2x)\,,\mathrm{e}^{-2x}\sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{2x},\mathrm{e}^{3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\mathrm{e}^{-2x}\cos(2x) + A_2\mathrm{e}^{-2x}\sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&18A_1\mathrm{e}^{-2x}\sin(2x) - 18A_2\mathrm{e}^{-2x}\cos(2x) + 16A_1\mathrm{e}^{-2x}\cos(2x) + 16A_2\mathrm{e}^{-2x}\sin(2x)\\ &= (18\sin(2x)+8\cos(2x))\,\mathrm{e}^{-2x}\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1=\frac{113}{145}, A_2=\frac{36}{145}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{113\,\mathrm{e}^{-2x}\cos(2x)}{145} + \frac{36\,\mathrm{e}^{-2x}\sin(2x)}{145}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\ &= \left(\mathrm{e}^{2x}c_1 + c_2\mathrm{e}^{3x}\right) + \left(\frac{113\,\mathrm{e}^{-2x}\cos(2x)}{145} + \frac{36\,\mathrm{e}^{-2x}\sin(2x)}{145}\right)\end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{2x}c_1 + c_2 e^{3x} + \frac{113\,e^{-2x}\cos(2x)}{145} + \frac{36\,e^{-2x}\sin(2x)}{145} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = \infty$ in the above gives

$$0 = \text{signum}(c_2)\,\infty \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

18.27.4 Maple step by step solution

Let's solve

$[y'' - 5y' + 6y = (18\sin(2x) + 8\cos(2x))\,e^{-2x}, y(\infty) = 0]$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -6y + 8\,e^{-2x}\cos(2x) + 18\,e^{-2x}\sin(2x) + 5y'$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - 5y' + 6y = 2\,e^{-2x}(9\sin(2x) + 4\cos(2x))$

- Characteristic polynomial of homogeneous ODE

  $r^2 - 5r + 6 = 0$

- Factor the characteristic polynomial

  $(r - 2)(r - 3) = 0$

- Roots of the characteristic polynomial

  $r = (2, 3)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{2x}$

- 2nd solution of the homogeneous ODE

$y_2(x) = e^{3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{2x} c_1 + c_2 e^{3x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 2\,e^{-2x}(9 \sin(2x) + 4\,\mathrm{co}\right.$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{2x} & e^{3x} \\ 2\,e^{2x} & 3\,e^{3x} \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{5x}$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -2\,e^{2x} \left(\int (9 \sin(2x) + 4 \cos(2x))\, e^{-4x} dx\right) + 2\,e^{3x} \left(\int (9 \sin(2x) + 4 \cos(2x))\, e^{-5x} dx\right)$

- ○ Compute integrals

  $y_p(x) = \frac{e^{-2x}(113 \cos(2x) + 36 \sin(2x))}{145}$

- Substitute particular solution into general solution to ODE

  $y = e^{2x} c_1 + c_2 e^{3x} + \frac{e^{-2x}(113 \cos(2x) + 36 \sin(2x))}{145}$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

Unable to solve or complete the solution.

$$\boxed{y'' - 4y' + 4y = \mathrm{e}^{-x}\left(9x^2 + 5x - 12\right)}$$

With initial conditions

$$[y(\infty) = 0]$$

18.28.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -4 \\ q(x) &= 4 \\ F &= \mathrm{e}^{-x}\left(9x^2 + 5x - 12\right) \end{aligned}$$

Hence the ode is

$$y'' - 4y' + 4y = \mathrm{e}^{-x}\left(9x^2 + 5x - 12\right)$$

The domain of $p(x) = -4$ is

$$\{-\infty < x < \infty\}$$

But the point $x_0 = \infty$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

18.28.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 4, f(x) = \mathrm{e}^{-x}(9x^2 + 5x - 12)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 4\lambda\,\mathrm{e}^{\lambda x} + 4\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-4)^2 - (4)(1)(4)}\\ &= 2\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -2$. Therefore the solution is

$$y = c_1 e^{2x} + c_2 x\, e^{2x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = e^{2x} c_1 + c_2 x\, e^{2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{-x}\left(9x^2 + 5x - 12\right)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\, e^{-x}, e^{-x} x^2, e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{2x}, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\, e^{-x} + A_2 e^{-x} x^2 + A_3 e^{-x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-6A_1\mathrm{e}^{-x} + 9A_1x\,\mathrm{e}^{-x} + 9A_2\mathrm{e}^{-x}x^2 - 12A_2\mathrm{e}^{-x}x + 2A_2\mathrm{e}^{-x} + 9A_3\mathrm{e}^{-x} = \mathrm{e}^{-x}\left(9x^2 + 5x - 12\right)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{17}{9}, A_2 = 1, A_3 = -\frac{8}{27}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{17x\,\mathrm{e}^{-x}}{9} + \mathrm{e}^{-x}x^2 - \frac{8\,\mathrm{e}^{-x}}{27}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{2x}c_1 + c_2x\,\mathrm{e}^{2x}\right) + \left(\frac{17x\,\mathrm{e}^{-x}}{9} + \mathrm{e}^{-x}x^2 - \frac{8\,\mathrm{e}^{-x}}{27}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{2x}(c_2x + c_1) + \frac{17x\,\mathrm{e}^{-x}}{9} + \mathrm{e}^{-x}x^2 - \frac{8\,\mathrm{e}^{-x}}{27}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \mathrm{e}^{2x}(c_2x + c_1) + \frac{17x\,\mathrm{e}^{-x}}{9} + \mathrm{e}^{-x}x^2 - \frac{8\,\mathrm{e}^{-x}}{27} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = \infty$ in the above gives

$$0 = \mathrm{signum}\left(c_2\right)\infty \tag{1A}$$

Equations $\{1\mathrm{A}\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

<u>Verification of solutions</u> N/A

18.28.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^{2} + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -4$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p \, dx} \\ &= e^{\int -4 \, dx} \\ &= \mathrm{e}^{-2x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} \left(M(x) y\right)'' &= \mathrm{e}^{-2x} \mathrm{e}^{-x} \left(9x^{2} + 5x - 12\right) \\ \left(\mathrm{e}^{-2x} y\right)'' &= \mathrm{e}^{-2x} \mathrm{e}^{-x} \left(9x^{2} + 5x - 12\right) \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{-2x} y\right)' = -\frac{\mathrm{e}^{-3x} \left(27x^{2} + 33x - 25\right)}{9} + c_1$$

Integrating again gives

$$\left(\mathrm{e}^{-2x} y\right) = \frac{\left(27x^{2} + 51x - 8\right) \mathrm{e}^{-3x}}{27} + c_1 x + c_2$$

Hence the solution is

$$y = \frac{\frac{\left(27x^{2} + 51x - 8\right) \mathrm{e}^{-3x}}{27} + c_1 x + c_2}{\mathrm{e}^{-2x}}$$

Or

$$y = c_1 x \,\mathrm{e}^{2x} + \mathrm{e}^{2x} c_2 + \mathrm{e}^{-x} x^{2} + \frac{17x \,\mathrm{e}^{-x}}{9} - \frac{8 \,\mathrm{e}^{-x}}{27}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 x \,\mathrm{e}^{2x} + \mathrm{e}^{2x} c_2 + \mathrm{e}^{-x} x^{2} + \frac{17x \,\mathrm{e}^{-x}}{9} - \frac{8 \,\mathrm{e}^{-x}}{27} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = \infty$ in the above gives

$$0 = \text{signum}\left(c_1\right)\infty \tag{1A}$$

Equations {1A} are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

18.28.4 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 611: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx} \\
&= z_1 e^{2x} \\
&= z_1 \left(\mathrm{e}^{2x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{4x}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{2x}\right) + c_2 \left(\mathrm{e}^{2x}(x)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''-4y'+4y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = e^{2x}c_1 + c_2 x\,e^{2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{-x}\left(9x^2+5x-12\right)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^{-x}, e^{-x}x^2, e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\,e^{2x}, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1x\,e^{-x} + A_2e^{-x}x^2 + A_3e^{-x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-6A_1e^{-x}+9A_1x\,e^{-x}+9A_2e^{-x}x^2-12A_2e^{-x}x+2A_2e^{-x}+9A_3e^{-x}=e^{-x}\left(9x^2+5x-12\right)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1=\frac{17}{9}, A_2=1, A_3=-\frac{8}{27}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{17x\,e^{-x}}{9}+e^{-x}x^2-\frac{8\,e^{-x}}{27}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(e^{2x} c_1 + c_2 x\, e^{2x}\right) + \left(\frac{17x\, e^{-x}}{9} + e^{-x} x^2 - \frac{8\, e^{-x}}{27}\right)
\end{aligned}
$$

Which simplifies to

$$
y = e^{2x}(c_2 x + c_1) + \frac{17x\, e^{-x}}{9} + e^{-x} x^2 - \frac{8\, e^{-x}}{27}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = e^{2x}(c_2 x + c_1) + \frac{17x\, e^{-x}}{9} + e^{-x} x^2 - \frac{8\, e^{-x}}{27} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = \infty$ in the above gives

$$
0 = \operatorname{signum}(c_2)\, \infty \tag{1A}
$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

18.28.5 Maple step by step solution

Let's solve

$\left[y'' - 4y' + 4y = e^{-x}(9x^2 + 5x - 12), y(\infty) = 0\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 4r + 4 = 0$

- Factor the characteristic polynomial

  $(r - 2)^2 = 0$

- Root of the characteristic polynomial

  $r = 2$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{2x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{2x} c_1 + c_2 x\,e^{2x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = e^{-x}(9x^2 + 5x - 12)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{2x} & x\,e^{2x} \\ 2\,e^{2x} & e^{2x} + 2x\,e^{2x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = e^{4x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = e^{2x}\left(-\left(\int x\,e^{-3x}(9x^2 + 5x - 12)\,dx\right) + \left(\int e^{-3x}(9x^2 + 5x - 12)\,dx\right)x\right)$

  - Compute integrals

    $y_p(x) = \frac{e^{-x}(27x^2 + 51x - 8)}{27}$

- Substitute particular solution into general solution to ODE

  $y = e^{2x} c_1 + c_2 x\,e^{2x} + \frac{e^{-x}(27x^2 + 51x - 8)}{27}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "exact linear second order ode", "second_order_integrable_as_is", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{x^2y'' + xy' - y = 0}$$

19.1.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + xrx^{r-1} - x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + r\,x^r - x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + r - 1 = 0$$

Or

$$r^2 - 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= -1 \\ r_2 &= 1 \end{aligned}$$

Since the roots are real and distinct, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = \frac{c_1}{x} + c_2 x$$

Summary
The solution(s) found are the following

$$y = \frac{c_1}{x} + c_2 x \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x} + c_2 x$$

Verified OK.

19.1.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2y'' + xy' - y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= -\frac{1}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\ &= \int \mathrm{e}^{-\left(\int \frac{1}{x}dx\right)}dx \\ &= \int e^{-\ln(x)}\,dx \\ &= \int \frac{1}{x}dx \\ &= \ln(x) \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned} q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{-\frac{1}{x^2}}{\frac{1}{x^2}} \\ &= -1 \end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned} \frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) - y(\tau) &= 0 \end{aligned}$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda\tau} - \mathrm{e}^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned} \lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)} \\ &= \pm 1 \end{aligned}$$

Hence

$$\begin{aligned} \lambda_1 &= +1 \\ \lambda_2 &= -1 \end{aligned}$$

Which simplifies to

$$\lambda_1 = 1$$
$$\lambda_2 = -1$$

Since roots are real and distinct, then the solution is

$$y(\tau) = c_1 e^{\lambda_1 \tau} + c_2 e^{\lambda_2 \tau}$$
$$y(\tau) = c_1 e^{(1)\tau} + c_2 e^{(-1)\tau}$$

Or

$$y(\tau) = c_1 \mathrm{e}^{\tau} + c_2 \mathrm{e}^{-\tau}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 x^2 + c_2}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 x^2 + c_2}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x^2 + c_2}{x}$$

Verified OK.

19.1.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2 y'' + x y' - y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = -\frac{1}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{-\frac{1}{x^2}}}{c} \\ \tau'' &= \frac{1}{c\sqrt{-\frac{1}{x^2}}\,x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{\frac{1}{c\sqrt{-\frac{1}{x^2}}\,x^3} + \frac{1}{x}\frac{\sqrt{-\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{-\frac{1}{x^2}}}{c}\right)^2} \\ &= 0 \end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned} y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0 \end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{-\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{-\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = \frac{(ic_2 + c_1)\,x^2 - ic_2 + c_1}{2x}
$$

Summary

The solution(s) found are the following

$$
y = \frac{(ic_2 + c_1)\,x^2 - ic_2 + c_1}{2x} \tag{1}
$$

Verification of solutions

$$
y = \frac{(ic_2 + c_1)\,x^2 - ic_2 + c_1}{2x}
$$

Verified OK.

19.1.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$
x^2y'' + xy' - y = 0 \tag{1}
$$

Becomes

$$
y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= \frac{1}{x} \\
q(x) &= -\frac{1}{x^2}
\end{aligned}
$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$
v''(x) + \left(\frac{2n}{x} + p\right)v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right)v(x) = 0 \tag{3}
$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n}{x^2} - \frac{1}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{3v'(x)}{x} &= 0 \\ v''(x) + \frac{3v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{3u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{3u}{x} \end{aligned}$$

Where $f(x) = -\frac{3}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{3}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{3}{x}\,dx \\ \ln(u) &= -3\ln(x) + c_1 \\ u &= \mathrm{e}^{-3\ln(x)+c_1} \\ &= \frac{c_1}{x^3} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= -\frac{c_1}{2x^2} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\,x^n \\
&= \left(-\frac{c_1}{2x^2} + c_2\right) x \\
&= \left(-\frac{c_1}{2x^2} + c_2\right) x
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(-\frac{c_1}{2x^2} + c_2\right) x \tag{1}$$

Verification of solutions

$$y = \left(-\frac{c_1}{2x^2} + c_2\right) x$$

Verified OK.

19.1.5 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\begin{aligned}
\int (x^2y'' + xy' - y)\,dx &= 0 \\
x^2y' - yx &= c_1
\end{aligned}$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= \frac{c_1}{x^2}
\end{aligned}$$

Hence the ode is

$$y' - \frac{y}{x} = \frac{c_1}{x^2}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{1}{x}dx} \\ &= \frac{1}{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{c_1}{x^2}\right) \\ \frac{d}{dx}\left(\frac{y}{x}\right) &= \left(\frac{1}{x}\right)\left(\frac{c_1}{x^2}\right) \\ d\left(\frac{y}{x}\right) &= \left(\frac{c_1}{x^3}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{y}{x} &= \int \frac{c_1}{x^3}\,dx \\ \frac{y}{x} &= -\frac{c_1}{2x^2} + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = -\frac{c_1}{2x} + c_2 x$$

Summary

The solution(s) found are the following

$$y = -\frac{c_1}{2x} + c_2 x \tag{1}$$

Verification of solutions

$$y = -\frac{c_1}{2x} + c_2 x$$

Verified OK.

19.1.6 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + \left(2AB' + B^2\right) v' + (AB'' + BB' + CB)\, v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right) v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= -1 \\ F &= 0 \end{aligned}$$

The above shows that for this ode

$$\begin{aligned} AB'' + BB' + CB &= \left(x^2\right)(0) + (x)(1) + (-1)(x) \\ &= 0 \end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$x^3v'' + (3x^2)\, v' = 0$$

Now by applying $v' = u$ the above becomes

$$x^2(u'(x)\, x + 3u(x)) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{3u}{x} \end{aligned}$$

Where $f(x) = -\frac{3}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{3}{x}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{3}{x}\, dx \\ \ln(u) &= -3\ln(x) + c_1 \\ u &= \mathrm{e}^{-3\ln(x) + c_1} \\ &= \frac{c_1}{x^3} \end{aligned}$$

The ode for v now becomes

$$\begin{aligned} v' &= u \\ &= \frac{c_1}{x^3} \end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned} v(x) &= \int \frac{c_1}{x^3}\, \mathrm{d}x \\ &= -\frac{c_1}{2x^2} + c_2 \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y(x) &= Bv \\ &= (x)\left(-\frac{c_1}{2x^2} + c_2\right) \\ &= \left(-\frac{c_1}{2x^2} + c_2\right) x \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \left(-\frac{c_1}{2x^2} + c_2\right) x \tag{1}$$

Verification of solutions

$$y = \left(-\frac{c_1}{2x^2} + c_2\right) x$$

Verified OK.

19.1.7 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$x^2y'' + xy' - y = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2y'' + xy' - y)\, dx = 0$$
$$x^2y' - yx = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{1}{x}$$
$$q(x) = \frac{c_1}{x^2}$$

Hence the ode is

$$y' - \frac{y}{x} = \frac{c_1}{x^2}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{x}dx}$$
$$= \frac{1}{x}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{c_1}{x^2}\right)\\
\frac{d}{dx}\left(\frac{y}{x}\right) &= \left(\frac{1}{x}\right)\left(\frac{c_1}{x^2}\right)\\
d\left(\frac{y}{x}\right) &= \left(\frac{c_1}{x^3}\right)\,dx
\end{aligned}$$

Integrating gives

$$\begin{aligned}
\frac{y}{x} &= \int \frac{c_1}{x^3}\,dx\\
\frac{y}{x} &= -\frac{c_1}{2x^2} + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = -\frac{c_1}{2x} + c_2 x$$

Summary

The solution(s) found are the following

$$y = -\frac{c_1}{2x} + c_2 x \tag{1}$$

Verification of solutions

$$y = -\frac{c_1}{2x} + c_2 x$$

Verified OK.

19.1.8 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' + x y' - y = 0 \tag{1}$$
$$A y'' + B y' + C y = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}
A &= x^2\\
B &= x \qquad (3)\\
C &= -1
\end{aligned}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 613: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{2x} + (-)(0) \\
&= -\frac{1}{2x} \\
&= -\frac{1}{2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(-\frac{1}{2x}\right)^2 - \left(\frac{3}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int -\frac{1}{2x} dx} \\ &= \frac{1}{\sqrt{x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2} \, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{x^2}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x}\right) + c_2 \left(\frac{1}{x}\left(\frac{x^2}{2}\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x} + \frac{c_2 x}{2} \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x} + \frac{c_2 x}{2}$$

Verified OK.

19.1.9 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}
p(x) &= x^2 \\
q(x) &= x \\
r(x) &= -1 \\
s(x) &= 0
\end{aligned}$$

Hence

$$
\begin{aligned}
p''(x) &= 2 \\
q'(x) &= 1
\end{aligned}
$$

Therefore (1) becomes

$$
2-(1)+(-1)=0
$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$
\left(p(x)\,y'+\left(q(x)-p'(x)\right)y\right)'=s(x)
$$

Integrating gives

$$
p(x)\,y'+\left(q(x)-p'(x)\right)y=\int s(x)\;dx
$$

Substituting the above values for p, q, r, s gives

$$
x^2y'-yx=c_1
$$

We now have a first order ode to solve which is

$$
x^2y'-yx=c_1
$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
y'+p(x)y=q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= \frac{c_1}{x^2}
\end{aligned}
$$

Hence the ode is

$$
y'-\frac{y}{x}=\frac{c_1}{x^2}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{1}{x}dx} \\
&= \frac{1}{x}
\end{aligned}
$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{c_1}{x^2}\right)$$
$$\frac{d}{dx}\left(\frac{y}{x}\right) = \left(\frac{1}{x}\right)\left(\frac{c_1}{x^2}\right)$$
$$d\left(\frac{y}{x}\right) = \left(\frac{c_1}{x^3}\right) dx$$

Integrating gives

$$\frac{y}{x} = \int \frac{c_1}{x^3}\, dx$$
$$\frac{y}{x} = -\frac{c_1}{2x^2} + c_2$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = -\frac{c_1}{2x} + c_2 x$$

<u>Summary</u>
The solution(s) found are the following

$$y = -\frac{c_1}{2x} + c_2 x \tag{1}$$

<u>Verification of solutions</u>

$$y = -\frac{c_1}{2x} + c_2 x$$

Verified OK.

19.1.10 Maple step by step solution

Let's solve

$x^2 y'' + x y' - y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y'}{x} + \frac{y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} - \frac{y}{x^2} = 0$

- Multiply by denominators of the ODE

  $x^2y'' + xy' - y = 0$
- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$
  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$
  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$
  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $x^2\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) + \frac{d}{dt}y(t) - y(t) = 0$
- Simplify

  $\frac{d^2}{dt^2}y(t) - y(t) = 0$
- Characteristic polynomial of ODE

  $r^2 - 1 = 0$
- Factor the characteristic polynomial

  $(r-1)(r+1) = 0$
- Roots of the characteristic polynomial

  $r = (-1, 1)$
- 1st solution of the ODE

  $y_1(t) = \mathrm{e}^{-t}$
- 2nd solution of the ODE

  $y_2(t) = \mathrm{e}^{t}$
- General solution of the ODE

$$y(t) = c_1 y_1(t) + c_2 y_2(t)$$

- Substitute in solutions

$$y(t) = c_1 \mathrm{e}^{-t} + c_2 \mathrm{e}^{t}$$

- Change variables back using $t = \ln(x)$

$$y = \frac{c_1}{x} + c_2 x$$

- Simplify

$$y = \frac{c_1}{x} + c_2 x$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "exact linear second order ode", "second_order_integrable_as_is", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{x^2y'' + 3xy' + y = 0}$$

19.2.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 3xrx^{r-1} + x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 3r\,x^r + x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 3r + 1 = 0$$

Or

$$r^2 + 2r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= -1 \\ r_2 &= -1 \end{aligned}$$

Since the roots are equal, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^r$ and $y_2 = x^r \ln(x)$. Hence

$$y = \frac{c_1}{x} + \frac{c_2 \ln(x)}{x}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1}{x} + \frac{c_2 \ln(x)}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x} + \frac{c_2 \ln(x)}{x}$$

Verified OK.

19.2.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2y'' + 3xy' + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{3}{x} \\ q(x) &= \frac{1}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\ &= \int \mathrm{e}^{-\left(\int \frac{3}{x}dx\right)}dx \\ &= \int e^{-3\ln(x)}\,dx \\ &= \int \frac{1}{x^3}dx \\ &= -\frac{1}{2x^2} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{1}{x^2}}{\frac{1}{x^6}} \\
&= x^4
\end{aligned} \tag{7}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + x^4 y(\tau) &= 0
\end{aligned}
$$

But in terms of τ

$$
x^4 = \frac{1}{4\tau^2}
$$

Hence the above ode becomes

$$
\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{4\tau^2} = 0
$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$
4\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + y(\tau) = 0
$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$
4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0
$$

Simplifying gives

$$
4r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0
$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$
4r(r-1) + 0 + 1 = 0
$$

Or

$$
4r^2 - 4r + 1 = 0 \tag{1}
$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$
\begin{aligned}
r_1 &= \frac{1}{2} \\
r_2 &= \frac{1}{2}
\end{aligned}
$$

Since the roots are equal, then the general solution is

$$
y(\tau) = c_1 y_1 + c_2 y_2
$$

Where $y_1 = \tau^r$ and $y_2 = \tau^r \ln(\tau)$. Hence

$$
y(\tau) = c_1 \sqrt{\tau} + c_2 \sqrt{\tau}\, \ln(\tau)
$$

The above solution is now transformed back to y using (6) which results in

$$
y = \frac{\sqrt{2}\, \sqrt{-\frac{1}{x^2}}\, \left(c_1 - c_2 \ln(2) + c_2 \ln\left(-\frac{1}{x^2}\right)\right)}{2}
$$

Summary

The solution(s) found are the following

$$
y = \frac{\sqrt{2}\, \sqrt{-\frac{1}{x^2}}\, \left(c_1 - c_2 \ln(2) + c_2 \ln\left(-\frac{1}{x^2}\right)\right)}{2} \tag{1}
$$

Verification of solutions

$$
y = \frac{\sqrt{2}\, \sqrt{-\frac{1}{x^2}}\, \left(c_1 - c_2 \ln(2) + c_2 \ln\left(-\frac{1}{x^2}\right)\right)}{2}
$$

Verified OK.

19.2.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$
x^2 y'' + 3xy' + y = 0 \tag{1}
$$

Becomes

$$
y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}
$$

Where

$$\begin{aligned} p(x) &= \frac{3}{x} \\ q(x) &= \frac{1}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{1}{c\sqrt{\frac{1}{x^2}}\,x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{1}{c\sqrt{\frac{1}{x^2}}\,x^3} + \frac{3}{x}\frac{\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= 2c \end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned} y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + 2c\left(\frac{d}{d\tau}y(\tau)\right) + c^2 y(\tau) &= 0 \end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = \mathrm{e}^{-c\tau} c_1$$

Now from (6)

$$\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\, dx \\
&= \frac{\int \sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{\frac{1}{x^2}}\, x \ln (x)}{c}
\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = \frac{c_1}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x}$$

Verified OK.

19.2.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2y'' + 3xy' + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned}
p(x) &= \frac{3}{x} \\
q(x) &= \frac{1}{x^2}
\end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{3n}{x^2} + \frac{1}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = -1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{v'(x)}{x} &= 0 \\ v''(x) + \frac{v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x) g(u) \\ &= -\frac{u}{x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= -\frac{1}{x}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{1}{x}\,dx \\
\ln(u) &= -\ln(x) + c_1 \\
u &= e^{-\ln(x)+c_1} \\
&= \frac{c_1}{x}
\end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= c_1 \ln(x) + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\,x^n \\
&= \frac{c_1 \ln(x) + c_2}{x} \\
&= \frac{c_1 \ln(x) + c_2}{x}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 \ln(x) + c_2}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \ln(x) + c_2}{x}$$

Verified OK.

19.2.5 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2y'' + 3xy' + y)\, dx = 0$$
$$x^2y' + yx = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{c_1}{x^2}$$

Hence the ode is

$$y' + \frac{y}{x} = \frac{c_1}{x^2}$$

The integrating factor μ is

$$\mu = e^{\int \frac{1}{x} dx}$$
$$= x$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{c_1}{x^2}\right)$$
$$\frac{d}{dx}(xy) = (x)\left(\frac{c_1}{x^2}\right)$$
$$d(xy) = \left(\frac{c_1}{x}\right) dx$$

Integrating gives

$$xy = \int \frac{c_1}{x}\, dx$$
$$xy = c_1 \ln(x) + c_2$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$y = \frac{c_1 \ln(x)}{x} + \frac{c_2}{x}$$

which simplifies to

$$y = \frac{c_1 \ln(x) + c_2}{x}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 \ln(x) + c_2}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \ln(x) + c_2}{x}$$

Verified OK.

19.2.6 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$x^2y'' + 3xy' + y = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2y'' + 3xy' + y)\,dx = 0$$
$$x^2y' + yx = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{c_1}{x^2}$$

Hence the ode is

$$y' + \frac{y}{x} = \frac{c_1}{x^2}$$

The integrating factor μ is

$$\mu = e^{\int \frac{1}{x}dx}$$
$$= x$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{c_1}{x^2}\right)$$
$$\frac{d}{dx}(xy) = (x)\left(\frac{c_1}{x^2}\right)$$
$$d(xy) = \left(\frac{c_1}{x}\right) dx$$

Integrating gives

$$xy = \int \frac{c_1}{x} dx$$
$$xy = c_1 \ln(x) + c_2$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$y = \frac{c_1 \ln(x)}{x} + \frac{c_2}{x}$$

which simplifies to

$$y = \frac{c_1 \ln(x) + c_2}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 \ln(x) + c_2}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \ln(x) + c_2}{x}$$

Verified OK.

19.2.7 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + 3xy' + y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 3x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 615: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{1}{4x^2}
$$

For the pole at $x=0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2} \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r=\frac{s}{t}=-\frac{1}{4x^2}
$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=-\frac{1}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\,(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3x}{x^2}\,dx} \\
&= z_1 e^{-\frac{3\ln(x)}{2}} \\
&= z_1\left(\frac{1}{x^{\frac{3}{2}}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-3\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{1}{x}\right) + c_2\left(\frac{1}{x}(\ln(x))\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1}{x} + \frac{c_2 \ln(x)}{x} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1}{x} + \frac{c_2 \ln(x)}{x}
$$

Verified OK.

19.2.8 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x^2 \\ q(x) &= 3x \\ r(x) &= 1 \\ s(x) &= 0 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 2 \\ q'(x) &= 3 \end{aligned}$$

Therefore (1) becomes

$$2 - (3) + (1) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$x^2y' + yx = c_1$$

We now have a first order ode to solve which is

$$x^2y' + yx = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= \frac{1}{x} \\
q(x) &= \frac{c_1}{x^2}
\end{aligned}
$$

Hence the ode is

$$
y' + \frac{y}{x} = \frac{c_1}{x^2}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int \frac{1}{x} dx} \\
&= x
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{c_1}{x^2}\right) \\
\frac{d}{dx}(xy) &= (x)\left(\frac{c_1}{x^2}\right) \\
d(xy) &= \left(\frac{c_1}{x}\right) dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
xy &= \int \frac{c_1}{x} dx \\
xy &= c_1 \ln(x) + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$
y = \frac{c_1 \ln(x)}{x} + \frac{c_2}{x}
$$

which simplifies to

$$
y = \frac{c_1 \ln(x) + c_2}{x}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1 \ln(x) + c_2}{x} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1 \ln(x) + c_2}{x}
$$

Verified OK.

19.2.9 Maple step by step solution

Let's solve

$x^2y'' + 3xy' + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{3y'}{x} - \frac{y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{3y'}{x} + \frac{y}{x^2} = 0$

- Multiply by denominators of the ODE

  $x^2y'' + 3xy' + y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right)t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $x^2\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) + 3\frac{d}{dt}y(t) + y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) + 2\frac{d}{dt}y(t) + y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 + 2r + 1 = 0$

- Factor the characteristic polynomial

  $(r+1)^2 = 0$
- Root of the characteristic polynomial

  $r = -1$
- 1st solution of the ODE

  $y_1(t) = \mathrm{e}^{-t}$
- Repeated root, multiply $y_1(t)$ by t to ensure linear independence

  $y_2(t) = t\,\mathrm{e}^{-t}$
- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$
- Substitute in solutions

  $y(t) = c_1 \mathrm{e}^{-t} + c_2 t\,\mathrm{e}^{-t}$
- Change variables back using $t = \ln(x)$

  $y = \frac{c_1}{x} + \frac{c_2 \ln(x)}{x}$
- Simplify

  $y = \frac{c_1}{x} + \frac{c_2 \ln(x)}{x}$

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^2y'' + 2xy' + 6y = 0}$$

19.3.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 2xrx^{r-1} + 6x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 2r\,x^r + 6x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 2r + 6 = 0$$

Or

$$r^2 + r + 6 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= -\frac{1}{2} - \frac{i\sqrt{23}}{2} \\ r_2 &= -\frac{1}{2} + \frac{i\sqrt{23}}{2} \end{aligned}$$

The roots are complex conjugate of each others. Let the roots be

$$\begin{aligned} r_1 &= \alpha + i\beta \\ r_2 &= \alpha - i\beta \end{aligned}$$

Where in this case $\alpha = -\frac{1}{2}$ and $\beta = -\frac{\sqrt{23}}{2}$. Hence the solution becomes

$$\begin{aligned} y &= c_1 x^{r_1} + c_2 x^{r_2} \\ &= c_1 x^{\alpha + i\beta} + c_2 x^{\alpha - i\beta} \\ &= x^{\alpha}\left(c_1 x^{i\beta} + c_2 x^{-i\beta}\right) \\ &= x^{\alpha}\left(c_1 e^{\ln\left(x^{i\beta}\right)} + c_2 e^{\ln\left(x^{-i\beta}\right)}\right) \\ &= x^{\alpha}\left(c_1 e^{i(\beta \ln x)} + c_2 e^{-i(\beta \ln x)}\right) \end{aligned}$$

Using the values for $\alpha = -\frac{1}{2}, \beta = -\frac{\sqrt{23}}{2}$, the above becomes

$$y = x^{-\frac{1}{2}}\left(c_1 e^{-\frac{i\sqrt{23}\,\ln(x)}{2}} + c_2 e^{\frac{i\sqrt{23}\,\ln(x)}{2}}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y = \frac{1}{\sqrt{x}}\left(c_1 \cos\left(\frac{\sqrt{23}\,\ln(x)}{2}\right) + c_2 \sin\left(\frac{\sqrt{23}\,\ln(x)}{2}\right)\right)$$

<u>Summary</u>
The solution(s) found are the following

$$y = \frac{c_1 \cos\left(\frac{\sqrt{23}\,\ln(x)}{2}\right) + c_2 \sin\left(\frac{\sqrt{23}\,\ln(x)}{2}\right)}{\sqrt{x}} \tag{1}$$

Verification of solutions

$$y=\frac{c_1\cos\left(\frac{\sqrt{23}\,\ln(x)}{2}\right)+c_2\sin\left(\frac{\sqrt{23}\,\ln(x)}{2}\right)}{\sqrt{x}}$$

Verified OK.

19.3.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2y''+2xy'+6y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned}p(x)&=\frac{2}{x}\\ q(x)&=\frac{6}{x^2}\end{aligned}$$

Applying change of variables $\tau=g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau)+p_1\left(\frac{d}{d\tau}y(\tau)\right)+q_1y(\tau)=0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau)=\frac{\tau''(x)+p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau)=\frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1=0$. Eq (4) simplifies to

$$\tau''(x)+p(x)\,\tau'(x)=0$$

This ode is solved resulting in

$$
\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int \frac{2}{x}dx\right)}dx \\
&= \int e^{-2\ln(x)}\,dx \\
&= \int \frac{1}{x^2}dx \\
&= -\frac{1}{x} \qquad (6)
\end{aligned}
$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{6}{x^2}}{\frac{1}{x^4}} \\
&= 6x^2 \qquad (7)
\end{aligned}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + 6x^2 y(\tau) &= 0
\end{aligned}
$$

But in terms of τ

$$
6x^2 = \frac{6}{\tau^2}
$$

Hence the above ode becomes

$$
\frac{d^2}{d\tau^2}y(\tau) + \frac{6y(\tau)}{\tau^2} = 0
$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$
\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 6y(\tau) = 0
$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$
\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 6\tau^r = 0
$$

Simplifying gives

$$r(r-1)\,\tau^r + 0\,\tau^r + 6\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$r(r-1) + 0 + 6 = 0$$

Or

$$r^2 - r + 6 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= \frac{1}{2} - \frac{i\sqrt{23}}{2} \\ r_2 &= \frac{1}{2} + \frac{i\sqrt{23}}{2} \end{aligned}$$

The roots are complex conjugate of each others. Let the roots be

$$\begin{aligned} r_1 &= \alpha + i\beta \\ r_2 &= \alpha - i\beta \end{aligned}$$

Where in this case $\alpha = \frac{1}{2}$ and $\beta = -\frac{\sqrt{23}}{2}$. Hence the solution becomes

$$\begin{aligned} y(\tau) &= c_1\tau^{r_1} + c_2\tau^{r_2} \\ &= c_1\tau^{\alpha+i\beta} + c_2\tau^{\alpha-i\beta} \\ &= \tau^\alpha\left(c_1\tau^{i\beta} + c_2\tau^{-i\beta}\right) \\ &= \tau^\alpha\left(c_1 e^{\ln\left(\tau^{i\beta}\right)} + c_2 e^{\ln\left(\tau^{-i\beta}\right)}\right) \\ &= \tau^\alpha\left(c_1 e^{i(\beta\ln\tau)} + c_2 e^{-i(\beta\ln\tau)}\right) \end{aligned}$$

Using the values for $\alpha = \frac{1}{2}, \beta = -\frac{\sqrt{23}}{2}$, the above becomes

$$y(\tau) = \tau^{\frac{1}{2}}\left(c_1 e^{-\frac{i\sqrt{23}\,\ln(\tau)}{2}} + c_2 e^{\frac{i\sqrt{23}\,\ln(\tau)}{2}}\right)$$

Using Euler relation, the expression $c_1e^{iA} + c_2e^{-iA}$ is transformed to $c_1\cos A + c_1\sin A$ where the constants are free to change. Applying this to the above result gives

$$y(\tau) = \sqrt{\tau}\left(c_1\cos\left(\frac{\sqrt{23}\,\ln(\tau)}{2}\right) + c_2\sin\left(\frac{\sqrt{23}\,\ln(\tau)}{2}\right)\right)$$

The above solution is now transformed back to y using (6) which results in

$$y=\sqrt{-\frac{1}{x}}\left(c_1\cos\left(\frac{\sqrt{23}\,\ln\left(-\frac{1}{x}\right)}{2}\right)+c_2\sin\left(\frac{\sqrt{23}\,\ln\left(-\frac{1}{x}\right)}{2}\right)\right)$$

Summary

The solution(s) found are the following

$$y=\sqrt{-\frac{1}{x}}\left(c_1\cos\left(\frac{\sqrt{23}\,\ln\left(-\frac{1}{x}\right)}{2}\right)+c_2\sin\left(\frac{\sqrt{23}\,\ln\left(-\frac{1}{x}\right)}{2}\right)\right) \tag{1}$$

Verification of solutions

$$y=\sqrt{-\frac{1}{x}}\left(c_1\cos\left(\frac{\sqrt{23}\,\ln\left(-\frac{1}{x}\right)}{2}\right)+c_2\sin\left(\frac{\sqrt{23}\,\ln\left(-\frac{1}{x}\right)}{2}\right)\right)$$

Verified OK.

19.3.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2y''+2xy'+6y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$p(x)=\frac{2}{x}$$
$$q(x)=\frac{6}{x^2}$$

Applying change of variables $\tau=g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau)+p_1\left(\frac{d}{d\tau}y(\tau)\right)+q_1y(\tau)=0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau)=\frac{\tau''(x)+p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau)=\frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{\sqrt{6}}{c\sqrt{\frac{1}{x^2}}\,x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{\sqrt{6}}{c\sqrt{\frac{1}{x^2}}\,x^3} + \frac{2}{x}\frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= \frac{c\sqrt{6}}{6} \end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned} y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + \frac{c\sqrt{6}\left(\frac{d}{d\tau}y(\tau)\right)}{6} + c^2 y(\tau) &= 0 \end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = \mathrm{e}^{-\frac{\sqrt{6}\,c\tau}{12}}\left(c_1\cos\left(\frac{c\sqrt{138}\,\tau}{12}\right) + c_2\sin\left(\frac{c\sqrt{138}\,\tau}{12}\right)\right)$$

Now from (6)

$$\begin{aligned} \tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int \sqrt{6}\,\sqrt{\frac{1}{x^2}}dx}{c} \\ &= \frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c} \end{aligned}$$

Substituting the above into the solution obtained gives

$$y = \frac{c_1 \cos\left(\frac{\sqrt{23}\, \ln(x)}{2}\right) + c_2 \sin\left(\frac{\sqrt{23}\, \ln(x)}{2}\right)}{\sqrt{x}}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 \cos\left(\frac{\sqrt{23}\, \ln(x)}{2}\right) + c_2 \sin\left(\frac{\sqrt{23}\, \ln(x)}{2}\right)}{\sqrt{x}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \cos\left(\frac{\sqrt{23}\, \ln(x)}{2}\right) + c_2 \sin\left(\frac{\sqrt{23}\, \ln(x)}{2}\right)}{\sqrt{x}}$$

Verified OK.

19.3.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2 y'' + 2xy' + 6y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{2}{x} \\ q(x) &= \frac{6}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{2n}{x^2} + \frac{6}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = -\frac{1}{2} + \frac{i\sqrt{23}}{2} \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{-1+i\sqrt{23}}{x} + \frac{2}{x}\right) v'(x) &= 0 \\ v''(x) + \frac{\left(i\sqrt{23}+1\right) v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{\left(i\sqrt{23}+1\right) u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{\left(-1-i\sqrt{23}\right) u}{x} \end{aligned}$$

Where $f(x) = \frac{-1-i\sqrt{23}}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= \frac{-1-i\sqrt{23}}{x}\, dx \\ \int \frac{1}{u}\, du &= \int \frac{-1-i\sqrt{23}}{x}\, dx \\ \ln(u) &= \left(-1-i\sqrt{23}\right)\ln(x) + c_1 \\ u &= e^{\left(-1-i\sqrt{23}\right)\ln(x)+c_1} \\ &= c_1 e^{\left(-1-i\sqrt{23}\right)\ln(x)} \end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1 x^{-i\sqrt{23}}}{x}$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= \frac{i\sqrt{23}\, c_1 x^{-i\sqrt{23}}}{23} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\, x^n \\
&= \left(\frac{i\sqrt{23}\, c_1 x^{-i\sqrt{23}}}{23} + c_2\right) x^{-\frac{1}{2}+\frac{i\sqrt{23}}{2}} \\
&= \frac{x^{-\frac{1}{2}-\frac{i\sqrt{23}}{2}} \left(i\sqrt{23}\, c_1 + 23 c_2 x^{i\sqrt{23}}\right)}{23}
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = \left(\frac{i\sqrt{23}\, c_1 x^{-i\sqrt{23}}}{23} + c_2\right) x^{-\frac{1}{2}+\frac{i\sqrt{23}}{2}} \tag{1}$$

Verification of solutions

$$y = \left(\frac{i\sqrt{23}\, c_1 x^{-i\sqrt{23}}}{23} + c_2\right) x^{-\frac{1}{2}+\frac{i\sqrt{23}}{2}}$$

Verified OK.

19.3.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + 2xy' + 6y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 2x \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-6}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -6 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{6}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 617: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{6}{x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -6$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{i\sqrt{23}}{2} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{i\sqrt{23}}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = -\frac{6}{x^2}
$$

Since the $\gcd(s, t) = 1$. This gives $b = -6$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{i\sqrt{23}}{2} \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{i\sqrt{23}}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{6}{x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2} + \frac{i\sqrt{23}}{2}$	$\frac{1}{2} - \frac{i\sqrt{23}}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2} + \frac{i\sqrt{23}}{2}$	$\frac{1}{2} - \frac{i\sqrt{23}}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = \frac{1}{2} - \frac{i\sqrt{23}}{2}$ then

$$
\begin{aligned}
d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= \frac{1}{2} - \frac{i\sqrt{23}}{2} - \left(\frac{1}{2} - \frac{i\sqrt{23}}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{\frac{1}{2} - \frac{i\sqrt{23}}{2}}{x} + (-)(0) \\
&= \frac{\frac{1}{2} - \frac{i\sqrt{23}}{2}}{x} \\
&= \frac{1 - i\sqrt{23}}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{\frac{1}{2} - \frac{i\sqrt{23}}{2}}{x}\right)(0) + \left(\left(-\frac{\frac{1}{2} - \frac{i\sqrt{23}}{2}}{x^2} \right) + \left(\frac{\frac{1}{2} - \frac{i\sqrt{23}}{2}}{x} \right)^2 - \left(-\frac{6}{x^2} \right) \right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \frac{\frac{1}{2} - \frac{i\sqrt{23}}{2}}{x} dx} \\
&= x^{\frac{1}{2} - \frac{i\sqrt{23}}{2}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x}{x^2}\,dx} \\
&= z_1 e^{-\ln(x)} \\
&= z_1\left(\frac{1}{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{-\frac{1}{2}-\frac{i\sqrt{23}}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{i x^{i\sqrt{23}}\sqrt{23}}{23}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^{-\frac{1}{2}-\frac{i\sqrt{23}}{2}}\right) + c_2\left(x^{-\frac{1}{2}-\frac{i\sqrt{23}}{2}}\left(-\frac{i x^{i\sqrt{23}}\sqrt{23}}{23}\right)\right)
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = c_1 x^{-\frac{1}{2}-\frac{i\sqrt{23}}{2}} - \frac{i c_2\sqrt{23}\, x^{-\frac{1}{2}+\frac{i\sqrt{23}}{2}}}{23} \tag{1}
$$

Verification of solutions

$$y = c_1 x^{-\frac{1}{2}-\frac{i\sqrt{23}}{2}} - \frac{i c_2 \sqrt{23}\, x^{-\frac{1}{2}+\frac{i\sqrt{23}}{2}}}{23}$$

Verified OK.

19.3.6 Maple step by step solution

Let's solve

$x^2 y'' + 2xy' + 6y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{2y'}{x} - \frac{6y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{2y'}{x} + \frac{6y}{x^2} = 0$

- Multiply by denominators of the ODE

  $x^2 y'' + 2xy' + 6y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt} y(t)\right) t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt} y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2} y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt} y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2} y(t)}{x^2} - \frac{\frac{d}{dt} y(t)}{x^2}$

  Substitute the change of variables back into the ODE

$$x^2\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2}-\frac{\frac{d}{dt}y(t)}{x^2}\right)+2\frac{d}{dt}y(t)+6y(t)=0$$

- Simplify

$$\frac{d^2}{dt^2}y(t)+\frac{d}{dt}y(t)+6y(t)=0$$

- Characteristic polynomial of ODE

$$r^2+r+6=0$$

- Use quadratic formula to solve for r

$$r=\frac{(-1)\pm\left(\sqrt{-23}\right)}{2}$$

- Roots of the characteristic polynomial

$$r=\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{23}}{2},-\frac{1}{2}+\frac{\mathrm{I}\sqrt{23}}{2}\right)$$

- 1st solution of the ODE

$$y_1(t)=\mathrm{e}^{-\frac{t}{2}}\cos\left(\frac{\sqrt{23}\,t}{2}\right)$$

- 2nd solution of the ODE

$$y_2(t)=\mathrm{e}^{-\frac{t}{2}}\sin\left(\frac{\sqrt{23}\,t}{2}\right)$$

- General solution of the ODE

$$y(t)=c_1y_1(t)+c_2y_2(t)$$

- Substitute in solutions

$$y(t)=c_1\mathrm{e}^{-\frac{t}{2}}\cos\left(\frac{\sqrt{23}\,t}{2}\right)+c_2\mathrm{e}^{-\frac{t}{2}}\sin\left(\frac{\sqrt{23}\,t}{2}\right)$$

- Change variables back using $t=\ln(x)$

$$y=\frac{c_1\cos\left(\frac{\sqrt{23}\,\ln(x)}{2}\right)}{\sqrt{x}}+\frac{c_2\sin\left(\frac{\sqrt{23}\,\ln(x)}{2}\right)}{\sqrt{x}}$$

- Simplify

$$y=\frac{c_1\cos\left(\frac{\sqrt{23}\,\ln(x)}{2}\right)}{\sqrt{x}}+\frac{c_2\sin\left(\frac{\sqrt{23}\,\ln(x)}{2}\right)}{\sqrt{x}}$$

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{xy'' + y' = 0}$$

19.4.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (xy'' + y')\, dx = 0$$
$$xy' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\begin{aligned} y &= \int \frac{c_1}{x}\, \mathrm{d}x \\ &= c_1 \ln(x) + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \ln(x) + c_2 \tag{1}$$

Verification of solutions

$$y = c_1 \ln(x) + c_2$$

Verified OK.

19.4.2 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$xp'(x) + p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned} p' &= F(x,p) \\ &= f(x)g(p) \\ &= -\frac{p}{x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(p) = p$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{p}\,dp &= -\frac{1}{x}\,dx \\
\int \frac{1}{p}\,dp &= \int -\frac{1}{x}\,dx \\
\ln(p) &= -\ln(x) + c_1 \\
p &= \mathrm{e}^{-\ln(x)+c_1} \\
&= \frac{c_1}{x}
\end{aligned}
$$

Since $p = y'$ then the new first order ode to solve is

$$
y' = \frac{c_1}{x}
$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int \frac{c_1}{x}\,\mathrm{d}x \\
&= c_1 \ln(x) + c_2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \ln(x) + c_2 \tag{1}
$$

Verification of solutions

$$
y = c_1 \ln(x) + c_2
$$

Verified OK.

19.4.3 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$
Ay'' + By' + Cy = F(x)
$$

This method reduces the order ode the ODE by one by applying the transformation

$$
y = Bv
$$

This results in

$$
\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}
$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + \left(2AB' + B^2\right) v' + \left(AB'' + BB' + CB\right) v &= 0 \qquad (1)
\end{aligned}
$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$
ABv'' + \left(2AB' + B^2\right) v' = 0
$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$
ABu' + \left(2AB' + B^2\right) u = 0
$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= x \\
B &= 1 \\
C &= 0 \\
F &= 0
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= (x)(0) + (1)(0) + (0)(1) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
xv'' + (1) v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
xu'(x) + u(x) = 0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x, u) \\
&= f(x)g(u) \\
&= -\frac{u}{x}
\end{aligned}
$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= -\frac{1}{x}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{1}{x}\,dx \\
\ln(u) &= -\ln(x) + c_1 \\
u &= \mathrm{e}^{-\ln(x)+c_1} \\
&= \frac{c_1}{x}
\end{aligned}
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= \frac{c_1}{x}
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int \frac{c_1}{x}\,\mathrm{d}x \\
&= c_1 \ln(x) + c_2
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y(x) &= Bv \\
&= (1)\,(c_1 \ln(x) + c_2) \\
&= c_1 \ln(x) + c_2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \ln(x) + c_2 \tag{1}
$$

Verification of solutions

$$
y = c_1 \ln(x) + c_2
$$

Verified OK.

19.4.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$xy'' + y' = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int (xy'' + y')\, dx = 0$$
$$xy' = c_1$$

Which is now solved for y. Integrating both sides gives

$$y = \int \frac{c_1}{x}\, \mathrm{d}x$$
$$= c_1 \ln (x) + c_2$$

Summary
The solution(s) found are the following

$$y = c_1 \ln (x) + c_2 \tag{1}$$

Verification of solutions

$$y = c_1 \ln (x) + c_2$$

Verified OK.

19.4.5 Solving using Kovacic algorithm

Writing the ode as

$$xy'' + y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= 1 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 619: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\,(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) &= 0\\ 0 &= 0\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega\, dx}\\ &= \mathrm{e}^{\int \frac{1}{2x} dx}\\ &= \sqrt{x}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{1}{x}\, dx}\\ &= z_1 e^{-\frac{\ln(x)}{2}}\\ &= z_1\left(\frac{1}{\sqrt{x}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{1}{x}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\, dx \\ &= y_1(\ln(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(1) + c_2(1(\ln(x))) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_2 \ln(x) + c_1 \tag{1}$$

Verification of solutions

$$y = c_2 \ln(x) + c_1$$

Verified OK.

19.4.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x \\ q(x) &= 1 \\ r(x) &= 0 \\ s(x) &= 0 \end{aligned}$$

Hence

$$p''(x) = 0$$
$$q'(x) = 0$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$xy' = c_1$$

We now have a first order ode to solve which is

$$xy' = c_1$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{c_1}{x}\, \mathrm{d}x \\ &= c_1 \ln(x) + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \ln(x) + c_2 \tag{1}$$

Verification of solutions

$$y = c_1 \ln(x) + c_2$$

Verified OK.

19.4.7 Maple step by step solution

Let's solve

$xy'' + y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} = 0$

- Multiply by denominators of the ODE

  $xy'' + y' = 0$

- Make a change of variables

  $t = \ln(x)$

☐ Substitute the change of variables back into the ODE

- ○ Calculate the 1st derivative of y with respect to x , using the chain rule

  $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

- ○ Compute derivative

  $y' = \frac{\frac{d}{dt}y(t)}{x}$

- ○ Calculate the 2nd derivative of y with respect to x , using the chain rule

  $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$

- ○ Compute derivative

  $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $x\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) + \frac{\frac{d}{dt}y(t)}{x} = 0$

- Simplify

  $\frac{\frac{d^2}{dt^2}y(t)}{x} = 0$

- Isolate 2nd derivative

$\frac{d^2}{dt^2}y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{0})}{2}$

- Roots of the characteristic polynomial

  $r = 0$

- 1st solution of the ODE

  $y_1(t) = 1$

- Repeated root, multiply $y_1(t)$ by t to ensure linear independence

  $y_2(t) = t$

- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$

- Substitute in solutions

  $y(t) = c_2 t + c_1$

- Change variables back using $t = \ln(x)$

  $y = c_2 \ln(x) + c_1$

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{(2+x)^2 y'' + 3(2+x) y' - 3y = 0}$$

19.5.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$(2+x)^2 y'' + (3x+6) y' - 3y = 0 \tag{1}$$

Becomes

$$y'' + p(x) y' + q(x) y = 0 \tag{2}$$

Where

$$p(x) = \frac{3}{2+x}$$
$$q(x) = -\frac{3}{(2+x)^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int \frac{3}{2+x}dx\right)}dx \\
&= \int e^{-3\ln(2+x)}\,dx \\
&= \int \frac{1}{(2+x)^3}dx \\
&= -\frac{1}{2\,(2+x)^2}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{-\frac{3}{(2+x)^2}}{\frac{1}{(2+x)^6}} \\
&= -3(2+x)^4
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$

$$\frac{d^2}{d\tau^2}y(\tau) - 3(2+x)^4\,y(\tau) = 0$$

But in terms of τ

$$-3(2+x)^4 = -\frac{3}{4\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) - \frac{3y(\tau)}{4\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$4\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 - 3y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} - 3\tau^r = 0$$

Simplifying gives

$$4r(r-1)\,\tau^r + 0\,\tau^r - 3\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$4r(r-1) + 0 - 3 = 0$$

Or

$$4r^2 - 4r - 3 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -\frac{1}{2}$$
$$r_2 = \frac{3}{2}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = \frac{c_1}{\sqrt{\tau}} + c_2\tau^{\frac{3}{2}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\left(c_1(2+x)^4 + \frac{c_2}{4}\right)\sqrt{2}}{\sqrt{-\frac{1}{(2+x)^2}}\,(2+x)^4}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(c_1(2+x)^4 + \frac{c_2}{4}\right)\sqrt{2}}{\sqrt{-\frac{1}{(2+x)^2}}\,(2+x)^4} \tag{1}$$

Verification of solutions

$$y = \frac{\left(c_1(2+x)^4 + \frac{c_2}{4}\right)\sqrt{2}}{\sqrt{-\frac{1}{(2+x)^2}}\,(2+x)^4}$$

Verified OK.

19.5.2 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}$$

And now the original ode becomes

$$\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + \left(2AB' + B^2\right)v' + \left(AB'' + BB' + CB\right)v &= 0
\end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right)v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + (2AB' + B^2)\, u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned}
A &= (2 + x)^2 \\
B &= 3x + 6 \\
C &= -3 \\
F &= 0
\end{aligned}$$

The above shows that for this ode

$$\begin{aligned}
AB'' + BB' + CB &= \left((2 + x)^2\right)(0) + (3x + 6)(3) + (-3)(3x + 6) \\
&= 0
\end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$3(2 + x)^3\, v'' + \left(15(2 + x)^2\right) v' = 0$$

Now by applying $v' = u$ the above becomes

$$3(2 + x)^3\, u'(x) + 15(2 + x)^2\, u(x) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x, u) \\
&= f(x)g(u) \\
&= -\frac{5u}{2 + x}
\end{aligned}$$

Where $f(x) = -\frac{5}{2+x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\, du &= -\frac{5}{2 + x}\, dx \\
\int \frac{1}{u}\, du &= \int -\frac{5}{2 + x}\, dx \\
\ln(u) &= -5\ln(2 + x) + c_1 \\
u &= \mathrm{e}^{-5\ln(2+x)+c_1} \\
&= \frac{c_1}{(2 + x)^5}
\end{aligned}$$

The ode for v now becomes

$$\begin{aligned} v' &= u \\ &= \frac{c_1}{(2+x)^5} \end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned} v(x) &= \int \frac{c_1}{(2+x)^5}\, dx \\ &= -\frac{c_1}{4(2+x)^4} + c_2 \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y(x) &= Bv \\ &= (3x+6)\left(-\frac{c_1}{4(2+x)^4} + c_2\right) \\ &= \frac{3c_2(2+x)^4 - \frac{3c_1}{4}}{(2+x)^3} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{3c_2(2+x)^4 - \frac{3c_1}{4}}{(2+x)^3} \tag{1}$$

Verification of solutions

$$y = \frac{3c_2(2+x)^4 - \frac{3c_1}{4}}{(2+x)^3}$$

Verified OK.

19.5.3 Solving using Kovacic algorithm

Writing the ode as

$$(2+x)^2 y'' + (3x+6) y' - 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= (2+x)^2 \\ B &= 3x+6 \\ C &= -3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{15}{4\left(2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 15 \\ t &= 4(2+x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{15}{4\left(2+x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 621: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2+x)^2$. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{15}{4 (2+x)^2}
$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(2+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{15}{4\left(2+x\right)^{2}}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{15}{4\left(2+x\right)^{2}}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-2	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = -\frac{3}{2}$ then

$$
\begin{aligned}
d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= -\frac{3}{2} - \left(-\frac{3}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{3}{2(2+x)} + (-)(0) \\
&= -\frac{3}{2(2+x)} \\
&= -\frac{3}{2(2+x)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{3}{2(2+x)}\right)(0) + \left(\left(\frac{3}{2(2+x)^2}\right) + \left(-\frac{3}{2(2+x)}\right)^2 - \left(\frac{15}{4(2+x)^2}\right) \right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int -\frac{3}{2(2+x)} dx} \\
&= \frac{1}{(2+x)^{\frac{3}{2}}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3x+6}{(2+x)^2}\,dx} \\
&= z_1 e^{-\frac{3\ln(2+x)}{2}} \\
&= z_1 \left(\frac{1}{(2+x)^{\frac{3}{2}}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{(2+x)^3}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x+6}{(2+x)^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-3\ln(2+x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{(2+x)^4}{4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{(2+x)^3}\right) + c_2 \left(\frac{1}{(2+x)^3}\left(\frac{(2+x)^4}{4}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1}{(2+x)^3} + c_2 \left(\frac{1}{2} + \frac{x}{4}\right) \tag{1}
$$

Verification of solutions

$$y = \frac{c_1}{(2+x)^3} + c_2\left(\frac{1}{2} + \frac{x}{4}\right)$$

Verified OK.

19.5.4 Maple step by step solution

Let's solve

$(2+x)^2 y'' + (3x+6) y' - 3y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{3y'}{2+x} + \frac{3y}{(2+x)^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{3y'}{2+x} - \frac{3y}{(2+x)^2} = 0$

□ Check to see if $x_0 = -2$ is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{3}{2+x}, P_3(x) = -\frac{3}{(2+x)^2}\right]$

  - $(2+x) \cdot P_2(x)$ is analytic at $x = -2$

    $\left((2+x) \cdot P_2(x)\right)\Big|_{x=-2} = 3$

  - $(2+x)^2 \cdot P_3(x)$ is analytic at $x = -2$

    $\left((2+x)^2 \cdot P_3(x)\right)\Big|_{x=-2} = -3$

  - $x = -2$is a regular singular point

  Check to see if $x_0 = -2$ is a regular singular point

  $x_0 = -2$

- Multiply by denominators

  $(2+x)^2 y'' + (3x+6) y' - 3y = 0$

- Change variables using $x = u - 2$ so that the regular singular point is at $u = 0$

  $u^2\left(\frac{d^2}{du^2}y(u)\right) + 3u\left(\frac{d}{du}y(u)\right) - 3y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite DE with series expansions

  - Convert $u \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion

    $u \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r}$

  - Convert $u^2 \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

    $u^2 \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r}$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} a_k(k+r+3)\,(k+r-1)\, u^{k+r} = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+3)\,(k-1) = 0$

- Recursion relation that defines series solution to ODE

  $a_k = 0$

- Recursion relation for $r = 0$

  $a_k = 0$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_k = 0\right]$

- Revert the change of variables $u = 2 + x$

  $\left[y = \sum_{k=0}^{\infty} a_k(2+x)^k, a_k = 0\right]$

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(1+2x)^2 y'' - 2(1+2x)\, y' + 4y = 0}$$

19.6.1 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$4\left(x+\frac{1}{2}\right)^2 y'' + (-4x-2)\, y' + 4y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= -\frac{2}{1+2x} \\
q(x) &= \frac{1}{\left(x+\frac{1}{2}\right)^{2}}
\end{aligned}
$$

Applying change of variables $\tau = g(x)$ to (2) results

$$
\frac{d^{2}}{d\tau^{2}}y(\tau) + p_{1}\left(\frac{d}{d\tau}y(\tau)\right) + q_{1}y(\tau) = 0 \tag{3}
$$

Where τ is the new independent variable, and

$$
p_{1}(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^{2}} \tag{4}
$$

$$
q_{1}(\tau) = \frac{q(x)}{\tau'(x)^{2}} \tag{5}
$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$
\begin{aligned}
\tau' &= \frac{1}{c}\sqrt{q} \\
&= \frac{\sqrt{\frac{1}{\left(x+\frac{1}{2}\right)^{2}}}}{c} \\
\tau'' &= -\frac{1}{c\sqrt{\frac{1}{\left(x+\frac{1}{2}\right)^{2}}}\left(x+\frac{1}{2}\right)^{3}}
\end{aligned} \tag{6}
$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_{1}(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^{2}} \\
&= \frac{-\frac{1}{c\sqrt{\frac{1}{\left(x+\frac{1}{2}\right)^{2}}}\left(x+\frac{1}{2}\right)^{3}} - \frac{2}{1+2x}\frac{\sqrt{\frac{1}{\left(x+\frac{1}{2}\right)^{2}}}}{c}}{\left(\frac{\sqrt{\frac{1}{\left(x+\frac{1}{2}\right)^{2}}}}{c}\right)^{2}} \\
&= -2c
\end{aligned}
$$

Therefore ode (3) now becomes

$$
y(\tau)'' + p_{1}y(\tau)' + q_{1}y(\tau) = 0
$$

$$
\frac{d^{2}}{d\tau^{2}}y(\tau) - 2c\left(\frac{d}{d\tau}y(\tau)\right) + c^{2}y(\tau) = 0 \tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = e^{c\tau} c_1$$

Now from (6)

$$\begin{aligned}\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int \sqrt{\frac{1}{\left(x+\frac{1}{2}\right)^2}}dx}{c} \\ &= \frac{\sqrt{\frac{1}{(1+2x)^2}}\,(1+2x)\,\sqrt{4}\,\ln\left(1+2x\right)}{2c}\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = (1+2x)\,c_1$$

Summary
The solution(s) found are the following

$$y = (1+2x)\,c_1 \tag{1}$$

Verification of solutions

$$y = (1+2x)\,c_1$$

Verified OK.

19.6.2 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned}y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v\end{aligned}$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B+2v'B'+B''v)+B(B'v+v'B)+CBv&=0\\
ABv''+\left(2AB'+B^2\right)v'+(AB''+BB'+CB)\,v&=0 \qquad (1)
\end{aligned}
$$

If the term $AB''+BB'+CB$ is zero, then this method works and can be used to solve

$$
ABv''+\left(2AB'+B^2\right)v'=0
$$

By Using $u=v'$ which reduces the order of the above ode to one. The new ode is

$$
ABu'+\left(2AB'+B^2\right)u=0
$$

The above ode is first order ode which is solved for u. Now a new ode $v'=u$ is solved for v as first order ode. Then the final solution is obtain from $y=Bv$.

This method works only if the term $AB''+BB'+CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A&=4\left(x+\frac{1}{2}\right)^2\\
B&=-4x-2\\
C&=4\\
F&=0
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB''+BB'+CB&=\left(4\left(x+\frac{1}{2}\right)^2\right)(0)+(-4x-2)(-4)+(4)(-4x-2)\\
&=0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
-2(1+2x)^3\,v''+\left(-16\left(x+\frac{1}{2}\right)^2\right)v'=0
$$

Now by applying $v'=u$ the above becomes

$$
-2(1+2x)^3\,u'(x)-4u(x)\,(1+2x)^2=0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u'&=F(x,u)\\
&=f(x)g(u)\\
&=-\frac{2u}{1+2x}
\end{aligned}
$$

Where $f(x) = -\frac{2}{1+2x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= -\frac{2}{1+2x}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{2}{1+2x}\,dx \\
\ln(u) &= -\ln(1+2x) + c_1 \\
u &= e^{-\ln(1+2x)+c_1} \\
&= \frac{c_1}{1+2x}
\end{aligned}
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= \frac{c_1}{1+2x}
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int \frac{c_1}{1+2x}\,\mathrm{d}x \\
&= \frac{c_1 \ln(1+2x)}{2} + c_2
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y(x) &= Bv \\
&= (-4x-2)\left(\frac{c_1 \ln(1+2x)}{2} + c_2\right) \\
&= -2(c_1 \ln(1+2x) + 2c_2)\left(x + \frac{1}{2}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = -2(c_1 \ln(1+2x) + 2c_2)\left(x + \frac{1}{2}\right) \tag{1}
$$

Verification of solutions

$$
y = -2(c_1 \ln(1+2x) + 2c_2)\left(x + \frac{1}{2}\right)
$$

Verified OK.

19.6.3 Solving using Kovacic algorithm

Writing the ode as

$$4\left(x+\frac{1}{2}\right)^{2} y''+(-4x-2)\, y'+4y = 0 \tag{1}$$

$$Ay''+By'+Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4\left(x+\frac{1}{2}\right)^{2} \\ B &= -4x-2 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^{2}-4AC}{4A^{2}} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{\left(1+2x\right)^{2}} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= \left(1+2x\right)^{2} \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{\left(1+2x\right)^{2}}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 623: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (1+2x)^2$. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4\left(x+\frac{1}{2}\right)^2}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{(1+2x)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{(1+2x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$-\frac{1}{2}$	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_{\infty}^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_{\infty}^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_{\infty}^{-} = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{+}\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\ &= \frac{1}{1+2x} + (-)\,(0) \\ &= \frac{1}{1+2x} \\ &= \frac{1}{1+2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{1+2x}\right)(0) + \left(\left(-\frac{1}{2\left(x+\frac{1}{2}\right)^2}\right) + \left(\frac{1}{1+2x}\right)^2 - \left(-\frac{1}{(1+2x)^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \frac{1}{1+2x} dx} \\
&= \sqrt{1+2x}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-4x-2}{4\left(x+\frac{1}{2}\right)^2} \, dx} \\
&= z_1 e^{\frac{\ln(1+2x)}{2}} \\
&= z_1 \left(\sqrt{1+2x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = 1 + 2x
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x-2}{4\left(x+\frac{1}{2}\right)^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{\ln(1+2x)}}{(y_1)^2} \, dx \\
&= y_1 \left(\frac{\ln(1+2x)}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 (1+2x) + c_2 \left(1 + 2x \left(\frac{\ln(1+2x)}{2}\right)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$y = (1+2x)\, c_1 + \frac{c_2(1+2x)\ln(1+2x)}{2} \tag{1}$$

Verification of solutions

$$y = (1+2x)\, c_1 + \frac{c_2(1+2x)\ln(1+2x)}{2}$$

Verified OK.

19.6.4 Maple step by step solution

Let's solve

$4\left(x+\frac{1}{2}\right)^2 y'' + (-4x-2)\, y' + 4y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{2y'}{1+2x} - \frac{4y}{(1+2x)^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{2y'}{1+2x} + \frac{4y}{(1+2x)^2} = 0$

□ Check to see if $x_0 = -\frac{1}{2}$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -\frac{2}{1+2x}, P_3(x) = \frac{4}{(1+2x)^2}\right]$

  ◦ $\left(x+\frac{1}{2}\right) \cdot P_2(x)$ is analytic at $x = -\frac{1}{2}$

    $\left(\left(x+\frac{1}{2}\right) \cdot P_2(x)\right)\bigg|_{x=-\frac{1}{2}} = -1$

  ◦ $\left(x+\frac{1}{2}\right)^2 \cdot P_3(x)$ is analytic at $x = -\frac{1}{2}$

    $\left(\left(x+\frac{1}{2}\right)^2 \cdot P_3(x)\right)\bigg|_{x=-\frac{1}{2}} = 1$

  ◦ $x = -\frac{1}{2}$is a regular singular point

  Check to see if $x_0 = -\frac{1}{2}$ is a regular singular point

  $x_0 = -\frac{1}{2}$

- Multiply by denominators

  $(1+2x)^2 y'' + (-4x-2) y' + 4y = 0$

- Change variables using $x = u - \frac{1}{2}$ so that the regular singular point is at $u = 0$

  $4u^2 \left(\frac{d^2}{du^2} y(u)\right) - 4u \left(\frac{d}{du} y(u)\right) + 4y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite DE with series expansions

  - Convert $u \cdot \left(\frac{d}{du} y(u)\right)$ to series expansion

    $u \cdot \left(\frac{d}{du} y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r}$

  - Convert $u^2 \cdot \left(\frac{d^2}{du^2} y(u)\right)$ to series expansion

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.4 Nonhomogeneous linear equations with constant coefficients. The Euler equations. Exercises page 143
Problem number: 624.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_missing_y"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{x^2y''' - 3xy'' + 3y' = 0}$$

Since y is missing from the ode then we can use the substitution $y' = v(x)$ to reduce the order by one. The ODE becomes

$$x^2v''(x) - 3xv'(x) + 3v(x) = 0$$

This is Euler second order ODE. Let the solution be $v(x) = x^r$, then $v' = rx^{r-1}$ and $v'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 3xrx^{r-1} + 3x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 3r\,x^r + 3x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 3r + 3 = 0$$

Or

$$r^2 - 4r + 3 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = 1$$
$$r_2 = 3$$

Since the roots are real and distinct, then the general solution is

$$v(x) = c_1v_1 + c_2v_2$$

Where $v_1 = x^{r_1}$ and $v_2 = x^{r_2}$. Hence

$$v(x) = c_2x^3 + c_1x$$

But since $y' = v(x)$ then we now need to solve the ode $y' = c_2x^3 + c_1x$. Integrating both sides gives

$$\begin{aligned} y &= \int c_2x^3 + c_1x \,\mathrm{d}x \\ &= \frac{(c_2x^2 + c_1)^2}{4c_2} + c_3 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{(c_2x^2 + c_1)^2}{4c_2} + c_3 \tag{1}$$

Verification of solutions

$$y = \frac{(c_2x^2 + c_1)^2}{4c_2} + c_3$$

Verified OK.

19.7.1 Maple step by step solution

Let's solve

$x^2y''' - 3xy'' + 3y' = 0$

- Highest derivative means the order of the ODE is 3

  y'''

- Isolate 3rd derivative

$y''' = \frac{3(xy''-y')}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''' - \frac{3y''}{x} + \frac{3y'}{x^2} = 0$

- Multiply by denominators of the ODE

  $x^2y''' - 3xy'' + 3y' = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  - Calculate the 3rd derivative of y with respect to x , using the chain rule

    $y''' = \left(\frac{d^3}{dt^3}y(t)\right) t'(x)^3 + 3t'(x)\, t''(x) \left(\frac{d^2}{dt^2}y(t)\right) + t'''(x) \left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y''' = \frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}$

  Substitute the change of variables back into the ODE

  $x^2\left(\frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}\right) - 3x\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) + \frac{3\left(\frac{d}{dt}y(t)\right)}{x} = 0$

- Simplify

  $\frac{\frac{d^3}{dt^3}y(t) - 6\frac{d^2}{dt^2}y(t) + 8\frac{d}{dt}y(t)}{x} = 0$

- Isolate 3rd derivative

  $\frac{d^3}{dt^3}y(t) = 6\frac{d^2}{dt^2}y(t) - 8\frac{d}{dt}y(t)$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^3}{dt^3}y(t) - 6\frac{d^2}{dt^2}y(t) + 8\frac{d}{dt}y(t) = 0$

□ Convert linear ODE into a system of first order ODEs

- Define new variable $y_1(t)$

  $y_1(t) = y(t)$

- Define new variable $y_2(t)$

  $y_2(t) = \frac{d}{dt}y(t)$

- Define new variable $y_3(t)$

  $y_3(t) = \frac{d^2}{dt^2}y(t)$

- Isolate for $\frac{d}{dt}y_3(t)$ using original ODE

  $\frac{d}{dt}y_3(t) = 6y_3(t) - 8y_2(t)$

  Convert linear ODE into a system of first order ODEs

  $\left[y_2(t) = \frac{d}{dt}y_1(t), y_3(t) = \frac{d}{dt}y_2(t), \frac{d}{dt}y_3(t) = 6y_3(t) - 8y_2(t)\right]$

- Define vector

$$\vec{y}(t) = \begin{bmatrix} y_1(t) \\ y_2(t) \\ y_3(t) \end{bmatrix}$$

- System to solve

$$\frac{d}{dt}\vec{y}(t) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -8 & 6 \end{bmatrix} \cdot \vec{y}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -8 & 6 \end{bmatrix}$$

- Rewrite the system as

  $\frac{d}{dt}\vec{y}(t) = A \cdot \vec{y}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right], \left[4, \begin{bmatrix} \frac{1}{16} \\ \frac{1}{4} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \mathrm{e}^{2t} \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[4, \begin{bmatrix} \frac{1}{16} \\ \frac{1}{4} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = \mathrm{e}^{4t} \cdot \begin{bmatrix} \frac{1}{16} \\ \frac{1}{4} \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

  $\overrightarrow{y} = c_1 \overrightarrow{y}_1 + c_2 \overrightarrow{y}_2 + c_3 \overrightarrow{y}_3$

- Substitute solutions into the general solution

$$\overrightarrow{y} = c_2 e^{2t} \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix} + c_3 e^{4t} \cdot \begin{bmatrix} \frac{1}{16} \\ \frac{1}{4} \\ 1 \end{bmatrix} + \begin{bmatrix} c_1 \\ 0 \\ 0 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

  $y(t) = \frac{c_2 e^{2t}}{4} + \frac{c_3 e^{4t}}{16} + c_1$

- Change variables back using $t = \ln(x)$

  $y = \frac{1}{4} c_2 x^2 + \frac{1}{16} c_3 x^4 + c_1$

The type(s) of ODE detected by this program : **"higher_order_missing_y"**

Maple gives the following as the ode type

`[[_3rd_order, _missing_y]]`

$$\boxed{x^2y''' - 2y' = 0}$$

Since y is missing from the ode then we can use the substitution $y' = v(x)$ to reduce the order by one. The ODE becomes

$$x^2v''(x) - 2v(x) = 0$$

This is Euler second order ODE. Let the solution be $v(x) = x^r$, then $v' = rx^{r-1}$ and $v'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 0rx^{r-1} - 2x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 0\,x^r - 2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 0 - 2 = 0$$

Or

$$r^2 - r - 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -1$$
$$r_2 = 2$$

Since the roots are real and distinct, then the general solution is

$$v(x) = c_1 v_1 + c_2 v_2$$

Where $v_1 = x^{r_1}$ and $v_2 = x^{r_2}$. Hence

$$v(x) = \frac{c_1}{x} + c_2 x^2$$

But since $y' = v(x)$ then we now need to solve the ode $y' = \frac{c_1}{x} + c_2 x^2$. Integrating both sides gives

$$\begin{aligned} y &= \int \frac{c_2 x^3 + c_1}{x} \, \mathrm{d}x \\ &= \frac{c_2 x^3}{3} + c_1 \ln(x) + c_3 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_2 x^3}{3} + c_1 \ln(x) + c_3 \tag{1}$$

Verification of solutions

$$y = \frac{c_2 x^3}{3} + c_1 \ln(x) + c_3$$

Verified OK.

19.8.1 Maple step by step solution

Let's solve

$x^2 y''' - 2y' = 0$

- Highest derivative means the order of the ODE is 3

  y'''

- Isolate 3rd derivative

$y''' = \frac{2y'}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y''' - \frac{2y'}{x^2} = 0$

- Multiply by denominators of the ODE

$x^2 y''' - 2y' = 0$

- Make a change of variables

$t = \ln(x)$

□ Substitute the change of variables back into the ODE
  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$
  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$
  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$
  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$
  - Calculate the 3rd derivative of y with respect to x , using the chain rule

    $y''' = \left(\frac{d^3}{dt^3}y(t)\right) t'(x)^3 + 3t'(x)\, t''(x)\left(\frac{d^2}{dt^2}y(t)\right) + t'''(x)\left(\frac{d}{dt}y(t)\right)$
  - Compute derivative

    $y''' = \frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}$

  Substitute the change of variables back into the ODE

  $x^2\left(\frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}\right) - \frac{2\left(\frac{d}{dt}y(t)\right)}{x} = 0$

- Simplify

$\frac{\frac{d^3}{dt^3}y(t) - 3\frac{d^2}{dt^2}y(t)}{x} = 0$

- Isolate 3rd derivative

$\frac{d^3}{dt^3}y(t) = 3\frac{d^2}{dt^2}y(t)$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^3}{dt^3}y(t) - 3\frac{d^2}{dt^2}y(t) = 0$

☐ Convert linear ODE into a system of first order ODEs

- Define new variable $y_1(t)$

  $y_1(t) = y(t)$

- Define new variable $y_2(t)$

  $y_2(t) = \frac{d}{dt}y(t)$

- Define new variable $y_3(t)$

  $y_3(t) = \frac{d^2}{dt^2}y(t)$

- Isolate for $\frac{d}{dt}y_3(t)$ using original ODE

  $\frac{d}{dt}y_3(t) = 3y_3(t)$

  Convert linear ODE into a system of first order ODEs

  $\left[y_2(t) = \frac{d}{dt}y_1(t), y_3(t) = \frac{d}{dt}y_2(t), \frac{d}{dt}y_3(t) = 3y_3(t)\right]$

- Define vector

  $$\vec{y}(t) = \begin{bmatrix} y_1(t) \\ y_2(t) \\ y_3(t) \end{bmatrix}$$

- System to solve

  $$\frac{d}{dt}\vec{y}(t) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 3 \end{bmatrix} \cdot \vec{y}(t)$$

- Define the coefficient matrix

  $$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 3 \end{bmatrix}$$

- Rewrite the system as

  $\frac{d}{dt}\vec{y}(t) = A \cdot \vec{y}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[0, \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[3, \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[3, \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = e^{3t} \cdot \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

  $\vec{y} = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3$

- Substitute solutions into the general solution

  $$\vec{y} = c_3 e^{3t} \cdot \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix} + \begin{bmatrix} c_1 \\ 0 \\ 0 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

  $y(t) = \frac{c_3 e^{3t}}{9} + c_1$

- Change variables back using $t = \ln(x)$

  $y = \frac{c_3 x^3}{9} + c_1$

Section: Chapter 2 (Higher order ODE's). Section 15.4 Nonhomogeneous linear equations with constant coefficients. The Euler equations. Exercises page 143
Problem number: 626.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_missing_y"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{(x+1)^2 y''' - 12y' = 0}$$

Since y is missing from the ode then we can use the substitution $y' = v(x)$ to reduce the order by one. The ODE becomes

$$-12v(x) + \left(x^2+2x+1\right) v''(x) = 0$$

Writing the ode as

$$v''(x) (x+1)^2 - 12v(x) = 0 \tag{1}$$
$$Av''(x) + Bv'(x) + Cv(x) = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= (x+1)^2 \\ B &= 0 \\ C &= -12 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = v(x)\, e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{12}{(x+1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 12 \\ t &= (x+1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{12}{(x+1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then $v(x)$ is found using the inverse transformation

$$v(x) = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 627: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x+1)^2$. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{12}{(x+1)^2}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 12$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 4 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -3 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{12}{(x+1)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = 12$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 4 \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -3 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{12}{(x+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	4	-3

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	4	-3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -3$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= -3 - (-3) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{3}{x+1} + (-)(0) \\
&= -\frac{3}{x+1} \\
&= -\frac{3}{x+1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{3}{x+1}\right)(0) + \left(\left(\frac{3}{(x+1)^2}\right) + \left(-\frac{3}{x+1}\right)^2 - \left(\frac{12}{(x+1)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int -\frac{3}{x+1} dx} \\ &= \frac{1}{(x+1)^3} \end{aligned}$$

The first solution to the original ode in $v(x)$ is found from

$$v_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} v_1 &= z_1 \\ &= \frac{1}{(x+1)^3} \end{aligned}$$

Which simplifies to

$$v_1 = \frac{1}{(x+1)^3}$$

The second solution v_2 to the original ode is found using reduction of order

$$v_2 = v_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{v_1^2}\, dx$$

Since $B=0$ then the above becomes

$$
\begin{aligned}
v_2 &= v_1 \int \frac{1}{v_1^2}\, dx \\
&= \frac{1}{(x+1)^3} \int \frac{1}{\frac{1}{(x+1)^6}}\, dx \\
&= \frac{1}{(x+1)^3} \left(\frac{(x+1)^7}{7}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
v(x) &= c_1 v_1 + c_2 v_2 \\
&= c_1 \left(\frac{1}{(x+1)^3}\right) + c_2 \left(\frac{1}{(x+1)^3} \left(\frac{(x+1)^7}{7}\right)\right)
\end{aligned}
$$

But since $y' = v(x)$ then we now need to solve the ode $y' = \frac{c_1}{(x+1)^3} + \frac{c_2(x+1)^4}{7}$. Integrating both sides gives

$$
\begin{aligned}
y &= \int \frac{c_2 x^7 + 7c_2 x^6 + 21c_2 x^5 + 35c_2 x^4 + 35c_2 x^3 + 21c_2 x^2 + 7c_2 x + 7c_1 + c_2}{7\,(x+1)^3}\, dx \\
&= \frac{c_2 x^5}{35} + \frac{c_2 x^4}{7} + \frac{2c_2 x^3}{7} + \frac{2c_2 x^2}{7} + \frac{c_2 x}{7} - \frac{c_1}{2\,(x+1)^2} + c_3
\end{aligned}
$$

This is higher order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$
-12y' + \left(x^2 + 2x + 1\right) y''' = 0
$$

Let the particular solution be

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$
U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)}\, dx
$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} 1 & \frac{1}{(x+1)^2} & \frac{x(x^4+5x^3+10x^2+10x+5)}{35} \\ 0 & -\frac{2}{(x+1)^3} & \frac{(x+1)^4}{7} \\ 0 & \frac{6}{(x+1)^4} & \frac{4(x+1)^3}{7} \end{bmatrix}$$
$$|W| = -2$$

The determinant simplifies to

$$|W| = -2$$

Now we determine W_i for each U_i.

$$W_1(x) = \det \begin{bmatrix} \frac{1}{(x+1)^2} & \frac{x(x^4+5x^3+10x^2+10x+5)}{35} \\ -\frac{2}{(x+1)^3} & \frac{(x+1)^4}{7} \end{bmatrix}$$
$$= \frac{7x^5 + 35x^4 + 70x^3 + 70x^2 + 35x + 5}{35(x+1)^3}$$

$$W_2(x) = \det \begin{bmatrix} 1 & \frac{x(x^4+5x^3+10x^2+10x+5)}{35} \\ 0 & \frac{(x+1)^4}{7} \end{bmatrix}$$
$$= \frac{(x+1)^4}{7}$$

$$W_3(x) = \det \begin{bmatrix} 1 & \frac{1}{(x+1)^2} \\ 0 & -\frac{2}{(x+1)^3} \end{bmatrix}$$
$$= -\frac{2}{(x+1)^3}$$

Now we are ready to evaluate each $U_i(x)$.

$$
\begin{aligned}
U_1 &= (-1)^{3-1} \int \frac{F(x)W_1(x)}{aW(x)}\, dx \\
&= (-1)^2 \int \frac{\left(-(x+1)^2 y''' + (x^2+2x+1)\, y'''\right)\left(\frac{7x^5+35x^4+70x^3+70x^2+35x+5}{35(x+1)^3}\right)}{(x^2+2x+1)(-2)}\, dx \\
&= \int \frac{\frac{\left(-(x+1)^2 y'''+(x^2+2x+1)y'''\right)(7x^5+35x^4+70x^3+70x^2+35x+5)}{35(x+1)^3}}{-2x^2-4x-2}\, dx \\
&= \int (0)\, dx \\
&= 0
\end{aligned}
$$

$$
\begin{aligned}
U_2 &= (-1)^{3-2} \int \frac{F(x)W_2(x)}{aW(x)}\, dx \\
&= (-1)^1 \int \frac{\left(-(x+1)^2 y''' + (x^2+2x+1)\, y'''\right)\left(\frac{(x+1)^4}{7}\right)}{(x^2+2x+1)(-2)}\, dx \\
&= -\int \frac{\frac{\left(-(x+1)^2 y'''+(x^2+2x+1)y'''\right)(x+1)^4}{7}}{-2x^2-4x-2}\, dx \\
&= -\int (0)\, dx \\
&= 0
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{3-3} \int \frac{F(x)W_3(x)}{aW(x)}\, dx \\
&= (-1)^0 \int \frac{\left(-(x+1)^2 y''' + (x^2+2x+1)\, y'''\right)\left(-\frac{2}{(x+1)^3}\right)}{(x^2+2x+1)(-2)}\, dx \\
&= \int \frac{-\frac{2\left(-(x+1)^2 y'''+(x^2+2x+1)y'''\right)}{(x+1)^3}}{-2x^2-4x-2}\, dx \\
&= \int (0)\, dx \\
&= 0
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Hence

$$
\begin{aligned}
y_p &= (0) \\
&+ (0)\left(\frac{1}{(x+1)^2}\right) \\
&+ (0)\left(\frac{1}{35}x^5 + \frac{1}{7}x^4 + \frac{2}{7}x^3 + \frac{2}{7}x^2 + \frac{1}{7}x\right)
\end{aligned}
$$

Therefore the particular solution is

$$y_p = 0$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \Bigg(y \\
&= \frac{c_2x^5}{35} + \frac{c_2x^4}{7} + \frac{2c_2x^3}{7} + \frac{2c_2x^2}{7} + \frac{c_2x}{7} - \frac{c_1}{2(x+1)^2} + c_3\Bigg) + (0)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = \frac{c_2x^5}{35} + \frac{c_2x^4}{7} + \frac{2c_2x^3}{7} + \frac{2c_2x^2}{7} + \frac{c_2x}{7} - \frac{c_1}{2(x+1)^2} + c_3 \tag{1}$$

Verification of solutions

$$y = \frac{c_2x^5}{35} + \frac{c_2x^4}{7} + \frac{2c_2x^3}{7} + \frac{2c_2x^2}{7} + \frac{c_2x}{7} - \frac{c_1}{2(x+1)^2} + c_3$$

Verified OK.

