Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}
y_1 &= z_1 \\
&= \cos(x)
\end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\
&= \cos(x) \int \frac{1}{\cos(x)^2}\,dx \\
&= \cos(x)\,(\tan(x))
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(x)) + c_2(\cos(x)(\tan(x)))
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \cos(x) + c_2 \sin(x) \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \alpha$ and $x = \frac{\pi}{2}$ in the above gives

$$
\alpha = c_2 \tag{1A}
$$

substituting $y = 0$ and $x = 0$ in the above gives

$$
0 = c_1 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 0 \\
c_2 &= \alpha
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \alpha \sin(x)
$$

Summary

The solution(s) found are the following

$$
y = \alpha \sin(x) \tag{1}
$$

Verification of solutions

$$
y = \alpha \sin(x)
$$

Verified OK.

22.6.4 Maple step by step solution

Let's solve

$\left[y''+y=0, y(0)=0, y\left(\frac{\pi}{2}\right)=\alpha\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2+1=0$

- Use quadratic formula to solve for r

  $r=\frac{0\pm(\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r=(-\mathrm{I}, \mathrm{I})$

- 1st solution of the ODE

  $y_1(x)=\cos(x)$

- 2nd solution of the ODE

  $y_2(x)=\sin(x)$

- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)$

- Substitute in solutions

  $y=c_1\cos(x)+c_2\sin(x)$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - y = 0}$$

With initial conditions

$$[y(0) = 0, y'(1) = 1]$$

22.7.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)}\\ &= \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +1\\ \lambda_2 &= -1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1\\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(1)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$y = \mathrm{e}^{x} c_1 + \mathrm{e}^{-x} c_2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \mathrm{e}^{x} c_1 + \mathrm{e}^{-x} c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = e^{x} c_1 - e^{-x} c_2$$

substituting $y' = 1$ and $x = 1$ in the above gives

$$1 = e c_1 - c_2 e^{-1} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{e}{e^2 + 1}$$
$$c_2 = -\frac{e}{e^2 + 1}$$

Substituting these values back in above solution results in

$$y = \frac{-e^{3-x} - e^{1-x} + e^{x+3} + e^{x+1}}{e^4 + 2 e^2 + 1}$$

Which simplifies to

$$y = \frac{-e^{3-x} - e^{1-x} + e^{x+3} + e^{x+1}}{e^4 + 2 e^2 + 1}$$

Summary

The solution(s) found are the following

$$y = \frac{-e^{3-x} - e^{1-x} + e^{x+3} + e^{x+1}}{e^4 + 2 e^2 + 1} \tag{1}$$

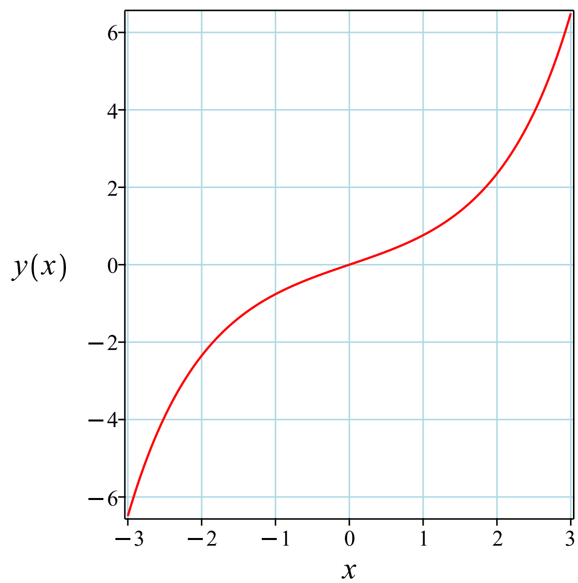

Figure 816: Solution plot

Verification of solutions

$$y = \frac{-e^{3-x} - e^{1-x} + e^{x+3} + e^{x+1}}{e^4 + 2e^2 + 1}$$

Verified OK.

22.7.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' - yy' = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' - yy')\, dx = 0$$
$$\frac{y'^2}{2} - \frac{y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{y^2 + 2c_1} \tag{1}$$
$$y' = -\sqrt{y^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{y^2 + 2c_1}} dy = \int dx$$
$$\ln\left(y + \sqrt{y^2 + 2c_1}\right) = x + c_2$$

Raising both side to exponential gives

$$y + \sqrt{y^2 + 2c_1} = e^{x + c_2}$$

Which simplifies to

$$y + \sqrt{y^2 + 2c_1} = e^x c_3$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{y^2+2c_1}}dy = \int dx$$
$$-\ln\left(y+\sqrt{y^2+2c_1}\right) = x + c_4$$

Raising both side to exponential gives

$$\frac{1}{y+\sqrt{y^2+2c_1}} = e^{x+c_4}$$

Which simplifies to

$$\frac{1}{y+\sqrt{y^2+2c_1}} = e^{x}c_5$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$y = \frac{\left(e^{2x}c_3^2 - 2c_1\right)e^{-x}}{2c_3} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = \frac{c_3^2 - 2c_1}{2c_3} \tag{1A}$$

Taking derivative of the solution gives

$$y' = e^{x}c_3 - \frac{\left(e^{2x}c_3^2 - 2c_1\right)e^{-x}}{2c_3}$$

substituting $y' = 1$ and $x = 1$ in the above gives

$$1 = \frac{ec_3^2 + 2\,e^{-1}c_1}{2c_3} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. Solving for the constants gives

$$c_1 = \frac{2\,e^2}{\left(e^2+1\right)^2}$$
$$c_3 = \frac{2\,e}{e^2+1}$$

Substituting these values back in above solution results in

$$y = \frac{-\mathrm{e}^{-x-1}\mathrm{e}^{2} + \mathrm{e}^{-x-1}\mathrm{e}^{6+2x} - \mathrm{e}^{-x-1}\mathrm{e}^{6} + 2\,\mathrm{e}^{-x-1}\mathrm{e}^{2x+4} + \mathrm{e}^{-x-1}\mathrm{e}^{2x+2} - 2\,\mathrm{e}^{-x-1}\mathrm{e}^{4}}{3\,\mathrm{e}^{4} + \mathrm{e}^{4}\mathrm{e}^{2} + 3\,\mathrm{e}^{2} + 1}$$

Which simplifies to

$$y = \frac{-\mathrm{e}^{1-x} + \mathrm{e}^{5+x} - \mathrm{e}^{5-x} + 2\,\mathrm{e}^{x+3} + \mathrm{e}^{x+1} - 2\,\mathrm{e}^{3-x}}{3\,\mathrm{e}^{4} + \mathrm{e}^{6} + 3\,\mathrm{e}^{2} + 1}$$

Looking at the Second solution

$$y = -\frac{(2c_1\mathrm{e}^{2x}c_5^2 - 1)\,\mathrm{e}^{-x}}{2c_5} \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = \frac{-2c_1c_5^2 + 1}{2c_5} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -2c_1\mathrm{e}^{x}c_5 + \frac{(2c_1\mathrm{e}^{2x}c_5^2 - 1)\,\mathrm{e}^{-x}}{2c_5}$$

substituting $y' = 1$ and $x = 1$ in the above gives

$$1 = \frac{-2\,\mathrm{e}c_1c_5^2 - \mathrm{e}^{-1}}{2c_5} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_5\}$. Solving for the constants gives

$$c_1 = \frac{2\,\mathrm{e}^{2}}{(\mathrm{e}^{2} + 1)^2}$$
$$c_5 = -\frac{\mathrm{e}}{2} - \frac{\mathrm{e}^{-1}}{2}$$

Substituting these values back in above solution results in

$$y = \frac{\mathrm{e}^{-x}\mathrm{e}^{2x} - 2\,\mathrm{e}^{-x}\mathrm{e}^{2} + \mathrm{e}^{-x}\mathrm{e}^{2x+4} + 2\,\mathrm{e}^{-x}\mathrm{e}^{2x+2} - \mathrm{e}^{-x}\mathrm{e}^{4} - \mathrm{e}^{-x}}{3\,\mathrm{e}^{3} + \mathrm{e}^{5} + 3\,\mathrm{e} + \mathrm{e}^{-1}}$$

Which simplifies to

$$y = \frac{\mathrm{e}^{1-x}(\mathrm{e}^{2x+4} + 2\,\mathrm{e}^{2x+2} + \mathrm{e}^{2x} - 2\,\mathrm{e}^{2} - \mathrm{e}^{4} - 1)}{3\,\mathrm{e}^{4} + \mathrm{e}^{6} + 3\,\mathrm{e}^{2} + 1}$$

Summary

The solution(s) found are the following

$$y = \frac{-e^{1-x} + e^{5+x} - e^{5-x} + 2\,e^{x+3} + e^{x+1} - 2\,e^{3-x}}{3\,e^{4} + e^{6} + 3\,e^{2} + 1} \tag{1}$$

$$y = \frac{e^{1-x}\left(e^{2x+4} + 2\,e^{2x+2} + e^{2x} - 2\,e^{2} - e^{4} - 1\right)}{3\,e^{4} + e^{6} + 3\,e^{2} + 1} \tag{2}$$

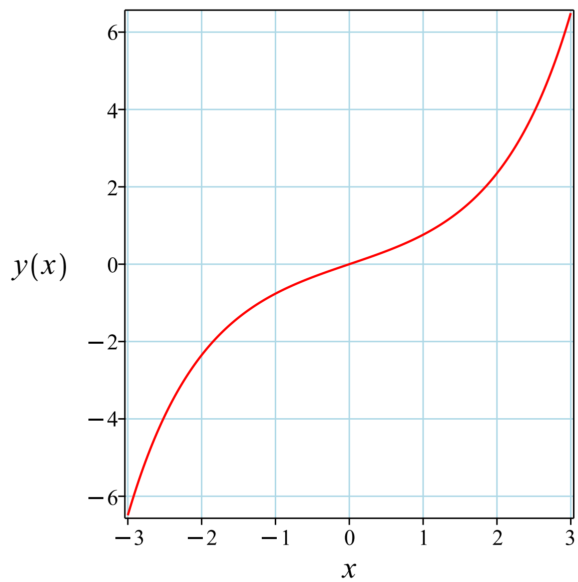

Figure 817: Solution plot

Verification of solutions

$$y = \frac{-e^{1-x} + e^{5+x} - e^{5-x} + 2\,e^{x+3} + e^{x+1} - 2\,e^{3-x}}{3\,e^{4} + e^{6} + 3\,e^{2} + 1}$$

Verified OK.

$$y = \frac{e^{1-x}\left(e^{2x+4} + 2\,e^{2x+2} + e^{2x} - 2\,e^{2} - e^{4} - 1\right)}{3\,e^{4} + e^{6} + 3\,e^{2} + 1}$$

Verified OK.

22.7.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 695: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-x}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B=0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \mathrm{e}^{-x}
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Since $B=0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \mathrm{e}^{-x} \int \frac{1}{\mathrm{e}^{-2x}}\, dx \\
&= \mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{x}}{2} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y=0$ and $x=0$ in the above gives

$$
0 = c_1 + \frac{c_2}{2} \tag{1A}
$$

Taking derivative of the solution gives

$$y' = -c_1 e^{-x} + \frac{c_2 e^x}{2}$$

substituting $y' = 1$ and $x = 1$ in the above gives

$$1 = -e^{-1} c_1 + \frac{c_2 e}{2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -\frac{e}{e^2 + 1}$$
$$c_2 = \frac{2\,e}{e^2 + 1}$$

Substituting these values back in above solution results in

$$y = \frac{-e^{3-x} - e^{1-x} + e^{x+3} + e^{x+1}}{e^4 + 2\,e^2 + 1}$$

Which simplifies to

$$y = \frac{-e^{3-x} - e^{1-x} + e^{x+3} + e^{x+1}}{e^4 + 2\,e^2 + 1}$$

Summary

The solution(s) found are the following

$$y = \frac{-e^{3-x} - e^{1-x} + e^{x+3} + e^{x+1}}{e^4 + 2\,e^2 + 1} \tag{1}$$

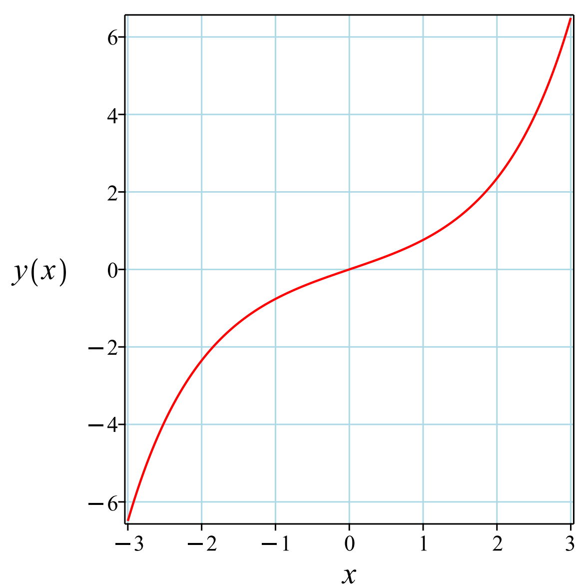

Figure 818: Solution plot

Verification of solutions

$$y = \frac{-e^{3-x} - e^{1-x} + e^{x+3} + e^{x+1}}{e^4 + 2e^2 + 1}$$

Verified OK.