19.9.1 Maple step by step solution

Let's solve

$(x+1)^2 y''' - 12y' = 0$

- Highest derivative means the order of the ODE is 3

  y'''

☐ Check to see if $x_0 = -1$ is a regular singular point

  ◦ Define functions

$\left[P_2(x) = 0, P_3(x) = -\frac{12}{(x+1)^2}, P_4(x) = 0\right]$

- $(x+1) \cdot P_2(x)$ is analytic at $x = -1$

  $\left((x+1) \cdot P_2(x)\right) \bigg|_{x=-1} = 0$

- $(x+1)^2 \cdot P_3(x)$ is analytic at $x = -1$

  $\left((x+1)^2 \cdot P_3(x)\right) \bigg|_{x=-1} = -12$

- $(x+1)^3 \cdot P_4(x)$ is analytic at $x = -1$

  $\left((x+1)^3 \cdot P_4(x)\right) \bigg|_{x=-1} = 0$

- $x = -1$is a regular singular point

  Check to see if $x_0 = -1$ is a regular singular point

  $x_0 = -1$

- Change variables using $x = u - 1$ so that the regular singular point is at $u = 0$

  $u^2 \left(\frac{d^3}{du^3} y(u)\right) - 12 \frac{d}{du} y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite DE with series expansions

- Convert $\frac{d}{du} y(u)$ to series expansion

  $\frac{d}{du} y(u) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r-1}$

- Shift index using $k- > k+1$

  $\frac{d}{du} y(u) = \sum_{k=-1}^{\infty} a_{k+1} (k+1+r)\, u^{k+r}$

- Convert $u^2 \cdot \left(\frac{d^3}{du^3} y(u)\right)$ to series expansion

  $u^2 \cdot \left(\frac{d^3}{du^3} y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)(k+r-2)\, u^{k+r-1}$

- Shift index using $k- > k+1$

  $u^2 \cdot \left(\frac{d^3}{du^3} y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1} (k+1+r)(k+r)(k+r-1)\, u^{k+r}$

Rewrite DE with series expansions

$$\sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+3+r)\,(k-4+r)\,u^{k+r} = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1)\,(k+3)\,(k-4) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = 0$

- Recursion relation for $r = 0$

  $a_{k+1} = 0$

- Solution for $r = 0$

  $$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = 0\right]$$

- Revert the change of variables $u = x+1$

  $$\left[y = \sum_{k=0}^{\infty} a_k(x+1)^k\,, a_{k+1} = 0\right]$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_missing_y"**

Maple gives the following as the ode type

`[[_3rd_order, _missing_y]]`

$$\boxed{(1+2x)^2 y''' + 2(1+2x) y'' + y' = 0}$$

Since y is missing from the ode then we can use the substitution $y' = v(x)$ to reduce the order by one. The ODE becomes

$$v(x) + (4x+2) v'(x) + (4x^2+4x+1) v''(x) = 0$$

In normal form the ode

$$4\left(x+\frac{1}{2}\right)^2 v''(x) + (4x+2) v'(x) + v(x) = 0 \tag{1}$$

Becomes

$$v''(x) + p(x) v'(x) + q(x) v(x) = 0 \tag{2}$$

Where

$$p(x) = \frac{4x+2}{4\left(x+\frac{1}{2}\right)^2}$$
$$q(x) = \frac{1}{4\left(x+\frac{1}{2}\right)^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}v(\tau) + p_1\left(\frac{d}{d\tau}v(\tau)\right) + q_1 v(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'\,(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'\,(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\
&= \int \mathrm{e}^{-\left(\int \frac{4x+2}{4\left(x+\frac{1}{2}\right)^2}dx\right)} dx \\
&= \int e^{-\ln(1+2x)}\,dx \\
&= \int \frac{1}{1+2x} dx \\
&= \frac{\ln\left(1+2x\right)}{2}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'\,(x)^2} \\
&= \frac{\frac{1}{4\left(x+\frac{1}{2}\right)^2}}{\frac{1}{(1+2x)^2}} \\
&= 1
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}v(\tau) + q_1 v(\tau) = 0 \\
\frac{d^2}{d\tau^2}v(\tau) + v(\tau) = 0
\end{aligned}$$

The above ode is now solved for $v(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Av''(\tau) + Bv'(\tau) + Cv(\tau) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $v(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda\tau} + e^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(1)}\\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i\\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i\\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$v(\tau) = e^{\alpha\tau}(c_1 \cos(\beta\tau) + c_2 \sin(\beta\tau))$$

Which becomes

$$v(\tau) = e^0(c_1 \cos(\tau) + c_2 \sin(\tau))$$

Or

$$v(\tau) = c_1 \cos(\tau) + c_2 \sin(\tau)$$

The above solution is now transformed back to $v(x)$ using (6) which results in

$$v(x) = c_1 \cos\left(\frac{\ln(1+2x)}{2}\right) + c_2 \sin\left(\frac{\ln(1+2x)}{2}\right)$$

But since $y' = v(x)$ then we now need to solve the ode $y' = c_1 \cos\left(\frac{\ln(1+2x)}{2}\right) + c_2 \sin\left(\frac{\ln(1+2x)}{2}\right)$. Integrating both sides gives

$$\begin{aligned} y &= \int c_1 \cos\left(\frac{\ln(1+2x)}{2}\right) + c_2 \sin\left(\frac{\ln(1+2x)}{2}\right) dx \\ &= c_1 \left(\frac{2\cos\left(\frac{\ln(1+2x)}{2}\right)(1+2x)}{5} + \frac{(1+2x)\sin\left(\frac{\ln(1+2x)}{2}\right)}{5}\right) + c_2 \left(-\frac{\cos\left(\frac{\ln(1+2x)}{2}\right)(1+2x)}{5} + \frac{2(1+2x)}{}\right. \end{aligned}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y' + (4x+2)\, y'' + (4x^2+4x+1)\, y''' = 0$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)}\, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} 1 & -\frac{(1+2x)\left(\cos\left(\frac{\ln(1+2x)}{2}\right)-2\sin\left(\frac{\ln(1+2x)}{2}\right)\right)}{5} & \frac{(1+2x)\left(2\cos\left(\frac{\ln(1+2x)}{2}\right)+\sin\left(\frac{\ln(1+2x)}{2}\right)\right)}{5} \\ 0 & \sin\left(\frac{\ln(1+2x)}{2}\right) & \cos\left(\frac{\ln(1+2x)}{2}\right) \\ 0 & \frac{\cos\left(\frac{\ln(1+2x)}{2}\right)}{1+2x} & -\frac{\sin\left(\frac{\ln(1+2x)}{2}\right)}{1+2x} \end{bmatrix}$$

$$|W| = -\frac{\cos\left(\frac{\ln(1+2x)}{2}\right)^2 + \sin\left(\frac{\ln(1+2x)}{2}\right)^2}{1+2x}$$

The determinant simplifies to

$$|W| = -\frac{1}{1+2x}$$

Now we determine W_i for each U_i.

$$\begin{aligned} W_1(x) &= \det \begin{bmatrix} -\frac{(1+2x)\left(\cos\left(\frac{\ln(1+2x)}{2}\right)-2\sin\left(\frac{\ln(1+2x)}{2}\right)\right)}{5} & \frac{(1+2x)\left(2\cos\left(\frac{\ln(1+2x)}{2}\right)+\sin\left(\frac{\ln(1+2x)}{2}\right)\right)}{5} \\ \sin\left(\frac{\ln(1+2x)}{2}\right) & \cos\left(\frac{\ln(1+2x)}{2}\right) \end{bmatrix} \\ &= -\frac{1}{5} - \frac{2x}{5} \end{aligned}$$

$$\begin{aligned} W_2(x) &= \det \begin{bmatrix} 1 & \frac{(1+2x)\left(2\cos\left(\frac{\ln(1+2x)}{2}\right)+\sin\left(\frac{\ln(1+2x)}{2}\right)\right)}{5} \\ 0 & \cos\left(\frac{\ln(1+2x)}{2}\right) \end{bmatrix} \\ &= \cos\left(\frac{\ln(1+2x)}{2}\right) \end{aligned}$$

$$\begin{aligned} W_3(x) &= \det \begin{bmatrix} 1 & -\frac{(1+2x)\left(\cos\left(\frac{\ln(1+2x)}{2}\right)-2\sin\left(\frac{\ln(1+2x)}{2}\right)\right)}{5} \\ 0 & \sin\left(\frac{\ln(1+2x)}{2}\right) \end{bmatrix} \\ &= \sin\left(\frac{\ln(1+2x)}{2}\right) \end{aligned}$$

Now we are ready to evaluate each $U_i(x)$.

$$
\begin{aligned}
U_1 &= (-1)^{3-1} \int \frac{F(x) W_1(x)}{a W(x)} \, dx \\
&= (-1)^2 \int \frac{\left(-(1+2x)^2 y''' - 2(1+2x) y'' + (4x+2) y'' + (4x^2+4x+1) y'''\right) \left(-\frac{1}{5} - \frac{2x}{5}\right)}{(4x^2+4x+1) \left(-\frac{1}{1+2x}\right)} \, dx \\
&= \int \frac{\left(-(1+2x)^2 y''' - 2(1+2x) y'' + (4x+2) y'' + (4x^2+4x+1) y'''\right) \left(-\frac{1}{5} - \frac{2x}{5}\right)}{-\frac{4x^2+4x+1}{1+2x}} \, dx \\
&= \int (0) \, dx \\
&= 0
\end{aligned}
$$

$$
\begin{aligned}
U_2 &= (-1)^{3-2} \int \frac{F(x) W_2(x)}{a W(x)} \, dx \\
&= (-1)^1 \int \frac{\left(-(1+2x)^2 y''' - 2(1+2x) y'' + (4x+2) y'' + (4x^2+4x+1) y'''\right) \left(\cos\left(\frac{\ln(1+2x)}{2}\right)\right)}{(4x^2+4x+1) \left(-\frac{1}{1+2x}\right)} \, dx \\
&= -\int \frac{\left(-(1+2x)^2 y''' - 2(1+2x) y'' + (4x+2) y'' + (4x^2+4x+1) y'''\right) \cos\left(\frac{\ln(1+2x)}{2}\right)}{-\frac{4x^2+4x+1}{1+2x}} \, dx \\
&= -\int (0) \, dx \\
&= 0
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{3-3} \int \frac{F(x) W_3(x)}{a W(x)} \, dx \\
&= (-1)^0 \int \frac{\left(-(1+2x)^2 y''' - 2(1+2x) y'' + (4x+2) y'' + (4x^2+4x+1) y'''\right) \left(\sin\left(\frac{\ln(1+2x)}{2}\right)\right)}{(4x^2+4x+1) \left(-\frac{1}{1+2x}\right)} \, dx \\
&= \int \frac{\left(-(1+2x)^2 y''' - 2(1+2x) y'' + (4x+2) y'' + (4x^2+4x+1) y'''\right) \sin\left(\frac{\ln(1+2x)}{2}\right)}{-\frac{4x^2+4x+1}{1+2x}} \, dx \\
&= \int (0) \, dx \\
&= 0
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Hence

$$
\begin{aligned}
y_p &= (0)\\
&+ (0)\left(-\frac{\cos\left(\frac{\ln(1+2x)}{2}\right)}{5}-\frac{2\cos\left(\frac{\ln(1+2x)}{2}\right)x}{5}+\frac{2\sin\left(\frac{\ln(1+2x)}{2}\right)}{5}+\frac{4\sin\left(\frac{\ln(1+2x)}{2}\right)x}{5}\right)\\
&+ (0)\left(\frac{2\cos\left(\frac{\ln(1+2x)}{2}\right)}{5}+\frac{4\cos\left(\frac{\ln(1+2x)}{2}\right)x}{5}+\frac{\sin\left(\frac{\ln(1+2x)}{2}\right)}{5}+\frac{2\sin\left(\frac{\ln(1+2x)}{2}\right)x}{5}\right)
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = 0
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p\\
&= \Bigg(y\\
&= c_1\left(\frac{2\cos\left(\frac{\ln(1+2x)}{2}\right)(1+2x)}{5}+\frac{(1+2x)\sin\left(\frac{\ln(1+2x)}{2}\right)}{5}\right)\\
&\quad + c_2\left(-\frac{\cos\left(\frac{\ln(1+2x)}{2}\right)(1+2x)}{5}+\frac{2(1+2x)\sin\left(\frac{\ln(1+2x)}{2}\right)}{5}\right)+c_3\Bigg)+(0)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = c_1\left(\frac{2\cos\left(\frac{\ln(1+2x)}{2}\right)(1+2x)}{5}+\frac{(1+2x)\sin\left(\frac{\ln(1+2x)}{2}\right)}{5}\right)\\
+ c_2\left(-\frac{\cos\left(\frac{\ln(1+2x)}{2}\right)(1+2x)}{5}+\frac{2(1+2x)\sin\left(\frac{\ln(1+2x)}{2}\right)}{5}\right)+c_3
\end{aligned} \tag{1}
$$

Verification of solutions

$$y = c_1\left(\frac{2\cos\left(\frac{\ln(1+2x)}{2}\right)(1+2x)}{5}+\frac{(1+2x)\sin\left(\frac{\ln(1+2x)}{2}\right)}{5}\right) + c_2\left(-\frac{\cos\left(\frac{\ln(1+2x)}{2}\right)(1+2x)}{5}+\frac{2(1+2x)\sin\left(\frac{\ln(1+2x)}{2}\right)}{5}\right)+c_3$$

Verified OK.

19.10.1 Maple step by step solution

Let's solve

$(1+2x)^2 y''' + 2(1+2x)y'' + y' = 0$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Check to see if $x_0 = -\frac{1}{2}$ is a regular singular point
  - Define functions

    $\left[P_2(x) = \frac{2}{1+2x}, P_3(x) = \frac{1}{(1+2x)^2}, P_4(x) = 0\right]$
  - $\left(x+\frac{1}{2}\right)\cdot P_2(x)$ is analytic at $x = -\frac{1}{2}$

    $\left(\left(x+\frac{1}{2}\right)\cdot P_2(x)\right)\Big|_{x=-\frac{1}{2}} = 1$
  - $\left(x+\frac{1}{2}\right)^2\cdot P_3(x)$ is analytic at $x = -\frac{1}{2}$

    $\left(\left(x+\frac{1}{2}\right)^2\cdot P_3(x)\right)\Big|_{x=-\frac{1}{2}} = \frac{1}{4}$
  - $\left(x+\frac{1}{2}\right)^3\cdot P_4(x)$ is analytic at $x = -\frac{1}{2}$

    $\left(\left(x+\frac{1}{2}\right)^3\cdot P_4(x)\right)\Big|_{x=-\frac{1}{2}} = 0$
  - $x = -\frac{1}{2}$is a regular singular point

  Check to see if $x_0 = -\frac{1}{2}$ is a regular singular point

  $x_0 = -\frac{1}{2}$

- Multiply by denominators

  $y' + (4x+2)y'' + (1+2x)^2 y''' = 0$

- Change variables using $x = u - \frac{1}{2}$ so that the regular singular point is at $u = 0$

  $4u^2 \left(\frac{d^3}{du^3} y(u)\right) + 4u \left(\frac{d^2}{du^2} y(u)\right) + \frac{d}{du} y(u) = 0$
- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite DE with series expansions

  - Convert $\frac{d}{du} y(u)$ to series expansion

    $\frac{d}{du} y(u) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r-1}$
  - Shift index using $k- > k+1$

    $\frac{d}{du} y(u) = \sum_{k=-1}^{\infty} a_{k+1} (k+1+r)\, u^{k+r}$
  - Convert $u \cdot \left(\frac{d^2}{du^2} y(u)\right)$ to series expansion

    $u \cdot \left(\frac{d^2}{du^2} y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, u^{k+r-1}$
  - Shift index using $k- > k+1$

    $u \cdot \left(\frac{d^2}{du^2} y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1} (k+1+r)\,(k+r)\, u^{k+r}$
  - Convert $u^2 \cdot \left(\frac{d^3}{du^3} y(u)\right)$ to series expansion

    $u^2 \cdot \left(\frac{d^3}{du^3} y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\,(k+r-2)\, u^{k+r-1}$
  - Shift index using $k- > k+1$

    $u^2 \cdot \left(\frac{d^3}{du^3} y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1} (k+1+r)\,(k+r)\,(k+r-1)\, u^{k+r}$

  Rewrite DE with series expansions

  $\sum_{k=-1}^{\infty} a_{k+1} (k+1+r) \left(4(k+1)^2 + 8(k+1)\, r + 4r^2 - 8k - 3 - 8r\right) u^{k+r} = 0$
- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r = 0$
- Each term in the series must be 0, giving the recursion relation

  $a_{k+1} (k+1)\,(4k^2+1) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = 0$

- Recursion relation for $r = 0$

  $a_{k+1} = 0$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = 0\right]$

- Revert the change of variables $u = x + \frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k \left(x + \frac{1}{2}\right)^k, a_{k+1} = 0\right]$

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + xy' + y = x(6 - \ln(x))}$$

19.11.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = 1, f(x) = -x\ln(x) + 6x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$.

Solving for y_h from

$$x^2y'' + xy' + y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + xrx^{r-1} + x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + r\,x^r + x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + r + 1 = 0$$

Or

$$r^2 + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= -i \\ r_2 &= i \end{aligned}$$

The roots are complex conjugate of each others. Let the roots be

$$\begin{aligned} r_1 &= \alpha + i\beta \\ r_2 &= \alpha - i\beta \end{aligned}$$

Where in this case $\alpha = 0$ and $\beta = -1$. Hence the solution becomes

$$\begin{aligned} y &= c_1x^{r_1} + c_2x^{r_2} \\ &= c_1x^{\alpha+i\beta} + c_2x^{\alpha-i\beta} \\ &= x^\alpha\left(c_1x^{i\beta} + c_2x^{-i\beta}\right) \\ &= x^\alpha\left(c_1e^{\ln\left(x^{i\beta}\right)} + c_2e^{\ln\left(x^{-i\beta}\right)}\right) \\ &= x^\alpha\left(c_1e^{i(\beta\ln x)} + c_2e^{-i(\beta\ln x)}\right) \end{aligned}$$

Using the values for $\alpha = 0, \beta = -1$, the above becomes

$$y = x^0\left(c_1e^{-i\ln(x)} + c_2e^{i\ln(x)}\right)$$

Using Euler relation, the expression $c_1 e^{iA} + c_2 e^{-iA}$ is transformed to $c_1 \cos A + c_1 \sin A$ where the constants are free to change. Applying this to the above result gives

$$y = c_1 \cos(\ln(x)) + c_2 \sin(\ln(x))$$

Next, we find the particular solution to the ODE

$$x^2 y'' + x y' + y = -x \ln(x) + 6x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \cos(\ln(x)) \\ y_2 &= -\sin(\ln(x)) \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(\ln(x)) & -\sin(\ln(x)) \\ \frac{d}{dx}(\cos(\ln(x))) & \frac{d}{dx}(-\sin(\ln(x))) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(\ln(x)) & -\sin(\ln(x)) \\ -\frac{\sin(\ln(x))}{x} & -\frac{\cos(\ln(x))}{x} \end{vmatrix}$$

Therefore

$$W = (\cos(\ln(x)))\left(-\frac{\cos(\ln(x))}{x}\right) - (-\sin(\ln(x)))\left(-\frac{\sin(\ln(x))}{x}\right)$$

Which simplifies to

$$W = -\frac{\cos(\ln(x))^2 + \sin(\ln(x))^2}{x}$$

Which simplifies to

$$W = -\frac{1}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\sin(\ln(x))(-x\ln(x) + 6x)}{-x}\,dx$$

Which simplifies to

$$u_1 = -\int -\sin(\ln(x))(\ln(x) - 6)\,dx$$

Hence

$$u_1 = \left(-\frac{\ln(x)}{2} + \frac{7}{2}\right)x\cos(\ln(x)) + \left(\frac{\ln(x)}{2} - 3\right)x\sin(\ln(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(\ln(x))(-x\ln(x) + 6x)}{-x}\,dx$$

Which simplifies to

$$u_2 = \int \cos(\ln(x))(\ln(x) - 6)\,dx$$

Hence

$$u_2 = \left(\frac{\ln(x)}{2} - 3\right)x\cos(\ln(x)) - \left(-\frac{\ln(x)}{2} + \frac{7}{2}\right)x\sin(\ln(x))$$

Which simplifies to

$$
\begin{aligned}
u_1 &= -\frac{x((-7+\ln(x))\cos(\ln(x)) - \sin(\ln(x))(\ln(x)-6))}{2} \\
u_2 &= \frac{x(\cos(\ln(x))(\ln(x)-6) + \sin(\ln(x))(-7+\ln(x)))}{2}
\end{aligned}
$$

Therefore the particular solution, from equation (1) is

$$
\begin{aligned}
y_p(x) = &-\frac{x((-7+\ln(x))\cos(\ln(x)) - \sin(\ln(x))(\ln(x)-6))\cos(\ln(x))}{2} \\
&- \frac{x(\cos(\ln(x))(\ln(x)-6) + \sin(\ln(x))(-7+\ln(x)))\sin(\ln(x))}{2}
\end{aligned}
$$

Which simplifies to

$$
y_p(x) = -\frac{x(-7+\ln(x))}{2}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= -\frac{x\ln(x)}{2} + c_1\cos(\ln(x)) + c_2\sin(\ln(x)) + \frac{7x}{2}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = -\frac{x\ln(x)}{2} + c_1\cos(\ln(x)) + c_2\sin(\ln(x)) + \frac{7x}{2} \tag{1}
$$

Verification of solutions

$$
y = -\frac{x\ln(x)}{2} + c_1\cos(\ln(x)) + c_2\sin(\ln(x)) + \frac{7x}{2}
$$

Verified OK.

19.11.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + xy' + y = 0$$

In normal form the ode

$$x^2y'' + xy' + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= \frac{1}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\, \tau'(x) = 0$$

This ode is solved resulting in

$$
\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\
&= \int \mathrm{e}^{-\left(\int \frac{1}{x}dx\right)} dx \\
&= \int e^{-\ln(x)}\, dx \\
&= \int \frac{1}{x} dx \\
&= \ln (x) \qquad (6)
\end{aligned}
$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{1}{x^2}}{\frac{1}{x^2}} \\
&= 1 \qquad (7)
\end{aligned}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2} y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2} y(\tau) + y(\tau) &= 0
\end{aligned}
$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$
Ay''(\tau) + By'(\tau) + Cy(\tau) = 0
$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y(\tau) = e^{\lambda \tau}$. Substituting this into the ODE gives

$$
\lambda^2 \mathrm{e}^{\lambda \tau} + \mathrm{e}^{\lambda \tau} = 0 \qquad (1)
$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda \tau}$ gives

$$
\lambda^2 + 1 = 0 \qquad (2)
$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$
\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}
$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\lambda_{1,2} = \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)} \sqrt{0^2 - (4)(1)(1)}$$
$$= \pm i$$

Hence

$$\lambda_1 = +i$$
$$\lambda_2 = -i$$

Which simplifies to

$$\lambda_1 = i$$
$$\lambda_2 = -i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y(\tau) = e^{\alpha\tau}(c_1 \cos(\beta\tau) + c_2 \sin(\beta\tau))$$

Which becomes

$$y(\tau) = e^0(c_1 \cos(\tau) + c_2 \sin(\tau))$$

Or

$$y(\tau) = c_1 \cos(\tau) + c_2 \sin(\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \cos(\ln(x)) + c_2 \sin(\ln(x))$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(\ln(x)) + c_2 \sin(\ln(x))$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(\ln(x))$$
$$y_2 = \sin(\ln(x))$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(\ln(x)) & \sin(\ln(x)) \\ \frac{d}{dx}(\cos(\ln(x))) & \frac{d}{dx}(\sin(\ln(x))) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(\ln(x)) & \sin(\ln(x)) \\ -\frac{\sin(\ln(x))}{x} & \frac{\cos(\ln(x))}{x} \end{vmatrix}$$

Therefore

$$W = (\cos(\ln(x)))\left(\frac{\cos(\ln(x))}{x}\right) - (\sin(\ln(x)))\left(-\frac{\sin(\ln(x))}{x}\right)$$

Which simplifies to

$$W = \frac{\cos(\ln(x))^2 + \sin(\ln(x))^2}{x}$$

Which simplifies to

$$W = \frac{1}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(\ln(x))(-x\ln(x)+6x)}{x}\,dx$$

Which simplifies to

$$u_1 = -\int -\sin(\ln(x))(\ln(x)-6)\,dx$$

Hence

$$u_1 = \left(-\frac{\ln(x)}{2}+\frac{7}{2}\right)x\cos(\ln(x)) + \left(\frac{\ln(x)}{2}-3\right)x\sin(\ln(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(\ln(x))(-x\ln(x)+6x)}{x}\,dx$$

Which simplifies to

$$u_2 = \int -\cos(\ln(x))(\ln(x)-6)\,dx$$

Hence

$$u_2 = -\left(\frac{\ln(x)}{2}-3\right)x\cos(\ln(x)) + \left(-\frac{\ln(x)}{2}+\frac{7}{2}\right)x\sin(\ln(x))$$

Which simplifies to

$$u_1 = -\frac{x((-7+\ln(x))\cos(\ln(x)) - \sin(\ln(x))(\ln(x)-6))}{2}$$
$$u_2 = -\frac{x(\cos(\ln(x))(\ln(x)-6) + \sin(\ln(x))(-7+\ln(x)))}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x((-7+\ln(x))\cos(\ln(x)) - \sin(\ln(x))(\ln(x)-6))\cos(\ln(x))}{2} - \frac{x(\cos(\ln(x))(\ln(x)-6) + \sin(\ln(x))(-7+\ln(x)))\sin(\ln(x))}{2}$$

Which simplifies to

$$y_p(x) = -\frac{x(-7+\ln(x))}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(\ln(x)) + c_2 \sin(\ln(x))) + \left(-\frac{x(-7+\ln(x))}{2}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = -\frac{x(-7+\ln(x))}{2} + c_1 \cos(\ln(x)) + c_2 \sin(\ln(x)) \tag{1}$$

Verification of solutions

$$y = -\frac{x(-7+\ln(x))}{2} + c_1 \cos(\ln(x)) + c_2 \sin(\ln(x))$$

Verified OK.

19.11.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = 1, f(x) = -x\ln(x) + 6x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + xy' + y = 0$$

In normal form the ode

$$x^2y'' + xy' + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= \frac{1}{x} \\
q(x) &= \frac{1}{x^2}
\end{aligned}
$$

Applying change of variables $\tau = g(x)$ to (2) results

$$
\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}
$$

Where τ is the new independent variable, and

$$
p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}
$$

$$
q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}
$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$
\begin{aligned}
\tau' &= \frac{1}{c}\sqrt{q} \\
&= \frac{\sqrt{\frac{1}{x^2}}}{c} \\
\tau'' &= -\frac{1}{c\sqrt{\frac{1}{x^2}}\,x^3}
\end{aligned} \tag{6}
$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{1}{c\sqrt{\frac{1}{x^2}}\,x^3} + \frac{1}{x}\frac{\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= 0
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0
\end{aligned} \tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$\begin{aligned}\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int \sqrt{\frac{1}{x^2}}dx}{c} \\ &= \frac{\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = c_1 \cos(\ln(x)) + c_2 \sin(\ln(x))$$

Now the particular solution to this ODE is found

$$x^2y'' + xy' + y = -x\ln(x) + 6x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}y_1 &= \cos(\ln(x)) \\ y_2 &= \sin(\ln(x))\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(\ln(x)) & \sin(\ln(x)) \\ \frac{d}{dx}(\cos(\ln(x))) & \frac{d}{dx}(\sin(\ln(x))) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(\ln(x)) & \sin(\ln(x)) \\ -\frac{\sin(\ln(x))}{x} & \frac{\cos(\ln(x))}{x} \end{vmatrix}$$

Therefore

$$W = (\cos(\ln(x)))\left(\frac{\cos(\ln(x))}{x}\right) - (\sin(\ln(x)))\left(-\frac{\sin(\ln(x))}{x}\right)$$

Which simplifies to

$$W = \frac{\cos(\ln(x))^2 + \sin(\ln(x))^2}{x}$$

Which simplifies to

$$W = \frac{1}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(\ln(x))(-x\ln(x) + 6x)}{x}\,dx$$

Which simplifies to

$$u_1 = -\int -\sin(\ln(x))(\ln(x) - 6)\,dx$$

Hence

$$u_1 = \left(-\frac{\ln(x)}{2} + \frac{7}{2}\right) x\cos(\ln(x)) + \left(\frac{\ln(x)}{2} - 3\right) x\sin(\ln(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(\ln(x))(-x\ln(x) + 6x)}{x}\,dx$$

Which simplifies to

$$u_2 = \int -\cos(\ln(x))(\ln(x) - 6)\,dx$$

Hence

$$u_2 = -\left(\frac{\ln(x)}{2} - 3\right) x\cos(\ln(x)) + \left(-\frac{\ln(x)}{2} + \frac{7}{2}\right) x\sin(\ln(x))$$

Which simplifies to

$$u_1 = -\frac{x((-7 + \ln(x))\cos(\ln(x)) - \sin(\ln(x))(\ln(x) - 6))}{2}$$
$$u_2 = -\frac{x(\cos(\ln(x))(\ln(x) - 6) + \sin(\ln(x))(-7 + \ln(x)))}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x((-7 + \ln(x))\cos(\ln(x)) - \sin(\ln(x))(\ln(x) - 6))\cos(\ln(x))}{2} - \frac{x(\cos(\ln(x))(\ln(x) - 6) + \sin(\ln(x))(-7 + \ln(x)))\sin(\ln(x))}{2}$$

Which simplifies to

$$y_p(x) = -\frac{x(-7 + \ln(x))}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(\ln(x)) + c_2\sin(\ln(x))) + \left(-\frac{x(-7 + \ln(x))}{2}\right) \\ &= -\frac{x(-7 + \ln(x))}{2} + c_1\cos(\ln(x)) + c_2\sin(\ln(x)) \end{aligned}$$

Which simplifies to

$$y = -\frac{x\ln(x)}{2} + c_1\cos(\ln(x)) + c_2\sin(\ln(x)) + \frac{7x}{2}$$

Summary
The solution(s) found are the following

$$y = -\frac{x \ln(x)}{2} + c_1 \cos(\ln(x)) + c_2 \sin(\ln(x)) + \frac{7x}{2} \tag{1}$$

Verification of solutions

$$y = -\frac{x \ln(x)}{2} + c_1 \cos(\ln(x)) + c_2 \sin(\ln(x)) + \frac{7x}{2}$$

Verified OK.

19.11.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = 1, f(x) = -x \ln(x) + 6x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + xy' + y = 0$$

In normal form the ode

$$x^2y'' + xy' + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{1}{x^2}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n}{x^2} + \frac{1}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = i \tag{6}$$

Substituting this value in (3) gives

$$v''(x) + \left(\frac{2i}{x} + \frac{1}{x}\right) v'(x) = 0$$

$$v''(x) + \frac{(1+2i)\, v'(x)}{x} = 0 \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(1+2i)\, u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= \frac{(-1-2i)\, u}{x} \end{aligned}$$

Where $f(x) = \frac{-1-2i}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= \frac{-1-2i}{x}\, dx \\ \int \frac{1}{u}\, du &= \int \frac{-1-2i}{x}\, dx \\ \ln(u) &= (-1-2i)\ln(x) + c_1 \\ u &= \mathrm{e}^{(-1-2i)\ln(x)+c_1} \\ &= c_1 \mathrm{e}^{(-1-2i)\ln(x)} \end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1 x^{-2i}}{x}$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= \frac{i c_1 x^{-2i}}{2} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\, x^n \\
&= \left(\frac{i c_1 x^{-2i}}{2} + c_2\right) x^i \\
&= x^i c_2 + \frac{i x^{-i} c_1}{2}
\end{aligned}$$

Now the particular solution to this ODE is found

$$x^2 y'' + x y' + y = -x \ln(x) + 6x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= x^i \\
y_2 &= x^{-i}
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^i & x^{-i} \\ \frac{d}{dx}(x^i) & \frac{d}{dx}(x^{-i}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^i & x^{-i} \\ \frac{i x^i}{x} & -\frac{i x^{-i}}{x} \end{vmatrix}$$

Therefore

$$W = (x^i)\left(-\frac{i x^{-i}}{x}\right) - (x^{-i})\left(\frac{i x^i}{x}\right)$$

Which simplifies to

$$W = -\frac{2i}{x}$$

Which simplifies to

$$W = -\frac{2i}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^{-i}(-x\ln(x) + 6x)}{-2ix}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{i(\ln(x) - 6)\,x^{-i}}{2} dx$$

Hence

$$u_1 = \frac{(7-6i+(-1+i)\ln(x))\,x^{1-i}}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^i(-x\ln(x)+6x)}{-2ix}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{ix^i(\ln(x)-6)}{2}dx$$

Hence

$$u_2 = -\frac{x^{1+i}(-7-6i+(1+i)\ln(x))}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{(7-6i+(-1+i)\ln(x))\,x^{1-i}x^i}{4} - \frac{x^{1+i}(-7-6i+(1+i)\ln(x))\,x^{-i}}{4}$$

Which simplifies to

$$y_p(x) = -\frac{x(-7+\ln(x))}{2}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(\left(\frac{ic_1x^{-2i}}{2}+c_2\right)x^i\right) + \left(-\frac{x(-7+\ln(x))}{2}\right) \\
&= -\frac{x(-7+\ln(x))}{2} + \left(\frac{ic_1x^{-2i}}{2}+c_2\right)x^i
\end{aligned}$$

Which simplifies to

$$y = \frac{ix^{-i}c_1}{2} + x^ic_2 - \frac{x(-7+\ln(x))}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{i x^{-i} c_1}{2} + x^i c_2 - \frac{x(-7 + \ln(x))}{2} \tag{1}$$

Verification of solutions

$$y = \frac{i x^{-i} c_1}{2} + x^i c_2 - \frac{x(-7 + \ln(x))}{2}$$

Verified OK.

19.11.5 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' + x y' + y = 0 \tag{1}$$
$$A y'' + B y' + C y = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-5}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -5 \\
t &= 4x^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(-\frac{5}{4x^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 630: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{5}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + i \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - i \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{5}{4x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{5}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + i \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - i \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{5}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2} + i$	$\frac{1}{2} - i$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}+i$	$\frac{1}{2}-i$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{1}{2}-i$ then

$$\begin{aligned}
d&=\alpha_\infty^{-}-\left(\alpha_{c_1}^{-}\right)\\
&=\frac{1}{2}-i-\left(\frac{1}{2}-i\right)\\
&=0
\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega&=\left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^{-}}{x-c_1}\right)+(-)[\sqrt{r}]_\infty\\
&=\frac{\frac{1}{2}-i}{x}+(-)\,(0)\\
&=\frac{\frac{1}{2}-i}{x}\\
&=\frac{\frac{1}{2}-i}{x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{\frac{1}{2}-i}{x}\right)(0)+\left(\left(\frac{-\frac{1}{2}+i}{x^2}\right)+\left(\frac{\frac{1}{2}-i}{x}\right)^2-\left(-\frac{5}{4x^2}\right)\right)=0$$

$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\,dx} \\
&= \mathrm{e}^{\int \frac{\frac{1}{2}-i}{x}dx} \\
&= x^{\frac{1}{2}-i}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2}\,dx} \\
&= z_1 e^{-\frac{\ln(x)}{2}} \\
&= z_1\left(\frac{1}{\sqrt{x}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x^{-i}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{i x^{2i}}{2}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{-i}\right) + c_2 \left(x^{-i} \left(-\frac{i x^{2i}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2 y'' + x y' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = x^{-i} c_1 - \frac{i c_2 x^i}{2}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x^{-i} \\
y_2 &= -\frac{i x^i}{2}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^{-i} & -\frac{i x^{i}}{2} \\ \frac{d}{dx}(x^{-i}) & \frac{d}{dx}\left(-\frac{i x^{i}}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^{-i} & -\frac{i x^{i}}{2} \\ -\frac{i x^{-i}}{x} & \frac{x^{i}}{2x} \end{vmatrix}$$

Therefore

$$W = (x^{-i})\left(\frac{x^{i}}{2x}\right) - \left(-\frac{i x^{i}}{2}\right)\left(-\frac{i x^{-i}}{x}\right)$$

Which simplifies to

$$W = \frac{x^{-i} x^{i}}{x}$$

Which simplifies to

$$W = \frac{1}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{i x^{i}(-x\ln(x)+6x)}{2}}{x}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{i x^{i}(\ln(x) - 6)}{2} dx$$

Hence

$$u_1 = -\frac{x^{1+i}(-7 - 6i + (1+i)\ln(x))}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^{-i}(-x\ln(x) + 6x)}{x}\, dx$$

Which simplifies to

$$u_2 = \int (6 - \ln(x))\, x^{-i} dx$$

Hence

$$u_2 = -\frac{(-6 - 7i + (1 + i)\ln(x))\, x^{1-i}}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^{1+i}(-7 - 6i + (1 + i)\ln(x))\, x^{-i}}{4} + \frac{i(-6 - 7i + (1 + i)\ln(x))\, x^{1-i} x^{i}}{4}$$

Which simplifies to

$$y_p(x) = -\frac{x(-7 + \ln(x))}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(x^{-i} c_1 - \frac{i c_2 x^{i}}{2}\right) + \left(-\frac{x(-7 + \ln(x))}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = x^{-i} c_1 - \frac{i c_2 x^{i}}{2} - \frac{x(-7 + \ln(x))}{2} \tag{1}$$

Verification of solutions

$$y = x^{-i} c_1 - \frac{i c_2 x^{i}}{2} - \frac{x(-7 + \ln(x))}{2}$$

Verified OK.

```
[[_2nd_order, _exact, _linear, _nonhomogeneous]]
```

$$\boxed{x^2y'' - 2y = \sin(\ln(x))}$$

19.12.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 0, C = -2, f(x) = \sin(\ln(x))$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 2y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 0rx^{r-1} - 2x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 0\,x^r - 2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 0 - 2 = 0$$

Or

$$r^2 - r - 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -1$$
$$r_2 = 2$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = \frac{c_1}{x} + c_2x^2$$

Next, we find the particular solution to the ODE

$$x^2y'' - 2y = \sin(\ln(x))$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = x^2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & x^2 \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(x^2\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & x^2 \\ -\frac{1}{x^2} & 2x \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)(2x) - \left(x^2\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = 3$$

Which simplifies to

$$W = 3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^2 \sin(\ln(x))}{3x^2}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(\ln(x))}{3} dx$$

Hence

$$u_1 = \frac{x\cos(\ln(x))}{6} - \frac{x\sin(\ln(x))}{6}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\sin(\ln(x))}{x}}{3x^2}\,dx$$

Which simplifies to

$$u_2 = \int \frac{\sin(\ln(x))}{3x^3}dx$$

Hence

$$u_2 = \frac{-\frac{1}{15} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{15} - \frac{4\tan\left(\frac{\ln(x)}{2}\right)}{15}}{x^2\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)}$$

Which simplifies to

$$u_1 = -\frac{x(-\cos(\ln(x)) + \sin(\ln(x)))}{6}$$

$$u_2 = \frac{-\cos(\ln(x)) - 2\sin(\ln(x))}{15x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\cos(\ln(x))}{10} - \frac{3\sin(\ln(x))}{10}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \frac{\cos(\ln(x))}{10} - \frac{3\sin(\ln(x))}{10} + \frac{c_1}{x} + c_2x^2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\cos(\ln(x))}{10} - \frac{3\sin(\ln(x))}{10} + \frac{c_1}{x} + c_2x^2 \tag{1}$$

Verification of solutions

$$y = \frac{\cos(\ln(x))}{10} - \frac{3\sin(\ln(x))}{10} + \frac{c_1}{x} + c_2x^2$$

Verified OK.

19.12.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2y'' - 2y)\,dx = \int \sin(\ln(x))\,dx$$

$$x^2y' - 2yx = -\frac{x\cos(\ln(x))}{2} + \frac{x\sin(\ln(x))}{2} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{2}{x}$$
$$q(x) = \frac{x\sin(\ln(x)) - x\cos(\ln(x)) + 2c_1}{2x^2}$$

Hence the ode is

$$y' - \frac{2y}{x} = \frac{x\sin(\ln(x)) - x\cos(\ln(x)) + 2c_1}{2x^2}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{2}{x}dx}$$
$$= \frac{1}{x^2}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{x\sin(\ln(x)) - x\cos(\ln(x)) + 2c_1}{2x^2}\right)$$
$$\frac{d}{dx}\left(\frac{y}{x^2}\right) = \left(\frac{1}{x^2}\right)\left(\frac{x\sin(\ln(x)) - x\cos(\ln(x)) + 2c_1}{2x^2}\right)$$
$$d\left(\frac{y}{x^2}\right) = \left(\frac{x\sin(\ln(x)) - x\cos(\ln(x)) + 2c_1}{2x^4}\right)dx$$

Integrating gives

$$\frac{y}{x^2} = \int \frac{x \sin(\ln(x)) - x \cos(\ln(x)) + 2c_1}{2x^4} \mathrm{d}x$$

$$\frac{y}{x^2} = -\frac{c_1}{3x^3} - \frac{-\frac{2}{5} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)^2}{5} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)}{5}}{2x^2\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)} + \frac{-\frac{1}{5} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{5} - \frac{4\tan\left(\frac{\ln(x)}{2}\right)}{5}}{2x^2\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)} + c_2$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$y = x^2\left(-\frac{c_1}{3x^3} - \frac{-\frac{2}{5} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)^2}{5} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)}{5}}{2x^2\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)} + \frac{-\frac{1}{5} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{5} - \frac{4\tan\left(\frac{\ln(x)}{2}\right)}{5}}{2x^2\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)}\right) + c_2x^2$$

which simplifies to

$$y = \frac{-\frac{(3\sin(\ln(x))-\cos(\ln(x)))x}{10} - \frac{c_1}{3} + c_2x^3}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{-\frac{(3\sin(\ln(x))-\cos(\ln(x)))x}{10} - \frac{c_1}{3} + c_2x^3}{x} \tag{1}$$

Verification of solutions

$$y = \frac{-\frac{(3\sin(\ln(x))-\cos(\ln(x)))x}{10} - \frac{c_1}{3} + c_2x^3}{x}$$

Verified OK.

19.12.3 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$x^2y'' - 2y = \sin(\ln(x))$$

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2y'' - 2y)\, dx = \int \sin(\ln(x))\, dx$$

$$x^2y' - 2yx = -\frac{x\cos(\ln(x))}{2} + \frac{x\sin(\ln(x))}{2} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= \frac{x\sin(\ln(x)) - x\cos(\ln(x)) + 2c_1}{2x^2} \end{aligned}$$

Hence the ode is

$$y' - \frac{2y}{x} = \frac{x\sin(\ln(x)) - x\cos(\ln(x)) + 2c_1}{2x^2}$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int -\frac{2}{x}dx} \\ &= \frac{1}{x^2} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{x\sin(\ln(x)) - x\cos(\ln(x)) + 2c_1}{2x^2}\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{x^2}\right) &= \left(\frac{1}{x^2}\right)\left(\frac{x\sin(\ln(x)) - x\cos(\ln(x)) + 2c_1}{2x^2}\right) \\ \mathrm{d}\left(\frac{y}{x^2}\right) &= \left(\frac{x\sin(\ln(x)) - x\cos(\ln(x)) + 2c_1}{2x^4}\right)\mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} \frac{y}{x^2} &= \int \frac{x\sin(\ln(x)) - x\cos(\ln(x)) + 2c_1}{2x^4}\,\mathrm{d}x \\ \frac{y}{x^2} &= -\frac{c_1}{3x^3} - \frac{-\frac{2}{5} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)^2}{5} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)}{5}}{2x^2\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)} + \frac{-\frac{1}{5} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{5} - \frac{4\tan\left(\frac{\ln(x)}{2}\right)}{5}}{2x^2\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$y = x^2\left(-\frac{c_1}{3x^3} - \frac{-\frac{2}{5} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)^2}{5} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)}{5}}{2x^2\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)} + \frac{-\frac{1}{5} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{5} - \frac{4\tan\left(\frac{\ln(x)}{2}\right)}{5}}{2x^2\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)}\right) + c_2x^2$$

which simplifies to

$$y = \frac{-\frac{(3\sin(\ln(x))-\cos(\ln(x)))x}{10} - \frac{c_1}{3} + c_2 x^3}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{-\frac{(3\sin(\ln(x))-\cos(\ln(x)))x}{10} - \frac{c_1}{3} + c_2 x^3}{x} \tag{1}$$

Verification of solutions

$$y = \frac{-\frac{(3\sin(\ln(x))-\cos(\ln(x)))x}{10} - \frac{c_1}{3} + c_2 x^3}{x}$$

Verified OK.

19.12.4 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 0 \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 2$$
$$t = x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 631: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2}{x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= -1 - (-1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{x} + (-)(0) \\
&= -\frac{1}{x} \\
&= -\frac{1}{x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{x}\right)(0) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x}\right)^2 - \left(\frac{2}{x^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int -\frac{1}{x} dx} \\ &= \frac{1}{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \frac{1}{x} \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2} \, dx \\ &= \frac{1}{x} \int \frac{1}{\frac{1}{x^2}} \, dx \\ &= \frac{1}{x}\left(\frac{x^3}{3}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x}\right) + c_2 \left(\frac{1}{x}\left(\frac{x^3}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' - 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \frac{c_1}{x} + \frac{c_2 x^2}{3}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \frac{1}{x} \\
y_2 &= \frac{x^2}{3}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x^2}{3} \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(\frac{x^2}{3}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x^2}{3} \\ -\frac{1}{x^2} & \frac{2x}{3} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)\left(\frac{2x}{3}\right) - \left(\frac{x^2}{3}\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = 1$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x^2 \sin(\ln(x))}{3}}{x^2}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(\ln(x))}{3} dx$$

Hence

$$u_1 = \frac{x\cos(\ln(x))}{6} - \frac{x\sin(\ln(x))}{6}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\sin(\ln(x))}{x}}{x^2}\, dx$$

Which simplifies to

$$u_2 = \int \frac{\sin(\ln(x))}{x^3} dx$$

Hence

$$u_2 = \frac{-\frac{1}{5} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{5} - \frac{4\tan\left(\frac{\ln(x)}{2}\right)}{5}}{x^2\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)}$$

Which simplifies to

$$u_1 = -\frac{x(-\cos(\ln(x)) + \sin(\ln(x)))}{6}$$
$$u_2 = \frac{-\cos(\ln(x)) - 2\sin(\ln(x))}{5x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\cos(\ln(x))}{10} - \frac{3\sin(\ln(x))}{10}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x} + \frac{c_2 x^2}{3}\right) + \left(\frac{\cos(\ln(x))}{10} - \frac{3\sin(\ln(x))}{10}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x} + \frac{c_2 x^2}{3} + \frac{\cos(\ln(x))}{10} - \frac{3\sin(\ln(x))}{10} \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x} + \frac{c_2 x^2}{3} + \frac{\cos(\ln(x))}{10} - \frac{3\sin(\ln(x))}{10}$$

Verified OK.

19.12.5 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x^2 \\ q(x) &= 0 \\ r(x) &= -2 \\ s(x) &= \sin(\ln(x)) \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 2 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$2 - (0) + (-2) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\;dx$$

Substituting the above values for p, q, r, s gives

$$x^2y' - 2yx = \int \sin(\ln(x))\;dx$$

We now have a first order ode to solve which is

$$x^2y' - 2yx = -\frac{x\cos(\ln(x))}{2} + \frac{x\sin(\ln(x))}{2} + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= \frac{c_1 + \frac{x(-\cos(\ln(x))+\sin(\ln(x)))}{2}}{x^2} \end{aligned}$$

Hence the ode is

$$y' - \frac{2y}{x} = \frac{c_1 + \frac{x(-\cos(\ln(x))+\sin(\ln(x)))}{2}}{x^2}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int -\frac{2}{x} dx} \\ &= \frac{1}{x^2} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(\frac{c_1 + \frac{x(-\cos(\ln(x))+\sin(\ln(x)))}{2}}{x^2}\right) \\ \frac{d}{dx}\left(\frac{y}{x^2}\right) &= \left(\frac{1}{x^2}\right)\left(\frac{c_1 + \frac{x(-\cos(\ln(x))+\sin(\ln(x)))}{2}}{x^2}\right) \\ d\left(\frac{y}{x^2}\right) &= \left(\frac{c_1 + \frac{x(-\cos(\ln(x))+\sin(\ln(x)))}{2}}{x^4}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} \frac{y}{x^2} &= \int \frac{c_1 + \frac{x(-\cos(\ln(x))+\sin(\ln(x)))}{2}}{x^4} dx \\ \frac{y}{x^2} &= -\frac{c_1}{3x^3} - \frac{-\frac{2}{5} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)^2}{5} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)}{5}}{2x^2\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)} + \frac{-\frac{1}{5} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{5} - \frac{4\tan\left(\frac{\ln(x)}{2}\right)}{5}}{2x^2\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$y = x^2\left(-\frac{c_1}{3x^3} - \frac{-\frac{2}{5} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)^2}{5} + \frac{2\tan\left(\frac{\ln(x)}{2}\right)}{5}}{2x^2\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)} + \frac{-\frac{1}{5} + \frac{\tan\left(\frac{\ln(x)}{2}\right)^2}{5} - \frac{4\tan\left(\frac{\ln(x)}{2}\right)}{5}}{2x^2\left(1+\tan\left(\frac{\ln(x)}{2}\right)^2\right)}\right) + c_2x^2$$

which simplifies to

$$y = \frac{-\frac{(3\sin(\ln(x))-\cos(\ln(x)))x}{10} - \frac{c_1}{3} + c_2 x^3}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{-\frac{(3\sin(\ln(x))-\cos(\ln(x)))x}{10} - \frac{c_1}{3} + c_2 x^3}{x} \tag{1}$$

Verification of solutions

$$y = \frac{-\frac{(3\sin(\ln(x))-\cos(\ln(x)))x}{10} - \frac{c_1}{3} + c_2 x^3}{x}$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _nonhomogeneous]]
```

$$x^2y'' - xy' - 3y = -\frac{16\ln(x)}{x}$$

19.13.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -x, C = -3, f(x) = -\frac{16\ln(x)}{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - xy' - 3y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - xrx^{r-1} - 3x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - r\,x^r - 3x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - r - 3 = 0$$

Or

$$r^2 - 2r - 3 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -1$$
$$r_2 = 3$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = \frac{c_1}{x} + c_2x^3$$

Next, we find the particular solution to the ODE

$$x^2y'' - xy' - 3y = -\frac{16\ln(x)}{x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = x^3$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & x^3 \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}(x^3) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & x^3 \\ -\frac{1}{x^2} & 3x^2 \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)\left(3x^2\right) - \left(x^3\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = 4x$$

Which simplifies to

$$W = 4x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-16x^2 \ln(x)}{4x^3}\, dx$$

Which simplifies to

$$u_1 = -\int -\frac{4\ln(x)}{x} dx$$

Hence

$$u_1 = 2\ln(x)^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{-\frac{16\ln(x)}{x^2}}{4x^3}\, dx$$

Which simplifies to

$$u_2 = \int -\frac{4\ln(x)}{x^5} dx$$

Hence

$$u_2 = \frac{\ln(x)}{x^4} + \frac{1}{4x^4}$$

Which simplifies to

$$u_1 = 2\ln(x)^2$$
$$u_2 = \frac{\frac{1}{4} + \ln(x)}{x^4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{2\ln(x)^2}{x} + \frac{\frac{1}{4} + \ln(x)}{x}$$

Which simplifies to

$$y_p(x) = \frac{2\ln(x)^2 + \frac{1}{4} + \ln(x)}{x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \frac{4c_2x^4 + 8\ln(x)^2 + 4\ln(x) + 4c_1 + 1}{4x} \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{4c_2x^4 + 8\ln(x)^2 + 4\ln(x) + 4c_1 + 1}{4x} \tag{1}$$

Verification of solutions

$$y = \frac{4c_2x^4 + 8\ln(x)^2 + 4\ln(x) + 4c_1 + 1}{4x}$$

Verified OK.

19.13.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - xy' - 3y = 0$$

In normal form the ode

$$x^2y'' - xy' - 3y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= -\frac{3}{x^2}
\end{aligned}
$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$
\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}
$$

Where τ is the new independent variable, and

$$
p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}
$$

$$
q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}
$$

Let $p_1 = 0$. Eq (4) simplifies to

$$
\tau''(x) + p(x)\, \tau'(x) = 0
$$

This ode is solved resulting in

$$
\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\
&= \int \mathrm{e}^{-\left(\int -\frac{1}{x} dx\right)} dx \\
&= \int e^{\ln(x)}\, dx \\
&= \int x dx \\
&= \frac{x^2}{2}
\end{aligned} \tag{6}
$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{-\frac{3}{x^2}}{x^2} \\
&= -\frac{3}{x^4}
\end{aligned} \tag{7}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) - \frac{3y(\tau)}{x^4} = 0$$

But in terms of τ

$$-\frac{3}{x^4} = -\frac{3}{4\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) - \frac{3y(\tau)}{4\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$4\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 - 3y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} - 3\tau^r = 0$$

Simplifying gives

$$4r(r-1)\,\tau^r + 0\,\tau^r - 3\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$4r(r-1) + 0 - 3 = 0$$

Or

$$4r^2 - 4r - 3 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -\frac{1}{2}$$
$$r_2 = \frac{3}{2}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = \frac{c_1}{\sqrt{\tau}} + c_2\tau^{\frac{3}{2}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{2}\,(c_2x^4 + 4c_1)}{4x}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{\sqrt{2}\,(c_2x^4 + 4c_1)}{4x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$

$$y_2 = x^3$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & x^3 \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}(x^3) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & x^3 \\ -\frac{1}{x^2} & 3x^2 \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)(3x^2) - (x^3)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = 4x$$

Which simplifies to

$$W = 4x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-16x^2 \ln(x)}{4x^3} dx$$

Which simplifies to

$$u_1 = -\int -\frac{4\ln(x)}{x} dx$$

Hence

$$u_1 = 2\ln(x)^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{-\frac{16\ln(x)}{x^2}}{4x^3} dx$$

Which simplifies to

$$u_2 = \int -\frac{4\ln(x)}{x^5} dx$$

Hence

$$u_2 = \frac{\ln(x)}{x^4} + \frac{1}{4x^4}$$

Which simplifies to

$$u_1 = 2\ln(x)^2$$

$$u_2 = \frac{\frac{1}{4}+\ln(x)}{x^4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{2\ln(x)^2}{x} + \frac{\frac{1}{4}+\ln(x)}{x}$$

Which simplifies to

$$y_p(x) = \frac{2\ln(x)^2+\frac{1}{4}+\ln(x)}{x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{\sqrt{2}\,(c_2x^4+4c_1)}{4x}\right) + \left(\frac{2\ln(x)^2+\frac{1}{4}+\ln(x)}{x}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{2}\,(c_2x^4+4c_1)}{4x} + \frac{2\ln(x)^2+\frac{1}{4}+\ln(x)}{x} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{2}\,(c_2x^4+4c_1)}{4x} + \frac{2\ln(x)^2+\frac{1}{4}+\ln(x)}{x}$$

Verified OK.

19.13.3 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -x, C = -3, f(x) = -\frac{16\ln(x)}{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - xy' - 3y = 0$$

In normal form the ode

$$x^2y'' - xy' - 3y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= -\frac{3}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{n}{x^2} - \frac{3}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 3 \tag{6}$$

Substituting this value in (3) gives

$$v''(x) + \frac{5v'(x)}{x} = 0$$
$$v''(x) + \frac{5v'(x)}{x} = 0 \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{5u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{5u}{x} \end{aligned}$$

Where $f(x) = -\frac{5}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{5}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{5}{x}\,dx \\ \ln(u) &= -5\ln(x) + c_1 \\ u &= \mathrm{e}^{-5\ln(x)+c_1} \\ &= \frac{c_1}{x^5} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= -\frac{c_1}{4x^4} + c_2 \end{aligned}$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(-\frac{c_1}{4x^4} + c_2\right) x^3 \\
&= \frac{4c_2x^4 - c_1}{4x}
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
x^2y'' - xy' - 3y = -\frac{16 \ln(x)}{x}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1y_1 + u_2y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \frac{1}{x} \\
y_2 &= x^3
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix} \frac{1}{x} & x^3 \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}(x^3) \end{vmatrix}
$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & x^3 \\ -\frac{1}{x^2} & 3x^2 \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)(3x^2) - (x^3)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = 4x$$

Which simplifies to

$$W = 4x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-16x^2 \ln(x)}{4x^3}\, dx$$

Which simplifies to

$$u_1 = -\int -\frac{4\ln(x)}{x} dx$$

Hence

$$u_1 = 2\ln(x)^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{-\frac{16\ln(x)}{x^2}}{4x^3}\, dx$$

Which simplifies to

$$u_2 = \int -\frac{4\ln(x)}{x^5} dx$$

Hence

$$u_2 = \frac{\ln(x)}{x^4} + \frac{1}{4x^4}$$

Which simplifies to

$$u_1 = 2\ln(x)^2$$

$$u_2 = \frac{\frac{1}{4} + \ln(x)}{x^4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{2\ln(x)^2}{x} + \frac{\frac{1}{4} + \ln(x)}{x}$$

Which simplifies to

$$y_p(x) = \frac{2\ln(x)^2 + \frac{1}{4} + \ln(x)}{x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(-\frac{c_1}{4x^4} + c_2\right)x^3\right) + \left(\frac{2\ln(x)^2 + \frac{1}{4} + \ln(x)}{x}\right) \\ &= \frac{2\ln(x)^2 + \frac{1}{4} + \ln(x)}{x} + \left(-\frac{c_1}{4x^4} + c_2\right)x^3 \end{aligned}$$

Which simplifies to

$$y = \frac{4c_2x^4 + 8\ln(x)^2 + 4\ln(x) - c_1 + 1}{4x}$$

Summary

The solution(s) found are the following

$$y = \frac{4c_2x^4 + 8\ln(x)^2 + 4\ln(x) - c_1 + 1}{4x} \tag{1}$$

Verification of solutions

$$y = \frac{4c_2x^4 + 8\ln(x)^2 + 4\ln(x) - c_1 + 1}{4x}$$

Verified OK.

19.13.4 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2y'' - xy' - 3y)\, dx = \int -\frac{16\ln(x)}{x} dx$$
$$x^2y' - 3yx = -8\ln(x)^2 + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{3}{x}$$
$$q(x) = \frac{-8\ln(x)^2 + c_1}{x^2}$$

Hence the ode is

$$y' - \frac{3y}{x} = \frac{-8\ln(x)^2 + c_1}{x^2}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{3}{x}dx}$$
$$= \frac{1}{x^3}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{-8\ln(x)^2 + c_1}{x^2}\right)$$
$$\frac{d}{dx}\left(\frac{y}{x^3}\right) = \left(\frac{1}{x^3}\right)\left(\frac{-8\ln(x)^2 + c_1}{x^2}\right)$$
$$d\left(\frac{y}{x^3}\right) = \left(\frac{-8\ln(x)^2 + c_1}{x^5}\right) dx$$

Integrating gives

$$\frac{y}{x^3} = \int \frac{-8\ln(x)^2 + c_1}{x^5} dx$$
$$\frac{y}{x^3} = \frac{2\ln(x)^2}{x^4} + \frac{\ln(x)}{x^4} + \frac{1}{4x^4} - \frac{c_1}{4x^4} + c_2$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^3}$ results in

$$y = x^3 \left(\frac{2\ln(x)^2}{x^4} + \frac{\ln(x)}{x^4} + \frac{1}{4x^4} - \frac{c_1}{4x^4}\right) + c_2 x^3$$

which simplifies to

$$y = \frac{4c_2x^4 + 8\ln(x)^2 + 4\ln(x) - c_1 + 1}{4x}$$

Summary

The solution(s) found are the following

$$y = \frac{4c_2x^4 + 8\ln(x)^2 + 4\ln(x) - c_1 + 1}{4x} \tag{1}$$

Verification of solutions

$$y = \frac{4c_2x^4 + 8\ln(x)^2 + 4\ln(x) - c_1 + 1}{4x}$$

Verified OK.

19.13.5 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$x^2y'' - xy' - 3y = -\frac{16\ln(x)}{x}$$

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2y'' - xy' - 3y)\, dx = \int -\frac{16\ln(x)}{x} dx$$
$$x^2y' - 3yx = -8\ln(x)^2 + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{3}{x}$$
$$q(x) = \frac{-8\ln(x)^2 + c_1}{x^2}$$

Hence the ode is

$$y' - \frac{3y}{x} = \frac{-8 \ln(x)^2 + c_1}{x^2}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{3}{x} dx} \\ &= \frac{1}{x^3}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{-8\ln(x)^2 + c_1}{x^2}\right) \\ \frac{d}{dx}\left(\frac{y}{x^3}\right) &= \left(\frac{1}{x^3}\right)\left(\frac{-8\ln(x)^2 + c_1}{x^2}\right) \\ d\left(\frac{y}{x^3}\right) &= \left(\frac{-8\ln(x)^2 + c_1}{x^5}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{y}{x^3} &= \int \frac{-8\ln(x)^2 + c_1}{x^5} dx \\ \frac{y}{x^3} &= \frac{2\ln(x)^2}{x^4} + \frac{\ln(x)}{x^4} + \frac{1}{4x^4} - \frac{c_1}{4x^4} + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^3}$ results in

$$y = x^3\left(\frac{2\ln(x)^2}{x^4} + \frac{\ln(x)}{x^4} + \frac{1}{4x^4} - \frac{c_1}{4x^4}\right) + c_2 x^3$$

which simplifies to

$$y = \frac{4c_2x^4 + 8\ln(x)^2 + 4\ln(x) - c_1 + 1}{4x}$$

Summary

The solution(s) found are the following

$$y = \frac{4c_2x^4 + 8\ln(x)^2 + 4\ln(x) - c_1 + 1}{4x} \tag{1}$$

Verification of solutions

$$y = \frac{4c_2x^4 + 8\ln(x)^2 + 4\ln(x) - c_1 + 1}{4x}$$

Verified OK.

19.13.6 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{align*}
x^2y'' - xy' - 3y &= 0 \tag{1}\\
Ay'' + By' + Cy &= 0 \tag{2}
\end{align*}
$$

Comparing (1) and (2) shows that

$$
\begin{align*}
A &= x^2\\
B &= -x \tag{3}\\
C &= -3
\end{align*}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A}\,dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \tag{4}
$$

Where r is given by

$$
\begin{align*}
r &= \frac{s}{t} \tag{5}\\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{align*}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{15}{4x^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{align*}
s &= 15\\
t &= 4x^2
\end{align*}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{15}{4x^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\,dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 632: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{15}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{15}{4x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{15}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{15}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = -\frac{3}{2}$ then

$$\begin{aligned} d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\ &= -\frac{3}{2} - \left(-\frac{3}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\ &= -\frac{3}{2x} + (-)\,(0) \\ &= -\frac{3}{2x} \\ &= -\frac{3}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{3}{2x}\right)(0) + \left(\left(\frac{3}{2x^2}\right) + \left(-\frac{3}{2x}\right)^2 - \left(\frac{15}{4x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int -\frac{3}{2x} dx} \\ &= \frac{1}{x^{\frac{3}{2}}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x}{x^2}\,dx} \\
&= z_1 e^{\frac{\ln(x)}{2}} \\
&= z_1\left(\sqrt{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{x^4}{4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{1}{x}\right) + c_2\left(\frac{1}{x}\left(\frac{x^4}{4}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' - xy' - 3y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_1}{x} + \frac{c_2 x^3}{4}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = \frac{x^3}{4}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x^3}{4} \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(\frac{x^3}{4}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x^3}{4} \\ -\frac{1}{x^2} & \frac{3x^2}{4} \end{vmatrix}$$

Therefore

$$W=\left(\frac{1}{x}\right)\left(\frac{3x^2}{4}\right)-\left(\frac{x^3}{4}\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W=x$$

Which simplifies to

$$W=x$$

Therefore Eq. (2) becomes

$$u_1=-\int\frac{-4x^2\ln(x)}{x^3}\,dx$$

Which simplifies to

$$u_1=-\int-\frac{4\ln(x)}{x}dx$$

Hence

$$u_1=2\ln(x)^2$$

And Eq. (3) becomes

$$u_2=\int\frac{-\frac{16\ln(x)}{x^2}}{x^3}\,dx$$

Which simplifies to

$$u_2=\int-\frac{16\ln(x)}{x^5}dx$$

Hence

$$u_2=\frac{4\ln(x)}{x^4}+\frac{1}{x^4}$$

Which simplifies to

$$u_1=2\ln(x)^2$$

$$u_2=\frac{1+4\ln(x)}{x^4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{2\ln(x)^2}{x} + \frac{1+4\ln(x)}{4x}$$

Which simplifies to

$$y_p(x) = \frac{2\ln(x)^2 + \frac{1}{4} + \ln(x)}{x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x} + \frac{c_2 x^3}{4}\right) + \left(\frac{2\ln(x)^2 + \frac{1}{4} + \ln(x)}{x}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x} + \frac{c_2 x^3}{4} + \frac{2\ln(x)^2 + \frac{1}{4} + \ln(x)}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x} + \frac{c_2 x^3}{4} + \frac{2\ln(x)^2 + \frac{1}{4} + \ln(x)}{x}$$

Verified OK.

19.13.7 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x^2 \\ q(x) &= -x \\ r(x) &= -3 \\ s(x) &= -\frac{16\ln(x)}{x} \end{aligned}$$

Hence

$$p''(x) = 2$$
$$q'(x) = -1$$

Therefore (1) becomes

$$2 - (-1) + (-3) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$x^2 y' - 3yx = \int -\frac{16\ln(x)}{x}\, dx$$

We now have a first order ode to solve which is

$$x^2 y' - 3yx = -8\ln(x)^2 + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{3}{x}$$
$$q(x) = \frac{-8\ln(x)^2 + c_1}{x^2}$$

Hence the ode is

$$y' - \frac{3y}{x} = \frac{-8\ln(x)^2 + c_1}{x^2}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{3}{x} dx}$$
$$= \frac{1}{x^3}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{-8\ln(x)^2 + c_1}{x^2}\right)$$

$$\frac{d}{dx}\left(\frac{y}{x^3}\right) = \left(\frac{1}{x^3}\right)\left(\frac{-8\ln(x)^2 + c_1}{x^2}\right)$$

$$d\left(\frac{y}{x^3}\right) = \left(\frac{-8\ln(x)^2 + c_1}{x^5}\right) dx$$

Integrating gives

$$\frac{y}{x^3} = \int \frac{-8\ln(x)^2 + c_1}{x^5} dx$$

$$\frac{y}{x^3} = \frac{2\ln(x)^2}{x^4} + \frac{\ln(x)}{x^4} + \frac{1}{4x^4} - \frac{c_1}{4x^4} + c_2$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^3}$ results in

$$y = x^3\left(\frac{2\ln(x)^2}{x^4} + \frac{\ln(x)}{x^4} + \frac{1}{4x^4} - \frac{c_1}{4x^4}\right) + c_2 x^3$$

which simplifies to

$$y = \frac{4c_2x^4 + 8\ln(x)^2 + 4\ln(x) - c_1 + 1}{4x}$$

Summary

The solution(s) found are the following

$$y = \frac{4c_2x^4 + 8\ln(x)^2 + 4\ln(x) - c_1 + 1}{4x} \tag{1}$$

Verification of solutions

$$y = \frac{4c_2x^4 + 8\ln(x)^2 + 4\ln(x) - c_1 + 1}{4x}$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.4 Nonhomogeneous linear equations with constant coefficients. The Euler equations. Exercises page 143
Problem number: 631.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - 2xy' - 2y = x^2 - 2x + 2}$$

19.14.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -2x, C = -2, f(x) = x^2 - 2x + 2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 2xy' - 2y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 2xrx^{r-1} - 2x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 2r\,x^r - 2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 2r - 2 = 0$$

Or

$$r^2 - 3r - 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{3}{2} - \frac{\sqrt{17}}{2}$$
$$r_2 = \frac{3}{2} + \frac{\sqrt{17}}{2}$$

Since the roots are real and distinct, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_1 x^{\frac{3}{2} - \frac{\sqrt{17}}{2}} + c_2 x^{\frac{3}{2} + \frac{\sqrt{17}}{2}}$$

Next, we find the particular solution to the ODE

$$x^2 y'' - 2xy' - 2y = x^2 - 2x + 2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^{\frac{3}{2} - \frac{\sqrt{17}}{2}}$$

$$y_2 = x^{\frac{3}{2} + \frac{\sqrt{17}}{2}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^{\frac{3}{2}-\frac{\sqrt{17}}{2}} & x^{\frac{3}{2}+\frac{\sqrt{17}}{2}} \\ \frac{d}{dx}\left(x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}\right) & \frac{d}{dx}\left(x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^{\frac{3}{2}-\frac{\sqrt{17}}{2}} & x^{\frac{3}{2}+\frac{\sqrt{17}}{2}} \\ \frac{x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}\left(\frac{3}{2}-\frac{\sqrt{17}}{2}\right)}{x} & \frac{x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}\left(\frac{3}{2}+\frac{\sqrt{17}}{2}\right)}{x} \end{vmatrix}$$

Therefore

$$W = \left(x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}\right)\left(\frac{x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}\left(\frac{3}{2}+\frac{\sqrt{17}}{2}\right)}{x}\right) - \left(x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}\right)\left(\frac{x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}\left(\frac{3}{2}-\frac{\sqrt{17}}{2}\right)}{x}\right)$$

Which simplifies to

$$W = \frac{x^{\frac{3}{2}-\frac{\sqrt{17}}{2}} x^{\frac{3}{2}+\frac{\sqrt{17}}{2}} \sqrt{17}}{x}$$

Which simplifies to

$$W = x^2\sqrt{17}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}(x^2-2x+2)}{x^4\sqrt{17}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{x^{-\frac{5}{2}+\frac{\sqrt{17}}{2}} \sqrt{17}\,(x^2-2x+2)}{17} dx$$

Hence

$$u_1 = -\frac{x^{-\frac{3}{2}+\frac{\sqrt{17}}{2}} \sqrt{17}\left(x^2\sqrt{17}-2\sqrt{17}\,x-x^2+4\sqrt{17}-2x+12\right)}{136}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}(x^2-2x+2)}{x^4\sqrt{17}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{x^{-\frac{5}{2}-\frac{\sqrt{17}}{2}} \sqrt{17}\,(x^2-2x+2)}{17} dx$$

Hence

$$u_2 = -\frac{x^{-\frac{3}{2}-\frac{\sqrt{17}}{2}} \sqrt{17}\left(x^2\sqrt{17}-2\sqrt{17}\,x+x^2+4\sqrt{17}+2x-12\right)}{136}$$

Which simplifies to

$$u_1 = -\frac{\left((x^2-2x+4)\sqrt{17}-x^2-2x+12\right)\sqrt{17}\,x^{-\frac{3}{2}+\frac{\sqrt{17}}{2}}}{136}$$

$$u_2 = -\frac{\left((x^2-2x+4)\sqrt{17}+x^2+2x-12\right)\sqrt{17}\,x^{-\frac{3}{2}-\frac{\sqrt{17}}{2}}}{136}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\left((x^2-2x+4)\sqrt{17}-x^2-2x+12\right)\sqrt{17}\,x^{-\frac{3}{2}+\frac{\sqrt{17}}{2}}\,x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}}{136} - \frac{\left((x^2-2x+4)\sqrt{17}+x^2+2x-12\right)\sqrt{17}\,x^{-\frac{3}{2}-\frac{\sqrt{17}}{2}}\,x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}}{136}$$

Which simplifies to

$$y_p(x) = -\frac{1}{4}x^2+\frac{1}{2}x-1$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= -\frac{x^2}{4} + \frac{x}{2} - 1 + c_1 x^{\frac{3}{2}-\frac{\sqrt{17}}{2}} + c_2 x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}
\end{aligned}
$$

<u>Summary</u>
The solution(s) found are the following

$$
y = -\frac{x^2}{4} + \frac{x}{2} - 1 + c_1 x^{\frac{3}{2}-\frac{\sqrt{17}}{2}} + c_2 x^{\frac{3}{2}+\frac{\sqrt{17}}{2}} \tag{1}
$$

<u>Verification of solutions</u>

$$
y = -\frac{x^2}{4} + \frac{x}{2} - 1 + c_1 x^{\frac{3}{2}-\frac{\sqrt{17}}{2}} + c_2 x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}
$$

Verified OK.

19.14.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' - 2xy' - 2y = 0
$$

In normal form the ode

$$
x^2y'' - 2xy' - 2y = 0 \tag{1}
$$

Becomes

$$
y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= -\frac{2}{x} \\
q(x) &= -\frac{2}{x^2}
\end{aligned}
$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\
&= \int \mathrm{e}^{-\left(\int -\frac{2}{x}dx\right)} dx \\
&= \int e^{2\ln(x)}\, dx \\
&= \int x^2 dx \\
&= \frac{x^3}{3}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{-\frac{2}{x^2}}{x^4} \\
&= -\frac{2}{x^6}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - \frac{2y(\tau)}{x^6} &= 0
\end{aligned}$$

But in terms of τ

$$-\frac{2}{x^6} = -\frac{2}{9\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) - \frac{2y(\tau)}{9\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$9\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 - 2y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$9\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} - 2\tau^r = 0$$

Simplifying gives

$$9r(r-1)\,\tau^r + 0\,\tau^r - 2\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$9r(r-1) + 0 - 2 = 0$$

Or

$$9r^2 - 9r - 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2} - \frac{\sqrt{17}}{6}$$
$$r_2 = \frac{1}{2} + \frac{\sqrt{17}}{6}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{\frac{1}{2}-\frac{\sqrt{17}}{6}} + c_2\tau^{\frac{1}{2}+\frac{\sqrt{17}}{6}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{3}\,\sqrt{x^3}\left(c_1 3^{\frac{\sqrt{17}}{6}} \left(x^3\right)^{-\frac{\sqrt{17}}{6}} + c_2 3^{-\frac{\sqrt{17}}{6}} \left(x^3\right)^{\frac{\sqrt{17}}{6}}\right)}{3}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{\sqrt{3}\,\sqrt{x^3}\left(c_1 3^{\frac{\sqrt{17}}{6}} \left(x^3\right)^{-\frac{\sqrt{17}}{6}} + c_2 3^{-\frac{\sqrt{17}}{6}} \left(x^3\right)^{\frac{\sqrt{17}}{6}}\right)}{3}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sqrt{x^3}\left(x^3\right)^{-\frac{\sqrt{17}}{6}}$$

$$y_2 = \sqrt{x^3}\left(x^3\right)^{\frac{\sqrt{17}}{6}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{x^3}\left(x^3\right)^{-\frac{\sqrt{17}}{6}} & \sqrt{x^3}\left(x^3\right)^{\frac{\sqrt{17}}{6}} \\ \frac{d}{dx}\left(\sqrt{x^3}\left(x^3\right)^{-\frac{\sqrt{17}}{6}}\right) & \frac{d}{dx}\left(\sqrt{x^3}\left(x^3\right)^{\frac{\sqrt{17}}{6}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{x^3}\left(x^3\right)^{-\frac{\sqrt{17}}{6}} & \sqrt{x^3}\left(x^3\right)^{\frac{\sqrt{17}}{6}} \\ \frac{3(x^3)^{-\frac{\sqrt{17}}{6}} x^2}{2\sqrt{x^3}} - \frac{\sqrt{x^3}\left(x^3\right)^{-\frac{\sqrt{17}}{6}}\sqrt{17}}{2x} & \frac{3(x^3)^{\frac{\sqrt{17}}{6}} x^2}{2\sqrt{x^3}} + \frac{\sqrt{x^3}\left(x^3\right)^{\frac{\sqrt{17}}{6}}\sqrt{17}}{2x} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{x^3}\left(x^3\right)^{-\frac{\sqrt{17}}{6}}\right)\left(\frac{3(x^3)^{\frac{\sqrt{17}}{6}} x^2}{2\sqrt{x^3}} + \frac{\sqrt{x^3}\left(x^3\right)^{\frac{\sqrt{17}}{6}}\sqrt{17}}{2x}\right) - \left(\sqrt{x^3}\left(x^3\right)^{\frac{\sqrt{17}}{6}}\right)\left(\frac{3(x^3)^{-\frac{\sqrt{17}}{6}} x^2}{2\sqrt{x^3}} - \frac{\sqrt{x^3}\left(x^3\right)^{-\frac{\sqrt{17}}{6}}\sqrt{17}}{2x}\right)$$

Which simplifies to

$$W = x^2\left(x^3\right)^{-\frac{\sqrt{17}}{6}}\left(x^3\right)^{\frac{\sqrt{17}}{6}}\sqrt{17}$$

Which simplifies to

$$W = x^2\sqrt{17}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sqrt{x^3}\left(x^3\right)^{\frac{\sqrt{17}}{6}}\left(x^2 - 2x + 2\right)}{x^4\sqrt{17}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\sqrt{17}\left(x^3\right)^{\frac{1}{2}+\frac{\sqrt{17}}{6}}\left(x^2 - 2x + 2\right)}{17x^4} dx$$

Hence

$$u_1 = -\frac{\left(x^2\sqrt{17} - 2\sqrt{17}\,x - x^2 + 4\sqrt{17} - 2x + 12\right)\sqrt{17}\left(x^3\right)^{\frac{1}{2}+\frac{\sqrt{17}}{6}}}{136x^3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sqrt{x^3}\left(x^3\right)^{-\frac{\sqrt{17}}{6}}\left(x^2 - 2x + 2\right)}{x^4\sqrt{17}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{\sqrt{17}\,(x^3)^{\frac{1}{2}-\frac{\sqrt{17}}{6}}\,(x^2-2x+2)}{17x^4}dx$$

Hence

$$u_2 = -\frac{\left(x^2\sqrt{17}-2\sqrt{17}\,x+x^2+4\sqrt{17}+2x-12\right)\sqrt{17}\,(x^3)^{\frac{1}{2}-\frac{\sqrt{17}}{6}}}{136x^3}$$

Which simplifies to

$$u_1 = -\frac{\left((x^2-2x+4)\sqrt{17}-x^2-2x+12\right)\sqrt{17}\,(x^3)^{\frac{1}{2}+\frac{\sqrt{17}}{6}}}{136x^3}$$

$$u_2 = -\frac{\left((x^2-2x+4)\sqrt{17}+x^2+2x-12\right)\sqrt{17}\,(x^3)^{\frac{1}{2}-\frac{\sqrt{17}}{6}}}{136x^3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\left((x^2-2x+4)\sqrt{17}-x^2-2x+12\right)\sqrt{17}\,(x^3)^{\frac{1}{2}+\frac{\sqrt{17}}{6}}\sqrt{x^3}\,(x^3)^{-\frac{\sqrt{17}}{6}}}{136x^3} - \frac{\left((x^2-2x+4)\sqrt{17}+x^2+2x-12\right)\sqrt{17}\,(x^3)^{\frac{1}{2}-\frac{\sqrt{17}}{6}}\sqrt{x^3}\,(x^3)^{\frac{\sqrt{17}}{6}}}{136x^3}$$

Which simplifies to

$$y_p(x) = -\frac{1}{4}x^2+\frac{1}{2}x-1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{\sqrt{3}\,\sqrt{x^3}\left(c_1 3^{\frac{\sqrt{17}}{6}}(x^3)^{-\frac{\sqrt{17}}{6}}+c_2 3^{-\frac{\sqrt{17}}{6}}(x^3)^{\frac{\sqrt{17}}{6}}\right)}{3}\right)+\left(-\frac{1}{4}x^2+\frac{1}{2}x-1\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{3}\,\sqrt{x^3}\left(c_1 3^{\frac{\sqrt{17}}{6}}(x^3)^{-\frac{\sqrt{17}}{6}}+c_2 3^{-\frac{\sqrt{17}}{6}}(x^3)^{\frac{\sqrt{17}}{6}}\right)}{3}-\frac{x^2}{4}+\frac{x}{2}-1 \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{3}\,\sqrt{x^3}\left(c_1 3^{\frac{\sqrt{17}}{6}} (x^3)^{-\frac{\sqrt{17}}{6}} + c_2 3^{-\frac{\sqrt{17}}{6}} (x^3)^{\frac{\sqrt{17}}{6}}\right)}{3} - \frac{x^2}{4} + \frac{x}{2} - 1$$

Verified OK.

19.14.3 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -2x, C = -2, f(x) = x^2 - 2x + 2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 2xy' - 2y = 0$$

In normal form the ode

$$x^2y'' - 2xy' - 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= -\frac{2}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2}+\frac{np}{x}+q=0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}-\frac{2n}{x^2}-\frac{2}{x^2}=0 \tag{5}$$

Solving (5) for n gives

$$n=\frac{3}{2}+\frac{\sqrt{17}}{2} \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x)+\left(\frac{3+\sqrt{17}}{x}-\frac{2}{x}\right)v'(x)&=0\\ v''(x)+\frac{\left(1+\sqrt{17}\right)v'(x)}{x}&=0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x)=v'(x)$$

Then (7) becomes

$$u'(x)+\frac{\left(1+\sqrt{17}\right)u(x)}{x}=0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u'&=F(x,u)\\ &=f(x)g(u)\\ &=\frac{\left(-1-\sqrt{17}\right)u}{x} \end{aligned}$$

Where $f(x) = \frac{-1-\sqrt{17}}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= \frac{-1-\sqrt{17}}{x}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{-1-\sqrt{17}}{x}\,dx \\
\ln(u) &= \left(-1-\sqrt{17}\right)\ln(x) + c_1 \\
u &= \mathrm{e}^{\left(-1-\sqrt{17}\right)\ln(x)+c_1} \\
&= c_1 \mathrm{e}^{\left(-1-\sqrt{17}\right)\ln(x)}
\end{aligned}
$$

Which simplifies to

$$
u(x) = \frac{c_1 x^{-\sqrt{17}}}{x}
$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= -\frac{\sqrt{17}\,c_1 x^{-\sqrt{17}}}{17} + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\,x^n \\
&= \left(-\frac{\sqrt{17}\,c_1 x^{-\sqrt{17}}}{17} + c_2\right) x^{\frac{3}{2}+\frac{\sqrt{17}}{2}} \\
&= -\frac{x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}\left(-17c_2 x^{\sqrt{17}} + \sqrt{17}\,c_1\right)}{17}
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
x^2y'' - 2xy' - 2y = x^2 - 2x + 2
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^{\frac{3}{2}} x^{\frac{\sqrt{17}}{2}}$$

$$y_2 = x^{\frac{3}{2}} x^{\frac{\sqrt{17}}{2}} x^{-\sqrt{17}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^{\frac{3}{2}} x^{\frac{\sqrt{17}}{2}} & x^{\frac{3}{2}} x^{\frac{\sqrt{17}}{2}} x^{-\sqrt{17}} \\ \frac{d}{dx}\left(x^{\frac{3}{2}} x^{\frac{\sqrt{17}}{2}}\right) & \frac{d}{dx}\left(x^{\frac{3}{2}} x^{\frac{\sqrt{17}}{2}} x^{-\sqrt{17}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^{\frac{3}{2}} x^{\frac{\sqrt{17}}{2}} & x^{\frac{3}{2}} x^{\frac{\sqrt{17}}{2}} x^{-\sqrt{17}} \\ \frac{3\sqrt{x}\, x^{\frac{\sqrt{17}}{2}}}{2} + \frac{\sqrt{x}\, x^{\frac{\sqrt{17}}{2}} \sqrt{17}}{2} & \frac{3\sqrt{x}\, x^{\frac{\sqrt{17}}{2}} x^{-\sqrt{17}}}{2} - \frac{\sqrt{x}\, x^{\frac{\sqrt{17}}{2}} \sqrt{17}\, x^{-\sqrt{17}}}{2} \end{vmatrix}$$

Therefore

$$W = \left(x^{\frac{3}{2}} x^{\frac{\sqrt{17}}{2}}\right) \left(\frac{3\sqrt{x}\, x^{\frac{\sqrt{17}}{2}} x^{-\sqrt{17}}}{2} - \frac{\sqrt{x}\, x^{\frac{\sqrt{17}}{2}} \sqrt{17}\, x^{-\sqrt{17}}}{2}\right) - \left(x^{\frac{3}{2}} x^{\frac{\sqrt{17}}{2}} x^{-\sqrt{17}}\right) \left(\frac{3\sqrt{x}\, x^{\frac{\sqrt{17}}{2}}}{2} + \frac{\sqrt{x}\, x^{\frac{\sqrt{17}}{2}} \sqrt{17}}{2}\right)$$

Which simplifies to

$$W = -x^2 x^{\sqrt{17}} \sqrt{17}\, x^{-\sqrt{17}}$$

Which simplifies to

$$W = -x^2 \sqrt{17}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^{\frac{3}{2}} x^{\frac{\sqrt{17}}{2}} x^{-\sqrt{17}} (x^2 - 2x + 2)}{-x^4 \sqrt{17}}\, dx$$

Which simplifies to

$$u_1 = -\int -\frac{x^{-\frac{5}{2}-\frac{\sqrt{17}}{2}} \sqrt{17}\, (x^2 - 2x + 2)}{17} dx$$

Hence

$$u_1 = -\frac{x^{-\frac{3}{2}-\frac{\sqrt{17}}{2}} \sqrt{17}\, \left(x^2\sqrt{17} - 2\sqrt{17}\, x + x^2 + 4\sqrt{17} + 2x - 12\right)}{136}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^{\frac{3}{2}} x^{\frac{\sqrt{17}}{2}} (x^2 - 2x + 2)}{-x^4 \sqrt{17}}\, dx$$

Which simplifies to

$$u_2 = \int -\frac{x^{-\frac{5}{2}+\frac{\sqrt{17}}{2}} \sqrt{17}\, (x^2 - 2x + 2)}{17} dx$$

Hence

$$u_2 = -\frac{x^{-\frac{3}{2}+\frac{\sqrt{17}}{2}} \sqrt{17}\, \left(x^2\sqrt{17} - 2\sqrt{17}\, x - x^2 + 4\sqrt{17} - 2x + 12\right)}{136}$$

Which simplifies to

$$u_1 = -\frac{\left((x^2 - 2x + 4)\sqrt{17} + x^2 + 2x - 12\right)\sqrt{17}\, x^{-\frac{3}{2}-\frac{\sqrt{17}}{2}}}{136}$$

$$u_2 = -\frac{\left((x^2 - 2x + 4)\sqrt{17} - x^2 - 2x + 12\right)\sqrt{17}\, x^{-\frac{3}{2}+\frac{\sqrt{17}}{2}}}{136}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\left(\left(x^2-2x+4\right)\sqrt{17}+x^2+2x-12\right)\sqrt{17}\,x^{-\frac{3}{2}-\frac{\sqrt{17}}{2}}x^{\frac{3}{2}}x^{\frac{\sqrt{17}}{2}}}{136} - \frac{\left(\left(x^2-2x+4\right)\sqrt{17}-x^2-2x+12\right)\sqrt{17}\,x^{-\frac{3}{2}+\frac{\sqrt{17}}{2}}x^{\frac{3}{2}}x^{-\frac{\sqrt{17}}{2}}x^{-\sqrt{17}}}{136}$$

Which simplifies to

$$y_p(x) = -\frac{1}{4}x^2 + \frac{1}{2}x - 1$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(\left(-\frac{\sqrt{17}\,c_1 x^{-\sqrt{17}}}{17} + c_2\right)x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}\right) + \left(-\frac{1}{4}x^2 + \frac{1}{2}x - 1\right) \\
&= -\frac{x^2}{4} + \frac{x}{2} - 1 + \left(-\frac{\sqrt{17}\,c_1 x^{-\sqrt{17}}}{17} + c_2\right)x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}
\end{aligned}$$

Which simplifies to

$$y = -\frac{x^2}{4} + \frac{x}{2} - 1 + \left(-\frac{\sqrt{17}\,c_1 x^{-\sqrt{17}}}{17} + c_2\right)x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}$$

Summary

The solution(s) found are the following

$$y = -\frac{x^2}{4} + \frac{x}{2} - 1 + \left(-\frac{\sqrt{17}\,c_1 x^{-\sqrt{17}}}{17} + c_2\right)x^{\frac{3}{2}+\frac{\sqrt{17}}{2}} \tag{1}$$

Verification of solutions

$$y = -\frac{x^2}{4} + \frac{x}{2} - 1 + \left(-\frac{\sqrt{17}\,c_1 x^{-\sqrt{17}}}{17} + c_2\right)x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}$$

Verified OK.

19.14.4 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 2xy' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 633: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{4}{x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 4$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{17}}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{17}}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{4}{x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = 4$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{17}}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{17}}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{4}{x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2} + \frac{\sqrt{17}}{2}$	$\frac{1}{2} - \frac{\sqrt{17}}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2} + \frac{\sqrt{17}}{2}$	$\frac{1}{2} - \frac{\sqrt{17}}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = \frac{1}{2} - \frac{\sqrt{17}}{2}$ then

$$\begin{aligned} d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\ &= \frac{1}{2} - \frac{\sqrt{17}}{2} - \left(\frac{1}{2} - \frac{\sqrt{17}}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\ &= \frac{\frac{1}{2} - \frac{\sqrt{17}}{2}}{x} + (-)\,(0) \\ &= \frac{\frac{1}{2} - \frac{\sqrt{17}}{2}}{x} \\ &= -\frac{\sqrt{17} - 1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{\frac{1}{2} - \frac{\sqrt{17}}{2}}{x}\right)(0) + \left(\left(-\frac{\frac{1}{2} - \frac{\sqrt{17}}{2}}{x^2}\right) + \left(\frac{\frac{1}{2} - \frac{\sqrt{17}}{2}}{x}\right)^2 - \left(\frac{4}{x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \frac{\frac{1}{2} - \frac{\sqrt{17}}{2}}{x} dx} \\ &= x^{\frac{1}{2} - \frac{\sqrt{17}}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2}\,dx} \\
&= z_1 e^{\ln(x)} \\
&= z_1(x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{x^{\sqrt{17}}\sqrt{17}}{17}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}\right) + c_2\left(x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}\left(\frac{x^{\sqrt{17}}\sqrt{17}}{17}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$x^2y''-2xy'-2y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 x^{\frac{3}{2}-\frac{\sqrt{17}}{2}} + \frac{c_2\sqrt{17}\, x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}}{17}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}$$

$$y_2 = \frac{\sqrt{17}\, x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}}{17}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^{\frac{3}{2}-\frac{\sqrt{17}}{2}} & \frac{\sqrt{17}\, x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}}{17} \\ \frac{d}{dx}\left(x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}\right) & \frac{d}{dx}\left(\frac{\sqrt{17}\, x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}}{17}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^{\frac{3}{2}-\frac{\sqrt{17}}{2}} & \frac{\sqrt{17}\, x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}}{17} \\ \frac{x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}\left(\frac{3}{2}-\frac{\sqrt{17}}{2}\right)}{x} & \frac{\sqrt{17}\, x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}\left(\frac{3}{2}+\frac{\sqrt{17}}{2}\right)}{17x} \end{vmatrix}$$

Therefore

$$W = \left(x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}\right)\left(\frac{\sqrt{17}\, x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}\left(\frac{3}{2}+\frac{\sqrt{17}}{2}\right)}{17x}\right) - \left(\frac{\sqrt{17}\, x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}}{17}\right)\left(\frac{x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}\left(\frac{3}{2}-\frac{\sqrt{17}}{2}\right)}{x}\right)$$

Which simplifies to

$$W = \frac{x^{\frac{3}{2}-\frac{\sqrt{17}}{2}} x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}}{x}$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sqrt{17}\, x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}(x^2-2x+2)}{17}}{x^4}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{x^{-\frac{5}{2}+\frac{\sqrt{17}}{2}}\sqrt{17}\,(x^2-2x+2)}{17} dx$$

Hence

$$u_1 = -\frac{x^{-\frac{3}{2}+\frac{\sqrt{17}}{2}}\sqrt{17}\,\left(x^2\sqrt{17} - 2\sqrt{17}\, x - x^2 + 4\sqrt{17} - 2x + 12\right)}{136}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}(x^2-2x+2)}{x^4}\, dx$$

Which simplifies to

$$u_2 = \int x^{-\frac{5}{2}-\frac{\sqrt{17}}{2}}\left(x^2-2x+2\right) dx$$

Hence

$$u_2 = -\frac{x^{-\frac{3}{2}-\frac{\sqrt{17}}{2}}\left(x^2\sqrt{17} - 2\sqrt{17}\,x + x^2 + 4\sqrt{17} + 2x - 12\right)}{8}$$

Which simplifies to

$$u_1 = -\frac{\left(\left(x^2-2x+4\right)\sqrt{17} - x^2 - 2x + 12\right)\sqrt{17}\,x^{-\frac{3}{2}+\frac{\sqrt{17}}{2}}}{136}$$

$$u_2 = -\frac{\left(\left(x^2-2x+4\right)\sqrt{17} + x^2 + 2x - 12\right)x^{-\frac{3}{2}-\frac{\sqrt{17}}{2}}}{8}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\left(\left(x^2-2x+4\right)\sqrt{17} - x^2 - 2x + 12\right)\sqrt{17}\,x^{-\frac{3}{2}+\frac{\sqrt{17}}{2}}\,x^{\frac{3}{2}-\frac{\sqrt{17}}{2}}}{136} - \frac{\left(\left(x^2-2x+4\right)\sqrt{17} + x^2 + 2x - 12\right)\sqrt{17}\,x^{-\frac{3}{2}-\frac{\sqrt{17}}{2}}\,x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}}{136}$$

Which simplifies to

$$y_p(x) = -\frac{1}{4}x^2 + \frac{1}{2}x - 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x^{\frac{3}{2}-\frac{\sqrt{17}}{2}} + \frac{c_2\sqrt{17}\,x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}}{17}\right) + \left(-\frac{1}{4}x^2 + \frac{1}{2}x - 1\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x^{\frac{3}{2}-\frac{\sqrt{17}}{2}} + \frac{c_2\sqrt{17}\,x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}}{17} - \frac{x^2}{4} + \frac{x}{2} - 1 \tag{1}$$

Verification of solutions

$$y = c_1 x^{\frac{3}{2}-\frac{\sqrt{17}}{2}} + \frac{c_2\sqrt{17}\,x^{\frac{3}{2}+\frac{\sqrt{17}}{2}}}{17} - \frac{x^2}{4} + \frac{x}{2} - 1$$

Verified OK.

$$\boxed{x^2y'' + xy' - y = x^m}$$

19.15.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = -1, f(x) = x^m$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + xy' - y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + xrx^{r-1} - x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + r\,x^r - x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + r - 1 = 0$$

Or

$$r^2 - 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -1$$
$$r_2 = 1$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = \frac{c_1}{x} + c_2x$$

Next, we find the particular solution to the ODE

$$x^2y'' + xy' - y = x^m$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & x \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & x \\ -\frac{1}{x^2} & 1 \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)(1) - (x)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = \frac{2}{x}$$

Which simplifies to

$$W = \frac{2}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x\, x^m}{2x} dx$$

Which simplifies to

$$u_1 = -\int \frac{x^m}{2} dx$$

Hence

$$u_1 = -\frac{x^{m+1}}{2\,(m+1)}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{x^m}{x}}{2x} dx$$

Which simplifies to

$$u_2 = \int \frac{x^{m-2}}{2} dx$$

Hence

$$u_2 = \frac{x^{m-1}}{2m-2}$$

Which simplifies to

$$u_1 = -\frac{x^{m+1}}{2m+2}$$
$$u_2 = \frac{x^{m-1}}{2m-2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^{m+1}}{(2m+2)\,x} + \frac{x^{m-1}x}{2m-2}$$

Which simplifies to

$$y_p(x) = \frac{x^m}{m^2-1}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\ &= \frac{x^m}{m^2-1} + \frac{c_1}{x} + c_2 x\end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \frac{x^m}{m^2-1} + \frac{c_1}{x} + c_2 x \tag{1}$$

<u>Verification of solutions</u>

$$y = \frac{x^m}{m^2-1} + \frac{c_1}{x} + c_2 x$$

Verified OK.

19.15.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + xy' - y = 0$$

In normal form the ode

$$x^2y'' + xy' - y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned}p(x) &= \frac{1}{x}\\ q(x) &= -\frac{1}{x^2}\end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int \frac{1}{x}dx\right)}dx \\
&= \int e^{-\ln(x)}\,dx \\
&= \int \frac{1}{x}dx \\
&= \ln(x)
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{-\frac{1}{x^2}}{\frac{1}{x^2}} \\
&= -1
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - y(\tau) &= 0
\end{aligned}$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y(\tau) = e^{\lambda \tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda \tau} - e^{\lambda \tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda \tau}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)} \\ &= \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +1 \\ \lambda_2 &= -1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 \\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y(\tau) &= c_1 e^{\lambda_1 \tau} + c_2 e^{\lambda_2 \tau} \\ y(\tau) &= c_1 e^{(1)\tau} + c_2 e^{(-1)\tau}\end{aligned}$$

Or

$$y(\tau) = c_1 e^{\tau} + c_2 e^{-\tau}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 x^2 + c_2}{x}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 x^2 + c_2}{x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = \frac{1}{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & \frac{1}{x} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(\frac{1}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & \frac{1}{x} \\ 1 & -\frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = (x)\left(-\frac{1}{x^2}\right) - \left(\frac{1}{x}\right)(1)$$

Which simplifies to

$$W = -\frac{2}{x}$$

Which simplifies to

$$W = -\frac{2}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x^m}{x}}{-2x}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{x^{m-2}}{2}dx$$

Hence

$$u_1 = \frac{x^{m-1}}{2m-2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x\,x^m}{-2x}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{x^m}{2}dx$$

Hence

$$u_2 = -\frac{x^{m+1}}{2\,(m+1)}$$

Which simplifies to

$$u_1 = \frac{x^{m-1}}{2m-2}$$
$$u_2 = -\frac{x^{m+1}}{2m+2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^{m+1}}{(2m+2)\,x} + \frac{x^{m-1}x}{2m-2}$$

Which simplifies to

$$y_p(x) = \frac{x^m}{m^2-1}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 x^2 + c_2}{x}\right) + \left(\frac{x^m}{m^2-1}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 x^2 + c_2}{x} + \frac{x^m}{m^2-1} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x^2 + c_2}{x} + \frac{x^m}{m^2-1}$$

Verified OK.

19.15.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = -1, f(x) = x^m$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + xy' - y = 0$$

In normal form the ode

$$x^2y'' + xy' - y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= -\frac{1}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{-\frac{1}{x^2}}}{c} \end{aligned} \tag{6}$$

$$\tau'' = \frac{1}{c\sqrt{-\frac{1}{x^2}}\, x^3}$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{\frac{1}{c\sqrt{-\frac{1}{x^2}}\,x^3} + \frac{1}{x}\frac{\sqrt{-\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{-\frac{1}{x^2}}}{c}\right)^2} \\
&= 0
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0 \qquad (7)
\end{aligned}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{-\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{-\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = \frac{(ic_2 + c_1)\,x^2 - ic_2 + c_1}{2x}
$$

Now the particular solution to this ODE is found

$$
x^2 y'' + xy' - y = x^m
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = \frac{1}{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & \frac{1}{x} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(\frac{1}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & \frac{1}{x} \\ 1 & -\frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = (x)\left(-\frac{1}{x^2}\right) - \left(\frac{1}{x}\right)(1)$$

Which simplifies to

$$W = -\frac{2}{x}$$

Which simplifies to

$$W = -\frac{2}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x^m}{x}}{-2x} dx$$

Which simplifies to

$$u_1 = -\int -\frac{x^{m-2}}{2} dx$$

Hence

$$u_1 = \frac{x^{m-1}}{2m-2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x\,x^m}{-2x} dx$$

Which simplifies to

$$u_2 = \int -\frac{x^m}{2} dx$$

Hence

$$u_2 = -\frac{x^{m+1}}{2(m+1)}$$

Which simplifies to

$$u_1 = \frac{x^{m-1}}{2m-2}$$
$$u_2 = -\frac{x^{m+1}}{2m+2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^{m+1}}{(2m+2)\,x} + \frac{x^{m-1}x}{2m-2}$$

Which simplifies to

$$y_p(x) = \frac{x^m}{m^2 - 1}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{(ic_2 + c_1)\, x^2 - ic_2 + c_1}{2x}\right) + \left(\frac{x^m}{m^2 - 1}\right) \\ &= \frac{x^m}{m^2 - 1} + \frac{(ic_2 + c_1)\, x^2 - ic_2 + c_1}{2x} \end{aligned}$$

Which simplifies to

$$y = \frac{x^m}{m^2 - 1} + \frac{(ic_2 + c_1)\, x^2 - ic_2 + c_1}{2x}$$

Summary

The solution(s) found are the following

$$y = \frac{x^m}{m^2 - 1} + \frac{(ic_2 + c_1)\, x^2 - ic_2 + c_1}{2x} \tag{1}$$

Verification of solutions

$$y = \frac{x^m}{m^2 - 1} + \frac{(ic_2 + c_1)\, x^2 - ic_2 + c_1}{2x}$$

Verified OK.

19.15.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = -1, f(x) = x^m$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + xy' - y = 0$$

In normal form the ode

$$x^2y'' + xy' - y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= -\frac{1}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n}{x^2} - \frac{1}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{3v'(x)}{x} &= 0 \\ v''(x) + \frac{3v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{3u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{3u}{x} \end{aligned}$$

Where $f(x) = -\frac{3}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{3}{x}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{3}{x}\, dx \\ \ln(u) &= -3\ln(x) + c_1 \\ u &= \mathrm{e}^{-3\ln(x)+c_1} \\ &= \frac{c_1}{x^3} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= -\frac{c_1}{2x^2} + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\, x^n \\ &= \left(-\frac{c_1}{2x^2} + c_2\right) x \\ &= \left(-\frac{c_1}{2x^2} + c_2\right) x \end{aligned}$$

Now the particular solution to this ODE is found

$$x^2y'' + xy' - y = x^m$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$

$$y_2 = \frac{1}{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & \frac{1}{x} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(\frac{1}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & \frac{1}{x} \\ 1 & -\frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = (x)\left(-\frac{1}{x^2}\right) - \left(\frac{1}{x}\right)(1)$$

Which simplifies to

$$W = -\frac{2}{x}$$

Which simplifies to

$$W = -\frac{2}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x^m}{x}}{-2x} dx$$

Which simplifies to

$$u_1 = -\int -\frac{x^{m-2}}{2} dx$$

Hence

$$u_1 = \frac{x^{m-1}}{2m-2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x\, x^m}{-2x} dx$$

Which simplifies to

$$u_2 = \int -\frac{x^m}{2} dx$$

Hence

$$u_2 = -\frac{x^{m+1}}{2\,(m+1)}$$

Which simplifies to

$$u_1 = \frac{x^{m-1}}{2m-2}$$
$$u_2 = -\frac{x^{m+1}}{2m+2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^{m+1}}{(2m+2)\,x} + \frac{x^{m-1}x}{2m-2}$$

Which simplifies to

$$y_p(x) = \frac{x^m}{m^2 - 1}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(-\frac{c_1}{2x^2} + c_2\right) x\right) + \left(\frac{x^m}{m^2 - 1}\right) \\ &= \frac{x^m}{m^2 - 1} + \left(-\frac{c_1}{2x^2} + c_2\right) x \end{aligned}$$

Which simplifies to

$$y = \frac{x^m}{m^2 - 1} + \left(-\frac{c_1}{2x^2} + c_2\right) x$$

Summary
The solution(s) found are the following

$$y = \frac{x^m}{m^2 - 1} + \left(-\frac{c_1}{2x^2} + c_2\right) x \tag{1}$$

Verification of solutions

$$y = \frac{x^m}{m^2 - 1} + \left(-\frac{c_1}{2x^2} + c_2\right) x$$

Verified OK.

19.15.5 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\begin{aligned} \int \left(x^2 y'' + x y' - y\right) dx &= \int x^m dx \\ x^2 y' - y x &= \frac{x^{m+1}}{m+1} + c_1 \end{aligned}$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x) y = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= \frac{c_1(m+1) + x^{m+1}}{x^2\,(m+1)}
\end{aligned}
$$

Hence the ode is

$$
y' - \frac{y}{x} = \frac{c_1(m+1) + x^{m+1}}{x^2\,(m+1)}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{1}{x}dx} \\
&= \frac{1}{x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1(m+1) + x^{m+1}}{x^2\,(m+1)}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{x}\right) &= \left(\frac{1}{x}\right)\left(\frac{c_1(m+1) + x^{m+1}}{x^2\,(m+1)}\right) \\
\mathrm{d}\left(\frac{y}{x}\right) &= \left(\frac{c_1(m+1) + x^{m+1}}{x^3\,(m+1)}\right)\,\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\frac{y}{x} &= \int \frac{c_1(m+1) + x^{m+1}}{x^3\,(m+1)}\,\mathrm{d}x \\
\frac{y}{x} &= \frac{\frac{\mathrm{e}^{(m+1)\ln(x)}}{m^2-1} - \frac{c_1}{2}}{x^2} + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$
y = \frac{\frac{\mathrm{e}^{(m+1)\ln(x)}}{m^2-1} - \frac{c_1}{2}}{x} + c_2 x
$$

which simplifies to

$$
y = \frac{\frac{x^{m+1}}{m^2-1} - \frac{c_1}{2}}{x} + c_2 x
$$

Summary

The solution(s) found are the following

$$
y = \frac{\frac{x^{m+1}}{m^2-1} - \frac{c_1}{2}}{x} + c_2 x \tag{1}
$$

Verification of solutions

$$y = \frac{\frac{x^{m+1}}{m^2-1} - \frac{c_1}{2}}{x} + c_2 x$$

Verified OK.

19.15.6 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + \left(2AB' + B^2\right) v' + (AB'' + BB' + CB)\, v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right) v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= -1 \\ F &= x^m \end{aligned}$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= \left(x^2\right)(0) + (x)(1) + (-1)(x) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
x^3 v'' + \left(3x^2\right) v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
x^2 (u'(x) x + 3u(x)) = 0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x,u) \\
&= f(x) g(u) \\
&= -\frac{3u}{x}
\end{aligned}
$$

Where $f(x) = -\frac{3}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\, du &= -\frac{3}{x}\, dx \\
\int \frac{1}{u}\, du &= \int -\frac{3}{x}\, dx \\
\ln(u) &= -3\ln(x) + c_1 \\
u &= \mathrm{e}^{-3\ln(x) + c_1} \\
&= \frac{c_1}{x^3}
\end{aligned}
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= \frac{c_1}{x^3}
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int \frac{c_1}{x^3}\, \mathrm{d}x \\
&= -\frac{c_1}{2x^2} + c_2
\end{aligned}
$$

Therefore the homogeneous solution is

$$\begin{aligned}y_h(x) &= Bv \\ &= (x)\left(-\frac{c_1}{2x^2}+c_2\right) \\ &= \left(-\frac{c_1}{2x^2}+c_2\right)x\end{aligned}$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}y_1 &= x \\ y_2 &= \frac{1}{x}\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & \frac{1}{x} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(\frac{1}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & \frac{1}{x} \\ 1 & -\frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = (x)\left(-\frac{1}{x^2}\right) - \left(\frac{1}{x}\right)(1)$$

Which simplifies to

$$W = -\frac{2}{x}$$

Which simplifies to

$$W = -\frac{2}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x^m}{x}}{-2x}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{x^{m-2}}{2}dx$$

Hence

$$u_1 = \frac{x^{m-1}}{2m-2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x\,x^m}{-2x}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{x^m}{2}dx$$

Hence

$$u_2 = -\frac{x^{m+1}}{2\,(m+1)}$$

Which simplifies to

$$u_1 = \frac{x^{m-1}}{2m-2}$$

$$u_2 = -\frac{x^{m+1}}{2m+2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^{m+1}}{(2m+2)\,x} + \frac{x^{m-1}x}{2m-2}$$

Which simplifies to

$$y_p(x) = \frac{x^m}{m^2-1}$$

Hence the complete solution is

$$\begin{aligned}
y(x) &= y_h + y_p \\
&= \left(\left(-\frac{c_1}{2x^2} + c_2\right)x\right) + \left(\frac{x^m}{m^2-1}\right) \\
&= \frac{x^m}{m^2-1} - \frac{-2c_2x^2 + c_1}{2x}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{x^m}{m^2-1} - \frac{-2c_2x^2 + c_1}{2x} \tag{1}$$

Verification of solutions

$$y = \frac{x^m}{m^2-1} - \frac{-2c_2x^2 + c_1}{2x}$$

Verified OK.

19.15.7 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$x^2y'' + xy' - y = x^m$$

Integrating both sides of the ODE w.r.t x gives

$$\begin{aligned}
\int (x^2y'' + xy' - y)\,dx &= \int x^m dx \\
x^2y' - yx &= \frac{x^{m+1}}{m+1} + c_1
\end{aligned}$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= \frac{c_1(m+1) + x^{m+1}}{x^2\,(m+1)} \end{aligned}$$

Hence the ode is

$$y' - \frac{y}{x} = \frac{c_1(m+1) + x^{m+1}}{x^2\,(m+1)}$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int -\frac{1}{x}dx} \\ &= \frac{1}{x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1(m+1) + x^{m+1}}{x^2\,(m+1)}\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{x}\right) &= \left(\frac{1}{x}\right)\left(\frac{c_1(m+1) + x^{m+1}}{x^2\,(m+1)}\right) \\ \mathrm{d}\left(\frac{y}{x}\right) &= \left(\frac{c_1(m+1) + x^{m+1}}{x^3\,(m+1)}\right)\,\mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} \frac{y}{x} &= \int \frac{c_1(m+1) + x^{m+1}}{x^3\,(m+1)}\,\mathrm{d}x \\ \frac{y}{x} &= \frac{\frac{\mathrm{e}^{(m+1)\ln(x)}}{m^2-1} - \frac{c_1}{2}}{x^2} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = \frac{\frac{\mathrm{e}^{(m+1)\ln(x)}}{m^2-1} - \frac{c_1}{2}}{x} + c_2 x$$

which simplifies to

$$y = \frac{\frac{x^{m+1}}{m^2-1} - \frac{c_1}{2}}{x} + c_2 x$$

Summary
The solution(s) found are the following

$$y = \frac{\frac{x^{m+1}}{m^2-1} - \frac{c_1}{2}}{x} + c_2 x \tag{1}$$

Verification of solutions

$$y = \frac{\frac{x^{m+1}}{m^2-1} - \frac{c_1}{2}}{x} + c_2 x$$

Verified OK.

19.15.8 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' + x y' - y = 0 \tag{1}$$
$$A y'' + B y' + C y = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 3 \\
t &= 4x^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{3}{4x^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 634: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3}{4x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2x} + (-)(0) \\ &= -\frac{1}{2x} \\ &= -\frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{2x}\right)(0)+\left(\left(\frac{1}{2x^2}\right)+\left(-\frac{1}{2x}\right)^2-\left(\frac{3}{4x^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int -\frac{1}{2x} dx} \\
&= \frac{1}{\sqrt{x}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2}\, dx} \\
&= z_1 e^{-\frac{\ln(x)}{2}} \\
&= z_1\left(\frac{1}{\sqrt{x}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\frac{1}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1\int \frac{e^{\int -\frac{x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1\int \frac{e^{-\ln(x)}}{(y_1)^2}\, dx \\
&= y_1\left(\frac{x^2}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{1}{x}\right) + c_2\left(\frac{1}{x}\left(\frac{x^2}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + xy' - y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_1}{x} + \frac{c_2 x}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \frac{1}{x} \\ y_2 &= \frac{x}{2} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x}{2} \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(\frac{x}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x}{2} \\ -\frac{1}{x^2} & \frac{1}{2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)\left(\frac{1}{2}\right) - \left(\frac{x}{2}\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = \frac{1}{x}$$

Which simplifies to

$$W = \frac{1}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x\,x^m}{2}}{x}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{x^m}{2}dx$$

Hence

$$u_1 = -\frac{x^{m+1}}{2\,(m+1)}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{x^m}{x}}{x}\,dx$$

Which simplifies to

$$u_2 = \int x^{m-2} dx$$

Hence

$$u_2 = \frac{x^{m-1}}{m-1}$$

Which simplifies to

$$u_1 = -\frac{x^{m+1}}{2m+2}$$
$$u_2 = \frac{x^{m-1}}{m-1}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^{m+1}}{(2m+2)\,x} + \frac{x^{m-1}x}{2m-2}$$

Which simplifies to

$$y_p(x) = \frac{x^m}{m^2-1}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x} + \frac{c_2 x}{2}\right) + \left(\frac{x^m}{m^2-1}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x} + \frac{c_2 x}{2} + \frac{x^m}{m^2-1} \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x} + \frac{c_2 x}{2} + \frac{x^m}{m^2-1}$$

Verified OK.

19.15.9 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}
p(x) &= x^2 \\
q(x) &= x \\
r(x) &= -1 \\
s(x) &= x^m
\end{aligned}$$

Hence

$$\begin{aligned}
p''(x) &= 2 \\
q'(x) &= 1
\end{aligned}$$

Therefore (1) becomes

$$2 - (1) + (-1) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$x^2y' - yx = \int x^m\,dx$$

We now have a first order ode to solve which is

$$x^2y' - yx = \frac{x^{m+1}}{m+1} + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= \frac{c_1(m+1) + x^{m+1}}{x^2 (m+1)} \end{aligned}$$

Hence the ode is

$$y' - \frac{y}{x} = \frac{c_1(m+1) + x^{m+1}}{x^2 (m+1)}$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int -\frac{1}{x}dx} \\ &= \frac{1}{x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu) \left(\frac{c_1(m+1) + x^{m+1}}{x^2 (m+1)}\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{x}\right) &= \left(\frac{1}{x}\right) \left(\frac{c_1(m+1) + x^{m+1}}{x^2 (m+1)}\right) \\ \mathrm{d}\left(\frac{y}{x}\right) &= \left(\frac{c_1(m+1) + x^{m+1}}{x^3 (m+1)}\right) \mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} \frac{y}{x} &= \int \frac{c_1(m+1) + x^{m+1}}{x^3 (m+1)} \,\mathrm{d}x \\ \frac{y}{x} &= \frac{\frac{\mathrm{e}^{(m+1)\ln(x)}}{m^2-1} - \frac{c_1}{2}}{x^2} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = \frac{\frac{\mathrm{e}^{(m+1)\ln(x)}}{m^2-1} - \frac{c_1}{2}}{x} + c_2 x$$

which simplifies to

$$y = \frac{\frac{x^{m+1}}{m^2-1} - \frac{c_1}{2}}{x} + c_2 x$$

Summary

The solution(s) found are the following

$$y = \frac{\frac{x^{m+1}}{m^2-1} - \frac{c_1}{2}}{x} + c_2 x \tag{1}$$

Verification of solutions

$$y = \frac{\frac{x^{m+1}}{m^2-1} - \frac{c_1}{2}}{x} + c_2 x$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.4 Nonhomogeneous linear equations with constant coefficients. The Euler equations. Exercises page 143
Problem number: 633.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "exact linear second order ode", "second_order_integrable_as_is", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_1", "second_order_change_of_variable_on_y_method_2", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _nonhomogeneous]]
```

$$x^2y'' + 4xy' + 2y = 2\ln(x)^2 + 12x$$

19.16.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 4x, C = 2, f(x) = 2\ln(x)^2 + 12x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 4xy' + 2y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 4xrx^{r-1} + 2x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 4r\,x^r + 2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 4r + 2 = 0$$

Or

$$r^2 + 3r + 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -2$$
$$r_2 = -1$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = \frac{c_1}{x^2} + \frac{c_2}{x}$$

Next, we find the particular solution to the ODE

$$x^2y'' + 4xy' + 2y = 2\ln(x)^2 + 12x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x^2}$$
$$y_2 = \frac{1}{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{1}{x} \\ \frac{d}{dx}\left(\frac{1}{x^2}\right) & \frac{d}{dx}\left(\frac{1}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{1}{x} \\ -\frac{2}{x^3} & -\frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^2}\right)\left(-\frac{1}{x^2}\right) - \left(\frac{1}{x}\right)\left(-\frac{2}{x^3}\right)$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{2\ln(x)^2+12x}{x}}{\frac{1}{x^2}}\,dx$$

Which simplifies to

$$u_1 = -\int \left(2x\ln(x)^2 + 12x^2\right) dx$$

Hence

$$u_1 = -x^2\ln(x)^2 + x^2\ln(x) - \frac{x^2}{2} - 4x^3$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{2\ln(x)^2+12x}{x^2}}{\frac{1}{x^2}}\,dx$$

Which simplifies to

$$u_2 = \int \left(2\ln(x)^2 + 12x\right) dx$$

Hence

$$u_2 = 2x\ln(x)^2 - 4x\ln(x) + 4x + 6x^2$$

Which simplifies to

$$u_1 = -\frac{x^2\left(2\ln(x)^2 - 2\ln(x) + 8x + 1\right)}{2}$$
$$u_2 = 2x\left(\ln(x)^2 - 2\ln(x) + 3x + 2\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \ln (x)^2 - 3\ln (x) + 2x + \frac{7}{2} + \frac{c_1}{x^2} + \frac{c_2}{x} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \ln (x)^2 - 3\ln (x) + 2x + \frac{7}{2} + \frac{c_1}{x^2} + \frac{c_2}{x} \tag{1}$$

Verification of solutions

$$y = \ln (x)^2 - 3\ln (x) + 2x + \frac{7}{2} + \frac{c_1}{x^2} + \frac{c_2}{x}$$

Verified OK.

19.16.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = \frac{4}{x}$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int \frac{4}{x}\, dx} \\ &= x^2 \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= 2\ln (x)^2 + 12x \\ \left(x^2 y\right)'' &= 2\ln (x)^2 + 12x \end{aligned}$$

Integrating once gives

$$\left(x^2 y\right)' = 2x\left(\ln (x)^2 - 2\ln (x) + 3x + 2\right) + c_1$$

Integrating again gives

$$\left(x^2 y\right) = x^2 \ln (x)^2 - 3x^2 \ln (x) + \frac{x(4x^2 + 2c_1 + 7x)}{2} + c_2$$

Hence the solution is

$$y = \frac{x^2 \ln(x)^2 - 3x^2 \ln(x) + \frac{x(4x^2+2c_1+7x)}{2} + c_2}{x^2}$$

Or

$$y = \ln(x)^2 + 2x - 3\ln(x) + \frac{c_1}{x} + \frac{c_2}{x^2} + \frac{7}{2}$$

Summary
The solution(s) found are the following

$$y = \ln(x)^2 + 2x - 3\ln(x) + \frac{c_1}{x} + \frac{c_2}{x^2} + \frac{7}{2} \tag{1}$$

Verification of solutions

$$y = \ln(x)^2 + 2x - 3\ln(x) + \frac{c_1}{x} + \frac{c_2}{x^2} + \frac{7}{2}$$

Verified OK.

19.16.3 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + 4xy' + 2y = 0$$

In normal form the ode

$$x^2y'' + 4xy' + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = \frac{4}{x}$$
$$q(x) = \frac{2}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int \frac{4}{x}dx\right)}dx \\
&= \int e^{-4\ln(x)}\,dx \\
&= \int \frac{1}{x^4}dx \\
&= -\frac{1}{3x^3}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{2}{x^2}}{\frac{1}{x^8}} \\
&= 2x^6
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + 2x^6 y(\tau) &= 0
\end{aligned}$$

But in terms of τ

$$2x^6 = \frac{2}{9\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{9\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$9\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 2y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$9\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 2\tau^r = 0$$

Simplifying gives

$$9r(r-1)\,\tau^r + 0\,\tau^r + 2\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$9r(r-1) + 0 + 2 = 0$$

Or

$$9r^2 - 9r + 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{3}$$
$$r_2 = \frac{2}{3}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{\frac{1}{3}} + c_2\tau^{\frac{2}{3}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 3^{\frac{2}{3}}\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}}\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}}{3}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 3^{\frac{2}{3}} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} \left(-\frac{1}{x^3}\right)^{\frac{2}{3}}}{3}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(-\frac{1}{x^3}\right)^{\frac{1}{3}}$$
$$y_2 = \left(-\frac{1}{x^3}\right)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} & \left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \\ \frac{d}{dx}\left(\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}\right) & \frac{d}{dx}\left(\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} & \left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \\ \frac{1}{\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^4} & \frac{2}{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^4} \end{vmatrix}$$

Therefore

$$W = \left(\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}\right)\left(\frac{2}{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^4}\right) - \left(\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}\right)\left(\frac{1}{\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^4}\right)$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \left(2\ln(x)^2 + 12x\right)}{\frac{1}{x^2}} dx$$

Which simplifies to

$$u_1 = -\int 2\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \left(\ln(x)^2 + 6x\right) x^2 dx$$

Hence

$$u_1 = -2x^3\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \ln(x)^2 - 6\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^4 + 4x^3\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \ln(x) - 4x^3\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} \left(2\ln(x)^2 + 12x\right)}{\frac{1}{x^2}} dx$$

Which simplifies to

$$u_2 = \int 2\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} \left(\ln(x)^2 + 6x\right) x^2 dx$$

Hence

$$u_2 = \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3 \ln(x)^2 - \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3 \ln(x) + 4\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^4 + \frac{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3}{2}$$

Which simplifies to

$$u_1 = -2x^3\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \left(\ln(x)^2 - 2\ln(x) + 3x + 2\right)$$

$$u_2 = \frac{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3\left(2\ln(x)^2 - 2\ln(x) + 8x + 1\right)}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 3^{\frac{2}{3}}\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}}\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}}{3}\right) + \left(\ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 3^{\frac{2}{3}}\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}}\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}}{3} + \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 3^{\frac{2}{3}}\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}}\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}}{3} + \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2}$$

Verified OK.

19.16.4 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 4x, C = 2, f(x) = 2\ln(x)^2 + 12x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 4xy' + 2y = 0$$

In normal form the ode

$$x^2y'' + 4xy' + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{4}{x} \\ q(x) &= \frac{2}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{2}\,\sqrt{\frac{1}{x^2}}}{c} \end{aligned} \tag{6}$$

$$\tau'' = -\frac{\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\,x^3}$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\,x^3} + \frac{4}{x}\frac{\sqrt{2}\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{2}\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= \frac{3c\sqrt{2}}{2}
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{3c\sqrt{2}\left(\frac{d}{d\tau}y(\tau)\right)}{2} + c^2 y(\tau) &= 0 \qquad (7)
\end{aligned}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = \mathrm{e}^{-\frac{3\sqrt{2}\,c\tau}{4}}\left(c_1\cosh\left(\frac{\sqrt{2}\,c\tau}{4}\right) + ic_2\sinh\left(\frac{\sqrt{2}\,c\tau}{4}\right)\right)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{2}\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{2}\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = \frac{c_1\cosh\left(\frac{\ln(x)}{2}\right) + ic_2\sinh\left(\frac{\ln(x)}{2}\right)}{x^{\frac{3}{2}}}
$$

Now the particular solution to this ODE is found

$$
x^2y'' + 4xy' + 2y = 2\ln(x)^2 + 12x
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(-\frac{1}{x^3}\right)^{\frac{1}{3}}$$

$$y_2 = \left(-\frac{1}{x^3}\right)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} & \left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \\ \frac{d}{dx}\left(\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}\right) & \frac{d}{dx}\left(\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} & \left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \\ \frac{1}{\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^4} & \frac{2}{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^4} \end{vmatrix}$$

Therefore

$$W = \left(\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}\right)\left(\frac{2}{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^4}\right) - \left(\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}\right)\left(\frac{1}{\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^4}\right)$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \left(2\ln\left(x\right)^2 + 12x\right)}{\frac{1}{x^2}} dx$$

Which simplifies to

$$u_1 = -\int 2\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \left(\ln\left(x\right)^2 + 6x\right) x^2 dx$$

Hence

$$u_1 = -2x^3\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \ln\left(x\right)^2 - 6\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^4 + 4x^3\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \ln\left(x\right) - 4x^3\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} \left(2\ln\left(x\right)^2 + 12x\right)}{\frac{1}{x^2}} dx$$

Which simplifies to

$$u_2 = \int 2\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} \left(\ln\left(x\right)^2 + 6x\right) x^2 dx$$

Hence

$$u_2 = \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3 \ln\left(x\right)^2 - \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3 \ln\left(x\right) + 4\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^4 + \frac{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3}{2}$$

Which simplifies to

$$u_1 = -2x^3 \left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \left(\ln(x)^2 - 2\ln(x) + 3x + 2\right)$$

$$u_2 = \frac{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3 \left(2\ln(x)^2 - 2\ln(x) + 8x + 1\right)}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)}{x^{\frac{3}{2}}}\right) + \left(\ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2}\right) \\ &= \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2} + \frac{c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)}{x^{\frac{3}{2}}} \end{aligned}$$

Which simplifies to

$$y = \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2} + \frac{c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)}{x^{\frac{3}{2}}}$$

Summary

The solution(s) found are the following

$$y = \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2} + \frac{c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)}{x^{\frac{3}{2}}} \tag{1}$$

Verification of solutions

$$y = \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2} + \frac{c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)}{x^{\frac{3}{2}}}$$

Verified OK.

19.16.5 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + 4xy' + 2y = 0$$

In normal form the given ode is written as

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{4}{x} \\ q(x) &= \frac{2}{x^2} \end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$\begin{aligned} Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\ &= \frac{2}{x^2} - \frac{\left(\frac{4}{x}\right)'}{2} - \frac{\left(\frac{4}{x}\right)^2}{4} \\ &= \frac{2}{x^2} - \frac{\left(-\frac{4}{x^2}\right)}{2} - \frac{\left(\frac{16}{x^2}\right)}{4} \\ &= \frac{2}{x^2} - \left(-\frac{2}{x^2}\right) - \frac{4}{x^2} \\ &= 0 \end{aligned}$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y = v(x)\,z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$\begin{aligned} z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2}dx\right)} \\ &= e^{-\int \frac{\frac{4}{x}}{2}} \\ &= \frac{1}{x^2} \end{aligned} \tag{5}$$

Hence (3) becomes

$$y = \frac{v(x)}{x^2} \tag{4}$$

Applying this change of variable to the original ode results in

$$v''(x) = 2\ln(x)^2 + 12x$$

Which is now solved for $v(x)$ Integrating once gives

$$v'(x) = 2x\ln(x)^2 - 4x\ln(x) + 4x + 6x^2 + c_1$$

Integrating again gives

$$v(x) = x^2\ln(x)^2 - 3x^2\ln(x) + \frac{7x^2}{2} + 2x^3 + c_1x + c_2$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\,z(x) \\ &= \left(x^2\ln(x)^2 - 3x^2\ln(x) + 2x^3 + c_1x + \frac{7x^2}{2} + c_2\right)(z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = \frac{1}{x^2}$$

Hence (7) becomes

$$y = \frac{x^2\ln(x)^2 - 3x^2\ln(x) + 2x^3 + c_1x + \frac{7x^2}{2} + c_2}{x^2}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{x^2\ln(x)^2 - 3x^2\ln(x) + 2x^3 + c_1x + \frac{7x^2}{2} + c_2}{x^2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(-\frac{1}{x^3}\right)^{\frac{1}{3}}$$

$$y_2 = \left(-\frac{1}{x^3}\right)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} & \left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \\ \frac{d}{dx}\left(\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}\right) & \frac{d}{dx}\left(\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} & \left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \\ \frac{1}{\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^4} & \frac{2}{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^4} \end{vmatrix}$$

Therefore

$$W = \left(\left(-\frac{1}{x^3}\right)^{\frac{1}{3}}\right)\left(\frac{2}{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^4}\right) - \left(\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}\right)\left(\frac{1}{\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^4}\right)$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \left(2\ln(x)^2 + 12x\right)}{\frac{1}{x^2}}\, dx$$

Which simplifies to

$$u_1 = -\int 2\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \left(\ln(x)^2 + 6x\right) x^2 dx$$

Hence

$$u_1 = -2x^3\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \ln(x)^2 - 6\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} x^4 + 4x^3\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \ln(x) - 4x^3\left(-\frac{1}{x^3}\right)^{\frac{2}{3}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} \left(2\ln(x)^2 + 12x\right)}{\frac{1}{x^2}}\, dx$$

Which simplifies to

$$u_2 = \int 2\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} \left(\ln(x)^2 + 6x\right) x^2 dx$$

Hence

$$u_2 = \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3 \ln(x)^2 - \left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3 \ln(x) + 4\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^4 + \frac{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3}{2}$$

Which simplifies to

$$u_1 = -2x^3\left(-\frac{1}{x^3}\right)^{\frac{2}{3}} \left(\ln(x)^2 - 2\ln(x) + 3x + 2\right)$$

$$u_2 = \frac{\left(-\frac{1}{x^3}\right)^{\frac{1}{3}} x^3 \left(2\ln(x)^2 - 2\ln(x) + 8x + 1\right)}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{x^2\ln(x)^2 - 3x^2\ln(x) + 2x^3 + c_1x + \frac{7x^2}{2} + c_2}{x^2}\right) + \left(\ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{x^2\ln(x)^2 - 3x^2\ln(x) + 2x^3 + c_1x + \frac{7x^2}{2} + c_2}{x^2} + \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2} \tag{1}$$

Verification of solutions

$$y = \frac{x^2\ln(x)^2 - 3x^2\ln(x) + 2x^3 + c_1x + \frac{7x^2}{2} + c_2}{x^2} + \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2}$$

Verified OK.

19.16.6 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 4x, C = 2, f(x) = 2\ln(x)^2 + 12x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 4xy' + 2y = 0$$

In normal form the ode

$$x^2y'' + 4xy' + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{4}{x} \\ q(x) &= \frac{2}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{4n}{x^2} + \frac{2}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = -1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{2v'(x)}{x} &= 0 \\ v''(x) + \frac{2v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{2u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}u' &= F(x,u)\\ &= f(x)g(u)\\ &= -\frac{2u}{x}\end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}\frac{1}{u}\,du &= -\frac{2}{x}\,dx\\ \int \frac{1}{u}\,du &= \int -\frac{2}{x}\,dx\\ \ln(u) &= -2\ln(x) + c_1\\ u &= \mathrm{e}^{-2\ln(x)+c_1}\\ &= \frac{c_1}{x^2}\end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned}v'(x) &= u(x)\\ v(x) &= \int u(x)\,dx + c_2\\ &= -\frac{c_1}{x} + c_2\end{aligned}$$

Hence

$$\begin{aligned}y &= v(x)\,x^n\\ &= \frac{-\frac{c_1}{x} + c_2}{x}\\ &= \frac{c_2 x - c_1}{x^2}\end{aligned}$$

Now the particular solution to this ODE is found

$$x^2 y'' + 4xy' + 2y = 2\ln(x)^2 + 12x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x^2}$$
$$y_2 = \frac{1}{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{1}{x} \\ \frac{d}{dx}\left(\frac{1}{x^2}\right) & \frac{d}{dx}\left(\frac{1}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{1}{x} \\ -\frac{2}{x^3} & -\frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^2}\right)\left(-\frac{1}{x^2}\right) - \left(\frac{1}{x}\right)\left(-\frac{2}{x^3}\right)$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{2\ln(x)^2+12x}{x}}{\frac{1}{x^2}} dx$$

Which simplifies to

$$u_1 = -\int \left(2x\ln(x)^2 + 12x^2\right) dx$$

Hence

$$u_1 = -x^2\ln(x)^2 + x^2\ln(x) - \frac{x^2}{2} - 4x^3$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{2\ln(x)^2+12x}{x^2}}{\frac{1}{x^2}} dx$$

Which simplifies to

$$u_2 = \int \left(2\ln(x)^2 + 12x\right) dx$$

Hence

$$u_2 = 2x\ln(x)^2 - 4x\ln(x) + 4x + 6x^2$$

Which simplifies to

$$u_1 = -\frac{x^2\left(2\ln(x)^2 - 2\ln(x) + 8x + 1\right)}{2}$$
$$u_2 = 2x\left(\ln(x)^2 - 2\ln(x) + 3x + 2\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(\frac{-\frac{c_1}{x} + c_2}{x}\right) + \left(\ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2}\right) \\
&= \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2} + \frac{-\frac{c_1}{x} + c_2}{x}
\end{aligned}$$

Which simplifies to

$$y = \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2} + \frac{-\frac{c_1}{x} + c_2}{x}$$

Summary

The solution(s) found are the following

$$y = \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2} + \frac{-\frac{c_1}{x} + c_2}{x} \tag{1}$$

Verification of solutions

$$y = \ln(x)^2 - 3\ln(x) + 2x + \frac{7}{2} + \frac{-\frac{c_1}{x} + c_2}{x}$$

Verified OK.

19.16.7 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2y'' + 4xy' + 2y)\,dx = \int (2\ln(x)^2 + 12x)\,dx$$
$$x^2y' + 2yx = 2x\ln(x)^2 - 4x\ln(x) + 4x + 6x^2 + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{2}{x}$$
$$q(x) = \frac{2x\ln(x)^2 - 4x\ln(x) + 4x + 6x^2 + c_1}{x^2}$$

Hence the ode is

$$y' + \frac{2y}{x} = \frac{2x\ln(x)^2 - 4x\ln(x) + 4x + 6x^2 + c_1}{x^2}$$

The integrating factor μ is

$$\mu = e^{\int \frac{2}{x}dx}$$
$$= x^2$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{2x\ln(x)^2-4x\ln(x)+4x+6x^2+c_1}{x^2}\right)\\
\frac{d}{dx}(x^2 y) &= (x^2)\left(\frac{2x\ln(x)^2-4x\ln(x)+4x+6x^2+c_1}{x^2}\right)\\
d(x^2 y) &= \left(2x\ln(x)^2-4x\ln(x)+4x+6x^2+c_1\right)\, dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
x^2 y &= \int 2x\ln(x)^2-4x\ln(x)+4x+6x^2+c_1\, dx\\
x^2 y &= c_1 x+x^2\ln(x)^2-3x^2\ln(x)+\frac{7x^2}{2}+2x^3+c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = x^2$ results in

$$
y = \frac{c_1 x+x^2\ln(x)^2-3x^2\ln(x)+\frac{7x^2}{2}+2x^3}{x^2}+\frac{c_2}{x^2}
$$

which simplifies to

$$
y = \frac{x^2\ln(x)^2-3x^2\ln(x)+2x^3+c_1 x+\frac{7x^2}{2}+c_2}{x^2}
$$

Summary
The solution(s) found are the following

$$
y = \frac{x^2\ln(x)^2-3x^2\ln(x)+2x^3+c_1 x+\frac{7x^2}{2}+c_2}{x^2} \tag{1}
$$

Verification of solutions

$$
y = \frac{x^2\ln(x)^2-3x^2\ln(x)+2x^3+c_1 x+\frac{7x^2}{2}+c_2}{x^2}
$$

Verified OK.

19.16.8 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$
x^2 y''+4xy'+2y = 2\ln(x)^2+12x
$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(x^2y'' + 4xy' + 2y\right) dx = \int \left(2\ln(x)^2 + 12x\right) dx$$

$$x^2y' + 2yx = 2x\ln(x)^2 - 4x\ln(x) + 4x + 6x^2 + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{2}{x}$$
$$q(x) = \frac{2x\ln(x)^2 - 4x\ln(x) + 4x + 6x^2 + c_1}{x^2}$$

Hence the ode is

$$y' + \frac{2y}{x} = \frac{2x\ln(x)^2 - 4x\ln(x) + 4x + 6x^2 + c_1}{x^2}$$

The integrating factor μ is

$$\mu = e^{\int \frac{2}{x}dx}$$
$$= x^2$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{2x\ln(x)^2 - 4x\ln(x) + 4x + 6x^2 + c_1}{x^2}\right)$$
$$\frac{d}{dx}\left(x^2y\right) = \left(x^2\right)\left(\frac{2x\ln(x)^2 - 4x\ln(x) + 4x + 6x^2 + c_1}{x^2}\right)$$
$$d\left(x^2y\right) = \left(2x\ln(x)^2 - 4x\ln(x) + 4x + 6x^2 + c_1\right) dx$$

Integrating gives

$$x^2y = \int 2x\ln(x)^2 - 4x\ln(x) + 4x + 6x^2 + c_1\, dx$$
$$x^2y = c_1x + x^2\ln(x)^2 - 3x^2\ln(x) + \frac{7x^2}{2} + 2x^3 + c_2$$

Dividing both sides by the integrating factor $\mu = x^2$ results in

$$y = \frac{c_1 x + x^2 \ln(x)^2 - 3x^2 \ln(x) + \frac{7x^2}{2} + 2x^3}{x^2} + \frac{c_2}{x^2}$$

which simplifies to

$$y = \frac{x^2 \ln(x)^2 - 3x^2 \ln(x) + 2x^3 + c_1 x + \frac{7x^2}{2} + c_2}{x^2}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2 \ln(x)^2 - 3x^2 \ln(x) + 2x^3 + c_1 x + \frac{7x^2}{2} + c_2}{x^2} \tag{1}$$

Verification of solutions

$$y = \frac{x^2 \ln(x)^2 - 3x^2 \ln(x) + 2x^3 + c_1 x + \frac{7x^2}{2} + c_2}{x^2}$$

Verified OK.

19.16.9 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' + 4xy' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 4x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 635: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4x}{x^2}\,dx} \\ &= z_1 e^{-2\ln(x)} \\ &= z_1\left(\frac{1}{x^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{4x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-4\ln(x)}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x^2}\right) + c_2 \left(\frac{1}{x^2}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2 y'' + 4xy' + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \frac{c_1}{x^2} + \frac{c_2}{x}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \frac{1}{x^2} \\
y_2 &= \frac{1}{x}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{1}{x} \\ \frac{d}{dx}\left(\frac{1}{x^2}\right) & \frac{d}{dx}\left(\frac{1}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{1}{x} \\ -\frac{2}{x^3} & -\frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^2}\right)\left(-\frac{1}{x^2}\right) - \left(\frac{1}{x}\right)\left(-\frac{2}{x^3}\right)$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Which simplifies to

$$W = \frac{1}{x^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{2\ln(x)^2+12x}{x}}{\frac{1}{x^2}}\,dx$$

Which simplifies to

$$u_1 = -\int \left(2x\ln(x)^2 + 12x^2\right) dx$$

Hence

$$u_1 = -x^2\ln(x)^2 + x^2\ln(x) - \frac{x^2}{2} - 4x^3$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{2\ln(x)^2+12x}{x^2}}{\frac{1}{x^2}}\,dx$$

Which simplifies to

$$u_2 = \int \left(2 \ln (x)^2 + 12x\right) dx$$

Hence

$$u_2 = 2x \ln (x)^2 - 4x \ln (x) + 4x + 6x^2$$

Which simplifies to

$$u_1 = -\frac{x^2 \left(2 \ln (x)^2 - 2 \ln (x) + 8x + 1\right)}{2}$$
$$u_2 = 2x \left(\ln (x)^2 - 2 \ln (x) + 3x + 2\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln (x)^2 - 3 \ln (x) + 2x + \frac{7}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x^2} + \frac{c_2}{x}\right) + \left(\ln (x)^2 - 3 \ln (x) + 2x + \frac{7}{2}\right) \end{aligned}$$

Which simplifies to

$$y = \frac{c_2 x + c_1}{x^2} + \ln (x)^2 - 3 \ln (x) + 2x + \frac{7}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{c_2 x + c_1}{x^2} + \ln (x)^2 - 3 \ln (x) + 2x + \frac{7}{2} \tag{1}$$

Verification of solutions

$$y = \frac{c_2 x + c_1}{x^2} + \ln (x)^2 - 3 \ln (x) + 2x + \frac{7}{2}$$

Verified OK.

19.16.10 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x^2 \\ q(x) &= 4x \\ r(x) &= 2 \\ s(x) &= 2\ln(x)^2 + 12x \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 2 \\ q'(x) &= 4 \end{aligned}$$

Therefore (1) becomes

$$2 - (4) + (2) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\ dx$$

Substituting the above values for p, q, r, s gives

$$x^2y' + 2yx = \int 2\ln(x)^2 + 12x\,dx$$

We now have a first order ode to solve which is

$$x^2y' + 2yx = 2x\ln(x)^2 - 4x\ln(x) + 4x + 6x^2 + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}
p(x) &= \frac{2}{x} \\
q(x) &= \frac{2x \ln(x)^2 - 4x \ln(x) + 4x + 6x^2 + c_1}{x^2}
\end{aligned}$$

Hence the ode is

$$y' + \frac{2y}{x} = \frac{2x \ln(x)^2 - 4x \ln(x) + 4x + 6x^2 + c_1}{x^2}$$

The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int \frac{2}{x} dx} \\
&= x^2
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu) \left(\frac{2x \ln(x)^2 - 4x \ln(x) + 4x + 6x^2 + c_1}{x^2}\right) \\
\frac{d}{dx}(x^2 y) &= (x^2) \left(\frac{2x \ln(x)^2 - 4x \ln(x) + 4x + 6x^2 + c_1}{x^2}\right) \\
d(x^2 y) &= \left(2x \ln(x)^2 - 4x \ln(x) + 4x + 6x^2 + c_1\right) dx
\end{aligned}$$

Integrating gives

$$\begin{aligned}
x^2 y &= \int 2x \ln(x)^2 - 4x \ln(x) + 4x + 6x^2 + c_1 \, dx \\
x^2 y &= c_1 x + x^2 \ln(x)^2 - 3x^2 \ln(x) + \frac{7x^2}{2} + 2x^3 + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = x^2$ results in

$$y = \frac{c_1 x + x^2 \ln(x)^2 - 3x^2 \ln(x) + \frac{7x^2}{2} + 2x^3}{x^2} + \frac{c_2}{x^2}$$

which simplifies to

$$y = \frac{x^2 \ln(x)^2 - 3x^2 \ln(x) + 2x^3 + c_1 x + \frac{7x^2}{2} + c_2}{x^2}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2 \ln(x)^2 - 3x^2 \ln(x) + 2x^3 + c_1 x + \frac{7x^2}{2} + c_2}{x^2} \tag{1}$$

Verification of solutions

$$y = \frac{x^2 \ln(x)^2 - 3x^2 \ln(x) + 2x^3 + c_1 x + \frac{7x^2}{2} + c_2}{x^2}$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{(x+1)^3 y'' + 3(x+1)^2 y' + (x+1) y = 6\ln(x+1)}$$

19.17.1 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$(x+1)^3 y'' + 3(x+1)^2 y' + (x+1) y = 0$$

In normal form the ode

$$(x+1)^3 y'' + 3(x+1)^2 y' + (x+1) y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{3}{x+1} \\ q(x) &= \frac{1}{(x+1)^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2} y(\tau) + p_1\left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\, \tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int e^{-\left(\int p(x) dx\right)} dx \\ &= \int e^{-\left(\int \frac{3}{x+1} dx\right)} dx \\ &= \int e^{-3\ln(x+1)}\, dx \\ &= \int \frac{1}{(x+1)^3} dx \\ &= -\frac{1}{2(x+1)^2} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned} q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{1}{(x+1)^2}}{\frac{1}{(x+1)^6}} \\ &= (x+1)^4 \end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) + (x+1)^4\, y(\tau) = 0$$

But in terms of τ

$$(x+1)^4 = \frac{1}{4\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{4\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$4\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0$$

Simplifying gives

$$4r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$4r(r-1) + 0 + 1 = 0$$

Or

$$4r^2 - 4r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2}$$
$$r_2 = \frac{1}{2}$$

Since the roots are equal, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^r$ and $y_2 = \tau^r \ln(\tau)$. Hence

$$y(\tau) = c_1\sqrt{\tau} + c_2\sqrt{\tau}\,\ln(\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{2}\,\sqrt{-\frac{1}{(x+1)^2}}\left(c_1 - c_2\ln(2) + c_2\ln\left(-\frac{1}{(x+1)^2}\right)\right)}{2}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{\sqrt{2}\,\sqrt{-\frac{1}{(x+1)^2}}\left(c_1 - c_2\ln(2) + c_2\ln\left(-\frac{1}{(x+1)^2}\right)\right)}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sqrt{-\frac{1}{(x+1)^2}}$$

$$y_2 = -\frac{\sqrt{2}\,\sqrt{-\frac{1}{(x+1)^2}}\,\ln(2)}{2} + \frac{\sqrt{2}\,\sqrt{-\frac{1}{(x+1)^2}}\,\ln\left(-\frac{1}{(x+1)^2}\right)}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{-\frac{1}{(x+1)^2}} & -\frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln\left(-\frac{1}{(x+1)^2}\right)}{2} \\ \frac{d}{dx}\left(\sqrt{-\frac{1}{(x+1)^2}}\right) & \frac{d}{dx}\left(-\frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln\left(-\frac{1}{(x+1)^2}\right)}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{-\frac{1}{(x+1)^2}} & -\frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln\left(-\frac{1}{(x+1)^2}\right)}{2} \\ \frac{1}{\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)^3} & -\frac{\sqrt{2}\ln(2)}{2\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)^3} + \frac{\sqrt{2}\ln\left(-\frac{1}{(x+1)^2}\right)}{2\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)^3} - \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}}{x+1} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{-\frac{1}{(x+1)^2}}\right)\left(-\frac{\sqrt{2}\ln(2)}{2\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)^3} + \frac{\sqrt{2}\ln\left(-\frac{1}{(x+1)^2}\right)}{2\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)^3} - \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}}{x+1}\right) - \left(-\frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln\left(-\frac{1}{(x+1)^2}\right)}{2}\right)\left(\frac{1}{\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)^3}\right)$$

Which simplifies to

$$W = \frac{\sqrt{2}}{(x+1)^3}$$

Which simplifies to

$$W = \frac{\sqrt{2}}{(x+1)^3}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{6\left(-\frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln\left(-\frac{1}{(x+1)^2}\right)}{2}\right)\ln(x+1)}{\sqrt{2}}\,dx$$

Which simplifies to

$$u_1 = -\int 3\sqrt{-\frac{1}{(x+1)^2}}\left(-\ln(2)+\ln\left(-\frac{1}{(x+1)^2}\right)\right)\ln(x+1)\,dx$$

Hence

$$u_1 = -\left(\int_0^x 3\sqrt{-\frac{1}{(\alpha+1)^2}}\left(-\ln(2)+\ln\left(-\frac{1}{(\alpha+1)^2}\right)\right)\ln(\alpha+1)\,d\alpha\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{6\sqrt{-\frac{1}{(x+1)^2}}\,\ln(x+1)}{\sqrt{2}}\,dx$$

Which simplifies to

$$u_2 = \int 3\sqrt{-\frac{1}{(x+1)^2}}\,\ln(x+1)\sqrt{2}dx$$

Hence

$$u_2 = \frac{3\sqrt{2}\,(x+1)\sqrt{-\frac{1}{(x+1)^2}}\,\ln(x+1)^2}{2}$$

Which simplifies to

$$u_1 = -3\left(\int_0^x \sqrt{-\frac{1}{(\alpha+1)^2}}\left(-\ln(2)+\ln\left(-\frac{1}{(\alpha+1)^2}\right)\right)\ln(\alpha+1)\,d\alpha\right)$$

$$u_2 = \frac{3\sqrt{2}\,(x+1)\sqrt{-\frac{1}{(x+1)^2}}\,\ln(x+1)^2}{2}$$

Therefore the particular solution, from equation (1) is

$$\begin{aligned} y_p(x) &= -3\left(\int_0^x \sqrt{-\frac{1}{(\alpha+1)^2}}\left(-\ln(2)+\ln\left(-\frac{1}{(\alpha+1)^2}\right)\right)\ln(\alpha+1)\,d\alpha\right)\sqrt{-\frac{1}{(x+1)^2}} \\ &\quad + \frac{3\sqrt{2}\,(x+1)\sqrt{-\frac{1}{(x+1)^2}}\,\ln(x+1)^2\left(-\frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln(2)}{2}+\frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln\left(-\frac{1}{(x+1)^2}\right)}{2}\right)}{2} \end{aligned}$$

Which simplifies to

$$y_p(x) = \frac{-6\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)\left(\int_0^x \sqrt{-\frac{1}{(\alpha+1)^2}}\left(-\ln(2)+\ln\left(-\frac{1}{(\alpha+1)^2}\right)\right)\ln(\alpha+1)\,d\alpha\right)+3\ln(x+1)^2\left(\ln(2)-\mathrm{l}\right.}{2x+2}$$

Therefore the general solution is

$$y = y_h + y_p$$
$$= \left(\frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\left(c_1 - c_2\ln(2)+c_2\ln\left(-\frac{1}{(x+1)^2}\right)\right)}{2}\right) + \left(\frac{-6\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)\left(\int_0^x \sqrt{-\frac{1}{(\alpha+1)^2}}\left(-\ln(2)+\ln\left(-\frac{1}{(\alpha+1)^2}\right)\right)\ln(\alpha+1)\,d\alpha\right)+3\ln(x+1)^2\left(\ln(\right.}{2x+2}\right.$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\left(c_1 - c_2\ln(2)+c_2\ln\left(-\frac{1}{(x+1)^2}\right)\right)}{2} + \frac{-6\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)\left(\int_0^x \sqrt{-\frac{1}{(\alpha+1)^2}}\left(-\ln(2)+\ln\left(-\frac{1}{(\alpha+1)^2}\right)\right)\ln(\alpha+1)\,d\alpha\right)+3\ln(x+1)^2\left(\ln(2)-\right.}{2x+2} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\left(c_1 - c_2\ln(2)+c_2\ln\left(-\frac{1}{(x+1)^2}\right)\right)}{2} + \frac{-6\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)\left(\int_0^x \sqrt{-\frac{1}{(\alpha+1)^2}}\left(-\ln(2)+\ln\left(-\frac{1}{(\alpha+1)^2}\right)\right)\ln(\alpha+1)\,d\alpha\right)+3\ln(x+1)^2\left(\ln(2)-\right.}{2x+2}$$

Verified OK.

19.17.2 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = (x+1)^3, B = 3(x+1)^2, C = x+1, f(x) = 6\ln(x+1)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$(x+1)^3 y'' + 3(x+1)^2 y' + (x+1)y = 0$$

In normal form the ode

$$(x+1)^3 y'' + 3(x+1)^2 y' + (x+1)y = 0 \tag{1}$$

Becomes

$$y'' + p(x)y' + q(x)y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{3}{x+1} \\ q(x) &= \frac{1}{(x+1)^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$
\begin{aligned}
\tau' &= \frac{1}{c}\sqrt{q} \\
&= \frac{\sqrt{\frac{1}{(x+1)^2}}}{c} \\
\tau'' &= -\frac{1}{c\sqrt{\frac{1}{(x+1)^2}}\,(x+1)^3}
\end{aligned} \tag{6}
$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{1}{c\sqrt{\frac{1}{(x+1)^2}}\,(x+1)^3} + \frac{3}{x+1}\frac{\sqrt{\frac{1}{(x+1)^2}}}{c}}{\left(\frac{\sqrt{\frac{1}{(x+1)^2}}}{c}\right)^2} \\
&= 2c
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + 2c\left(\frac{d}{d\tau}y(\tau)\right) + c^2 y(\tau) &= 0
\end{aligned} \tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = \mathrm{e}^{-c\tau}c_1
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{\frac{1}{(x+1)^2}}dx}{c} \\
&= \frac{\sqrt{\frac{1}{(x+1)^2}}\,(x+1)\ln(x+1)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = \frac{c_1}{x+1}
$$

Now the particular solution to this ODE is found

$$(x+1)^3 y'' + 3(x+1)^2 y' + (x+1) y = 6\ln(x+1)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sqrt{-\frac{1}{(x+1)^2}}$$

$$y_2 = -\frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln\left(-\frac{1}{(x+1)^2}\right)}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{-\frac{1}{(x+1)^2}} & -\frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln\left(-\frac{1}{(x+1)^2}\right)}{2} \\ \frac{d}{dx}\left(\sqrt{-\frac{1}{(x+1)^2}}\right) & \frac{d}{dx}\left(-\frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln\left(-\frac{1}{(x+1)^2}\right)}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{-\frac{1}{(x+1)^2}} & -\frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln\left(-\frac{1}{(x+1)^2}\right)}{2} \\ \frac{1}{\sqrt{-\frac{1}{(x+1)^2}}(x+1)^3} & -\frac{\sqrt{2}\ln(2)}{2\sqrt{-\frac{1}{(x+1)^2}}(x+1)^3} + \frac{\sqrt{2}\ln\left(-\frac{1}{(x+1)^2}\right)}{2\sqrt{-\frac{1}{(x+1)^2}}(x+1)^3} - \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}}{x+1} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{-\frac{1}{(x+1)^2}}\right)\left(-\frac{\sqrt{2}\ln(2)}{2\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)^3} + \frac{\sqrt{2}\ln\left(-\frac{1}{(x+1)^2}\right)}{2\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)^3} - \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}}{x+1}\right) - \left(-\frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln\left(-\frac{1}{(x+1)^2}\right)}{2}\right)\left(\frac{1}{\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)^3}\right)$$

Which simplifies to

$$W = \frac{\sqrt{2}}{(x+1)^3}$$

Which simplifies to

$$W = \frac{\sqrt{2}}{(x+1)^3}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{6\left(-\frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{(x+1)^2}}\ln\left(-\frac{1}{(x+1)^2}\right)}{2}\right)\ln(x+1)}{\sqrt{2}}\,dx$$

Which simplifies to

$$u_1 = -\int 3\sqrt{-\frac{1}{(x+1)^2}}\left(-\ln(2) + \ln\left(-\frac{1}{(x+1)^2}\right)\right)\ln(x+1)\,dx$$

Hence

$$u_1 = -\left(\int_0^x 3\sqrt{-\frac{1}{(\alpha+1)^2}}\left(-\ln(2) + \ln\left(-\frac{1}{(\alpha+1)^2}\right)\right)\ln(\alpha+1)\,d\alpha\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{6\sqrt{-\frac{1}{(x+1)^2}}\, \ln(x+1)}{\sqrt{2}} dx$$

Which simplifies to

$$u_2 = \int 3\sqrt{-\frac{1}{(x+1)^2}}\, \ln(x+1)\, \sqrt{2}dx$$

Hence

$$u_2 = \frac{3\sqrt{2}\,(x+1)\,\sqrt{-\frac{1}{(x+1)^2}}\, \ln(x+1)^2}{2}$$

Which simplifies to

$$u_1 = 3\left(\int_0^x \sqrt{-\frac{1}{(\alpha+1)^2}}\, \left(\ln(2) - \ln\left(-\frac{1}{(\alpha+1)^2}\right)\right) \ln(\alpha+1)\, d\alpha\right)$$

$$u_2 = \frac{3\sqrt{2}\,(x+1)\,\sqrt{-\frac{1}{(x+1)^2}}\, \ln(x+1)^2}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = 3\left(\int_0^x \sqrt{-\frac{1}{(\alpha+1)^2}}\, \left(\ln(2) - \ln\left(-\frac{1}{(\alpha+1)^2}\right)\right) \ln(\alpha+1)\, d\alpha\right) \sqrt{-\frac{1}{(x+1)^2}} + \frac{3\sqrt{2}\,(x+1)\,\sqrt{-\frac{1}{(x+1)^2}}\, \ln(x+1)^2 \left(-\frac{\sqrt{2}\,\sqrt{-\frac{1}{(x+1)^2}}\, \ln(2)}{2} + \frac{\sqrt{2}\,\sqrt{-\frac{1}{(x+1)^2}}\, \ln\left(-\frac{1}{(x+1)^2}\right)}{2}\right)}{2}$$

Which simplifies to

$$y_p(x) = \frac{6\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)\left(\int_0^x \sqrt{-\frac{1}{(\alpha+1)^2}}\, \left(\ln(2) - \ln\left(-\frac{1}{(\alpha+1)^2}\right)\right) \ln(\alpha+1)\, d\alpha\right) + 3\ln(x+1)^2 \left(\ln(2) - \ln\left(-\right.\right.}{2x+2}$$

Therefore the general solution is

$$y = y_h + y_p$$

$$= \left(\frac{c_1}{x+1}\right)$$

$$+ \left(\frac{6\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)\left(\int_0^x \sqrt{-\frac{1}{(\alpha+1)^2}}\left(\ln(2)-\ln\left(-\frac{1}{(\alpha+1)^2}\right)\right)\ln(\alpha+1)\,d\alpha\right)+3\ln(x+1)^2\left(\ln(2)-\right.}{2x+2}\right.$$

$$= \frac{6\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)\left(\int_0^x \sqrt{-\frac{1}{(\alpha+1)^2}}\left(\ln(2)-\ln\left(-\frac{1}{(\alpha+1)^2}\right)\right)\ln(\alpha+1)\,d\alpha\right)+3\ln(x+1)^2\left(\ln(2)-\ln\left(\right.\right.}{2x+2}$$

$$+ \frac{c_1}{x+1}$$

Which simplifies to

$$y = \frac{6\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)\left(\int_0^x \sqrt{-\frac{1}{(\alpha+1)^2}}\left(\ln(2)-\ln\left(-\frac{1}{(\alpha+1)^2}\right)\right)\ln(\alpha+1)\,d\alpha\right)+3\ln(x+1)^2\ln(2)-3\ln(x}{2x+2}$$

Summary

The solution(s) found are the following

$$y = \frac{6\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)\left(\int_0^x \sqrt{-\frac{1}{(\alpha+1)^2}}\left(\ln(2)-\ln\left(-\frac{1}{(\alpha+1)^2}\right)\right)\ln(\alpha+1)\,d\alpha\right)+3\ln(x+1)^2\ln(2)-3\ln(x}{2x+2} \tag{1}$$

Verification of solutions

$$y = \frac{6\sqrt{-\frac{1}{(x+1)^2}}\,(x+1)\left(\int_0^x \sqrt{-\frac{1}{(\alpha+1)^2}}\left(\ln(2)-\ln\left(-\frac{1}{(\alpha+1)^2}\right)\right)\ln(\alpha+1)\,d\alpha\right)+3\ln(x+1)^2\ln(2)-3\ln(x}{2x+2}$$

Verified OK.

19.17.3 Solving using Kovacic algorithm

Writing the ode as

$$(x+1)^3 y'' + 3(x+1)^2 y' + (x+1) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= (x+1)^3 \\ B &= 3(x+1)^2 \\ C &= x+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4(x+1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4(x+1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4(x+1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 636: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 2 - 0\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x+1)^2$. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4(x+1)^2}$$

For the pole at $x=-1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2} \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r=\frac{s}{t}=-\frac{1}{4\,(x+1)^2}
$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=-\frac{1}{4\,(x+1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-1	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x + 2} + (-)(0) \\ &= \frac{1}{2x + 2} \\ &= \frac{1}{2x + 2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2x + 2}\right)(0) + \left(\left(-\frac{1}{2(x+1)^2}\right) + \left(\frac{1}{2x + 2}\right)^2 - \left(-\frac{1}{4(x+1)^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{1}{2x+2} dx} \\ &= \sqrt{x + 1} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3(x+1)^2}{(x+1)^3}\,dx} \\
&= z_1 e^{-\frac{3\ln(x+1)}{2}} \\
&= z_1\left(\frac{1}{(x+1)^{\frac{3}{2}}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x+1}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3(x+1)^2}{(x+1)^3}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-3\ln(x+1)}}{(y_1)^2}\,dx \\
&= y_1(\ln(x+1))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{1}{x+1}\right) + c_2\left(\frac{1}{x+1}(\ln(x+1))\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$(x+1)^3 y'' + 3(x+1)^2 y' + (x+1)\, y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_1}{x+1} + \frac{c_2 \ln(x+1)}{x+1}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x+1}$$
$$y_2 = \frac{\ln(x+1)}{x+1}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x+1} & \frac{\ln(x+1)}{x+1} \\ \frac{d}{dx}\left(\frac{1}{x+1}\right) & \frac{d}{dx}\left(\frac{\ln(x+1)}{x+1}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x+1} & \frac{\ln(x+1)}{x+1} \\ -\frac{1}{(x+1)^2} & -\frac{\ln(x+1)}{(x+1)^2} + \frac{1}{(x+1)^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x+1}\right)\left(-\frac{\ln(x+1)}{(x+1)^2} + \frac{1}{(x+1)^2}\right) - \left(\frac{\ln(x+1)}{x+1}\right)\left(-\frac{1}{(x+1)^2}\right)$$

Which simplifies to

$$W = \frac{1}{(x+1)^3}$$

Which simplifies to

$$W = \frac{1}{(x+1)^3}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{6\ln(x+1)^2}{x+1}}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{6\ln(x+1)^2}{x+1}dx$$

Hence

$$u_1 = -2\ln(x+1)^3$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{6\ln(x+1)}{x+1}}{1}\,dx$$

Which simplifies to

$$u_2 = \int \frac{6\ln(x+1)}{x+1}dx$$

Hence

$$u_2 = 3\ln(x+1)^2$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\ln(x+1)^3}{x+1}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x+1} + \frac{c_2 \ln(x+1)}{x+1}\right) + \left(\frac{\ln(x+1)^3}{x+1}\right) \end{aligned}$$

Which simplifies to

$$y = \frac{c_2 \ln(x+1) + c_1}{x+1} + \frac{\ln(x+1)^3}{x+1}$$

Summary

The solution(s) found are the following

$$y = \frac{c_2 \ln(x+1) + c_1}{x+1} + \frac{\ln(x+1)^3}{x+1} \tag{1}$$

Verification of solutions

$$y = \frac{c_2 \ln(x+1) + c_1}{x+1} + \frac{\ln(x+1)^3}{x+1}$$

Verified OK.