22.7.4 Maple step by step solution

Let's solve

$\left[y'' - y = 0, y(0) = 0, y'\Big|_{\{x=1\}} = 1\right]$

- Highest derivative means the order of the ODE is 2

  y''
- Characteristic polynomial of ODE

  $r^2 - 1 = 0$
- Factor the characteristic polynomial

  $(r-1)(r+1) = 0$
- Roots of the characteristic polynomial

  $r = (-1, 1)$
- 1st solution of the ODE

  $y_1(x) = e^{-x}$
- 2nd solution of the ODE

  $y_2(x) = e^x$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$
- Substitute in solutions

  $y = c_1 e^{-x} + c_2 e^x$

□ Check validity of solution $y = c_1 e^{-x} + c_2 e^x$

- ◦ Use initial condition $y(0) = 0$

  $0 = c_1 + c_2$
- ◦ Compute derivative of the solution

  $y' = -c_1 e^{-x} + c_2 e^x$

- Use the initial condition $y'\Big|_{\{x=1\}} = 1$

  $1 = -\mathrm{e}^{-1} c_1 + c_2 \mathrm{e}$

- Solve for c_1 and c_2

  $\left\{c_1 = -\frac{1}{\mathrm{e}+\mathrm{e}^{-1}}, c_2 = \frac{1}{\mathrm{e}+\mathrm{e}^{-1}}\right\}$

- Substitute constant values into general solution and simplify

  $y = \frac{\mathrm{e}^{1-x}(\mathrm{e}^{2x}-1)}{\mathrm{e}^2+1}$

- Solution to the IVP

  $y = \frac{\mathrm{e}^{1-x}(\mathrm{e}^{2x}-1)}{\mathrm{e}^2+1}$

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y''-2y'+2y=0}$$

With initial conditions

$$[y(0)=0, y'(\pi)=\mathrm{e}^{\pi}]$$

22.8.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=1, B=-2, C=2$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2\mathrm{e}^{\lambda x}-2\lambda\,\mathrm{e}^{\lambda x}+2\,\mathrm{e}^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2-2\lambda+2=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-2^2 - (4)(1)(2)} \\ &= 1 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 1 + i \\ \lambda_2 &= 1 - i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 + i \\ \lambda_2 &= 1 - i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 1$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^x(c_1 \cos(x) + c_2 \sin(x))$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \mathrm{e}^x(c_1 \cos(x) + c_2 \sin(x)) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = e^x (c_1 \cos(x) + c_2 \sin(x)) + e^x (-c_1 \sin(x) + c_2 \cos(x))$$

substituting $y' = e^\pi$ and $x = \pi$ in the above gives

$$e^\pi = (-c_1 - c_2) e^\pi \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = -1$$

Substituting these values back in above solution results in

$$y = -e^x \sin(x)$$

Summary

The solution(s) found are the following

$$y = -e^x \sin(x) \tag{1}$$

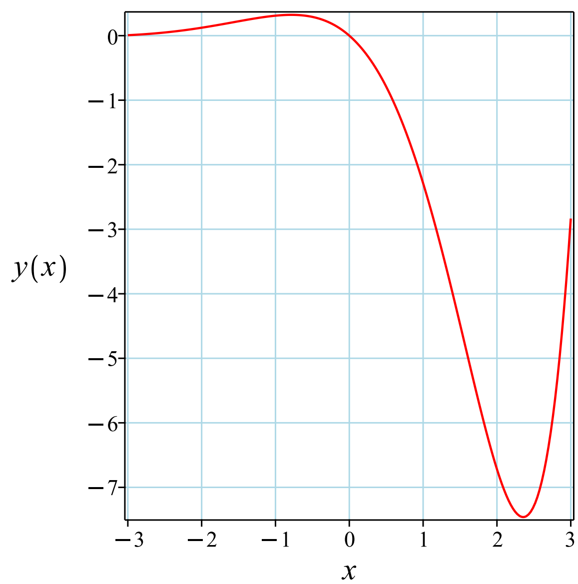

Figure 819: Solution plot

Verification of solutions

$$y = -e^x \sin(x)$$

Verified OK.

22.8.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + 2y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 697: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^x \\
&= z_1(\mathrm{e}^x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \cos(x)\,\mathrm{e}^x
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\
&= y_1(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(x)\,\mathrm{e}^x) + c_2(\cos(x)\,\mathrm{e}^x(\tan(x)))
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \cos(x)\,\mathrm{e}^x + \mathrm{e}^x \sin(x)\,c_2 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$
0 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -c_1 \sin(x)\,\mathrm{e}^x + c_1 \cos(x)\,\mathrm{e}^x + \mathrm{e}^x \sin(x)\,c_2 + \mathrm{e}^x \cos(x)\,c_2
$$

substituting $y' = \mathrm{e}^{\pi}$ and $x = \pi$ in the above gives

$$\mathrm{e}^{\pi} = (-c_1 - c_2)\,\mathrm{e}^{\pi} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = -1$$

Substituting these values back in above solution results in

$$y = -\mathrm{e}^{x} \sin(x)$$

Summary

The solution(s) found are the following

$$y = -\mathrm{e}^{x} \sin(x) \tag{1}$$

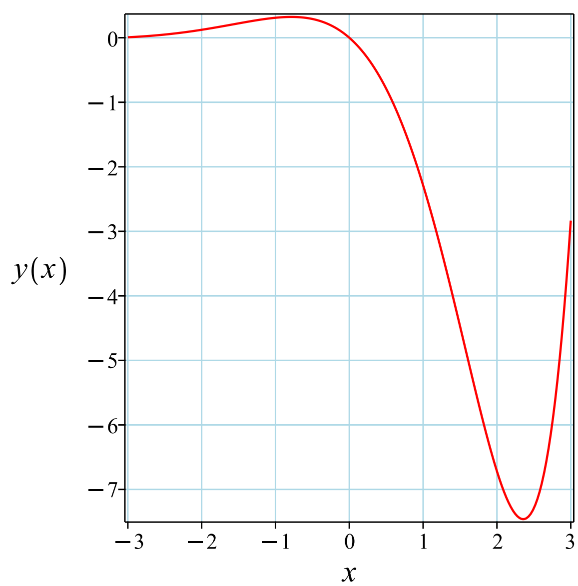

Figure 820: Solution plot

Verification of solutions

$$y = -\mathrm{e}^{x} \sin(x)$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + \alpha y' = 0}$$

With initial conditions

$$[y(0) = e^{\alpha}, y'(1) = 0]$$

22.9.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = \alpha, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \alpha\lambda\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\alpha\lambda + \lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = \alpha, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-\alpha}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{\alpha^2 - (4)(1)(0)}\\ &= -\frac{\alpha}{2} \pm \frac{\sqrt{\alpha^2}}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{\alpha}{2} + \frac{\sqrt{\alpha^2}}{2}\\ \lambda_2 &= -\frac{\alpha}{2} - \frac{\sqrt{\alpha^2}}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -\frac{\alpha}{2} + \frac{\sqrt{\alpha^2}}{2}\\ \lambda_2 &= -\frac{\alpha}{2} - \frac{\sqrt{\alpha^2}}{2}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{\left(-\frac{\alpha}{2}+\frac{\sqrt{\alpha^2}}{2}\right)x} + c_2 e^{\left(-\frac{\alpha}{2}-\frac{\sqrt{\alpha^2}}{2}\right)x}\end{aligned}$$

Or

$$y = c_1 e^{\left(-\frac{\alpha}{2}+\frac{\sqrt{\alpha^2}}{2}\right)x} + c_2 e^{\left(-\frac{\alpha}{2}-\frac{\sqrt{\alpha^2}}{2}\right)x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{\left(-\frac{\alpha}{2}+\frac{\sqrt{\alpha^2}}{2}\right)x} + c_2 e^{\left(-\frac{\alpha}{2}-\frac{\sqrt{\alpha^2}}{2}\right)x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = e^{\alpha}$ and $x = 0$ in the above gives

$$e^{\alpha} = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 \left(-\frac{\alpha}{2}+\frac{\sqrt{\alpha^2}}{2}\right) e^{\left(-\frac{\alpha}{2}+\frac{\sqrt{\alpha^2}}{2}\right)x} + c_2 \left(-\frac{\alpha}{2}-\frac{\sqrt{\alpha^2}}{2}\right) e^{\left(-\frac{\alpha}{2}-\frac{\sqrt{\alpha^2}}{2}\right)x}$$

substituting $y' = 0$ and $x = 1$ in the above gives

$$0 = \frac{\left(c_1(-1+\operatorname{csgn}(\alpha))\, e^{\frac{\alpha(-1+\operatorname{csgn}(\alpha))}{2}} - c_2 e^{-\frac{\alpha(1+\operatorname{csgn}(\alpha))}{2}}(1+\operatorname{csgn}(\alpha))\right)\alpha}{2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{(1+\operatorname{csgn}(\alpha))\, e^{-\frac{\alpha(-1+\operatorname{csgn}(\alpha))}{2}}}{\operatorname{csgn}(\alpha)\, e^{-\frac{\alpha(1+\operatorname{csgn}(\alpha))}{2}} + \operatorname{csgn}(\alpha)\, e^{\frac{\alpha(-1+\operatorname{csgn}(\alpha))}{2}} + e^{-\frac{\alpha(1+\operatorname{csgn}(\alpha))}{2}} - e^{\frac{\alpha(-1+\operatorname{csgn}(\alpha))}{2}}}$$

$$c_2 = \frac{(-1+\operatorname{csgn}(\alpha))\, e^{\alpha(1+\operatorname{csgn}(\alpha))}}{\operatorname{csgn}(\alpha)\, e^{\operatorname{csgn}(\alpha)\alpha} - e^{\operatorname{csgn}(\alpha)\alpha} + \operatorname{csgn}(\alpha) + 1}$$

Substituting these values back in above solution results in

$$y = \frac{2\, e^{-\frac{\alpha(x\ \operatorname{csgn}(\alpha)-3\ \operatorname{csgn}(\alpha)+x-1)}{2}} + 2\, e^{\frac{\alpha(x-1)}{}}}{\operatorname{csgn}(\alpha)^2 e^{-\frac{\alpha(1+\operatorname{csgn}(\alpha))}{2}} e^{\operatorname{csgn}(\alpha)\alpha} + \operatorname{csgn}(\alpha)^2 e^{\frac{\alpha(-1+\operatorname{csgn}(\alpha))}{2}} e^{\operatorname{csgn}(\alpha)\alpha} + \operatorname{csgn}(\alpha)^2 e^{-\frac{\alpha(1+\operatorname{csgn}(\alpha))}{2}} + \operatorname{csgn}(\alpha)^2 e^{\frac{\alpha(}{}}}$$

Which simplifies to

$$y = \frac{(1-\operatorname{csgn}(\alpha))\, e^{-\frac{((-3+x)\operatorname{csgn}(\alpha)+x-1)\alpha}{2}} + (1+\operatorname{csgn}(\alpha))\, e^{\frac{\alpha(x-1)(-1+\operatorname{csgn}(\alpha))}{2}}}{(1-\operatorname{csgn}(\alpha))\, e^{\frac{\alpha(3\ \operatorname{csgn}(\alpha)-1)}{2}} + e^{-\frac{\alpha(1+\operatorname{csgn}(\alpha))}{2}}(1+\operatorname{csgn}(\alpha))}$$

Summary

The solution(s) found are the following

$$y = \frac{(1-\operatorname{csgn}(\alpha))\,\mathrm{e}^{-\frac{((-3+x)\operatorname{csgn}(\alpha)+x-1)\alpha}{2}} + (1+\operatorname{csgn}(\alpha))\,\mathrm{e}^{\frac{\alpha(x-1)(-1+\operatorname{csgn}(\alpha))}{2}}}{(1-\operatorname{csgn}(\alpha))\,\mathrm{e}^{\frac{\alpha(3\operatorname{csgn}(\alpha)-1)}{2}} + \mathrm{e}^{-\frac{\alpha(1+\operatorname{csgn}(\alpha))}{2}}(1+\operatorname{csgn}(\alpha))} \tag{1}$$

Verification of solutions

$$y = \frac{(1-\operatorname{csgn}(\alpha))\,\mathrm{e}^{-\frac{((-3+x)\operatorname{csgn}(\alpha)+x-1)\alpha}{2}} + (1+\operatorname{csgn}(\alpha))\,\mathrm{e}^{\frac{\alpha(x-1)(-1+\operatorname{csgn}(\alpha))}{2}}}{(1-\operatorname{csgn}(\alpha))\,\mathrm{e}^{\frac{\alpha(3\operatorname{csgn}(\alpha)-1)}{2}} + \mathrm{e}^{-\frac{\alpha(1+\operatorname{csgn}(\alpha))}{2}}(1+\operatorname{csgn}(\alpha))}$$

Verified OK.