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{(x-2)^2 y''-3(x-2) y'+4y=x}$$

19.18.1 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$(x-2)^2 y''+(-3x+6) y'+4y=0$$

In normal form the ode

$$(x-2)^2 y''+(-3x+6) y'+4y=0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{3}{-x+2} \\ q(x) &= \frac{4}{(x-2)^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\, \tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\ &= \int \mathrm{e}^{-\left(\int \frac{3}{-x+2} dx\right)} dx \\ &= \int e^{3\ln(-x+2)}\, dx \\ &= \int (-x+2)^3\, dx \\ &= -\frac{(-x+2)^4}{4} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned} q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{4}{(x-2)^2}}{(-x+2)^6} \\ &= \frac{4}{(x-2)^8} \end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0\\ \frac{d^2}{d\tau^2}y(\tau) + \frac{4y(\tau)}{(x-2)^8} &= 0\end{aligned}$$

But in terms of τ

$$\frac{4}{(x-2)^8} = \frac{1}{4\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{4\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$4\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0$$

Simplifying gives

$$4r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$4r(r-1) + 0 + 1 = 0$$

Or

$$4r^2 - 4r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned}r_1 &= \frac{1}{2}\\ r_2 &= \frac{1}{2}\end{aligned}$$

Since the roots are equal, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^r$ and $y_2 = \tau^r \ln(\tau)$. Hence

$$y(\tau) = c_1\sqrt{\tau} + c_2\sqrt{\tau}\,\ln(\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\left(c_2 \ln\left(-(x-2)^4\right) - 2c_2 \ln(2) + c_1\right)\sqrt{-(x-2)^4}}{2}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{\left(c_2 \ln\left(-(x-2)^4\right) - 2c_2 \ln(2) + c_1\right)\sqrt{-(x-2)^4}}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sqrt{-x^4 + 8x^3 - 24x^2 + 32x - 16}$$
$$y_2 = \frac{\sqrt{-x^4 + 8x^3 - 24x^2 + 32x - 16}\,\ln\left(-(x-2)^4\right)}{2} - \sqrt{-x^4 + 8x^3 - 24x^2 + 32x - 16}\,\ln(2)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{-x^4+8x^3-24x^2+32x-16} & \frac{\sqrt{-x^4+8x^3-24x^2+32x-16}\,\ln\left(-(x-2)^4\right)}{2} - \sqrt{-x^4+8x^3-24x^2+3 \\ \frac{d}{dx}\left(\sqrt{-x^4+8x^3-24x^2+32x-16}\right) & \frac{d}{dx}\left(\frac{\sqrt{-x^4+8x^3-24x^2+32x-16}\,\ln\left(-(x-2)^4\right)}{2} - \sqrt{-x^4+8x^3-24x^2+ \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{-x^4+8x^3-24x^2+32x-16} & \frac{\sqrt{-x^4+8x^3-24x^2+32x-16}\,\ln\left(-(x-2)^4\right)}{2} - \sqrt{-x^4+8x^3-24x^2+32x- \\ \frac{-4x^3+24x^2-48x+32}{2\sqrt{-x^4+8x^3-24x^2+32x-16}} & \frac{\ln\left(-(x-2)^4\right)\left(-4x^3+24x^2-48x+32\right)}{4\sqrt{-x^4+8x^3-24x^2+32x-16}} + \frac{2\sqrt{-x^4+8x^3-24x^2+32x-16}}{x-2} - \frac{\ln(2)\left(-4x^3+\right.}{2\sqrt{-x^4+8x^3} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{-x^4+8x^3-24x^2+32x-16}\right)\left(\frac{\ln\left(-(x-2)^4\right)\left(-4x^3+24x^2-48x+32\right)}{4\sqrt{-x^4+8x^3-24x^2+32x-16}} + \frac{2\sqrt{-x^4+8x^3-24x^2+32x-16}}{x-2} - \frac{\ln(2)\left(-4x^3+24x^2-48x+32\right)}{2\sqrt{-x^4+8x^3-24x^2+32x-16}}\right) - \left(\frac{\sqrt{-x^4+8x^3-24x^2+32x-16}\,\ln\left(-(x-2)^4\right)}{2} - \sqrt{-x^4+8x^3-24x^2+32x-16}\,\ln(2)\right)\left(\frac{-4x^3+24x^2-48x+32}{2\sqrt{-x^4+8x^3-24x^2+32x-16}}\right)$$

Which simplifies to

$$W = -2(x-2)\left(x^2-4x+4\right)$$

Which simplifies to

$$W = -2(x-2)^3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(\frac{\sqrt{-x^4+8x^3-24x^2+32x-16}\,\ln\left(-(x-2)^4\right)}{2} - \sqrt{-x^4+8x^3-24x^2+32x-16}\,\ln(2)\right)x}{-2\,(x-2)^5}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{\sqrt{-\left(x-2\right)^4}\,\left(-2\ln\left(2\right)+\ln\left(-\left(x-2\right)^4\right)\right)x}{4\left(x-2\right)^5}dx$$

Hence

$$u_1 = -\frac{\sqrt{-\left(x-2\right)^4}\,\left(x-1\right)\ln\left(-\left(x-2\right)^4\right)}{4\left(x-2\right)^4}+\frac{\sqrt{-\left(x-2\right)^4}\,\left(\ln\left(2\right)x-\ln\left(2\right)-2x+3\right)}{2\left(x-2\right)^4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sqrt{-x^4+8x^3-24x^2+32x-16}\,x}{-2\left(x-2\right)^5}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{\sqrt{-\left(x-2\right)^4}\,x}{2\left(x-2\right)^5}dx$$

Hence

$$u_2 = \frac{\left(x-1\right)\sqrt{-\left(x-2\right)^4}}{2\left(x-2\right)^4}$$

Which simplifies to

$$u_1 = \frac{\left(\left(1-x\right)\ln\left(-\left(x-2\right)^4\right)+\left(2x-2\right)\ln\left(2\right)-4x+6\right)\sqrt{-\left(x-2\right)^4}}{4\left(x-2\right)^4}$$

$$u_2 = \frac{\left(x-1\right)\sqrt{-\left(x-2\right)^4}}{2\left(x-2\right)^4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\left(\left(1-x\right)\ln\left(-\left(x-2\right)^4\right)+\left(2x-2\right)\ln\left(2\right)-4x+6\right)\sqrt{-\left(x-2\right)^4}\,\sqrt{-x^4+8x^3-24x^2+32x-16}}{4\left(x-2\right)^4} + \frac{\left(x-1\right)\sqrt{-\left(x-2\right)^4}\,\left(\frac{\sqrt{-x^4+8x^3-24x^2+32x-16}\,\ln\left(-\left(x-2\right)^4\right)}{2}-\sqrt{-x^4+8x^3-24x^2+32x-16}\,\ln\left(2\right)\right)}{2\left(x-2\right)^4}$$

Which simplifies to

$$y_p(x) = x - \frac{3}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{\left(c_2 \ln\left(-(x-2)^4\right) - 2c_2 \ln(2) + c_1\right)\sqrt{-\left(x-2\right)^4}}{2}\right) + \left(x - \frac{3}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(c_2 \ln\left(-(x-2)^4\right) - 2c_2 \ln(2) + c_1\right)\sqrt{-\left(x-2\right)^4}}{2} + x - \frac{3}{2} \tag{1}$$

Verification of solutions

$$y = \frac{\left(c_2 \ln\left(-(x-2)^4\right) - 2c_2 \ln(2) + c_1\right)\sqrt{-\left(x-2\right)^4}}{2} + x - \frac{3}{2}$$

Verified OK.

19.18.2 Solving using Kovacic algorithm

Writing the ode as

$$\left(x-2\right)^2 y'' + \left(-3x+6\right) y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= \left(x-2\right)^2 \\ B &= -3x+6 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4(x-2)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 4(x-2)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4(x-2)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 637: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x-2)^2$. There is a pole at $x = 2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4(x-2)^2}$$

For the pole at $x = 2$ let b be the coefficient of $\frac{1}{(x-2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4(x-2)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4(x-2)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
2	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^+) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x-4} + (-)(0) \\ &= \frac{1}{2x-4} \\ &= \frac{1}{2x-4} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x-4}\right)(0) + \left(\left(-\frac{1}{2\left(x-2\right)^2}\right) + \left(\frac{1}{2x-4}\right)^2 - \left(-\frac{1}{4\left(x-2\right)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \frac{1}{2x-4} dx} \\
&= \sqrt{x-2}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3x+6}{(x-2)^2}\, dx} \\
&= z_1 e^{\frac{3\ln(x-2)}{2}} \\
&= z_1\left(\left(x-2\right)^{\frac{3}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \left(x-2\right)^2$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3x+6}{(x-2)^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{3\ln(x-2)}}{(y_1)^2}\, dx \\
&= y_1(\ln(x-2))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left((x-2)^2\right) + c_2\left((x-2)^2 (\ln(x-2))\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
(x-2)^2 y'' + (-3x+6)\, y' + 4y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1(x-2)^2 + c_2(x-2)^2 \ln(x-2)
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= (x-2)^2 \\
y_2 &= (x-2)^2 \ln(x-2)
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x-2)^2 & (x-2)^2 \ln(x-2) \\ \frac{d}{dx}\left((x-2)^2\right) & \frac{d}{dx}\left((x-2)^2 \ln(x-2)\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x-2)^2 & (x-2)^2 \ln(x-2) \\ 2x-4 & 2(x-2)\ln(x-2) + x - 2 \end{vmatrix}$$

Therefore

$$W = \left((x-2)^2\right)\left(2(x-2)\ln(x-2) + x - 2\right) - \left((x-2)^2 \ln(x-2)\right)(2x-4)$$

Which simplifies to

$$W = x^3 - 6x^2 + 12x - 8$$

Which simplifies to

$$W = (x-2)^3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x-2)^2 \ln(x-2)\, x}{(x-2)^5} dx$$

Which simplifies to

$$u_1 = -\int \frac{\ln(x-2)\, x}{(x-2)^3} dx$$

Hence

$$u_1 = \frac{\ln(x-2)}{(x-2)^2} + \frac{1}{2(x-2)^2} + \frac{\ln(x-2)}{x-2} + \frac{1}{x-2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x-2)^2 x}{(x-2)^5}\, dx$$

Which simplifies to

$$u_2 = \int \frac{x}{(x-2)^3} dx$$

Hence

$$u_2 = -\frac{1}{(x-2)^2} - \frac{1}{x-2}$$

Which simplifies to

$$u_1 = \frac{(2x-2)\ln(x-2) + 2x - 3}{2(x-2)^2}$$
$$u_2 = \frac{1-x}{(x-2)^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{(2x-2)\ln(x-2)}{2} + x - \frac{3}{2} + (1-x)\ln(x-2)$$

Which simplifies to

$$y_p(x) = x - \frac{3}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1(x-2)^2 + c_2(x-2)^2 \ln(x-2)\right) + \left(x - \frac{3}{2}\right) \end{aligned}$$

Which simplifies to

$$y = (x-2)^2 (c_1 + c_2 \ln(x-2)) + x - \frac{3}{2}$$

Summary

The solution(s) found are the following

$$y = (x-2)^2 (c_1 + c_2 \ln(x-2)) + x - \frac{3}{2} \tag{1}$$

Verification of solutions

$$y = (x-2)^2 (c_1 + c_2 \ln(x-2)) + x - \frac{3}{2}$$

Verified OK.

$$\boxed{(1+2x)\,y''+(4x-2)\,y'-8y=0}$$

20.1.1 Solving using Kovacic algorithm

Writing the ode as

$$(1+2x)\,y''+(4x-2)\,y'-8y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1+2x \\ B &= 4x-2 \\ C &= -8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^2 + 12x + 13}{(1 + 2x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^2 + 12x + 13 \\ t &= (1 + 2x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^2 + 12x + 13}{(1 + 2x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 638: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (1+2x)^2$. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = 1 + \frac{2}{\left(x+\frac{1}{2}\right)^2} + \frac{2}{x+\frac{1}{2}}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx 1 + \frac{1}{x} - \frac{3}{4x^3} + \frac{11}{8x^4} - \frac{29}{16x^5} + \frac{29}{16x^6} - \frac{61}{64x^7} - \frac{5}{4x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= 1 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = 1$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^2 + 12x + 13}{4x^2 + 4x + 1} \\ &= Q + \frac{R}{4x^2 + 4x + 1} \\ &= (1) + \left(\frac{8x + 12}{4x^2 + 4x + 1}\right) \\ &= 1 + \frac{8x + 12}{4x^2 + 4x + 1} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 8. Dividing this by leading coefficient in t which is 4 gives 2. Now b can be found.

$$\begin{aligned} b &= (2) - (0) \\ &= 2 \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 1 \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{2}{1} - 0\right) &= 1 \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{2}{1} - 0\right) &= -1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{4x^2 + 12x + 13}{(1 + 2x)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$-\frac{1}{2}$	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	1	1	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -1$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= -1 - (-1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{x+\frac{1}{2}} + (-)(1) \\
&= -\frac{1}{x+\frac{1}{2}} - 1 \\
&= \frac{-2x-3}{1+2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{x+\frac{1}{2}} - 1\right)(0) + \left(\left(\frac{1}{\left(x+\frac{1}{2}\right)^2}\right) + \left(-\frac{1}{x+\frac{1}{2}} - 1\right)^2 - \left(\frac{4x^2+12x+13}{(1+2x)^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{x+\frac{1}{2}} - 1\right) dx} \\
&= \frac{\mathrm{e}^{-x}}{1+2x}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4x-2}{1+2x} \, dx} \\
&= z_1 e^{-x+\ln(1+2x)} \\
&= z_1\left((1+2x)\,\mathrm{e}^{-x}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4x-2}{1+2x}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-2x+2\ln(1+2x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{(4x^2+1)\,\mathrm{e}^{2x}}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-2x}\right) + c_2\left(\mathrm{e}^{-2x}\left(\frac{(4x^2+1)\,\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\mathrm{e}^{-2x} + c_2\left(2x^2 + \frac{1}{2}\right) \tag{1}$$

Verification of solutions

$$y = c_1\mathrm{e}^{-2x} + c_2\left(2x^2 + \frac{1}{2}\right)$$

Verified OK.

20.1.2 Maple step by step solution

Let's solve

$(1 + 2x)\, y'' + (4x - 2)\, y' - 8y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{8y}{1+2x} - \frac{2(2x-1)y'}{1+2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{2(2x-1)y'}{1+2x} - \frac{8y}{1+2x} = 0$

□ Check to see if $x_0 = -\frac{1}{2}$ is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{2(2x-1)}{1+2x}, P_3(x) = -\frac{8}{1+2x}\right]$

  - $\left(x + \frac{1}{2}\right) \cdot P_2(x)$ is analytic at $x = -\frac{1}{2}$

    $\left(\left(x + \frac{1}{2}\right) \cdot P_2(x)\right)\bigg|_{x=-\frac{1}{2}} = -2$

  - $\left(x + \frac{1}{2}\right)^2 \cdot P_3(x)$ is analytic at $x = -\frac{1}{2}$

    $\left(\left(x + \frac{1}{2}\right)^2 \cdot P_3(x)\right)\bigg|_{x=-\frac{1}{2}} = 0$

  - $x = -\frac{1}{2}$is a regular singular point

  Check to see if $x_0 = -\frac{1}{2}$ is a regular singular point

  $x_0 = -\frac{1}{2}$

- Multiply by denominators

  $(1 + 2x)\, y'' + (4x - 2)\, y' - 8y = 0$

- Change variables using $x = u - \frac{1}{2}$ so that the regular singular point is at $u = 0$

  $2u\left(\frac{d^2}{du^2} y(u)\right) + (4u - 4)\left(\frac{d}{du} y(u)\right) - 8y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^{m} \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $u^{m} \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_{k}(k+r)\, u^{k+r-1+m}$
- Shift index using $k- >k+1-m$

  $u^{m} \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$
- Convert $u \cdot \left(\frac{d^{2}}{du^{2}}y(u)\right)$ to series expansion

  $u \cdot \left(\frac{d^{2}}{du^{2}}y(u)\right) = \sum_{k=0}^{\infty} a_{k}(k+r)\,(k+r-1)\, u^{k+r-1}$
- Shift index using $k- >k+1$

  $u \cdot \left(\frac{d^{2}}{du^{2}}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $2a_{0}r(-3+r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(2a_{k+1}(k+1+r)\,(k+r-2) + 4a_{k}(k+r-2)\right) u^{k+r}\right) = 0$

- a_{0}cannot be 0 by assumption, giving the indicial equation

  $2r(-3+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{0, 3\}$
- Each term in the series must be 0, giving the recursion relation

  $2\left(a_{k+1}(k+1+r) + 2a_{k}\right)(k+r-2) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{2a_{k}}{k+1+r}$
- Recursion relation for $r = 0$

  $a_{k+1} = -\frac{2a_{k}}{k+1}$
- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_{k} u^{k}, a_{k+1} = -\frac{2a_{k}}{k+1}\right]$
- Revert the change of variables $u = x + \frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_{k} \left(x+\frac{1}{2}\right)^{k}, a_{k+1} = -\frac{2a_{k}}{k+1}\right]$

- Recursion relation for $r = 3$

  $a_{k+1} = -\frac{2a_k}{k+4}$

- Solution for $r = 3$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+3}, a_{k+1} = -\frac{2a_k}{k+4}\right]$

- Revert the change of variables $u = x + \frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k \left(x+\frac{1}{2}\right)^{k+3}, a_{k+1} = -\frac{2a_k}{k+4}\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k \left(x+\frac{1}{2}\right)^{k}\right) + \left(\sum_{k=0}^{\infty} b_k \left(x+\frac{1}{2}\right)^{k+3}\right), a_{k+1} = -\frac{2a_k}{k+1}, b_{k+1} = -\frac{2b_k}{k+4}\right]$

Maple gives the following as the ode type

`[_Jacobi]`

$$\boxed{(x^2 - x)\, y'' + (2x - 3)\, y' - 2y = 0}$$

20.2.1 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$(x^2 - x)\, y'' + (2x - 3)\, y' - 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = \frac{2x - 3}{x\,(x - 1)}$$
$$q(x) = -\frac{2}{x\,(x - 1)}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n(2x-3)}{x^2\,(x-1)} - \frac{2}{x\,(x-1)} = 0 \tag{5}$$

Solving (5) for n gives

$$n = -2 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(-\frac{4}{x} + \frac{2x-3}{x\,(x-1)}\right) v'(x) &= 0 \\ v''(x) + \frac{(-2x+1)\,v'(x)}{x\,(x-1)} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(-2x+1)\,u(x)}{x\,(x-1)} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{u(2x-1)}{x\,(x-1)} \end{aligned}$$

Where $f(x) = \frac{2x-1}{x(x-1)}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= \frac{2x-1}{x(x-1)}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{2x-1}{x(x-1)}\,dx \\
\ln(u) &= \ln(x(x-1)) + c_1 \\
u &= e^{\ln(x(x-1))+c_1} \\
&= c_1 x(x-1)
\end{aligned}
$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= c_1\left(\frac{1}{3}x^3 - \frac{1}{2}x^2\right) + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\,x^n \\
&= \frac{c_1\left(\frac{1}{3}x^3 - \frac{1}{2}x^2\right) + c_2}{x^2} \\
&= \frac{2c_1x^3 - 3c_1x^2 + 6c_2}{6x^2}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1\left(\frac{1}{3}x^3 - \frac{1}{2}x^2\right) + c_2}{x^2} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1\left(\frac{1}{3}x^3 - \frac{1}{2}x^2\right) + c_2}{x^2}
$$

Verified OK.

20.2.2 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + (2AB' + B^2)\, v' + (AB'' + BB' + CB)\, v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + (2AB' + B^2)\, v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + (2AB' + B^2)\, u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned} A &= x^2 - x \\ B &= 2x - 3 \\ C &= -2 \\ F &= 0 \end{aligned}$$

The above shows that for this ode

$$\begin{aligned} AB'' + BB' + CB &= (x^2 - x)\,(0) + (2x - 3)\,(2) + (-2)\,(2x - 3) \\ &= 0 \end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$2x^3 - 5x^2 + 3xv'' + (8x^2 - 16x + 9)\, v' = 0$$

Now by applying $v' = u$ the above becomes

$$(2x^3 - 5x^2 + 3x)\, u'(x) + 8\left(x^2 - 2x + \frac{9}{8}\right) u(x) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= -\frac{u(8x^2 - 16x + 9)}{x\,(2x^2 - 5x + 3)}
\end{aligned}$$

Where $f(x) = -\frac{8x^2-16x+9}{x(2x^2-5x+3)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\, du &= -\frac{8x^2 - 16x + 9}{x\,(2x^2 - 5x + 3)}\, dx \\
\int \frac{1}{u}\, du &= \int -\frac{8x^2 - 16x + 9}{x\,(2x^2 - 5x + 3)}\, dx \\
\ln(u) &= -2\ln(2x - 3) + \ln(x - 1) - 3\ln(x) + c_1 \\
u &= \mathrm{e}^{-2\ln(2x-3)+\ln(x-1)-3\ln(x)+c_1} \\
&= c_1 \mathrm{e}^{-2\ln(2x-3)+\ln(x-1)-3\ln(x)}
\end{aligned}$$

Which simplifies to

$$u(x) = c_1\left(\frac{1}{(2x-3)^2 x^2} - \frac{1}{(2x-3)^2 x^3}\right)$$

The ode for v now becomes

$$\begin{aligned}
v' &= u \\
&= c_1\left(\frac{1}{(2x-3)^2 x^2} - \frac{1}{(2x-3)^2 x^3}\right)
\end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned}
v(x) &= \int \frac{c_1(x-1)}{(2x-3)^2 x^3}\, \mathrm{d}x \\
&= c_1\left(-\frac{2}{27\,(2x-3)} + \frac{1}{18x^2} + \frac{1}{27x}\right) + c_2
\end{aligned}$$

Therefore the solution is

$$\begin{aligned} y(x) &= Bv \\ &= (2x-3)\left(c_1\left(-\frac{2}{27(2x-3)}+\frac{1}{18x^2}+\frac{1}{27x}\right)+c_2\right) \\ &= \frac{12c_2x^3-18c_2x^2-c_1}{6x^2} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{12c_2x^3-18c_2x^2-c_1}{6x^2} \tag{1}$$

Verification of solutions

$$y = \frac{12c_2x^3-18c_2x^2-c_1}{6x^2}$$

Verified OK.

20.2.3 Solving using Kovacic algorithm

Writing the ode as

$$(x^2-x)\,y''+(2x-3)\,y'-2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2-x \\ B &= 2x-3 \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{8x^2 - 8x + 3}{4\left(x^2 - x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 8x^2 - 8x + 3 \\ t &= 4\left(x^2 - x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{8x^2 - 8x + 3}{4\left(x^2 - x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 640: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4(x-1)^2} + \frac{3}{4x^2} - \frac{1}{2x} + \frac{1}{2x-2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{8x^2 - 8x + 3}{4(x^2 - x)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{8x^2 - 8x + 3}{4\left(x^2 - x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -1$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\ &= -1 - (-1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2x} - \frac{1}{2\left(x - 1\right)} + (-)\left(0\right) \\ &= -\frac{1}{2x} - \frac{1}{2\left(x - 1\right)} \\ &= -\frac{2x - 1}{2x\left(x - 1\right)} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2x} - \frac{1}{2(x-1)}\right)(0) + \left(\left(\frac{1}{2x^2} + \frac{1}{2(x-1)^2}\right) + \left(-\frac{1}{2x} - \frac{1}{2(x-1)}\right)^2 - \left(\frac{8x^2 - 8x + 3}{4(x^2 - x)^2}\right)\right) = 0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= e^{\int \left(-\frac{1}{2x} - \frac{1}{2(x-1)}\right) dx} \\
&= \frac{1}{\sqrt{x}\,\sqrt{x-1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x-3}{x^2-x}\, dx} \\
&= z_1 e^{\frac{\ln(x-1)}{2} - \frac{3\ln(x)}{2}} \\
&= z_1 \left(\frac{\sqrt{x-1}}{x^{\frac{3}{2}}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{x-1}}{\sqrt{x(x-1)}\, x^{\frac{3}{2}}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x-3}{x^2-x}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\ln(x-1)-3\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{1}{3}x^3 - \frac{1}{2}x^2\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\sqrt{x-1}}{\sqrt{x\,(x-1)}\, x^{\frac{3}{2}}}\right) + c_2 \left(\frac{\sqrt{x-1}}{\sqrt{x\,(x-1)}\, x^{\frac{3}{2}}} \left(\frac{1}{3}x^3 - \frac{1}{2}x^2\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1\sqrt{x-1}}{\sqrt{x\,(x-1)}\, x^{\frac{3}{2}}} + \frac{c_2\sqrt{x-1}\,(2x-3)\,\sqrt{x}}{6\sqrt{x\,(x-1)}} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1\sqrt{x-1}}{\sqrt{x\,(x-1)}\, x^{\frac{3}{2}}} + \frac{c_2\sqrt{x-1}\,(2x-3)\,\sqrt{x}}{6\sqrt{x\,(x-1)}}
$$

Verified OK.

20.2.4 Maple step by step solution

Let's solve

$(x^2-x)\, y'' + (2x-3)\, y' - 2y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{2y}{x(x-1)} - \frac{(2x-3)y'}{x(x-1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' + \frac{(2x-3)y'}{x(x-1)} - \frac{2y}{x(x-1)} = 0$

☐ Check to see if x_0 is a regular singular point

- Define functions

  $\left[P_2(x) = \frac{2x-3}{x(x-1)}, P_3(x) = -\frac{2}{x(x-1)}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = 3$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 0$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x(x-1) + (2x-3)\, y' - 2y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$

- Shift index using $k- >k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^m \cdot y''$ to series expansion for $m = 1..2$

  $x^m \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-2+m}$

- Shift index using $k- >k+2-m$

  $x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

$$-a_0 r(2+r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-a_{k+1}(k+1+r)\,(k+3+r) + a_k(k+r+2)\,(k+r-1)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-r(2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-2, 0\}$

- Each term in the series must be 0, giving the recursion relation

  $-a_{k+1}(k+1+r)\,(k+3+r) + a_k(k+r+2)\,(k+r-1) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+r+2)(k+r-1)}{(k+1+r)(k+3+r)}$

- Recursion relation for $r = -2$; series terminates at $k = 3$

  $a_{k+1} = \frac{a_k k(k-3)}{(k-1)(k+1)}$

- Series not valid for $r = -2$, division by 0 in the recursion relation at $k = 1$

  $a_{k+1} = \frac{a_k k(k-3)}{(k-1)(k+1)}$

- Recursion relation for $r = 0$; series terminates at $k = 1$

  $a_{k+1} = \frac{a_k(k+2)(k-1)}{(k+1)(k+3)}$

- Apply recursion relation for $k = 0$

  $a_1 = -\frac{2a_0}{3}$

- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second li

  $y = a_0 \cdot \left(1 - \frac{2x}{3}\right)$

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{(2x^2+3x)\,y''-6y'(x+1)+6y=6}$$

20.3.1 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=2x^2+3x, B=-6x-6, C=6, f(x)=6$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. Solving for y_h from

$$(2x^2+3x)\,y''+(-6x-6)\,y'+6y=0$$

In normal form the ode

$$\left(2x^2+3x\right) y''+(-6x-6)\, y'+6y = 0 \tag{1}$$

Becomes

$$y''+p(x)\, y'+q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{-6x-6}{x\,(2x+3)} \\ q(x) &= \frac{6}{(2x+3)\, x} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x)+\left(\frac{2n}{x}+p\right) v'(x)+\left(\frac{n(n-1)}{x^2}+\frac{np}{x}+q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2}+\frac{np}{x}+q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}+\frac{n(-6x-6)}{x^2\,(2x+3)}+\frac{6}{(2x+3)\, x} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 3 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x)+\left(\frac{6}{x}+\frac{-6x-6}{x\,(2x+3)}\right) v'(x) &= 0 \\ v''(x)+\frac{(6x+12)\, v'(x)}{x\,(2x+3)} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x)+\frac{(6x+12)\,u(x)}{x\,(2x+3)}=0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u)\\
&= f(x)g(u)\\
&= -\frac{6u(2+x)}{x\,(2x+3)}
\end{aligned}$$

Where $f(x)=-\frac{6(2+x)}{x(2x+3)}$ and $g(u)=u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= -\frac{6(2+x)}{x\,(2x+3)}\,dx\\
\int\frac{1}{u}\,du &= \int -\frac{6(2+x)}{x\,(2x+3)}\,dx\\
\ln(u) &= \ln(2x+3)-4\ln(x)+c_1\\
u &= \mathrm{e}^{\ln(2x+3)-4\ln(x)+c_1}\\
&= c_1\mathrm{e}^{\ln(2x+3)-4\ln(x)}
\end{aligned}$$

Which simplifies to

$$u(x)=c_1\left(\frac{2}{x^3}+\frac{3}{x^4}\right)$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x)\\
v(x) &= \int u(x)\,dx+c_2\\
&= c_1\left(-\frac{1}{x^3}-\frac{1}{x^2}\right)+c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\,x^n\\
&= \left(c_1\left(-\frac{1}{x^3}-\frac{1}{x^2}\right)+c_2\right)x^3\\
&= (-x-1)\,c_1+c_2x^3
\end{aligned}$$

Now the particular solution to this ODE is found

$$(2x^2 + 3x)\, y'' + (-6x - 6)\, y' + 6y = 6$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= x^3 \\ y_2 &= -x - 1 \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^3 & -x - 1 \\ \frac{d}{dx}(x^3) & \frac{d}{dx}(-x - 1) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^3 & -x - 1 \\ 3x^2 & -1 \end{vmatrix}$$

Therefore

$$W = (x^3)(-1) - (-x - 1)(3x^2)$$

Which simplifies to

$$W = 2x^3 + 3x^2$$

Which simplifies to

$$W = 2x^3 + 3x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-6x - 6}{(2x^2 + 3x)(2x^3 + 3x^2)}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{-6x - 6}{x^3 (2x + 3)^2} dx$$

Hence

$$u_1 = -\frac{4}{9(2x + 3)} - \frac{1}{3x^2} + \frac{2}{9x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{6x^3}{(2x^2 + 3x)(2x^3 + 3x^2)}\, dx$$

Which simplifies to

$$u_2 = \int \frac{6}{(2x + 3)^2} dx$$

Hence

$$u_2 = -\frac{3}{2x + 3}$$

Which simplifies to

$$u_1 = -\frac{1}{x^2 (2x + 3)}$$

$$u_2 = -\frac{3}{2x + 3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x}{2x+3} - \frac{3(-x-1)}{2x+3}$$

Which simplifies to

$$y_p(x) = 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(c_1\left(-\frac{1}{x^3} - \frac{1}{x^2}\right) + c_2\right) x^3\right) + (1) \\ &= 1 + \left(c_1\left(-\frac{1}{x^3} - \frac{1}{x^2}\right) + c_2\right) x^3 \end{aligned}$$

Which simplifies to

$$y = c_2 x^3 - c_1 x - c_1 + 1$$

Summary

The solution(s) found are the following

$$y = c_2 x^3 - c_1 x - c_1 + 1 \tag{1}$$

Verification of solutions

$$y = c_2 x^3 - c_1 x - c_1 + 1$$

Verified OK.

20.3.2 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$
\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}
$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv = 0 \\
ABv'' + \left(2AB' + B^2\right) v' + (AB'' + BB' + CB)\, v = 0 \qquad (1)
\end{aligned}
$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$
ABv'' + \left(2AB' + B^2\right) v' = 0
$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$
ABu' + \left(2AB' + B^2\right) u = 0
$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= 2x^2 + 3x \\
B &= -6x - 6 \\
C &= 6 \\
F &= 6
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= \left(2x^2 + 3x\right)(0) + (-6x - 6)(-6) + (6)(-6x - 6) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
-12x^3 - 30x^2 - 18xv'' + \left(12x^2 + 36x + 36\right) v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
\left(-12x^3 - 30x^2 - 18x\right) u'(x) + 12\left(x^2 + 3x + 3\right) u(x) = 0
$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= \frac{2u(x^2+3x+3)}{x\left(2x^2+5x+3\right)}
\end{aligned}$$

Where $f(x) = \frac{2x^2+6x+6}{x(2x^2+5x+3)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= \frac{2x^2+6x+6}{x\left(2x^2+5x+3\right)}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{2x^2+6x+6}{x\left(2x^2+5x+3\right)}\,dx \\
\ln\left(u\right) &= -2\ln\left(x+1\right)+\ln\left(2x+3\right)+2\ln\left(x\right)+c_1 \\
u &= \mathrm{e}^{-2\ln(x+1)+\ln(2x+3)+2\ln(x)+c_1} \\
&= c_1\mathrm{e}^{-2\ln(x+1)+\ln(2x+3)+2\ln(x)}
\end{aligned}$$

Which simplifies to

$$u(x) = c_1\left(\frac{2x^3}{\left(x+1\right)^2}+\frac{3x^2}{\left(x+1\right)^2}\right)$$

The ode for v now becomes

$$\begin{aligned}
v' &= u \\
&= c_1\left(\frac{2x^3}{\left(x+1\right)^2}+\frac{3x^2}{\left(x+1\right)^2}\right)
\end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned}
v(x) &= \int \frac{c_1x^2(2x+3)}{\left(x+1\right)^2}\,\mathrm{d}x \\
&= c_1\left(x^2-x-\frac{1}{x+1}\right)+c_2
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= Bv \\
&= (-6x-6)\left(c_1\left(x^2-x-\frac{1}{x+1}\right)+c_2\right) \\
&= \left(-6x^3+6x+6\right)c_1-6c_2(x+1)
\end{aligned}$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = -6x - 6$$
$$y_2 = -6x^3 + 6x + 6$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} -6x - 6 & -6x^3 + 6x + 6 \\ \frac{d}{dx}(-6x - 6) & \frac{d}{dx}(-6x^3 + 6x + 6) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} -6x - 6 & -6x^3 + 6x + 6 \\ -6 & -18x^2 + 6 \end{vmatrix}$$

Therefore

$$W = (-6x - 6)\left(-18x^2 + 6\right) - \left(-6x^3 + 6x + 6\right)(-6)$$

Which simplifies to

$$W = 72x^3 + 108x^2$$

Which simplifies to

$$W = 72x^3 + 108x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-36x^3 + 36x + 36}{(2x^2 + 3x)(72x^3 + 108x^2)} dx$$

Which simplifies to

$$u_1 = -\int \frac{-x^3 + x + 1}{x^3 (2x + 3)^2} dx$$

Hence

$$u_1 = -\frac{23}{54 (2x + 3)} + \frac{1}{18x^2} - \frac{1}{27x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{-36x - 36}{(2x^2 + 3x)(72x^3 + 108x^2)} dx$$

Which simplifies to

$$u_2 = \int \frac{-x - 1}{x^3 (2x + 3)^2} dx$$

Hence

$$u_2 = \frac{2}{27 (2x + 3)} + \frac{1}{18x^2} - \frac{1}{27x}$$

Which simplifies to

$$u_1 = \frac{-3x^2 + 1}{12x^3 + 18x^2}$$
$$u_2 = \frac{1}{12x^3 + 18x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{(-3x^2 + 1)(-6x - 6)}{12x^3 + 18x^2} + \frac{-6x^3 + 6x + 6}{12x^3 + 18x^2}$$

Which simplifies to

$$y_p(x) = 1$$

Hence the complete solution is

$$\begin{aligned}y(x) &= y_h + y_p \\ &= \left(\left(-6x^3 + 6x + 6\right) c_1 - 6c_2(x+1)\right) + (1) \\ &= \left(-6x^3 + 6x + 6\right) c_1 - 6c_2 x - 6c_2 + 1\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(-6x^3 + 6x + 6\right) c_1 - 6c_2 x - 6c_2 + 1 \tag{1}$$

Verification of solutions

$$y = \left(-6x^3 + 6x + 6\right) c_1 - 6c_2 x - 6c_2 + 1$$

Verified OK.

20.3.3 Solving using Kovacic algorithm

Writing the ode as

$$\left(2x^2 + 3x\right) y'' + (-6x - 6) y' + 6y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A &= 2x^2 + 3x \\ B &= -6x - 6 \\ C &= 6\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3x^2 + 12x + 18}{(2x^2 + 3x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3x^2 + 12x + 18 \\ t &= (2x^2 + 3x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3x^2 + 12x + 18}{(2x^2 + 3x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 642: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x^2 + 3x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{3}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4\left(x + \frac{3}{2}\right)^2} + \frac{4}{3\left(x + \frac{3}{2}\right)} + \frac{2}{x^2} - \frac{4}{3x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1
\end{aligned}$$

For the pole at $x = -\frac{3}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{3}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3x^2 + 12x + 18}{(2x^2 + 3x)^2}$$

Since the gcd$(s,t)=1$. This gives $b=\frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b} = \frac{3}{2}\\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{3x^2+12x+18}{(2x^2+3x)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1
$-\frac{3}{2}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+=\frac{3}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right)\\
&= \frac{3}{2} - \left(\frac{3}{2}\right)\\
&= 0
\end{aligned}
$$

Since d an integer and $d\ge 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{2}{x} - \frac{1}{2\left(x+\frac{3}{2}\right)} + (0) \\
&= \frac{2}{x} - \frac{1}{2\left(x+\frac{3}{2}\right)} \\
&= \frac{3x+6}{x(2x+3)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{2}{x} - \frac{1}{2\left(x+\frac{3}{2}\right)}\right)(0) + \left(\left(-\frac{2}{x^2} + \frac{1}{2\left(x+\frac{3}{2}\right)^2}\right) + \left(\frac{2}{x} - \frac{1}{2\left(x+\frac{3}{2}\right)}\right)^2 - \left(\frac{3x^2+12x+18}{\left(2x^2+3x\right)^2}\right)\right) = 0 = 0
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{2}{x} - \frac{1}{2\left(x+\frac{3}{2}\right)}\right) dx} \\
&= \frac{x^2}{\sqrt{2x+3}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-6x-6}{2x^2+3x} \, dx} \\
&= z_1 e^{\frac{\ln(2x+3)}{2} + \ln(x)} \\
&= z_1 \left(\sqrt{2x+3}\, x\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = x^3$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-6x-6}{2x^2+3x} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{\ln(2x+3)+2\ln(x)}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{-x-1}{x^3} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 (x^3) + c_2 \left(x^3 \left(\frac{-x-1}{x^3} \right) \right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$\left(2x^2 + 3x\right) y'' + (-6x - 6)\, y' + 6y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 x^3 + c_2(-x - 1)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= x^3 \\ y_2 &= -x - 1 \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^3 & -x - 1 \\ \frac{d}{dx}(x^3) & \frac{d}{dx}(-x - 1) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^3 & -x - 1 \\ 3x^2 & -1 \end{vmatrix}$$

Therefore

$$W = (x^3)(-1) - (-x - 1)(3x^2)$$

Which simplifies to

$$W = 2x^3 + 3x^2$$

Which simplifies to

$$W = 2x^3 + 3x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-6x-6}{(2x^2+3x)(2x^3+3x^2)}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{-6x-6}{x^3 (2x+3)^2} dx$$

Hence

$$u_1 = -\frac{4}{9(2x+3)} - \frac{1}{3x^2} + \frac{2}{9x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{6x^3}{(2x^2+3x)(2x^3+3x^2)}\, dx$$

Which simplifies to

$$u_2 = \int \frac{6}{(2x+3)^2} dx$$

Hence

$$u_2 = -\frac{3}{2x+3}$$

Which simplifies to

$$u_1 = -\frac{1}{x^2(2x+3)}$$

$$u_2 = -\frac{3}{2x+3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x}{2x+3} - \frac{3(-x-1)}{2x+3}$$

Which simplifies to

$$y_p(x) = 1$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 x^3 + c_2(-x-1)\right) + (1)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 x^3 + c_2(-x-1) + 1 \tag{1}
$$

Verification of solutions

$$
y = c_1 x^3 + c_2(-x-1) + 1
$$

Verified OK.

ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_change_of_variable_on_y_method_2", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2(\ln(x)-1)\,y''-xy'+y=0}$$

Given that one solution of the ode is

$$y_1=x$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x)=y_1\left(\int\frac{\mathrm{e}^{-\left(\int p dx\right)}}{y_1^2}dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y''+p(x)\,y'+q(x)\,y=f(x)$$

Looking at the ode to solve shows that

$$p(x)=-\frac{1}{x\,(\ln(x)-1)}$$

Therefore

$$y_2(x) = x\left(\int \frac{e^{-\left(\int -\frac{1}{x(\ln(x)-1)}dx\right)}}{x^2}dx\right)$$

$$y_2(x) = x\int \frac{\ln(x)-1}{x^2}, dx$$

$$y_2(x) = x\left(\int \frac{\ln(x)-1}{x^2}dx\right)$$

$$y_2(x) = -\ln(x)$$

Hence the solution is

$$\begin{aligned} y &= c_1y_1(x) + c_2y_2(x) \\ &= c_1x - c_2\ln(x) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1x - c_2\ln(x) \tag{1}$$

Verification of solutions

$$y = c_1x - c_2\ln(x)$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.5 Linear equations with variable coefficients. The Lagrange method. Exercises page 148
Problem number: 640.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_change_of_variable_on_x_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + (\tan(x) - 2\cot(x))\, y' + 2\cot(x)^2\, y = 0}$$

Given that one solution of the ode is

$$y_1 = \sin(x)$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{\mathrm{e}^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \tan(x) - 2\cot(x)$$

Therefore

$$y_2(x) = \sin(x)\left(\int \frac{e^{-\left(\int (\tan(x)-2\cot(x))dx\right)}}{\sin(x)^2} dx\right)$$

$$y_2(x) = \sin(x)\int \frac{e^{2\ln(\sin(x))+\ln(\cos(x))}}{\sin(x)^2}, dx$$

$$y_2(x) = \sin(x)\left(\int \csc(x)^2 \sin(x)^2 \cos(x)\, dx\right)$$

$$y_2(x) = \sin(x)^2$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= \sin(x)\, c_1 + c_2 \sin(x)^2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \sin(x)\, c_1 + c_2 \sin(x)^2 \tag{1}$$

Verification of solutions

$$y = \sin(x)\, c_1 + c_2 \sin(x)^2$$

Verified OK.

ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + y' \tan(x) + \cos(x)^2 y = 0}$$

Given that one solution of the ode is

$$y_1 = \cos(\sin(x))$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \tan(x)$$

Therefore

$$y_2(x) = \cos(\sin(x)) \left(\int \frac{e^{-\left(\int \tan(x)dx\right)}}{\cos(\sin(x))^2} dx\right)$$

$$y_2(x) = \cos(\sin(x)) \int \frac{\cos(x)}{\cos(\sin(x))^2}, dx$$

$$y_2(x) = \cos(\sin(x)) \left(\int \sec(\sin(x))^2 \cos(x)\, dx\right)$$

$$y_2(x) = \cos(\sin(x)) \tan(\sin(x))$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= \cos(\sin(x))\, c_1 + c_2 \cos(\sin(x)) \tan(\sin(x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \cos(\sin(x))\, c_1 + c_2 \cos(\sin(x)) \tan(\sin(x)) \tag{1}$$

Verification of solutions

$$y = \cos(\sin(x))\, c_1 + c_2 \cos(\sin(x)) \tan(\sin(x))$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _nonhomogeneous]]
```

$$\boxed{(x^2+1)\,y''+xy'-y=1}$$

Given that one solution of the ode is

$$y_1 = x$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=x^2+1, B=x, C=-1, f(x)=1$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$(x^2+1)\,y''+xy'-y=0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-\left(\int p dx\right)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x) y' + q(x) y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{x}{x^2 + 1}$$

Therefore

$$y_2(x) = x \left(\int \frac{e^{-\left(\int \frac{x}{x^2+1} dx\right)}}{x^2} dx \right)$$

$$y_2(x) = x \int \frac{\frac{1}{\sqrt{x^2+1}}}{x^2}, dx$$

$$y_2(x) = x \left(\int \frac{1}{\sqrt{x^2+1}\, x^2} dx \right)$$

$$y_2(x) = -\sqrt{x^2+1}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x - c_2 \sqrt{x^2+1} \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 x - c_2 \sqrt{x^2+1}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = -\sqrt{x^2+1}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & -\sqrt{x^2+1} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(-\sqrt{x^2+1}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & -\sqrt{x^2+1} \\ 1 & -\frac{x}{\sqrt{x^2+1}} \end{vmatrix}$$

Therefore

$$W = (x)\left(-\frac{x}{\sqrt{x^2+1}}\right) - \left(-\sqrt{x^2+1}\right)(1)$$

Which simplifies to

$$W = \frac{1}{\sqrt{x^2+1}}$$

Which simplifies to

$$W = \frac{1}{\sqrt{x^2+1}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\sqrt{x^2+1}}{\sqrt{x^2+1}}\,dx$$

Which simplifies to

$$u_1 = -\int (-1)\,dx$$

Hence

$$u_1 = x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x}{\sqrt{x^2+1}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{x}{\sqrt{x^2+1}}dx$$

Hence

$$u_2 = \sqrt{x^2+1}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x - c_2\sqrt{x^2+1}\right) + (-1) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x - c_2\sqrt{x^2+1} - 1 \tag{1}$$

Verification of solutions

$$y = c_1 x - c_2\sqrt{x^2+1} - 1$$

Verified OK.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_euler_ode", "exact linear second order ode", "second_order_integrable_as_is", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _nonhomogeneous]]
```

$$\boxed{x^2y'' - xy' - 3y = 5x^4}$$

Given that one solution of the ode is

$$y_1 = \frac{1}{x}$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -x, C = -3, f(x) = 5x^4$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - xy' - 3y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x) y' + q(x) y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = -\frac{1}{x}$$

Therefore

$$y_2(x) = \frac{\int e^{-(\int -\frac{1}{x} dx)} x^2 dx}{x}$$

$$y_2(x) = \frac{1}{x} \int \frac{x}{\frac{1}{x^2}}, dx$$

$$y_2(x) = \frac{\int x^3 dx}{x}$$

$$y_2(x) = \frac{x^3}{4}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= \frac{c_1}{x} + \frac{c_2 x^3}{4} \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1}{x} + \frac{c_2 x^3}{4}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$

$$y_2 = \frac{x^3}{4}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x^3}{4} \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(\frac{x^3}{4}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x^3}{4} \\ -\frac{1}{x^2} & \frac{3x^2}{4} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)\left(\frac{3x^2}{4}\right) - \left(\frac{x^3}{4}\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = x$$

Which simplifies to

$$W = x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{5x^7}{4}}{x^3}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{5x^4}{4}dx$$

Hence

$$u_1 = -\frac{x^5}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{5x^3}{x^3}\,dx$$

Which simplifies to

$$u_2 = \int 5dx$$

Hence

$$u_2 = 5x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x^4$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x} + \frac{c_2 x^3}{4}\right) + (x^4) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x} + \frac{c_2 x^3}{4} + x^4 \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x} + \frac{c_2 x^3}{4} + x^4$$

Verified OK.

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_change_of_variable_on_y_method_2", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x-1)\,y''-xy'+y=(x-1)^2\,\mathrm{e}^{x}}$$

Given that one solution of the ode is

$$y_1=\mathrm{e}^{x}$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=x-1, B=-x, C=1, f(x)=(x-1)^2\,\mathrm{e}^{x}$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$(x-1)\,y''-xy'+y=0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{e^{-\left(\int p dx\right)}}{y_1^2}dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\,y' + q(x)\,y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = -\frac{x}{x-1}$$

Therefore

$$y_2(x) = e^x\left(\int e^{-\left(\int -\frac{x}{x-1}dx\right)}e^{-2x}dx\right)$$

$$y_2(x) = e^x\int \frac{e^{x+\ln(x-1)}}{e^{2x}}, dx$$

$$y_2(x) = e^x\left(\int e^{-x}(x-1)\,dx\right)$$

$$y_2(x) = -e^x x\,e^{-x}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= e^x c_1 - c_2 e^x x\,e^{-x} \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = e^x c_1 - c_2 e^x x\,e^{-x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^x$$
$$y_2 = -e^x x\, e^{-x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x & -e^x x\, e^{-x} \\ \frac{d}{dx}(e^x) & \frac{d}{dx}(-e^x x\, e^{-x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^x & -e^x x\, e^{-x} \\ e^x & -e^{-x} e^x \end{vmatrix}$$

Therefore

$$W = (e^x)\left(-e^{-x} e^x\right) - \left(-e^x x\, e^{-x}\right)(e^x)$$

Which simplifies to

$$W = -e^{-x} e^{2x} + e^{2x} x\, e^{-x}$$

Which simplifies to

$$W = (x-1)\, e^x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-e^{2x} x\, e^{-x} (x-1)^2}{(x-1)^2 e^x}\, dx$$

Which simplifies to

$$u_1 = -\int -x dx$$

Hence

$$u_1 = \frac{x^2}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x-1)^2 \, e^{2x}}{(x-1)^2 \, e^{x}} \, dx$$

Which simplifies to

$$u_2 = \int e^{x} dx$$

Hence

$$u_2 = e^{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{e^{x} x^2}{2} - e^{2x} x \, e^{-x}$$

Which simplifies to

$$y_p(x) = \frac{e^{x} x(x-2)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{x} c_1 - c_2 e^{x} x \, e^{-x}\right) + \left(\frac{e^{x} x(x-2)}{2}\right) \end{aligned}$$

Which simplifies to

$$y = e^{x} c_1 - c_2 x + \frac{e^{x} x(x-2)}{2}$$

Summary
The solution(s) found are the following

$$y = e^{x} c_1 - c_2 x + \frac{e^{x} x(x-2)}{2} \tag{1}$$

Verification of solutions

$$y = e^x c_1 - c_2 x + \frac{e^x x(x-2)}{2}$$

Verified OK.

Problem number: 645.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_bessel_ode_form_A", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y' + \mathrm{e}^{-2x}y = \mathrm{e}^{-3x}}$$

Given that one solution of the ode is

$$y_1 = \cos\left(\mathrm{e}^{-x}\right)$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = \mathrm{e}^{-2x}, f(x) = \mathrm{e}^{-3x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' + \mathrm{e}^{-2x}y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-\left(\int p dx\right)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = 1$$

Therefore

$$y_2(x) = \cos\left(e^{-x}\right) \left(\int \frac{e^{-\left(\int 1 dx\right)}}{\cos\left(e^{-x}\right)^2} dx \right)$$

$$y_2(x) = \cos\left(e^{-x}\right) \int \frac{e^{-x}}{\cos\left(e^{-x}\right)^2}, dx$$

$$y_2(x) = \cos\left(e^{-x}\right) \left(\int \sec\left(e^{-x}\right)^2 e^{-x} dx \right)$$

$$y_2(x) = -\cos\left(e^{-x}\right) \tan\left(e^{-x}\right)$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= \cos\left(e^{-x}\right) c_1 - c_2 \cos\left(e^{-x}\right) \tan\left(e^{-x}\right) \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = \cos\left(e^{-x}\right) c_1 - c_2 \cos\left(e^{-x}\right) \tan\left(e^{-x}\right)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \cos\left(\mathrm{e}^{-x}\right) \\
y_2 &= -\cos\left(\mathrm{e}^{-x}\right)\tan\left(\mathrm{e}^{-x}\right)
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix} \cos\left(\mathrm{e}^{-x}\right) & -\cos\left(\mathrm{e}^{-x}\right)\tan\left(\mathrm{e}^{-x}\right) \\ \frac{d}{dx}\left(\cos\left(\mathrm{e}^{-x}\right)\right) & \frac{d}{dx}\left(-\cos\left(\mathrm{e}^{-x}\right)\tan\left(\mathrm{e}^{-x}\right)\right) \end{vmatrix}
$$

Which gives

$$
W = \begin{vmatrix} \cos\left(\mathrm{e}^{-x}\right) & -\cos\left(\mathrm{e}^{-x}\right)\tan\left(\mathrm{e}^{-x}\right) \\ \mathrm{e}^{-x}\sin\left(\mathrm{e}^{-x}\right) & -\mathrm{e}^{-x}\sin\left(\mathrm{e}^{-x}\right)\tan\left(\mathrm{e}^{-x}\right) + \cos\left(\mathrm{e}^{-x}\right)\mathrm{e}^{-x}\left(1+\tan\left(\mathrm{e}^{-x}\right)^2\right) \end{vmatrix}
$$

Therefore

$$
\begin{aligned}
W = {} & \left(\cos\left(\mathrm{e}^{-x}\right)\right)\left(-\mathrm{e}^{-x}\sin\left(\mathrm{e}^{-x}\right)\tan\left(\mathrm{e}^{-x}\right) + \cos\left(\mathrm{e}^{-x}\right)\mathrm{e}^{-x}\left(1+\tan\left(\mathrm{e}^{-x}\right)^2\right)\right) \\
& - \left(-\cos\left(\mathrm{e}^{-x}\right)\tan\left(\mathrm{e}^{-x}\right)\right)\left(\mathrm{e}^{-x}\sin\left(\mathrm{e}^{-x}\right)\right)
\end{aligned}
$$

Which simplifies to

$$
W = \cos\left(\mathrm{e}^{-x}\right)^2\tan\left(\mathrm{e}^{-x}\right)^2\mathrm{e}^{-x} + \cos\left(\mathrm{e}^{-x}\right)^2\mathrm{e}^{-x}
$$

Which simplifies to

$$
W = \mathrm{e}^{-x}
$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\cos\left(\mathrm{e}^{-x}\right)\tan\left(\mathrm{e}^{-x}\right)\mathrm{e}^{-3x}}{\mathrm{e}^{-x}}\, dx$$

Which simplifies to

$$u_1 = -\int -\sin\left(\mathrm{e}^{-x}\right)\mathrm{e}^{-2x} dx$$

Hence

$$u_1 = -\frac{\mathrm{e}^{-x}\tan\left(\frac{\mathrm{e}^{-x}}{2}\right)^2 - \mathrm{e}^{-x} + 2\tan\left(\frac{\mathrm{e}^{-x}}{2}\right)}{1+\tan\left(\frac{\mathrm{e}^{-x}}{2}\right)^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos\left(\mathrm{e}^{-x}\right)\mathrm{e}^{-3x}}{\mathrm{e}^{-x}}\, dx$$

Which simplifies to

$$u_2 = \int \cos\left(\mathrm{e}^{-x}\right)\mathrm{e}^{-2x} dx$$

Hence

$$u_2 = \frac{-2\,\mathrm{e}^{-x}\tan\left(\frac{\mathrm{e}^{-x}}{2}\right) - 2}{1+\tan\left(\frac{\mathrm{e}^{-x}}{2}\right)^2}$$

Which simplifies to

$$u_1 = \mathrm{e}^{-x}\cos\left(\mathrm{e}^{-x}\right) - \sin\left(\mathrm{e}^{-x}\right)$$
$$u_2 = -\mathrm{e}^{-x}\sin\left(\mathrm{e}^{-x}\right) - \cos\left(\mathrm{e}^{-x}\right) - 1$$

Therefore the particular solution, from equation (1) is

$$\begin{aligned} y_p(x) = {} & \left(\mathrm{e}^{-x}\cos\left(\mathrm{e}^{-x}\right) - \sin\left(\mathrm{e}^{-x}\right)\right)\cos\left(\mathrm{e}^{-x}\right) \\ & - \left(-\mathrm{e}^{-x}\sin\left(\mathrm{e}^{-x}\right) - \cos\left(\mathrm{e}^{-x}\right) - 1\right)\cos\left(\mathrm{e}^{-x}\right)\tan\left(\mathrm{e}^{-x}\right) \end{aligned}$$

Which simplifies to

$$y_p(x) = \mathrm{e}^{-x} + \sin\left(\mathrm{e}^{-x}\right)$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\cos\left(\mathrm{e}^{-x}\right) c_1 - c_2 \cos\left(\mathrm{e}^{-x}\right) \tan\left(\mathrm{e}^{-x}\right)\right) + \left(\mathrm{e}^{-x} + \sin\left(\mathrm{e}^{-x}\right)\right)
\end{aligned}
$$

Which simplifies to

$$
y = \cos\left(\mathrm{e}^{-x}\right) c_1 - c_2 \sin\left(\mathrm{e}^{-x}\right) + \mathrm{e}^{-x} + \sin\left(\mathrm{e}^{-x}\right)
$$

Summary

The solution(s) found are the following

$$
y = \cos\left(\mathrm{e}^{-x}\right) c_1 - c_2 \sin\left(\mathrm{e}^{-x}\right) + \mathrm{e}^{-x} + \sin\left(\mathrm{e}^{-x}\right) \tag{1}
$$

Verification of solutions

$$
y = \cos\left(\mathrm{e}^{-x}\right) c_1 - c_2 \sin\left(\mathrm{e}^{-x}\right) + \mathrm{e}^{-x} + \sin\left(\mathrm{e}^{-x}\right)
$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{\left(x^{4}-x^{3}\right) y''+\left(2x^{3}-2x^{2}-x\right) y'-y=\frac{\left(x-1\right)^{2}}{x}}$$

Given that one solution of the ode is

$$y_1=\frac{1}{x}$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=x^4-x^3, B=2x^3-2x^2-x, C=-1, f(x)=\frac{(x-1)^2}{x}$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$\left(x^{4}-x^{3}\right) y''+\left(2x^{3}-2x^{2}-x\right) y'-y=0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x) y' + q(x) y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{2x^3 - 2x^2 - x}{x^4 - x^3}$$

Therefore

$$y_2(x) = \frac{\int e^{-\left(\int \frac{2x^3-2x^2-x}{x^4-x^3} dx\right)} x^2 dx}{x}$$

$$y_2(x) = \frac{1}{x} \int \frac{e^{\ln(x-1)+\frac{1}{x}-3\ln(x)}}{\frac{1}{x^2}}, dx$$

$$y_2(x) = \frac{\int \frac{(x-1)e^{\frac{1}{x}}}{x} dx}{x}$$

$$y_2(x) = e^{\frac{1}{x}}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= \frac{c_1}{x} + c_2 e^{\frac{1}{x}} \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1}{x} + c_2 e^{\frac{1}{x}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$

$$y_2 = e^{\frac{1}{x}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & e^{\frac{1}{x}} \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(e^{\frac{1}{x}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & e^{\frac{1}{x}} \\ -\frac{1}{x^2} & -\frac{e^{\frac{1}{x}}}{x^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)\left(-\frac{e^{\frac{1}{x}}}{x^2}\right) - \left(e^{\frac{1}{x}}\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = \frac{(x-1)\,e^{\frac{1}{x}}}{x^3}$$

Which simplifies to

$$W = \frac{(x-1)\,e^{\frac{1}{x}}}{x^3}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{e^{\frac{1}{x}}(x-1)^2}{x}}{\frac{(x^4-x^3)(x-1)e^{\frac{1}{x}}}{x^3}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{1}{x}dx$$

Hence

$$u_1 = -\ln(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{(x-1)^2}{x^2}}{\frac{(x^4-x^3)(x-1)e^{\frac{1}{x}}}{x^3}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{e^{-\frac{1}{x}}}{x^2}dx$$

Hence

$$u_2 = e^{-\frac{1}{x}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\ln(x)}{x} + e^{-\frac{1}{x}}e^{\frac{1}{x}}$$

Which simplifies to

$$y_p(x) = \frac{-\ln(x) + x}{x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x} + c_2 e^{\frac{1}{x}}\right) + \left(\frac{-\ln(x) + x}{x}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1}{x} + c_2 e^{\frac{1}{x}} + \frac{-\ln(x) + x}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x} + c_2 e^{\frac{1}{x}} + \frac{-\ln(x) + x}{x}$$

Verified OK.

Problem number: 647.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_bessel_ode_form_A", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - y' + e^{2x} y = x\, e^{2x} - 1}$$

Given that one solution of the ode is

$$y_1 = \sin(e^x)$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -1, C = e^{2x}, f(x) = x\, e^{2x} - 1$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' + e^{2x} y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x) y' + q(x) y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = -1$$

Therefore

$$y_2(x) = \sin(e^x) \left(\int \frac{e^{-(\int (-1) dx)}}{\sin(e^x)^2} dx \right)$$

$$y_2(x) = \sin(e^x) \int \frac{e^x}{\sin(e^x)^2}, dx$$

$$y_2(x) = \sin(e^x) \left(\int \csc(e^x)^2 e^x dx \right)$$

$$y_2(x) = -\sin(e^x) \cot(e^x)$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= \sin(e^x) c_1 - c_2 \sin(e^x) \cot(e^x) \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = \sin(e^x) c_1 - c_2 \sin(e^x) \cot(e^x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sin(e^x)$$
$$y_2 = -\sin(e^x)\cot(e^x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sin(e^x) & -\sin(e^x)\cot(e^x) \\ \frac{d}{dx}(\sin(e^x)) & \frac{d}{dx}(-\sin(e^x)\cot(e^x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sin(e^x) & -\sin(e^x)\cot(e^x) \\ e^x\cos(e^x) & -e^x\cos(e^x)\cot(e^x) - \sin(e^x)e^x(-1-\cot(e^x)^2) \end{vmatrix}$$

Therefore

$$W = (\sin(e^x))\left(-e^x\cos(e^x)\cot(e^x) - \sin(e^x)e^x(-1-\cot(e^x)^2)\right) - (-\sin(e^x)\cot(e^x))(e^x\cos(e^x))$$

Which simplifies to

$$W = \cot(e^x)^2\sin(e^x)^2 e^x + \sin(e^x)^2 e^x$$

Which simplifies to

$$W = e^x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\sin\left(e^{x}\right) \cot\left(e^{x}\right) \left(x\,e^{2x}-1\right)}{e^{x}}\,dx$$

Which simplifies to

$$u_1 = -\int -\cos\left(e^{x}\right) \left(x\,e^{x}-e^{-x}\right) dx$$

Hence

$$u_1 = -\frac{\left(-1+\tan\left(\frac{e^{x}}{2}\right)^{2}-2\,e^{x} x \tan\left(\frac{e^{x}}{2}\right)\right) e^{-x}}{1+\tan\left(\frac{e^{x}}{2}\right)^{2}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sin\left(e^{x}\right) \left(x\,e^{2x}-1\right)}{e^{x}}\,dx$$

Which simplifies to

$$u_2 = \int \sin\left(e^{x}\right) \left(x\,e^{x}-e^{-x}\right) dx$$

Hence

$$u_2 = \frac{\left(e^{x} x \tan\left(\frac{e^{x}}{2}\right)^{2}-x\,e^{x}+2\tan\left(\frac{e^{x}}{2}\right)\right) e^{-x}}{1+\tan\left(\frac{e^{x}}{2}\right)^{2}}$$

Which simplifies to

$$u_1 = x\sin\left(e^{x}\right)+\cos\left(e^{x}\right) e^{-x}$$
$$u_2 = -x\cos\left(e^{x}\right)+\sin\left(e^{x}\right) e^{-x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(x\sin\left(e^{x}\right)+\cos\left(e^{x}\right) e^{-x}\right) \sin\left(e^{x}\right)-\left(-x\cos\left(e^{x}\right)+\sin\left(e^{x}\right) e^{-x}\right) \sin\left(e^{x}\right) \cot\left(e^{x}\right)$$

Which simplifies to

$$y_p(x) = x$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (\sin(e^x) c_1 - c_2 \sin(e^x) \cot(e^x)) + (x)
\end{aligned}
$$

Which simplifies to

$$y = \sin(e^x) c_1 - c_2 \cos(e^x) + x$$

Summary

The solution(s) found are the following

$$y = \sin(e^x) c_1 - c_2 \cos(e^x) + x \tag{1}$$

Verification of solutions

$$y = \sin(e^x) c_1 - c_2 \cos(e^x) + x$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x(x-1)\, y''-(2x-1)\, y'+2y=(2x-3)\, x^{2}}$$

Given that one solution of the ode is

$$y_1 = x^2$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2 - x, B = -2x + 1, C = 2, f(x) = 2x^3 - 3x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$\left(x^{2}-x\right) y''+\left(-2x+1\right) y'+2y=0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-\left(\int p dx\right)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x) y' + q(x) y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{-2x + 1}{x^2 - x}$$

Therefore

$$y_2(x) = x^2 \left(\int \frac{e^{-\left(\int \frac{-2x+1}{x^2-x} dx\right)}}{x^4} dx \right)$$

$$y_2(x) = x^2 \int \frac{x(x-1)}{x^4}, dx$$

$$y_2(x) = x^2 \left(\int \frac{x-1}{x^3} dx \right)$$

$$y_2(x) = x^2 \left(\frac{1}{2x^2} - \frac{1}{x} \right)$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^2 + c_2 x^2 \left(\frac{1}{2x^2} - \frac{1}{x} \right) \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 x^2 + c_2 x^2 \left(\frac{1}{2x^2} - \frac{1}{x} \right)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= x^2 \\ y_2 &= x^2\left(\frac{1}{2x^2} - \frac{1}{x}\right) \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & x^2\left(\frac{1}{2x^2} - \frac{1}{x}\right) \\ \frac{d}{dx}(x^2) & \frac{d}{dx}\left(x^2\left(\frac{1}{2x^2} - \frac{1}{x}\right)\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & x^2\left(\frac{1}{2x^2} - \frac{1}{x}\right) \\ 2x & 2x\left(\frac{1}{2x^2} - \frac{1}{x}\right) + x^2\left(-\frac{1}{x^3} + \frac{1}{x^2}\right) \end{vmatrix}$$

Therefore

$$W = (x^2)\left(2x\left(\frac{1}{2x^2} - \frac{1}{x}\right) + x^2\left(-\frac{1}{x^3} + \frac{1}{x^2}\right)\right) - \left(x^2\left(\frac{1}{2x^2} - \frac{1}{x}\right)\right)(2x)$$

Which simplifies to

$$W = x(x - 1)$$

Which simplifies to

$$W = x(x-1)$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^2 \left(\frac{1}{2x^2} - \frac{1}{x}\right)(2x^3 - 3x^2)}{(x^2 - x)\, x\,(x-1)}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{-4x^2 + 8x - 3}{2\,(x-1)^2} dx$$

Hence

$$u_1 = 2x + \frac{1}{2x-2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2(2x^3 - 3x^2)}{(x^2 - x)\, x\,(x-1)}\, dx$$

Which simplifies to

$$u_2 = \int \frac{x^2(2x-3)}{(x-1)^2} dx$$

Hence

$$u_2 = x^2 + x + \frac{1}{x-1}$$

Which simplifies to

$$u_1 = 2x + \frac{1}{2x-2}$$
$$u_2 = x^2 + x + \frac{1}{x-1}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(2x + \frac{1}{2x-2}\right) x^2 + \left(x^2 + x + \frac{1}{x-1}\right) x^2 \left(\frac{1}{2x^2} - \frac{1}{x}\right)$$

Which simplifies to

$$y_p(x) = x^3 - \frac{1}{2}x^2 + x - \frac{1}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x^2 + c_2 x^2 \left(\frac{1}{2x^2} - \frac{1}{x}\right)\right) + \left(x^3 - \frac{1}{2}x^2 + x - \frac{1}{2}\right) \end{aligned}$$

Which simplifies to

$$y = c_1 x^2 - c_2 x + \frac{1}{2}c_2 + x^3 - \frac{1}{2}x^2 + x - \frac{1}{2}$$

Summary

The solution(s) found are the following

$$y = c_1 x^2 - c_2 x + \frac{1}{2}c_2 + x^3 - \frac{1}{2}x^2 + x - \frac{1}{2} \tag{1}$$

Verification of solutions

$$y = c_1 x^2 - c_2 x + \frac{1}{2}c_2 + x^3 - \frac{1}{2}x^2 + x - \frac{1}{2}$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = \frac{1}{\sin(x)}}$$

20.14.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = \csc(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\csc(x)}{1}\,dx$$

Which simplifies to

$$u_1 = -\int 1dx$$

Hence

$$u_1 = -x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\csc(x)}{1}\,dx$$

Which simplifies to

$$u_2 = \int \cot(x)\,dx$$

Hence

$$u_2 = \ln(\sin(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\cos(x)\,x + \ln(\sin(x))\sin(x)$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + (-\cos(x)\, x + \ln(\sin(x)) \sin(x))
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(x) + c_2 \sin(x) - \cos(x)\, x + \ln(\sin(x)) \sin(x) \tag{1}
$$

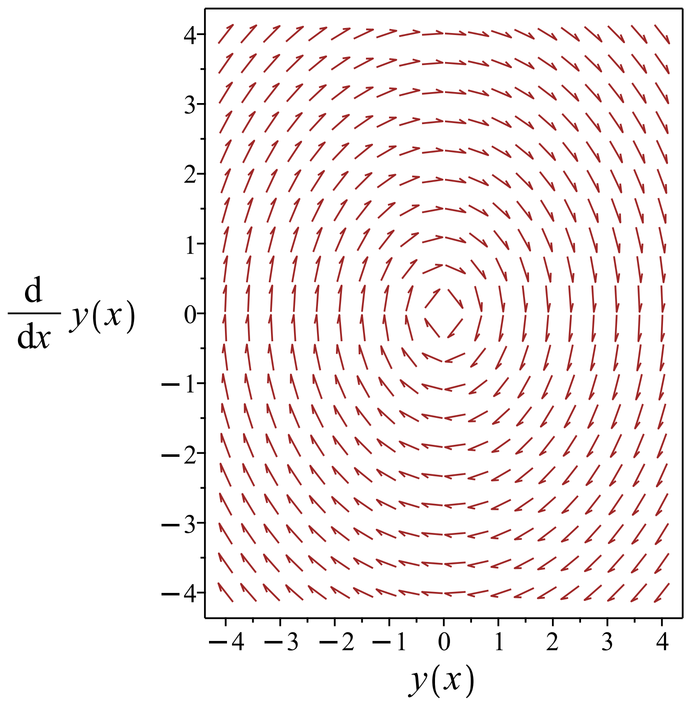

Figure 775: Slope field plot

Verification of solutions

$$
y = c_1 \cos(x) + c_2 \sin(x) - \cos(x)\, x + \ln(\sin(x)) \sin(x)
$$

Verified OK.

20.14.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 643: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}
$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \cos(x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \cos(x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\
&= \cos(x) \int \frac{1}{\cos(x)^2}\,dx \\
&= \cos(x)\,(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \cos(x) + c_2 \sin(x)
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\csc(x)}{1}\,dx$$

Which simplifies to

$$u_1 = -\int 1 dx$$

Hence

$$u_1 = -x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\csc(x)}{1}\,dx$$

Which simplifies to

$$u_2 = \int \cot(x)\,dx$$

Hence

$$u_2 = \ln(\sin(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\cos(x)\,x + \ln(\sin(x))\sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + (-\cos(x)\,x + \ln(\sin(x))\sin(x)) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1\cos(x) + c_2\sin(x) - \cos(x)\,x + \ln(\sin(x))\sin(x) \tag{1}$$

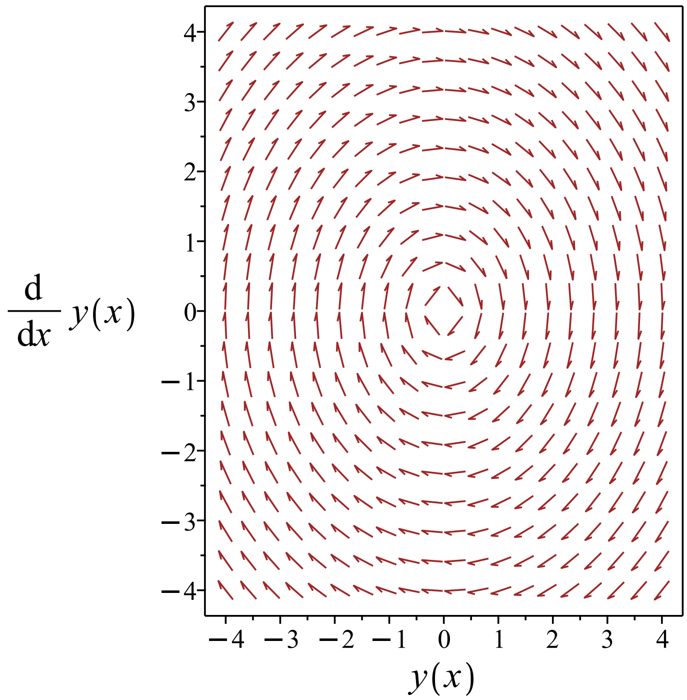

Figure 776: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) - \cos(x)\, x + \ln(\sin(x)) \sin(x)$$

Verified OK.

20.14.3 Maple step by step solution

Let's solve

$y'' + y = \csc(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

$r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$
- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \csc(x)\right]$
- Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$
- Compute Wronskian

  $W(y_1(x), y_2(x)) = 1$
- Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\cos(x)\left(\int 1 dx\right) + \sin(x)\left(\int \cot(x) dx\right)$
- Compute integrals

  $y_p(x) = -\cos(x) x + \ln(\sin(x)) \sin(x)$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(x) + c_2 \sin(x) - \cos(x) x + \ln(\sin(x)) \sin(x)$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + y' = \frac{1}{1 + e^{x}}}$$

20.15.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = 0, f(x) = \frac{1}{1+e^x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 1, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + \lambda e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + \lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 1, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-1}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{1^2 - (4)\,(1)\,(0)} \\ &= -\frac{1}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\lambda_1 = -\frac{1}{2} + \frac{1}{2}$$

$$\lambda_2 = -\frac{1}{2} - \frac{1}{2}$$

Which simplifies to

$$\lambda_1 = 0$$
$$\lambda_2 = -1$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(0)x} + c_2 e^{(-1)x}$$

Or

$$y = c_1 + \mathrm{e}^{-x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + \mathrm{e}^{-x} c_2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = 1$$
$$y_2 = \mathrm{e}^{-x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & e^{-x} \\ \frac{d}{dx}(1) & \frac{d}{dx}(e^{-x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & e^{-x} \\ 0 & -e^{-x} \end{vmatrix}$$

Therefore

$$W = (1)\left(-e^{-x}\right) - \left(e^{-x}\right)(0)$$

Which simplifies to

$$W = -e^{-x}$$

Which simplifies to

$$W = -e^{-x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{e^{-x}}{1+e^x}}{-e^{-x}}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{1}{1+e^x}dx$$

Hence

$$u_1 = -\ln(1+e^x) + \ln(e^x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{1}{1+e^x}}{-e^{-x}}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{e^x}{1+e^x}dx$$

Hence

$$u_2 = -\ln(1 + e^x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\ln(1 + e^x) + \ln(e^x) - \ln(1 + e^x)\, e^{-x}$$

Which simplifies to

$$y_p(x) = (-e^{-x} - 1) \ln(1 + e^x) + \ln(e^x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 + e^{-x} c_2) + ((-e^{-x} - 1) \ln(1 + e^x) + \ln(e^x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + e^{-x} c_2 + (-e^{-x} - 1) \ln(1 + e^x) + \ln(e^x) \tag{1}$$

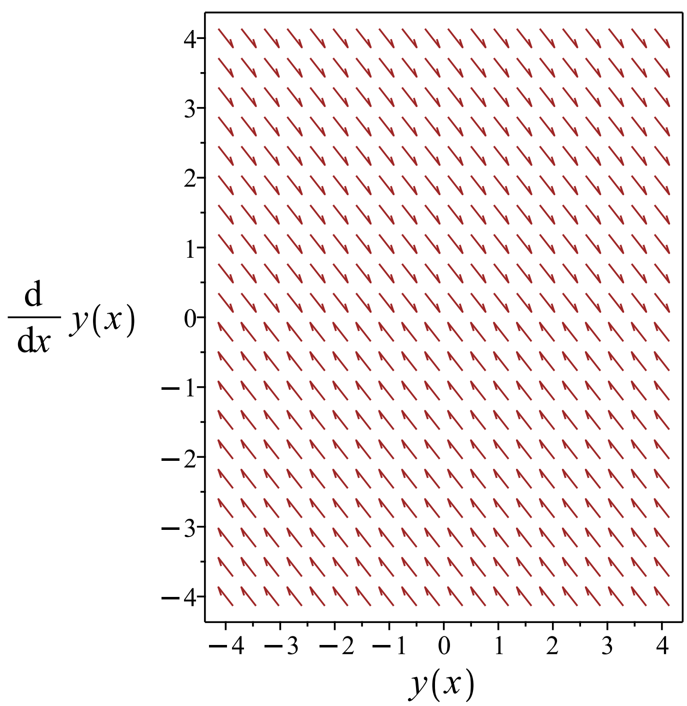

Figure 777: Slope field plot

Verification of solutions

$$y = c_1 + e^{-x}c_2 + \left(-e^{-x} - 1\right)\ln\left(1 + e^x\right) + \ln\left(e^x\right)$$

Verified OK.

20.15.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(y'' + y'\right) dx = \int \frac{1}{1 + e^x} dx$$
$$y' + y = -\ln\left(1 + e^x\right) + \ln\left(e^x\right) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 1$$
$$q(x) = -\ln\left(1 + e^x\right) + \ln\left(e^x\right) + c_1$$

Hence the ode is

$$y' + y = -\ln\left(1 + e^x\right) + \ln\left(e^x\right) + c_1$$

The integrating factor μ is

$$\mu = e^{\int 1 dx}$$
$$= e^x$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(-\ln\left(1 + e^x\right) + \ln\left(e^x\right) + c_1\right)$$
$$\frac{d}{dx}\left(e^x y\right) = \left(e^x\right)\left(-\ln\left(1 + e^x\right) + \ln\left(e^x\right) + c_1\right)$$
$$d\left(e^x y\right) = \left(\left(-\ln\left(1 + e^x\right) + \ln\left(e^x\right) + c_1\right)e^x\right) dx$$

Integrating gives

$$e^x y = \int \left(-\ln\left(1 + e^x\right) + \ln\left(e^x\right) + c_1\right)e^x \, dx$$
$$e^x y = e^x c_1 - \left(1 + e^x\right)\ln\left(1 + e^x\right) + 1 + e^x\ln\left(e^x\right) + c_2$$

Dividing both sides by the integrating factor $\mu = e^x$ results in

$$y = e^{-x}\left(e^x c_1 - (1 + e^x)\ln(1 + e^x) + 1 + e^x \ln(e^x)\right) + e^{-x} c_2$$

which simplifies to

$$y = \left(-e^{-x} - 1\right)\ln(1 + e^x) + (1 + c_2)\, e^{-x} + c_1 + \ln(e^x)$$

Summary

The solution(s) found are the following

$$y = \left(-e^{-x} - 1\right)\ln(1 + e^x) + (1 + c_2)\, e^{-x} + c_1 + \ln(e^x) \tag{1}$$

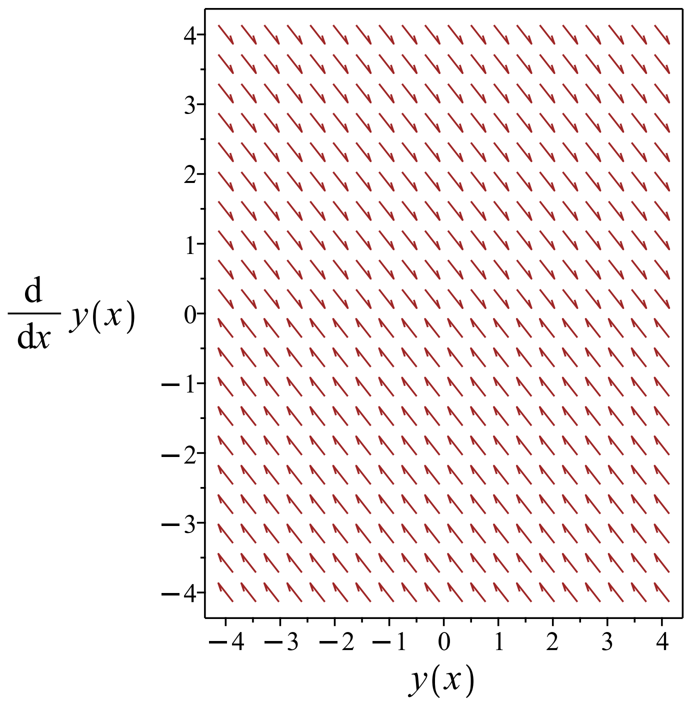

Figure 778: Slope field plot

Verification of solutions

$$y = \left(-e^{-x} - 1\right)\ln(1 + e^x) + (1 + c_2)\, e^{-x} + c_1 + \ln(e^x)$$

Verified OK.

20.15.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + p(x) - \frac{1}{1 + e^x} = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= 1 \\ q(x) &= \frac{1}{1 + e^x} \end{aligned}$$

Hence the ode is

$$p'(x) + p(x) = \frac{1}{1 + e^x}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 1dx} \\ &= e^x \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu)\left(\frac{1}{1 + e^x}\right) \\ \frac{d}{dx}(p\,e^x) &= (e^x)\left(\frac{1}{1 + e^x}\right) \\ d(p\,e^x) &= \left(\frac{e^x}{1 + e^x}\right) dx \end{aligned}$$

Integrating gives

$$
\begin{aligned}
p\,\mathrm{e}^{x} &= \int \frac{\mathrm{e}^{x}}{1+\mathrm{e}^{x}}\,\mathrm{d}x \\
p\,\mathrm{e}^{x} &= \ln\left(1+\mathrm{e}^{x}\right)+c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{x}$ results in

$$
p(x) = \ln\left(1+\mathrm{e}^{x}\right)\mathrm{e}^{-x}+c_1\mathrm{e}^{-x}
$$

which simplifies to

$$
p(x) = \mathrm{e}^{-x}\left(\ln\left(1+\mathrm{e}^{x}\right)+c_1\right)
$$

Since $p = y'$ then the new first order ode to solve is

$$
y' = \mathrm{e}^{-x}\left(\ln\left(1+\mathrm{e}^{x}\right)+c_1\right)
$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int \mathrm{e}^{-x}\left(\ln\left(1+\mathrm{e}^{x}\right)+c_1\right)\,\mathrm{d}x \\
&= -c_1\mathrm{e}^{-x}+\ln\left(\mathrm{e}^{x}\right)-\ln\left(1+\mathrm{e}^{x}\right)\left(1+\mathrm{e}^{x}\right)\mathrm{e}^{-x}+c_2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = -c_1\mathrm{e}^{-x}+\ln\left(\mathrm{e}^{x}\right)-\ln\left(1+\mathrm{e}^{x}\right)\left(1+\mathrm{e}^{x}\right)\mathrm{e}^{-x}+c_2 \tag{1}
$$

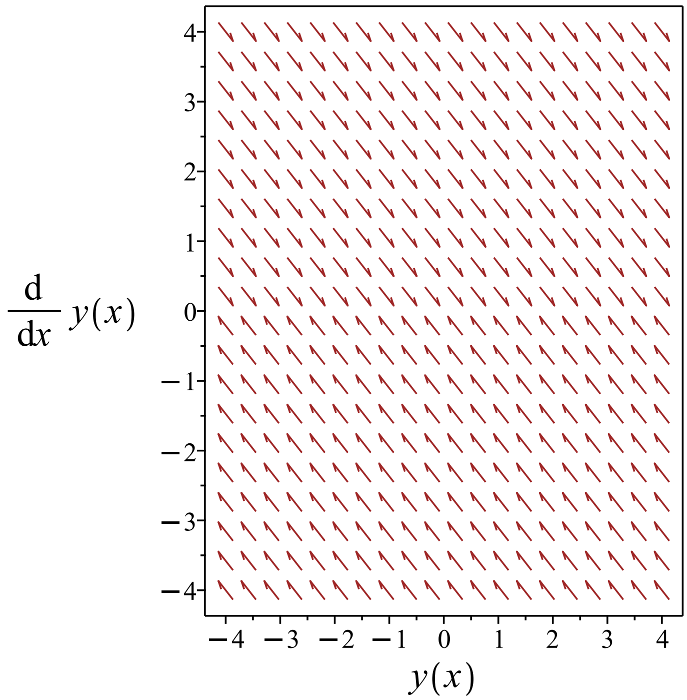

Figure 779: Slope field plot

Verification of solutions

$$y = -c_1 e^{-x} + \ln(e^x) - \ln(1 + e^x)(1 + e^x) e^{-x} + c_2$$

Verified OK.

20.15.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + y' = \frac{1}{1 + e^x}$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + y')\,dx = \int \frac{1}{1 + e^x} dx$$

$$y' + y = -\ln(1 + e^x) + \ln(e^x) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= 1 \\
q(x) &= -\ln(1+\mathrm{e}^{x}) + \ln(\mathrm{e}^{x}) + c_1
\end{aligned}
$$

Hence the ode is

$$
y' + y = -\ln(1+\mathrm{e}^{x}) + \ln(\mathrm{e}^{x}) + c_1
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int 1dx} \\
&= \mathrm{e}^{x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(-\ln(1+\mathrm{e}^{x}) + \ln(\mathrm{e}^{x}) + c_1\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}(\mathrm{e}^{x} y) &= (\mathrm{e}^{x})\left(-\ln(1+\mathrm{e}^{x}) + \ln(\mathrm{e}^{x}) + c_1\right) \\
\mathrm{d}(\mathrm{e}^{x} y) &= \left(\left(-\ln(1+\mathrm{e}^{x}) + \ln(\mathrm{e}^{x}) + c_1\right)\mathrm{e}^{x}\right)\,\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{x} y &= \int \left(-\ln(1+\mathrm{e}^{x}) + \ln(\mathrm{e}^{x}) + c_1\right)\mathrm{e}^{x}\,\mathrm{d}x \\
\mathrm{e}^{x} y &= \mathrm{e}^{x} c_1 - (1+\mathrm{e}^{x})\ln(1+\mathrm{e}^{x}) + 1 + \mathrm{e}^{x}\ln(\mathrm{e}^{x}) + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{x}$ results in

$$
y = \mathrm{e}^{-x}\left(\mathrm{e}^{x} c_1 - (1+\mathrm{e}^{x})\ln(1+\mathrm{e}^{x}) + 1 + \mathrm{e}^{x}\ln(\mathrm{e}^{x})\right) + \mathrm{e}^{-x} c_2
$$

which simplifies to

$$
y = \left(-\mathrm{e}^{-x} - 1\right)\ln(1+\mathrm{e}^{x}) + (1+c_2)\,\mathrm{e}^{-x} + c_1 + \ln(\mathrm{e}^{x})
$$

Summary

The solution(s) found are the following

$$
y = \left(-\mathrm{e}^{-x} - 1\right)\ln(1+\mathrm{e}^{x}) + (1+c_2)\,\mathrm{e}^{-x} + c_1 + \ln(\mathrm{e}^{x}) \tag{1}
$$

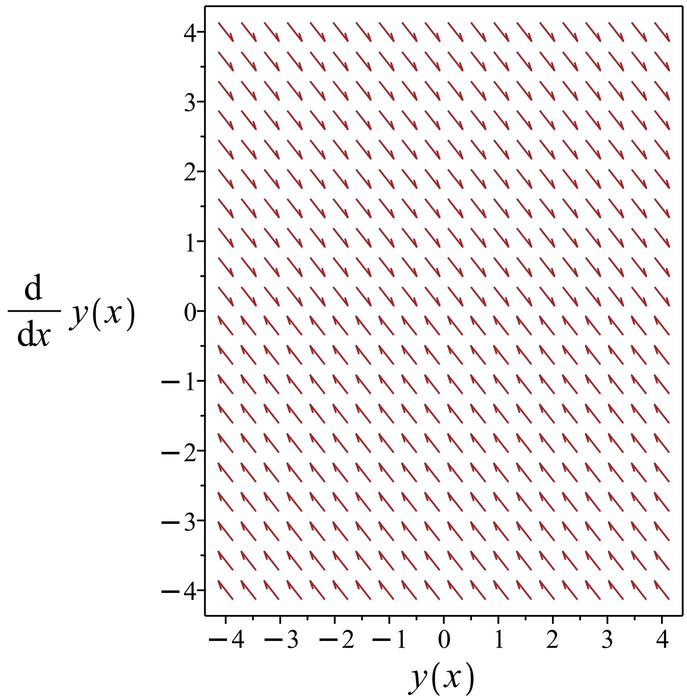

Figure 780: Slope field plot

Verification of solutions

$$y = \left(-\mathrm{e}^{-x} - 1\right) \ln\left(1 + \mathrm{e}^{x}\right) + (1 + c_2)\,\mathrm{e}^{-x} + c_1 + \ln\left(\mathrm{e}^{x}\right)$$

Verified OK.