22.9.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + \alpha y')\, dx = 0$$
$$\alpha y + y' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{1}{-\alpha y + c_1} dy = \int dx$$
$$-\frac{\ln(-\alpha y + c_1)}{\alpha} = x + c_2$$

Raising both side to exponential gives

$$\mathrm{e}^{-\frac{\ln(-\alpha y + c_1)}{\alpha}} = \mathrm{e}^{x+c_2}$$

Which simplifies to

$$(-\alpha y + c_1)^{-\frac{1}{\alpha}} = \mathrm{e}^x c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{(\mathrm{e}^x c_3)^{-\alpha} - c_1}{\alpha} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \mathrm{e}^{\alpha}$ and $x = 0$ in the above gives

$$\mathrm{e}^{\alpha} = \frac{-c_3^{-\alpha} + c_1}{\alpha} \tag{1A}$$

Taking derivative of the solution gives

$$y' = (\mathrm{e}^{x} c_3)^{-\alpha}$$

substituting $y' = 0$ and $x = 1$ in the above gives

$$0 = c_3^{-\alpha} \mathrm{e}^{-\alpha} \tag{2A}$$

Equations $\{1\text{A},2\text{A}\}$ are now solved for $\{c_1, c_3\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= \mathrm{e}^{\alpha}\alpha \\ c_3 &= 0 \end{aligned}$$

Substituting these values back in above solution results in

$$y = \lim_{c_3 \to 0} \frac{-(\mathrm{e}^{x} c_3)^{-\alpha} + \mathrm{e}^{\alpha}\alpha}{\alpha}$$

Summary
The solution(s) found are the following

$$y = \lim_{c_3 \to 0} \frac{-(\mathrm{e}^{x} c_3)^{-\alpha} + \mathrm{e}^{\alpha}\alpha}{\alpha} \tag{1}$$

Verification of solutions

$$y = \lim_{c_3 \to 0} \frac{-(\mathrm{e}^{x} c_3)^{-\alpha} + \mathrm{e}^{\alpha}\alpha}{\alpha}$$

Verified OK.

22.9.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + \alpha p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int -\frac{1}{\alpha p} dp = \int dx$$
$$-\frac{\ln(p)}{\alpha} = x + c_1$$

Raising both side to exponential gives

$$e^{-\frac{\ln(p)}{\alpha}} = e^{x+c_1}$$

Which simplifies to

$$p^{-\frac{1}{\alpha}} = c_2 e^x$$

Initial conditions are used to solve for c_2. Substituting $x = 1$ and $p = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_2^{-\alpha} e^{-\alpha}$$

$$c_2 = 0$$

Substituting c_2 found above in the general solution gives

$$p(x) = \lim_{c_2 \to 0} (c_2 e^x)^{-\alpha}$$

But this does not satisfy the initial conditions. Hence no solution can be found.

22.9.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + \alpha y' = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + \alpha y')\, dx = 0$$

$$\alpha y + y' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{1}{-\alpha y + c_1} dy = \int dx$$
$$-\frac{\ln(-\alpha y + c_1)}{\alpha} = x + c_2$$

Raising both side to exponential gives

$$e^{-\frac{\ln(-\alpha y+c_1)}{\alpha}} = e^{x+c_2}$$

Which simplifies to

$$(-\alpha y + c_1)^{-\frac{1}{\alpha}} = e^x c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{(e^x c_3)^{-\alpha} - c_1}{\alpha} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = e^\alpha$ and $x = 0$ in the above gives

$$e^\alpha = \frac{-c_3^{-\alpha} + c_1}{\alpha} \tag{1A}$$

Taking derivative of the solution gives

$$y' = (e^x c_3)^{-\alpha}$$

substituting $y' = 0$ and $x = 1$ in the above gives

$$0 = c_3^{-\alpha} e^{-\alpha} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. Solving for the constants gives

$$c_1 = e^\alpha \alpha$$
$$c_3 = 0$$

Substituting these values back in above solution results in

$$y = \lim_{c_3 \to 0} \frac{-(e^x c_3)^{-\alpha} + e^\alpha \alpha}{\alpha}$$

Summary
The solution(s) found are the following

$$y = \lim_{c_3 \to 0} \frac{-(e^x c_3)^{-\alpha} + e^\alpha \alpha}{\alpha} \tag{1}$$

Verification of solutions

$$y = \lim_{c_3 \to 0} \frac{-(e^x c_3)^{-\alpha} + e^\alpha \alpha}{\alpha}$$

Verified OK.

22.9.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' + \alpha y' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= \alpha \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{\alpha^2}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= \alpha^2 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{\alpha^2}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 698: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{\alpha^2}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{\frac{x\sqrt{\alpha^2}}{2}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}
$$

$$
\begin{aligned}
&= z_1 e^{-\int \frac{1}{2}\frac{\alpha}{1}\, dx} \\
&= z_1 e^{-\frac{x\alpha}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{x\alpha}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{\frac{x\alpha(-1+\operatorname{csgn}(\alpha))}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{\alpha}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-x\alpha}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{\operatorname{csgn}(\alpha)\, \mathrm{e}^{-x \operatorname{csgn}(\alpha)\alpha}}{\alpha}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{\frac{x\alpha(-1+\operatorname{csgn}(\alpha))}{2}}\right) + c_2 \left(\mathrm{e}^{\frac{x\alpha(-1+\operatorname{csgn}(\alpha))}{2}} \left(-\frac{\operatorname{csgn}(\alpha)\, \mathrm{e}^{-x \operatorname{csgn}(\alpha)\alpha}}{\alpha}\right)\right)
\end{aligned}
$$

Simplifying the solution $y = c_1 \mathrm{e}^{\frac{x\alpha(-1+\operatorname{csgn}(\alpha))}{2}} - \frac{c_2 \operatorname{csgn}(\alpha) \mathrm{e}^{-\frac{x\alpha(1+\operatorname{csgn}(\alpha))}{2}}}{\alpha}$ to $y = c_1 - \frac{c_2 \mathrm{e}^{-x\alpha}}{\alpha}$ Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 - \frac{c_2 \mathrm{e}^{-x\alpha}}{\alpha} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \mathrm{e}^{\alpha}$ and $x = 0$ in the above gives

$$
\mathrm{e}^{\alpha} = \frac{\alpha c_1 - c_2}{\alpha} \tag{1A}
$$

Taking derivative of the solution gives

$$y' = c_2 e^{-x\alpha}$$

substituting $y' = 0$ and $x = 1$ in the above gives

$$0 = c_2 e^{-\alpha} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= e^{\alpha} \\ c_2 &= 0 \end{aligned}$$

Substituting these values back in above solution results in

$$y = e^{\alpha}$$

Summary
The solution(s) found are the following

$$y = e^{\alpha} \tag{1}$$

Verification of solutions

$$y = e^{\alpha}$$

Verified OK.

22.9.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= \alpha \\ r(x) &= 0 \\ s(x) &= 0 \end{aligned}$$

Hence

$$p''(x) = 0$$
$$q'(x) = 0$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$\alpha y + y' = c_1$$

We now have a first order ode to solve which is

$$\alpha y + y' = c_1$$

Integrating both sides gives

$$\int \frac{1}{-\alpha y + c_1} dy = \int dx$$
$$-\frac{\ln (-\alpha y + c_1)}{\alpha} = x + c_2$$

Raising both side to exponential gives

$$\mathrm{e}^{-\frac{\ln(-\alpha y + c_1)}{\alpha}} = \mathrm{e}^{x + c_2}$$

Which simplifies to

$$(-\alpha y + c_1)^{-\frac{1}{\alpha}} = \mathrm{e}^{x} c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{(\mathrm{e}^{x} c_3)^{-\alpha} - c_1}{\alpha} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = e^{\alpha}$ and $x = 0$ in the above gives

$$e^{\alpha} = \frac{-c_3^{-\alpha} + c_1}{\alpha} \tag{1A}$$

Taking derivative of the solution gives

$$y' = (e^{x} c_3)^{-\alpha}$$

substituting $y' = 0$ and $x = 1$ in the above gives

$$0 = c_3^{-\alpha} e^{-\alpha} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. Solving for the constants gives

$$c_1 = e^{\alpha}\alpha$$
$$c_3 = 0$$

Substituting these values back in above solution results in

$$y = \lim_{c_3 \to 0} \frac{-(e^{x} c_3)^{-\alpha} + e^{\alpha}\alpha}{\alpha}$$

Summary

The solution(s) found are the following

$$y = \lim_{c_3 \to 0} \frac{-(e^{x} c_3)^{-\alpha} + e^{\alpha}\alpha}{\alpha} \tag{1}$$

Verification of solutions

$$y = \lim_{c_3 \to 0} \frac{-(e^{x} c_3)^{-\alpha} + e^{\alpha}\alpha}{\alpha}$$

Verified OK.

22.9.7 Maple step by step solution

Let's solve

$$\left[y'' + \alpha y' = 0, y(0) = e^{\alpha}, y'\Big|_{\{x=1\}} = 0\right]$$

- Highest derivative means the order of the ODE is 2

y''

- Characteristic polynomial of ODE

  $\alpha r + r^2 = 0$
- Factor the characteristic polynomial

  $r(\alpha + r) = 0$
- Roots of the characteristic polynomial

  $r = (0, -\alpha)$
- 1st solution of the ODE

  $y_1(x) = 1$
- 2nd solution of the ODE

  $y_2(x) = e^{-x\alpha}$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$
- Substitute in solutions

  $y = c_1 + c_2 e^{-x\alpha}$

□ Check validity of solution $y = c_1 + c_2 e^{-x\alpha}$

  - Use initial condition $y(0) = e^{\alpha}$

    $e^{\alpha} = c_1 + c_2$
  - Compute derivative of the solution

    $y' = -c_2 \alpha e^{-x\alpha}$
  - Use the initial condition $y'\Big|_{\{x=1\}} = 0$

    $0 = -c_2 \alpha e^{-\alpha}$
  - Solve for c_1 and c_2

    $\{c_1 = e^{\alpha}, c_2 = 0\}$
  - Substitute constant values into general solution and simplify

    $y = e^{\alpha}$

- Solution to the IVP

  $y = e^{\alpha}$

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + \alpha^2 y = 1}$$

With initial conditions

$$[y'(0) = \alpha, y'(\pi) = 0]$$

22.10.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = \alpha^2, f(x) = 1$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + \alpha^2 y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = \alpha^2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + \alpha^2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\alpha^2 + \lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = \alpha^2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(\alpha^2)}\\ &= \pm\sqrt{-\alpha^2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{-\alpha^2}\\ \lambda_2 &= -\sqrt{-\alpha^2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{-\alpha^2}\\ \lambda_2 &= -\sqrt{-\alpha^2}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{\left(\sqrt{-\alpha^2}\right)x} + c_2 e^{\left(-\sqrt{-\alpha^2}\right)x}\end{aligned}$$

Or

$$y = c_1 e^{\sqrt{-\alpha^2}\, x} + c_2 e^{-\sqrt{-\alpha^2}\, x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{\sqrt{-\alpha^2}\, x} + c_2 e^{-\sqrt{-\alpha^2}\, x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^{\sqrt{-\alpha^2}\, x}, e^{-\sqrt{-\alpha^2}\, x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\alpha^2 A_1 = 1$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{\alpha^2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{\alpha^2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{\sqrt{-\alpha^2}\, x} + c_2 e^{-\sqrt{-\alpha^2}\, x}\right) + \left(\frac{1}{\alpha^2}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{\sqrt{-\alpha^2}\, x} + c_2 e^{-\sqrt{-\alpha^2}\, x} + \frac{1}{\alpha^2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. Taking derivative of the solution gives

$$y' = c_1 \sqrt{-\alpha^2}\, e^{\sqrt{-\alpha^2}\, x} - c_2 \sqrt{-\alpha^2}\, e^{-\sqrt{-\alpha^2}\, x}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = \left(c_1 e^{\pi\sqrt{-\alpha^2}} - e^{-\pi\sqrt{-\alpha^2}} c_2\right) \sqrt{-\alpha^2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 \sqrt{-\alpha^2}\, e^{\sqrt{-\alpha^2}\, x} - c_2 \sqrt{-\alpha^2}\, e^{-\sqrt{-\alpha^2}\, x}$$

substituting $y' = \alpha$ and $x = 0$ in the above gives

$$\alpha = (c_1 - c_2) \sqrt{-\alpha^2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{\alpha}{\left(-e^{2\pi\sqrt{-\alpha^2}} + 1\right)\sqrt{-\alpha^2}}$$

$$c_2 = \frac{e^{2\pi\sqrt{-\alpha^2}}\alpha}{\left(-e^{2\pi\sqrt{-\alpha^2}} + 1\right)\sqrt{-\alpha^2}}$$

Substituting these values back in above solution results in

$$y = \frac{-\alpha^3 e^{\sqrt{-\alpha^2}\,(x+2\pi)} + \alpha^3 e^{-\sqrt{-\alpha^2}\,(-2\pi+x)} - \alpha^3 e^{-\sqrt{-\alpha^2}\,(x-4\pi)} + e^{\sqrt{-\alpha^2}\,x}\alpha^3 + \sqrt{-\alpha^2}\, e^{4\pi\sqrt{-\alpha^2}} - 2\sqrt{-\alpha^2}\, e^{2\pi\sqrt{-\alpha^2}} \cdots}{\sqrt{-\alpha^2}\,\alpha^2 e^{4\pi\sqrt{-\alpha^2}} - 2\sqrt{-\alpha^2}\,\alpha^2 e^{2\pi\sqrt{-\alpha^2}} + \sqrt{-\alpha^2}\,\alpha^2}$$

Which simplifies to

$$y = \frac{-\alpha^3 e^{\sqrt{-\alpha^2}\,(x+2\pi)} + \alpha^3 e^{-\sqrt{-\alpha^2}\,(-2\pi+x)} - \alpha^3 e^{-\sqrt{-\alpha^2}\,(x-4\pi)} + e^{\sqrt{-\alpha^2}\,x}\alpha^3 + \sqrt{-\alpha^2}\, e^{4\pi\sqrt{-\alpha^2}} - 2\sqrt{-\alpha^2}\, e^{2\pi\sqrt{-\alpha^2}} \cdots}{\sqrt{-\alpha^2}\,\alpha^2 \left(e^{4\pi\sqrt{-\alpha^2}} - 2\, e^{2\pi\sqrt{-\alpha^2}} + 1\right)}$$

Summary

The solution(s) found are the following

$$y = \frac{-\alpha^3 e^{\sqrt{-\alpha^2}\,(x+2\pi)} + \alpha^3 e^{-\sqrt{-\alpha^2}\,(-2\pi+x)} - \alpha^3 e^{-\sqrt{-\alpha^2}\,(x-4\pi)} + e^{\sqrt{-\alpha^2}\,x}\alpha^3 + \sqrt{-\alpha^2}\, e^{4\pi\sqrt{-\alpha^2}} - 2\sqrt{-\alpha^2}\, e^{2\pi\sqrt{-\alpha^2}} \cdots}{\sqrt{-\alpha^2}\,\alpha^2 \left(e^{4\pi\sqrt{-\alpha^2}} - 2\, e^{2\pi\sqrt{-\alpha^2}} + 1\right)} \tag{1}$$

Verification of solutions

$$y = \frac{-\alpha^3 e^{\sqrt{-\alpha^2}\,(x+2\pi)} + \alpha^3 e^{-\sqrt{-\alpha^2}\,(-2\pi+x)} - \alpha^3 e^{-\sqrt{-\alpha^2}\,(x-4\pi)} + e^{\sqrt{-\alpha^2}\,x}\alpha^3 + \sqrt{-\alpha^2}\, e^{4\pi\sqrt{-\alpha^2}} - 2\sqrt{-\alpha^2}\, e^{2\pi\sqrt{-\alpha^2}}}{\sqrt{-\alpha^2}\,\alpha^2 \left(e^{4\pi\sqrt{-\alpha^2}} - 2\, e^{2\pi\sqrt{-\alpha^2}} + 1\right)}$$

Verified OK.

22.10.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + \alpha^2 y'y - y' = 0$$

Integrating the above w.r.t x gives

$$\int \left(y'y'' + \alpha^2 y'y - y'\right) dx = 0$$
$$\frac{y'^2}{2} + \frac{\alpha^2 y^2}{2} - y = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-\alpha^2 y^2 + 2y + 2c_1} \tag{1}$$
$$y' = -\sqrt{-\alpha^2 y^2 + 2y + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-\alpha^2 y^2 + 2c_1 + 2y}} dy = \int dx$$
$$\frac{\arctan\left(\frac{\sqrt{\alpha^2}\left(y - \frac{1}{\alpha^2}\right)}{\sqrt{-\alpha^2 y^2 + 2y + 2c_1}}\right)}{\sqrt{\alpha^2}} = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-\alpha^2 y^2 + 2c_1 + 2y}} dy = \int dx$$

$$-\frac{\arctan\left(\frac{\sqrt{\alpha^2}\left(y-\frac{1}{\alpha^2}\right)}{\sqrt{-\alpha^2 y^2+2y+2c_1}}\right)}{\sqrt{\alpha^2}} = x + c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$\frac{\arctan\left(\frac{\sqrt{\alpha^2}\left(y-\frac{1}{\alpha^2}\right)}{\sqrt{-\alpha^2 y^2+2y+2c_1}}\right)}{\sqrt{\alpha^2}} = x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. Taking derivative of the solution gives

$$y' = \frac{2\tan\left(c_2\sqrt{\alpha^2} + x\sqrt{\alpha^2}\right)\sqrt{\alpha^2}\left(\tan\left(c_2\sqrt{\alpha^2} + x\sqrt{\alpha^2}\right)^2 + 1\right) + \frac{8\tan\left(c_2\sqrt{\alpha^2}+x\sqrt{\alpha^2}\right)^3 c_1\alpha^2\sqrt{\alpha^2}\left(\tan\left(c_2\sqrt{\alpha^2}+x\sqrt{\alpha\right.\right.}}{}}{}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = \frac{\left(2\cos\left(\alpha(\pi + c_2)\right)^2 - \cos\left(\operatorname{csgn}\left(\alpha\right)\alpha(\pi + c_2)\right)^2\right)\sqrt{\sec\left(\operatorname{csgn}\left(\alpha\right)\alpha\left(\pi + c_2\right)\right)^4\sin\left(\alpha\left(\pi + c_2\right)\right)^2\left(2\alpha^2 c_1 + \right.}}{\alpha} \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{2\tan\left(c_2\sqrt{\alpha^2} + x\sqrt{\alpha^2}\right)\sqrt{\alpha^2}\left(\tan\left(c_2\sqrt{\alpha^2} + x\sqrt{\alpha^2}\right)^2 + 1\right) + \frac{8\tan\left(c_2\sqrt{\alpha^2}+x\sqrt{\alpha^2}\right)^3 c_1\alpha^2\sqrt{\alpha^2}\left(\tan\left(c_2\sqrt{\alpha^2}+x\sqrt{\alpha\right.\right.}}{}}{}$$

substituting $y' = \alpha$ and $x = 0$ in the above gives

$$\alpha = \frac{\csc\left(\alpha c_2\right)\sqrt{\sec\left(c_2\operatorname{csgn}\left(\alpha\right)\alpha\right)^4\sin\left(\alpha c_2\right)^2\left(2\alpha^2 c_1 + 1\right)}\cos\left(c_2\operatorname{csgn}\left(\alpha\right)\alpha\right)\left(2\cos\left(\alpha c_2\right)^2 - \cos\left(c_2\operatorname{csgn}\left(\alpha\right.\right.\right.}{\alpha} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Looking at the Second solution

$$-\frac{\arctan\left(\frac{\sqrt{\alpha^2}\left(y-\frac{1}{\alpha^2}\right)}{\sqrt{-\alpha^2 y^2+2y+2c_1}}\right)}{\sqrt{\alpha^2}} = x + c_3 \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. Taking derivative of the solution gives

$$y' = \frac{2\tan\left(c_3\sqrt{\alpha^2}+x\sqrt{\alpha^2}\right)\sqrt{\alpha^2}\left(\tan\left(c_3\sqrt{\alpha^2}+x\sqrt{\alpha^2}\right)^2+1\right)+\frac{8\tan\left(c_3\sqrt{\alpha^2}+x\sqrt{\alpha^2}\right)^3 c_1\alpha^2\sqrt{\alpha^2}\left(\tan\left(c_3\sqrt{\alpha^2}+x\sqrt{\alpha\right.\right.}{}}{}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = \frac{\left(2\cos\left(\alpha(\pi+c_3)\right)^2-\cos\left(\operatorname{csgn}\left(\alpha\right)\alpha(\pi+c_3)\right)^2\right)\sqrt{\sec\left(\operatorname{csgn}\left(\alpha\right)\alpha\left(\pi+c_3\right)\right)^4\left(2\alpha^2c_1+1\right)\sin\left(\alpha\left(\pi+c_3\right)\right.}}{\alpha} \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{2\tan\left(c_3\sqrt{\alpha^2}+x\sqrt{\alpha^2}\right)\sqrt{\alpha^2}\left(\tan\left(c_3\sqrt{\alpha^2}+x\sqrt{\alpha^2}\right)^2+1\right)+\frac{8\tan\left(c_3\sqrt{\alpha^2}+x\sqrt{\alpha^2}\right)^3 c_1\alpha^2\sqrt{\alpha^2}\left(\tan\left(c_3\sqrt{\alpha^2}+x\sqrt{\alpha\right.\right.}{}}{}$$

substituting $y' = \alpha$ and $x = 0$ in the above gives

$$\alpha = \frac{\csc\left(\alpha c_3\right)\sqrt{\sec\left(c_3\operatorname{csgn}\left(\alpha\right)\alpha\right)^4\sin\left(\alpha c_3\right)^2\left(2\alpha^2c_1+1\right)}\cos\left(c_3\operatorname{csgn}\left(\alpha\right)\alpha\right)\left(2\cos\left(\alpha c_3\right)^2-\cos\left(c_3\operatorname{csgn}\left(\alpha\right.\right.\right.}{\alpha} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. There is no solution for the constants of integrations. This solution is removed.

<u>Verification of solutions</u> N/A

22.10.3 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{align*}
y'' + \alpha^2 y &= 0 \tag{1} \\
Ay'' + By' + Cy &= 0 \tag{2}
\end{align*}
$$

Comparing (1) and (2) shows that

$$
\begin{align*}
A &= 1 \\
B &= 0 \tag{3} \\
C &= \alpha^2
\end{align*}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \tag{4}
$$

Where r is given by

$$
\begin{align*}
r &= \frac{s}{t} \tag{5} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{align*}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-\alpha^2}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{align*}
s &= -\alpha^2 \\
t &= 1
\end{align*}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(-\alpha^2\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 700: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -\alpha^2$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{\sqrt{-\alpha^2}\, x}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A}\, dx}
$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \mathrm{e}^{\sqrt{-\alpha^2}\, x}
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{\sqrt{-\alpha^2}\, x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \mathrm{e}^{\sqrt{-\alpha^2}\, x} \int \frac{1}{\mathrm{e}^{2\sqrt{-\alpha^2}\, x}}\, dx \\
&= \mathrm{e}^{\sqrt{-\alpha^2}\, x} \left(\frac{\sqrt{-\alpha^2}\, \mathrm{e}^{-2\sqrt{-\alpha^2}\, x}}{2\alpha^2} \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{\sqrt{-\alpha^2}\, x} \right) + c_2 \left(\mathrm{e}^{\sqrt{-\alpha^2}\, x} \left(\frac{\sqrt{-\alpha^2}\, \mathrm{e}^{-2\sqrt{-\alpha^2}\, x}}{2\alpha^2} \right) \right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + \alpha^2 y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{\sqrt{-\alpha^2}\, x} + \frac{c_2 \sqrt{-\alpha^2}\, e^{-\sqrt{-\alpha^2}\, x}}{2\alpha^2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sqrt{-\alpha^2}\, e^{-\sqrt{-\alpha^2}\, x}}{2\alpha^2}, e^{\sqrt{-\alpha^2}\, x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\alpha^2 A_1 = 1$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{\alpha^2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{\alpha^2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{\sqrt{-\alpha^2}\, x} + \frac{c_2 \sqrt{-\alpha^2}\, e^{-\sqrt{-\alpha^2}\, x}}{2\alpha^2}\right) + \left(\frac{1}{\alpha^2}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{\sqrt{-\alpha^2}\, x} + \frac{c_2 \sqrt{-\alpha^2}\, e^{-\sqrt{-\alpha^2}\, x}}{2\alpha^2} + \frac{1}{\alpha^2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. Taking derivative of the solution gives

$$y' = c_1 \sqrt{-\alpha^2}\, e^{\sqrt{-\alpha^2}\, x} + \frac{c_2 e^{-\sqrt{-\alpha^2}\, x}}{2}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = e^{\pi\sqrt{-\alpha^2}} \sqrt{-\alpha^2}\, c_1 + \frac{e^{-\pi\sqrt{-\alpha^2}} c_2}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 \sqrt{-\alpha^2}\, e^{\sqrt{-\alpha^2}\, x} + \frac{c_2 e^{-\sqrt{-\alpha^2}\, x}}{2}$$

substituting $y' = \alpha$ and $x = 0$ in the above gives

$$\alpha = c_1 \sqrt{-\alpha^2} + \frac{c_2}{2} \tag{2A}$$

Equations $\{1A, 2A\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{\alpha}{\left(-e^{2\pi\sqrt{-\alpha^2}} + 1\right)\sqrt{-\alpha^2}}$$

$$c_2 = \frac{2\alpha\, e^{2\pi\sqrt{-\alpha^2}}}{e^{2\pi\sqrt{-\alpha^2}} - 1}$$

Substituting these values back in above solution results in

$$y = \frac{-\alpha^3 e^{\sqrt{-\alpha^2}\,(x+2\pi)} + \alpha^3 e^{-\sqrt{-\alpha^2}\,(-2\pi+x)} - \alpha^3 e^{-\sqrt{-\alpha^2}\,(x-4\pi)} + e^{\sqrt{-\alpha^2}\, x}\alpha^3 + \sqrt{-\alpha^2}\, e^{4\pi\sqrt{-\alpha^2}} - 2\sqrt{-\alpha^2}\, e^{2\pi\sqrt{-\alpha^2}}}{\sqrt{-\alpha^2}\,\alpha^2 e^{4\pi\sqrt{-\alpha^2}} - 2\sqrt{-\alpha^2}\,\alpha^2 e^{2\pi\sqrt{-\alpha^2}} + \sqrt{-\alpha^2}\,\alpha^2}$$