20.15.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 1 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 645: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-\frac{x}{2}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\,dx} \\
&= z_1 e^{-\frac{x}{2}} \\
&= z_1\left(\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x}}{(y_1)^2}\,dx \\
&= y_1(\mathrm{e}^{x})
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} (\mathrm{e}^{x})\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + y' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-x} + c_2
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \mathrm{e}^{-x} \\
y_2 &= 1
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-x} & 1 \\ \frac{d}{dx}\left(e^{-x}\right) & \frac{d}{dx}(1) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-x} & 1 \\ -e^{-x} & 0 \end{vmatrix}$$

Therefore

$$W = \left(e^{-x}\right)(0) - (1)\left(-e^{-x}\right)$$

Which simplifies to

$$W = e^{-x}$$

Which simplifies to

$$W = e^{-x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{1}{1+e^{x}}}{e^{-x}}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{e^{x}}{1+e^{x}} dx$$

Hence

$$u_1 = -\ln\left(1+e^{x}\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{e^{-x}}{1+e^{x}}}{e^{-x}}\, dx$$

Which simplifies to

$$u_2 = \int \frac{1}{1+e^{x}} dx$$

Hence

$$u_2 = -\ln(1+e^x) + \ln(e^x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\ln(1+e^x) + \ln(e^x) - \ln(1+e^x)\,e^{-x}$$

Which simplifies to

$$y_p(x) = \left(-e^{-x} - 1\right)\ln(1+e^x) + \ln(e^x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2\right) + \left(\left(-e^{-x} - 1\right)\ln(1+e^x) + \ln(e^x)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 + \left(-e^{-x} - 1\right)\ln(1+e^x) + \ln(e^x) \tag{1}$$

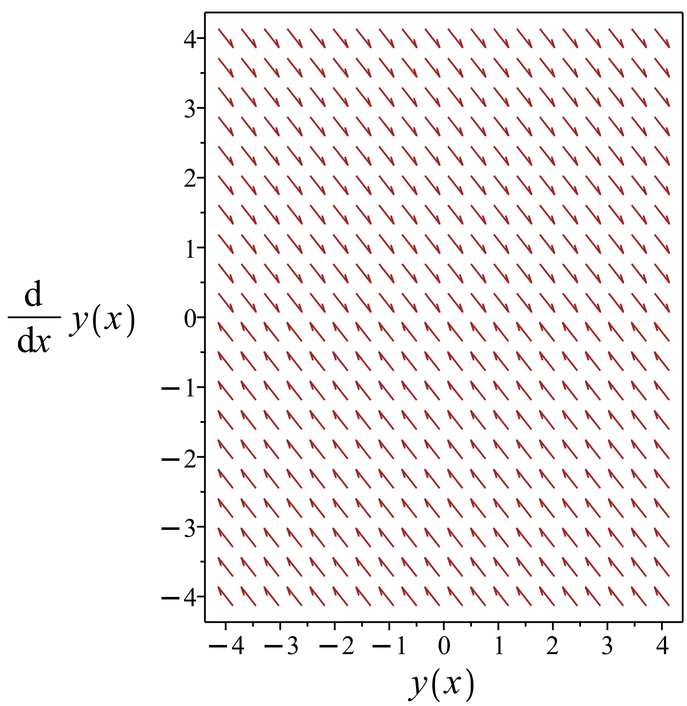

Figure 781: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + c_2 + \left(-e^{-x} - 1\right) \ln\left(1 + e^{x}\right) + \ln\left(e^{x}\right)$$

Verified OK.

20.15.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 1 \\ r(x) &= 0 \\ s(x) &= \frac{1}{1 + e^{x}} \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\, y' + \left(q(x) - p'(x)\right) y\right)' = s(x)$$

Integrating gives

$$p(x)\, y' + \left(q(x) - p'(x)\right) y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$y' + y = \int \frac{1}{1 + e^{x}}\, dx$$

We now have a first order ode to solve which is

$$y' + y = -\ln(1 + e^x) + \ln(e^x) + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 1 \\ q(x) &= -\ln(1 + e^x) + \ln(e^x) + c_1 \end{aligned}$$

Hence the ode is

$$y' + y = -\ln(1 + e^x) + \ln(e^x) + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 1dx} \\ &= e^x \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)(-\ln(1 + e^x) + \ln(e^x) + c_1) \\ \frac{d}{dx}(e^x y) &= (e^x)(-\ln(1 + e^x) + \ln(e^x) + c_1) \\ d(e^x y) &= ((-\ln(1 + e^x) + \ln(e^x) + c_1) e^x)\, dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^x y &= \int (-\ln(1 + e^x) + \ln(e^x) + c_1) e^x\, dx \\ e^x y &= e^x c_1 - (1 + e^x)\ln(1 + e^x) + 1 + e^x \ln(e^x) + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^x$ results in

$$y = e^{-x}(e^x c_1 - (1 + e^x)\ln(1 + e^x) + 1 + e^x \ln(e^x)) + e^{-x} c_2$$

which simplifies to

$$y = (-e^{-x} - 1)\ln(1 + e^x) + (1 + c_2) e^{-x} + c_1 + \ln(e^x)$$

Summary

The solution(s) found are the following

$$y = \left(-e^{-x} - 1\right) \ln\left(1 + e^{x}\right) + \left(1 + c_2\right) e^{-x} + c_1 + \ln\left(e^{x}\right) \tag{1}$$

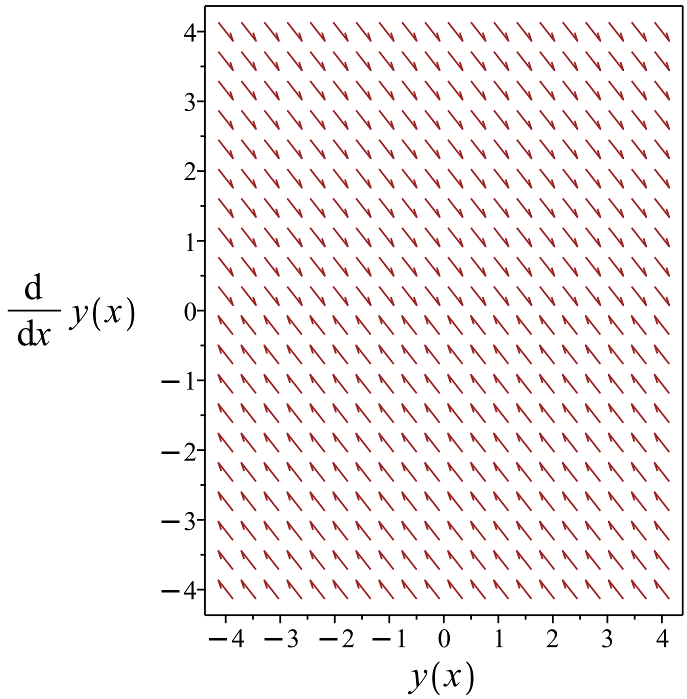

Figure 782: Slope field plot

Verification of solutions

$$y = \left(-e^{-x} - 1\right) \ln\left(1 + e^{x}\right) + \left(1 + c_2\right) e^{-x} + c_1 + \ln\left(e^{x}\right)$$

Verified OK.

20.15.7 Maple step by step solution

Let's solve

$y'' + y' = \frac{1}{1+e^{x}}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + r = 0$

- Factor the characteristic polynomial

  $r(r+1)=0$
- Roots of the characteristic polynomial

  $r=(-1,0)$
- 1st solution of the homogeneous ODE

  $y_1(x)=\mathrm{e}^{-x}$
- 2nd solution of the homogeneous ODE

  $y_2(x)=1$
- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)+y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y=c_1\mathrm{e}^{-x}+c_2+y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x)=-y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right)+y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x)=\frac{1}{1+\mathrm{e}^x}\right]$
  - Wronskian of solutions of the homogeneous equation

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''+y=\frac{1}{\cos\left(x\right)^{3}}}$$

20.16.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=1, B=0, C=1, f(x)=\sec\left(x\right)^{3}$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+y=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\sec(x)^3}{1} dx$$

Which simplifies to

$$u_1 = -\int \tan(x)\sec(x)^2 dx$$

Hence

$$u_1 = -\frac{\sec(x)^2}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\sec(x)^3}{1} dx$$

Which simplifies to

$$u_2 = \int \sec(x)^2 dx$$

Hence

$$u_2 = \tan(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\sec(x)^2\cos(x)}{2} + \tan(x)\sin(x)$$

Which simplifies to

$$y_p(x) = -\cos(x) + \frac{\sec(x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + \left(-\cos(x) + \frac{\sec(x)}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) - \cos(x) + \frac{\sec(x)}{2} \tag{1}$$

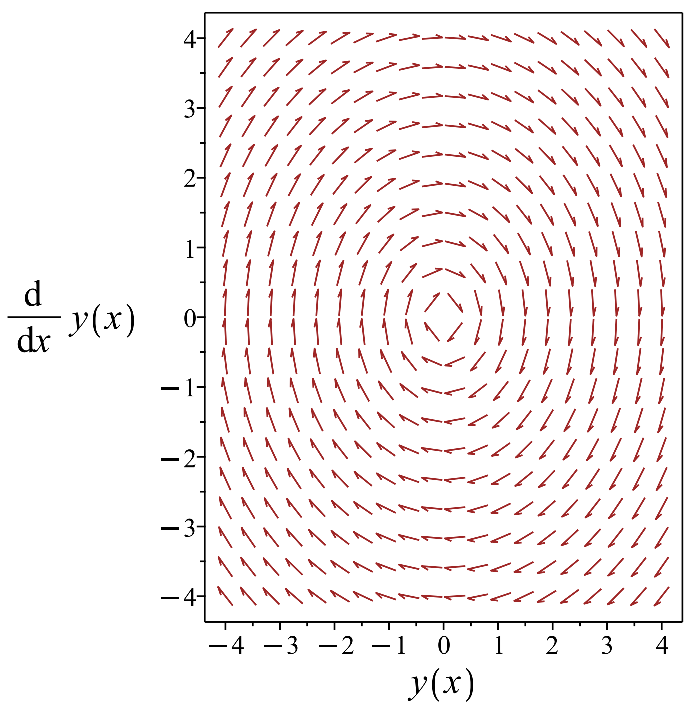

Figure 783: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) - \cos(x) + \frac{\sec(x)}{2}$$

Verified OK.

20.16.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 647: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \cos(x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \cos(x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\
&= \cos(x)\,(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \cos(x) + c_2 \sin(x)
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\sec(x)^3}{1} dx$$

Which simplifies to

$$u_1 = -\int \tan(x)\sec(x)^2 dx$$

Hence

$$u_1 = -\frac{\sec(x)^2}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\sec(x)^3}{1} dx$$

Which simplifies to

$$u_2 = \int \sec(x)^2 dx$$

Hence

$$u_2 = \tan(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\sec(x)^2\cos(x)}{2} + \tan(x)\sin(x)$$

Which simplifies to

$$y_p(x) = -\cos(x) + \frac{\sec(x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + \left(-\cos(x) + \frac{\sec(x)}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) - \cos(x) + \frac{\sec(x)}{2} \tag{1}$$

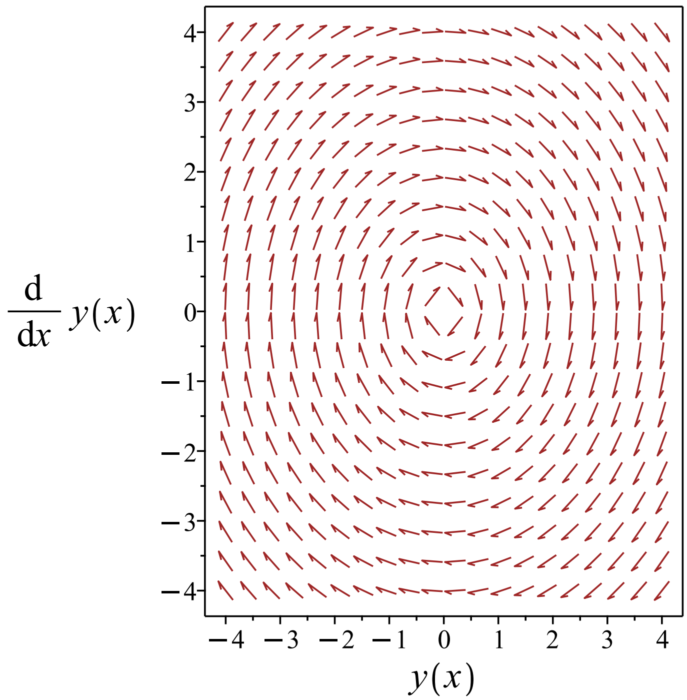

Figure 784: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) - \cos(x) + \frac{\sec(x)}{2}$$

Verified OK.

20.16.3 Maple step by step solution

Let's solve

$y'' + y = \sec(x)^3$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \sec(x)^3\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \left[\begin{array}{cc} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{array}\right]$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 1$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\cos(x) \left(\int \tan(x) \sec(x)^2 dx\right) + \sin(x) \left(\int \sec(x)^2 dx\right)$

  ◦ Compute integrals

  $y_p(x) = -\cos(x) + \frac{\sec(x)}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(x) + c_2 \sin(x) - \cos(x) + \frac{\sec(x)}{2}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = \frac{1}{\sqrt{\sin(x)^5 \cos(x)}}}$$

20.17.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = \frac{1}{\sqrt{\sin(x)^5 \cos(x)}}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sin(x)}{\sqrt{\sin(x)^5 \cos(x)}}}{1} dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(x)}{\sqrt{\sin(x)^5 \cos(x)}} dx$$

Hence

$$u_1 = \frac{\cos(x)\sin(x)^2 \sqrt{2}\, \sqrt{32}}{4\sqrt{\sin(x)^5 \cos(x)}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\cos(x)}{\sqrt{\sin(x)^5 \cos(x)}}}{1} dx$$

Which simplifies to

$$u_2 = \int \frac{\cos(x)}{\sqrt{\sin(x)^5 \cos(x)}} dx$$

Hence

$$u_2 = -\frac{\sqrt{2}\, \cos(x)^2 \sin(x)\, \sqrt{32}}{12\sqrt{\sin(x)^5 \cos(x)}}$$

Which simplifies to

$$u_1 = \frac{2\cos(x)\sin(x)^2}{\sqrt{\sin(x)^5\cos(x)}}$$

$$u_2 = -\frac{2\cos(x)^2\sin(x)}{3\sqrt{\sin(x)^5\cos(x)}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{4\cos(x)^2\sin(x)^2}{3\sqrt{\sin(x)^5\cos(x)}}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + \left(\frac{4\cos(x)^2\sin(x)^2}{3\sqrt{\sin(x)^5\cos(x)}}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1\cos(x) + c_2\sin(x) + \frac{4\cos(x)^2\sin(x)^2}{3\sqrt{\sin(x)^5\cos(x)}} \tag{1}$$

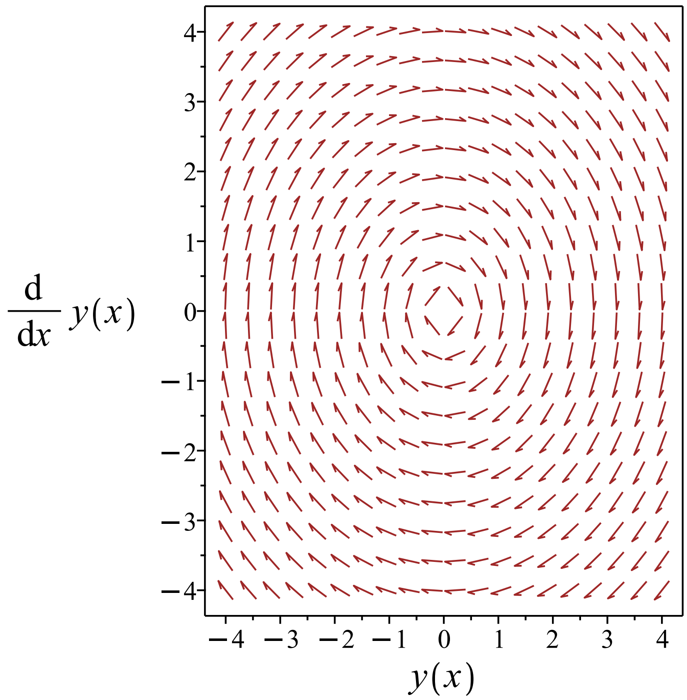

Figure 785: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{4 \cos(x)^2 \sin(x)^2}{3 \sqrt{\sin(x)^5 \cos(x)}}$$

Verified OK.

20.17.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 649: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2} \, dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2} \, dx \\ &= \cos(x) (\tan(x)) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(x)) + c_2(\cos(x)(\tan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \cos(x) + c_2 \sin(x)
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \cos(x) \\
y_2 &= \sin(x)
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sin(x)}{\sqrt{\sin(x)^5 \cos(x)}}}{1} dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(x)}{\sqrt{\sin(x)^5 \cos(x)}} dx$$

Hence

$$u_1 = \frac{\cos(x)\sin(x)^2 \sqrt{2}\sqrt{32}}{4\sqrt{\sin(x)^5 \cos(x)}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\cos(x)}{\sqrt{\sin(x)^5 \cos(x)}}}{1} dx$$

Which simplifies to

$$u_2 = \int \frac{\cos(x)}{\sqrt{\sin(x)^5 \cos(x)}} dx$$

Hence

$$u_2 = -\frac{\sqrt{2}\,\cos(x)^2 \sin(x)\,\sqrt{32}}{12\sqrt{\sin(x)^5 \cos(x)}}$$

Which simplifies to

$$u_1 = \frac{2\cos(x)\sin(x)^2}{\sqrt{\sin(x)^5 \cos(x)}}$$

$$u_2 = -\frac{2\cos(x)^2 \sin(x)}{3\sqrt{\sin(x)^5 \cos(x)}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{4\cos(x)^2 \sin(x)^2}{3\sqrt{\sin(x)^5 \cos(x)}}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + \left(\frac{4\cos(x)^2 \sin(x)^2}{3\sqrt{\sin(x)^5 \cos(x)}}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{4\cos(x)^2 \sin(x)^2}{3\sqrt{\sin(x)^5 \cos(x)}} \tag{1}$$

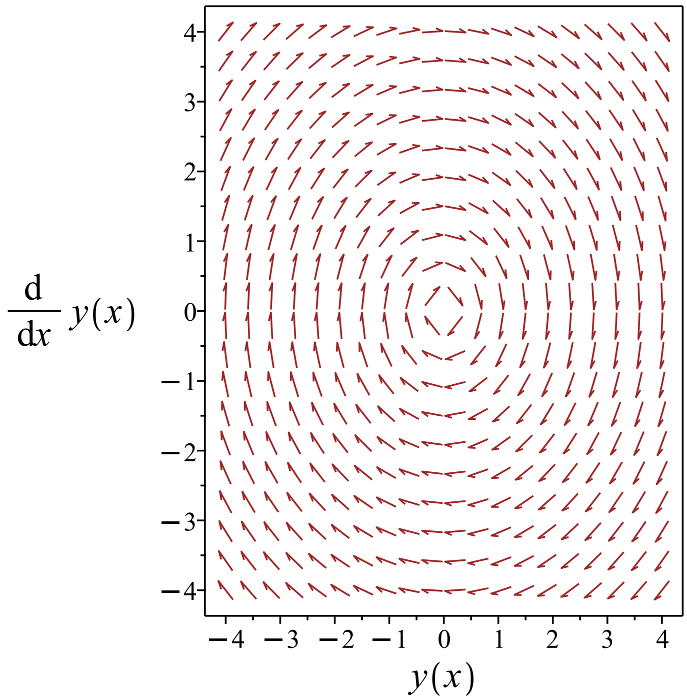

Figure 786: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{4 \cos(x)^2 \sin(x)^2}{3\sqrt{\sin(x)^5 \cos(x)}}$$

Verified OK.

20.17.3 Maple step by step solution

Let's solve

$y'' + y = \frac{1}{\sqrt{\sin(x)^5 \cos(x)}}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $$\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \frac{1}{\sqrt{\sin(x)^5 \cos(x)}}\right]$$

  ○ Wronskian of solutions of the homogeneous equation

  $$W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$$

  ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 1$

  ○ Substitute functions into equation for $y_p(x)$

  $$y_p(x) = -\cos(x)\left(\int \frac{\sin(x)}{\sqrt{\sin(x)^5 \cos(x)}} dx\right) + \sin(x)\left(\int \frac{\cos(x)}{\sqrt{\sin(x)^5 \cos(x)}} dx\right)$$

  ○ Compute integrals

  $$y_p(x) = \frac{4\cos(x)^2 \sin(x)^2}{3\sqrt{\sin(x)^5 \cos(x)}}$$

- Substitute particular solution into general solution to ODE

  $$y = c_1 \cos(x) + c_2 \sin(x) + \frac{4\cos(x)^2 \sin(x)^2}{3\sqrt{\sin(x)^5 \cos(x)}}$$

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' - 2y' + y = \frac{e^x}{x^2 + 1}}$$

20.18.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 1, f(x) = \frac{e^x}{x^2+1}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 1$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-2)^2 - (4)(1)(1)} \\
&= 1
\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -1$. Therefore the solution is

$$y = c_1 e^x + c_2 x e^x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = e^x c_1 + x e^x c_2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= e^x \\
y_2 &= x e^x
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x & x\,e^x \\ \frac{d}{dx}(e^x) & \frac{d}{dx}(x\,e^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^x & x\,e^x \\ e^x & x\,e^x + e^x \end{vmatrix}$$

Therefore

$$W = (e^x)(x\,e^x + e^x) - (x\,e^x)(e^x)$$

Which simplifies to

$$W = e^{2x}$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x\,e^{2x}}{x^2+1}}{e^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{x}{x^2+1} dx$$

Hence

$$u_1 = -\frac{\ln(x^2+1)}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{e^{2x}}{x^2+1}}{e^{2x}} dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x^2+1} dx$$

Hence

$$u_2 = \arctan(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\ln(x^2+1)\,e^x}{2} + \arctan(x)\,x\,e^x$$

Which simplifies to

$$y_p(x) = e^x \left(-\frac{\ln(x^2+1)}{2} + x\arctan(x)\right)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x c_1 + x\,e^x c_2) + \left(e^x \left(-\frac{\ln(x^2+1)}{2} + x\arctan(x)\right)\right) \end{aligned}$$

Which simplifies to

$$y = e^x(c_2 x + c_1) + e^x \left(-\frac{\ln(x^2+1)}{2} + x\arctan(x)\right)$$

Summary

The solution(s) found are the following

$$y = e^x(c_2 x + c_1) + e^x \left(-\frac{\ln(x^2+1)}{2} + x\arctan(x)\right) \tag{1}$$

Verification of solutions

$$y = e^x(c_2 x + c_1) + e^x \left(-\frac{\ln(x^2+1)}{2} + x\arctan(x)\right)$$

Verified OK.

20.18.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^{2} + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -2$. Therefore, there is an integrating factor given by

$$\begin{aligned}
M(x) &= e^{\frac{1}{2}\int p\, dx} \\
&= e^{\int -2\, dx} \\
&= \mathrm{e}^{-x}
\end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned}
(M(x)y)'' &= \frac{\mathrm{e}^{-x} \mathrm{e}^{x}}{x^{2}+1} \\
\left(\mathrm{e}^{-x} y\right)'' &= \frac{\mathrm{e}^{-x} \mathrm{e}^{x}}{x^{2}+1}
\end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{-x} y\right)' = \arctan(x) + c_{1}$$

Integrating again gives

$$\left(\mathrm{e}^{-x} y\right) = c_{1} x + x \arctan(x) - \frac{\ln(x^{2}+1)}{2} + c_{2}$$

Hence the solution is

$$y = \frac{c_{1} x + x \arctan(x) - \frac{\ln(x^{2}+1)}{2} + c_{2}}{\mathrm{e}^{-x}}$$

Or

$$y = c_{1} x\, \mathrm{e}^{x} + x \arctan(x)\, \mathrm{e}^{x} + c_{2} \mathrm{e}^{x} - \frac{\mathrm{e}^{x} \ln(x^{2}+1)}{2}$$

<u>Summary</u>

The solution(s) found are the following

$$y = c_{1} x\, \mathrm{e}^{x} + x \arctan(x)\, \mathrm{e}^{x} + c_{2} \mathrm{e}^{x} - \frac{\mathrm{e}^{x} \ln(x^{2}+1)}{2} \tag{1}$$

Verification of solutions

$$y = c_1 x\, e^{x} + x \arctan(x)\, e^{x} + c_2 e^{x} - \frac{e^{x} \ln(x^2+1)}{2}$$

Verified OK.

20.18.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 651: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\
&= z_1 e^{x} \\
&= z_1 (\mathrm{e}^{x})
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^{x}) + c_2(\mathrm{e}^{x}(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = e^x c_1 + x\,e^x c_2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= e^x \\ y_2 &= x\,e^x \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x & x\,e^x \\ \frac{d}{dx}(e^x) & \frac{d}{dx}(x\,e^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^x & x\,e^x \\ e^x & x\,e^x + e^x \end{vmatrix}$$

Therefore

$$W = (e^x)(x\,e^x + e^x) - (x\,e^x)(e^x)$$

Which simplifies to

$$W = e^{2x}$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x\,e^{2x}}{x^2+1}}{e^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{x}{x^2+1}dx$$

Hence

$$u_1 = -\frac{\ln(x^2+1)}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{e^{2x}}{x^2+1}}{e^{2x}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x^2+1}dx$$

Hence

$$u_2 = \arctan(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{e^x \ln(x^2+1)}{2} + x\arctan(x)\,e^x$$

Which simplifies to

$$y_p(x) = e^x\left(-\frac{\ln(x^2+1)}{2} + x\arctan(x)\right)$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (\mathrm{e}^{x} c_1 + x\,\mathrm{e}^{x} c_2) + \left(\mathrm{e}^{x}\left(-\frac{\ln(x^2+1)}{2} + x\arctan(x)\right)\right)
\end{aligned}
$$

Which simplifies to

$$
y = \mathrm{e}^{x}(c_2 x + c_1) + \mathrm{e}^{x}\left(-\frac{\ln(x^2+1)}{2} + x\arctan(x)\right)
$$

Summary

The solution(s) found are the following

$$
y = \mathrm{e}^{x}(c_2 x + c_1) + \mathrm{e}^{x}\left(-\frac{\ln(x^2+1)}{2} + x\arctan(x)\right) \tag{1}
$$

Verification of solutions

$$
y = \mathrm{e}^{x}(c_2 x + c_1) + \mathrm{e}^{x}\left(-\frac{\ln(x^2+1)}{2} + x\arctan(x)\right)
$$

Verified OK.

20.18.4 Maple step by step solution

Let's solve

$y'' - 2y' + y = \frac{\mathrm{e}^{x}}{x^2+1}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 1 = 0$

- Factor the characteristic polynomial

  $(r-1)^2 = 0$

- Root of the characteristic polynomial

  $r = 1$

- 1st solution of the homogeneous ODE

$y_1(x) = e^x$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^x c_1 + x\,e^x c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \frac{e^x}{x^2+1}\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^x & x\,e^x \\ e^x & x\,e^x + e^x \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = e^{2x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = e^x\left(-\left(\int \frac{x}{x^2+1} dx\right) + \left(\int \frac{1}{x^2+1} dx\right) x\right)$

  - Compute integrals

    $y_p(x) = -\frac{e^x\left(-2x\arctan(x) + \ln(x^2+1)\right)}{2}$

- Substitute particular solution into general solution to ODE

  $y = e^x c_1 + x\,e^x c_2 - \frac{e^x\left(-2x\arctan(x) + \ln(x^2+1)\right)}{2}$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 2y' + 2y = \frac{e^{-x}}{\sin(x)}}$$

20.19.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 2, f(x) = \csc(x) e^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda\, e^{\lambda x} + 2\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{2^2 - (4)\,(1)\,(2)}\\ &= -1 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -1 + i\\ \lambda_2 &= -1 - i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 + i\\ \lambda_2 &= -1 - i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -1$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-x}(c_1 \cos(x) + c_2 \sin(x))$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^{-x} \cos(x)$$
$$y_2 = e^{-x} \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-x} \cos(x) & e^{-x} \sin(x) \\ \frac{d}{dx}(e^{-x} \cos(x)) & \frac{d}{dx}(e^{-x} \sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-x} \cos(x) & e^{-x} \sin(x) \\ -e^{-x} \cos(x) - e^{-x} \sin(x) & -e^{-x} \sin(x) + e^{-x} \cos(x) \end{vmatrix}$$

Therefore

$$W = (e^{-x} \cos(x)) (-e^{-x} \sin(x) + e^{-x} \cos(x)) - (e^{-x} \sin(x)) (-e^{-x} \cos(x) - e^{-x} \sin(x))$$

Which simplifies to

$$W = \sin(x)^2 e^{-2x} + \cos(x)^2 e^{-2x}$$

Which simplifies to

$$W = e^{-2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{e^{-2x} \sin(x) \csc(x)}{e^{-2x}} dx$$

Which simplifies to

$$u_1 = -\int 1 dx$$

Hence

$$u_1 = -x$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{-2x} \cos(x) \csc(x)}{e^{-2x}} dx$$

Which simplifies to

$$u_2 = \int \cot(x) dx$$

Hence

$$u_2 = \ln(\sin(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -x \cos(x) e^{-x} + \ln(\sin(x)) e^{-x} \sin(x)$$

Which simplifies to

$$y_p(x) = e^{-x}(-\cos(x) x + \ln(\sin(x)) \sin(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{-x}(c_1 \cos(x) + c_2 \sin(x))\right) + \left(\mathrm{e}^{-x}(-\cos(x)\, x + \ln(\sin(x)) \sin(x))\right) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \mathrm{e}^{-x}(c_1 \cos(x) + c_2 \sin(x)) + \mathrm{e}^{-x}(-\cos(x)\, x + \ln(\sin(x)) \sin(x)) \tag{1}$$

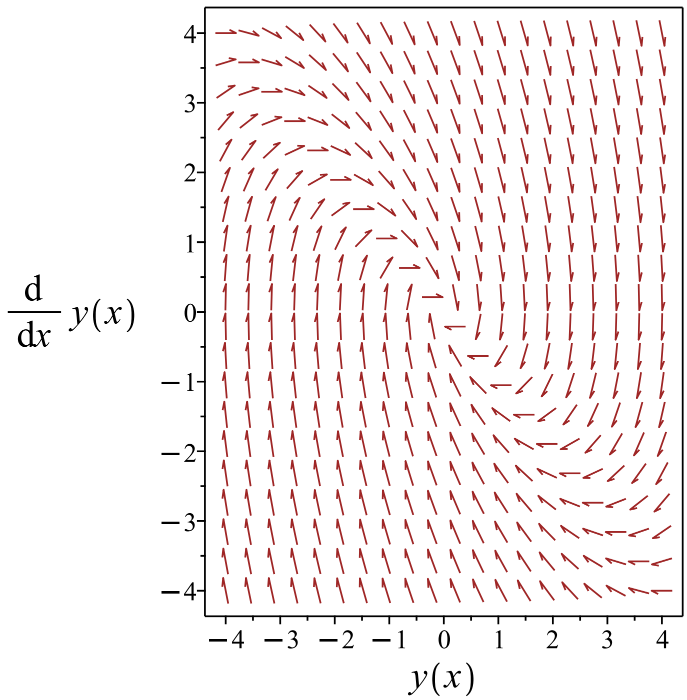

Figure 787: Slope field plot

<u>Verification of solutions</u>

$$y = \mathrm{e}^{-x}(c_1 \cos(x) + c_2 \sin(x)) + \mathrm{e}^{-x}(-\cos(x)\, x + \ln(\sin(x)) \sin(x))$$

Verified OK.

20.19.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + 2y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 653: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx}
\end{aligned}$$

$$
\begin{aligned}
&= z_1 e^{-x} \\
&= z_1 \left(\mathrm{e}^{-x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-x} \cos(x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-2x}}{(y_1)^2}\, dx \\
&= y_1 (\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x} \cos(x)\right) + c_2 \left(\mathrm{e}^{-x} \cos(x) (\tan(x))\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 2y' + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^{-x} \cos(x) c_1 + \mathrm{e}^{-x} \sin(x) c_2
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^{-x} \cos(x)$$
$$y_2 = e^{-x} \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-x}\cos(x) & e^{-x}\sin(x) \\ \frac{d}{dx}(e^{-x}\cos(x)) & \frac{d}{dx}(e^{-x}\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-x}\cos(x) & e^{-x}\sin(x) \\ -e^{-x}\cos(x) - e^{-x}\sin(x) & -e^{-x}\sin(x) + e^{-x}\cos(x) \end{vmatrix}$$

Therefore

$$W = \left(e^{-x}\cos(x)\right)\left(-e^{-x}\sin(x) + e^{-x}\cos(x)\right) - \left(e^{-x}\sin(x)\right)\left(-e^{-x}\cos(x) - e^{-x}\sin(x)\right)$$

Which simplifies to

$$W = \sin(x)^2 e^{-2x} + \cos(x)^2 e^{-2x}$$

Which simplifies to

$$W = \mathrm{e}^{-2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\mathrm{e}^{-2x}\sin(x)\csc(x)}{\mathrm{e}^{-2x}}\,dx$$

Which simplifies to

$$u_1 = -\int 1dx$$

Hence

$$u_1 = -x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\mathrm{e}^{-2x}\cos(x)\csc(x)}{\mathrm{e}^{-2x}}\,dx$$

Which simplifies to

$$u_2 = \int \cot(x)\,dx$$

Hence

$$u_2 = \ln(\sin(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -x\cos(x)\,\mathrm{e}^{-x} + \ln(\sin(x))\,\mathrm{e}^{-x}\sin(x)$$

Which simplifies to

$$y_p(x) = \mathrm{e}^{-x}(-\cos(x)\,x + \ln(\sin(x))\sin(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{-x}\cos(x)\,c_1 + \mathrm{e}^{-x}\sin(x)\,c_2\right) + \left(\mathrm{e}^{-x}(-\cos(x)\,x + \ln(\sin(x))\sin(x))\right) \end{aligned}$$

Which simplifies to

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x)) + e^{-x}(-\cos(x) x + \ln(\sin(x)) \sin(x))$$

Summary

The solution(s) found are the following

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x)) + e^{-x}(-\cos(x) x + \ln(\sin(x)) \sin(x)) \tag{1}$$

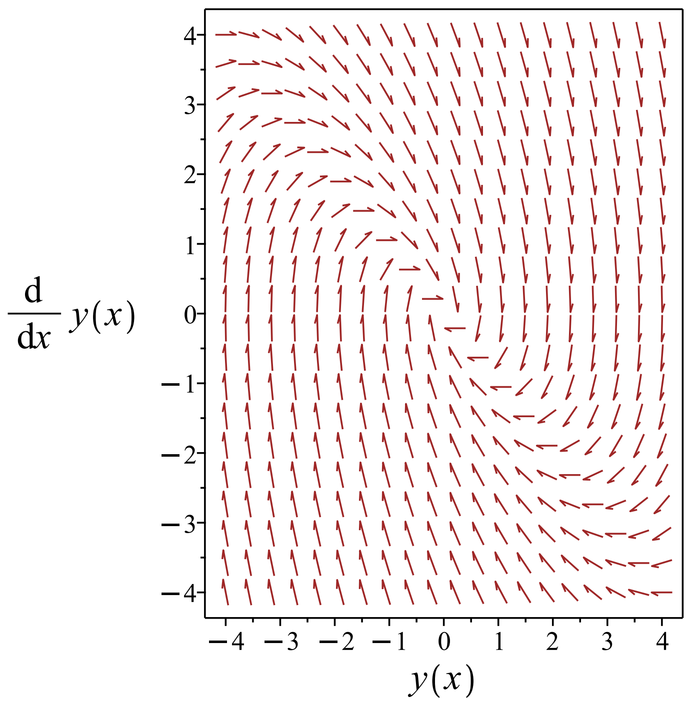

Figure 788: Slope field plot

Verification of solutions

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x)) + e^{-x}(-\cos(x) x + \ln(\sin(x)) \sin(x))$$

Verified OK.

20.19.3 Maple step by step solution

Let's solve

$y'' + 2y' + 2y = \csc(x)\, e^{-x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r + 2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-2)\pm(\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-1 - I, -1 + I)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x}\cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-x}\sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{-x}\cos(x)\, c_1 + e^{-x}\sin(x)\, c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \csc(x)\, e^{-x}\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x}\cos(x) & e^{-x}\sin(x) \\ -e^{-x}\cos(x) - e^{-x}\sin(x) & -e^{-x}\sin(x) + e^{-x}\cos(x) \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{-2x}$

- ○ Substitute functions into equation for $y_p(x)$

$$y_p(x) = \mathrm{e}^{-x}\left(-\cos(x)\left(\int 1dx\right) + \sin(x)\left(\int \cot(x)\,dx\right)\right)$$

- Compute integrals

$$y_p(x) = \mathrm{e}^{-x}(-\cos(x)\,x + \ln(\sin(x))\sin(x))$$

- Substitute particular solution into general solution to ODE

$$y = \mathrm{e}^{-x}\cos(x)\,c_1 + \mathrm{e}^{-x}\sin(x)\,c_2 + \mathrm{e}^{-x}(-\cos(x)\,x + \ln(\sin(x))\sin(x))$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$y'' + y = \frac{2}{\sin(x)^3}$$

20.20.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = 2\csc(x)^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\lambda_1 = +i$$
$$\lambda_2 = -i$$

Which simplifies to

$$\lambda_1 = i$$
$$\lambda_2 = -i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2\sin(x)\csc(x)^3}{1}\,dx$$

Which simplifies to

$$u_1 = -\int 2\csc(x)^2\,dx$$

Hence

$$u_1 = 2\cot(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{2\cos(x)\csc(x)^3}{1}\,dx$$

Which simplifies to

$$u_2 = \int 2\csc(x)^2\cot(x)\,dx$$

Hence

$$u_2 = -\cot(x)^2$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = 2\cot(x)\cos(x) - \cot(x)^2\sin(x)$$

Which simplifies to

$$y_p(x) = \cot(x)\cos(x)$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + (\cot(x)\cos(x))
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(x) + c_2 \sin(x) + \cot(x)\cos(x) \tag{1}
$$

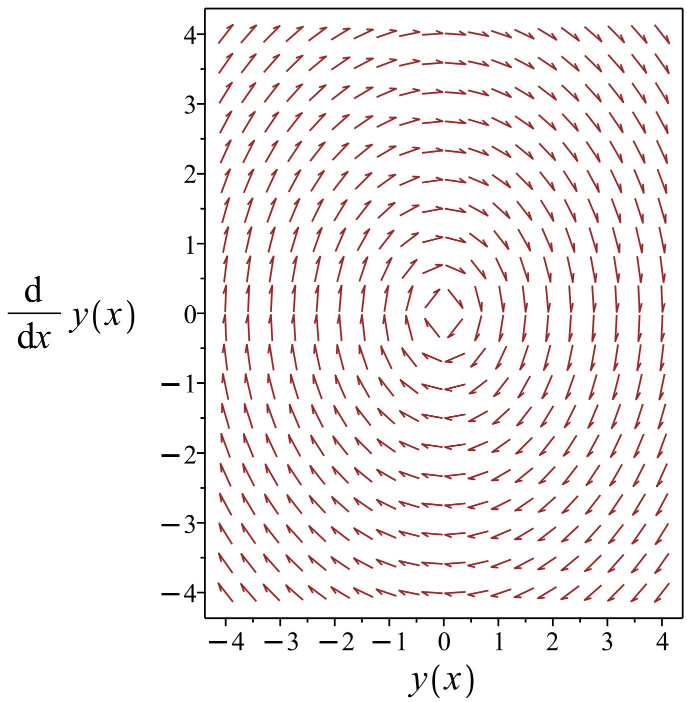

Figure 789: Slope field plot

Verification of solutions

$$
y = c_1 \cos(x) + c_2 \sin(x) + \cot(x)\cos(x)
$$

Verified OK.

20.20.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 655: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \cos(x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \cos(x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\
&= \cos(x) (\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(x)) + c_2(\cos(x) (\tan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \cos(x) + c_2 \sin(x)
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2\sin(x)\csc(x)^3}{1} dx$$

Which simplifies to

$$u_1 = -\int 2\csc(x)^2 dx$$

Hence

$$u_1 = 2\cot(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{2\cos(x)\csc(x)^3}{1} dx$$

Which simplifies to

$$u_2 = \int 2\csc(x)^2 \cot(x) dx$$

Hence

$$u_2 = -\cot(x)^2$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = 2\cot(x)\cos(x) - \cot(x)^2 \sin(x)$$

Which simplifies to

$$y_p(x) = \cot(x)\cos(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + (\cot(x)\cos(x)) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) + \cot(x)\cos(x) \tag{1}$$

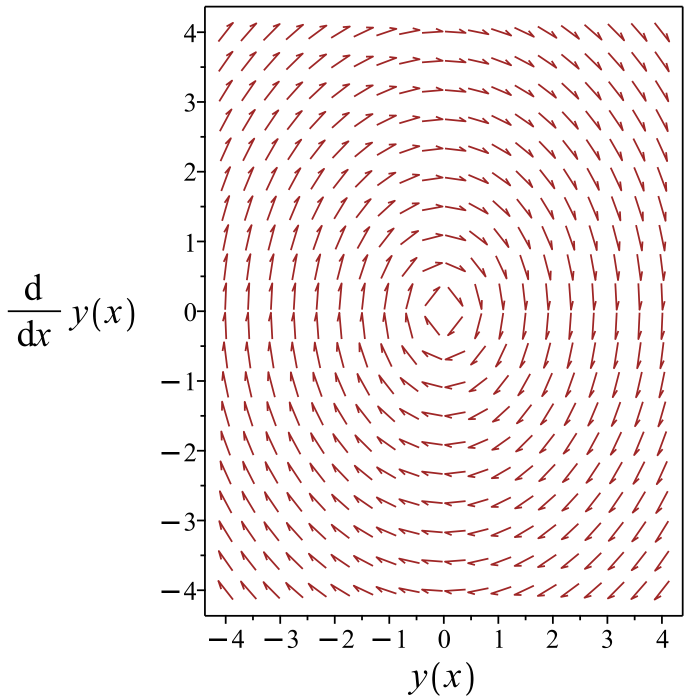

Figure 790: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + \cot(x)\cos(x)$$

Verified OK.

20.20.3 Maple step by step solution

Let's solve

$y'' + y = 2\csc(x)^3$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

- ☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 2\csc(x)^3\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -2\cos(x)\left(\int \csc(x)^2 dx\right) + 2\sin(x)\left(\int \csc(x)^2 \cot(x) dx\right)$

  - Compute integrals

    $y_p(x) = \cot(x)\cos(x)$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + \cot(x)\cos(x)$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + y' = e^{2x} \cos\left(e^{x}\right)}$$

20.21.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = 0, f(x) = e^{2x} \cos\left(e^{x}\right)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=1, B=1, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x}+\lambda \mathrm{e}^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2+\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=1, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{-1}{(2)(1)}\pm\frac{1}{(2)(1)}\sqrt{1^2-(4)(1)(0)}\\&=-\frac{1}{2}\pm\frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1&=-\frac{1}{2}+\frac{1}{2}\\\lambda_2&=-\frac{1}{2}-\frac{1}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1&=0\\\lambda_2&=-1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y&=c_1e^{\lambda_1x}+c_2e^{\lambda_2x}\\y&=c_1e^{(0)x}+c_2e^{(-1)x}\end{aligned}$$

Or

$$y = c_1 + e^{-x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + e^{-x} c_2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = 1$$
$$y_2 = e^{-x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & e^{-x} \\ \frac{d}{dx}(1) & \frac{d}{dx}(e^{-x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & e^{-x} \\ 0 & -e^{-x} \end{vmatrix}$$

Therefore

$$W = (1)\left(-\mathrm{e}^{-x}\right) - \left(\mathrm{e}^{-x}\right)(0)$$

Which simplifies to

$$W = -\mathrm{e}^{-x}$$

Which simplifies to

$$W = -\mathrm{e}^{-x}$$

Therefore Eq. (2) becomes

$$u_1 = -\left(\int \frac{\mathrm{e}^{-x}\mathrm{e}^{2x}\cos\left(\mathrm{e}^{x}\right)}{-\mathrm{e}^{-x}}dx\right)$$

Which simplifies to

$$u_1 = -\left(\int -\mathrm{e}^{2x}\cos\left(\mathrm{e}^{x}\right)dx\right)$$

Hence

$$u_1 = -\frac{-2\,\mathrm{e}^{x}\tan\left(\frac{\mathrm{e}^{x}}{2}\right) - 2}{1 + \tan\left(\frac{\mathrm{e}^{x}}{2}\right)^{2}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\mathrm{e}^{2x}\cos\left(\mathrm{e}^{x}\right)}{-\mathrm{e}^{-x}}dx$$

Which simplifies to

$$u_2 = \int -\cos\left(\mathrm{e}^{x}\right)\mathrm{e}^{3x}dx$$

Hence

$$u_2 = \frac{2\,\mathrm{e}^{x}\tan\left(\frac{\mathrm{e}^{x}}{2}\right)^{2} - 2\,\mathrm{e}^{2x}\tan\left(\frac{\mathrm{e}^{x}}{2}\right) - 2\,\mathrm{e}^{x} + 4\tan\left(\frac{\mathrm{e}^{x}}{2}\right)}{1 + \tan\left(\frac{\mathrm{e}^{x}}{2}\right)^{2}}$$

Which simplifies to

$$u_1 = 1 + \mathrm{e}^{x}\sin\left(\mathrm{e}^{x}\right) + \cos\left(\mathrm{e}^{x}\right)$$
$$u_2 = -\mathrm{e}^{2x}\sin\left(\mathrm{e}^{x}\right) - 2\,\mathrm{e}^{x}\cos\left(\mathrm{e}^{x}\right) + 2\sin\left(\mathrm{e}^{x}\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = 1 + e^x \sin(e^x) + \cos(e^x) + \left(-e^{2x}\sin(e^x) - 2\,e^x\cos(e^x) + 2\sin(e^x)\right)e^{-x}$$

Which simplifies to

$$y_p(x) = -\cos(e^x) + 2\sin(e^x)\,e^{-x} + 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + e^{-x}c_2\right) + \left(-\cos(e^x) + 2\sin(e^x)\,e^{-x} + 1\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + e^{-x}c_2 - \cos(e^x) + 2\sin(e^x)\,e^{-x} + 1 \tag{1}$$

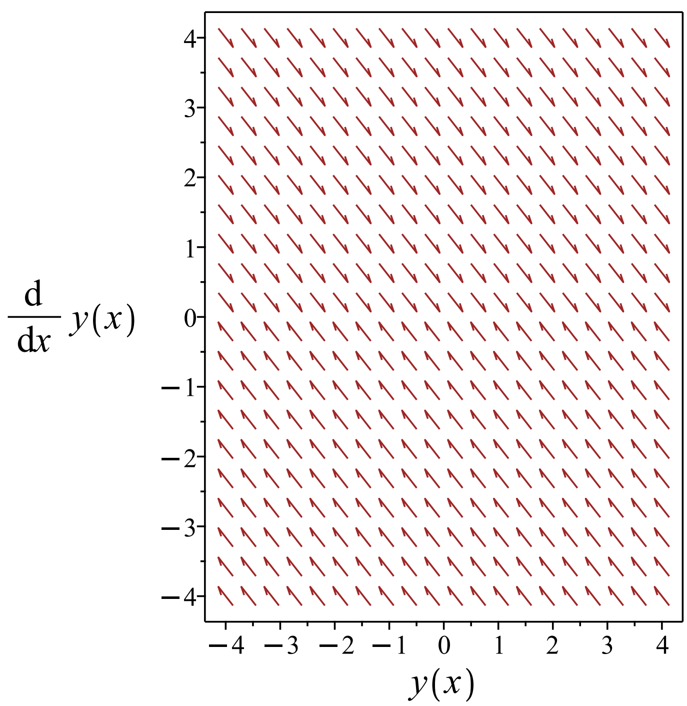

Figure 791: Slope field plot

Verification of solutions

$$y = c_1 + e^{-x}c_2 - \cos(e^x) + 2\sin(e^x)\,e^{-x} + 1$$

Verified OK.

20.21.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y''+y')\,dx = \int \mathrm{e}^{2x}\cos(\mathrm{e}^{x})\,dx$$

$$y'+y = \frac{2\,\mathrm{e}^{x}\tan\left(\frac{\mathrm{e}^{x}}{2}\right)+2}{1+\tan\left(\frac{\mathrm{e}^{x}}{2}\right)^{2}}+c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= 1\\ q(x) &= \mathrm{e}^{x}\sin(\mathrm{e}^{x})+\cos(\mathrm{e}^{x})+c_1+1\end{aligned}$$

Hence the ode is

$$y'+y = \mathrm{e}^{x}\sin(\mathrm{e}^{x})+\cos(\mathrm{e}^{x})+c_1+1$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int 1dx}\\ &= \mathrm{e}^{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\mathrm{e}^{x}\sin(\mathrm{e}^{x})+\cos(\mathrm{e}^{x})+c_1+1\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}(\mathrm{e}^{x}y) &= (\mathrm{e}^{x})\left(\mathrm{e}^{x}\sin(\mathrm{e}^{x})+\cos(\mathrm{e}^{x})+c_1+1\right)\\ \mathrm{d}(\mathrm{e}^{x}y) &= \left(\left(\mathrm{e}^{x}\sin(\mathrm{e}^{x})+\cos(\mathrm{e}^{x})+c_1+1\right)\mathrm{e}^{x}\right)\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\mathrm{e}^{x}y &= \int \left(\mathrm{e}^{x}\sin(\mathrm{e}^{x})+\cos(\mathrm{e}^{x})+c_1+1\right)\mathrm{e}^{x}\,\mathrm{d}x\\ \mathrm{e}^{x}y &= \mathrm{e}^{x}c_1+\mathrm{e}^{x}+2\sin(\mathrm{e}^{x})-\mathrm{e}^{x}\cos(\mathrm{e}^{x})+c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu=\mathrm{e}^{x}$ results in

$$y = \mathrm{e}^{-x}\left(\mathrm{e}^{x}c_1+\mathrm{e}^{x}+2\sin(\mathrm{e}^{x})-\mathrm{e}^{x}\cos(\mathrm{e}^{x})\right)+\mathrm{e}^{-x}c_2$$

which simplifies to

$$y = (c_2 + 2\sin(e^x))e^{-x} + c_1 - \cos(e^x) + 1$$

Summary

The solution(s) found are the following

$$y = (c_2 + 2\sin(e^x))e^{-x} + c_1 - \cos(e^x) + 1 \tag{1}$$

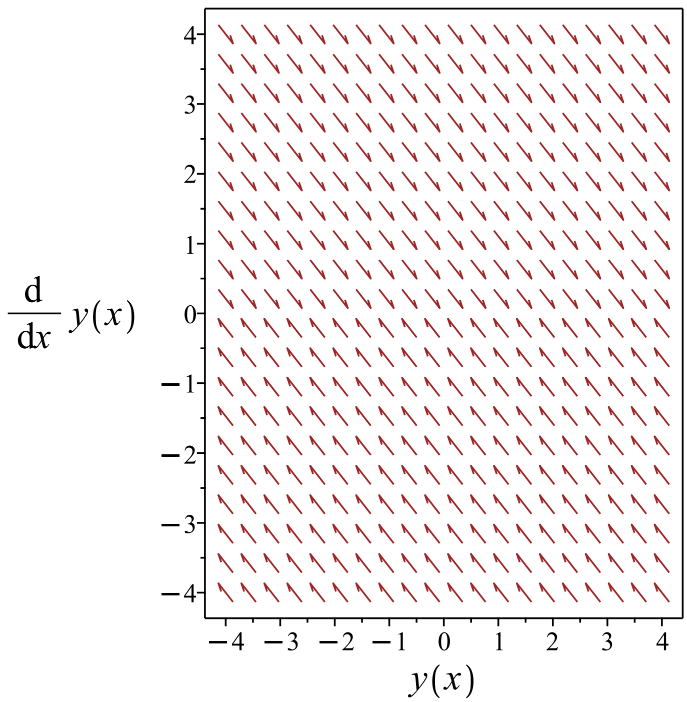

Figure 792: Slope field plot

Verification of solutions

$$y = (c_2 + 2\sin(e^x))e^{-x} + c_1 - \cos(e^x) + 1$$

Verified OK.

20.21.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + p(x) - e^{2x} \cos(e^x) = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= 1 \\ q(x) &= e^{2x} \cos(e^x) \end{aligned}$$

Hence the ode is

$$p'(x) + p(x) = e^{2x} \cos(e^x)$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 1 dx} \\ &= e^x \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu) \left(e^{2x} \cos(e^x)\right) \\ \frac{d}{dx}(e^x p) &= (e^x) \left(e^{2x} \cos(e^x)\right) \\ d(e^x p) &= \left(\cos(e^x) e^{3x}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^x p &= \int \cos(e^x) e^{3x} dx \\ e^x p &= \frac{-2 e^x \tan\left(\frac{e^x}{2}\right)^2 + 2 e^{2x} \tan\left(\frac{e^x}{2}\right) + 2 e^x - 4 \tan\left(\frac{e^x}{2}\right)}{1 + \tan\left(\frac{e^x}{2}\right)^2} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{x}$ results in

$$p(x) = \frac{\mathrm{e}^{-x}\left(-2\,\mathrm{e}^{x} \tan\left(\frac{\mathrm{e}^{x}}{2}\right)^{2}+2\,\mathrm{e}^{2x} \tan\left(\frac{\mathrm{e}^{x}}{2}\right)+2\,\mathrm{e}^{x}-4\tan\left(\frac{\mathrm{e}^{x}}{2}\right)\right)}{1+\tan\left(\frac{\mathrm{e}^{x}}{2}\right)^{2}}+c_1\mathrm{e}^{-x}$$

which simplifies to

$$p(x) = (c_1 - 2\sin(\mathrm{e}^{x}))\,\mathrm{e}^{-x}+\mathrm{e}^{x}\sin(\mathrm{e}^{x})+2\cos(\mathrm{e}^{x})$$

Since $p = y'$ then the new first order ode to solve is

$$y' = (c_1 - 2\sin(\mathrm{e}^{x}))\,\mathrm{e}^{-x}+\mathrm{e}^{x}\sin(\mathrm{e}^{x})+2\cos(\mathrm{e}^{x})$$

Integrating both sides gives

$$\begin{aligned}
y &= \int \mathrm{e}^{x}\sin(\mathrm{e}^{x})+2\cos(\mathrm{e}^{x})+c_1\mathrm{e}^{-x}-2\sin(\mathrm{e}^{x})\,\mathrm{e}^{-x}\,\mathrm{d}x \\
&= \frac{\left(-2\,\mathrm{e}^{x}-c_1-\tan\left(\frac{\mathrm{e}^{x}}{2}\right)^{2} c_1+4\tan\left(\frac{\mathrm{e}^{x}}{2}\right)\right)\mathrm{e}^{-x}}{1+\tan\left(\frac{\mathrm{e}^{x}}{2}\right)^{2}}+c_2
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{\left(-2\,\mathrm{e}^{x}-c_1-\tan\left(\frac{\mathrm{e}^{x}}{2}\right)^{2} c_1+4\tan\left(\frac{\mathrm{e}^{x}}{2}\right)\right)\mathrm{e}^{-x}}{1+\tan\left(\frac{\mathrm{e}^{x}}{2}\right)^{2}}+c_2 \tag{1}$$

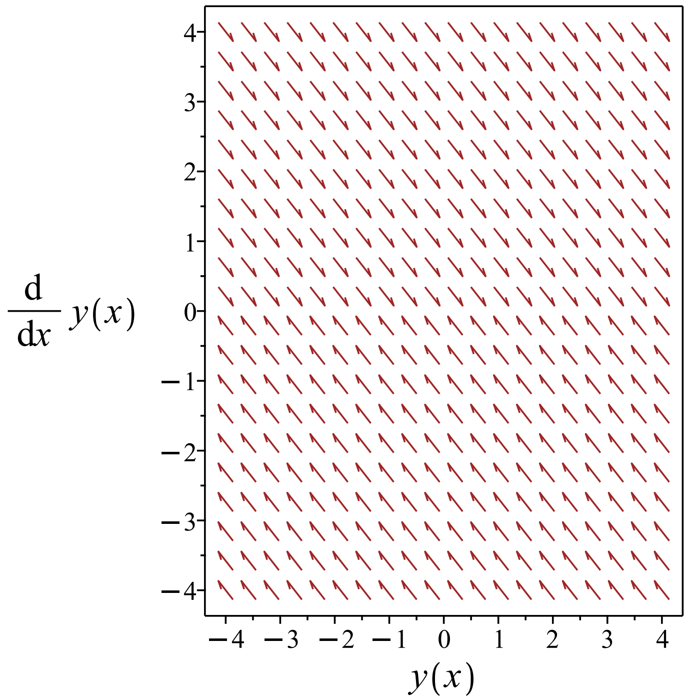

Figure 793: Slope field plot

Verification of solutions

$$y = \frac{\left(-2\,\mathrm{e}^{x} - c_1 - \tan\left(\frac{\mathrm{e}^{x}}{2}\right)^2 c_1 + 4\tan\left(\frac{\mathrm{e}^{x}}{2}\right)\right)\mathrm{e}^{-x}}{1+\tan\left(\frac{\mathrm{e}^{x}}{2}\right)^2} + c_2$$

Verified OK.

20.21.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + y' = \mathrm{e}^{2x}\cos\left(\mathrm{e}^{x}\right)$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(y'' + y'\right) dx = \int \mathrm{e}^{2x}\cos\left(\mathrm{e}^{x}\right) dx$$

$$y' + y = \frac{2\,\mathrm{e}^{x}\tan\left(\frac{\mathrm{e}^{x}}{2}\right) + 2}{1+\tan\left(\frac{\mathrm{e}^{x}}{2}\right)^2} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}
p(x) &= 1 \\
q(x) &= e^x \sin(e^x) + \cos(e^x) + c_1 + 1
\end{aligned}$$

Hence the ode is

$$y' + y = e^x \sin(e^x) + \cos(e^x) + c_1 + 1$$

The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int 1dx} \\
&= e^x
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(e^x \sin(e^x) + \cos(e^x) + c_1 + 1\right) \\
\frac{d}{dx}(e^x y) &= (e^x)\left(e^x \sin(e^x) + \cos(e^x) + c_1 + 1\right) \\
d(e^x y) &= \left(\left(e^x \sin(e^x) + \cos(e^x) + c_1 + 1\right) e^x\right) dx
\end{aligned}$$

Integrating gives

$$\begin{aligned}
e^x y &= \int \left(e^x \sin(e^x) + \cos(e^x) + c_1 + 1\right) e^x \, dx \\
e^x y &= e^x c_1 + e^x + 2\sin(e^x) - e^x \cos(e^x) + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^x$ results in

$$y = e^{-x}\left(e^x c_1 + e^x + 2\sin(e^x) - e^x \cos(e^x)\right) + e^{-x} c_2$$

which simplifies to

$$y = (c_2 + 2\sin(e^x))\, e^{-x} + c_1 - \cos(e^x) + 1$$

Summary

The solution(s) found are the following

$$y = (c_2 + 2\sin(e^x))\, e^{-x} + c_1 - \cos(e^x) + 1 \tag{1}$$

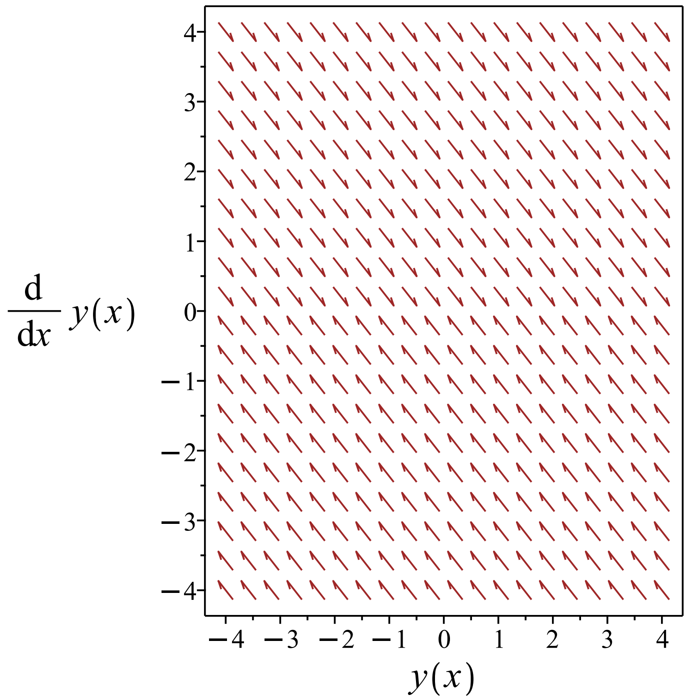

Figure 794: Slope field plot

<u>Verification of solutions</u>

$$y = (c_2 + 2\sin(e^x))\,e^{-x} + c_1 - \cos(e^x) + 1$$

Verified OK.

20.21.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$A = 1$$
$$B = 1 \tag{3}$$
$$C = 0$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 657: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\,dx} \\ &= z_1 e^{-\frac{x}{2}} \\ &= z_1\left(\mathrm{e}^{-\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{1}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-x}}{(y_1)^2}\,dx \\ &= y_1(\mathrm{e}^{x}) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(\mathrm{e}^{x}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + y' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-x} + c_2
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \mathrm{e}^{-x} \\
y_2 &= 1
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-x} & 1 \\ \frac{d}{dx}\left(e^{-x}\right) & \frac{d}{dx}(1) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-x} & 1 \\ -e^{-x} & 0 \end{vmatrix}$$

Therefore

$$W = \left(e^{-x}\right)(0) - (1)\left(-e^{-x}\right)$$

Which simplifies to

$$W = e^{-x}$$

Which simplifies to

$$W = e^{-x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{e^{2x} \cos\left(e^x\right)}{e^{-x}}\, dx$$

Which simplifies to

$$u_1 = -\int \cos\left(e^x\right) e^{3x} dx$$

Hence

$$u_1 = -\frac{-2\, e^x \tan\left(\frac{e^x}{2}\right)^2 + 2\, e^{2x} \tan\left(\frac{e^x}{2}\right) + 2\, e^x - 4 \tan\left(\frac{e^x}{2}\right)}{1 + \tan\left(\frac{e^x}{2}\right)^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{-x} e^{2x} \cos\left(e^x\right)}{e^{-x}}\, dx$$

Which simplifies to

$$u_2 = \int e^{2x} \cos(e^x) \, dx$$

Hence

$$u_2 = \frac{2\,e^x \tan\left(\frac{e^x}{2}\right) + 2}{1 + \tan\left(\frac{e^x}{2}\right)^2}$$

Which simplifies to

$$\begin{aligned} u_1 &= -e^{2x} \sin(e^x) - 2\,e^x \cos(e^x) + 2\sin(e^x) \\ u_2 &= 1 + e^x \sin(e^x) + \cos(e^x) \end{aligned}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = 1 + e^x \sin(e^x) + \cos(e^x) + \left(-e^{2x} \sin(e^x) - 2\,e^x \cos(e^x) + 2\sin(e^x)\right) e^{-x}$$

Which simplifies to

$$y_p(x) = -\cos(e^x) + 2\sin(e^x)\,e^{-x} + 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2\right) + \left(-\cos(e^x) + 2\sin(e^x)\,e^{-x} + 1\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 - \cos(e^x) + 2\sin(e^x)\,e^{-x} + 1 \tag{1}$$

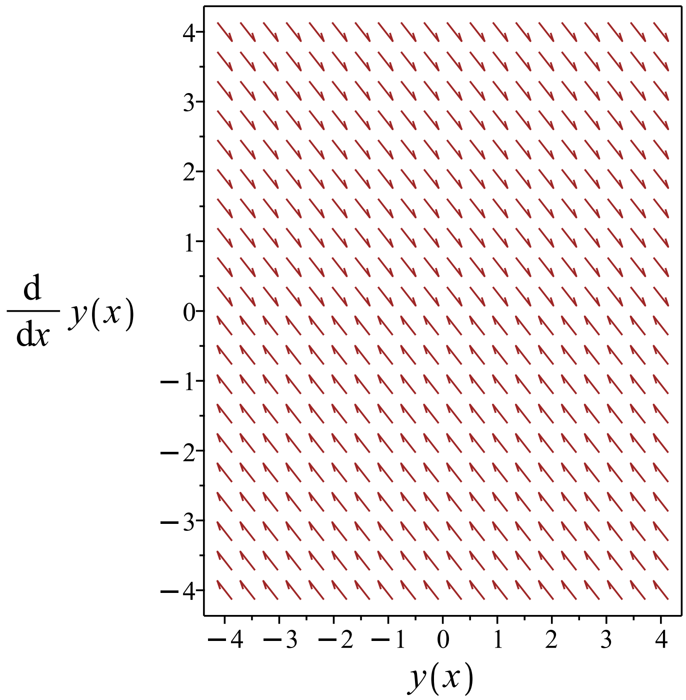

Figure 795: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + c_2 - \cos(e^x) + 2\sin(e^x)\,e^{-x} + 1$$

Verified OK.

20.21.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 1 \\ r(x) &= 0 \\ s(x) &= e^{2x}\cos(e^x) \end{aligned}$$

Hence

$$p''(x) = 0$$
$$q'(x) = 0$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$y' + y = \int e^{2x} \cos(e^{x})\, dx$$

We now have a first order ode to solve which is

$$y' + y = \frac{2\, e^{x} \tan\left(\frac{e^{x}}{2}\right) + 2}{1 + \tan\left(\frac{e^{x}}{2}\right)^{2}} + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 1$$
$$q(x) = e^{x} \sin(e^{x}) + \cos(e^{x}) + c_1 + 1$$

Hence the ode is

$$y' + y = e^{x} \sin(e^{x}) + \cos(e^{x}) + c_1 + 1$$

The integrating factor μ is

$$\mu = e^{\int 1 dx}$$
$$= e^{x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(e^{x} \sin\left(e^{x}\right)+\cos\left(e^{x}\right)+c_1+1\right)$$
$$\frac{d}{dx}\left(e^{x} y\right) = \left(e^{x}\right)\left(e^{x} \sin\left(e^{x}\right)+\cos\left(e^{x}\right)+c_1+1\right)$$
$$d\left(e^{x} y\right) = \left(\left(e^{x} \sin\left(e^{x}\right)+\cos\left(e^{x}\right)+c_1+1\right) e^{x}\right)\,dx$$

Integrating gives

$$e^{x} y = \int \left(e^{x} \sin\left(e^{x}\right)+\cos\left(e^{x}\right)+c_1+1\right) e^{x}\,dx$$
$$e^{x} y = e^{x} c_1 + e^{x} + 2\sin\left(e^{x}\right) - e^{x}\cos\left(e^{x}\right) + c_2$$

Dividing both sides by the integrating factor $\mu = e^{x}$ results in

$$y = e^{-x}\left(e^{x} c_1 + e^{x} + 2\sin\left(e^{x}\right) - e^{x}\cos\left(e^{x}\right)\right) + e^{-x} c_2$$

which simplifies to

$$y = \left(c_2 + 2\sin\left(e^{x}\right)\right) e^{-x} + c_1 - \cos\left(e^{x}\right) + 1$$

Summary

The solution(s) found are the following

$$y = \left(c_2 + 2\sin\left(e^{x}\right)\right) e^{-x} + c_1 - \cos\left(e^{x}\right) + 1 \tag{1}$$

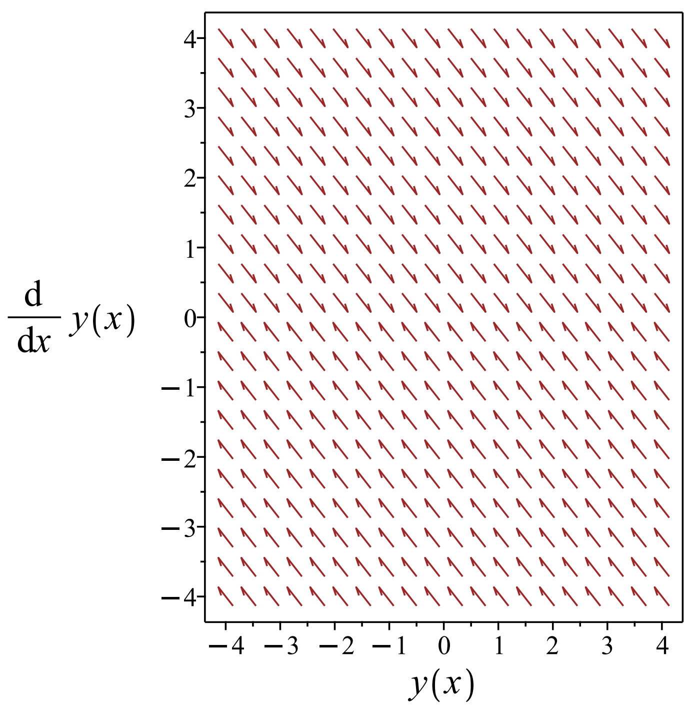

Figure 796: Slope field plot

Verification of solutions

$$y = (c_2 + 2\sin(e^x))\,e^{-x} + c_1 - \cos(e^x) + 1$$

Verified OK.

20.21.7 Maple step by step solution

Let's solve

$y'' + y' = e^{2x}\cos(e^x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + r = 0$

- Factor the characteristic polynomial

  $r(r+1) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 0)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-x} + c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = e^{2x}\cos(e^x)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x} & 1 \\ -e^{-x} & 0 \end{bmatrix}$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{-x}$

- Substitute functions into equation for $y_p(x)$

  $y_p(x) = -e^{-x}\left(\int \cos(e^x) e^{3x} dx\right) + \int e^{2x} \cos(e^x) dx$

- Compute integrals

  $y_p(x) = -\cos(e^x) + 2\sin(e^x) e^{-x} + 1$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-x} + c_2 - \cos(e^x) + 2\sin(e^x) e^{-x} + 1$

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' + y'' = \frac{x - 1}{x^3}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + y'' = 0$$

The characteristic equation is

$$\lambda^3 + \lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = -1$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 + c_3 x$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= e^{-x} \\ y_2 &= 1 \\ y_3 &= x \end{aligned}$$

Now the particular solution to the given ODE is found

$$y''' + y'' = \frac{x-1}{x^3}$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)} \, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} e^{-x} & 1 & x \\ -e^{-x} & 0 & 1 \\ e^{-x} & 0 & 0 \end{bmatrix}$$

$$|W| = e^{-x}$$

The determinant simplifies to

$$|W| = e^{-x}$$

Now we determine W_i for each U_i.

$$\begin{aligned} W_1(x) &= \det \begin{bmatrix} 1 & x \\ 0 & 1 \end{bmatrix} \\ &= 1 \end{aligned}$$

$$\begin{aligned} W_2(x) &= \det \begin{bmatrix} e^{-x} & x \\ -e^{-x} & 1 \end{bmatrix} \\ &= e^{-x}(x+1) \end{aligned}$$

$$\begin{aligned} W_3(x) &= \det \begin{bmatrix} e^{-x} & 1 \\ -e^{-x} & 0 \end{bmatrix} \\ &= e^{-x} \end{aligned}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned} U_1 &= (-1)^{3-1} \int \frac{F(x) W_1(x)}{a W(x)} \, dx \\ &= (-1)^2 \int \frac{\left(\frac{x-1}{x^3}\right)(1)}{(1)\left(e^{-x}\right)} \, dx \\ &= \int \frac{\frac{x-1}{x^3}}{e^{-x}} \, dx \\ &= \int \left(\frac{(x-1)\, e^x}{x^3}\right) dx \\ &= -\frac{e^x}{2x} - \frac{\text{expIntegral}_1(-x)}{2} + \frac{e^x}{2x^2} \end{aligned}$$

$$
\begin{aligned}
U_2 &= (-1)^{3-2} \int \frac{F(x)W_2(x)}{aW(x)}\,dx \\
&= (-1)^1 \int \frac{\left(\frac{x-1}{x^3}\right)\left(\mathrm{e}^{-x}(x+1)\right)}{(1)\left(\mathrm{e}^{-x}\right)}\,dx \\
&= -\int \frac{\frac{(x-1)\mathrm{e}^{-x}(x+1)}{x^3}}{\mathrm{e}^{-x}}\,dx \\
&= -\int \left(\frac{x^2-1}{x^3}\right)dx \\
&= -\frac{1}{2x^2} - \ln(x)
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{3-3} \int \frac{F(x)W_3(x)}{aW(x)}\,dx \\
&= (-1)^0 \int \frac{\left(\frac{x-1}{x^3}\right)\left(\mathrm{e}^{-x}\right)}{(1)\left(\mathrm{e}^{-x}\right)}\,dx \\
&= \int \frac{\frac{(x-1)\mathrm{e}^{-x}}{x^3}}{\mathrm{e}^{-x}}\,dx \\
&= \int \left(\frac{x-1}{x^3}\right)dx \\
&= \frac{1}{2x^2} - \frac{1}{x}
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Hence

$$
\begin{aligned}
y_p = &\left(-\frac{\mathrm{e}^{x}}{2x} - \frac{\text{expIntegral}_1(-x)}{2} + \frac{\mathrm{e}^{x}}{2x^2}\right)\left(\mathrm{e}^{-x}\right) \\
&+ \left(-\frac{1}{2x^2} - \ln(x)\right) \\
&+ \left(\frac{1}{2x^2} - \frac{1}{x}\right)(x)
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = -\frac{\text{expIntegral}_1(-x)\,\mathrm{e}^{-x}}{2} - \ln(x) - 1
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \mathrm{e}^{-x} + c_2 + c_3 x\right) + \left(-\frac{\text{expIntegral}_1(-x)\,\mathrm{e}^{-x}}{2} - \ln(x) - 1\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-x} + c_2 + c_3 x - \frac{\mathrm{expIntegral}_1(-x)\,\mathrm{e}^{-x}}{2} - \ln(x) - 1 \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-x} + c_2 + c_3 x - \frac{\mathrm{expIntegral}_1(-x)\,\mathrm{e}^{-x}}{2} - \ln(x) - 1$$

Verified OK.

20.22.1 Maple step by step solution

Let's solve

$y''' + y'' = \frac{x-1}{x^3}$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = -\frac{y_3(x)x^3 - x + 1}{x^3}$

  Convert linear ODE into a system of first order ODEs

  $\left[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = -\frac{y_3(x)x^3 - x + 1}{x^3}\right]$

- Define vector

  $\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & -1 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & -1 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[0, \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = e^{-x} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 0, \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{y} = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 e^{-x} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix} + \begin{bmatrix} c_2 \\ 0 \\ 0 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = c_1 e^{-x} + c_2$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_ode_missing_y"**

Maple gives the following as the ode type

`[[_2nd_order, _missing_y]]`

$$\boxed{xy'' - (2x^2+1)\, y' = 4x^3 \mathrm{e}^{x^2}}$$

20.23.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$xp'(x) + (-2x^2-1)\, p(x) - 4x^3 \mathrm{e}^{x^2} = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned}p(x) &= -\frac{2x^2+1}{x}\\ q(x) &= 4x^2 e^{x^2}\end{aligned}$$

Hence the ode is

$$p'(x) - \frac{(2x^2+1)\, p(x)}{x} = 4x^2 e^{x^2}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{2x^2+1}{x}dx}\\ &= e^{-x^2-\ln(x)}\end{aligned}$$

Which simplifies to

$$\mu = \frac{e^{-x^2}}{x}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu p) &= (\mu)\left(4x^2 e^{x^2}\right)\\ \frac{d}{dx}\left(\frac{e^{-x^2} p}{x}\right) &= \left(\frac{e^{-x^2}}{x}\right)\left(4x^2 e^{x^2}\right)\\ d\left(\frac{e^{-x^2} p}{x}\right) &= (4x)\ dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{e^{-x^2} p}{x} &= \int 4x\, dx\\ \frac{e^{-x^2} p}{x} &= 2x^2 + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{e^{-x^2}}{x}$ results in

$$p(x) = 2x^3 e^{x^2} + c_1 x\, e^{x^2}$$

which simplifies to

$$p(x) = e^{x^2} x(2x^2 + c_1)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = e^{x^2} x(2x^2 + c_1)$$

Integrating both sides gives

$$\begin{aligned} y &= \int e^{x^2} x(2x^2 + c_1) \, dx \\ &= \frac{(2x^2 + c_1 - 2) e^{x^2}}{2} + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{(2x^2 + c_1 - 2) e^{x^2}}{2} + c_2 \tag{1}$$

Verification of solutions

$$y = \frac{(2x^2 + c_1 - 2) e^{x^2}}{2} + c_2$$

Verified OK.

20.23.2 Solving using Kovacic algorithm

Writing the ode as

$$xy'' + (-2x^2 - 1) y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= -2x^2 - 1 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^4 + 3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^4 + 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^4 + 3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 660: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = x^2 + \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx x + \frac{3}{8x^3} - \frac{9}{128x^7} + \frac{27}{1024x^{11}} - \frac{405}{32768x^{15}} + \frac{1701}{262144x^{19}} - \frac{15309}{4194304x^{23}} + \frac{72171}{33554432x^{27}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= x \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = x^2$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^4 + 3}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= (x^2) + \left(\frac{3}{4x^2}\right) \\ &= x^2 + \frac{3}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= x \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a}-v\right) &&= \frac{1}{2}\left(\frac{0}{1}-1\right) &&= -\frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a}-v\right) &&= \frac{1}{2}\left(-\frac{0}{1}-1\right) &&= -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{4x^4+3}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	x	$-\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{2x} + (-)(x) \\
&= -\frac{1}{2x} - x \\
&= -\frac{1}{2x} - x
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{2x} - x\right)(0) + \left(\left(\frac{1}{2x^2} - 1\right) + \left(-\frac{1}{2x} - x\right)^2 - \left(\frac{4x^4 + 3}{4x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2x} - x\right) dx} \\
&= \frac{\mathrm{e}^{-\frac{x^2}{2}}}{\sqrt{x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-2x^2 - 1}{x} \, dx} \\
&= z_1 e^{\frac{x^2}{2} + \frac{\ln(x)}{2}} \\
&= z_1 \left(\sqrt{x}\, \mathrm{e}^{\frac{x^2}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x^2-1}{x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{x^2+\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{e^{x^2}}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2 \left(1\left(\frac{e^{x^2}}{2}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$xy'' + \left(-2x^2 - 1\right) y' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 + \frac{c_2 e^{x^2}}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = 1$$

$$y_2 = \frac{e^{x^2}}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & \frac{e^{x^2}}{2} \\ \frac{d}{dx}(1) & \frac{d}{dx}\left(\frac{e^{x^2}}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & \frac{e^{x^2}}{2} \\ 0 & x\,e^{x^2} \end{vmatrix}$$

Therefore

$$W = (1)\left(x\,e^{x^2}\right) - \left(\frac{e^{x^2}}{2}\right)(0)$$

Which simplifies to

$$W = x\,e^{x^2}$$

Which simplifies to

$$W = x\,e^{x^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2\,e^{2x^2} x^3}{x^2 e^{x^2}}\,dx$$

Which simplifies to

$$u_1 = -\int 2x\,e^{x^2}\,dx$$

Hence

$$u_1 = -e^{x^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{4x^3 e^{x^2}}{x^2 e^{x^2}}\,dx$$

Which simplifies to

$$u_2 = \int 4x dx$$

Hence

$$u_2 = 2x^2$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -e^{x^2} + x^2 e^{x^2}$$

Which simplifies to

$$y_p(x) = e^{x^2}\left(x^2 - 1\right)$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 + \frac{c_2 \mathrm{e}^{x^2}}{2}\right) + \left(\mathrm{e}^{x^2} \left(x^2 - 1\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 + \frac{c_2 \mathrm{e}^{x^2}}{2} + \mathrm{e}^{x^2} \left(x^2 - 1\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 + \frac{c_2 \mathrm{e}^{x^2}}{2} + \mathrm{e}^{x^2} \left(x^2 - 1\right)
$$

Verified OK.