Which simplifies to

$$y = \frac{-\alpha^3 e^{\sqrt{-\alpha^2}\,(x+2\pi)} + \alpha^3 e^{-\sqrt{-\alpha^2}\,(-2\pi+x)} - \alpha^3 e^{-\sqrt{-\alpha^2}\,(x-4\pi)} + e^{\sqrt{-\alpha^2}\, x}\alpha^3 + \sqrt{-\alpha^2}\, e^{4\pi\sqrt{-\alpha^2}} - 2\sqrt{-\alpha^2}\, e^{2\pi\sqrt{-\alpha^2}}}{\sqrt{-\alpha^2}\,\alpha^2\left(e^{4\pi\sqrt{-\alpha^2}} - 2\, e^{2\pi\sqrt{-\alpha^2}} + 1\right)}$$

Summary

The solution(s) found are the following

$$y = \frac{-\alpha^3 e^{\sqrt{-\alpha^2}\,(x+2\pi)} + \alpha^3 e^{-\sqrt{-\alpha^2}\,(-2\pi+x)} - \alpha^3 e^{-\sqrt{-\alpha^2}\,(x-4\pi)} + e^{\sqrt{-\alpha^2}\,x}\alpha^3 + \sqrt{-\alpha^2}\, e^{4\pi\sqrt{-\alpha^2}} - 2\sqrt{-\alpha^2}\, e^{2\pi\sqrt{-\alpha^2}}}{\sqrt{-\alpha^2}\,\alpha^2 \left(e^{4\pi\sqrt{-\alpha^2}} - 2\, e^{2\pi\sqrt{-\alpha^2}} + 1\right)} \tag{1}$$

Verification of solutions

$$y = \frac{-\alpha^3 e^{\sqrt{-\alpha^2}\,(x+2\pi)} + \alpha^3 e^{-\sqrt{-\alpha^2}\,(-2\pi+x)} - \alpha^3 e^{-\sqrt{-\alpha^2}\,(x-4\pi)} + e^{\sqrt{-\alpha^2}\,x}\alpha^3 + \sqrt{-\alpha^2}\, e^{4\pi\sqrt{-\alpha^2}} - 2\sqrt{-\alpha^2}\, e^{2\pi\sqrt{-\alpha^2}}}{\sqrt{-\alpha^2}\,\alpha^2 \left(e^{4\pi\sqrt{-\alpha^2}} - 2\, e^{2\pi\sqrt{-\alpha^2}} + 1\right)}$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + y = 1}$$

With initial conditions

$$[y(0) = 0, y'(\pi) = 0]$$

22.11.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = 1$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)}\\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i\\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i\\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 = 1$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + (1) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(x) + c_2 \sin(x) + 1 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + 1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 \sin(x) + c_2 \cos(x)$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = -c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -1$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = -\cos(x) + 1$$

Summary

The solution(s) found are the following

$$y = -\cos(x) + 1 \tag{1}$$

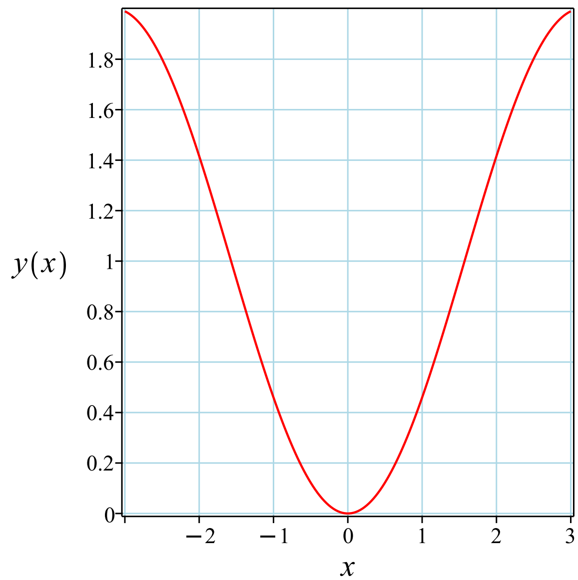

Figure 821: Solution plot

Verification of solutions

$$y = -\cos(x) + 1$$

Verified OK.

22.11.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + yy' - y' = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' + yy' - y')\, dx = 0$$
$$\frac{y'^2}{2} + \frac{y^2}{2} - y = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-y^2 + 2y + 2c_1} \tag{1}$$
$$y' = -\sqrt{-y^2 + 2y + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-y^2+2c_1+2y}}dy = \int dx$$
$$\arctan\left(\frac{y-1}{\sqrt{-y^2+2y+2c_1}}\right) = x+c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-y^2+2c_1+2y}}dy = \int dx$$
$$-\arctan\left(\frac{y-1}{\sqrt{-y^2+2y+2c_1}}\right) = x+c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$\arctan\left(\frac{y-1}{\sqrt{-y^2+2y+2c_1}}\right) = x+c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y=0$ and $x=0$ in the above gives

$$-\arctan\left(\frac{\sqrt{2}}{2\sqrt{c_1}}\right) = c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \left(\tan(x+c_2)^2+1\right)\sqrt{\frac{1+2c_1}{\tan(x+c_2)^2+1}} - \frac{\tan(x+c_2)^2(1+2c_1)}{\sqrt{\frac{1+2c_1}{\tan(x+c_2)^2+1}}\left(\tan(x+c_2)^2+1\right)}$$

substituting $y'=0$ and $x=\pi$ in the above gives

$$0 = \sqrt{\cos(c_2)^2(1+2c_1)} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$

Substituting these values back in above solution results in

$$\arctan\left(\frac{y-1}{\sqrt{-y^2+2y}}\right) = x + c_2$$

Which can be written as

$$\arctan\left(\frac{y-1}{\sqrt{-y(y-2)}}\right) = x + c_2$$

Looking at the Second solution

$$-\arctan\left(\frac{y-1}{\sqrt{-y^2+2y+2c_1}}\right) = x + c_3 \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$\arctan\left(\frac{\sqrt{2}}{2\sqrt{c_1}}\right) = c_3 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\left(\tan(x+c_3)^2 + 1\right)\sqrt{\frac{1+2c_1}{\tan(x+c_3)^2+1}} + \frac{\tan(x+c_3)^2(1+2c_1)}{\sqrt{\frac{1+2c_1}{\tan(x+c_3)^2+1}}\left(\tan(x+c_3)^2+1\right)}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = \frac{\cos(c_3)^2(-2c_1-1)}{\sqrt{\cos(c_3)^2(1+2c_1)}} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. There is no solution for the constants of integrations. This solution is removed.

Summary

The solution(s) found are the following

$$\arctan\left(\frac{y-1}{\sqrt{-y(y-2)}}\right) = x + c_2 \tag{1}$$

Verification of solutions

$$\arctan\left(\frac{y-1}{\sqrt{-y\,(y-2)}}\right) = x + c_2$$

Verified OK.

22.11.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 701: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\,dx \\ &= \cos(x)\,(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 = 1$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + (1) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(x) + c_2 \sin(x) + 1 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + 1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 \sin(x) + c_2 \cos(x)$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = -c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -1$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = -\cos(x) + 1$$

Summary

The solution(s) found are the following

$$y = -\cos(x) + 1 \tag{1}$$

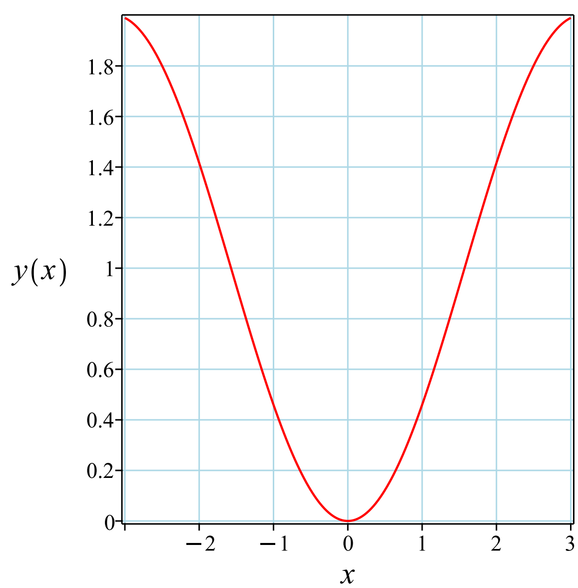

Figure 822: Solution plot

Verification of solutions

$$y = -\cos(x) + 1$$

Verified OK.

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + \lambda^2 y = 0}$$

With initial conditions

$$[y'(0) = 0, y'(\pi) = 0]$$

22.12.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = \lambda^2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + \lambda^2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + \lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = \lambda^2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(\lambda^2)} \\ &= \pm\sqrt{-\lambda^2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{-\lambda^2} \\ \lambda_2 &= -\sqrt{-\lambda^2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{-\lambda^2} \\ \lambda_2 &= -\sqrt{-\lambda^2}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{\left(\sqrt{-\lambda^2}\right)x} + c_2 e^{\left(-\sqrt{-\lambda^2}\right)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{\sqrt{-\lambda^2}\, x} + c_2 \mathrm{e}^{-\sqrt{-\lambda^2}\, x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{\sqrt{-\lambda^2}\, x} + c_2 \mathrm{e}^{-\sqrt{-\lambda^2}\, x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. Taking derivative of the solution gives

$$y' = c_1\sqrt{-\lambda^2}\, \mathrm{e}^{\sqrt{-\lambda^2}\, x} - c_2\sqrt{-\lambda^2}\, \mathrm{e}^{-\sqrt{-\lambda^2}\, x}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = \left(c_1 e^{\pi\sqrt{-\lambda^2}} - c_2 e^{-\pi\sqrt{-\lambda^2}}\right)\sqrt{-\lambda^2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1\sqrt{-\lambda^2}\, e^{\sqrt{-\lambda^2}\, x} - c_2\sqrt{-\lambda^2}\, e^{-\sqrt{-\lambda^2}\, x}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = (c_1 - c_2)\sqrt{-\lambda^2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = 0$$

Summary

The solution(s) found are the following

$$y = 0 \tag{1}$$

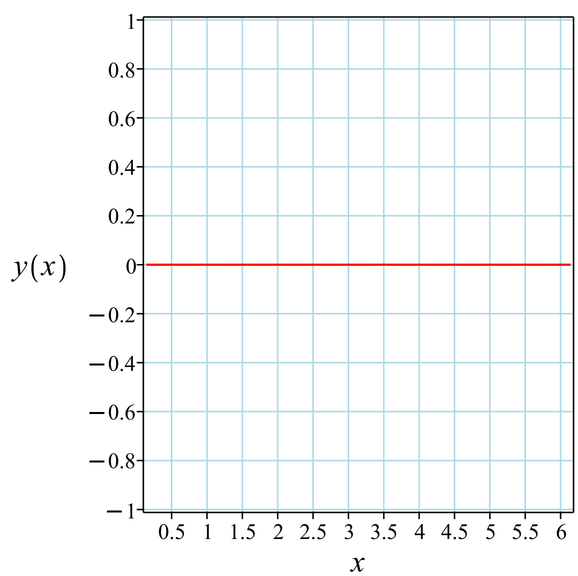

Figure 823: Solution plot

Verification of solutions

$$y = 0$$

Verified OK.

22.12.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + \lambda^2 y' y = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' + \lambda^2 y' y)\, dx = 0$$
$$\frac{y'^2}{2} + \frac{\lambda^2 y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-\lambda^2 y^2 + 2c_1} \tag{1}$$
$$y' = -\sqrt{-\lambda^2 y^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-\lambda^2 y^2 + 2c_1}} dy = \int dx$$
$$\frac{\arctan\left(\frac{\sqrt{\lambda^2}\, y}{\sqrt{-\lambda^2 y^2 + 2c_1}}\right)}{\sqrt{\lambda^2}} = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-\lambda^2 y^2 + 2c_1}} dy = \int dx$$
$$-\frac{\arctan\left(\frac{\sqrt{\lambda^2}\, y}{\sqrt{-\lambda^2 y^2 + 2c_1}}\right)}{\sqrt{\lambda^2}} = x + c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$\frac{\arctan\left(\frac{\sqrt{\lambda^2}\, y}{\sqrt{-\lambda^2 y^2+2c_1}}\right)}{\sqrt{\lambda^2}} = x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. Taking derivative of the solution gives

$$y' = -\frac{2\sqrt{2}\sqrt{\left(\tan\left(c_2\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2+1\right)c_1}\,\tan\left(c_2\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2\sqrt{\lambda^2}}{\left(\tan\left(c_2\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2+1\right)\lambda} + \frac{\sqrt{2}\tan\left(c_2\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2}{\sqrt{\left(\tan\left(c_2\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2 \right.}}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = -\left(\cos\left(\lambda(\pi+c_2)\right)^2 - 2\cos\left(\operatorname{csgn}(\lambda)\,\lambda(\pi+c_2)\right)^2\right)\sqrt{\sec\left(\operatorname{csgn}(\lambda)\,\lambda\,(\pi+c_2)\right)^2 c_1}\,\sqrt{2}\,\operatorname{csgn}(\lambda) \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{2\sqrt{2}\sqrt{\left(\tan\left(c_2\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2+1\right)c_1}\,\tan\left(c_2\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2\sqrt{\lambda^2}}{\left(\tan\left(c_2\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2+1\right)\lambda} + \frac{\sqrt{2}\tan\left(c_2\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2}{\sqrt{\left(\tan\left(c_2\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2 \right.}}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = \left(-\cos\left(\lambda c_2\right)^2 + 2\cos\left(c_2\operatorname{csgn}(\lambda)\,\lambda\right)^2\right)\sqrt{\sec\left(c_2\operatorname{csgn}(\lambda)\,\lambda\right)^2 c_1}\,\sqrt{2}\,\operatorname{csgn}(\lambda) \tag{2A}$$

Equations $\{1\text{A},2\text{A}\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$

Substituting these values back in above solution results in

$$\operatorname{signum}\left(\frac{y}{\sqrt{-\lambda^2 y^2}}\right)\infty = x + c_2$$

Looking at the Second solution

$$-\frac{\arctan\left(\frac{\sqrt{\lambda^2}\, y}{\sqrt{-\lambda^2 y^2+2c_1}}\right)}{\sqrt{\lambda^2}} = x + c_3 \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. Taking derivative of the solution gives

$$y' = \frac{2\sqrt{2}\,\sqrt{\left(\tan\left(c_3\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2+1\right)c_1}\,\tan\left(c_3\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2\sqrt{\lambda^2}}{\left(\tan\left(c_3\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2+1\right)\lambda} - \frac{\sqrt{2}\,\tan\left(c_3\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2 \cdots}{\sqrt{\left(\tan\left(c_3\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2+\cdots}}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = \left(\cos\left(\lambda(\pi+c_3)\right)^2 - 2\cos\left(\operatorname{csgn}\left(\lambda\right)\lambda(\pi+c_3)\right)^2\right)\sqrt{\sec\left(\operatorname{csgn}\left(\lambda\right)\lambda\left(\pi+c_3\right)\right)^2 c_1}\,\sqrt{2}\operatorname{csgn}\left(\lambda\right) \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{2\sqrt{2}\,\sqrt{\left(\tan\left(c_3\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2+1\right)c_1}\,\tan\left(c_3\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2\sqrt{\lambda^2}}{\left(\tan\left(c_3\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2+1\right)\lambda} - \frac{\sqrt{2}\,\tan\left(c_3\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2 \cdots}{\sqrt{\left(\tan\left(c_3\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2+\cdots}}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = \left(\cos\left(\lambda c_3\right)^2 - 2\cos\left(c_3\operatorname{csgn}\left(\lambda\right)\lambda\right)^2\right)\sqrt{\sec\left(c_3\operatorname{csgn}\left(\lambda\right)\lambda\right)^2 c_1}\,\sqrt{2}\operatorname{csgn}\left(\lambda\right) \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. Solving for the constants gives

$$c_1 = 0$$

Substituting these values back in above solution results in

$$-\operatorname{signum}\left(\frac{y}{\sqrt{-\lambda^2 y^2}}\right)\infty = x + c_3$$

Summary

The solution(s) found are the following

$$\operatorname{signum}\left(\frac{y}{\sqrt{-\lambda^2 y^2}}\right)\infty = x + c_2 \tag{1}$$

$$-\operatorname{signum}\left(\frac{y}{\sqrt{-\lambda^2 y^2}}\right)\infty = x + c_3 \tag{2}$$

Verification of solutions

$$\operatorname{signum}\left(\frac{y}{\sqrt{-\lambda^2 y^2}}\right)\infty = x + c_2$$

Warning, solution could not be verified

$$-\operatorname{signum}\left(\frac{y}{\sqrt{-\lambda^2 y^2}}\right)\infty = x + c_3$$

Warning, solution could not be verified

22.12.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + \lambda^2 y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= \lambda^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-\lambda^2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -\lambda^2 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(-\lambda^2\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 702: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -\lambda^2$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{\sqrt{-\lambda^2}\, x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \mathrm{e}^{\sqrt{-\lambda^2}\, x} \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\sqrt{-\lambda^2}\, x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \mathrm{e}^{\sqrt{-\lambda^2}\, x} \int \frac{1}{\mathrm{e}^{2\sqrt{-\lambda^2}\, x}}\, dx \\ &= \mathrm{e}^{\sqrt{-\lambda^2}\, x} \left(\frac{\sqrt{-\lambda^2}\, \mathrm{e}^{-2\sqrt{-\lambda^2}\, x}}{2\lambda^2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{\sqrt{-\lambda^2}\, x}\right) + c_2 \left(\mathrm{e}^{\sqrt{-\lambda^2}\, x} \left(\frac{\sqrt{-\lambda^2}\, \mathrm{e}^{-2\sqrt{-\lambda^2}\, x}}{2\lambda^2}\right)\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{\sqrt{-\lambda^2}\, x} + \frac{c_2 \sqrt{-\lambda^2}\, e^{-\sqrt{-\lambda^2}\, x}}{2 \lambda^2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. Taking derivative of the solution gives

$$y' = c_1 \sqrt{-\lambda^2}\, e^{\sqrt{-\lambda^2}\, x} + \frac{c_2 e^{-\sqrt{-\lambda^2}\, x}}{2}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = \sqrt{-\lambda^2}\, e^{\pi \sqrt{-\lambda^2}} c_1 + \frac{c_2 e^{-\pi \sqrt{-\lambda^2}}}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 \sqrt{-\lambda^2}\, e^{\sqrt{-\lambda^2}\, x} + \frac{c_2 e^{-\sqrt{-\lambda^2}\, x}}{2}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = c_1 \sqrt{-\lambda^2} + \frac{c_2}{2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = 0$$

Summary

The solution(s) found are the following

$$y = 0 \tag{1}$$

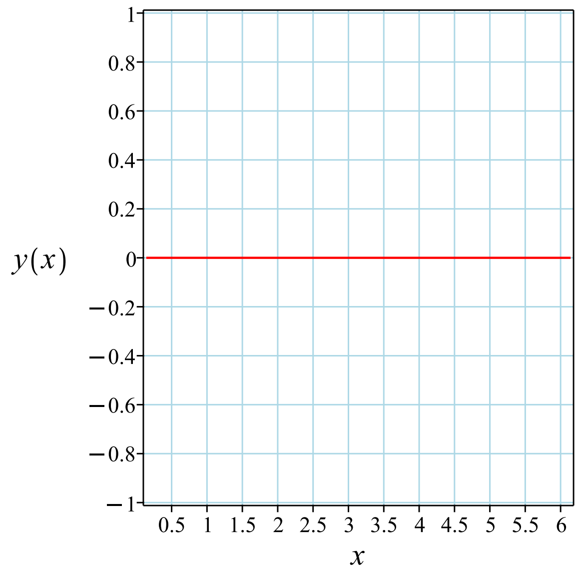

Figure 824: Solution plot

Verification of solutions

$$y = 0$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + \lambda^2 y = 0}$$

With initial conditions

$$[y(0) = 0, y'(\pi) = 0]$$

22.13.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = \lambda^2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + \lambda^2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + \lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = \lambda^2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(\lambda^2)} \\ &= \pm\sqrt{-\lambda^2}\end{aligned}$$

Hence

$$\lambda_1 = +\sqrt{-\lambda^2}$$
$$\lambda_2 = -\sqrt{-\lambda^2}$$

Which simplifies to

$$\lambda_1 = \sqrt{-\lambda^2}$$
$$\lambda_2 = -\sqrt{-\lambda^2}$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{\left(\sqrt{-\lambda^2}\right)x} + c_2 e^{\left(-\sqrt{-\lambda^2}\right)x}$$

Or

$$y = c_1 \mathrm{e}^{\sqrt{-\lambda^2}\, x} + c_2 \mathrm{e}^{-\sqrt{-\lambda^2}\, x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{\sqrt{-\lambda^2}\, x} + c_2 \mathrm{e}^{-\sqrt{-\lambda^2}\, x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1\sqrt{-\lambda^2}\,\mathrm{e}^{\sqrt{-\lambda^2}\,x} - c_2\sqrt{-\lambda^2}\,\mathrm{e}^{-\sqrt{-\lambda^2}\,x}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = \left(c_1\mathrm{e}^{\pi\sqrt{-\lambda^2}} - c_2\mathrm{e}^{-\pi\sqrt{-\lambda^2}}\right)\sqrt{-\lambda^2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = 0$$

Summary
The solution(s) found are the following

$$y = 0 \tag{1}$$

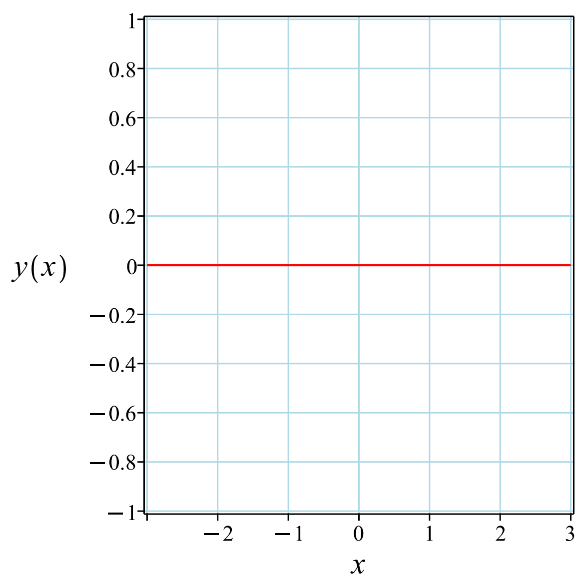

Figure 825: Solution plot

Verification of solutions

$$y = 0$$

Verified OK.

22.13.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + \lambda^2 y' y = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' + \lambda^2 y' y)\, dx = 0$$

$$\frac{y'^2}{2} + \frac{\lambda^2 y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-\lambda^2 y^2 + 2c_1} \tag{1}$$

$$y' = -\sqrt{-\lambda^2 y^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-\lambda^2 y^2 + 2c_1}} dy = \int dx$$

$$\frac{\arctan\left(\frac{\sqrt{\lambda^2}\, y}{\sqrt{-\lambda^2 y^2 + 2c_1}}\right)}{\sqrt{\lambda^2}} = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-\lambda^2 y^2 + 2c_1}} dy = \int dx$$

$$-\frac{\arctan\left(\frac{\sqrt{\lambda^2}\, y}{\sqrt{-\lambda^2 y^2 + 2c_1}}\right)}{\sqrt{\lambda^2}} = x + c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$\frac{\arctan\left(\frac{\sqrt{\lambda^2}\, y}{\sqrt{-\lambda^2 y^2+2c_1}}\right)}{\sqrt{\lambda^2}} = x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{2\sqrt{2}\,\sqrt{\left(\tan\left(c_2\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2+1\right)c_1}\,\tan\left(c_2\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2\sqrt{\lambda^2}}{\left(\tan\left(c_2\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2+1\right)\lambda} + \frac{\sqrt{2}\,\tan\left(c_2\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2}{\sqrt{\left(\tan\left(c_2\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2 +}}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = -\left(\cos\left(\lambda(\pi+c_2)\right)^2 - 2\cos\left(\operatorname{csgn}(\lambda)\,\lambda(\pi+c_2)\right)^2\right)\sqrt{\sec\left(\operatorname{csgn}(\lambda)\,\lambda\,(\pi+c_2)\right)^2 c_1}\,\sqrt{2}\,\operatorname{csgn}(\lambda) \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$\operatorname{signum}\left(\frac{y}{\sqrt{-\lambda^2 y^2}}\right)\infty = x$$

Looking at the Second solution

$$-\frac{\arctan\left(\frac{\sqrt{\lambda^2}\, y}{\sqrt{-\lambda^2 y^2+2c_1}}\right)}{\sqrt{\lambda^2}} = x + c_3 \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_3 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{2\sqrt{2}\,\sqrt{\left(\tan\left(c_3\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2+1\right)c_1}\,\tan\left(c_3\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2\sqrt{\lambda^2}}{\left(\tan\left(c_3\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2+1\right)\lambda} - \frac{\sqrt{2}\,\tan\left(c_3\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2 \sqrt{}}{\sqrt{\left(\tan\left(c_3\sqrt{\lambda^2}+x\sqrt{\lambda^2}\right)^2+\right.}}$$

substituting $y'=0$ and $x=\pi$ in the above gives

$$0 = \left(\cos\left(\lambda(\pi+c_3)\right)^2 - 2\cos\left(\operatorname{csgn}(\lambda)\,\lambda(\pi+c_3)\right)^2\right)\sqrt{\sec\left(\operatorname{csgn}(\lambda)\,\lambda\,(\pi+c_3)\right)^2 c_1}\,\sqrt{2}\,\operatorname{csgn}(\lambda) \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_3 = 0$$

Substituting these values back in above solution results in

$$-\operatorname{signum}\left(\frac{y}{\sqrt{-\lambda^2 y^2}}\right)\infty = x$$

Summary

The solution(s) found are the following

$$\operatorname{signum}\left(\frac{y}{\sqrt{-\lambda^2 y^2}}\right)\infty = x \tag{1}$$

$$-\operatorname{signum}\left(\frac{y}{\sqrt{-\lambda^2 y^2}}\right)\infty = x \tag{2}$$