20.23.3 Maple step by step solution

Let's solve

$xy'' + (-2x^2 - 1)\, y' = 4x^3 \mathrm{e}^{x^2}$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $xu'(x) + (-2x^2 - 1)\, u(x) = 4x^3 \mathrm{e}^{x^2}$

- Isolate the derivative

  $u'(x) = \frac{(2x^2+1)u(x)}{x} + 4x^2 \mathrm{e}^{x^2}$

- Group terms with $u(x)$ on the lhs of the ODE and the rest on the rhs of the ODE

  $u'(x) - \frac{(2x^2+1)u(x)}{x} = 4x^2 \mathrm{e}^{x^2}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x) \left(u'(x) - \frac{(2x^2+1)u(x)}{x}\right) = 4\mu(x)\, x^2 \mathrm{e}^{x^2}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, u(x))$

  $\mu(x) \left(u'(x) - \frac{(2x^2+1)u(x)}{x}\right) = \mu'(x)\, u(x) + \mu(x)\, u'(x)$

- Isolate $\mu'(x)$

  $\mu'(x) = -\frac{\mu(x)(2x^2+1)}{x}$
- Solve to find the integrating factor

  $\mu(x) = \frac{\mathrm{e}^{-x^2}}{x}$
- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x) u(x))\right) dx = \int 4\mu(x) x^2 \mathrm{e}^{x^2} dx + c_1$
- Evaluate the integral on the lhs

  $\mu(x) u(x) = \int 4\mu(x) x^2 \mathrm{e}^{x^2} dx + c_1$
- Solve for $u(x)$

  $u(x) = \frac{\int 4\mu(x)x^2\mathrm{e}^{x^2} dx + c_1}{\mu(x)}$
- Substitute $\mu(x) = \frac{\mathrm{e}^{-x^2}}{x}$

  $u(x) = \frac{x\left(\int 4x\,\mathrm{e}^{x^2}\mathrm{e}^{-x^2} dx + c_1\right)}{\mathrm{e}^{-x^2}}$
- Evaluate the integrals on the rhs

  $u(x) = \frac{x(2x^2+c_1)}{\mathrm{e}^{-x^2}}$
- Simplify

  $u(x) = \mathrm{e}^{x^2} x(2x^2 + c_1)$
- Solve 1st ODE for $u(x)$

  $u(x) = \mathrm{e}^{x^2} x(2x^2 + c_1)$
- Make substitution $u = y'$

  $y' = \mathrm{e}^{x^2} x(2x^2 + c_1)$
- Integrate both sides to solve for y

  $\int y' dx = \int \mathrm{e}^{x^2} x(2x^2 + c_1)\, dx + c_2$
- Compute integrals

  $y = \frac{(2x^2+c_1-2)\mathrm{e}^{x^2}}{2} + c_2$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.5 Linear equations with variable coefficients. The Lagrange method. Exercises page 148
Problem number: 663.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_ode_missing_y", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' - 2y' \tan(x) = 1}$$

20.24.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - 2p(x) \tan(x) - 1 = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -2\tan(x) \\ q(x) &= 1 \end{aligned}$$

Hence the ode is

$$p'(x) - 2p(x)\tan(x) = 1$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int -2\tan(x)dx} \\ &= \cos(x)^2 \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu p) &= \mu \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\cos(x)^2 p\right) &= \cos(x)^2 \\ \mathrm{d}\left(\cos(x)^2 p\right) &= \cos(x)^2 \,\mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} \cos(x)^2 p &= \int \cos(x)^2 \,\mathrm{d}x \\ \cos(x)^2 p &= \frac{\cos(x)\sin(x)}{2} + \frac{x}{2} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \cos(x)^2$ results in

$$p(x) = \sec(x)^2 \left(\frac{\cos(x)\sin(x)}{2} + \frac{x}{2}\right) + c_1 \sec(x)^2$$

which simplifies to

$$p(x) = \frac{(2c_1 + x)\sec(x)^2}{2} + \frac{\tan(x)}{2}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{(2c_1 + x)\sec(x)^2}{2} + \frac{\tan(x)}{2}$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int \frac{\tan(x)}{2} + c_1 \sec(x)^2 + \frac{\sec(x)^2 x}{2} \, \mathrm{d}x \\
&= \frac{\tan(x) x}{2} + c_1 \tan(x) + c_2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{\tan(x) x}{2} + c_1 \tan(x) + c_2 \tag{1}
$$

Verification of solutions

$$
y = \frac{\tan(x) x}{2} + c_1 \tan(x) + c_2
$$

Verified OK.

20.24.2 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$
Ay'' + By' + Cy = F(x)
$$

This method reduces the order ode the ODE by one by applying the transformation

$$
y = Bv
$$

This results in

$$
\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}
$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + (2AB' + B^2) v' + (AB'' + BB' + CB) v &= 0
\end{aligned} \tag{1}
$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$
ABv'' + (2AB' + B^2) v' = 0
$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$AB u' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned}
A &= 1 \\
B &= -2\tan(x) \\
C &= 0 \\
F &= 1
\end{aligned}$$

The above shows that for this ode

$$\begin{aligned}
AB'' + BB' + CB &= (1)\left(-4\tan(x)\left(1+\tan(x)^2\right)\right) + (-2\tan(x))\left(-2-2\tan(x)^2\right) + (0)(-2\tan(x)) \\
&= -4\tan(x)\left(1+\tan(x)^2\right) - 2\tan(x)\left(-2-2\tan(x)^2\right) \\
&= 0
\end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$-2\tan(x)\, v'' + (-4)\, v' = 0$$

Now by applying $v' = u$ the above becomes

$$-2\tan(x)\, u'(x) - 4u(x) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= -\frac{2u}{\tan(x)}
\end{aligned}$$

Where $f(x) = -\frac{2}{\tan(x)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\, du &= -\frac{2}{\tan(x)}\, dx \\
\int \frac{1}{u}\, du &= \int -\frac{2}{\tan(x)}\, dx \\
\ln(u) &= -2\ln(\sin(x)) + c_1 \\
u &= e^{-2\ln(\sin(x)) + c_1} \\
&= \frac{c_1}{\sin(x)^2}
\end{aligned}$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= \frac{c_1}{\sin(x)^2}
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int \frac{c_1}{\sin(x)^2}\, \mathrm{d}x \\
&= -c_1 \cot(x) + c_2
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= Bv \\
&= (-2\tan(x))\,(-c_1 \cot(x) + c_2) \\
&= 2c_1 - 2\tan(x)\, c_2
\end{aligned}
$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= 2 \\
y_2 &= \tan(x)
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 2 & \tan(x) \\ \frac{d}{dx}(2) & \frac{d}{dx}(\tan(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 2 & \tan(x) \\ 0 & 1 + \tan(x)^2 \end{vmatrix}$$

Therefore

$$W = (2)\left(1 + \tan(x)^2\right) - (\tan(x))(0)$$

Which simplifies to

$$W = 2 + 2\tan(x)^2$$

Which simplifies to

$$W = 2\sec(x)^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\tan(x)}{2\sec(x)^2}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(2x)}{4} dx$$

Hence

$$u_1 = \frac{\cos(2x)}{8}$$

And Eq. (3) becomes

$$u_2 = \int \frac{2}{2\sec(x)^2}\, dx$$

Which simplifies to

$$u_2 = \int \cos(x)^2 \, dx$$

Hence

$$u_2 = \frac{\cos(x)\sin(x)}{2} + \frac{x}{2}$$

Which simplifies to

$$u_1 = \frac{\cos(2x)}{8}$$

$$u_2 = \frac{\sin(2x)}{4} + \frac{x}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\cos(2x)}{4} + \left(\frac{\sin(2x)}{4} + \frac{x}{2}\right)\tan(x)$$

Which simplifies to

$$y_p(x) = \frac{1}{4} + \frac{\tan(x)\, x}{2}$$

Hence the complete solution is

$$\begin{aligned} y(x) &= y_h + y_p \\ &= (2c_1 - 2\tan(x)\, c_2) + \left(\frac{1}{4} + \frac{\tan(x)\, x}{2}\right) \\ &= \frac{(-8c_2 + 2x)\tan(x)}{4} + 2c_1 + \frac{1}{4} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{(-8c_2 + 2x)\tan(x)}{4} + 2c_1 + \frac{1}{4} \tag{1}$$

Verification of solutions

$$y = \frac{(-8c_2 + 2x)\tan(x)}{4} + 2c_1 + \frac{1}{4}$$

Verified OK.

20.24.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' \tan(x) = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2\tan(x) \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 662: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}
$$

$$
\begin{aligned}
&= z_1 e^{-\int \frac{1}{2} \frac{-2\tan(x)}{1}\, dx} \\
&= z_1 e^{-\ln(\cos(x))} \\
&= z_1(\sec(x))
\end{aligned}
$$

Which simplifies to

$$
y_1 = 1
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2\tan(x)}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-2\ln(\cos(x))}}{(y_1)^2}\, dx \\
&= y_1(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2(1(\tan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y'\tan(x) = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 + \tan(x)\, c_2
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = 1$$
$$y_2 = \tan(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & \tan(x) \\ \frac{d}{dx}(1) & \frac{d}{dx}(\tan(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & \tan(x) \\ 0 & 1 + \tan(x)^2 \end{vmatrix}$$

Therefore

$$W = (1)\left(1 + \tan(x)^2\right) - (\tan(x))(0)$$

Which simplifies to

$$W = 1 + \tan(x)^2$$

Which simplifies to

$$W = \sec(x)^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\tan(x)}{\sec(x)^2} dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(2x)}{2} dx$$

Hence

$$u_1 = \frac{\cos(2x)}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{1}{\sec(x)^2} dx$$

Which simplifies to

$$u_2 = \int \cos(x)^2 dx$$

Hence

$$u_2 = \frac{\cos(x)\sin(x)}{2} + \frac{x}{2}$$

Which simplifies to

$$u_1 = \frac{\cos(2x)}{4}$$

$$u_2 = \frac{\sin(2x)}{4} + \frac{x}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\cos(2x)}{4} + \left(\frac{\sin(2x)}{4} + \frac{x}{2}\right)\tan(x)$$

Which simplifies to

$$y_p(x) = \frac{1}{4} + \frac{\tan(x)\, x}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 + \tan(x)\, c_2) + \left(\frac{1}{4} + \frac{\tan(x)\, x}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + \tan(x)\, c_2 + \frac{1}{4} + \frac{\tan(x)\, x}{2} \tag{1}$$

Verification of solutions

$$y = c_1 + \tan(x)\, c_2 + \frac{1}{4} + \frac{\tan(x)\, x}{2}$$

Verified OK.

20.24.4 Maple step by step solution

Let's solve

$y'' - 2y' \tan(x) = 1$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) - 2u(x) \tan(x) = 1$

- Isolate the derivative

  $u'(x) = 2u(x) \tan(x) + 1$

- Group terms with $u(x)$ on the lhs of the ODE and the rest on the rhs of the ODE

  $u'(x) - 2u(x) \tan(x) = 1$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x) (u'(x) - 2u(x) \tan(x)) = \mu(x)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, u(x))$

$$\mu(x)\left(u'(x)-2u(x)\tan(x)\right)=\mu'(x)\,u(x)+\mu(x)\,u'(x)$$

- Isolate $\mu'(x)$

$$\mu'(x)=-2\mu(x)\tan(x)$$

- Solve to find the integrating factor

$$\mu(x)=\cos(x)^2$$

- Integrate both sides with respect to x

$$\int\left(\frac{d}{dx}(\mu(x)\,u(x))\right)dx=\int\mu(x)\,dx+c_1$$

- Evaluate the integral on the lhs

$$\mu(x)\,u(x)=\int\mu(x)\,dx+c_1$$

- Solve for $u(x)$

$$u(x)=\frac{\int\mu(x)dx+c_1}{\mu(x)}$$

- Substitute $\mu(x)=\cos(x)^2$

$$u(x)=\frac{\int\cos(x)^2dx+c_1}{\cos(x)^2}$$

- Evaluate the integrals on the rhs

$$u(x)=\frac{\frac{\cos(x)\sin(x)}{2}+\frac{x}{2}+c_1}{\cos(x)^2}$$

- Simplify

$$u(x)=\frac{(2c_1+x)\sec(x)^2}{2}+\frac{\tan(x)}{2}$$

- Solve 1st ODE for $u(x)$

$$u(x)=\frac{(2c_1+x)\sec(x)^2}{2}+\frac{\tan(x)}{2}$$

- Make substitution $u=y'$

$$y'=\frac{(2c_1+x)\sec(x)^2}{2}+\frac{\tan(x)}{2}$$

- Integrate both sides to solve for y

$$\int y'dx=\int\left(\frac{(2c_1+x)\sec(x)^2}{2}+\frac{\tan(x)}{2}\right)dx+c_2$$

- Compute integrals

$$y=\frac{\tan(x)x}{2}+c_1\tan(x)+c_2$$

The type(s) of ODE detected by this program : **"second_order_ode_missing_y", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{x \ln(x) y'' - y' = \ln(x)^2}$$

20.25.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$x \ln(x) p'(x) - p(x) - \ln(x)^2 = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1}{x \ln(x)} \\ q(x) &= \frac{\ln(x)}{x} \end{aligned}$$

Hence the ode is

$$p'(x) - \frac{p(x)}{x \ln(x)} = \frac{\ln(x)}{x}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int -\frac{1}{x \ln(x)} dx} \\ &= \frac{1}{\ln(x)} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu) \left(\frac{\ln(x)}{x}\right) \\ \frac{d}{dx}\left(\frac{p}{\ln(x)}\right) &= \left(\frac{1}{\ln(x)}\right) \left(\frac{\ln(x)}{x}\right) \\ d\left(\frac{p}{\ln(x)}\right) &= \frac{1}{x} dx \end{aligned}$$

Integrating gives

$$\begin{aligned} \frac{p}{\ln(x)} &= \int \frac{1}{x} dx \\ \frac{p}{\ln(x)} &= \ln(x) + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{\ln(x)}$ results in

$$p(x) = \ln(x)^2 + c_1 \ln(x)$$

which simplifies to

$$p(x) = \ln(x) (\ln(x) + c_1)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \ln(x)(\ln(x) + c_1)$$

Integrating both sides gives

$$\begin{aligned}
y &= \int \ln(x)(\ln(x) + c_1) \, \mathrm{d}x \\
&= x \ln(x)^2 - 2x \ln(x) + 2x + c_1(x \ln(x) - x) + c_2
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = x \ln(x)^2 - 2x \ln(x) + 2x + c_1(x \ln(x) - x) + c_2 \tag{1}$$

Verification of solutions

$$y = x \ln(x)^2 - 2x \ln(x) + 2x + c_1(x \ln(x) - x) + c_2$$

Verified OK.

20.25.2 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}$$

And now the original ode becomes

$$\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + (2AB' + B^2) v' + (AB'' + BB' + CB) v &= 0
\end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + (2AB' + B^2) v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$AB u' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned}
A &= x \ln(x) \\
B &= -1 \\
C &= 0 \\
F &= \ln(x)^2
\end{aligned}$$

The above shows that for this ode

$$\begin{aligned}
AB'' + BB' + CB &= (x \ln(x))(0) + (-1)(0) + (0)(-1) \\
&= 0
\end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$-x \ln(x) v'' + (1) v' = 0$$

Now by applying $v' = u$ the above becomes

$$-x \ln(x) u'(x) + u(x) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x, u) \\
&= f(x) g(u) \\
&= \frac{u}{x \ln(x)}
\end{aligned}$$

Where $f(x) = \frac{1}{x \ln(x)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u} du &= \frac{1}{x \ln(x)} dx \\
\int \frac{1}{u} du &= \int \frac{1}{x \ln(x)} dx \\
\ln(u) &= \ln(\ln(x)) + c_1 \\
u &= e^{\ln(\ln(x)) + c_1} \\
&= c_1 \ln(x)
\end{aligned}$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= c_1 \ln(x)
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int c_1 \ln(x) \,\mathrm{d}x \\
&= c_1(x \ln(x) - x) + c_2
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= Bv \\
&= (-1)\,(c_1(x \ln(x) - x) + c_2) \\
&= -x \ln(x)\, c_1 + c_1 x - c_2
\end{aligned}
$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= -1 \\
y_2 &= -x \ln(x) + x
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix} -1 & -x \ln(x) + x \\ \frac{d}{dx}(-1) & \frac{d}{dx}(-x \ln(x) + x) \end{vmatrix}
$$

Which gives

$$W = \begin{vmatrix} -1 & -x\ln(x) + x \\ 0 & -\ln(x) \end{vmatrix}$$

Therefore

$$W = (-1)(-\ln(x)) - (-x\ln(x) + x)(0)$$

Which simplifies to

$$W = \ln(x)$$

Which simplifies to

$$W = \ln(x)$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(-x\ln(x) + x)\ln(x)^2}{x\ln(x)^2}\,dx$$

Which simplifies to

$$u_1 = -\int (-\ln(x) + 1)\,dx$$

Hence

$$u_1 = -2x + x\ln(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{-\ln(x)^2}{x\ln(x)^2}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{1}{x}dx$$

Hence

$$u_2 = -\ln(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = 2x - x\ln(x) - \ln(x)(-x\ln(x) + x)$$

Which simplifies to

$$y_p(x) = x\left(\ln(x)^2 - 2\ln(x) + 2\right)$$

Hence the complete solution is

$$\begin{aligned}y(x) &= y_h + y_p \\ &= (-x\ln(x)\,c_1 + c_1 x - c_2) + \left(x\left(\ln(x)^2 - 2\ln(x) + 2\right)\right) \\ &= x\ln(x)^2 - x(2+c_1)\ln(x) + x(2+c_1) - c_2\end{aligned}$$

Summary
The solution(s) found are the following

$$y = x\ln(x)^2 - x(2+c_1)\ln(x) + x(2+c_1) - c_2 \tag{1}$$

Verification of solutions

$$y = x\ln(x)^2 - x(2+c_1)\ln(x) + x(2+c_1) - c_2$$

Verified OK.

20.25.3 Maple step by step solution

Let's solve
$x\ln(x)\,y'' - y' = \ln(x)^2$

- Highest derivative means the order of the ODE is 2
  y''
- Make substitution $u = y'$ to reduce order of ODE
  $x\ln(x)\,u'(x) - u(x) = \ln(x)^2$
- Isolate the derivative
  $u'(x) = \frac{u(x)}{x\ln(x)} + \frac{\ln(x)}{x}$
- Group terms with $u(x)$ on the lhs of the ODE and the rest on the rhs of the ODE
  $u'(x) - \frac{u(x)}{x\ln(x)} = \frac{\ln(x)}{x}$
- The ODE is linear; multiply by an integrating factor $\mu(x)$
  $\mu(x)\left(u'(x) - \frac{u(x)}{x\ln(x)}\right) = \frac{\mu(x)\ln(x)}{x}$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,u(x))$

$\mu(x)\left(u'(x)-\frac{u(x)}{x\ln(x)}\right)=\mu'(x)\,u(x)+\mu(x)\,u'(x)$

- Isolate $\mu'(x)$

  $\mu'(x)=-\frac{\mu(x)}{x\ln(x)}$

- Solve to find the integrating factor

  $\mu(x)=\frac{1}{\ln(x)}$

- Integrate both sides with respect to x

  $\int\left(\frac{d}{dx}(\mu(x)\,u(x))\right)dx=\int\frac{\mu(x)\ln(x)}{x}dx+c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,u(x)=\int\frac{\mu(x)\ln(x)}{x}dx+c_1$

- Solve for $u(x)$

  $u(x)=\frac{\int\frac{\mu(x)\ln(x)}{x}dx+c_1}{\mu(x)}$

- Substitute $\mu(x)=\frac{1}{\ln(x)}$

  $u(x)=\ln(x)\left(\int\frac{1}{x}dx+c_1\right)$

- Evaluate the integrals on the rhs

  $u(x)=\ln(x)\,(\ln(x)+c_1)$

- Solve 1st ODE for $u(x)$

  $u(x)=\ln(x)\,(\ln(x)+c_1)$

- Make substitution $u=y'$

  $y'=\ln(x)\,(\ln(x)+c_1)$

- Integrate both sides to solve for y

  $\int y'dx=\int\ln(x)\,(\ln(x)+c_1)\,dx+c_2$

- Compute integrals

  $y=x\ln(x)^2-2x\ln(x)+2x+c_1(x\ln(x)-x)+c_2$

The type(s) of ODE detected by this program : **"kovacic", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{xy'' + (2x - 1)\, y' = -4x^2}$$

20.26.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$xp'(x) + (2x - 1)\, p(x) + 4x^2 = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned}p(x) &= -\frac{-2x+1}{x}\\ q(x) &= -4x\end{aligned}$$

Hence the ode is

$$p'(x) - \frac{(-2x+1)\,p(x)}{x} = -4x$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{-2x+1}{x}dx}\\ &= \mathrm{e}^{2x-\ln(x)}\end{aligned}$$

Which simplifies to

$$\mu = \frac{\mathrm{e}^{2x}}{x}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu p) &= (\mu)\,(-4x)\\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\mathrm{e}^{2x}p}{x}\right) &= \left(\frac{\mathrm{e}^{2x}}{x}\right)(-4x)\\ \mathrm{d}\left(\frac{\mathrm{e}^{2x}p}{x}\right) &= \left(-4\,\mathrm{e}^{2x}\right)\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{\mathrm{e}^{2x}p}{x} &= \int -4\,\mathrm{e}^{2x}\,\mathrm{d}x\\ \frac{\mathrm{e}^{2x}p}{x} &= -2\,\mathrm{e}^{2x} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{\mathrm{e}^{2x}}{x}$ results in

$$p(x) = -2x\,\mathrm{e}^{-2x}\mathrm{e}^{2x} + c_1 x\,\mathrm{e}^{-2x}$$

which simplifies to

$$p(x) = x\left(-2 + c_1\mathrm{e}^{-2x}\right)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = x\left(-2 + c_1 \mathrm{e}^{-2x}\right)$$

Integrating both sides gives

$$\begin{aligned} y &= \int x\left(-2 + c_1 \mathrm{e}^{-2x}\right) \mathrm{d}x \\ &= \frac{c_1\left(-2x\,\mathrm{e}^{-2x} - \mathrm{e}^{-2x}\right)}{4} - x^2 + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1\left(-2x\,\mathrm{e}^{-2x} - \mathrm{e}^{-2x}\right)}{4} - x^2 + c_2 \tag{1}$$

Verification of solutions

$$y = \frac{c_1\left(-2x\,\mathrm{e}^{-2x} - \mathrm{e}^{-2x}\right)}{4} - x^2 + c_2$$

Verified OK.

20.26.2 Solving using Kovacic algorithm

Writing the ode as

$$xy'' + (2x - 1)\,y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= 2x - 1 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^2 - 4x + 3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 4x^2 - 4x + 3$$
$$t = 4x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^2 - 4x + 3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 665: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = 1 + \frac{3}{4x^2} - \frac{1}{x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx 1 - \frac{1}{2x} + \frac{1}{4x^2} + \frac{1}{8x^3} + \frac{1}{32x^4} - \frac{1}{64x^5} - \frac{3}{128x^6} - \frac{3}{256x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= 1 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = 1$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^2 - 4x + 3}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= (1) + \left(\frac{-4x + 3}{4x^2}\right) \\ &= 1 + \frac{-4x + 3}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -4. Dividing this by leading coefficient in t which is 4 gives -1. Now b can be found.

$$\begin{aligned} b &= (-1) - (0) \\ &= -1 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 1 \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-1}{1} - 0\right) &&= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-1}{1} - 0\right) &&= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^2 - 4x + 3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	1	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + (+)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{2x} + (1) \\
&= 1 - \frac{1}{2x} \\
&= 1 - \frac{1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(1 - \frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(1 - \frac{1}{2x}\right)^2 - \left(\frac{4x^2 - 4x + 3}{4x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(1 - \frac{1}{2x}\right) dx} \\
&= \frac{\mathrm{e}^{x}}{\sqrt{x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{2x-1}{x} \, dx} \\
&= z_1 e^{-x + \frac{\ln(x)}{2}} \\
&= z_1 \left(\sqrt{x}\, \mathrm{e}^{-x}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2x-1}{x}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-2x+\ln(x)}}{(y_1)^2}\,dx \\ &= y_1 \left(-\frac{(1+2x)\,e^{-2x}}{4}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(1) + c_2\left(1\left(-\frac{(1+2x)\,e^{-2x}}{4}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$xy'' + (2x-1)\,y' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 - \frac{c_2(1+2x)\,e^{-2x}}{4}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= 1 \\ y_2 &= -\frac{(1+2x)\,\mathrm{e}^{-2x}}{4} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & -\frac{(1+2x)\mathrm{e}^{-2x}}{4} \\ \frac{d}{dx}(1) & \frac{d}{dx}\left(-\frac{(1+2x)\mathrm{e}^{-2x}}{4}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & -\frac{(1+2x)\mathrm{e}^{-2x}}{4} \\ 0 & -\frac{\mathrm{e}^{-2x}}{2} + \frac{(1+2x)\mathrm{e}^{-2x}}{2} \end{vmatrix}$$

Therefore

$$W = (1)\left(-\frac{\mathrm{e}^{-2x}}{2} + \frac{(1+2x)\,\mathrm{e}^{-2x}}{2}\right) - \left(-\frac{(1+2x)\,\mathrm{e}^{-2x}}{4}\right)(0)$$

Which simplifies to

$$W = x\,\mathrm{e}^{-2x}$$

Which simplifies to

$$W = x\,\mathrm{e}^{-2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(1+2x)\,\mathrm{e}^{-2x}x^2}{\mathrm{e}^{-2x}x^2}\,dx$$

Which simplifies to

$$u_1 = -\int (1+2x)\,dx$$

Hence

$$u_1 = -x^2 - x$$

And Eq. (3) becomes

$$u_2 = \int \frac{-4x^2}{\mathrm{e}^{-2x}x^2}\,dx$$

Which simplifies to

$$u_2 = \int -4\,\mathrm{e}^{2x}dx$$

Hence

$$u_2 = -2\,\mathrm{e}^{2x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -x^2 - x + \frac{\mathrm{e}^{2x}(1+2x)\,\mathrm{e}^{-2x}}{2}$$

Which simplifies to

$$y_p(x) = -x^2 + \frac{1}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 - \frac{c_2(1+2x)\,\mathrm{e}^{-2x}}{4}\right) + \left(-x^2 + \frac{1}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 - \frac{c_2(1+2x)\,\mathrm{e}^{-2x}}{4} - x^2 + \frac{1}{2} \tag{1}$$

Verification of solutions

$$y = c_1 - \frac{c_2(1+2x)\,\mathrm{e}^{-2x}}{4} - x^2 + \frac{1}{2}$$

Verified OK.

20.26.3 Maple step by step solution

Let's solve

$xy'' + (2x-1)\,y' = -4x^2$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $xu'(x) + (2x-1)\,u(x) = -4x^2$

- Isolate the derivative

  $u'(x) = -\frac{(2x-1)u(x)}{x} - 4x$

- Group terms with $u(x)$ on the lhs of the ODE and the rest on the rhs of the ODE

  $u'(x) + \frac{(2x-1)u(x)}{x} = -4x$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(u'(x) + \frac{(2x-1)u(x)}{x}\right) = -4\mu(x)\,x$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,u(x))$

  $\mu(x)\left(u'(x) + \frac{(2x-1)u(x)}{x}\right) = \mu'(x)\,u(x) + \mu(x)\,u'(x)$

- Isolate $\mu'(x)$

  $\mu'(x) = \frac{\mu(x)(2x-1)}{x}$

- Solve to find the integrating factor

  $\mu(x) = \frac{\mathrm{e}^{2x}}{x}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,u(x))\right) dx = \int -4\mu(x)\,x dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,u(x) = \int -4\mu(x)\,x dx + c_1$
- Solve for $u(x)$

  $u(x) = \frac{\int -4\mu(x)x dx + c_1}{\mu(x)}$
- Substitute $\mu(x) = \frac{e^{2x}}{x}$

  $u(x) = \frac{x\left(\int -4\,e^{2x} dx + c_1\right)}{e^{2x}}$
- Evaluate the integrals on the rhs

  $u(x) = \frac{x(-2\,e^{2x} + c_1)}{e^{2x}}$
- Simplify

  $u(x) = x(-2 + c_1 e^{-2x})$
- Solve 1st ODE for $u(x)$

  $u(x) = x(-2 + c_1 e^{-2x})$
- Make substitution $u = y'$

  $y' = x(-2 + c_1 e^{-2x})$
- Integrate both sides to solve for y

  $\int y' dx = \int x(-2 + c_1 e^{-2x})\, dx + c_2$
- Compute integrals

  $y = \frac{c_1(-2x\,e^{-2x} - e^{-2x})}{4} - x^2 + c_2$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.5 Linear equations with variable coefficients. The Lagrange method. Exercises page 148
Problem number: 666.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + y' \tan(x) = \cot(x)\cos(x)}$$

20.27.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + p(x)\tan(x) - \cot(x)\cos(x) = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= \tan(x) \\
q(x) &= \cot(x)\cos(x)
\end{aligned}
$$

Hence the ode is

$$
p'(x) + p(x)\tan(x) = \cot(x)\cos(x)
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int \tan(x)dx} \\
&= \frac{1}{\cos(x)}
\end{aligned}
$$

Which simplifies to

$$
\mu = \sec(x)
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu p) &= (\mu)(\cot(x)\cos(x)) \\
\frac{d}{dx}(\sec(x)\, p) &= (\sec(x))(\cot(x)\cos(x)) \\
d(\sec(x)\, p) &= \cot(x)\, dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\sec(x)\, p &= \int \cot(x)\, dx \\
\sec(x)\, p &= \ln(\sin(x)) + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \sec(x)$ results in

$$
p(x) = \cos(x)\ln(\sin(x)) + c_1\cos(x)
$$

which simplifies to

$$
p(x) = \cos(x)(\ln(\sin(x)) + c_1)
$$

Since $p = y'$ then the new first order ode to solve is

$$
y' = \cos(x)(\ln(\sin(x)) + c_1)
$$

Integrating both sides gives

$$\begin{aligned} y &= \int \cos(x)\left(\ln(\sin(x)) + c_1\right) \mathrm{d}x \\ &= c_1 \sin(x) + \ln(\sin(x)) \sin(x) - \sin(x) + c_2 \end{aligned}$$

<u>Summary</u>

The solution(s) found are the following

$$y = c_1 \sin(x) + \ln(\sin(x)) \sin(x) - \sin(x) + c_2 \tag{1}$$

<u>Verification of solutions</u>

$$y = c_1 \sin(x) + \ln(\sin(x)) \sin(x) - \sin(x) + c_2$$

Verified OK.

20.27.2 Maple step by step solution

Let's solve

$y'' + y' \tan(x) = \cot(x)\cos(x)$

- Highest derivative means the order of the ODE is 2

  y''
- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) + u(x)\tan(x) = \cot(x)\cos(x)$
- Isolate the derivative

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

Unable to solve or complete the solution.

$$\boxed{4xy'' + 2y' + y = 1}$$

With initial conditions

$$[y(\infty) = 1]$$

20.28.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= \frac{1}{2x} \\ q(x) &= \frac{1}{4x} \\ F &= \frac{1}{4x} \end{aligned}$$

Hence the ode is

$$y'' + \frac{y'}{2x} + \frac{y}{4x} = \frac{1}{4x}$$

The domain of $p(x) = \frac{1}{2x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = \infty$ is inside this domain. The domain of $q(x) = \frac{1}{4x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = \infty$ is also inside this domain. The domain of $F = \frac{1}{4x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = \infty$ is also inside this domain. Hence solution exists and is unique.

20.28.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$4xy'' + 2y' + y = 0$$

In normal form the ode

$$4xy'' + 2y' + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{2x} \\ q(x) &= \frac{1}{4x} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2} y(\tau) + p_1\left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\, \tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int e^{-\left(\int p(x)dx\right)} dx \\ &= \int e^{-\left(\int \frac{1}{2x} dx\right)} dx \\ &= \int e^{-\frac{\ln(x)}{2}} dx \\ &= \int \frac{1}{\sqrt{x}} dx \\ &= 2\sqrt{x} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{1}{4x}}{\frac{1}{x}} \\
&= \frac{1}{4}
\end{aligned}
\tag{7}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{4} &= 0
\end{aligned}
$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$
Ay''(\tau) + By'(\tau) + Cy(\tau) = 0
$$

Where in the above $A = 1, B = 0, C = \frac{1}{4}$. Let the solution be $y(\tau) = e^{\lambda \tau}$. Substituting this into the ODE gives

$$
\lambda^2 \mathrm{e}^{\lambda \tau} + \frac{\mathrm{e}^{\lambda \tau}}{4} = 0 \tag{1}
$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda \tau}$ gives

$$
\lambda^2 + \frac{1}{4} = 0 \tag{2}
$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$
\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}
$$

Substituting $A = 1, B = 0, C = \frac{1}{4}$ into the above gives

$$
\begin{aligned}
\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)\left(\frac{1}{4}\right)} \\
&= \pm \frac{i}{2}
\end{aligned}
$$

Hence

$$
\begin{aligned}
\lambda_1 &= +\frac{i}{2} \\
\lambda_2 &= -\frac{i}{2}
\end{aligned}
$$

Which simplifies to

$$\lambda_1 = \frac{i}{2}$$
$$\lambda_2 = -\frac{i}{2}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = \frac{1}{2}$. Therefore the final solution, when using Euler relation, can be written as

$$y(\tau) = e^{\alpha\tau}(c_1 \cos(\beta\tau) + c_2 \sin(\beta\tau))$$

Which becomes

$$y(\tau) = e^0\left(c_1 \cos\left(\frac{\tau}{2}\right) + c_2 \sin\left(\frac{\tau}{2}\right)\right)$$

Or

$$y(\tau) = c_1 \cos\left(\frac{\tau}{2}\right) + c_2 \sin\left(\frac{\tau}{2}\right)$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos\left(\sqrt{x}\right)$$
$$y_2 = \sin\left(\sqrt{x}\right)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos\left(\sqrt{x}\right) & \sin\left(\sqrt{x}\right) \\ \frac{d}{dx}\left(\cos\left(\sqrt{x}\right)\right) & \frac{d}{dx}\left(\sin\left(\sqrt{x}\right)\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos\left(\sqrt{x}\right) & \sin\left(\sqrt{x}\right) \\ -\frac{\sin\left(\sqrt{x}\right)}{2\sqrt{x}} & \frac{\cos\left(\sqrt{x}\right)}{2\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = \left(\cos\left(\sqrt{x}\right)\right)\left(\frac{\cos\left(\sqrt{x}\right)}{2\sqrt{x}}\right) - \left(\sin\left(\sqrt{x}\right)\right)\left(-\frac{\sin\left(\sqrt{x}\right)}{2\sqrt{x}}\right)$$

Which simplifies to

$$W = \frac{\cos\left(\sqrt{x}\right)^2 + \sin\left(\sqrt{x}\right)^2}{2\sqrt{x}}$$

Which simplifies to

$$W = \frac{1}{2\sqrt{x}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin\left(\sqrt{x}\right)}{2\sqrt{x}}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin\left(\sqrt{x}\right)}{2\sqrt{x}} dx$$

Hence

$$u_1 = \cos\left(\sqrt{x}\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos\left(\sqrt{x}\right)}{2\sqrt{x}}\, dx$$

Which simplifies to

$$u_2 = \int \frac{\cos\left(\sqrt{x}\right)}{2\sqrt{x}} dx$$

Hence

$$u_2 = \sin\left(\sqrt{x}\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \cos\left(\sqrt{x}\right)^2 + \sin\left(\sqrt{x}\right)^2$$

Which simplifies to

$$y_p(x) = 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right)\right) + (1) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right) + 1 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = \infty$ in the above gives

$$1 = -|c_1| - |c_2| + 1..|c_1| + |c_2| + 1 \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

20.28.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 4x, B = 2, C = 1, f(x) = 1$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$4xy'' + 2y' + y = 0$$

In normal form the ode

$$4xy'' + 2y' + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{2x} \\ q(x) &= \frac{1}{4x} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{\frac{1}{x}}}{2c} \end{aligned} \tag{6}$$

$$\tau'' = -\frac{1}{4c\sqrt{\frac{1}{x}}\, x^2}$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{1}{4c\sqrt{\frac{1}{x}}\,x^2} + \frac{1}{2x}\frac{\sqrt{\frac{1}{x}}}{2c}}{\left(\frac{\sqrt{\frac{1}{x}}}{2c}\right)^2} \\
&= 0
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2} y(\tau) + c^2 y(\tau) &= 0
\end{aligned} \tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \frac{\sqrt{\frac{1}{x}}}{2} dx}{c} \\
&= \frac{x\sqrt{\frac{1}{x}}}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right)
$$

Now the particular solution to this ODE is found

$$
4xy'' + 2y' + y = 1
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos\left(x\sqrt{\frac{1}{x}}\right)$$

$$y_2 = \sin\left(x\sqrt{\frac{1}{x}}\right)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos\left(x\sqrt{\frac{1}{x}}\right) & \sin\left(x\sqrt{\frac{1}{x}}\right) \\ \frac{d}{dx}\left(\cos\left(x\sqrt{\frac{1}{x}}\right)\right) & \frac{d}{dx}\left(\sin\left(x\sqrt{\frac{1}{x}}\right)\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos\left(x\sqrt{\frac{1}{x}}\right) & \sin\left(x\sqrt{\frac{1}{x}}\right) \\ -\left(\sqrt{\frac{1}{x}} - \frac{1}{2x\sqrt{\frac{1}{x}}}\right)\sin\left(x\sqrt{\frac{1}{x}}\right) & \left(\sqrt{\frac{1}{x}} - \frac{1}{2x\sqrt{\frac{1}{x}}}\right)\cos\left(x\sqrt{\frac{1}{x}}\right) \end{vmatrix}$$

Therefore

$$W = \left(\cos\left(x\sqrt{\frac{1}{x}}\right)\right)\left(\left(\sqrt{\frac{1}{x}} - \frac{1}{2x\sqrt{\frac{1}{x}}}\right)\cos\left(x\sqrt{\frac{1}{x}}\right)\right) - \left(\sin\left(x\sqrt{\frac{1}{x}}\right)\right)\left(-\left(\sqrt{\frac{1}{x}} - \frac{1}{2x\sqrt{\frac{1}{x}}}\right)\sin\left(x\sqrt{\frac{1}{x}}\right)\right)$$

Which simplifies to

$$W = \frac{\cos\left(x\sqrt{\frac{1}{x}}\right)^2 + \sin\left(x\sqrt{\frac{1}{x}}\right)^2}{2x\sqrt{\frac{1}{x}}}$$

Which simplifies to

$$W = \frac{1}{2x\sqrt{\frac{1}{x}}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin\left(x\sqrt{\frac{1}{x}}\right)}{\frac{2}{\sqrt{\frac{1}{x}}}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin\left(x\sqrt{\frac{1}{x}}\right)\sqrt{\frac{1}{x}}}{2}dx$$

Hence

$$u_1 = \cos\left(x\sqrt{\frac{1}{x}}\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos\left(x\sqrt{\frac{1}{x}}\right)}{\frac{2}{\sqrt{\frac{1}{x}}}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{\cos\left(x\sqrt{\frac{1}{x}}\right)\sqrt{\frac{1}{x}}}{2}dx$$

Hence

$$u_2 = \sin\left(x\sqrt{\frac{1}{x}}\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \cos\left(x\sqrt{\frac{1}{x}}\right)^2 + \sin\left(x\sqrt{\frac{1}{x}}\right)^2$$

Which simplifies to

$$y_p(x) = 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\cos\left(\sqrt{x}\right) + c_2\sin\left(\sqrt{x}\right)\right) + (1) \\ &= c_1\cos\left(\sqrt{x}\right) + c_2\sin\left(\sqrt{x}\right) + 1 \end{aligned}$$

Which simplifies to

$$y = c_1\cos\left(\sqrt{x}\right) + c_2\sin\left(\sqrt{x}\right) + 1$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1\cos\left(\sqrt{x}\right) + c_2\sin\left(\sqrt{x}\right) + 1 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = \infty$ in the above gives

$$1 = -|c_1| - |c_2| + 1..|c_1| + |c_2| + 1 \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

20.28.4 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \frac{xy'}{2} + \frac{yx}{4} = \frac{x}{4} \tag{1}$$

Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE and y_p is a particular solution to the non-homogeneous ODE. Bessel ode has the form

$$x^2y'' + xy' + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha) xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{4}$$
$$\beta = 1$$
$$n = \frac{1}{2}$$
$$\gamma = \frac{1}{2}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1\sqrt{2}\,\sin\left(\sqrt{x}\right)}{\sqrt{\pi}} - \frac{c_2\sqrt{2}\,\cos\left(\sqrt{x}\right)}{\sqrt{\pi}}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1\sqrt{2}\,\sin\left(\sqrt{x}\right)}{\sqrt{\pi}} - \frac{c_2\sqrt{2}\,\cos\left(\sqrt{x}\right)}{\sqrt{\pi}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{\sqrt{2}\,\sin\left(\sqrt{x}\right)}{\sqrt{\pi}}$$

$$y_2 = -\frac{\sqrt{2}\,\cos\left(\sqrt{x}\right)}{\sqrt{\pi}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{\sqrt{2}\sin(\sqrt{x})}{\sqrt{\pi}} & -\frac{\sqrt{2}\cos(\sqrt{x})}{\sqrt{\pi}} \\ \frac{d}{dx}\left(\frac{\sqrt{2}\sin(\sqrt{x})}{\sqrt{\pi}}\right) & \frac{d}{dx}\left(-\frac{\sqrt{2}\cos(\sqrt{x})}{\sqrt{\pi}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{\sqrt{2}\sin(\sqrt{x})}{\sqrt{\pi}} & -\frac{\sqrt{2}\cos(\sqrt{x})}{\sqrt{\pi}} \\ \frac{\sqrt{2}\cos(\sqrt{x})}{2\sqrt{\pi}\,\sqrt{x}} & \frac{\sqrt{2}\sin(\sqrt{x})}{2\sqrt{\pi}\,\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = \left(\frac{\sqrt{2}\,\sin\left(\sqrt{x}\right)}{\sqrt{\pi}}\right)\left(\frac{\sqrt{2}\,\sin\left(\sqrt{x}\right)}{2\sqrt{\pi}\,\sqrt{x}}\right) - \left(-\frac{\sqrt{2}\,\cos\left(\sqrt{x}\right)}{\sqrt{\pi}}\right)\left(\frac{\sqrt{2}\,\cos\left(\sqrt{x}\right)}{2\sqrt{\pi}\,\sqrt{x}}\right)$$

Which simplifies to

$$W = \frac{\cos\left(\sqrt{x}\right)^2 + \sin\left(\sqrt{x}\right)^2}{\pi \sqrt{x}}$$

Which simplifies to

$$W = \frac{1}{\pi \sqrt{x}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{\sqrt{2}\, \cos(\sqrt{x})x}{4\sqrt{\pi}}}{\frac{x^{\frac{3}{2}}}{\pi}} dx$$

Which simplifies to

$$u_1 = -\int -\frac{\sqrt{2}\,\sqrt{\pi}\, \cos\left(\sqrt{x}\right)}{4\sqrt{x}} dx$$

Hence

$$u_1 = \frac{\sqrt{2}\,\sqrt{\pi}\, \sin\left(\sqrt{x}\right)}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\sqrt{2}\, \sin(\sqrt{x})x}{4\sqrt{\pi}}}{\frac{x^{\frac{3}{2}}}{\pi}} dx$$

Which simplifies to

$$u_2 = \int \frac{\sqrt{2}\,\sqrt{\pi}\, \sin\left(\sqrt{x}\right)}{4\sqrt{x}} dx$$

Hence

$$u_2 = -\frac{\sqrt{2}\,\sqrt{\pi}\, \cos\left(\sqrt{x}\right)}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \cos\left(\sqrt{x}\right)^2 + \sin\left(\sqrt{x}\right)^2$$

Which simplifies to

$$y_p(x) = 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1\sqrt{2}\,\sin\left(\sqrt{x}\right)}{\sqrt{\pi}} - \frac{c_2\sqrt{2}\,\cos\left(\sqrt{x}\right)}{\sqrt{\pi}}\right) + (1) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1\sqrt{2}\,\sin\left(\sqrt{x}\right)}{\sqrt{\pi}} - \frac{c_2\sqrt{2}\,\cos\left(\sqrt{x}\right)}{\sqrt{\pi}} + 1 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = \infty$ in the above gives

$$1 = -\frac{-\sqrt{\pi} + (|c_1| + |c_2|)\sqrt{2}}{\sqrt{\pi}} .. \frac{\sqrt{\pi} + (|c_1| + |c_2|)\sqrt{2}}{\sqrt{\pi}} \tag{1A}$$

Equations $\{1\text{A}\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

20.28.5 Solving using Kovacic algorithm

Writing the ode as

$$4xy'' + 2y' + y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x \\ B &= 2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4x - 3}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4x - 3 \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-4x - 3}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 668: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 1 \\ &= 1 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [2]$$

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16x^2} - \frac{1}{4x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is $1 < 2$ then

$$E_\infty = \{1\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{1, 2, 3\}$

Order of r at ∞	E_∞
1	$\{1\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 1, \; e_\infty = 1$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned}
d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right)\\
&= \frac{1}{2}(1 - (1))\\
&= 0
\end{aligned}$$

We now form the following rational function

$$\begin{aligned}
\theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x - c}\\
&= \frac{1}{2}\left(\frac{1}{(x - (0))}\right)\\
&= \frac{1}{2x}
\end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right) p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right) p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p} \\ &= \frac{1}{2x}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \frac{w}{2x} + \frac{4x+1}{16x^2} = 0$$

Solving for ω gives

$$\omega = \frac{1 + 2\sqrt{-x}}{4x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{1+2\sqrt{-x}}{4x} dx} \\ &= x^{\frac{1}{4}} \mathrm{e}^{\sqrt{-x}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{4x} \, dx} \\ &= z_1 e^{-\frac{\ln(x)}{4}} \\ &= z_1 \left(\frac{1}{x^{\frac{1}{4}}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\sqrt{-x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2}{4x}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{\ln(x)}{2}}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\sqrt{-x}\left(-1+\mathrm{e}^{-2\sqrt{-x}}\right)}{\sqrt{x}}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{\sqrt{-x}}\right) + c_2\left(\mathrm{e}^{\sqrt{-x}}\left(\frac{\sqrt{-x}\left(-1+\mathrm{e}^{-2\sqrt{-x}}\right)}{\sqrt{x}}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
4xy'' + 2y' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1\mathrm{e}^{\sqrt{-x}} + \frac{c_2\sqrt{-x}\left(-\mathrm{e}^{\sqrt{-x}} + \mathrm{e}^{-\sqrt{-x}}\right)}{\sqrt{x}}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^{\sqrt{-x}}$$
$$y_2 = \frac{\sqrt{-x}\left(-e^{\sqrt{-x}} + e^{-\sqrt{-x}}\right)}{\sqrt{x}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{\sqrt{-x}} & \frac{\sqrt{-x}\left(-e^{\sqrt{-x}}+e^{-\sqrt{-x}}\right)}{\sqrt{x}} \\ \frac{d}{dx}\left(e^{\sqrt{-x}}\right) & \frac{d}{dx}\left(\frac{\sqrt{-x}\left(-e^{\sqrt{-x}}+e^{-\sqrt{-x}}\right)}{\sqrt{x}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{\sqrt{-x}} & \frac{\sqrt{-x}\left(-e^{\sqrt{-x}}+e^{-\sqrt{-x}}\right)}{\sqrt{x}} \\ -\frac{e^{\sqrt{-x}}}{2\sqrt{-x}} & -\frac{-e^{\sqrt{-x}}+e^{-\sqrt{-x}}}{2\sqrt{-x}\sqrt{x}} + \frac{\sqrt{-x}\left(\frac{e^{\sqrt{-x}}}{2\sqrt{-x}}+\frac{e^{-\sqrt{-x}}}{2\sqrt{-x}}\right)}{\sqrt{x}} - \frac{\sqrt{-x}\left(-e^{\sqrt{-x}}+e^{-\sqrt{-x}}\right)}{2x^{\frac{3}{2}}} \end{vmatrix}$$

Therefore

$$W = \left(e^{\sqrt{-x}}\right)\left(-\frac{-e^{\sqrt{-x}} + e^{-\sqrt{-x}}}{2\sqrt{-x}\sqrt{x}} + \frac{\sqrt{-x}\left(\frac{e^{\sqrt{-x}}}{2\sqrt{-x}} + \frac{e^{-\sqrt{-x}}}{2\sqrt{-x}}\right)}{\sqrt{x}} - \frac{\sqrt{-x}\left(-e^{\sqrt{-x}} + e^{-\sqrt{-x}}\right)}{2x^{\frac{3}{2}}}\right) - \left(\frac{\sqrt{-x}\left(-e^{\sqrt{-x}} + e^{-\sqrt{-x}}\right)}{\sqrt{x}}\right)\left(-\frac{e^{\sqrt{-x}}}{2\sqrt{-x}}\right)$$

Which simplifies to

$$W = \frac{e^{\sqrt{-x}} e^{-\sqrt{-x}}}{\sqrt{x}}$$

Which simplifies to

$$W = \frac{1}{\sqrt{x}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sqrt{-x}\left(-e^{\sqrt{-x}}+e^{-\sqrt{-x}}\right)}{\sqrt{x}}}{4\sqrt{x}}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{e^{\sqrt{-x}} - e^{-\sqrt{-x}}}{4\sqrt{-x}} dx$$

Hence

$$u_1 = \frac{e^{\sqrt{-x}}}{2} + \frac{e^{-\sqrt{-x}}}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{\sqrt{-x}}}{4\sqrt{x}}\, dx$$

Which simplifies to

$$u_2 = \int \frac{e^{\sqrt{-x}}}{4\sqrt{x}} dx$$

Hence

$$u_2 = \frac{\sqrt{-x}\left(1 - e^{\sqrt{-x}}\right)}{2\sqrt{x}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{e^{\sqrt{-x}}}{2} + \frac{e^{-\sqrt{-x}}}{2}\right) e^{\sqrt{-x}} - \frac{\left(1 - e^{\sqrt{-x}}\right)\left(-e^{\sqrt{-x}} + e^{-\sqrt{-x}}\right)}{2}$$

Which simplifies to

$$y_p(x) = 1 + \frac{e^{\sqrt{-x}}}{2} - \frac{e^{-\sqrt{-x}}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{\sqrt{-x}} + \frac{c_2 \sqrt{-x}\left(-e^{\sqrt{-x}} + e^{-\sqrt{-x}}\right)}{\sqrt{x}}\right) + \left(1 + \frac{e^{\sqrt{-x}}}{2} - \frac{e^{-\sqrt{-x}}}{2}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{\sqrt{-x}} + \frac{c_2 \sqrt{-x}\left(-e^{\sqrt{-x}} + e^{-\sqrt{-x}}\right)}{\sqrt{x}} + 1 + \frac{e^{\sqrt{-x}}}{2} - \frac{e^{-\sqrt{-x}}}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = \infty$ in the above gives

$$1 = -|\Re((1+i)\, c_1)\,| - i|\Im((1+i)\, c_1)\,| + 2\min\left(-\Re((1-i)\, c_2)\,, -\Re((1+i)\, c_2)\,, \Re((1-i)\, c_2)\,, \Re((1+i)\, c_2 \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Problem number: 668.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

Unable to solve or complete the solution.

$$\boxed{4xy'' + 2y' + y = \frac{6 + x}{x^2}}$$

With initial conditions

$$[y(\infty) = 0]$$

20.29.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= \frac{1}{2x} \\ q(x) &= \frac{1}{4x} \\ F &= \frac{6+x}{4x^3} \end{aligned}$$

Hence the ode is

$$y'' + \frac{y'}{2x} + \frac{y}{4x} = \frac{6+x}{4x^3}$$

The domain of $p(x) = \frac{1}{2x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = \infty$ is inside this domain. The domain of $q(x) = \frac{1}{4x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = \infty$ is also inside this domain. The domain of $F = \frac{6+x}{4x^3}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = \infty$ is also inside this domain. Hence solution exists and is unique.

20.29.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$4xy'' + 2y' + y = 0$$

In normal form the ode

$$4xy'' + 2y' + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{2x} \\ q(x) &= \frac{1}{4x} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\ &= \int \mathrm{e}^{-\left(\int \frac{1}{2x}dx\right)}dx \\ &= \int e^{-\frac{\ln(x)}{2}}\,dx \\ &= \int \frac{1}{\sqrt{x}}dx \\ &= 2\sqrt{x} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned} q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{1}{4x}}{\frac{1}{x}} \\ &= \frac{1}{4} \end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned} \frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{4} &= 0 \end{aligned}$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = \frac{1}{4}$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda\tau} + \frac{e^{\lambda\tau}}{4} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 + \frac{1}{4} = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = \frac{1}{4}$ into the above gives

$$\begin{aligned} \lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)\left(\frac{1}{4}\right)} \\ &= \pm\frac{i}{2} \end{aligned}$$

Hence

$$\begin{aligned} \lambda_1 &= +\frac{i}{2} \\ \lambda_2 &= -\frac{i}{2} \end{aligned}$$

Which simplifies to

$$\lambda_1 = \frac{i}{2}$$
$$\lambda_2 = -\frac{i}{2}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = \frac{1}{2}$. Therefore the final solution, when using Euler relation, can be written as

$$y(\tau) = e^{\alpha\tau}(c_1 \cos(\beta\tau) + c_2 \sin(\beta\tau))$$

Which becomes

$$y(\tau) = e^0\left(c_1 \cos\left(\frac{\tau}{2}\right) + c_2 \sin\left(\frac{\tau}{2}\right)\right)$$

Or

$$y(\tau) = c_1 \cos\left(\frac{\tau}{2}\right) + c_2 \sin\left(\frac{\tau}{2}\right)$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos\left(\sqrt{x}\right)$$
$$y_2 = \sin\left(\sqrt{x}\right)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(\sqrt{x}) & \sin(\sqrt{x}) \\ \frac{d}{dx}(\cos(\sqrt{x})) & \frac{d}{dx}(\sin(\sqrt{x})) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(\sqrt{x}) & \sin(\sqrt{x}) \\ -\frac{\sin(\sqrt{x})}{2\sqrt{x}} & \frac{\cos(\sqrt{x})}{2\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = (\cos(\sqrt{x}))\left(\frac{\cos(\sqrt{x})}{2\sqrt{x}}\right) - (\sin(\sqrt{x}))\left(-\frac{\sin(\sqrt{x})}{2\sqrt{x}}\right)$$

Which simplifies to

$$W = \frac{\cos(\sqrt{x})^2 + \sin(\sqrt{x})^2}{2\sqrt{x}}$$

Which simplifies to

$$W = \frac{1}{2\sqrt{x}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sin(\sqrt{x})(6+x)}{x^2}}{\frac{1}{2\sqrt{x}}} dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin\left(\sqrt{x}\right)(6+x)}{2x^{\frac{5}{2}}} dx$$

Hence

$$u_1 = \frac{2\sin\left(\sqrt{x}\right)}{x^{\frac{3}{2}}} + \frac{\cos\left(\sqrt{x}\right)}{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\cos\left(\sqrt{x}\right)(6+x)}{x^2}}{2\sqrt{x}} dx$$

Which simplifies to

$$u_2 = \int \frac{\cos\left(\sqrt{x}\right)(6+x)}{2x^{\frac{5}{2}}} dx$$

Hence

$$u_2 = -\frac{2\cos\left(\sqrt{x}\right)}{x^{\frac{3}{2}}} + \frac{\sin\left(\sqrt{x}\right)}{x}$$

Which simplifies to

$$u_1 = \frac{\cos\left(\sqrt{x}\right)\sqrt{x} + 2\sin\left(\sqrt{x}\right)}{x^{\frac{3}{2}}}$$

$$u_2 = \frac{\sin\left(\sqrt{x}\right)\sqrt{x} - 2\cos\left(\sqrt{x}\right)}{x^{\frac{3}{2}}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\left(\cos\left(\sqrt{x}\right)\sqrt{x} + 2\sin\left(\sqrt{x}\right)\right)\cos\left(\sqrt{x}\right)}{x^{\frac{3}{2}}} + \frac{\left(\sin\left(\sqrt{x}\right)\sqrt{x} - 2\cos\left(\sqrt{x}\right)\right)\sin\left(\sqrt{x}\right)}{x^{\frac{3}{2}}}$$

Which simplifies to

$$y_p(x) = \frac{1}{x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right)\right) + \left(\frac{1}{x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right) + \frac{1}{x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = \infty$ in the above gives

$$0 = -|c_1| - |c_2|..|c_1| + |c_2| \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

20.29.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 4x, B = 2, C = 1, f(x) = \frac{6+x}{x^2}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$4xy'' + 2y' + y = 0$$

In normal form the ode

$$4xy'' + 2y' + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = \frac{1}{2x}$$
$$q(x) = \frac{1}{4x}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{\frac{1}{x}}}{2c} \\ \tau'' &= -\frac{1}{4c\sqrt{\frac{1}{x}}\,x^2} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{1}{4c\sqrt{\frac{1}{x}}\,x^2} + \frac{1}{2x}\frac{\sqrt{\frac{1}{x}}}{2c}}{\left(\frac{\sqrt{\frac{1}{x}}}{2c}\right)^2} \\ &= 0 \end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned} y(\tau)'' + p_1y(\tau)' + q_1y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + c^2y(\tau) &= 0 \end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1\cos(c\tau) + c_2\sin(c\tau)$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \frac{\sqrt{\frac{1}{x}}}{2}dx}{c} \\
&= \frac{x\sqrt{\frac{1}{x}}}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right)
$$

Now the particular solution to this ODE is found

$$
4xy'' + 2y' + y = \frac{6+x}{x^2}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \cos\left(x\sqrt{\frac{1}{x}}\right) \\
y_2 &= \sin\left(x\sqrt{\frac{1}{x}}\right)
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos\left(x\sqrt{\frac{1}{x}}\right) & \sin\left(x\sqrt{\frac{1}{x}}\right) \\ \frac{d}{dx}\left(\cos\left(x\sqrt{\frac{1}{x}}\right)\right) & \frac{d}{dx}\left(\sin\left(x\sqrt{\frac{1}{x}}\right)\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos\left(x\sqrt{\frac{1}{x}}\right) & \sin\left(x\sqrt{\frac{1}{x}}\right) \\ -\left(\sqrt{\frac{1}{x}} - \frac{1}{2x\sqrt{\frac{1}{x}}}\right)\sin\left(x\sqrt{\frac{1}{x}}\right) & \left(\sqrt{\frac{1}{x}} - \frac{1}{2x\sqrt{\frac{1}{x}}}\right)\cos\left(x\sqrt{\frac{1}{x}}\right) \end{vmatrix}$$

Therefore

$$W = \left(\cos\left(x\sqrt{\frac{1}{x}}\right)\right)\left(\left(\sqrt{\frac{1}{x}} - \frac{1}{2x\sqrt{\frac{1}{x}}}\right)\cos\left(x\sqrt{\frac{1}{x}}\right)\right) - \left(\sin\left(x\sqrt{\frac{1}{x}}\right)\right)\left(-\left(\sqrt{\frac{1}{x}} - \frac{1}{2x\sqrt{\frac{1}{x}}}\right)\sin\left(x\sqrt{\frac{1}{x}}\right)\right)$$

Which simplifies to

$$W = \frac{\cos\left(x\sqrt{\frac{1}{x}}\right)^2 + \sin\left(x\sqrt{\frac{1}{x}}\right)^2}{2x\sqrt{\frac{1}{x}}}$$

Which simplifies to

$$W = \frac{1}{2x\sqrt{\frac{1}{x}}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sin\left(x\sqrt{\frac{1}{x}}\right)(6+x)}{x^2}}{\frac{2}{\sqrt{\frac{1}{x}}}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin\left(x\sqrt{\frac{1}{x}}\right)(6+x)\sqrt{\frac{1}{x}}}{2x^2}dx$$

Hence

$$u_1 = -\frac{3\sqrt{\pi}\left(-\frac{8}{\sqrt{\pi}\,x} - \frac{4\left(2\gamma - \frac{11}{3} + \ln(x) + 2\ln\left(\sqrt{\frac{1}{x}}\,\sqrt{x}\right)\right)}{3\sqrt{\pi}} + \frac{-\frac{44x}{9}+8}{\sqrt{\pi}\,x} + \frac{8\gamma}{3\sqrt{\pi}} + \frac{8\ln(2)}{3\sqrt{\pi}} + \frac{8\ln\left(\frac{\sqrt{x}}{2}\right)}{3\sqrt{\pi}} - \frac{8\cos\left(\sqrt{x}\right)}{3\sqrt{\pi}\,x} - \frac{16\left(-\frac{5x}{2}+5\right)\sin}{15\sqrt{\pi}\,x^{\frac{3}{2}}}}{8}$$

$$- \frac{\sqrt{\pi}\left(\frac{4\gamma - 4 + 2\ln(x) + 4\ln\left(\sqrt{\frac{1}{x}}\,\sqrt{x}\right)}{\sqrt{\pi}} + \frac{4}{\sqrt{\pi}} - \frac{4\gamma}{\sqrt{\pi}} - \frac{4\ln(2)}{\sqrt{\pi}} - \frac{4\ln\left(\frac{\sqrt{x}}{2}\right)}{\sqrt{\pi}} - \frac{4\sin\left(\sqrt{x}\right)}{\sqrt{\pi}\,\sqrt{x}} + \frac{4\,\operatorname{Ci}\left(\sqrt{x}\right)}{\sqrt{\pi}}\right)}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\cos\left(x\sqrt{\frac{1}{x}}\right)(6+x)}{x^2}}{\frac{2}{\sqrt{\frac{1}{x}}}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{\cos\left(x\sqrt{\frac{1}{x}}\right)(6+x)\sqrt{\frac{1}{x}}}{2x^2}dx$$

Hence

$$u_2 = \frac{3\sqrt{\pi}\,\sqrt{\frac{1}{x}}\,\sqrt{x}\left(-\frac{8(-x+2)\cos\left(\sqrt{x}\right)}{3x^{\frac{3}{2}}\sqrt{\pi}} + \frac{8\sin\left(\sqrt{x}\right)}{3x\sqrt{\pi}} + \frac{8\,\operatorname{Si}\left(\sqrt{x}\right)}{3\sqrt{\pi}}\right)}{8} + \frac{\sqrt{\pi}\,\sqrt{\frac{1}{x}}\,\sqrt{x}\left(-\frac{4\cos\left(\sqrt{x}\right)}{\sqrt{x}\,\sqrt{\pi}} - \frac{4\,\operatorname{Si}\left(\sqrt{x}\right)}{\sqrt{\pi}}\right)}{4}$$

Which simplifies to

$$u_1 = \frac{\cos\left(\sqrt{x}\right)\sqrt{x} + 2\sin\left(\sqrt{x}\right)}{x^{\frac{3}{2}}}$$

$$u_2 = \frac{\sqrt{\frac{1}{x}}\left(\sin\left(\sqrt{x}\right)\sqrt{x} - 2\cos\left(\sqrt{x}\right)\right)}{x}$$

Therefore the particular solution, from equation (1) is

$$
\begin{aligned}
y_p(x) = {} & \frac{\left(\cos \left(\sqrt{x}\right) \sqrt{x}+2 \sin \left(\sqrt{x}\right)\right) \cos \left(x \sqrt{\frac{1}{x}}\right)}{x^{\frac{3}{2}}} \\
& + \frac{\sqrt{\frac{1}{x}}\, \left(\sin \left(\sqrt{x}\right) \sqrt{x}-2 \cos \left(\sqrt{x}\right)\right) \sin \left(x \sqrt{\frac{1}{x}}\right)}{x}
\end{aligned}
$$

Which simplifies to

$$
\begin{aligned}
& y_p(x) \\
& = \frac{\left(\cos \left(\sqrt{x}\right) \sqrt{x}+2 \sin \left(\sqrt{x}\right)\right) \cos \left(x \sqrt{\frac{1}{x}}\right)+\sqrt{\frac{1}{x}}\, \sin \left(x \sqrt{\frac{1}{x}}\right) \left(\sin \left(\sqrt{x}\right) x-2 \cos \left(\sqrt{x}\right) \sqrt{x}\right)}{x^{\frac{3}{2}}}
\end{aligned}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \cos \left(\sqrt{x}\right)+c_2 \sin \left(\sqrt{x}\right)\right) \\
&\quad + \left(\frac{\left(\cos \left(\sqrt{x}\right) \sqrt{x}+2 \sin \left(\sqrt{x}\right)\right) \cos \left(x \sqrt{\frac{1}{x}}\right)+\sqrt{\frac{1}{x}}\, \sin \left(x \sqrt{\frac{1}{x}}\right) \left(\sin \left(\sqrt{x}\right) x-2 \cos \left(\sqrt{x}\right) \sqrt{x}\right)}{x^{\frac{3}{2}}}\right) \\
&= \frac{\left(\cos \left(\sqrt{x}\right) \sqrt{x}+2 \sin \left(\sqrt{x}\right)\right) \cos \left(x \sqrt{\frac{1}{x}}\right)+\sqrt{\frac{1}{x}}\, \sin \left(x \sqrt{\frac{1}{x}}\right) \left(\sin \left(\sqrt{x}\right) x-2 \cos \left(\sqrt{x}\right) \sqrt{x}\right)}{x^{\frac{3}{2}}} \\
&\quad + c_1 \cos \left(\sqrt{x}\right)+c_2 \sin \left(\sqrt{x}\right)
\end{aligned}
$$

Which simplifies to

$$
\begin{aligned}
& y \\
& = \frac{\left(\cos \left(\sqrt{x}\right) \sqrt{x}+2 \sin \left(\sqrt{x}\right)\right) \cos \left(x \sqrt{\frac{1}{x}}\right)+\sqrt{\frac{1}{x}}\, \sin \left(x \sqrt{\frac{1}{x}}\right) \left(\sin \left(\sqrt{x}\right) x-2 \cos \left(\sqrt{x}\right) \sqrt{x}\right)}{x^{\frac{3}{2}}} \\
& \quad + c_1 \cos \left(\sqrt{x}\right)+c_2 \sin \left(\sqrt{x}\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \frac{\left(\cos \left(\sqrt{x}\right) \sqrt{x}+2 \sin \left(\sqrt{x}\right)\right) \cos \left(x \sqrt{\frac{1}{x}}\right)+\sqrt{\frac{1}{x}}\, \sin \left(x \sqrt{\frac{1}{x}}\right) \left(\sin \left(\sqrt{x}\right) x-2 \cos \left(\sqrt{x}\right) \sqrt{x}\right)}{x^{\frac{3}{2}}} + c_1 \cos \left(\sqrt{\right. \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = \infty$ in the above gives

$$0 = -|c_1| - |c_2|..|c_1| + |c_2| \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

20.29.4 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \frac{xy'}{2} + \frac{yx}{4} = \frac{6+x}{4x} \tag{1}$$

Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE and y_p is a particular solution to the non-homogeneous ODE. Bessel ode has the form

$$x^2y'' + xy' + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\, xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha(c_1 \,\text{BesselJ}\,(n, \beta\, x^\gamma) + c_2 \,\text{BesselY}\,(n, \beta\, x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{4}$$
$$\beta = 1$$
$$n = \frac{1}{2}$$
$$\gamma = \frac{1}{2}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1 \sqrt{2}\, \sin\left(\sqrt{x}\right)}{\sqrt{\pi}} - \frac{c_2 \sqrt{2}\, \cos\left(\sqrt{x}\right)}{\sqrt{\pi}}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 \sqrt{2}\, \sin\left(\sqrt{x}\right)}{\sqrt{\pi}} - \frac{c_2 \sqrt{2}\, \cos\left(\sqrt{x}\right)}{\sqrt{\pi}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{\sqrt{2}\, \sin\left(\sqrt{x}\right)}{\sqrt{\pi}}$$

$$y_2 = -\frac{\sqrt{2}\, \cos\left(\sqrt{x}\right)}{\sqrt{\pi}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{\sqrt{2}\, \sin(\sqrt{x})}{\sqrt{\pi}} & -\frac{\sqrt{2}\, \cos(\sqrt{x})}{\sqrt{\pi}} \\ \frac{d}{dx}\left(\frac{\sqrt{2}\, \sin(\sqrt{x})}{\sqrt{\pi}}\right) & \frac{d}{dx}\left(-\frac{\sqrt{2}\, \cos(\sqrt{x})}{\sqrt{\pi}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{\sqrt{2}\,\sin(\sqrt{x})}{\sqrt{\pi}} & -\frac{\sqrt{2}\,\cos(\sqrt{x})}{\sqrt{\pi}} \\ \frac{\sqrt{2}\,\cos(\sqrt{x})}{2\sqrt{\pi}\,\sqrt{x}} & \frac{\sqrt{2}\,\sin(\sqrt{x})}{2\sqrt{\pi}\,\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = \left(\frac{\sqrt{2}\,\sin\left(\sqrt{x}\right)}{\sqrt{\pi}}\right)\left(\frac{\sqrt{2}\,\sin\left(\sqrt{x}\right)}{2\sqrt{\pi}\,\sqrt{x}}\right) - \left(-\frac{\sqrt{2}\,\cos\left(\sqrt{x}\right)}{\sqrt{\pi}}\right)\left(\frac{\sqrt{2}\,\cos\left(\sqrt{x}\right)}{2\sqrt{\pi}\,\sqrt{x}}\right)$$

Which simplifies to

$$W = \frac{\cos\left(\sqrt{x}\right)^2 + \sin\left(\sqrt{x}\right)^2}{\pi\sqrt{x}}$$

Which simplifies to

$$W = \frac{1}{\pi\sqrt{x}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{\sqrt{2}\,\cos(\sqrt{x})(6+x)}{4\sqrt{\pi}\,x}}{\frac{x^{\frac{3}{2}}}{\pi}}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{\sqrt{2}\,\sqrt{\pi}\,\cos\left(\sqrt{x}\right)(6+x)}{4x^{\frac{5}{2}}}dx$$

Hence

$$u_1 = \frac{\sqrt{2}\,\sqrt{\pi}\left(-\frac{4\cos(\sqrt{x})}{x^{\frac{3}{2}}} + \frac{2\sin(\sqrt{x})}{x}\right)}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\sqrt{2}\,\sin(\sqrt{x})(6+x)}{4\sqrt{\pi}\,x}}{\frac{x^{\frac{3}{2}}}{\pi}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{\sqrt{2}\,\sqrt{\pi}\,\sin\left(\sqrt{x}\right)(6+x)}{4x^{\frac{5}{2}}}dx$$

Hence

$$u_2 = \frac{\sqrt{2}\,\sqrt{\pi}\left(-\frac{4\sin\left(\sqrt{x}\right)}{x^{\frac{3}{2}}} - \frac{2\cos\left(\sqrt{x}\right)}{x}\right)}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\left(-\frac{4\cos\left(\sqrt{x}\right)}{x^{\frac{3}{2}}} + \frac{2\sin\left(\sqrt{x}\right)}{x}\right)\sin\left(\sqrt{x}\right)}{2} - \frac{\left(-\frac{4\sin\left(\sqrt{x}\right)}{x^{\frac{3}{2}}} - \frac{2\cos\left(\sqrt{x}\right)}{x}\right)\cos\left(\sqrt{x}\right)}{2}$$

Which simplifies to

$$y_p(x) = \frac{1}{x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1\sqrt{2}\,\sin\left(\sqrt{x}\right)}{\sqrt{\pi}} - \frac{c_2\sqrt{2}\,\cos\left(\sqrt{x}\right)}{\sqrt{\pi}}\right) + \left(\frac{1}{x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1\sqrt{2}\,\sin\left(\sqrt{x}\right)}{\sqrt{\pi}} - \frac{c_2\sqrt{2}\,\cos\left(\sqrt{x}\right)}{\sqrt{\pi}} + \frac{1}{x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = \infty$ in the above gives

$$0 = \frac{(-|c_1| - |c_2|)\sqrt{2}}{\sqrt{\pi}} .. \frac{\sqrt{2}\,(|c_1| + |c_2|)}{\sqrt{\pi}} \tag{1A}$$

Equations {1A} are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

20.29.5 Solving using Kovacic algorithm

Writing the ode as

$$4xy'' + 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x \\ B &= 2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4x - 3}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4x - 3 \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-4x - 3}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 669: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 1 \\
&= 1
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [2]$$

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16x^2} - \frac{1}{4x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned}
E_c &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\
&= \{1, 2, 3\}
\end{aligned}$$

Since the order of r at ∞ is $1 < 2$ then

$$E_\infty = \{1\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{1, 2, 3\}$

Order of r at ∞	E_∞
1	$\{1\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 1, \; e_\infty = 1$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(1 - (1)) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{1}{(x-(0))}\right) \\ &= \frac{1}{2x} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right) p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right) p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p} \\ &= \frac{1}{2x}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \frac{w}{2x} + \frac{4x+1}{16x^2} = 0$$

Solving for ω gives

$$\omega = \frac{1 + 2\sqrt{-x}}{4x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{1+2\sqrt{-x}}{4x} dx} \\ &= x^{\frac{1}{4}} \mathrm{e}^{\sqrt{-x}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{4x} \, dx} \\ &= z_1 e^{-\frac{\ln(x)}{4}} \\ &= z_1 \left(\frac{1}{x^{\frac{1}{4}}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\sqrt{-x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2}{4x}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{\ln(x)}{2}}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\sqrt{-x}\left(-1+\mathrm{e}^{-2\sqrt{-x}}\right)}{\sqrt{x}} \right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{\sqrt{-x}}\right) + c_2 \left(\mathrm{e}^{\sqrt{-x}} \left(\frac{\sqrt{-x}\left(-1+\mathrm{e}^{-2\sqrt{-x}}\right)}{\sqrt{x}} \right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$4xy'' + 2y' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{\sqrt{-x}} + \frac{c_2\sqrt{-x}\left(-\mathrm{e}^{\sqrt{-x}} + \mathrm{e}^{-\sqrt{-x}}\right)}{\sqrt{x}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \mathrm{e}^{\sqrt{-x}} \\ y_2 &= \frac{\sqrt{-x}\left(-\mathrm{e}^{\sqrt{-x}} + \mathrm{e}^{-\sqrt{-x}}\right)}{\sqrt{x}} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{\sqrt{-x}} & \frac{\sqrt{-x}\left(-\mathrm{e}^{\sqrt{-x}}+\mathrm{e}^{-\sqrt{-x}}\right)}{\sqrt{x}} \\ \frac{d}{dx}\left(\mathrm{e}^{\sqrt{-x}}\right) & \frac{d}{dx}\left(\frac{\sqrt{-x}\left(-\mathrm{e}^{\sqrt{-x}}+\mathrm{e}^{-\sqrt{-x}}\right)}{\sqrt{x}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{\sqrt{-x}} & \frac{\sqrt{-x}\left(-\mathrm{e}^{\sqrt{-x}}+\mathrm{e}^{-\sqrt{-x}}\right)}{\sqrt{x}} \\ -\frac{\mathrm{e}^{\sqrt{-x}}}{2\sqrt{-x}} & -\frac{-\mathrm{e}^{\sqrt{-x}}+\mathrm{e}^{-\sqrt{-x}}}{2\sqrt{-x}\,\sqrt{x}} + \frac{\sqrt{-x}\left(\frac{\mathrm{e}^{\sqrt{-x}}}{2\sqrt{-x}}+\frac{\mathrm{e}^{-\sqrt{-x}}}{2\sqrt{-x}}\right)}{\sqrt{x}} - \frac{\sqrt{-x}\left(-\mathrm{e}^{\sqrt{-x}}+\mathrm{e}^{-\sqrt{-x}}\right)}{2x^{\frac{3}{2}}} \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{\sqrt{-x}}\right)\left(-\frac{-\mathrm{e}^{\sqrt{-x}}+\mathrm{e}^{-\sqrt{-x}}}{2\sqrt{-x}\,\sqrt{x}}+\frac{\sqrt{-x}\left(\frac{\mathrm{e}^{\sqrt{-x}}}{2\sqrt{-x}}+\frac{\mathrm{e}^{-\sqrt{-x}}}{2\sqrt{-x}}\right)}{\sqrt{x}}-\frac{\sqrt{-x}\left(-\mathrm{e}^{\sqrt{-x}}+\mathrm{e}^{-\sqrt{-x}}\right)}{2x^{\frac{3}{2}}}\right)
- \left(\frac{\sqrt{-x}\left(-\mathrm{e}^{\sqrt{-x}}+\mathrm{e}^{-\sqrt{-x}}\right)}{\sqrt{x}}\right)\left(-\frac{\mathrm{e}^{\sqrt{-x}}}{2\sqrt{-x}}\right)$$

Which simplifies to

$$W = \frac{\mathrm{e}^{\sqrt{-x}}\mathrm{e}^{-\sqrt{-x}}}{\sqrt{x}}$$

Which simplifies to

$$W = \frac{1}{\sqrt{x}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sqrt{-x}\left(-\mathrm{e}^{\sqrt{-x}}+\mathrm{e}^{-\sqrt{-x}}\right)(6+x)}{x^{\frac{5}{2}}}}{4\sqrt{x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{(6+x)\left(\mathrm{e}^{\sqrt{-x}}-\mathrm{e}^{-\sqrt{-x}}\right)}{4\,(-x)^{\frac{5}{2}}}dx$$

Hence

$$u_1 = \frac{\mathrm{e}^{-\sqrt{-x}}}{(-x)^{\frac{3}{2}}}+\frac{\mathrm{e}^{-\sqrt{-x}}}{2x}-\frac{\mathrm{e}^{\sqrt{-x}}}{(-x)^{\frac{3}{2}}}+\frac{\mathrm{e}^{\sqrt{-x}}}{2x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\mathrm{e}^{\sqrt{-x}}(6+x)}{x^2}}{4\sqrt{x}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{\mathrm{e}^{\sqrt{-x}}(6+x)}{4x^{\frac{5}{2}}}dx$$

Hence

$$u_2 = \frac{3(-x)^{\frac{5}{2}} \left(\frac{1}{3(-x)^{\frac{3}{2}}} - \frac{1}{2x} + \frac{1}{2\sqrt{-x}} + \frac{11}{36} - \frac{\ln(x)}{12} - \frac{\ln\left(-\frac{\sqrt{-x}}{\sqrt{x}}\right)}{6} - \frac{\sqrt{-x}\left(22(-x)^{\frac{3}{2}} - 36x + 36\sqrt{-x} + 24\right)}{72x^2} + \frac{\sqrt{-x}\,(-4x+4\sqrt{-x}+8)\mathrm{e}}{24x^2}}{x^{\frac{5}{2}}} + \frac{(-x)^{\frac{3}{2}} \left(\frac{1}{\sqrt{-x}} + 1 - \frac{\ln(x)}{2} - \ln\left(-\frac{\sqrt{-x}}{\sqrt{x}}\right) + \frac{\sqrt{-x}\,(2\sqrt{-x}+2)}{2x} - \frac{\sqrt{-x}\,\mathrm{e}^{\sqrt{-x}}}{x} + \ln\left(-\sqrt{-x}\right) + \mathrm{expIntegral}_1\left(-\sqrt{-}\right.\right.}{2x^{\frac{3}{2}}}$$

Which simplifies to

$$u_1 = -\frac{\left(\sqrt{-x}-2\right)\mathrm{e}^{-\sqrt{-x}} + \mathrm{e}^{\sqrt{-x}}\left(\sqrt{-x}+2\right)}{2\,(-x)^{\frac{3}{2}}}$$

$$u_2 = -\frac{\mathrm{e}^{\sqrt{-x}}\left(\sqrt{-x}+2\right)}{2x^{\frac{3}{2}}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\left(\left(\sqrt{-x}-2\right)\mathrm{e}^{-\sqrt{-x}} + \mathrm{e}^{\sqrt{-x}}\left(\sqrt{-x}+2\right)\right)\mathrm{e}^{\sqrt{-x}}}{2\,(-x)^{\frac{3}{2}}} - \frac{\mathrm{e}^{\sqrt{-x}}\left(\sqrt{-x}+2\right)\sqrt{-x}\left(-\mathrm{e}^{\sqrt{-x}} + \mathrm{e}^{-\sqrt{-x}}\right)}{2x^2}$$

Which simplifies to

$$y_p(x) = \frac{1}{x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{\sqrt{-x}} + \frac{c_2\sqrt{-x}\left(-\mathrm{e}^{\sqrt{-x}} + \mathrm{e}^{-\sqrt{-x}}\right)}{\sqrt{x}}\right) + \left(\frac{1}{x}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{\sqrt{-x}} + \frac{c_2 \sqrt{-x}\left(-e^{\sqrt{-x}} + e^{-\sqrt{-x}}\right)}{\sqrt{x}} + \frac{1}{x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = \infty$ in the above gives

$$0 = -|\Re((1+i)\,c_1)| - i|\Im((1+i)\,c_1)| + 2\min\left(-\Re((1-i)\,c_2), -\Re((1+i)\,c_2), \Re((1-i)\,c_2), \Re((1+i)\,c_2 \right. \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{\left(x^2+1\right) y''+2xy'=\frac{1}{x^2+1}}$$

With initial conditions

$$\left[y(\infty)=\frac{\pi^2}{8}, y'(0)=0\right]$$

20.30.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(\left(x^2+1\right) y''+2xy'\right) dx = \int \frac{1}{x^2+1} dx$$
$$\left(x^2+1\right) y' = \arctan\left(x\right)+c_1$$

Which is now solved for y. Integrating both sides gives

$$\begin{aligned} y &= \int \frac{\arctan\left(x\right)+c_1}{x^2+1}\,\mathrm{d}x \\ &= \frac{\arctan\left(x\right)^2}{2}+\arctan\left(x\right) c_1+c_2 \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{\arctan\left(x\right)^2}{2}+\arctan\left(x\right) c_1+c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y=\frac{\pi^2}{8}$ and $x=\infty$ in the above gives

$$\frac{\pi^2}{8} = \frac{1}{8}\pi^2+\frac{1}{2}\pi c_1+c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{\arctan\left(x\right)}{x^2+1}+\frac{c_1}{x^2+1}$$

substituting $y'=0$ and $x=0$ in the above gives

$$0 = c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 0 \\ c_2 &= 0 \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{\arctan\left(x\right)^2}{2}$$

Summary
The solution(s) found are the following

$$y = \frac{\arctan(x)^2}{2} \tag{1}$$

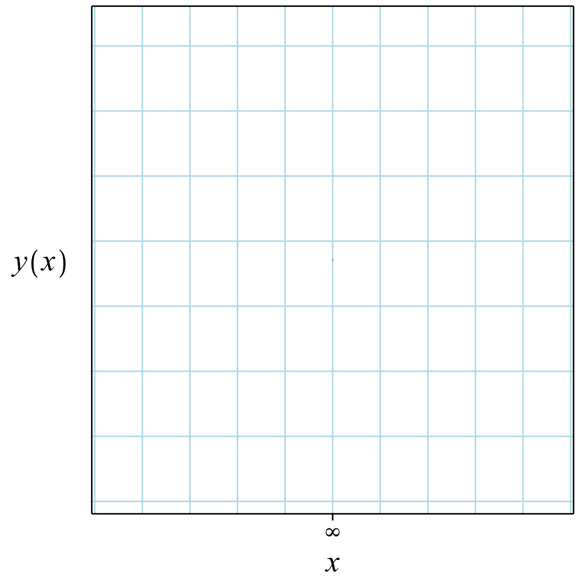

Figure 797: Solution plot

Verification of solutions

$$y = \frac{\arctan(x)^2}{2}$$

Verified OK.

20.30.2 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$(x^2+1)\, p'(x) + 2p(x)\, x - \frac{1}{x^2+1} = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{2x}{x^2+1}dx}\\ &= x^2+1\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu p) &= (\mu)\left(\frac{1}{(x^2+1)^2}\right)\\ \frac{d}{dx}\left((x^2+1)\,p\right) &= (x^2+1)\left(\frac{1}{(x^2+1)^2}\right)\\ d\left((x^2+1)\,p\right) &= \frac{1}{x^2+1}\,dx\end{aligned}$$

Integrating gives

$$\begin{aligned}(x^2+1)\,p &= \int \frac{1}{x^2+1}\,dx\\ (x^2+1)\,p &= \arctan(x)+c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = x^2+1$ results in

$$p(x) = \frac{\arctan(x)}{x^2+1}+\frac{c_1}{x^2+1}$$

which simplifies to

$$p(x) = \frac{\arctan(x)+c_1}{x^2+1}$$

Initial conditions are used to solve for c_1. Substituting $x=0$ and $p=0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$p(x) = \frac{\arctan(x)}{x^2+1}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{\arctan(x)}{x^2+1}$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{\arctan(x)}{x^2+1}\, \mathrm{d}x \\ &= \frac{\arctan(x)^2}{2} + c_2 \end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $x = \infty$ and $y = \frac{\pi^2}{8}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{\pi^2}{8} = \frac{\pi^2}{8} + c_2$$

$$c_2 = 0$$

Substituting c_2 found above in the general solution gives

$$y = \frac{\arctan(x)^2}{2}$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$y = \frac{\arctan(x)^2}{2} \tag{1}$$

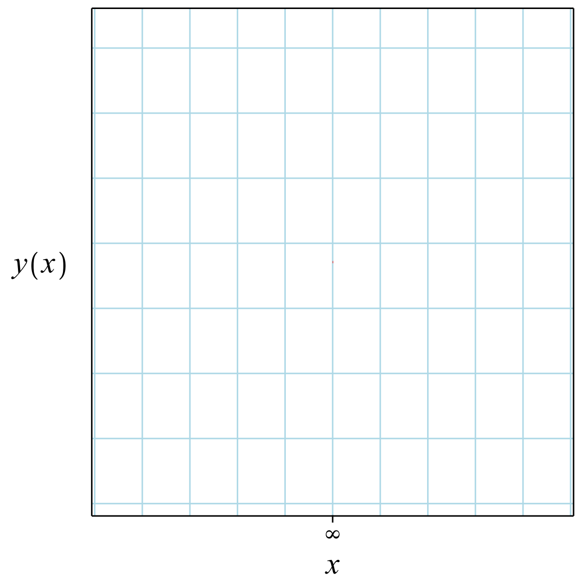

Figure 798: Solution plot

Verification of solutions

$$y = \frac{\arctan(x)^2}{2}$$

Verified OK.