Verification of solutions

$$\operatorname{signum}\left(\frac{y}{\sqrt{-\lambda^2 y^2}}\right)\infty = x$$

Warning, solution could not be verified

$$-\operatorname{signum}\left(\frac{y}{\sqrt{-\lambda^2 y^2}}\right)\infty = x$$

Warning, solution could not be verified

22.13.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + \lambda^2 y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= \lambda^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-\lambda^2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -\lambda^2 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\lambda^2\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 703: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -\lambda^2$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{\sqrt{-\lambda^2}\, x}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}
$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \mathrm{e}^{\sqrt{-\lambda^2}\, x} \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\sqrt{-\lambda^2}\, x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \mathrm{e}^{\sqrt{-\lambda^2}\, x} \int \frac{1}{\mathrm{e}^{2\sqrt{-\lambda^2}\, x}}\, dx \\ &= \mathrm{e}^{\sqrt{-\lambda^2}\, x} \left(\frac{\sqrt{-\lambda^2}\, \mathrm{e}^{-2\sqrt{-\lambda^2}\, x}}{2\lambda^2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{\sqrt{-\lambda^2}\, x}\right) + c_2 \left(\mathrm{e}^{\sqrt{-\lambda^2}\, x} \left(\frac{\sqrt{-\lambda^2}\, \mathrm{e}^{-2\sqrt{-\lambda^2}\, x}}{2\lambda^2}\right)\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{\sqrt{-\lambda^2}\, x} + \frac{c_2 \sqrt{-\lambda^2}\, \mathrm{e}^{-\sqrt{-\lambda^2}\, x}}{2\lambda^2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = \frac{2c_1\lambda^2 + c_2\sqrt{-\lambda^2}}{2\lambda^2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1\sqrt{-\lambda^2}\,\mathrm{e}^{\sqrt{-\lambda^2}\,x} + \frac{c_2\mathrm{e}^{-\sqrt{-\lambda^2}\,x}}{2}$$

substituting $y' = 0$ and $x = \pi$ in the above gives

$$0 = \sqrt{-\lambda^2}\,\mathrm{e}^{\pi\sqrt{-\lambda^2}}c_1 + \frac{c_2\mathrm{e}^{-\pi\sqrt{-\lambda^2}}}{2} \tag{2A}$$

Equations $\{1\text{A},2\text{A}\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = 0$$

Summary
The solution(s) found are the following

$$y = 0 \tag{1}$$

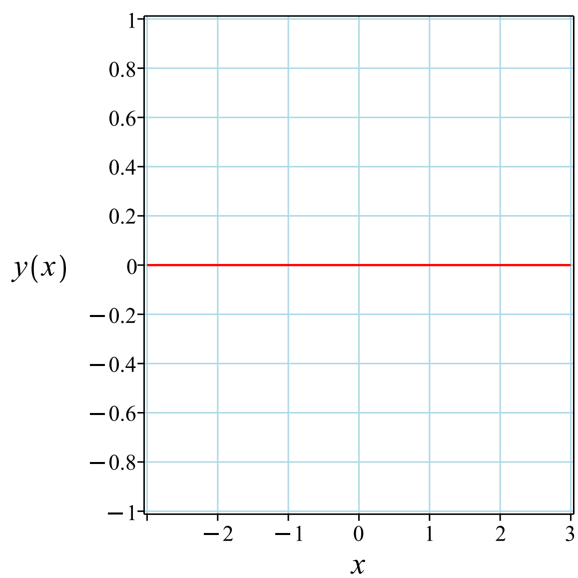

Figure 826: Solution plot

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{xy'' + y' = 0}$$

22.16.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (xy'' + y')\, dx = 0$$
$$xy' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\begin{aligned} y &= \int \frac{c_1}{x}\, \mathrm{d}x \\ &= c_1 \ln(x) + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \ln(x) + c_2 \tag{1}$$

Verification of solutions

$$y = c_1 \ln(x) + c_2$$

Verified OK.

22.16.2 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$xp'(x) + p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned} p' &= F(x,p) \\ &= f(x)g(p) \\ &= -\frac{p}{x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(p) = p$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{p}\,dp &= -\frac{1}{x}\,dx \\
\int \frac{1}{p}\,dp &= \int -\frac{1}{x}\,dx \\
\ln(p) &= -\ln(x) + c_1 \\
p &= \mathrm{e}^{-\ln(x)+c_1} \\
&= \frac{c_1}{x}
\end{aligned}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{c_1}{x}$$

Integrating both sides gives

$$\begin{aligned}
y &= \int \frac{c_1}{x}\,\mathrm{d}x \\
&= c_1 \ln(x) + c_2
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \ln(x) + c_2 \tag{1}$$

Verification of solutions

$$y = c_1 \ln(x) + c_2$$

Verified OK.

22.16.3 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + \left(2AB' + B^2\right) v' + \left(AB'' + BB' + CB\right) v &= 0 \qquad (1)
\end{aligned}
$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$
ABv'' + \left(2AB' + B^2\right) v' = 0
$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$
ABu' + \left(2AB' + B^2\right) u = 0
$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= x \\
B &= 1 \\
C &= 0 \\
F &= 0
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= (x)(0) + (1)(0) + (0)(1) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
xv'' + (1) v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
xu'(x) + u(x) = 0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x, u) \\
&= f(x)g(u) \\
&= -\frac{u}{x}
\end{aligned}
$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\, du &= -\frac{1}{x}\, dx \\
\int \frac{1}{u}\, du &= \int -\frac{1}{x}\, dx \\
\ln(u) &= -\ln(x) + c_1 \\
u &= \mathrm{e}^{-\ln(x)+c_1} \\
&= \frac{c_1}{x}
\end{aligned}
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= \frac{c_1}{x}
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int \frac{c_1}{x}\, \mathrm{d}x \\
&= c_1 \ln(x) + c_2
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y(x) &= Bv \\
&= (1)\,(c_1 \ln(x) + c_2) \\
&= c_1 \ln(x) + c_2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \ln(x) + c_2 \tag{1}
$$

Verification of solutions

$$
y = c_1 \ln(x) + c_2
$$

Verified OK.

22.16.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$xy'' + y' = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int (xy'' + y')\, dx = 0$$
$$xy' = c_1$$

Which is now solved for y. Integrating both sides gives

$$y = \int \frac{c_1}{x}\, \mathrm{d}x$$
$$= c_1 \ln(x) + c_2$$

Summary

The solution(s) found are the following

$$y = c_1 \ln(x) + c_2 \tag{1}$$

Verification of solutions

$$y = c_1 \ln(x) + c_2$$

Verified OK.

22.16.5 Solving using Kovacic algorithm

Writing the ode as

$$xy'' + y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= 1 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 704: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{1}{4x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = -\frac{1}{4x^2}
$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) &= 0 \\ 0 &= 0\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{1}{2x} dx} \\ &= \sqrt{x}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{1}{x} \, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1}{x}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\, dx \\
&= y_1(\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2(1(\ln(x)))
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 + c_2 \ln(x) \tag{1}
$$

Verification of solutions

$$
y = c_1 + c_2 \ln(x)
$$

Verified OK.

22.16.6 Solving as exact linear second order ode ode

An ode of the form

$$
p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)
$$

is exact if

$$
p''(x) - q'(x) + r(x) = 0 \tag{1}
$$

For the given ode we have

$$
\begin{aligned}
p(x) &= x \\
q(x) &= 1 \\
r(x) &= 0 \\
s(x) &= 0
\end{aligned}
$$

Hence

$$p''(x) = 0$$
$$q'(x) = 0$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$xy' = c_1$$

We now have a first order ode to solve which is

$$xy' = c_1$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{c_1}{x}\, \mathrm{d}x \\ &= c_1 \ln(x) + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \ln(x) + c_2 \tag{1}$$

Verification of solutions

$$y = c_1 \ln(x) + c_2$$

Verified OK.

22.16.7 Maple step by step solution

Let's solve

$xy'' + y' = 0$

- Highest derivative means the order of the ODE is 2

y''

- Isolate 2nd derivative

$y'' = -\frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' + \frac{y'}{x} = 0$

- Multiply by denominators of the ODE

$xy'' + y' = 0$

- Make a change of variables

$t = \ln(x)$

□ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

  $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

  ◦ Compute derivative

  $y' = \frac{\frac{d}{dt}y(t)}{x}$

  ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

  $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$

  ◦ Compute derivative

  $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $x\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) + \frac{\frac{d}{dt}y(t)}{x} = 0$

- Simplify

$\frac{\frac{d^2}{dt^2}y(t)}{x} = 0$

- Isolate 2nd derivative

$\frac{d^2}{dt^2}y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{0})}{2}$

- Roots of the characteristic polynomial

  $r = 0$

- 1st solution of the ODE

  $y_1(t) = 1$

- Repeated root, multiply $y_1(t)$ by t to ensure linear independence

  $y_2(t) = t$

- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$

- Substitute in solutions

  $y(t) = c_2 t + c_1$

- Change variables back using $t = \ln(x)$

  $y = c_1 + c_2 \ln(x)$

22.17 problem 722

Internal problem ID [15466]
Internal file name [`OUTPUT/15466_Wednesday_May_08_2024_04_00_55_PM_99259692/index.tex`]

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 17. Boundary value problems. Exercises page 163
Problem number: 722.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_missing_y"**

Maple gives the following as the ode type

`[[_high_order, _missing_y]]`

$$\boxed{x^2y'''' + 4xy''' + 2y'' = 0}$$

With initial conditions

$$[y(1) = 0, y'(1) = 0]$$

Since y is missing from the ode then we can use the substitution $y' = v(x)$ to reduce the order by one. The ODE becomes

$$x^2v'''(x) + 4xv''(x) + 2v'(x) = 0$$

Since $v(x)$ is missing from the ode then we can use the substitution $v'(x) = w(x)$ to reduce the order by one. The ODE becomes

$$x^2w''(x) + 4xw'(x) + 2w(x) = 0$$

This is Euler second order ODE. Let the solution be $w(x) = x^r$, then $w' = rx^{r-1}$ and $w'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 4xrx^{r-1} + 2x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 4r\,x^r + 2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 4r + 2 = 0$$

Or

$$r^2 + 3r + 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= -2 \\ r_2 &= -1 \end{aligned}$$

Since the roots are real and distinct, then the general solution is

$$w(x) = c_1 w_1 + c_2 w_2$$

Where $w_1 = x^{r_1}$ and $w_2 = x^{r_2}$. Hence

$$w(x) = \frac{c_1}{x^2} + \frac{c_2}{x}$$

But since $v'(x) = w(x)$ then we now need to solve the ode $v'(x) = \frac{c_1}{x^2} + \frac{c_2}{x}$. Integrating both sides gives

$$\begin{aligned} v(x) &= \int \frac{c_2 x + c_1}{x^2}\, dx \\ &= -\frac{c_1}{x} + c_2 \ln(x) + c_3 \end{aligned}$$

But since $y' = v(x)$ then we now need to solve the ode $y' = -\frac{c_1}{x} + c_2 \ln(x) + c_3$. Integrating both sides gives

$$\begin{aligned} y &= \int \frac{c_2 \ln(x)\, x + c_3 x - c_1}{x}\, dx \\ &= c_2(x \ln(x) - x) + c_3 x - c_1 \ln(x) + c_4 \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_2(x \ln(x) - x) + c_3 x - c_1 \ln(x) + c_4 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 1$ in the above gives

$$0 = -c_2 + c_3 + c_4 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{c_1}{x} + c_2 \ln(x) + c_3$$

substituting $y' = 0$ and $x = 1$ in the above gives

$$0 = -c_1 + c_3 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2, c_3, c_4\}$. Solving for the constants gives

$$c_1 = c_3$$
$$c_2 = c_3 + c_4$$

Substituting these values back in above solution results in

$$y = x\ln(x) c_3 + x\ln(x) c_4 - xc_4 - c_3\ln(x) + c_4$$

Which simplifies to

$$y = (xc_4 + c_3(x-1))\ln(x) - c_4(x-1)$$

Summary
The solution(s) found are the following

$$y = (xc_4 + c_3(x-1))\ln(x) - c_4(x-1) \tag{1}$$

Verification of solutions

$$y = (xc_4 + c_3(x-1))\ln(x) - c_4(x-1)$$

Verified OK.