20.30.3 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$(x^2+1)\,y'' + 2xy' = \frac{1}{x^2+1}$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left((x^2+1)\,y'' + 2xy'\right) dx = \int \frac{1}{x^2+1} dx$$
$$(x^2+1)\,y' = \arctan(x) + c_1$$

Which is now solved for y. Integrating both sides gives

$$\begin{aligned} y &= \int \frac{\arctan(x) + c_1}{x^2+1}\, \mathrm{d}x \\ &= \frac{\arctan(x)^2}{2} + \arctan(x)\, c_1 + c_2 \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{\arctan(x)^2}{2} + \arctan(x) c_1 + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{\pi^2}{8}$ and $x = \infty$ in the above gives

$$\frac{\pi^2}{8} = \frac{1}{8}\pi^2 + \frac{1}{2}\pi c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{\arctan(x)}{x^2+1} + \frac{c_1}{x^2+1}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = c_1 \tag{2A}$$

Equations $\{1\text{A},2\text{A}\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = \frac{\arctan(x)^2}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{\arctan(x)^2}{2} \tag{1}$$

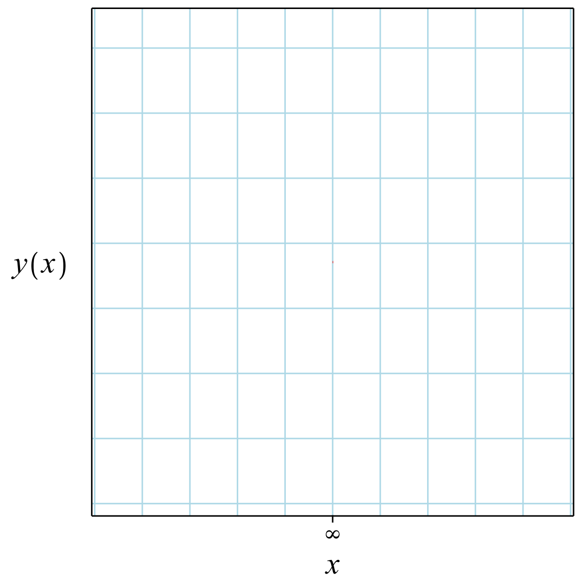

Figure 799: Solution plot

Verification of solutions

$$y = \frac{\arctan(x)^2}{2}$$

Verified OK.

20.30.4 Solving using Kovacic algorithm

Writing the ode as

$$(x^2+1)\, y'' + 2xy' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 + 1 \\ B &= 2x \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{\left(x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 1$$
$$t = \left(x^2+1\right)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{1}{\left(x^2+1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 670: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4(x-i)^2} - \frac{1}{4(x+i)^2} - \frac{i}{4(x-i)} + \frac{i}{4x+4i}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{1}{(x^2+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$-i$	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\ &= 1 - (1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x-2i} + \frac{1}{2x+2i} + (-)(0) \\ &= \frac{1}{2x-2i} + \frac{1}{2x+2i} \\ &= \frac{x}{x^2+1} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x - 2i} + \frac{1}{2x + 2i}\right)(0) + \left(\left(-\frac{1}{2\left(x - i\right)^2} - \frac{1}{2\left(x + i\right)^2}\right) + \left(\frac{1}{2x - 2i} + \frac{1}{2x + 2i}\right)^2 - \left(\frac{1}{\left(x^2 + 1\right)^2}\right.\right.$$
$$0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x - 2i} + \frac{1}{2x + 2i}\right) dx} \\
&= \sqrt{x^2 + 1}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{2x}{x^2 + 1} \, dx} \\
&= z_1 e^{-\frac{\ln\left(x^2 + 1\right)}{2}} \\
&= z_1 \left(\frac{1}{\sqrt{x^2 + 1}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x}{x^2+1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(x^2+1)}}{(y_1)^2}\, dx \\
&= y_1(\arctan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2(1(\arctan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
(x^2+1)\, y'' + 2xy' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 + c_2 \arctan(x)
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= 1 \\
y_2 &= \arctan(x)
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & \arctan(x) \\ \frac{d}{dx}(1) & \frac{d}{dx}(\arctan(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & \arctan(x) \\ 0 & \frac{1}{x^2+1} \end{vmatrix}$$

Therefore

$$W = (1)\left(\frac{1}{x^2+1}\right) - (\arctan(x))(0)$$

Which simplifies to

$$W = \frac{1}{x^2+1}$$

Which simplifies to

$$W = \frac{1}{x^2+1}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\arctan(x)}{x^2+1}}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\arctan(x)}{x^2+1}dx$$

Hence

$$u_1 = -\frac{\arctan(x)^2}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{1}{x^2+1}}{1}\, dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x^2+1} dx$$

Hence

$$u_2 = \arctan(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\arctan(x)^2}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 + c_2 \arctan(x)) + \left(\frac{\arctan(x)^2}{2}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 + c_2 \arctan(x) + \frac{\arctan(x)^2}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{\pi^2}{8}$ and $x = \infty$ in the above gives

$$\frac{\pi^2}{8} = c_1 + \frac{1}{2}c_2\pi + \frac{1}{8}\pi^2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{c_2}{x^2+1} + \frac{\arctan(x)}{x^2+1}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = \frac{\arctan(x)^2}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{\arctan(x)^2}{2} \tag{1}$$

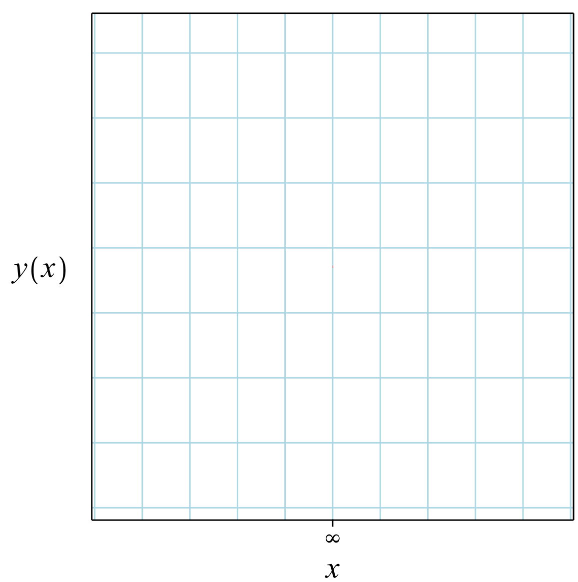

Figure 800: Solution plot

Verification of solutions

$$y = \frac{\arctan(x)^2}{2}$$

Verified OK.

20.30.5 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y''+q(x)\,y'+r(x)\,y=s(x)$$

is exact if

$$p''(x)-q'(x)+r(x)=0 \tag{1}$$

For the given ode we have

$$\begin{aligned}p(x)&=x^2+1\\q(x)&=2x\\r(x)&=0\\s(x)&=\frac{1}{x^2+1}\end{aligned}$$

Hence

$$\begin{aligned}p''(x)&=2\\q'(x)&=2\end{aligned}$$

Therefore (1) becomes

$$2-(2)+(0)=0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y'+(q(x)-p'(x))\,y)'=s(x)$$

Integrating gives

$$p(x)\,y'+(q(x)-p'(x))\,y=\int s(x)\,dx$$

Substituting the above values for p,q,r,s gives

$$\left(x^2+1\right)y'=\int\frac{1}{x^2+1}\,dx$$

We now have a first order ode to solve which is

$$\left(x^2+1\right)y'=\arctan\left(x\right)+c_1$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int \frac{\arctan(x) + c_1}{x^2 + 1}\, \mathrm{d}x \\
&= \frac{\arctan(x)^2}{2} + \arctan(x)\, c_1 + c_2
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \frac{\arctan(x)^2}{2} + \arctan(x)\, c_1 + c_2 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{\pi^2}{8}$ and $x = \infty$ in the above gives

$$
\frac{\pi^2}{8} = \frac{1}{8}\pi^2 + \frac{1}{2}\pi c_1 + c_2 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = \frac{\arctan(x)}{x^2 + 1} + \frac{c_1}{x^2 + 1}
$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$
0 = c_1 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 0 \\
c_2 &= 0
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \frac{\arctan(x)^2}{2}
$$

Summary

The solution(s) found are the following

$$
y = \frac{\arctan(x)^2}{2} \tag{1}
$$

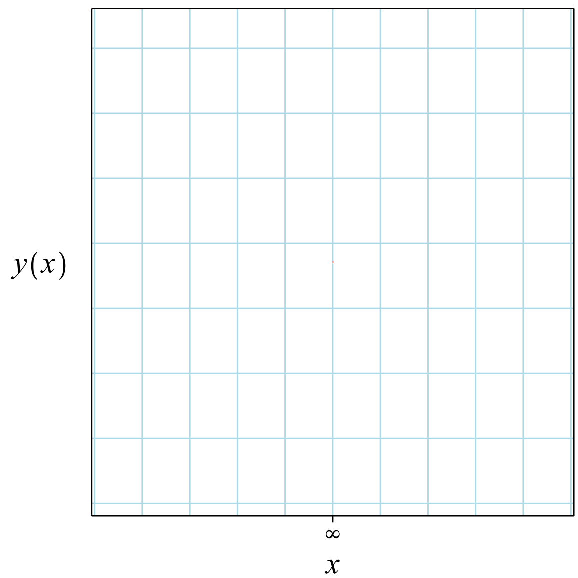

Figure 801: Solution plot

Verification of solutions

$$y = \frac{\arctan(x)^2}{2}$$

Verified OK.

20.30.6 Maple step by step solution

Let's solve

$$\left[(x^2+1)\,y'' + 2xy' = \frac{1}{x^2+1}, y(\infty) = \frac{\pi^2}{8}, y'\Big|_{\{x=0\}} = 0\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $(x^2+1)\,u'(x) + 2xu(x) = \frac{1}{x^2+1}$

- Isolate the derivative

  $u'(x) = -\frac{2xu(x)}{x^2+1} + \frac{1}{(x^2+1)^2}$

- Group terms with $u(x)$ on the lhs of the ODE and the rest on the rhs of the ODE

  $u'(x) + \frac{2xu(x)}{x^2+1} = \frac{1}{(x^2+1)^2}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(u'(x)+\frac{2xu(x)}{x^2+1}\right)=\frac{\mu(x)}{(x^2+1)^2}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,u(x))$

  $\mu(x)\left(u'(x)+\frac{2xu(x)}{x^2+1}\right)=\mu'(x)\,u(x)+\mu(x)\,u'(x)$

- Isolate $\mu'(x)$

  $\mu'(x)=\frac{2\mu(x)x}{x^2+1}$

- Solve to find the integrating factor

  $\mu(x)=x^2+1$

- Integrate both sides with respect to x

  $\int\left(\frac{d}{dx}(\mu(x)\,u(x))\right)dx=\int\frac{\mu(x)}{(x^2+1)^2}dx+c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,u(x)=\int\frac{\mu(x)}{(x^2+1)^2}dx+c_1$

- Solve for $u(x)$

  $u(x)=\frac{\int\frac{\mu(x)}{\left(x^2+1\right)^2}dx+c_1}{\mu(x)}$

- Substitute $\mu(x)=x^2+1$

  $u(x)=\frac{\int\frac{1}{x^2+1}dx+c_1}{x^2+1}$

- Evaluate the integrals on the rhs

  $u(x)=\frac{\arctan(x)+c_1}{x^2+1}$

- Solve 1st ODE for $u(x)$

  $u(x)=\frac{\arctan(x)+c_1}{x^2+1}$

- Make substitution $u=y'$

  $y'=\frac{\arctan(x)+c_1}{x^2+1}$

- Integrate both sides to solve for y

  $\int y'dx=\int\frac{\arctan(x)+c_1}{x^2+1}dx+c_2$

- Compute integrals

  $y=\frac{\arctan(x)^2}{2}+\arctan(x)\,c_1+c_2$

☐ Check validity of solution $y=\frac{\arctan(x)^2}{2}+\arctan(x)\,c_1+c_2$

- Use initial condition $y(\infty) = \frac{\pi^2}{8}$

  $\frac{\pi^2}{8} = \frac{1}{8}\pi^2 + \frac{1}{2}\pi c_1 + c_2$

- Compute derivative of the solution

  $y' = \frac{\arctan(x)}{x^2+1} + \frac{c_1}{x^2+1}$

- Use the initial condition $y'\Big|_{\{x=0\}} = 0$

  $0 = c_1$

- Solve for c_1 and c_2

  $\{c_1 = 0, c_2 = 0\}$

- Substitute constant values into general solution and simplify

  $y = \frac{\arctan(x)^2}{2}$

- Solution to the IVP

  $y = \frac{\arctan(x)^2}{2}$

With initial conditions

$$[y(-\infty)=0, y'(0)=1]$$

20.31.1 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1 - x, B = x, C = -1, f(x) = (x-1)^2 e^x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$(1-x)\,y'' + xy' - y = 0$$

In normal form the ode

$$(1-x)\,y'' + xy' - y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{x}{x-1} \\ q(x) &= \frac{1}{x-1} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{n}{x-1} + \frac{1}{x-1} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{2}{x} - \frac{x}{x-1}\right) v'(x) &= 0 \\ v''(x) + \left(\frac{2}{x} - \frac{x}{x-1}\right) v'(x) &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \left(\frac{2}{x} - \frac{x}{x-1}\right) u(x) = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= \frac{u(x^2 - 2x + 2)}{x(x-1)} \end{aligned}$$

Where $f(x) = \frac{x^2-2x+2}{x(x-1)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= \frac{x^2 - 2x + 2}{x(x-1)}\, dx \\ \int \frac{1}{u}\, du &= \int \frac{x^2 - 2x + 2}{x(x-1)}\, dx \\ \ln(u) &= x + \ln(x-1) - 2\ln(x) + c_1 \\ u &= e^{x + \ln(x-1) - 2\ln(x) + c_1} \\ &= c_1 e^{x + \ln(x-1) - 2\ln(x)} \end{aligned}$$

Which simplifies to

$$u(x) = c_1 \left(\frac{e^x}{x} - \frac{e^x}{x^2}\right)$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= \frac{e^x c_1}{x} + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(\frac{e^x c_1}{x} + c_2\right) x \\
&= e^x c_1 + c_2 x
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
(1-x)\, y'' + xy' - y = (x-1)^2\, e^x
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x \\
y_2 &= e^x
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & e^x \\ \frac{d}{dx}(x) & \frac{d}{dx}(e^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & e^x \\ 1 & e^x \end{vmatrix}$$

Therefore

$$W = (x)(e^x) - (e^x)(1)$$

Which simplifies to

$$W = x\,e^x - e^x$$

Which simplifies to

$$W = (x - 1)\,e^x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x-1)^2\,e^{2x}}{(1-x)(x-1)\,e^x}\,dx$$

Which simplifies to

$$u_1 = -\int -e^x dx$$

Hence

$$u_1 = e^x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(x-1)^2\,e^x}{(1-x)(x-1)\,e^x}\,dx$$

Which simplifies to

$$u_2 = \int -x dx$$

Hence

$$u_2 = -\frac{x^2}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x\,\mathrm{e}^{x} - \frac{\mathrm{e}^{x} x^2}{2}$$

Which simplifies to

$$y_p(x) = -\frac{\mathrm{e}^{x} x(x-2)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(\frac{\mathrm{e}^{x} c_1}{x} + c_2\right) x\right) + \left(-\frac{\mathrm{e}^{x} x(x-2)}{2}\right) \\ &= -\frac{\mathrm{e}^{x} x(x-2)}{2} + \left(\frac{\mathrm{e}^{x} c_1}{x} + c_2\right) x \end{aligned}$$

Which simplifies to

$$y = \frac{(-x^2 + 2c_1 + 2x)\,\mathrm{e}^{x}}{2} + c_2 x$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{(-x^2 + 2c_1 + 2x)\,\mathrm{e}^{x}}{2} + c_2 x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = -\infty$ in the above gives

$$0 = -\operatorname{signum}(c_2)\,\infty \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{(2-2x)\,\mathrm{e}^{x}}{2} + \frac{(-x^{2}+2c_1+2x)\,\mathrm{e}^{x}}{2} + c_2$$

substituting $y'=1$ and $x=0$ in the above gives

$$1 = 1 + c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Warning, unable to solve for constants of integrations.

Verification of solutions N/A

20.31.2 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + \left(2AB' + B^{2}\right)v' + (AB'' + BB' + CB)\,v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^{2}\right)v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^{2}\right)u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= 1-x \\
B &= x \\
C &= -1 \\
F &= (x-1)^2 \, \mathrm{e}^x
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= (1-x)(0) + (x)(1) + (-1)(x) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
-x(x-1) \, v'' + (x^2 - 2x + 2) \, v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
(-x^2 + x) \, u'(x) + (x^2 - 2x + 2) \, u(x) = 0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= \frac{u(x^2 - 2x + 2)}{x\,(x-1)}
\end{aligned}
$$

Where $f(x) = \frac{x^2-2x+2}{x(x-1)}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u} \, du &= \frac{x^2 - 2x + 2}{x\,(x-1)} \, dx \\
\int \frac{1}{u} \, du &= \int \frac{x^2 - 2x + 2}{x\,(x-1)} \, dx \\
\ln(u) &= x + \ln(x-1) - 2\ln(x) + c_1 \\
u &= \mathrm{e}^{x + \ln(x-1) - 2\ln(x) + c_1} \\
&= c_1 \mathrm{e}^{x + \ln(x-1) - 2\ln(x)}
\end{aligned}
$$

Which simplifies to

$$
u(x) = c_1 \left(\frac{\mathrm{e}^x}{x} - \frac{\mathrm{e}^x}{x^2} \right)
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= c_1 \left(\frac{e^x}{x} - \frac{e^x}{x^2} \right)
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int \frac{c_1 e^x (x-1)}{x^2} \, dx \\
&= \frac{e^x c_1}{x} + c_2
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= Bv \\
&= (x) \left(\frac{e^x c_1}{x} + c_2 \right) \\
&= e^x c_1 + c_2 x
\end{aligned}
$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x \\
y_2 &= e^x
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & e^x \\ \frac{d}{dx}(x) & \frac{d}{dx}(e^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & e^x \\ 1 & e^x \end{vmatrix}$$

Therefore

$$W = (x)(e^x) - (e^x)(1)$$

Which simplifies to

$$W = x\,e^x - e^x$$

Which simplifies to

$$W = (x-1)\,e^x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x-1)^2 e^{2x}}{(1-x)(x-1)e^x}\,dx$$

Which simplifies to

$$u_1 = -\int -e^x dx$$

Hence

$$u_1 = e^x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(x-1)^2 e^x}{(1-x)(x-1)e^x}\,dx$$

Which simplifies to

$$u_2 = \int -x dx$$

Hence

$$u_2 = -\frac{x^2}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x\,\mathrm{e}^x - \frac{\mathrm{e}^x x^2}{2}$$

Which simplifies to

$$y_p(x) = -\frac{\mathrm{e}^x x(x-2)}{2}$$

Hence the complete solution is

$$\begin{aligned} y(x) &= y_h + y_p \\ &= (\mathrm{e}^x c_1 + c_2 x) + \left(-\frac{\mathrm{e}^x x(x-2)}{2}\right) \\ &= \frac{(-x^2 + 2c_1 + 2x)\,\mathrm{e}^x}{2} + c_2 x \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{(-x^2 + 2c_1 + 2x)\,\mathrm{e}^x}{2} + c_2 x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = -\infty$ in the above gives

$$0 = -\operatorname{signum}(c_2)\,\infty \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{(2-2x)\,\mathrm{e}^x}{2} + \frac{(-x^2 + 2c_1 + 2x)\,\mathrm{e}^x}{2} + c_2$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = 1 + c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Warning, unable to solve for constants of integrations.

Verification of solutions N/A

20.31.3 Solving using Kovacic algorithm

Writing the ode as

$$(1 - x) y'' + xy' - y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 - x \\ B &= x \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 4x + 6}{4 (x - 1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 4x + 6 \\ t &= 4(x - 1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 4x + 6}{4\left(x - 1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 672: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x-1)^2$. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4(x-1)^2} - \frac{1}{2(x-1)}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{x^3} + \frac{11}{4x^4} + \frac{21}{4x^5} + \frac{15}{2x^6} + \frac{6}{x^7} - \frac{117}{16x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{2}
\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 4x + 6}{4x^2 - 8x + 4} \\ &= Q + \frac{R}{4x^2 - 8x + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x + 5}{4x^2 - 8x + 4}\right) \\ &= \frac{1}{4} + \frac{-2x + 5}{4x^2 - 8x + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 4x + 6}{4\left(x-1\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{1}{2\left(x-1\right)} + \left(\frac{1}{2}\right) \\ &= -\frac{1}{2\left(x-1\right)} + \frac{1}{2} \\ &= \frac{x-2}{2x-2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2(x-1)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2(x-1)^2}\right) + \left(-\frac{1}{2(x-1)} + \frac{1}{2}\right)^2 - \left(\frac{x^2 - 4x + 6}{4(x-1)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(-\frac{1}{2(x-1)} + \frac{1}{2}\right) dx} \\ &= \frac{e^{\frac{x}{2}}}{\sqrt{x-1}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{1-x}\, dx} \\ &= z_1 e^{\frac{x}{2} + \frac{\ln(x-1)}{2}} \\ &= z_1 \left(\sqrt{x-1}\, e^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1-x}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{x+\ln(x-1)}}{(y_1)^2}\, dx \\
&= y_1 \left(-x\, \mathrm{e}^{-x}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{x}\right) + c_2 \left(\mathrm{e}^{x} \left(-x\, \mathrm{e}^{-x}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
(1-x)\, y'' + xy' - y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^{x} c_1 - c_2 x
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \mathrm{e}^{x} \\
y_2 &= -x
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{x} & -x \\ \frac{d}{dx}(\mathrm{e}^{x}) & \frac{d}{dx}(-x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{x} & -x \\ \mathrm{e}^{x} & -1 \end{vmatrix}$$

Therefore

$$W = (\mathrm{e}^{x})(-1) - (-x)(\mathrm{e}^{x})$$

Which simplifies to

$$W = x\,\mathrm{e}^{x} - \mathrm{e}^{x}$$

Which simplifies to

$$W = (x-1)\,\mathrm{e}^{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-x(x-1)^2\,\mathrm{e}^{x}}{(1-x)(x-1)\,\mathrm{e}^{x}}\,dx$$

Which simplifies to

$$u_1 = -\int x\,dx$$

Hence

$$u_1 = -\frac{x^2}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x-1)^2 \,\mathrm{e}^{2x}}{(1-x)\,(x-1)\,\mathrm{e}^{x}}\,dx$$

Which simplifies to

$$u_2 = \int -\mathrm{e}^{x} dx$$

Hence

$$u_2 = -\mathrm{e}^{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x\,\mathrm{e}^{x} - \frac{\mathrm{e}^{x} x^2}{2}$$

Which simplifies to

$$y_p(x) = -\frac{\mathrm{e}^{x} x(x-2)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (\mathrm{e}^{x} c_1 - c_2 x) + \left(-\frac{\mathrm{e}^{x} x(x-2)}{2}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \mathrm{e}^{x} c_1 - c_2 x - \frac{\mathrm{e}^{x} x(x-2)}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = -\infty$ in the above gives

$$0 = \operatorname{signum}(c_2)\,\infty \tag{1A}$$

Taking derivative of the solution gives

$$y' = \mathrm{e}^{x} c_1 - c_2 - \frac{\mathrm{e}^{x} x(x-2)}{2} - \frac{(x-2)\,\mathrm{e}^{x}}{2} - \frac{x\,\mathrm{e}^{x}}{2}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = c_1 - c_2 + 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Warning, unable to solve for constants of integrations.

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

Unable to solve or complete the solution.

$$\boxed{2x^2(2-\ln(x))\,y''+x(4-\ln(x))\,y'-y=\frac{(2-\ln(x))^2}{\sqrt{x}}}$$

With initial conditions

$$[y(\infty)=0]$$

20.32.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y''+p(x)y'+q(x)y=F$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{-x \ln(x) + 4x}{2x^2 (\ln(x) - 2)} \\
q(x) &= \frac{1}{2x^2 (\ln(x) - 2)} \\
F &= -\frac{\ln(x) - 2}{2x^{\frac{5}{2}}}
\end{aligned}
$$

Hence the ode is

$$
y'' - \frac{(-x \ln(x) + 4x) y'}{2x^2 (\ln(x) - 2)} + \frac{y}{2x^2 (\ln(x) - 2)} = -\frac{\ln(x) - 2}{2x^{\frac{5}{2}}}
$$

The domain of $p(x) = -\frac{-x \ln(x)+4x}{2x^2(\ln(x)-2)}$ is

$$
\{0 < x < e^2, e^2 < x \leq \infty\}
$$

And the point $x_0 = \infty$ is inside this domain. The domain of $q(x) = \frac{1}{2x^2(\ln(x)-2)}$ is

$$
\{0 < x < e^2, e^2 < x \leq \infty\}
$$

And the point $x_0 = \infty$ is also inside this domain. The domain of $F = -\frac{\ln(x)-2}{2x^{\frac{5}{2}}}$ is

$$
\{0 < x\}
$$

And the point $x_0 = \infty$ is also inside this domain. Hence solution exists and is unique.

20.32.2 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$
Ay''(x) + By'(x) + Cy(x) = f(x)
$$

Where $A = -2x^2(\ln(x) - 2), B = -x \ln(x) + 4x, C = -1, f(x) = \frac{(\ln(x)-2)^2}{\sqrt{x}}$. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. Solving for y_h from

$$
-2y''x^2(\ln(x) - 2) + (-x \ln(x) + 4x) y' - y = 0
$$

In normal form the ode

$$-2y''x^2(\ln(x)-2)+(-x\ln(x)+4x)\,y'-y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned}p(x)&=\frac{4-\ln(x)}{x(-2\ln(x)+4)}\\q(x)&=\frac{1}{2x^2(\ln(x)-2)}\end{aligned}$$

Applying change of variables on the depndent variable $y=v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x)+\left(\frac{2n}{x}+p\right)v'(x)+\left(\frac{n(n-1)}{x^2}+\frac{np}{x}+q\right)v(x)=0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2}+\frac{np}{x}+q=0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}+\frac{n(4-\ln(x))}{x^2(-2\ln(x)+4)}+\frac{1}{2x^2(\ln(x)-2)}=0 \tag{5}$$

Solving (5) for n gives

$$n=\frac{1}{2} \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned}v''(x)+\left(\frac{1}{x}+\frac{4-\ln(x)}{x(-2\ln(x)+4)}\right)v'(x)&=0\\v''(x)+\frac{(3\ln(x)-8)\,v'(x)}{2x(\ln(x)-2)}&=0\end{aligned} \tag{7}$$

Using the substitution

$$u(x)=v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(3\ln(x) - 8)\, u(x)}{2x\,(\ln(x) - 2)} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{(3\ln(x) - 8)\, u}{2x\,(\ln(x) - 2)} \end{aligned}$$

Where $f(x) = -\frac{3\ln(x)-8}{2x(\ln(x)-2)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{3\ln(x) - 8}{2x\,(\ln(x) - 2)}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{3\ln(x) - 8}{2x\,(\ln(x) - 2)}\, dx \\ \ln(u) &= -\frac{3\ln(x)}{2} + \ln(\ln(x) - 2) + c_1 \\ u &= \mathrm{e}^{-\frac{3\ln(x)}{2} + \ln(\ln(x)-2) + c_1} \\ &= c_1 \mathrm{e}^{-\frac{3\ln(x)}{2} + \ln(\ln(x)-2)} \end{aligned}$$

Which simplifies to

$$u(x) = c_1 \left(\frac{\ln(x)}{x^{\frac{3}{2}}} - \frac{2}{x^{\frac{3}{2}}}\right)$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= -\frac{2c_1 \ln(x)}{\sqrt{x}} + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\, x^n \\ &= \left(-\frac{2c_1 \ln(x)}{\sqrt{x}} + c_2\right) \sqrt{x} \\ &= c_2 \sqrt{x} - 2c_1 \ln(x) \end{aligned}$$

Now the particular solution to this ODE is found

$$-2y''x^2(\ln(x)-2)+(-x\ln(x)+4x)\,y'-y=\frac{(\ln(x)-2)^2}{\sqrt{x}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x)=u_1y_1+u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1=\sqrt{x}$$
$$y_2=\ln(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1=-\int\frac{y_2f(x)}{aW(x)} \tag{2}$$

$$u_2=\int\frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W=\begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W=\begin{vmatrix} \sqrt{x} & \ln(x) \\ \frac{d}{dx}(\sqrt{x}) & \frac{d}{dx}(\ln(x)) \end{vmatrix}$$

Which gives

$$W=\begin{vmatrix} \sqrt{x} & \ln(x) \\ \frac{1}{2\sqrt{x}} & \frac{1}{x} \end{vmatrix}$$

Therefore

$$W = (\sqrt{x})\left(\frac{1}{x}\right) - (\ln(x))\left(\frac{1}{2\sqrt{x}}\right)$$

Which simplifies to

$$W = -\frac{\ln(x) - 2}{2\sqrt{x}}$$

Which simplifies to

$$W = -\frac{\ln(x) - 2}{2\sqrt{x}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\ln(x)(\ln(x)-2)^2}{\sqrt{x}}}{x^{\frac{3}{2}}(\ln(x) - 2)^2} dx$$

Which simplifies to

$$u_1 = -\int \frac{\ln(x)}{x^2} dx$$

Hence

$$u_1 = \frac{\ln(x)}{x} + \frac{1}{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(\ln(x) - 2)^2}{x^{\frac{3}{2}}(\ln(x) - 2)^2} dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x^{\frac{3}{2}}} dx$$

Hence

$$u_2 = -\frac{2}{\sqrt{x}}$$

Which simplifies to

$$
\begin{aligned}
u_1 &= \frac{\ln (x) + 1}{x} \\
u_2 &= -\frac{2}{\sqrt{x}}
\end{aligned}
$$

Therefore the particular solution, from equation (1) is

$$
y_p(x) = \frac{\ln (x) + 1}{\sqrt{x}} - \frac{2 \ln (x)}{\sqrt{x}}
$$

Which simplifies to

$$
y_p(x) = -\frac{\ln (x) - 1}{\sqrt{x}}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\left(-\frac{2c_1 \ln (x)}{\sqrt{x}} + c_2\right) \sqrt{x}\right) + \left(-\frac{\ln (x) - 1}{\sqrt{x}}\right) \\
&= -\frac{\ln (x) - 1}{\sqrt{x}} + \left(-\frac{2c_1 \ln (x)}{\sqrt{x}} + c_2\right) \sqrt{x}
\end{aligned}
$$

Which simplifies to

$$
y = \frac{c_2 x - 2\sqrt{x}\, \ln (x)\, c_1 - \ln (x) + 1}{\sqrt{x}}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \frac{c_2 x - 2\sqrt{x}\, \ln (x)\, c_1 - \ln (x) + 1}{\sqrt{x}} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = \infty$ in the above gives

$$
0 = \operatorname{signum}(c_2)\, \infty \tag{1A}
$$

Equations {1A} are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode", "second_order_change_of_variable_on_y_method_1"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

Unable to solve or complete the solution.

$$\boxed{y'' + \frac{2y'}{x} - y = 4\,\mathrm{e}^{x}}$$

With initial conditions

$$[y(-\infty) = 0, y'(-1) = -\mathrm{e}^{-1}]$$

20.33.1 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + \frac{2y'}{x} - y = 0$$

In normal form the given ode is written as

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{2}{x} \\ q(x) &= -1 \end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$\begin{aligned} Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\ &= -1 - \frac{\left(\frac{2}{x}\right)'}{2} - \frac{\left(\frac{2}{x}\right)^2}{4} \\ &= -1 - \frac{\left(-\frac{2}{x^2}\right)}{2} - \frac{\left(\frac{4}{x^2}\right)}{4} \\ &= -1 - \left(-\frac{1}{x^2}\right) - \frac{1}{x^2} \\ &= -1 \end{aligned}$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y = v(x)\,z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$\begin{aligned} z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\ &= e^{-\int \frac{\frac{2}{x}}{2}} \\ &= \frac{1}{x} \end{aligned} \tag{5}$$

Hence (3) becomes

$$y = \frac{v(x)}{x} \tag{4}$$

Applying this change of variable to the original ode results in

$$-v(x) + v''(x) = 4x\,\mathrm{e}^{x}$$

Which is now solved for $v(x)$ This is second order non-homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = f(x)$$

Where $A = 1, B = 0, C = -1, f(x) = 4x\,\mathrm{e}^{x}$. Let the solution be

$$v(x) = v_h + v_p$$

Where v_h is the solution to the homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = 0$, and v_p is a particular solution to the non-homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = f(x)$. v_h is the solution to

$$-v(x) + v''(x) = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(-1)}\\ &= \pm 1\end{aligned}$$

Hence

$$\lambda_1 = +1$$
$$\lambda_2 = -1$$

Which simplifies to

$$\lambda_1 = 1$$
$$\lambda_2 = -1$$

Since roots are real and distinct, then the solution is

$$v(x) = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$v(x) = c_1 e^{(1)x} + c_2 e^{(-1)x}$$

Or

$$v(x) = e^x c_1 + e^{-x} c_2$$

Therefore the homogeneous solution v_h is

$$v_h = e^x c_1 + e^{-x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4x\,e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^x, e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x, e^{-x}\}$$

Since e^x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^x, e^x x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$v_p = A_1 x\,e^x + A_2 e^x x^2$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution v_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^x + 4A_2 e^x x + 2A_2 e^x = 4x\,e^x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1, A_2 = 1]$$

Substituting the above back in the above trial solution v_p, gives the particular solution

$$v_p = -x\,e^x + e^x x^2$$

Therefore the general solution is

$$\begin{aligned}v &= v_h + v_p\\ &= \left(e^x c_1 + e^{-x} c_2\right) + \left(-x\,e^x + e^x x^2\right)\end{aligned}$$

Now that $v(x)$ is known, then

$$\begin{aligned}y &= v(x)\,z(x)\\ &= \left(e^x c_1 + e^{-x} c_2 - x\,e^x + e^x x^2\right)(z(x))\end{aligned} \tag{7}$$

But from (5)

$$z(x) = \frac{1}{x}$$

Hence (7) becomes

$$y = \frac{e^x c_1 + e^{-x} c_2 - x\,e^x + e^x x^2}{x}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{e^x c_1 + e^{-x} c_2 - x\,e^x + e^x x^2}{x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{e^x}{x}$$

$$y_2 = \frac{e^{-x}}{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{e^x}{x} & \frac{e^{-x}}{x} \\ \frac{d}{dx}\left(\frac{e^x}{x}\right) & \frac{d}{dx}\left(\frac{e^{-x}}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{e^x}{x} & \frac{e^{-x}}{x} \\ \frac{e^x}{x} - \frac{e^x}{x^2} & -\frac{e^{-x}}{x} - \frac{e^{-x}}{x^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{e^x}{x}\right)\left(-\frac{e^{-x}}{x} - \frac{e^{-x}}{x^2}\right) - \left(\frac{e^{-x}}{x}\right)\left(\frac{e^x}{x} - \frac{e^x}{x^2}\right)$$

Which simplifies to

$$W = -\frac{2\,e^x e^{-x}}{x^2}$$

Which simplifies to

$$W = -\frac{2}{x^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{4\,e^{-x}e^{x}}{x}}{-\frac{2}{x^2}} dx$$

Which simplifies to

$$u_1 = -\int -2x dx$$

Hence

$$u_1 = x^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{4\,e^{2x}}{x}}{-\frac{2}{x^2}} dx$$

Which simplifies to

$$u_2 = \int -2x\,e^{2x} dx$$

Hence

$$u_2 = -\frac{(2x-1)\,e^{2x}}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x\,e^{x} - \frac{(2x-1)\,e^{2x} e^{-x}}{2x}$$

Which simplifies to

$$y_p(x) = \frac{e^{x}(2x^2 - 2x + 1)}{2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{e^{x} c_1 + e^{-x} c_2 - x\,e^{x} + e^{x} x^2}{x}\right) + \left(\frac{e^{x}(2x^2 - 2x + 1)}{2x}\right) \end{aligned}$$

Which simplifies to

$$y = \frac{\mathrm{e}^{-x} c_2 + \mathrm{e}^{x}(x^2 + c_1 - x)}{x} + \frac{\mathrm{e}^{x}(2x^2 - 2x + 1)}{2x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{\mathrm{e}^{-x} c_2 + \mathrm{e}^{x}(x^2 + c_1 - x)}{x} + \frac{\mathrm{e}^{x}(2x^2 - 2x + 1)}{2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = -\infty$ in the above gives

$$0 = -\operatorname{signum}(c_2)\,\infty \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{-\mathrm{e}^{-x} c_2 + \mathrm{e}^{x}(x^2 + c_1 - x) + (2x - 1)\,\mathrm{e}^{x}}{x} - \frac{\mathrm{e}^{-x} c_2 + \mathrm{e}^{x}(x^2 + c_1 - x)}{x^2} + \frac{\mathrm{e}^{x}(2x^2 - 2x + 1)}{2x} + \frac{\mathrm{e}^{x}(4x - 2)}{2x}$$

substituting $y' = -\mathrm{e}^{-1}$ and $x = -1$ in the above gives

$$-\mathrm{e}^{-1} = \mathrm{e}^{-1}(-3 - 2c_1) \tag{2A}$$

Equations $\{1A, 2A\}$ are now solved for $\{c_1, c_2\}$. Warning, unable to solve for constants of integrations.

Verification of solutions N/A

20.33.2 Solving as second order bessel ode ode

Writing the ode as

$$x^2 y'' + 2xy' - yx^2 = 4\,\mathrm{e}^{x} x^2 \tag{1}$$

Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE and y_p is a particular solution to the non-homogeneous ODE. Bessel ode has the form

$$x^2 y'' + xy' + (-n^2 + x^2)\,y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1-2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}
\alpha &= -\frac{1}{2}\\
\beta &= i\\
n &= \frac{1}{2}\\
\gamma &= 1
\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{i c_1 \sqrt{2}\, \sinh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}} - \frac{c_2\sqrt{2}\, \cosh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{i c_1 \sqrt{2}\, \sinh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}} - \frac{c_2\sqrt{2}\, \cosh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= \frac{i\sqrt{2}\, \sinh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}}\\
y_2 &= -\frac{\sqrt{2}\, \cosh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}}
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{i\sqrt{2}\,\sinh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}} & -\frac{\sqrt{2}\,\cosh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}} \\ \frac{d}{dx}\left(\frac{i\sqrt{2}\,\sinh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}}\right) & \frac{d}{dx}\left(-\frac{\sqrt{2}\,\cosh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{i\sqrt{2}\,\sinh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}} & -\frac{\sqrt{2}\,\cosh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}} \\ -\frac{i\sqrt{2}\,\sinh(x)}{2x^{\frac{3}{2}}\sqrt{\pi}\,\sqrt{ix}} + \frac{\sqrt{2}\,\sinh(x)}{2\sqrt{x}\,\sqrt{\pi}\,(ix)^{\frac{3}{2}}} + \frac{i\sqrt{2}\,\cosh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}} & \frac{\sqrt{2}\,\cosh(x)}{2x^{\frac{3}{2}}\sqrt{\pi}\,\sqrt{ix}} + \frac{i\sqrt{2}\,\cosh(x)}{2\sqrt{x}\,\sqrt{\pi}\,(ix)^{\frac{3}{2}}} - \frac{\sqrt{2}\,\sinh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}} \end{vmatrix}$$

Therefore

$$\begin{aligned} W = {} & \left(\frac{i\sqrt{2}\,\sinh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}}\right)\left(\frac{\sqrt{2}\,\cosh(x)}{2x^{\frac{3}{2}}\sqrt{\pi}\,\sqrt{ix}} + \frac{i\sqrt{2}\,\cosh(x)}{2\sqrt{x}\,\sqrt{\pi}\,(ix)^{\frac{3}{2}}} - \frac{\sqrt{2}\,\sinh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}}\right) \\ & - \left(-\frac{\sqrt{2}\,\cosh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}}\right)\left(-\frac{i\sqrt{2}\,\sinh(x)}{2x^{\frac{3}{2}}\sqrt{\pi}\,\sqrt{ix}} + \frac{\sqrt{2}\,\sinh(x)}{2\sqrt{x}\,\sqrt{\pi}\,(ix)^{\frac{3}{2}}} + \frac{i\sqrt{2}\,\cosh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{ix}}\right) \end{aligned}$$

Which simplifies to

$$W = -\frac{2\left(\sinh(x)^2 - \cosh(x)^2\right)}{x^2\pi}$$

Which simplifies to

$$W = \frac{2}{x^2\pi}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{4x^{\frac{3}{2}}\sqrt{2}\,\cosh(x)\mathrm{e}^{x}}{\sqrt{\pi}\,\sqrt{ix}}}{\frac{2}{\pi}}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{2x^{\frac{3}{2}}\sqrt{2}\,\sqrt{\pi}\,\cosh(x)\,\mathrm{e}^{x}}{\sqrt{ix}}dx$$

Hence

$$u_1 = -\left(\int_0^x -\frac{2\alpha^{\frac{3}{2}}\sqrt{2}\,\sqrt{\pi}\,\cosh(\alpha)\,\mathrm{e}^{\alpha}}{\sqrt{i\alpha}}d\alpha\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{4ix^{\frac{3}{2}}\sqrt{2}\,\sinh(x)\mathrm{e}^{x}}{\sqrt{\pi}\,\sqrt{ix}}}{\frac{2}{\pi}}dx$$

Which simplifies to

$$u_2 = \int \frac{2ix^{\frac{3}{2}}\sqrt{2}\,\sqrt{\pi}\,\sinh(x)\,\mathrm{e}^{x}}{\sqrt{ix}}dx$$

Hence

$$u_2 = \int_0^x \frac{2i\alpha^{\frac{3}{2}}\sqrt{2}\,\sqrt{\pi}\,\sinh(\alpha)\,\mathrm{e}^{\alpha}}{\sqrt{i\alpha}}d\alpha$$

Which simplifies to

$$u_1 = 2\sqrt{2}\,\sqrt{\pi}\left(\int_0^x \frac{\alpha^{\frac{3}{2}}\cosh(\alpha)\,\mathrm{e}^{\alpha}}{\sqrt{i\alpha}}d\alpha\right)$$

$$u_2 = 2i\sqrt{2}\,\sqrt{\pi}\left(\int_0^x \frac{\alpha^{\frac{3}{2}}\sinh(\alpha)\,\mathrm{e}^{\alpha}}{\sqrt{i\alpha}}d\alpha\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{4i\left(\int_0^x \frac{\alpha^{\frac{3}{2}}\cosh(\alpha)\mathrm{e}^{\alpha}}{\sqrt{i\alpha}}d\alpha\right)\sinh(x)}{\sqrt{x}\,\sqrt{ix}} - \frac{4i\left(\int_0^x \frac{\alpha^{\frac{3}{2}}\sinh(\alpha)\mathrm{e}^{\alpha}}{\sqrt{i\alpha}}d\alpha\right)\cosh(x)}{\sqrt{x}\,\sqrt{ix}}$$

Which simplifies to

$$y_p(x) = \frac{4i\left(\left(\int_0^x \frac{\alpha^{\frac{3}{2}}\cosh(\alpha)\mathrm{e}^{\alpha}}{\sqrt{i\alpha}}d\alpha\right)\sinh(x) - \left(\int_0^x \frac{\alpha^{\frac{3}{2}}\sinh(\alpha)\mathrm{e}^{\alpha}}{\sqrt{i\alpha}}d\alpha\right)\cosh(x)\right)}{\sqrt{x}\,\sqrt{ix}}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\frac{i c_1 \sqrt{2}\, \sinh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{i x}} - \frac{c_2 \sqrt{2}\, \cosh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{i x}}\right) \\
&\quad + \left(\frac{4 i \left(\left(\int_0^x \frac{\alpha^{\frac{3}{2}} \cosh(\alpha) \mathrm{e}^{\alpha}}{\sqrt{i \alpha}} d\alpha\right) \sinh(x) - \left(\int_0^x \frac{\alpha^{\frac{3}{2}} \sinh(\alpha) \mathrm{e}^{\alpha}}{\sqrt{i \alpha}} d\alpha\right) \cosh(x)\right)}{\sqrt{x}\,\sqrt{i x}}\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \frac{i c_1 \sqrt{2}\, \sinh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{i x}} - \frac{c_2 \sqrt{2}\, \cosh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{i x}} + \frac{4 i \left(\left(\int_0^x \frac{\alpha^{\frac{3}{2}} \cosh(\alpha) \mathrm{e}^{\alpha}}{\sqrt{i \alpha}} d\alpha\right) \sinh(x) - \left(\int_0^x \frac{\alpha^{\frac{3}{2}} \sinh(\alpha) \mathrm{e}^{\alpha}}{\sqrt{i \alpha}} d\alpha\right) \cosh(x)\right)}{\sqrt{x}\,\sqrt{i x}} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = -\infty$ in the above gives

$$
0 = \frac{\lim_{x \to -\infty} \left(-\frac{4\left(-i \sinh(x) \left(\int_0^x \frac{\alpha^{\frac{3}{2}} \cosh(\alpha) \mathrm{e}^{\alpha}}{\sqrt{i \alpha}} d\alpha\right) \sqrt{\pi} + i \cosh(x) \left(\int_0^x \frac{\alpha^{\frac{3}{2}} \sinh(\alpha) \mathrm{e}^{\alpha}}{\sqrt{i \alpha}} d\alpha\right) \sqrt{\pi} - \frac{(i \sinh(x) c_1 - \cosh(x) c_2)\sqrt{2}}{4}\right)}{\sqrt{x}\,\sqrt{i x}}\right)}{\sqrt{\pi}} \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -\frac{i c_1 \sqrt{2}\, \sinh(x)}{2 x^{\frac{3}{2}} \sqrt{\pi}\,\sqrt{i x}} + \frac{c_1 \sqrt{2}\, \sinh(x)}{2\sqrt{x}\,\sqrt{\pi}\,(i x)^{\frac{3}{2}}} + \frac{i c_1 \sqrt{2}\, \cosh(x)}{\sqrt{x}\,\sqrt{\pi}\,\sqrt{i x}} + \frac{c_2 \sqrt{2}\, \cosh(x)}{2 x^{\frac{3}{2}} \sqrt{\pi}\,\sqrt{i x}} + \frac{i c_2 \sqrt{2}\, \cosh(x)}{2\sqrt{x}\,\sqrt{\pi}\,(i x)^{\frac{3}{2}}} - \frac{c_2 \sqrt{2}\, \mathrm{sin}}{\sqrt{x}\,\sqrt{\pi}}
$$

substituting $y' = -\mathrm{e}^{-1}$ and $x = -1$ in the above gives

$$
-\mathrm{e}^{-1} = \frac{(1+i)\, \mathrm{e}^{-1} \left((-1+i)\sqrt{\pi} + i c_2 + c_1\right)}{\sqrt{\pi}} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

20.33.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + \frac{2y'}{x} - y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= \frac{2}{x} \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 673: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-x}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

$$
\begin{aligned}
&= z_1 e^{-\int \frac{1}{2} \frac{\frac{2}{x}}{1}\, dx} \\
&= z_1 e^{-\ln(x)} \\
&= z_1 \left(\frac{1}{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\mathrm{e}^{-x}}{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{\frac{2}{x}}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-2\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\mathrm{e}^{2x}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\mathrm{e}^{-x}}{x}\right) + c_2 \left(\frac{\mathrm{e}^{-x}}{x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + \frac{2y'}{x} - y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_1 e^{-x}}{x} + \frac{c_2 e^{x}}{2x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \frac{e^{-x}}{x} \\ y_2 &= \frac{e^{x}}{2x} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{e^{-x}}{x} & \frac{e^{x}}{2x} \\ \frac{d}{dx}\left(\frac{e^{-x}}{x}\right) & \frac{d}{dx}\left(\frac{e^{x}}{2x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{e^{-x}}{x} & \frac{e^{x}}{2x} \\ -\frac{e^{-x}}{x} - \frac{e^{-x}}{x^2} & \frac{e^{x}}{2x} - \frac{e^{x}}{2x^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{e^{-x}}{x}\right)\left(\frac{e^{x}}{2x} - \frac{e^{x}}{2x^{2}}\right) - \left(\frac{e^{x}}{2x}\right)\left(-\frac{e^{-x}}{x} - \frac{e^{-x}}{x^{2}}\right)$$

Which simplifies to

$$W = \frac{e^{x} e^{-x}}{x^{2}}$$

Which simplifies to

$$W = \frac{1}{x^{2}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{2\,e^{2x}}{x}}{\frac{1}{x^{2}}}\, dx$$

Which simplifies to

$$u_1 = -\int 2x\,e^{2x} dx$$

Hence

$$u_1 = -\frac{(2x-1)\,e^{2x}}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{4\,e^{-x} e^{x}}{x}}{\frac{1}{x^{2}}}\, dx$$

Which simplifies to

$$u_2 = \int 4x dx$$

Hence

$$u_2 = 2x^{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x\,e^{x} - \frac{(2x-1)\,e^{2x} e^{-x}}{2x}$$

Which simplifies to

$$y_p(x) = \frac{e^x(2x^2 - 2x + 1)}{2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 e^{-x}}{x} + \frac{c_2 e^x}{2x}\right) + \left(\frac{e^x(2x^2 - 2x + 1)}{2x}\right) \end{aligned}$$

Which simplifies to

$$y = \frac{2c_1 e^{-x} + c_2 e^x}{2x} + \frac{e^x(2x^2 - 2x + 1)}{2x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{2c_1 e^{-x} + c_2 e^x}{2x} + \frac{e^x(2x^2 - 2x + 1)}{2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = -\infty$ in the above gives

$$0 = -\operatorname{signum}(c_1)\infty \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{-2c_1 e^{-x} + c_2 e^x}{2x} - \frac{2c_1 e^{-x} + c_2 e^x}{2x^2} + \frac{e^x(2x^2 - 2x + 1)}{2x} + \frac{e^x(4x - 2)}{2x} - \frac{e^x(2x^2 - 2x + 1)}{2x^2}$$

substituting $y' = -e^{-1}$ and $x = -1$ in the above gives

$$-e^{-1} = e^{-1}(-2 - c_2) \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Warning, unable to solve for constants of integrations.

With initial conditions

$$[y(\infty)=0]$$

20.34.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y''+p(x)y'+q(x)y=F$$

Where here

$$p(x)=-\frac{1}{x\,(\ln(x)-1)}$$
$$q(x)=\frac{1}{x^2\,(\ln(x)-1)}$$
$$F=\frac{2\ln(x)}{x^3\,(\ln(x)-1)}$$

Hence the ode is

$$y'' - \frac{y'}{x\left(\ln\left(x\right)-1\right)} + \frac{y}{x^{2}\left(\ln\left(x\right)-1\right)} = \frac{2\ln\left(x\right)}{x^{3}\left(\ln\left(x\right)-1\right)}$$

The domain of $p(x) = -\frac{1}{x(\ln(x)-1)}$ is

$$\{0 < x < \mathrm{e}, \mathrm{e} < x \leq \infty\}$$

And the point $x_0 = \infty$ is inside this domain. The domain of $q(x) = \frac{1}{x^2(\ln(x)-1)}$ is

$$\{0 < x < \mathrm{e}, \mathrm{e} < x \leq \infty\}$$

And the point $x_0 = \infty$ is also inside this domain. The domain of $F = \frac{2\ln(x)}{x^3(\ln(x)-1)}$ is

$$\{0 < x < \mathrm{e}, \mathrm{e} < x \leq \infty\}$$

And the point $x_0 = \infty$ is also inside this domain. Hence solution exists and is unique.

20.34.2 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^3(\ln(x) - 1), B = -x^2, C = x, f(x) = 2\ln(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^3(\ln(x) - 1)\, y'' - x^2 y' + yx = 0$$

In normal form the ode

$$x^3(\ln(x) - 1)\, y'' - x^2 y' + yx = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= -\frac{1}{x\left(\ln\left(x\right)-1\right)} \\
q(x) &= \frac{1}{x^{2}\left(\ln\left(x\right)-1\right)}
\end{aligned}
$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$
v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}
$$

Let the coefficient of $v(x)$ above be zero. Hence

$$
\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}
$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$
\frac{n(n-1)}{x^2} - \frac{n}{x^{2}\left(\ln\left(x\right)-1\right)} + \frac{1}{x^{2}\left(\ln\left(x\right)-1\right)} = 0 \tag{5}
$$

Solving (5) for n gives

$$
n = 1 \tag{6}
$$

Substituting this value in (3) gives

$$
\begin{aligned}
v''(x) + \left(\frac{2}{x} - \frac{1}{x\left(\ln\left(x\right)-1\right)}\right) v'(x) &= 0 \\
v''(x) + \left(\frac{2}{x} - \frac{1}{x\left(\ln\left(x\right)-1\right)}\right) v'(x) &= 0
\end{aligned} \tag{7}
$$

Using the substitution

$$
u(x) = v'(x)
$$

Then (7) becomes

$$
u'(x) + \left(\frac{2}{x} - \frac{1}{x\left(\ln\left(x\right)-1\right)}\right) u(x) = 0 \tag{8}
$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{u(2\ln(x)-3)}{x(\ln(x)-1)} \end{aligned}$$

Where $f(x) = -\frac{2\ln(x)-3}{x(\ln(x)-1)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{2\ln(x)-3}{x(\ln(x)-1)}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{2\ln(x)-3}{x(\ln(x)-1)}\,dx \\ \ln(u) &= -2\ln(x)+\ln(\ln(x)-1)+c_1 \\ u &= \mathrm{e}^{-2\ln(x)+\ln(\ln(x)-1)+c_1} \\ &= c_1\mathrm{e}^{-2\ln(x)+\ln(\ln(x)-1)} \end{aligned}$$

Which simplifies to

$$u(x) = c_1\left(\frac{\ln(x)}{x^2}-\frac{1}{x^2}\right)$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= -\frac{c_1\ln(x)}{x} + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\,x^n \\ &= \left(-\frac{c_1\ln(x)}{x}+c_2\right)x \\ &= -c_1\ln(x)+c_2x \end{aligned}$$

Now the particular solution to this ODE is found

$$x^3(\ln(x)-1)\,y'' - x^2y' + yx = 2\ln(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = \ln(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & \ln(x) \\ \frac{d}{dx}(x) & \frac{d}{dx}(\ln(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & \ln(x) \\ 1 & \frac{1}{x} \end{vmatrix}$$

Therefore

$$W = (x)\left(\frac{1}{x}\right) - (\ln(x))(1)$$

Which simplifies to

$$W = -\ln(x) + 1$$

Which simplifies to

$$W = -\ln(x) + 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2\ln(x)^2}{x^3(\ln(x)-1)(-\ln(x)+1)}dx$$

Which simplifies to

$$u_1 = -\int -\frac{2\ln(x)^2}{x^3(\ln(x)-1)^2}dx$$

Hence

$$u_1 = -\frac{\ln(x)+1}{(\ln(x)-1)x^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{2x\ln(x)}{x^3(\ln(x)-1)(-\ln(x)+1)}dx$$

Which simplifies to

$$u_2 = \int -\frac{2\ln(x)}{x^2(\ln(x)-1)^2}dx$$

Hence

$$u_2 = \frac{2}{x(\ln(x)-1)}$$

Which simplifies to

$$u_1 = \frac{-\ln(x)-1}{x^2(\ln(x)-1)}$$

$$u_2 = \frac{2}{x(\ln(x)-1)}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{-\ln(x)-1}{x(\ln(x)-1)} + \frac{2\ln(x)}{x(\ln(x)-1)}$$

Which simplifies to

$$y_p(x) = \frac{1}{x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(-\frac{c_1 \ln (x)}{x} + c_2\right) x\right) + \left(\frac{1}{x}\right) \\ &= \frac{1}{x} + \left(-\frac{c_1 \ln (x)}{x} + c_2\right) x \end{aligned}$$

Which simplifies to

$$y = \frac{1}{x} + \left(-\frac{c_1 \ln (x)}{x} + c_2\right) x$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{1}{x} + \left(-\frac{c_1 \ln (x)}{x} + c_2\right) x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = \infty$ in the above gives

$$0 = \operatorname{signum}(c_2) \infty \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

```
[[_2nd_order, _with_linear_symmetries]]
```

Unable to solve or complete the solution.

$$\boxed{(x^2-2x)\,y''+(-x^2+2)\,y'-2(1-x)\,y=2x-2}$$

With initial conditions

$$[y(\infty)=1]$$

20.35.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y''+p(x)y'+q(x)y=F$$

Where here

$$
\begin{aligned}
p(x) &= \frac{-x^2+2}{x^2-2x} \\
q(x) &= \frac{2x-2}{x^2-2x} \\
F &= \frac{2x-2}{x^2-2x}
\end{aligned}
$$

Hence the ode is

$$
y'' + \frac{(-x^2+2)\, y'}{x^2-2x} + \frac{(2x-2)\, y}{x^2-2x} = \frac{2x-2}{x^2-2x}
$$

The domain of $p(x) = \frac{-x^2+2}{x^2-2x}$ is

$$
\{-\infty \le x < 0, 0 < x < 2, 2 < x \le \infty\}
$$

And the point $x_0 = \infty$ is inside this domain. The domain of $q(x) = \frac{2x-2}{x^2-2x}$ is

$$
\{-\infty \le x < 0, 0 < x < 2, 2 < x \le \infty\}
$$

And the point $x_0 = \infty$ is also inside this domain. The domain of $F = \frac{2x-2}{x^2-2x}$ is

$$
\{-\infty \le x < 0, 0 < x < 2, 2 < x \le \infty\}
$$

And the point $x_0 = \infty$ is also inside this domain. Hence solution exists and is unique.

20.35.2 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$
Ay''(x) + By'(x) + Cy(x) = f(x)
$$

Where $A = x^2 - 2x, B = -x^2 + 2, C = 2x - 2, f(x) = 2x - 2$. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$
\left(x^2-2x\right) y'' + \left(-x^2+2\right) y' + (2x-2)\, y = 0
$$

In normal form the ode

$$\left(x^2-2x\right) y''+\left(-x^2+2\right) y'+\left(2x-2\right) y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{-x^2+2}{x\left(x-2\right)}\\ q(x) &= \frac{2x-2}{x\left(x-2\right)} \end{aligned}$$

Applying change of variables on the depndent variable $y=v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x)+\left(\frac{2n}{x}+p\right) v'(x)+\left(\frac{n(n-1)}{x^2}+\frac{np}{x}+q\right) v(x)=0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2}+\frac{np}{x}+q=0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}+\frac{n(-x^2+2)}{x^2\left(x-2\right)}+\frac{2x-2}{x\left(x-2\right)}=0 \tag{5}$$

Solving (5) for n gives

$$n=2 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x)+\left(\frac{4}{x}+\frac{-x^2+2}{x\left(x-2\right)}\right) v'(x) &= 0\\ v''(x)+\frac{\left(-x^2+4x-6\right) v'(x)}{x\left(x-2\right)} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x)=v'(x)$$

Then (7) becomes

$$u'(x)+\frac{(-x^2+4x-6)\,u(x)}{x\,(x-2)}=0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}u' &= F(x,u)\\ &= f(x)g(u)\\ &= \frac{u(x^2-4x+6)}{x\,(x-2)}\end{aligned}$$

Where $f(x)=\frac{x^2-4x+6}{x(x-2)}$ and $g(u)=u$. Integrating both sides gives

$$\begin{aligned}\frac{1}{u}\,du &= \frac{x^2-4x+6}{x\,(x-2)}\,dx\\ \int\frac{1}{u}\,du &= \int\frac{x^2-4x+6}{x\,(x-2)}\,dx\\ \ln(u) &= x+\ln(x-2)-3\ln(x)+c_1\\ u &= \mathrm{e}^{x+\ln(x-2)-3\ln(x)+c_1}\\ &= c_1\mathrm{e}^{x+\ln(x-2)-3\ln(x)}\end{aligned}$$

Which simplifies to

$$u(x)=c_1\left(\frac{\mathrm{e}^x}{x^2}-\frac{2\,\mathrm{e}^x}{x^3}\right)$$

Now that $u(x)$ is known, then

$$\begin{aligned}v'(x) &= u(x)\\ v(x) &= \int u(x)\,dx+c_2\\ &= \frac{\mathrm{e}^x c_1}{x^2}+c_2\end{aligned}$$

Hence

$$\begin{aligned}y &= v(x)\,x^n\\ &= \left(\frac{\mathrm{e}^x c_1}{x^2}+c_2\right)x^2\\ &= c_2x^2+\mathrm{e}^x c_1\end{aligned}$$

Now the particular solution to this ODE is found

$$(x^2-2x)\,y''+(-x^2+2)\,y'+(2x-2)\,y=2x-2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x)=u_1y_1+u_2y_2 \tag{1}$$

Where u_1,u_2 to be determined, and y_1,y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1=x^2$$
$$y_2=\mathrm{e}^x$$

In the Variation of parameters u_1,u_2 are found using

$$u_1=-\int\frac{y_2f(x)}{aW(x)} \tag{2}$$

$$u_2=\int\frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W=\begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W=\begin{vmatrix} x^2 & \mathrm{e}^x \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(\mathrm{e}^x) \end{vmatrix}$$

Which gives

$$W=\begin{vmatrix} x^2 & \mathrm{e}^x \\ 2x & \mathrm{e}^x \end{vmatrix}$$

Therefore

$$W=(x^2)(\mathrm{e}^x)-(\mathrm{e}^x)(2x)$$

Which simplifies to

$$W = e^{x}x^{2} - 2x\,e^{x}$$

Which simplifies to

$$W = e^{x}x(x-2)$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{e^{x}(2x-2)}{(x^{2}-2x)\,e^{x}x\,(x-2)}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{2x-2}{x^{2}\,(x-2)^{2}}dx$$

Hence

$$u_1 = \frac{1}{2x-4} - \frac{1}{2x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^{2}(2x-2)}{(x^{2}-2x)\,e^{x}x\,(x-2)}\,dx$$

Which simplifies to

$$u_2 = \int \frac{2(x-1)\,e^{-x}}{(x-2)^{2}}dx$$

Hence

$$u_2 = -\frac{2\,e^{-x}}{x-2}$$

Which simplifies to

$$u_1 = \frac{1}{x\,(x-2)}$$

$$u_2 = -\frac{2\,e^{-x}}{x-2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x}{x-2} - \frac{2\,\mathrm{e}^{-x}\mathrm{e}^{x}}{x-2}$$

Which simplifies to

$$y_p(x) = 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(\frac{\mathrm{e}^{x} c_1}{x^2} + c_2\right) x^2\right) + (1) \\ &= 1 + \left(\frac{\mathrm{e}^{x} c_1}{x^2} + c_2\right) x^2 \end{aligned}$$

Which simplifies to

$$y = c_2 x^2 + \mathrm{e}^{x} c_1 + 1$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_2 x^2 + \mathrm{e}^{x} c_1 + 1 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = \infty$ in the above gives

$$1 = \operatorname{signum}(c_1)\,\infty \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

20.35.3 Solving using Kovacic algorithm

Writing the ode as

$$(x^2 - 2x) y'' + (-x^2 + 2) y' + (2x - 2) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 - 2x \\ B &= -x^2 + 2 \\ C &= 2x - 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4\left(x^2 - 2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^4 - 8x^3 + 24x^2 - 24x + 12 \\ t &= 4\left(x^2 - 2x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4\left(x^2 - 2x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 674: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 4 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 - 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4(x-2)^2} - \frac{1}{4(x-2)} + \frac{3}{4x^2} - \frac{3}{4x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

For the pole at $x = 2$ let b be the coefficient of $\frac{1}{(x-2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i \qquad (8)
\end{aligned}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{x} + \frac{2}{x^3} + \frac{11}{x^4} + \frac{42}{x^5} + \frac{132}{x^6} + \frac{348}{x^7} + \frac{711}{x^8} + \dots \qquad (9)$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{2} \qquad (10)
\end{aligned}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4x^4 - 16x^3 + 16x^2} \\
&= Q + \frac{R}{4x^4 - 16x^3 + 16x^2} \\
&= \left(\frac{1}{4}\right) + \left(\frac{-4x^3 + 20x^2 - 24x + 12}{4x^4 - 16x^3 + 16x^2}\right) \\
&= \frac{1}{4} + \frac{-4x^3 + 20x^2 - 24x + 12}{4x^4 - 16x^3 + 16x^2}
\end{aligned}$$

Since the degree of t is 4, then we see that the coefficient of the term x^3 in the remainder R is -4. Dividing this by leading coefficient in t which is 4 gives -1. Now b can be found.

$$\begin{aligned}
b &= (-1) - (0) \\
&= -1
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-1}{\frac{1}{2}} - 0\right) &= -1 \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-1}{\frac{1}{2}} - 0\right) &= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4\left(x^2 - 2x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
2	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	-1	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -1$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\ &= -1 - (-1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{1}{2x} - \frac{1}{2(x-2)} + \left(\frac{1}{2}\right) \\ &= -\frac{1}{2x} - \frac{1}{2(x-2)} + \frac{1}{2} \\ &= -\frac{1}{2x} - \frac{1}{2x - 4} + \frac{1}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2x} - \frac{1}{2(x-2)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2x^2} + \frac{1}{2(x-2)^2}\right) + \left(-\frac{1}{2x} - \frac{1}{2(x-2)} + \frac{1}{2}\right)^2 - \left(\frac{x^4 - 8x^3 +}{4(}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2x} - \frac{1}{2(x-2)} + \frac{1}{2}\right) dx} \\
&= \frac{\mathrm{e}^{\frac{x}{2}}}{\sqrt{x}\,\sqrt{x-2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-x^2+2}{x^2-2x} \, dx} \\
&= z_1 e^{\frac{x}{2} + \frac{\ln(x-2)}{2} + \frac{\ln(x)}{2}} \\
&= z_1 \left(\sqrt{x}\,\sqrt{x-2}\,\mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^x \sqrt{x}\,\sqrt{x-2}}{\sqrt{x(x-2)}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+2}{x^2-2x}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{x+\ln(x-2)+\ln(x)}}{(y_1)^2}\, dx \\
&= y_1\left(-\mathrm{e}^{-x} x^2\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\mathrm{e}^{x} \sqrt{x}\, \sqrt{x-2}}{\sqrt{x\,(x-2)}}\right) + c_2 \left(\frac{\mathrm{e}^{x} \sqrt{x}\, \sqrt{x-2}}{\sqrt{x\,(x-2)}}\left(-\mathrm{e}^{-x} x^2\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
\left(x^2-2x\right) y'' + \left(-x^2+2\right) y' + (2x-2)\, y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \frac{c_1 \mathrm{e}^{x} \sqrt{x}\, \sqrt{x-2}}{\sqrt{x\,(x-2)}} - \frac{c_2 x^{\frac{5}{2}} \sqrt{x-2}}{\sqrt{x\,(x-2)}}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{e^{x}\sqrt{x}\,\sqrt{x-2}}{\sqrt{x\,(x-2)}}$$

$$y_2 = -\frac{x^{\frac{5}{2}}\sqrt{x-2}}{\sqrt{x\,(x-2)}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{e^{x}\sqrt{x}\,\sqrt{x-2}}{\sqrt{x(x-2)}} & -\frac{x^{\frac{5}{2}}\sqrt{x-2}}{\sqrt{x(x-2)}} \\ \frac{d}{dx}\left(\frac{e^{x}\sqrt{x}\,\sqrt{x-2}}{\sqrt{x(x-2)}}\right) & \frac{d}{dx}\left(-\frac{x^{\frac{5}{2}}\sqrt{x-2}}{\sqrt{x(x-2)}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{e^{x}\sqrt{x}\,\sqrt{x-2}}{\sqrt{x(x-2)}} & -\frac{x^{\frac{5}{2}}\sqrt{x-2}}{\sqrt{x(x-2)}} \\ \frac{e^{x}\sqrt{x}\,\sqrt{x-2}}{\sqrt{x(x-2)}} - \frac{e^{x}\sqrt{x}\,\sqrt{x-2}\,(2x-2)}{2(x(x-2))^{\frac{3}{2}}} + \frac{e^{x}\sqrt{x-2}}{2\sqrt{x(x-2)}\,\sqrt{x}} + \frac{e^{x}\sqrt{x}}{2\sqrt{x(x-2)}\,\sqrt{x-2}} & -\frac{5x^{\frac{3}{2}}\sqrt{x-2}}{2\sqrt{x(x-2)}} - \frac{x^{\frac{5}{2}}}{2\sqrt{x-2}\,\sqrt{x(x-2)}} + \frac{x^{\frac{5}{2}}\sqrt{x-2}\,(2x-2)}{2(x(x-2))^{\frac{3}{2}}} \end{vmatrix}$$

Therefore

$$W = \left(\frac{e^{x}\sqrt{x}\,\sqrt{x-2}}{\sqrt{x\,(x-2)}}\right)\left(-\frac{5x^{\frac{3}{2}}\sqrt{x-2}}{2\sqrt{x\,(x-2)}} - \frac{x^{\frac{5}{2}}}{2\sqrt{x-2}\,\sqrt{x\,(x-2)}} + \frac{x^{\frac{5}{2}}\sqrt{x-2}\,(2x-2)}{2\,(x\,(x-2))^{\frac{3}{2}}}\right) - \left(-\frac{x^{\frac{5}{2}}\sqrt{x-2}}{\sqrt{x\,(x-2)}}\right)\left(\frac{e^{x}\sqrt{x}\,\sqrt{x-2}}{\sqrt{x\,(x-2)}} - \frac{e^{x}\sqrt{x}\,\sqrt{x-2}\,(2x-2)}{2\,(x\,(x-2))^{\frac{3}{2}}} + \frac{e^{x}\sqrt{x-2}}{2\sqrt{x\,(x-2)}\,\sqrt{x}} + \frac{e^{x}\sqrt{x}}{2\sqrt{x\,(x-2)}\,\sqrt{x-2}}\right)$$

Which simplifies to

$$W = e^{x} x(x-2)$$

Which simplifies to

$$W = e^{x} x(x-2)$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{x^{\frac{5}{2}} \sqrt{x-2}\,(2x-2)}{\sqrt{x(x-2)}}}{(x^2-2x)\,e^{x} x\,(x-2)}\, dx$$

Which simplifies to

$$u_1 = -\int -\frac{2\sqrt{x}\,(x-1)\,e^{-x}}{(x-2)^{\frac{3}{2}} \sqrt{x\,(x-2)}} dx$$

Hence

$$u_1 = -\frac{2\sqrt{x}\,e^{-x}}{\sqrt{x-2}\,\sqrt{x\,(x-2)}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{e^{x} \sqrt{x}\,\sqrt{x-2}\,(2x-2)}{\sqrt{x(x-2)}}}{(x^2-2x)\,e^{x} x\,(x-2)}\, dx$$

Which simplifies to

$$u_2 = \int \frac{2x-2}{\sqrt{x\,(x-2)}\,x^{\frac{3}{2}}\,(x-2)^{\frac{3}{2}}} dx$$

Hence

$$u_2 = -\frac{1}{\sqrt{x}\,\sqrt{x-2}\,\sqrt{x\,(x-2)}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x}{x-2} - \frac{2\,e^{-x} e^{x}}{x-2}$$

Which simplifies to

$$y_p(x) = 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 \mathrm{e}^x \sqrt{x}\,\sqrt{x-2}}{\sqrt{x\,(x-2)}} - \frac{c_2 x^{\frac{5}{2}} \sqrt{x-2}}{\sqrt{x\,(x-2)}}\right) + (1) \end{aligned}$$

Which simplifies to

$$y = \frac{\sqrt{x}\,\sqrt{x-2}\,(-c_2 x^2 + \mathrm{e}^x c_1)}{\sqrt{x\,(x-2)}} + 1$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{\sqrt{x}\,\sqrt{x-2}\,(-c_2 x^2 + \mathrm{e}^x c_1)}{\sqrt{x\,(x-2)}} + 1 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = \infty$ in the above gives

$$1 = \operatorname{signum}(c_1)\,\infty \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

```
[[_2nd_order, _missing_x]]
```

$$\boxed{x'' + x' + x = 0}$$

21.1.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ax''(t) + Bx'(t) + Cx(t) = 0$$

Where in the above $A = 1, B = 1, C = 1$. Let the solution be $x = e^{\lambda t}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda t} + \lambda \, \mathrm{e}^{\lambda t} + \mathrm{e}^{\lambda t} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda t}$ gives

$$\lambda^2 + \lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 1, C = 1$ into the above gives

$$\lambda_{1,2} = \frac{-1}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{1^2 - (4)(1)(1)}$$
$$= -\frac{1}{2} \pm \frac{i\sqrt{3}}{2}$$

Hence

$$\lambda_1 = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$$
$$\lambda_2 = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$$

Which simplifies to

$$\lambda_1 = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$$
$$\lambda_2 = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -\frac{1}{2}$ and $\beta = \frac{\sqrt{3}}{2}$. Therefore the final solution, when using Euler relation, can be written as

$$x = e^{\alpha t}(c_1 \cos(\beta t) + c_2 \sin(\beta t))$$

Which becomes

$$x = e^{-\frac{t}{2}}\left(c_1 \cos\left(\frac{\sqrt{3}\,t}{2}\right) + c_2 \sin\left(\frac{\sqrt{3}\,t}{2}\right)\right)$$

Summary

The solution(s) found are the following

$$x = \mathrm{e}^{-\frac{t}{2}}\left(c_1 \cos\left(\frac{\sqrt{3}\,t}{2}\right) + c_2 \sin\left(\frac{\sqrt{3}\,t}{2}\right)\right) \tag{1}$$

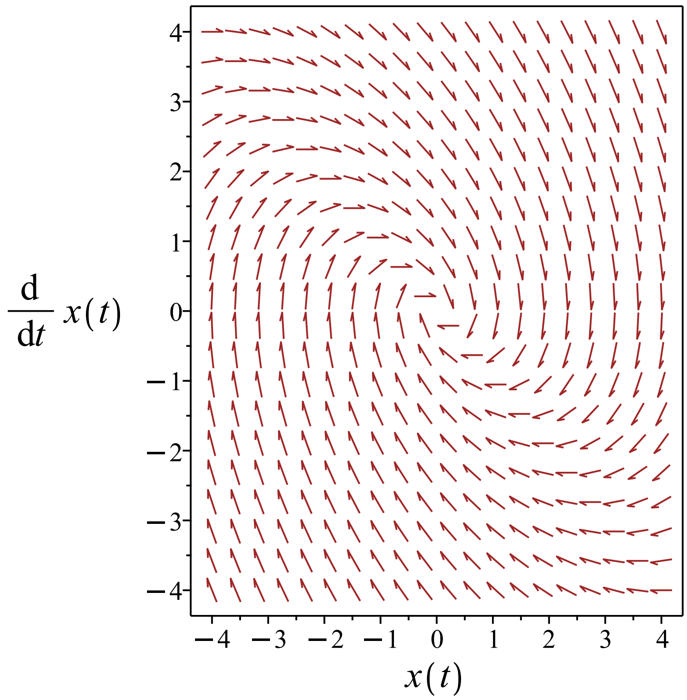

Figure 802: Slope field plot

Verification of solutions

$$x = e^{-\frac{t}{2}} \left(c_1 \cos\left(\frac{\sqrt{3}\, t}{2}\right) + c_2 \sin\left(\frac{\sqrt{3}\, t}{2}\right)\right)$$

Verified OK.

21.1.2 Solving using Kovacic algorithm

Writing the ode as

$$x'' + x' + x = 0 \tag{1}$$

$$Ax'' + Bx' + Cx = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 1 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = xe^{\int \frac{B}{2A}\, dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = -\frac{3z(t)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then x is found using the inverse transformation

$$x = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 675: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -\frac{3}{4}$ is not a function of t, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(t) = \cos\left(\frac{\sqrt{3}\,t}{2}\right)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in x is found from

$$\begin{aligned} x_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\,dt} \\ &= z_1 e^{-\frac{t}{2}} \\ &= z_1 \left(\mathrm{e}^{-\frac{t}{2}}\right) \end{aligned}$$

Which simplifies to

$$x_1 = \mathrm{e}^{-\frac{t}{2}} \cos\left(\frac{\sqrt{3}\,t}{2}\right)$$

The second solution x_2 to the original ode is found using reduction of order

$$x_2 = x_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{x_1^2}\,dt$$

Substituting gives

$$
\begin{aligned}
x_2 &= x_1 \int \frac{e^{\int -\frac{1}{1}\,dt}}{(x_1)^2}\,dt \\
&= x_1 \int \frac{e^{-t}}{(x_1)^2}\,dt \\
&= x_1 \left(\frac{2\sqrt{3}\,\tan\left(\frac{\sqrt{3}\,t}{2}\right)}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
x &= c_1 x_1 + c_2 x_2 \\
&= c_1\left(\mathrm{e}^{-\frac{t}{2}}\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right) + c_2\left(\mathrm{e}^{-\frac{t}{2}}\cos\left(\frac{\sqrt{3}\,t}{2}\right)\left(\frac{2\sqrt{3}\,\tan\left(\frac{\sqrt{3}\,t}{2}\right)}{3}\right)\right)
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
x = c_1\mathrm{e}^{-\frac{t}{2}}\cos\left(\frac{\sqrt{3}\,t}{2}\right) + \frac{2c_2\sin\left(\frac{\sqrt{3}\,t}{2}\right)\mathrm{e}^{-\frac{t}{2}}\sqrt{3}}{3} \tag{1}
$$

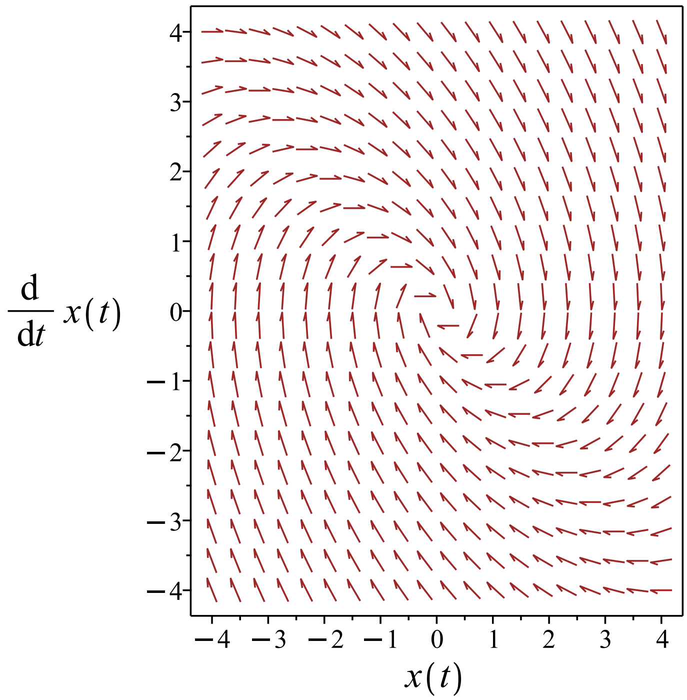

Figure 803: Slope field plot

Verification of solutions

$$x = c_1 e^{-\frac{t}{2}} \cos\left(\frac{\sqrt{3}\, t}{2}\right) + \frac{2c_2 \sin\left(\frac{\sqrt{3}\, t}{2}\right) e^{-\frac{t}{2}} \sqrt{3}}{3}$$

Verified OK.

21.1.3 Maple step by step solution

Let's solve

$x'' + x' + x = 0$

- Highest derivative means the order of the ODE is 2

  x''

- Characteristic polynomial of ODE

  $r^2 + r + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-1)\pm(\sqrt{-3})}{2}$

- Roots of the characteristic polynomial

  $r = \left(-\frac{1}{2} - \frac{\mathrm{I}\sqrt{3}}{2}, -\frac{1}{2} + \frac{\mathrm{I}\sqrt{3}}{2}\right)$

- 1st solution of the ODE

  $x_1(t) = \mathrm{e}^{-\frac{t}{2}} \cos\left(\frac{\sqrt{3}\,t}{2}\right)$

- 2nd solution of the ODE

  $x_2(t) = \mathrm{e}^{-\frac{t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)$

- General solution of the ODE

  $x = c_1 x_1(t) + c_2 x_2(t)$

- Substitute in solutions

  $x = c_1 \mathrm{e}^{-\frac{t}{2}} \cos\left(\frac{\sqrt{3}\,t}{2}\right) + c_2 \mathrm{e}^{-\frac{t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)$

Problem number: 697.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{x'' + 2x' + 6x = 0}$$

21.2.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ax''(t) + Bx'(t) + Cx(t) = 0$$

Where in the above $A = 1, B = 2, C = 6$. Let the solution be $x = e^{\lambda t}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda t} + 2\lambda\, e^{\lambda t} + 6\, e^{\lambda t} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda t}$ gives

$$\lambda^2 + 2\lambda + 6 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 6$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{2^2 - (4)(1)(6)}\\ &= -1 \pm i\sqrt{5}\end{aligned}$$

Hence

$$\lambda_1 = -1 + i\sqrt{5}$$
$$\lambda_2 = -1 - i\sqrt{5}$$

Which simplifies to

$$\lambda_1 = -1 + i\sqrt{5}$$
$$\lambda_2 = -1 - i\sqrt{5}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -1$ and $\beta = \sqrt{5}$. Therefore the final solution, when using Euler relation, can be written as

$$x = e^{\alpha t}(c_1 \cos(\beta t) + c_2 \sin(\beta t))$$

Which becomes

$$x = e^{-t}\left(c_1 \cos\left(\sqrt{5}\, t\right) + c_2 \sin\left(\sqrt{5}\, t\right)\right)$$

Summary

The solution(s) found are the following

$$x = \mathrm{e}^{-t}\left(c_1 \cos\left(\sqrt{5}\, t\right) + c_2 \sin\left(\sqrt{5}\, t\right)\right) \tag{1}$$

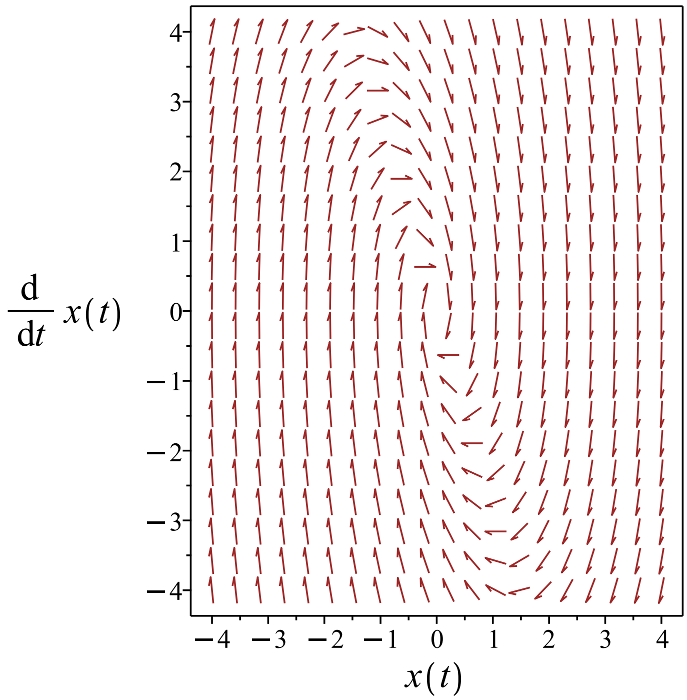

Figure 804: Slope field plot

Verification of solutions

$$x = e^{-t}\left(c_1 \cos\left(\sqrt{5}\, t\right) + c_2 \sin\left(\sqrt{5}\, t\right)\right)$$

Verified OK.

21.2.2 Solving using Kovacic algorithm

Writing the ode as

$$x'' + 2x' + 6x = 0 \tag{1}$$

$$Ax'' + Bx' + Cx = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = x e^{\int \frac{B}{2A}\, dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-5}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -5 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = -5z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then x is found using the inverse transformation

$$x = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 677: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -5$ is not a function of t, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(t) = \cos\left(\sqrt{5}\, t\right)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in x is found from

$$
\begin{aligned}
x_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A}\, dt} \\
&= z_1 e^{-\int \frac{1}{2} \frac{2}{1}\, dt} \\
&= z_1 e^{-t} \\
&= z_1 \left(\mathrm{e}^{-t}\right)
\end{aligned}
$$

Which simplifies to

$$
x_1 = \mathrm{e}^{-t} \cos\left(\sqrt{5}\, t\right)
$$

The second solution x_2 to the original ode is found using reduction of order

$$
x_2 = x_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{x_1^2}\, dt
$$

Substituting gives

$$
\begin{aligned}
x_2 &= x_1 \int \frac{e^{\int -\frac{2}{1}\, dt}}{\left(x_1\right)^2}\, dt \\
&= x_1 \int \frac{e^{-2t}}{\left(x_1\right)^2}\, dt \\
&= x_1 \left(\frac{\sqrt{5}\, \tan\left(\sqrt{5}\, t\right)}{5}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
x &= c_1 x_1 + c_2 x_2 \\
&= c_1\left(\mathrm{e}^{-t} \cos\left(\sqrt{5}\, t\right)\right) + c_2\left(\mathrm{e}^{-t} \cos\left(\sqrt{5}\, t\right)\left(\frac{\sqrt{5}\, \tan\left(\sqrt{5}\, t\right)}{5}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
x = c_1 \mathrm{e}^{-t} \cos\left(\sqrt{5}\, t\right) + \frac{c_2 \sin\left(\sqrt{5}\, t\right) \mathrm{e}^{-t} \sqrt{5}}{5} \tag{1}
$$

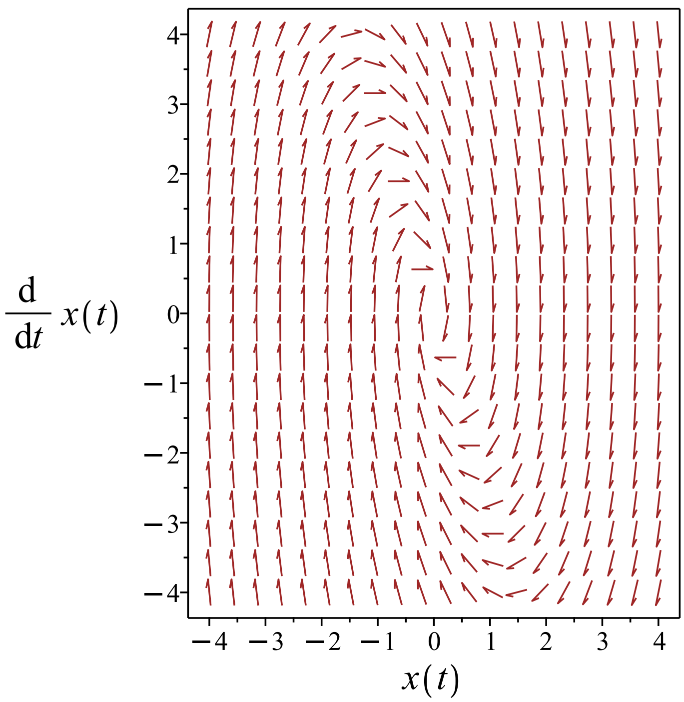

Figure 805: Slope field plot

Verification of solutions

$$
x = c_1 \mathrm{e}^{-t} \cos\left(\sqrt{5}\, t\right) + \frac{c_2 \sin\left(\sqrt{5}\, t\right) \mathrm{e}^{-t} \sqrt{5}}{5}
$$

Verified OK.

21.2.3 Maple step by step solution

Let's solve

$x'' + 2x' + 6x = 0$

- Highest derivative means the order of the ODE is 2

  x''

- Characteristic polynomial of ODE

  $r^2 + 2r + 6 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-2)\pm(\sqrt{-20})}{2}$

- Roots of the characteristic polynomial

  $r = \left(-1 - \mathrm{I}\sqrt{5}, -1 + \mathrm{I}\sqrt{5}\right)$

- 1st solution of the ODE

  $x_1(t) = \mathrm{e}^{-t} \cos\left(\sqrt{5}\, t\right)$

- 2nd solution of the ODE

  $x_2(t) = \mathrm{e}^{-t} \sin\left(\sqrt{5}\, t\right)$

- General solution of the ODE

  $x = c_1 x_1(t) + c_2 x_2(t)$

- Substitute in solutions

  $x = c_1 \mathrm{e}^{-t} \cos\left(\sqrt{5}\, t\right) + c_2 \mathrm{e}^{-t} \sin\left(\sqrt{5}\, t\right)$

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{x'' + 2x' + x = 0}$$

21.3.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ax''(t) + Bx'(t) + Cx(t) = 0$$

Where in the above $A = 1, B = 2, C = 1$. Let the solution be $x = e^{\lambda t}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda t} + 2\lambda\, e^{\lambda t} + e^{\lambda t} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda t}$ gives

$$\lambda^2 + 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(2)^2 - (4)(1)(1)} \\ &= -1\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 1$. Therefore the solution is

$$x = c_1 e^{-t} + c_2 t\, e^{-t} \tag{1}$$

Summary

The solution(s) found are the following

$$x = c_1 e^{-t} + c_2 t\, e^{-t} \tag{1}$$

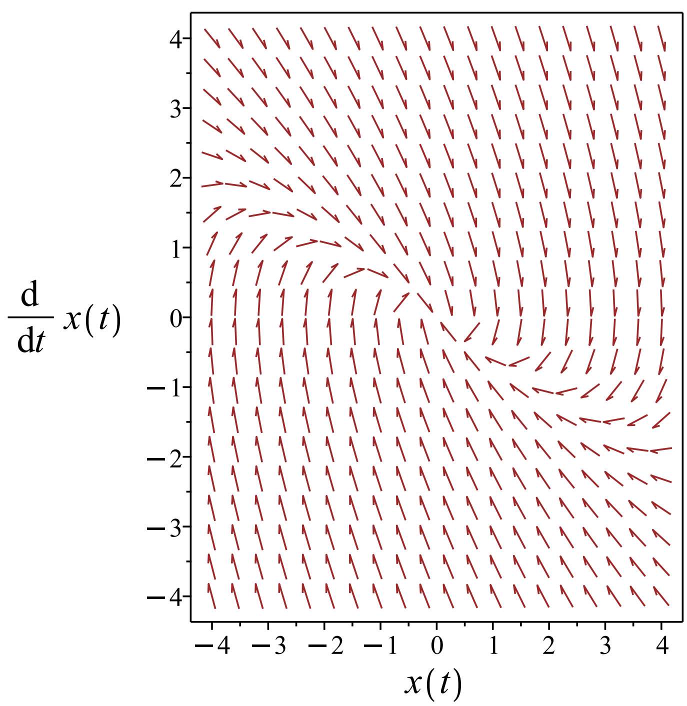

Figure 806: Slope field plot

Verification of solutions

$$x = c_1 e^{-t} + c_2 t\, e^{-t}$$

Verified OK.

21.3.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$x'' + p(t)\, x' + \frac{\left(p(t)^2 + p'(t)\right) x}{2} = f(t)$$

Where $p(t) = 2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2} \int p \, dx} \\ &= e^{\int 2 \, dx} \\ &= \mathrm{e}^{t} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)x)'' &= 0 \\ \left(\mathrm{e}^{t} x\right)'' &= 0 \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{t} x\right)' = c_1$$

Integrating again gives

$$\left(\mathrm{e}^{t} x\right) = c_1 t + c_2$$

Hence the solution is

$$x = \frac{c_1 t + c_2}{\mathrm{e}^{t}}$$

Or

$$x = c_1 t\, \mathrm{e}^{-t} + \mathrm{e}^{-t} c_2$$

Summary
The solution(s) found are the following

$$x = c_1 t\, \mathrm{e}^{-t} + \mathrm{e}^{-t} c_2 \tag{1}$$

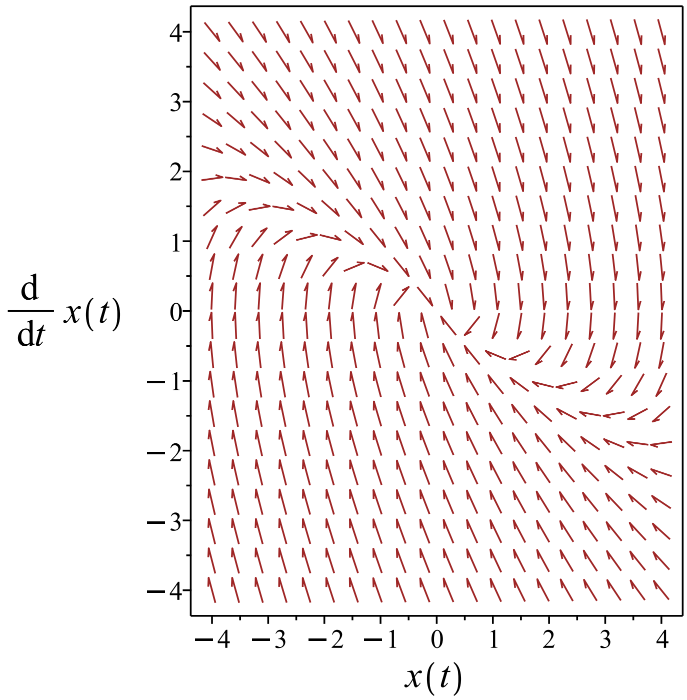

Figure 807: Slope field plot

Verification of solutions

$$x = c_1 t\, e^{-t} + e^{-t} c_2$$

Verified OK.

21.3.3 Solving using Kovacic algorithm

Writing the ode as

$$x'' + 2x' + x = 0 \tag{1}$$

$$Ax'' + Bx' + Cx = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = x e^{\int \frac{B}{2A}\, dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(t) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then x is found using the inverse transformation

$$x = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 679: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of t, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(t) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in x is found from

$$\begin{aligned}x_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dt} \\ &= z_1 e^{-t} \\ &= z_1 \left(\mathrm{e}^{-t}\right)\end{aligned}$$

Which simplifies to

$$x_1 = \mathrm{e}^{-t}$$

The second solution x_2 to the original ode is found using reduction of order

$$x_2 = x_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{x_1^2}\,dt$$

Substituting gives

$$\begin{aligned}x_2 &= x_1 \int \frac{e^{\int -\frac{2}{1}\,dt}}{(x_1)^2}\,dt \\ &= x_1 \int \frac{e^{-2t}}{(x_1)^2}\,dt \\ &= x_1(t)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
x &= c_1 x_1 + c_2 x_2 \\
&= c_1\left(\mathrm{e}^{-t}\right) + c_2\left(\mathrm{e}^{-t}(t)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
x = c_1 \mathrm{e}^{-t} + c_2 t\, \mathrm{e}^{-t} \tag{1}
$$

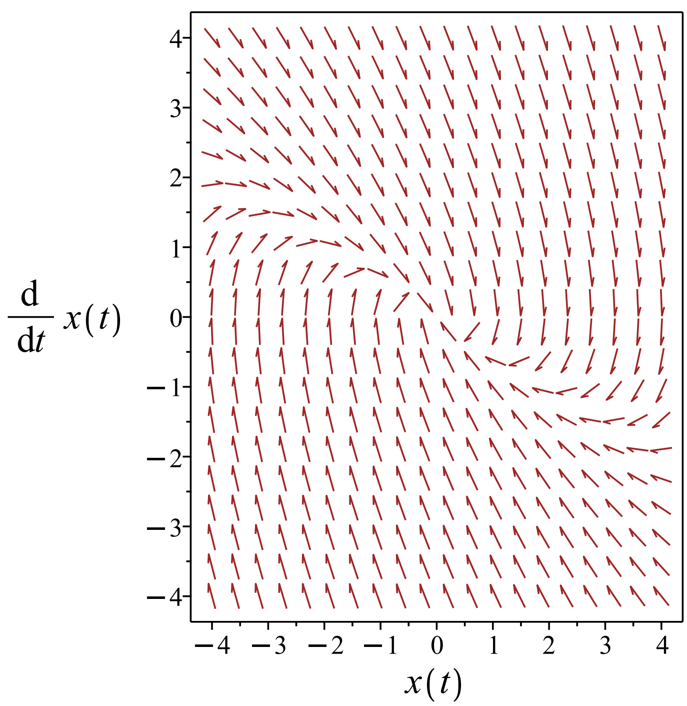

Figure 808: Slope field plot

Verification of solutions

$$
x = c_1 \mathrm{e}^{-t} + c_2 t\, \mathrm{e}^{-t}
$$

Verified OK.

Problem number: 699.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{x'' + x'^2 + x = 0}$$

21.4.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable x an independent variable. Using

$$x' = p(x)$$

Then

$$\begin{aligned} x'' &= \frac{dp}{dt} \\ &= \frac{dx}{dt}\frac{dp}{dx} \\ &= p\frac{dp}{dx} \end{aligned}$$

Hence the ode becomes

$$p(x)\left(\frac{d}{dx}p(x)\right) + p(x)^2 + x = 0$$

Which is now solved as first order ode for $p(x)$. Writing the ode as

$$\frac{d}{dx}p(x) = -\frac{p^2 + x}{p}$$
$$\frac{d}{dx}p(x) = \omega(x, p)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_p - \xi_x) - \omega^2\xi_p - \omega_x\xi - \omega_p\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 681: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,p) &= 0\\ \eta(x,p) &= \frac{e^{-2x}}{p}\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,p) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dp}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial p}\right) S(x,p) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy\\ &= \int \frac{1}{\frac{e^{-2x}}{p}} dy\end{aligned}$$

Which results in

$$S = \frac{p^2 e^{2x}}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,p)S_p}{R_x + \omega(x,p)R_p} \tag{2}$$

Where in the above R_x, R_p, S_x, S_p are all partial derivatives and $\omega(x,p)$ is the right hand side of the original ode given by

$$\omega(x,p) = -\frac{p^2 + x}{p}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_p &= 0 \\
S_x &= p^2 \mathrm{e}^{2x} \\
S_p &= p\,\mathrm{e}^{2x}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = -x\,\mathrm{e}^{2x} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, p in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = -R\,\mathrm{e}^{2R}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = -\frac{(2R-1)\,\mathrm{e}^{2R}}{4} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, p coordinates. This results in

$$
\frac{p(x)^2\,\mathrm{e}^{2x}}{2} = -\frac{(2x-1)\,\mathrm{e}^{2x}}{4} + c_1
$$

Which simplifies to

$$
\frac{\left(2p(x)^2 + 2x - 1\right)\mathrm{e}^{2x}}{4} - c_1 = 0
$$

For solution (1) found earlier, since $p = x'$ then we now have a new first order ode to solve which is

$$
\frac{\left(2x'^2 + 2x - 1\right)\mathrm{e}^{2x}}{4} - c_1 = 0
$$

Solving the given ode for x' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$
x' = \frac{\mathrm{e}^{-2x}\sqrt{-2\,\mathrm{e}^{2x}\left(2\,\mathrm{e}^{2x}x - \mathrm{e}^{2x} - 4c_1\right)}}{2} \tag{1}
$$

$$
x' = -\frac{\mathrm{e}^{-2x}\sqrt{-2\,\mathrm{e}^{2x}\left(2\,\mathrm{e}^{2x}x - \mathrm{e}^{2x} - 4c_1\right)}}{2} \tag{2}
$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{2\,e^{2x}}{\sqrt{-2\,e^{2x}\left(2x\,e^{2x}-e^{2x}-4c_1\right)}}dx = \int dt$$

$$2\left(\int^{x}\frac{e^{2\_a}}{\sqrt{-2\,e^{2\_a}\left(2\_a\,e^{2\_a}-e^{2\_a}-4c_1\right)}}d\_a\right) = t+c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{2\,e^{2x}}{\sqrt{-2\,e^{2x}\left(2x\,e^{2x}-e^{2x}-4c_1\right)}}dx = \int dt$$

$$-2\left(\int^{x}\frac{e^{2\_a}}{\sqrt{-2\,e^{2\_a}\left(2\_a\,e^{2\_a}-e^{2\_a}-4c_1\right)}}d\_a\right) = t+c_3$$

Summary

The solution(s) found are the following

$$2\left(\int^{x}\frac{e^{2\_a}}{\sqrt{-2\,e^{2\_a}\left(2\_a\,e^{2\_a}-e^{2\_a}-4c_1\right)}}d\_a\right) = t+c_2 \tag{1}$$

$$-2\left(\int^{x}\frac{e^{2\_a}}{\sqrt{-2\,e^{2\_a}\left(2\_a\,e^{2\_a}-e^{2\_a}-4c_1\right)}}d\_a\right) = t+c_3 \tag{2}$$

Verification of solutions

$$2\left(\int^{x}\frac{e^{2\_a}}{\sqrt{-2\,e^{2\_a}\left(2\_a\,e^{2\_a}-e^{2\_a}-4c_1\right)}}d\_a\right) = t+c_2$$

Verified OK.

$$-2\left(\int^{x}\frac{e^{2\_a}}{\sqrt{-2\,e^{2\_a}\left(2\_a\,e^{2\_a}-e^{2\_a}-4c_1\right)}}d\_a\right) = t+c_3$$

Verified OK.

Section: Chapter 2 (Higher order ODE's). Section 16. The method of isoclines for differential equations of the second order. Exercises page 158
Problem number: 701.
ODE order: 2.
ODE degree: 0.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1]]
```

$$\boxed{x'' - x\,\mathrm{e}^{x'} = 0}$$

21.6.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable x an independent variable. Using

$$x' = p(x)$$

Then

$$\begin{aligned} x'' &= \frac{dp}{dt} \\ &= \frac{dx}{dt}\frac{dp}{dx} \\ &= p\frac{dp}{dx} \end{aligned}$$

Hence the ode becomes

$$p(x)\left(\frac{d}{dx}p(x)\right) - x\,\mathrm{e}^{p(x)} = 0$$

Which is now solved as first order ode for $p(x)$. In canonical form the ODE is

$$\begin{aligned} p' &= F(x,p) \\ &= f(x)g(p) \\ &= \frac{x\,\mathrm{e}^{p}}{p} \end{aligned}$$

Where $f(x) = x$ and $g(p) = \frac{\mathrm{e}^{p}}{p}$. Integrating both sides gives

$$\frac{1}{\frac{\mathrm{e}^{p}}{p}}\, dp = x\, dx$$

$$\int \frac{1}{\frac{\mathrm{e}^{p}}{p}}\, dp = \int x\, dx$$

$$-(p+1)\,\mathrm{e}^{-p} = \frac{x^2}{2} + c_1$$

The solution is

$$-(p(x)+1)\,\mathrm{e}^{-p(x)} - \frac{x^2}{2} - c_1 = 0$$

For solution (1) found earlier, since $p = x'$ then we now have a new first order ode to solve which is

$$-(x'+1)\,\mathrm{e}^{-x'} - \frac{x^2}{2} - c_1 = 0$$

Integrating both sides gives

$$\int \frac{1}{-\mathrm{LambertW}\left(\frac{(x^2+2c_1)\mathrm{e}^{-1}}{2}\right) - 1} dx = \int dt$$

$$\int^{x} \frac{1}{-\mathrm{LambertW}\left(\frac{(\_a^2+2c_1)\mathrm{e}^{-1}}{2}\right) - 1} d\_a = t + c_2$$

Summary

The solution(s) found are the following

$$\int^{x} \frac{1}{-\mathrm{LambertW}\left(\frac{(\_a^2+2c_1)\mathrm{e}^{-1}}{2}\right) - 1} d\_a = t + c_2 \tag{1}$$

Verification of solutions

$$\int^{x} \frac{1}{-\operatorname{LambertW}\left(\frac{(\_a^{2}+2c_{1})\,\mathrm{e}^{-1}}{2}\right)-1}d\_a = t+c_{2}$$

Verified OK.

$$\boxed{x'' + x{x'}^2 = 0}$$

21.8.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable x an independent variable. Using

$$x' = p(x)$$

Then

$$\begin{aligned} x'' &= \frac{dp}{dt} \\ &= \frac{dx}{dt}\frac{dp}{dx} \\ &= p\frac{dp}{dx} \end{aligned}$$

Hence the ode becomes

$$p(x)\left(\frac{d}{dx}p(x)\right)+xp(x)^2=0$$

Which is now solved as first order ode for $p(x)$. In canonical form the ODE is

$$\begin{aligned}p' &= F(x,p)\\ &= f(x)g(p)\\ &= -px\end{aligned}$$

Where $f(x)=-x$ and $g(p)=p$. Integrating both sides gives

$$\begin{aligned}\frac{1}{p}\,dp &= -x\,dx\\ \int\frac{1}{p}\,dp &= \int -x\,dx\\ \ln(p) &= -\frac{x^2}{2}+c_1\\ p &= \mathrm{e}^{-\frac{x^2}{2}+c_1}\\ &= c_1\mathrm{e}^{-\frac{x^2}{2}}\end{aligned}$$

For solution (1) found earlier, since $p=x'$ then we now have a new first order ode to solve which is

$$x'=c_1\mathrm{e}^{-\frac{x^2}{2}}$$

Integrating both sides gives

$$\begin{aligned}\int\frac{\mathrm{e}^{\frac{x^2}{2}}}{c_1}dx &= \int dt\\ \int^x\frac{\mathrm{e}^{\frac{\_a^2}{2}}}{c_1}d\_a &= t+c_2\end{aligned}$$

Summary

The solution(s) found are the following

$$\int^x\frac{\mathrm{e}^{\frac{\_a^2}{2}}}{c_1}d\_a=t+c_2 \tag{1}$$

Verification of solutions

$$\int^x\frac{\mathrm{e}^{\frac{\_a^2}{2}}}{c_1}d\_a=t+c_2$$

Verified OK.

21.8.2 Maple step by step solution

Let's solve

$x'' + x x'^2 = 0$

- Highest derivative means the order of the ODE is 2

  x''

- Define new dependent variable u

  $u(t) = x'$

- Compute x''

  $u'(t) = x''$

- Use chain rule on the lhs

  $x' \left(\frac{d}{dx} u(x)\right) = x''$

- Substitute in the definition of u

  $u(x) \left(\frac{d}{dx} u(x)\right) = x''$

- Make substitutions $x' = u(x)\,, x'' = u(x) \left(\frac{d}{dx} u(x)\right)$ to reduce order of ODE

  $u(x) \left(\frac{d}{dx} u(x)\right) + x u(x)^2 = 0$

- Separate variables

  $\frac{\frac{d}{dx} u(x)}{u(x)} = -x$

- Integrate both sides with respect to x

  $\int \frac{\frac{d}{dx} u(x)}{u(x)} dx = \int -x dx + c_1$

- Evaluate integral

  $\ln\left(u(x)\right) = -\frac{x^2}{2} + c_1$

- Solve for $u(x)$

  $u(x) = \mathrm{e}^{-\frac{x^2}{2} + c_1}$

- Solve 1st ODE for $u(x)$

  $u(x) = \mathrm{e}^{-\frac{x^2}{2} + c_1}$

- Revert to original variables with substitution $u(x) = x', x = x$

  $x' = \mathrm{e}^{-\frac{x^2}{2} + c_1}$

- Separate variables

$$\frac{x'}{e^{-\frac{x^2}{2}+c_1}} = 1$$

- Integrate both sides with respect to t

$$\int \frac{x'}{e^{-\frac{x^2}{2}+c_1}} dt = \int 1 dt + c_2$$

- Evaluate integral

$$\frac{-\frac{I}{2}\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{I}{2}\sqrt{2}\,x\right)}{e^{c_1}} = t + c_2$$

- Solve for x

$$\left\{-I\,\mathit{RootOf}\left(I\,e^{c_1}\sqrt{2}\,c_2 + I\,e^{c_1}\sqrt{2}\,t - \mathrm{erf}(\_Z)\,\sqrt{\pi}\right)\sqrt{2}\right\}$$

$$\boxed{x'' + (x+2)\,x' = 0}$$

21.9.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t t gives

$$\int (x'' + (x+2)\,x')\,dt = 0$$

$$2x + \frac{x^2}{2} + x' = c_1$$

Which is now solved for x. Integrating both sides gives

$$\int \frac{1}{-2x - \frac{1}{2}x^2 + c_1} dx = t + c_2$$
$$\frac{2 \operatorname{arctanh}\left(\frac{2x+4}{2\sqrt{2c_1+4}}\right)}{\sqrt{2c_1 + 4}} = t + c_2$$

Solving for x gives these solutions

$$x_1 = \tanh\left(\frac{c_2\sqrt{2c_1 + 4}}{2} + \frac{t\sqrt{2c_1 + 4}}{2}\right)\sqrt{2c_1 + 4} - 2$$

Summary

The solution(s) found are the following

$$x = \tanh\left(\frac{c_2\sqrt{2c_1 + 4}}{2} + \frac{t\sqrt{2c_1 + 4}}{2}\right)\sqrt{2c_1 + 4} - 2 \tag{1}$$

Verification of solutions

$$x = \tanh\left(\frac{c_2\sqrt{2c_1 + 4}}{2} + \frac{t\sqrt{2c_1 + 4}}{2}\right)\sqrt{2c_1 + 4} - 2$$

Verified OK.

21.9.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable x an independent variable. Using

$$x' = p(x)$$

Then

$$\begin{aligned} x'' &= \frac{dp}{dt} \\ &= \frac{dx}{dt}\frac{dp}{dx} \\ &= p\frac{dp}{dx} \end{aligned}$$

Hence the ode becomes

$$p(x)\left(\frac{d}{dx}p(x)\right) + (2 + x)\, p(x) = 0$$

Which is now solved as first order ode for $p(x)$. Integrating both sides gives

$$\begin{aligned} p(x) &= \int -x - 2 \,\mathrm{d}x \\ &= -2x - \frac{1}{2}x^2 + c_1 \end{aligned}$$

For solution (1) found earlier, since $p = x'$ then we now have a new first order ode to solve which is

$$x' = -2x - \frac{x^2}{2} + c_1$$

Integrating both sides gives

$$\begin{aligned} \int \frac{1}{-2x - \frac{1}{2}x^2 + c_1} dx &= t + c_2 \\ \frac{2\,\operatorname{arctanh}\left(\frac{2x+4}{2\sqrt{2c_1+4}}\right)}{\sqrt{2c_1 + 4}} &= t + c_2 \end{aligned}$$

Solving for x gives these solutions

$$x_1 = \tanh\left(\frac{c_2\sqrt{2c_1 + 4}}{2} + \frac{t\sqrt{2c_1 + 4}}{2}\right)\sqrt{2c_1 + 4} - 2$$

Summary

The solution(s) found are the following

$$x = \tanh\left(\frac{c_2\sqrt{2c_1 + 4}}{2} + \frac{t\sqrt{2c_1 + 4}}{2}\right)\sqrt{2c_1 + 4} - 2 \tag{1}$$

Verification of solutions

$$x = \tanh\left(\frac{c_2\sqrt{2c_1 + 4}}{2} + \frac{t\sqrt{2c_1 + 4}}{2}\right)\sqrt{2c_1 + 4} - 2$$

Verified OK.

21.9.3 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$x'' + (x + 2)\,x' = 0$$

Integrating both sides of the ODE w.r.t t gives

$$\begin{aligned} \int (x'' + (x + 2)\,x')\,dt &= 0 \\ 2x + \frac{x^2}{2} + x' &= c_1 \end{aligned}$$

Which is now solved for x. Integrating both sides gives

$$\int \frac{1}{-2x-\frac{1}{2}x^2+c_1}dx = t+c_2$$
$$\frac{2\,\mathrm{arctanh}\left(\frac{2x+4}{2\sqrt{2c_1+4}}\right)}{\sqrt{2c_1+4}} = t+c_2$$

Solving for x gives these solutions

$$x_1 = \tanh\left(\frac{c_2\sqrt{2c_1+4}}{2}+\frac{t\sqrt{2c_1+4}}{2}\right)\sqrt{2c_1+4}-2$$

Summary

The solution(s) found are the following

$$x = \tanh\left(\frac{c_2\sqrt{2c_1+4}}{2}+\frac{t\sqrt{2c_1+4}}{2}\right)\sqrt{2c_1+4}-2 \tag{1}$$

Verification of solutions

$$x = \tanh\left(\frac{c_2\sqrt{2c_1+4}}{2}+\frac{t\sqrt{2c_1+4}}{2}\right)\sqrt{2c_1+4}-2$$

Verified OK.

21.9.4 Solving as exact nonlinear second order ode ode

An exact non-linear second order ode has the form

$$a_2(t,x,x')\,x''+a_1(t,x,x')\,x'+a_0(t,x,x')=0$$

Where the following conditions are satisfied

$$\frac{\partial a_2}{\partial x} = \frac{\partial a_1}{\partial x'}$$
$$\frac{\partial a_2}{\partial t} = \frac{\partial a_0}{\partial x'}$$
$$\frac{\partial a_1}{\partial t} = \frac{\partial a_0}{\partial x}$$

Looking at the the ode given we see that

$$a_2 = 1$$
$$a_1 = x+2$$
$$a_0 = 0$$

Applying the conditions to the above shows this is a nonlinear exact second order ode. Therefore it can be reduced to first order ode given by

$$\int a_2 \, dx' + \int a_1 \, dx + \int a_0 \, dt = c_1$$
$$\int 1 \, dx' + \int x + 2 \, dx + \int 0 \, dt = c_1$$

Which results in

$$2x + \frac{x^2}{2} + x' = c_1$$

Which is now solved Integrating both sides gives

$$\int \frac{1}{-2x - \frac{1}{2}x^2 + c_1} dx = t + c_2$$
$$\frac{2 \operatorname{arctanh}\left(\frac{2x+4}{2\sqrt{2c_1+4}}\right)}{\sqrt{2c_1 + 4}} = t + c_2$$

Solving for x gives these solutions

$$x_1 = \tanh\left(\frac{c_2\sqrt{2c_1 + 4}}{2} + \frac{t\sqrt{2c_1 + 4}}{2}\right)\sqrt{2c_1 + 4} - 2$$

Summary
The solution(s) found are the following

$$x = \tanh\left(\frac{c_2\sqrt{2c_1 + 4}}{2} + \frac{t\sqrt{2c_1 + 4}}{2}\right)\sqrt{2c_1 + 4} - 2 \tag{1}$$

Verification of solutions

$$x = \tanh\left(\frac{c_2\sqrt{2c_1 + 4}}{2} + \frac{t\sqrt{2c_1 + 4}}{2}\right)\sqrt{2c_1 + 4} - 2$$

Verified OK.

21.9.5 Maple step by step solution

Let's solve

$x'' + (x + 2)\, x' = 0$

- Highest derivative means the order of the ODE is 2

  x''

- Define new dependent variable u

  $u(t) = x'$
- Compute x''

  $u'(t) = x''$
- Use chain rule on the lhs

  $x'\left(\frac{d}{dx}u(x)\right) = x''$
- Substitute in the definition of u

  $u(x)\left(\frac{d}{dx}u(x)\right) = x''$
- Make substitutions $x' = u(x)\,, x'' = u(x)\left(\frac{d}{dx}u(x)\right)$ to reduce order of ODE

  $u(x)\left(\frac{d}{dx}u(x)\right) + (2+x)\,u(x) = 0$
- Separate variables

  $\frac{d}{dx}u(x) = -x-2$
- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}u(x)\right) dx = \int (-x-2)\, dx + c_1$
- Evaluate integral

  $u(x) = -2x - \frac{1}{2}x^2 + c_1$
- Solve for $u(x)$

  $u(x) = -2x - \frac{1}{2}x^2 + c_1$
- Solve 1st ODE for $u(x)$

  $u(x) = -2x - \frac{1}{2}x^2 + c_1$
- Revert to original variables with substitution $u(x) = x', x = x$

  $x' = -2x - \frac{x^2}{2} + c_1$
- Separate variables

  $\frac{x'}{-2x-\frac{x^2}{2}+c_1} = 1$
- Integrate both sides with respect to t

  $\int \frac{x'}{-2x-\frac{x^2}{2}+c_1} dt = \int 1 dt + c_2$
- Evaluate integral

  $\frac{2\,\mathrm{arctanh}\left(\frac{2x+4}{2\sqrt{2c_1+4}}\right)}{\sqrt{2c_1+4}} = t + c_2$

- Solve for x

  $x = \tanh\left(\frac{c_2\sqrt{2c_1+4}}{2} + \frac{t\sqrt{2c_1+4}}{2}\right)\sqrt{2c_1+4} - 2$

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

Unable to solve or complete the solution.

$$\boxed{x'' - x' + x - x^2 = 0}$$

21.10.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable x an independent variable. Using

$$x' = p(x)$$

Then

$$\begin{aligned} x'' &= \frac{dp}{dt} \\ &= \frac{dx}{dt}\frac{dp}{dx} \\ &= p\frac{dp}{dx} \end{aligned}$$

Hence the ode becomes

$$p(x)\left(\frac{d}{dx}p(x)\right) - p(x) + (1 - x)\, x = 0$$

Which is now solved as first order ode for $p(x)$. Unable to determine ODE type.

Unable to solve. Terminating

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + \lambda y = 0}$$

With initial conditions

$$[y'(0) = 0, y'(\pi) = 0]$$

22.1.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = \lambda$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + \lambda e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + \lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = \lambda$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(\lambda)}\\ &= \pm\sqrt{-\lambda}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{-\lambda}\\ \lambda_2 &= -\sqrt{-\lambda}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{-\lambda}\\ \lambda_2 &= -\sqrt{-\lambda}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(\sqrt{-\lambda})x} + c_2 e^{(-\sqrt{-\lambda})x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{\sqrt{-\lambda}\, x} + c_2 \mathrm{e}^{-\sqrt{-\lambda}\, x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{\sqrt{-\lambda}\, x} + c_2 \mathrm{e}^{-\sqrt{-\lambda}\, x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. Taking derivative of the solution gives

$$y' = c_1\sqrt{-\lambda}\,\mathrm{e}^{\sqrt{-\lambda}\, x} - c_2\sqrt{-\lambda}\,\mathrm{e}^{-\sqrt{-\lambda}\, x}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = \left(c_1 e^{\pi\sqrt{-\lambda}} - c_2 e^{-\pi\sqrt{-\lambda}}\right)\sqrt{-\lambda} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1\sqrt{-\lambda}\, e^{\sqrt{-\lambda}\, x} - c_2\sqrt{-\lambda}\, e^{-\sqrt{-\lambda}\, x}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = (c_1 - c_2)\sqrt{-\lambda} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = 0$$

Summary

The solution(s) found are the following

$$y = 0 \tag{1}$$

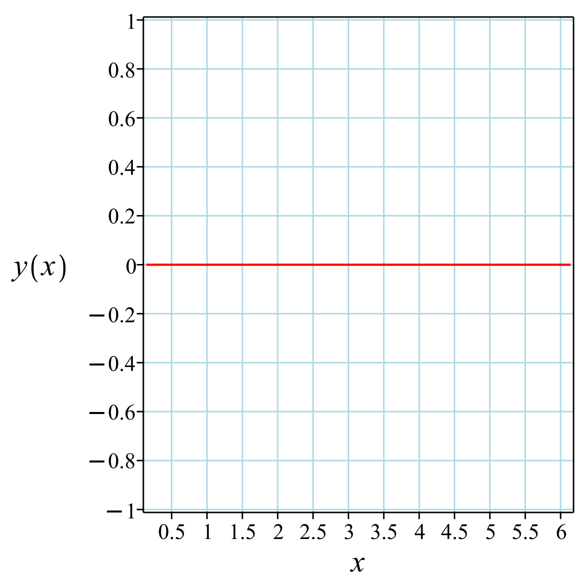

Figure 809: Solution plot

Verification of solutions

$$y = 0$$

Verified OK.

22.1.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + \lambda y'y = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' + \lambda y'y)\, dx = 0$$
$$\frac{y'^2}{2} + \frac{\lambda y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-\lambda y^2 + 2c_1} \tag{1}$$
$$y' = -\sqrt{-\lambda y^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-\lambda\, y^2 + 2c_1}} dy = \int dx$$
$$\frac{\arctan\left(\frac{\sqrt{\lambda}\, y}{\sqrt{-\lambda y^2+2c_1}}\right)}{\sqrt{\lambda}} = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-\lambda\, y^2 + 2c_1}} dy = \int dx$$
$$-\frac{\arctan\left(\frac{\sqrt{\lambda}\, y}{\sqrt{-\lambda y^2+2c_1}}\right)}{\sqrt{\lambda}} = x + c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$\frac{\arctan\left(\frac{\sqrt{\lambda}\, y}{\sqrt{-\lambda y^{2}+2 c_{1}}}\right)}{\sqrt{\lambda}} = x + c_{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. Taking derivative of the solution gives

$$y' = \frac{\sqrt{2}\,\sqrt{\lambda}\,\tan\left(c_{2}\sqrt{\lambda}+x\sqrt{\lambda}\right)^{2} c_{1}}{\sqrt{\lambda\left(\tan\left(c_{2}\sqrt{\lambda}+x\sqrt{\lambda}\right)^{2}+1\right) c_{1}}} - \frac{2\sqrt{2}\,\sqrt{\lambda\left(\tan\left(c_{2}\sqrt{\lambda}+x\sqrt{\lambda}\right)^{2}+1\right) c_{1}}\,\tan\left(c_{2}\sqrt{\lambda}+x\sqrt{\lambda}\right)^{2}}{\sqrt{\lambda}\left(\tan\left(c_{2}\sqrt{\lambda}+x\sqrt{\lambda}\right)^{2}+1\right)}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = \frac{\sqrt{\lambda}\, c_{1}\sqrt{2}}{\sqrt{\sec\left(\left(\pi + c_{2}\right)\sqrt{\lambda}\right)^{2} c_{1}\lambda}} \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{\sqrt{2}\,\sqrt{\lambda}\,\tan\left(c_{2}\sqrt{\lambda}+x\sqrt{\lambda}\right)^{2} c_{1}}{\sqrt{\lambda\left(\tan\left(c_{2}\sqrt{\lambda}+x\sqrt{\lambda}\right)^{2}+1\right) c_{1}}} - \frac{2\sqrt{2}\,\sqrt{\lambda\left(\tan\left(c_{2}\sqrt{\lambda}+x\sqrt{\lambda}\right)^{2}+1\right) c_{1}}\,\tan\left(c_{2}\sqrt{\lambda}+x\sqrt{\lambda}\right)^{2}}{\sqrt{\lambda}\left(\tan\left(c_{2}\sqrt{\lambda}+x\sqrt{\lambda}\right)^{2}+1\right)}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = \frac{\sqrt{\lambda}\, c_{1}\sqrt{2}}{\sqrt{\sec\left(c_{2}\sqrt{\lambda}\right)^{2} c_{1}\lambda}} \tag{2A}$$

Equations $\{1A, 2A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Looking at the Second solution

$$-\frac{\arctan\left(\frac{\sqrt{\lambda}\, y}{\sqrt{-\lambda y^{2}+2 c_{1}}}\right)}{\sqrt{\lambda}} = x + c_{3} \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. Taking derivative of the solution gives

$$y' = -\frac{\sqrt{2}\,\sqrt{\lambda}\,\tan\left(c_3\sqrt{\lambda}+x\sqrt{\lambda}\right)^2 c_1}{\sqrt{\lambda\left(\tan\left(c_3\sqrt{\lambda}+x\sqrt{\lambda}\right)^2+1\right)c_1}} + \frac{2\sqrt{2}\,\sqrt{\lambda\left(\tan\left(c_3\sqrt{\lambda}+x\sqrt{\lambda}\right)^2+1\right)c_1}\,\tan\left(c_3\sqrt{\lambda}+x\sqrt{\lambda}\right)^2}{\sqrt{\lambda}\left(\tan\left(c_3\sqrt{\lambda}+x\sqrt{\lambda}\right)^2+1\right)}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = -\frac{\sqrt{\lambda}\,c_1\sqrt{2}}{\sqrt{\sec\left((\pi+c_3)\sqrt{\lambda}\right)^2 c_1\lambda}} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{\sqrt{2}\,\sqrt{\lambda}\,\tan\left(c_3\sqrt{\lambda}+x\sqrt{\lambda}\right)^2 c_1}{\sqrt{\lambda\left(\tan\left(c_3\sqrt{\lambda}+x\sqrt{\lambda}\right)^2+1\right)c_1}} + \frac{2\sqrt{2}\,\sqrt{\lambda\left(\tan\left(c_3\sqrt{\lambda}+x\sqrt{\lambda}\right)^2+1\right)c_1}\,\tan\left(c_3\sqrt{\lambda}+x\sqrt{\lambda}\right)^2}{\sqrt{\lambda}\left(\tan\left(c_3\sqrt{\lambda}+x\sqrt{\lambda}\right)^2+1\right)}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -\frac{\sqrt{\lambda}\,c_1\sqrt{2}}{\sqrt{\sec\left(c_3\sqrt{\lambda}\right)^2 c_1\lambda}} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

22.1.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + \lambda y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= \lambda \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-\lambda}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -\lambda \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = (-\lambda)\, z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 685: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -\lambda$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = e^{\sqrt{-\lambda}\, x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= e^{\sqrt{-\lambda}\, x} \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\sqrt{-\lambda}\, x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \mathrm{e}^{\sqrt{-\lambda}\, x} \int \frac{1}{\mathrm{e}^{2\sqrt{-\lambda}\, x}}\, dx \\ &= \mathrm{e}^{\sqrt{-\lambda}\, x} \left(-\frac{\mathrm{e}^{-2\sqrt{-\lambda}\, x}}{2\sqrt{-\lambda}} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{\sqrt{-\lambda}\, x} \right) + c_2 \left(\mathrm{e}^{\sqrt{-\lambda}\, x} \left(-\frac{\mathrm{e}^{-2\sqrt{-\lambda}\, x}}{2\sqrt{-\lambda}} \right) \right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{\sqrt{-\lambda}\, x} - \frac{c_2 \mathrm{e}^{-\sqrt{-\lambda}\, x}}{2\sqrt{-\lambda}} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. Taking derivative of the solution gives

$$y' = c_1 \sqrt{-\lambda}\, \mathrm{e}^{\sqrt{-\lambda}\, x} + \frac{c_2 \mathrm{e}^{-\sqrt{-\lambda}\, x}}{2}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = \sqrt{-\lambda}\, \mathrm{e}^{\pi\sqrt{-\lambda}} c_1 + \frac{c_2 \mathrm{e}^{-\pi\sqrt{-\lambda}}}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1\sqrt{-\lambda}\,\mathrm{e}^{\sqrt{-\lambda}\,x} + \frac{c_2 \mathrm{e}^{-\sqrt{-\lambda}\,x}}{2}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = c_1\sqrt{-\lambda} + \frac{c_2}{2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = 0$$

Summary
The solution(s) found are the following

$$y = 0 \tag{1}$$

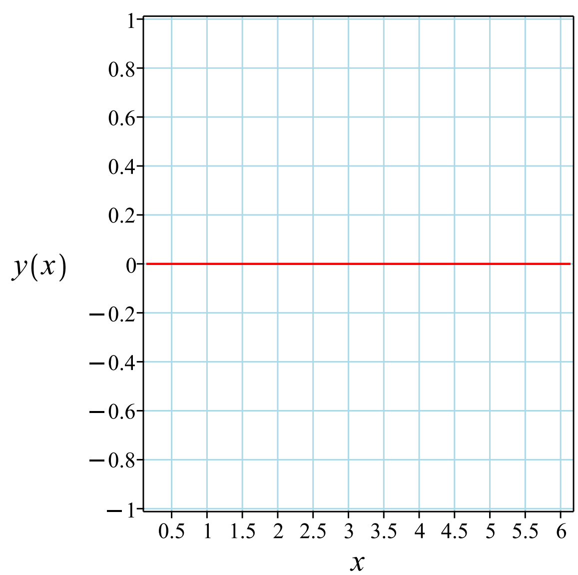

Figure 810: Solution plot

Verification of solutions

$$y = 0$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + \lambda y = 0}$$

With initial conditions

$$[y(0) = 0, y(1) = 0]$$

22.2.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = \lambda$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + \lambda e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + \lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = \lambda$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(\lambda)}\\ &= \pm\sqrt{-\lambda}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{-\lambda}\\ \lambda_2 &= -\sqrt{-\lambda}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{-\lambda}\\ \lambda_2 &= -\sqrt{-\lambda}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(\sqrt{-\lambda})x} + c_2 e^{(-\sqrt{-\lambda})x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{\sqrt{-\lambda}\,x} + c_2 \mathrm{e}^{-\sqrt{-\lambda}\,x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{\sqrt{-\lambda}\,x} + c_2 \mathrm{e}^{-\sqrt{-\lambda}\,x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 1$ in the above gives

$$0 = c_1 \mathrm{e}^{\sqrt{-\lambda}} + c_2 \mathrm{e}^{-\sqrt{-\lambda}} \tag{1A}$$

substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = 0$$

Summary
The solution(s) found are the following

$$y = 0 \tag{1}$$

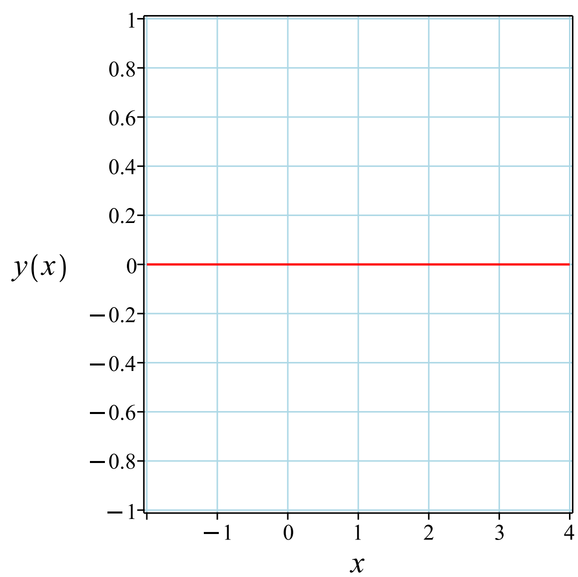

Figure 811: Solution plot

Verification of solutions

$$y = 0$$

Verified OK.

22.2.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + \lambda y'y = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' + \lambda y'y)\, dx = 0$$
$$\frac{y'^2}{2} + \frac{\lambda y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-\lambda y^2 + 2c_1} \tag{1}$$
$$y' = -\sqrt{-\lambda y^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-\lambda\, y^2 + 2c_1}} dy = \int dx$$
$$\frac{\arctan\left(\frac{\sqrt{\lambda}\, y}{\sqrt{-\lambda y^2+2c_1}}\right)}{\sqrt{\lambda}} = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-\lambda\, y^2 + 2c_1}} dy = \int dx$$
$$-\frac{\arctan\left(\frac{\sqrt{\lambda}\, y}{\sqrt{-\lambda y^2+2c_1}}\right)}{\sqrt{\lambda}} = x + c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$\frac{\arctan\left(\frac{\sqrt{\lambda}\, y}{\sqrt{-\lambda y^2+2c_1}}\right)}{\sqrt{\lambda}} = x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 1$ in the above gives

$$0 = 1 + c_2 \tag{1A}$$

substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Looking at the Second solution

$$-\frac{\arctan\left(\frac{\sqrt{\lambda}\, y}{\sqrt{-\lambda y^2+2c_1}}\right)}{\sqrt{\lambda}} = x + c_3 \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 1$ in the above gives

$$0 = 1 + c_3 \tag{1A}$$

substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_3 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

22.2.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + \lambda y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= \lambda \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-\lambda}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -\lambda \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = (-\lambda) \, z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 686: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -\lambda$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{\sqrt{-\lambda}\, x}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A}\, dx}
$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \mathrm{e}^{\sqrt{-\lambda}\, x}
\end{aligned}
$$

Which simplifies to

$$y_1 = \mathrm{e}^{\sqrt{-\lambda}\, x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \mathrm{e}^{\sqrt{-\lambda}\, x} \int \frac{1}{\mathrm{e}^{2\sqrt{-\lambda}\, x}}\, dx \\ &= \mathrm{e}^{\sqrt{-\lambda}\, x} \left(-\frac{\mathrm{e}^{-2\sqrt{-\lambda}\, x}}{2\sqrt{-\lambda}}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{\sqrt{-\lambda}\, x}\right) + c_2 \left(\mathrm{e}^{\sqrt{-\lambda}\, x} \left(-\frac{\mathrm{e}^{-2\sqrt{-\lambda}\, x}}{2\sqrt{-\lambda}}\right)\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{\sqrt{-\lambda}\, x} - \frac{c_2 \mathrm{e}^{-\sqrt{-\lambda}\, x}}{2\sqrt{-\lambda}} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 1$ in the above gives

$$0 = c_1 \mathrm{e}^{\sqrt{-\lambda}} - \frac{c_2 \mathrm{e}^{-\sqrt{-\lambda}}}{2\sqrt{-\lambda}} \tag{1A}$$

substituting $y = 0$ and $x = 0$ in the above gives

$$0 = \frac{2c_1\sqrt{-\lambda} - c_2}{2\sqrt{-\lambda}} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = 0$$

Summary

The solution(s) found are the following

$$y = 0 \tag{1}$$

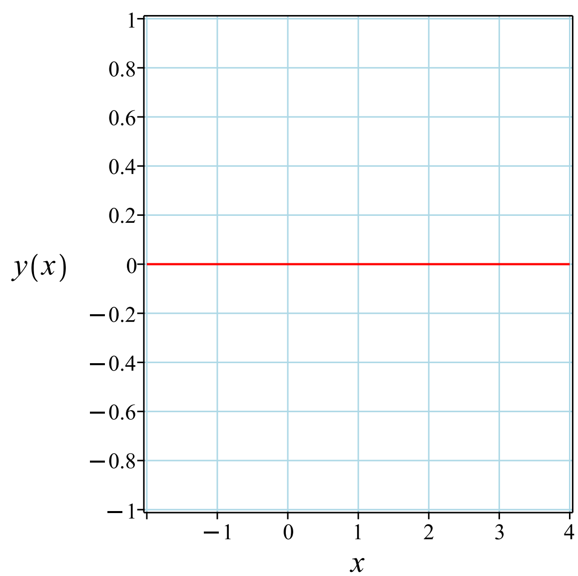

Figure 812: Solution plot

Verification of solutions

$$y = 0$$

Verified OK.

22.2.4 Maple step by step solution

Let's solve

$[y'' + \lambda y = 0, y(0) = 0, y(1) = 0]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 + \lambda = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4\lambda})}{2}$

- Roots of the characteristic polynomial

  $r = (\sqrt{-\lambda}, -\sqrt{-\lambda})$

- 1st solution of the ODE

  $y_1(x) = \mathrm{e}^{\sqrt{-\lambda}\, x}$

- 2nd solution of the ODE

  $y_2(x) = \mathrm{e}^{-\sqrt{-\lambda}\, x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 \mathrm{e}^{\sqrt{-\lambda}\, x} + c_2 \mathrm{e}^{-\sqrt{-\lambda}\, x}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - y = 0}$$

With initial conditions

$$[y(0) = 0, y(2\pi) = 1]$$

22.3.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)} \\ &= \pm 1\end{aligned}$$

Hence

$$\lambda_1 = +1$$
$$\lambda_2 = -1$$

Which simplifies to

$$\lambda_1 = 1$$
$$\lambda_2 = -1$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(1)x} + c_2 e^{(-1)x}$$

Or

$$y = \mathrm{e}^{x} c_1 + \mathrm{e}^{-x} c_2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \mathrm{e}^{x} c_1 + \mathrm{e}^{-x} c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 2\pi$ in the above gives

$$1 = \mathrm{e}^{2\pi} c_1 + \mathrm{e}^{-2\pi} c_2 \tag{1A}$$

substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= \frac{e^{2\pi}}{e^{4\pi} - 1} \\ c_2 &= -\frac{e^{2\pi}}{e^{4\pi} - 1} \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{e^{2\pi - x} - e^{6\pi - x} + e^{x + 6\pi} - e^{x + 2\pi}}{e^{8\pi} - 2\,e^{4\pi} + 1}$$

Summary
The solution(s) found are the following

$$y = \frac{e^{2\pi - x} - e^{6\pi - x} + e^{x + 6\pi} - e^{x + 2\pi}}{e^{8\pi} - 2\,e^{4\pi} + 1} \tag{1}$$

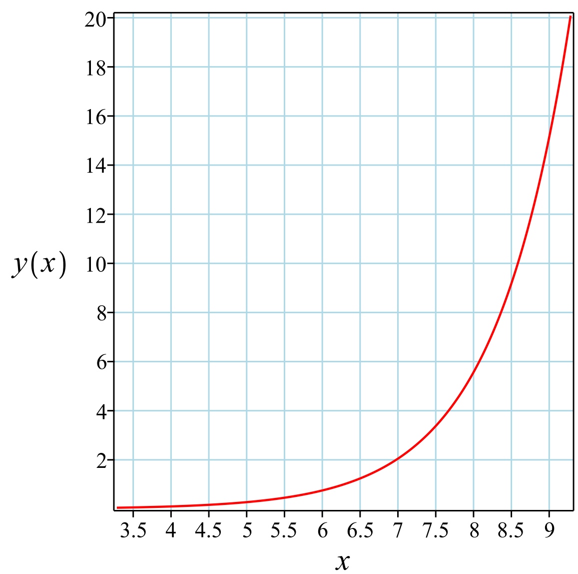

Figure 813: Solution plot

Verification of solutions

$$y = \frac{e^{2\pi - x} - e^{6\pi - x} + e^{x + 6\pi} - e^{x + 2\pi}}{e^{8\pi} - 2\,e^{4\pi} + 1}$$

Verified OK.

22.3.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' - yy' = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' - yy')\, dx = 0$$
$$\frac{y'^2}{2} - \frac{y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{y^2 + 2c_1} \tag{1}$$
$$y' = -\sqrt{y^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{y^2 + 2c_1}} dy = \int dx$$
$$\ln\left(y + \sqrt{y^2 + 2c_1}\right) = x + c_2$$

Raising both side to exponential gives

$$y + \sqrt{y^2 + 2c_1} = e^{x + c_2}$$

Which simplifies to

$$y + \sqrt{y^2 + 2c_1} = e^x c_3$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{y^2 + 2c_1}} dy = \int dx$$
$$-\ln\left(y + \sqrt{y^2 + 2c_1}\right) = x + c_4$$

Raising both side to exponential gives

$$\frac{1}{y+\sqrt{y^2+2c_1}} = \mathrm{e}^{x+c_4}$$

Which simplifies to

$$\frac{1}{y+\sqrt{y^2+2c_1}} = \mathrm{e}^{x} c_5$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$y = \frac{\left(\mathrm{e}^{2x} c_3^2 - 2c_1\right)\mathrm{e}^{-x}}{2c_3} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 2\pi$ in the above gives

$$1 = \frac{c_3^2 \mathrm{e}^{2\pi} - 2\,\mathrm{e}^{-2\pi} c_1}{2c_3} \tag{1A}$$

substituting $y = 0$ and $x = 0$ in the above gives

$$0 = \frac{c_3^2 - 2c_1}{2c_3} \tag{2A}$$

Equations $\{1\text{A},2\text{A}\}$ are now solved for $\{c_1, c_3\}$. Solving for the constants gives

$$c_1 = \frac{2\,\mathrm{e}^{4\pi}}{\left(\mathrm{e}^{4\pi}-1\right)^2}$$
$$c_3 = \frac{2\,\mathrm{e}^{2\pi}}{\mathrm{e}^{4\pi}-1}$$

Substituting these values back in above solution results in

$$y = \frac{\mathrm{e}^{-2\pi-x}\mathrm{e}^{4\pi} - 2\,\mathrm{e}^{-2\pi-x}\mathrm{e}^{8\pi} + 2\,\mathrm{e}^{-2\pi-x}\mathrm{e}^{8\pi+2x} - \mathrm{e}^{-2\pi-x}\mathrm{e}^{4\pi+2x} - \mathrm{e}^{-2\pi-x}\mathrm{e}^{12\pi+2x} + \mathrm{e}^{-2\pi-x}\mathrm{e}^{12\pi}}{3\,\mathrm{e}^{8\pi} - \mathrm{e}^{8\pi}\mathrm{e}^{4\pi} - 3\,\mathrm{e}^{4\pi} + 1}$$

Which simplifies to

$$y = \frac{-\mathrm{e}^{2\pi-x} + 2\,\mathrm{e}^{6\pi-x} - 2\,\mathrm{e}^{x+6\pi} + \mathrm{e}^{x+2\pi} + \mathrm{e}^{10\pi+x} - \mathrm{e}^{10\pi-x}}{-3\,\mathrm{e}^{8\pi} + \mathrm{e}^{12\pi} + 3\,\mathrm{e}^{4\pi} - 1}$$

Looking at the Second solution

$$y = -\frac{\left(2c_1 \mathrm{e}^{2x} c_5^2 - 1\right)\mathrm{e}^{-x}}{2c_5} \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 2\pi$ in the above gives

$$1 = \frac{-2c_1 c_5^2 \mathrm{e}^{2\pi} + \mathrm{e}^{-2\pi}}{2c_5} \tag{1A}$$

substituting $y = 0$ and $x = 0$ in the above gives

$$0 = \frac{-2c_1 c_5^2 + 1}{2c_5} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_5\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= \frac{2\,\mathrm{e}^{4\pi}}{\left(\mathrm{e}^{4\pi} - 1\right)^2} \\ c_5 &= -\frac{\mathrm{e}^{2\pi}}{2} + \frac{\mathrm{e}^{-2\pi}}{2} \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{2\,\mathrm{e}^{-x}\mathrm{e}^{4\pi} - \mathrm{e}^{-x}\mathrm{e}^{8\pi} + \mathrm{e}^{-x}\mathrm{e}^{8\pi+2x} - 2\,\mathrm{e}^{-x}\mathrm{e}^{4\pi+2x} + \mathrm{e}^{-x}\mathrm{e}^{2x} - \mathrm{e}^{-x}}{-3\,\mathrm{e}^{6\pi} + \mathrm{e}^{10\pi} + 3\,\mathrm{e}^{2\pi} - \mathrm{e}^{-2\pi}}$$

Which simplifies to

$$y = \frac{\mathrm{e}^{2\pi-x}\left(\mathrm{e}^{8\pi+2x} - 2\,\mathrm{e}^{4\pi+2x} + \mathrm{e}^{2x} + 2\,\mathrm{e}^{4\pi} - \mathrm{e}^{8\pi} - 1\right)}{-3\,\mathrm{e}^{8\pi} + \mathrm{e}^{12\pi} + 3\,\mathrm{e}^{4\pi} - 1}$$

Summary

The solution(s) found are the following

$$y = \frac{-\mathrm{e}^{2\pi-x} + 2\,\mathrm{e}^{6\pi-x} - 2\,\mathrm{e}^{x+6\pi} + \mathrm{e}^{x+2\pi} + \mathrm{e}^{10\pi+x} - \mathrm{e}^{10\pi-x}}{-3\,\mathrm{e}^{8\pi} + \mathrm{e}^{12\pi} + 3\,\mathrm{e}^{4\pi} - 1} \tag{1}$$

$$y = \frac{\mathrm{e}^{2\pi-x}\left(\mathrm{e}^{8\pi+2x} - 2\,\mathrm{e}^{4\pi+2x} + \mathrm{e}^{2x} + 2\,\mathrm{e}^{4\pi} - \mathrm{e}^{8\pi} - 1\right)}{-3\,\mathrm{e}^{8\pi} + \mathrm{e}^{12\pi} + 3\,\mathrm{e}^{4\pi} - 1} \tag{2}$$

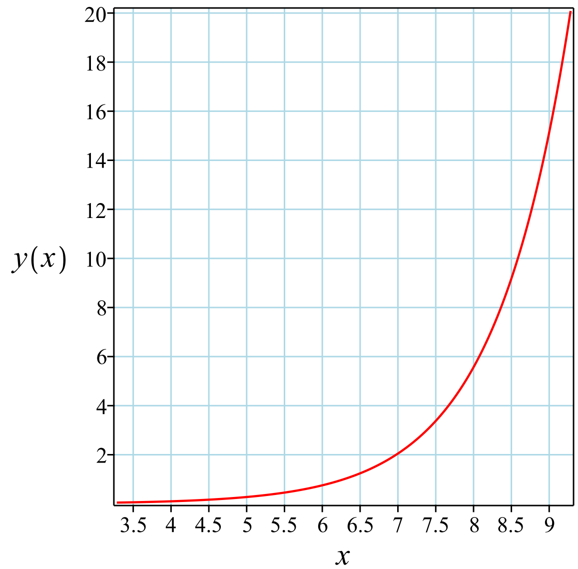

Figure 814: Solution plot

Verification of solutions

$$y = \frac{-e^{2\pi - x} + 2\,e^{6\pi - x} - 2\,e^{x + 6\pi} + e^{x + 2\pi} + e^{10\pi + x} - e^{10\pi - x}}{-3\,e^{8\pi} + e^{12\pi} + 3\,e^{4\pi} - 1}$$

Verified OK.

$$y = \frac{e^{2\pi - x}\left(e^{8\pi + 2x} - 2\,e^{4\pi + 2x} + e^{2x} + 2\,e^{4\pi} - e^{8\pi} - 1\right)}{-3\,e^{8\pi} + e^{12\pi} + 3\,e^{4\pi} - 1}$$

Verified OK.

22.3.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 688: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}
y_1 &= z_1 \\
&= \mathrm{e}^{-x}
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\
&= \mathrm{e}^{-x} \int \frac{1}{\mathrm{e}^{-2x}}\,dx \\
&= \mathrm{e}^{-x}\left(\frac{\mathrm{e}^{2x}}{2}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-x}\right) + c_2\left(\mathrm{e}^{-x}\left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{x}}{2} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 2\pi$ in the above gives

$$
1 = \mathrm{e}^{-2\pi} c_1 + \frac{c_2 \mathrm{e}^{2\pi}}{2} \tag{1A}
$$

substituting $y = 0$ and $x = 0$ in the above gives

$$
0 = c_1 + \frac{c_2}{2} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= -\frac{\mathrm{e}^{2\pi}}{\mathrm{e}^{4\pi} - 1} \\
c_2 &= \frac{2\,\mathrm{e}^{2\pi}}{\mathrm{e}^{4\pi} - 1}
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \frac{\mathrm{e}^{2\pi - x} - \mathrm{e}^{6\pi - x} + \mathrm{e}^{x + 6\pi} - \mathrm{e}^{x + 2\pi}}{\mathrm{e}^{8\pi} - 2\,\mathrm{e}^{4\pi} + 1}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = \frac{\mathrm{e}^{2\pi - x} - \mathrm{e}^{6\pi - x} + \mathrm{e}^{x + 6\pi} - \mathrm{e}^{x + 2\pi}}{\mathrm{e}^{8\pi} - 2\,\mathrm{e}^{4\pi} + 1} \tag{1}
$$

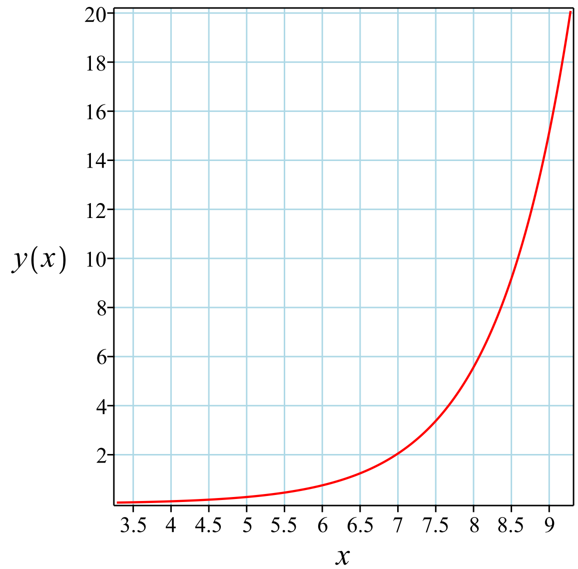

Figure 815: Solution plot

Verification of solutions

$$y = \frac{e^{2\pi - x} - e^{6\pi - x} + e^{x+6\pi} - e^{x+2\pi}}{e^{8\pi} - 2\,e^{4\pi} + 1}$$

Verified OK.

22.3.4 Maple step by step solution

Let's solve

$[y'' - y = 0, y(0) = 0, y(2\pi) = 1]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 1 = 0$

- Factor the characteristic polynomial

  $(r - 1)(r + 1) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 1)$

- 1st solution of the ODE

$$y_1(x) = e^{-x}$$

- 2nd solution of the ODE

$$y_2(x) = e^{x}$$

- General solution of the ODE

$$y = c_1 y_1(x) + c_2 y_2(x)$$

- Substitute in solutions

$$y = c_1 e^{-x} + c_2 e^{x}$$

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

Unable to solve or complete the solution.

$$\boxed{y'' + y = 0}$$

With initial conditions

$$[y(0) = 0, y(2\pi) = 1]$$

22.4.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(x) + c_2 \sin(x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 2\pi$ in the above gives

$$1 = c_1 \tag{1A}$$

substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

22.4.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + yy' = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' + yy')\,dx = 0$$
$$\frac{y'^2}{2} + \frac{y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-y^2 + 2c_1} \tag{1}$$
$$y' = -\sqrt{-y^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-y^2 + 2c_1}}dy = \int dx$$
$$\arctan\left(\frac{y}{\sqrt{-y^2 + 2c_1}}\right) = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-y^2+2c_1}}dy = \int dx$$

$$-\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = x + c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 2\pi$ in the above gives

$$\arctan\left(\frac{1}{\sqrt{-1+2c_1}}\right) = 2\pi + c_2 \tag{1A}$$

substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Warning, unable to solve for constants of integrations.

Looking at the Second solution

$$-\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = x + c_3 \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 2\pi$ in the above gives

$$-\arctan\left(\frac{1}{\sqrt{-1+2c_1}}\right) = 2\pi + c_3 \tag{1A}$$

substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_3 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. Warning, unable to solve for constants of integrations.

Verification of solutions N/A

22.4.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 690: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\ &= \cos(x)\,(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x))) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(x) + c_2 \sin(x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 2\pi$ in the above gives

$$1 = c_1 \tag{1A}$$

substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

22.4.4 Maple step by step solution

Problem number: 710.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_integrable_as_is", "second_order_ode_missing_x", "exact nonlinear second order ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _exact, _nonlinear], [
   _2nd_order, _reducible, _mu_x_y1], [_2nd_order, _reducible,
   _mu_xy]]
```

$$\boxed{yy'' + y'^2 = -1}$$

With initial conditions

$$[y(0) = 1, y(1) = 2]$$

22.5.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(yy'' + y'^2\right) dx = \int (-1)\, dx$$
$$yy' = -x + c_1$$

Which is now solved for y. In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= f(x)g(y) \\ &= \frac{-x + c_1}{y} \end{aligned}$$

Where $f(x) = -x + c_1$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y}}\, dy = -x + c_1\, dx$$
$$\int \frac{1}{\frac{1}{y}}\, dy = \int -x + c_1\, dx$$
$$\frac{y^2}{2} = -\frac{1}{2}x^2 + c_1 x + c_2$$

The solution is

$$\frac{y^2}{2} + \frac{x^2}{2} - c_1 x - c_2 = 0$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$\frac{y^2}{2} + \frac{x^2}{2} - c_1 x - c_2 = 0 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 1$ in the above gives

$$\frac{5}{2} - c_1 - c_2 = 0 \tag{1A}$$

substituting $y = 1$ and $x = 0$ in the above gives

$$\frac{1}{2} - c_2 = 0 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 2 \\ c_2 &= \frac{1}{2} \end{aligned}$$

Substituting these values back in above solution results in

$$\frac{y^2}{2} + \frac{x^2}{2} - 2x - \frac{1}{2} = 0$$

Summary

The solution(s) found are the following

$$\frac{y^2}{2} + \frac{x^2}{2} - 2x - \frac{1}{2} = 0 \tag{1}$$

Verification of solutions

$$\frac{y^2}{2} + \frac{x^2}{2} - 2x - \frac{1}{2} = 0$$

Verified OK.

22.5.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$yp(y)\left(\frac{d}{dy}p(y)\right) + p(y)^2 = -1$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$
\begin{aligned}
p' &= F(y,p) \\
&= f(y)g(p) \\
&= -\frac{p^2+1}{yp}
\end{aligned}
$$

Where $f(y) = -\frac{1}{y}$ and $g(p) = \frac{p^2+1}{p}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{p^2+1}{p}}\,dp &= -\frac{1}{y}\,dy \\
\int \frac{1}{\frac{p^2+1}{p}}\,dp &= \int -\frac{1}{y}\,dy \\
\frac{\ln(p^2+1)}{2} &= -\ln(y) + c_1
\end{aligned}
$$

Raising both side to exponential gives

$$
\sqrt{p^2+1} = \mathrm{e}^{-\ln(y)+c_1}
$$

Which simplifies to

$$
\sqrt{p^2+1} = \frac{c_2}{y}
$$

Which simplifies to

$$
\sqrt{p(y)^2+1} = \frac{c_2\mathrm{e}^{c_1}}{y}
$$

The solution is

$$
\sqrt{p(y)^2+1} = \frac{c_2\mathrm{e}^{c_1}}{y}
$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$
\sqrt{y'^2+1} = \frac{c_2\mathrm{e}^{c_1}}{y}
$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{\sqrt{c_2^2 e^{2c_1} - y^2}}{y} \tag{1}$$

$$y' = -\frac{\sqrt{c_2^2 e^{2c_1} - y^2}}{y} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{y}{\sqrt{c_2^2 e^{2c_1} - y^2}} dy = \int dx$$

$$-\sqrt{c_2^2 e^{2c_1} - y^2} = x + c_3$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$-\sqrt{c_2^2 e^{2c_1} - 4} = 1 + c_3$$

$$c_1 = \frac{\ln\left(\frac{c_3^2 + 2c_3 + 5}{c_2^2}\right)}{2}$$

Substituting c_1 found above in the general solution gives

$$-\sqrt{c_3^2 - y^2 + 2c_3 + 5} = x + c_3$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{y}{\sqrt{c_2^2 e^{2c_1} - y^2}} dy = \int dx$$

$$\sqrt{c_2^2 e^{2c_1} - y^2} = x + c_4$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$\sqrt{c_2^2 e^{2c_1} - 4} = 1 + c_4$$

$$c_1 = \frac{\ln\left(\frac{c_4^2+2c_4+5}{c_2^2}\right)}{2}$$

Substituting c_1 found above in the general solution gives

$$\sqrt{c_4^2 - y^2 + 2c_4 + 5} = x + c_4$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$-\sqrt{c_3^2 - y^2 + 2c_3 + 5} = x + c_3 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 1$ in the above gives

$$-\operatorname{csgn}(1 + c_3)(1 + c_3) = 1 + c_3 \tag{1A}$$

substituting $y = 1$ and $x = 0$ in the above gives

$$-\sqrt{c_3^2 + 2c_3 + 4} = c_3 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_3\}$. Solving for the constants gives

$$c_3 = -2$$

Substituting these values back in above solution results in

$$-\sqrt{5 - y^2} = x - 2$$

Looking at the Second solution

$$\sqrt{c_4^2 - y^2 + 2c_4 + 5} = x + c_4 \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 1$ in the above gives

$$\operatorname{csgn}(1 + c_4)(1 + c_4) = 1 + c_4 \tag{1A}$$

substituting $y = 1$ and $x = 0$ in the above gives

$$\sqrt{c_4^2 + 2c_4 + 4} = c_4 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_4\}$. There is no solution for the constants of integrations. This solution is removed.

Summary

The solution(s) found are the following

$$
-\sqrt{5-y^2} = x-2 \tag{1}
$$

Verification of solutions

$$
-\sqrt{5-y^2} = x-2
$$

Verified OK.

22.5.3 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$
yy'' + y'^2 = -1
$$

Integrating both sides of the ODE w.r.t x gives

$$
\begin{aligned}
\int \left(yy'' + y'^2\right) dx &= \int (-1)\, dx \\
yy' &= -x + c_1
\end{aligned}
$$

Which is now solved for y. In canonical form the ODE is

$$
\begin{aligned}
y' &= F(x,y) \\
&= f(x)g(y) \\
&= \frac{-x+c_1}{y}
\end{aligned}
$$

Where $f(x) = -x + c_1$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{1}{y}}\, dy &= -x + c_1\, dx \\
\int \frac{1}{\frac{1}{y}}\, dy &= \int -x + c_1\, dx \\
\frac{y^2}{2} &= -\frac{1}{2}x^2 + c_1 x + c_2
\end{aligned}
$$

The solution is

$$\frac{y^2}{2}+\frac{x^2}{2}-c_1x-c_2=0$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$\frac{y^2}{2}+\frac{x^2}{2}-c_1x-c_2=0 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y=2$ and $x=1$ in the above gives

$$\frac{5}{2}-c_1-c_2=0 \tag{1A}$$

substituting $y=1$ and $x=0$ in the above gives

$$\frac{1}{2}-c_2=0 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1,c_2\}$. Solving for the constants gives

$$c_1=2$$
$$c_2=\frac{1}{2}$$

Substituting these values back in above solution results in

$$\frac{y^2}{2}+\frac{x^2}{2}-2x-\frac{1}{2}=0$$

Summary

The solution(s) found are the following

$$\frac{y^2}{2}+\frac{x^2}{2}-2x-\frac{1}{2}=0 \tag{1}$$

Verification of solutions

$$\frac{y^2}{2}+\frac{x^2}{2}-2x-\frac{1}{2}=0$$

Verified OK.

22.5.4 Solving as exact nonlinear second order ode ode

An exact non-linear second order ode has the form

$$a_2(x, y, y')\, y'' + a_1(x, y, y')\, y' + a_0(x, y, y') = 0$$

Where the following conditions are satisfied

$$\begin{aligned}\frac{\partial a_2}{\partial y} &= \frac{\partial a_1}{\partial y'} \\ \frac{\partial a_2}{\partial x} &= \frac{\partial a_0}{\partial y'} \\ \frac{\partial a_1}{\partial x} &= \frac{\partial a_0}{\partial y}\end{aligned}$$

Looking at the the ode given we see that

$$\begin{aligned}a_2 &= y \\ a_1 &= y' \\ a_0 &= 1\end{aligned}$$

Applying the conditions to the above shows this is a nonlinear exact second order ode. Therefore it can be reduced to first order ode given by

$$\begin{aligned}\int a_2\, dy' + \int a_1\, dy + \int a_0\, dx &= c_1 \\ \int y\, dy' + \int y'\, dy + \int 1\, dx &= c_1\end{aligned}$$

Which results in

$$2yy' + x = c_1$$

Which is now solved In canonical form the ODE is

$$\begin{aligned}y' &= F(x, y) \\ &= f(x)g(y) \\ &= \frac{-\frac{x}{2} + \frac{c_1}{2}}{y}\end{aligned}$$

Where $f(x) = -\frac{x}{2} + \frac{c_1}{2}$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\begin{aligned}\frac{1}{\frac{1}{y}}\, dy &= -\frac{x}{2} + \frac{c_1}{2}\, dx \\ \int \frac{1}{\frac{1}{y}}\, dy &= \int -\frac{x}{2} + \frac{c_1}{2}\, dx \\ \frac{y^2}{2} &= -\frac{1}{4}x^2 + \frac{1}{2}c_1 x + c_2\end{aligned}$$

The solution is

$$\frac{y^2}{2}+\frac{x^2}{4}-\frac{c_1 x}{2}-c_2=0$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$\frac{y^2}{2}+\frac{x^2}{4}-\frac{c_1 x}{2}-c_2=0 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y=2$ and $x=1$ in the above gives

$$\frac{9}{4}-\frac{c_1}{2}-c_2=0 \tag{1A}$$

substituting $y=1$ and $x=0$ in the above gives

$$\frac{1}{2}-c_2=0 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1=\frac{7}{2}$$
$$c_2=\frac{1}{2}$$

Substituting these values back in above solution results in

$$\frac{y^2}{2}+\frac{x^2}{4}-\frac{7x}{4}-\frac{1}{2}=0$$

Summary
The solution(s) found are the following

$$\frac{y^2}{2}+\frac{x^2}{4}-\frac{7x}{4}-\frac{1}{2}=0 \tag{1}$$

Verification of solutions

$$\frac{y^2}{2}+\frac{x^2}{4}-\frac{7x}{4}-\frac{1}{2}=0$$

Warning, solution could not be verified

22.5.5 Maple step by step solution

Let's solve

$[yy'' + y'^2 = -1, y(0) = 1, y(1) = 2]$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x) = y'$

- Compute y''

  $u'(x) = y''$

- Use chain rule on the lhs

  $y'\left(\frac{d}{dy}u(y)\right) = y''$

- Substitute in the definition of u

  $u(y)\left(\frac{d}{dy}u(y)\right) = y''$

- Make substitutions $y' = u(y)\, , y'' = u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

  $yu(y)\left(\frac{d}{dy}u(y)\right) + u(y)^2 = -1$

- Separate variables

  $\frac{\left(\frac{d}{dy}u(y)\right)u(y)}{-u(y)^2-1} = \frac{1}{y}$

- Integrate both sides with respect to y

  $\int \frac{\left(\frac{d}{dy}u(y)\right)u(y)}{-u(y)^2-1}dy = \int \frac{1}{y}dy + c_1$

- Evaluate integral

  $-\frac{\ln\left(u(y)^2+1\right)}{2} = \ln(y) + c_1$

- Solve for $u(y)$

  $\left\{u(y) = \frac{\sqrt{1-y^2(\mathrm{e}^{c_1})^2}}{\mathrm{e}^{c_1}y}, u(y) = -\frac{\sqrt{1-y^2(\mathrm{e}^{c_1})^2}}{\mathrm{e}^{c_1}y}\right\}$

- Solve 1st ODE for $u(y)$

  $u(y) = \frac{\sqrt{1-y^2(\mathrm{e}^{c_1})^2}}{\mathrm{e}^{c_1}y}$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = \frac{\sqrt{1-y^2 (\mathrm{e}^{c_1})^2}}{\mathrm{e}^{c_1} y}$$

- Separate variables

$$\frac{y' y}{\sqrt{1-y^2 (\mathrm{e}^{c_1})^2}} = \frac{1}{\mathrm{e}^{c_1}}$$

- Integrate both sides with respect to x

$$\int \frac{y' y}{\sqrt{1-y^2 (\mathrm{e}^{c_1})^2}} dx = \int \frac{1}{\mathrm{e}^{c_1}} dx + c_2$$

- Evaluate integral

$$-\frac{\sqrt{1-y^2 (\mathrm{e}^{c_1})^2}}{(\mathrm{e}^{c_1})^2} = \frac{x}{\mathrm{e}^{c_1}} + c_2$$

- Solve for y

$$\left\{y = \frac{\sqrt{1-(\mathrm{e}^{c_1})^4 c_2^2 - 2(\mathrm{e}^{c_1})^3 c_2 x - (\mathrm{e}^{c_1})^2 x^2}}{\mathrm{e}^{c_1}}, y = -\frac{\sqrt{1-(\mathrm{e}^{c_1})^4 c_2^2 - 2(\mathrm{e}^{c_1})^3 c_2 x - (\mathrm{e}^{c_1})^2 x^2}}{\mathrm{e}^{c_1}}\right\}$$

- Solve 2nd ODE for $u(y)$

$$u(y) = -\frac{\sqrt{1-y^2 (\mathrm{e}^{c_1})^2}}{\mathrm{e}^{c_1} y}$$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = -\frac{\sqrt{1-y^2 (\mathrm{e}^{c_1})^2}}{\mathrm{e}^{c_1} y}$$

- Separate variables

$$\frac{y' y}{\sqrt{1-y^2 (\mathrm{e}^{c_1})^2}} = -\frac{1}{\mathrm{e}^{c_1}}$$

- Integrate both sides with respect to x

$$\int \frac{y' y}{\sqrt{1-y^2 (\mathrm{e}^{c_1})^2}} dx = \int -\frac{1}{\mathrm{e}^{c_1}} dx + c_2$$

- Evaluate integral

$$-\frac{\sqrt{1-y^2 (\mathrm{e}^{c_1})^2}}{(\mathrm{e}^{c_1})^2} = -\frac{x}{\mathrm{e}^{c_1}} + c_2$$

- Solve for y

$$\left\{y = \frac{\sqrt{1-(\mathrm{e}^{c_1})^4 c_2^2 + 2(\mathrm{e}^{c_1})^3 c_2 x - (\mathrm{e}^{c_1})^2 x^2}}{\mathrm{e}^{c_1}}, y = -\frac{\sqrt{1-(\mathrm{e}^{c_1})^4 c_2^2 + 2(\mathrm{e}^{c_1})^3 c_2 x - (\mathrm{e}^{c_1})^2 x^2}}{\mathrm{e}^{c_1}}\right\}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + y = 0}$$

With initial conditions

$$\left[y(0) = 0, y\left(\frac{\pi}{2}\right) = \alpha\right]$$

22.6.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)}\\ &= \pm i\end{aligned}$$

Hence

$$\lambda_1 = +i$$
$$\lambda_2 = -i$$

Which simplifies to

$$\lambda_1 = i$$
$$\lambda_2 = -i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(x) + c_2 \sin(x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \alpha$ and $x = \frac{\pi}{2}$ in the above gives

$$\alpha = c_2 \tag{1A}$$

substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 0 \\ c_2 &= \alpha \end{aligned}$$

Substituting these values back in above solution results in

$$y = \alpha \sin(x)$$

Summary

The solution(s) found are the following

$$y = \alpha \sin(x) \tag{1}$$

Verification of solutions

$$y = \alpha \sin(x)$$

Verified OK.

22.6.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + yy' = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' + yy')\,dx = 0$$

$$\frac{y'^2}{2} + \frac{y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-y^2+2c_1} \tag{1}$$

$$y' = -\sqrt{-y^2+2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-y^2+2c_1}}dy = \int dx$$

$$\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-y^2+2c_1}}dy = \int dx$$

$$-\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = x + c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \alpha$ and $x = \frac{\pi}{2}$ in the above gives

$$\arctan\left(\frac{\alpha}{\sqrt{-\alpha^2+2c_1}}\right) = \frac{\pi}{2} + c_2 \tag{1A}$$

substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Warning, unable to solve for constants of integrations.

Looking at the Second solution

$$-\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = x + c_3 \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \alpha$ and $x = \frac{\pi}{2}$ in the above gives

$$-\arctan\left(\frac{\alpha}{\sqrt{-\alpha^2+2c_1}}\right) = \frac{\pi}{2} + c_3 \tag{1A}$$

substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_3 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. Warning, unable to solve for constants of integrations.

Verification of solutions N/A

22.6.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 693: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$