22.17.1 Maple step by step solution

Let's solve

$$\left[x^2y'''' + 4xy''' + 2y'' = 0, y(1) = 0, y'\Big|_{\{x=1\}} = 0\right]$$

- Highest derivative means the order of the ODE is 4

  y''''

- Isolate 4th derivative

  $y'''' = -\frac{2(2xy'''+y'')}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'''' + \frac{4y'''}{x} + \frac{2y''}{x^2} = 0$

- Multiply by denominators of the ODE

  $x^2y'''' + 4xy''' + 2y'' = 0$

- Make a change of variables

  $t = \ln{(x)}$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right)t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  - Calculate the 3rd derivative of y with respect to x , using the chain rule

    $y''' = \left(\frac{d^3}{dt^3}y(t)\right)t'(x)^3 + 3t'(x)\,t''(x)\left(\frac{d^2}{dt^2}y(t)\right) + t'''(x)\left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y''' = \frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}$

  - Calculate the 4th derivative of y with respect to x , using the chain rule

    $y'''' = \left(\frac{d^4}{dt^4}y(t)\right)t'(x)^4 + 3t'(x)^2t''(x)\left(\frac{d^3}{dt^3}y(t)\right) + 3t''(x)^2\left(\frac{d^2}{dt^2}y(t)\right) + 3\left(t'''(x)\left(\frac{d^2}{dt^2}y(t)\right) + \left(\frac{d^3}{dt^3}y(\right.\right.$

  - Compute derivative

    $y'''' = \frac{\frac{d^4}{dt^4}y(t)}{x^4} - \frac{3\left(\frac{d^3}{dt^3}y(t)\right)}{x^4} + \frac{5\left(\frac{d^2}{dt^2}y(t)\right)}{x^4} + \frac{3\left(\frac{2\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} - \frac{\frac{d^3}{dt^3}y(t)}{x^3}\right)}{x} - \frac{6\left(\frac{d}{dt}y(t)\right)}{x^4}$

Substitute the change of variables back into the ODE

$$x^2\left(\frac{\frac{d^4}{dt^4}y(t)}{x^4}-\frac{3\left(\frac{d^3}{dt^3}y(t)\right)}{x^4}+\frac{5\left(\frac{d^2}{dt^2}y(t)\right)}{x^4}+\frac{3\left(\frac{2\left(\frac{d^2}{dt^2}y(t)\right)}{x^3}-\frac{\frac{d^3}{dt^3}y(t)}{x^3}\right)}{x}-\frac{6\left(\frac{d}{dt}y(t)\right)}{x^4}\right)+4x\left(\frac{\frac{d^3}{dt^3}y(t)}{x^3}-\frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3}+\right.$$

- Simplify

$$\frac{\frac{d^4}{dt^4}y(t)-2\frac{d^3}{dt^3}y(t)+\frac{d^2}{dt^2}y(t)}{x^2}=0$$

- Isolate 4th derivative

$$\frac{d^4}{dt^4}y(t)=2\frac{d^3}{dt^3}y(t)-\frac{d^2}{dt^2}y(t)$$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$$\frac{d^4}{dt^4}y(t)-2\frac{d^3}{dt^3}y(t)+\frac{d^2}{dt^2}y(t)=0$$

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(t)$

$$y_1(t)=y(t)$$

  ◦ Define new variable $y_2(t)$

$$y_2(t)=\frac{d}{dt}y(t)$$

  ◦ Define new variable $y_3(t)$

$$y_3(t)=\frac{d^2}{dt^2}y(t)$$

  ◦ Define new variable $y_4(t)$

$$y_4(t)=\frac{d^3}{dt^3}y(t)$$

  ◦ Isolate for $\frac{d}{dt}y_4(t)$ using original ODE

$$\frac{d}{dt}y_4(t)=2y_4(t)-y_3(t)$$

Convert linear ODE into a system of first order ODEs

$$\left[y_2(t)=\frac{d}{dt}y_1(t),y_3(t)=\frac{d}{dt}y_2(t),y_4(t)=\frac{d}{dt}y_3(t),\frac{d}{dt}y_4(t)=2y_4(t)-y_3(t)\right]$$

- Define vector

$$\vec{y}(t)=\begin{bmatrix}y_1(t)\\y_2(t)\\y_3(t)\\y_4(t)\end{bmatrix}$$

- System to solve

$$\frac{d}{dt}\vec{y}(t) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 2 \end{bmatrix} \cdot \vec{y}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 2 \end{bmatrix}$$

- Rewrite the system as

$$\frac{d}{dt}\vec{y}(t) = A \cdot \vec{y}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[0, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 0, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\begin{bmatrix} 1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} \end{bmatrix}$$

- First solution from eigenvalue 1

$$\vec{y}_3(t) = e^t \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\vec{p}$ is to be solved for, $\lambda = 1$ is the eigenvalue, an

$$\vec{y}_4(t) = e^{\lambda t}\left(t\vec{v} + \vec{p}\right)$$

- Note that the t multiplying $\vec{v}$ makes this solution linearly independent to the 1st solution obta
- Substitute $\vec{y}_4(t)$ into the homogeneous system

$$\lambda\, e^{\lambda t}\left(t\vec{v} + \vec{p}\right) + e^{\lambda t}\vec{v} = \left(e^{\lambda t}A\right) \cdot \left(t\vec{v} + \vec{p}\right)$$

- Use the fact that $\vec{v}$ is an eigenvector of A

$$\lambda\, e^{\lambda t}\left(t\vec{v} + \vec{p}\right) + e^{\lambda t}\vec{v} = e^{\lambda t}\left(\lambda t\vec{v} + A \cdot \vec{p}\right)$$

- Simplify equation

$$\lambda\vec{p} + \vec{v} = A \cdot \vec{p}$$

- Make use of the identity matrix I

$(\lambda \cdot I) \cdot \overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$

- Condition $\overrightarrow{p}$ must meet for $\overrightarrow{y}_4(t)$ to be a solution to the homogeneous system

$(A - \lambda \cdot I) \cdot \overrightarrow{p} = \overrightarrow{v}$

- Choose $\overrightarrow{p}$ to use in the second solution to the homogeneous system from eigenvalue 1

$$\left(\left[\begin{array}{cccc} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 2 \end{array}\right] - 1 \cdot \left[\begin{array}{cccc} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{array}\right]\right) \cdot \overrightarrow{p} = \left[\begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array}\right]$$

- Choice of $\overrightarrow{p}$

$$\overrightarrow{p} = \left[\begin{array}{c} -1 \\ 0 \\ 0 \\ 0 \end{array}\right]$$

- Second solution from eigenvalue 1

$$\overrightarrow{y}_4(t) = \mathrm{e}^{t} \cdot \left(t \cdot \left[\begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array}\right] + \left[\begin{array}{c} -1 \\ 0 \\ 0 \\ 0 \end{array}\right]\right)$$

- General solution to the system of ODEs

$\overrightarrow{y} = c_1 \overrightarrow{y}_1 + c_2 \overrightarrow{y}_2 + c_3 \overrightarrow{y}_3(t) + c_4 \overrightarrow{y}_4(t)$

- Substitute solutions into the general solution

$$\overrightarrow{y} = c_3 \mathrm{e}^{t} \cdot \left[\begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array}\right] + c_4 \mathrm{e}^{t} \cdot \left(t \cdot \left[\begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array}\right] + \left[\begin{array}{c} -1 \\ 0 \\ 0 \\ 0 \end{array}\right]\right) + \left[\begin{array}{c} c_1 \\ 0 \\ 0 \\ 0 \end{array}\right]$$

- First component of the vector is the solution to the ODE

$y(t) = ((t-1)\, c_4 + c_3)\, \mathrm{e}^{t} + c_1$

- Change variables back using $t = \ln(x)$

$$y = ((\ln(x) - 1) c_4 + c_3) x + c_1$$

- Simplify

$$y = x \ln(x) c_4 + (c_3 - c_4) x + c_1$$

Problem number: 723.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_missing_y"**

Maple gives the following as the ode type

```
[[_high_order, _missing_y]]
```

$$\boxed{x^3y'''' + 6x^2y''' + 6xy'' = 0}$$

With initial conditions

$$[y(1) = 0, y'(1) = 0]$$

Since y is missing from the ode then we can use the substitution $y' = v(x)$ to reduce the order by one. The ODE becomes

$$x^2v'''(x) + 6xv''(x) + 6v'(x) = 0$$

Since $v(x)$ is missing from the ode then we can use the substitution $v'(x) = w(x)$ to reduce the order by one. The ODE becomes

$$x^2w''(x) + 6xw'(x) + 6w(x) = 0$$

This is Euler second order ODE. Let the solution be $w(x) = x^r$, then $w' = rx^{r-1}$ and $w'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 6xrx^{r-1} + 6x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r+6r\,x^r+6x^r=0$$

Since $x^r\neq 0$ then dividing throughout by x^r gives

$$r(r-1)+6r+6=0$$

Or

$$r^2+5r+6=0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned}r_1&=-3\\ r_2&=-2\end{aligned}$$

Since the roots are real and distinct, then the general solution is

$$w(x)=c_1w_1+c_2w_2$$

Where $w_1=x^{r_1}$ and $w_2=x^{r_2}$. Hence

$$w(x)=\frac{c_1}{x^3}+\frac{c_2}{x^2}$$

But since $v'(x)=w(x)$ then we now need to solve the ode $v'(x)=\frac{c_1}{x^3}+\frac{c_2}{x^2}$. Integrating both sides gives

$$\begin{aligned}v(x)&=\int\frac{c_2x+c_1}{x^3}\,\mathrm{d}x\\ &=-\frac{c_1}{2x^2}-\frac{c_2}{x}+c_3\end{aligned}$$

But since $y'=v(x)$ then we now need to solve the ode $y'=-\frac{c_1}{2x^2}-\frac{c_2}{x}+c_3$. Integrating both sides gives

$$\begin{aligned}y&=\int-\frac{-2c_3x^2+2c_2x+c_1}{2x^2}\,\mathrm{d}x\\ &=c_3x+\frac{c_1}{2x}-c_2\ln(x)+c_4\end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y=c_3x+\frac{c_1}{2x}-c_2\ln(x)+c_4 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 1$ in the above gives

$$0 = \frac{c_1}{2} + c_3 + c_4 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{c_1}{2x^2} - \frac{c_2}{x} + c_3$$

substituting $y' = 0$ and $x = 1$ in the above gives

$$0 = -\frac{c_1}{2} - c_2 + c_3 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2, c_3, c_4\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= -2c_3 - 2c_4 \\ c_2 &= 2c_3 + c_4 \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{-2x \ln(x) c_3 - x \ln(x) c_4 + c_3 x^2 + x c_4 - c_3 - c_4}{x}$$

Which simplifies to

$$y = \frac{-2x\left(c_3 + \frac{c_4}{2}\right) \ln(x) + (x-1)(c_3 x + c_3 + c_4)}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{-2x\left(c_3 + \frac{c_4}{2}\right) \ln(x) + (x-1)(c_3 x + c_3 + c_4)}{x} \tag{1}$$

Verification of solutions

$$y = \frac{-2x\left(c_3 + \frac{c_4}{2}\right) \ln(x) + (x-1)(c_3 x + c_3 + c_4)}{x}$$

Verified OK.

22.18.1 Maple step by step solution

Let's solve

$$\left[x^2y'''' + 6xy''' + 6y'' = 0, y(1) = 0, y'\Big|_{\{x=1\}} = 0\right]$$

- Highest derivative means the order of the ODE is 4

  y''''

- Isolate 4th derivative

  $y'''' = -\frac{6(xy'''+y'')}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'''' + \frac{6y'''}{x} + \frac{6y''}{x^2} = 0$

- Multiply by denominators of the ODE

  $x^2y'''' + 6xy''' + 6y'' = 0$

- Make a change of variables

  $t = \ln(x)$

☐ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

  $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

  ◦ Compute derivative

  $y' = \frac{\frac{d}{dt}y(t)}{x}$

  ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

  $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$

  ◦ Compute derivative

  $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  ◦ Calculate the 3rd derivative of y with respect to x , using the chain rule

  $y''' = \left(\frac{d^3}{dt^3}y(t)\right) t'(x)^3 + 3t'(x)\, t''(x) \left(\frac{d^2}{dt^2}y(t)\right) + t'''(x) \left(\frac{d}{dt}y(t)\right)$

  ◦ Compute derivative

  $y''' = \frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}$

  ◦ Calculate the 4th derivative of y with respect to x , using the chain rule

$$y'''' = \left(\frac{d^4}{dt^4}y(t)\right)t'(x)^4 + 3t'(x)^2 t''(x)\left(\frac{d^3}{dt^3}y(t)\right) + 3t''(x)^2\left(\frac{d^2}{dt^2}y(t)\right) + 3\left(t'''(x)\left(\frac{d^2}{dt^2}y(t)\right) + \left(\frac{d^3}{dt^3}y(\right.\right.$$

- Compute derivative

$$y'''' = \frac{\frac{d^4}{dt^4}y(t)}{x^4} - \frac{3\left(\frac{d^3}{dt^3}y(t)\right)}{x^4} + \frac{5\left(\frac{d^2}{dt^2}y(t)\right)}{x^4} + \frac{3\left(\frac{2\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} - \frac{\frac{d^3}{dt^3}y(t)}{x^3}\right)}{x} - \frac{6\left(\frac{d}{dt}y(t)\right)}{x^4}$$

Substitute the change of variables back into the ODE

$$x^2\left(\frac{\frac{d^4}{dt^4}y(t)}{x^4} - \frac{3\left(\frac{d^3}{dt^3}y(t)\right)}{x^4} + \frac{5\left(\frac{d^2}{dt^2}y(t)\right)}{x^4} + \frac{3\left(\frac{2\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} - \frac{\frac{d^3}{dt^3}y(t)}{x^3}\right)}{x} - \frac{6\left(\frac{d}{dt}y(t)\right)}{x^4}\right) + 6x\left(\frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \right.$$

- Simplify

$$\frac{\frac{d^4}{dt^4}y(t) - \frac{d^2}{dt^2}y(t)}{x^2} = 0$$

- Isolate 4th derivative

$$\frac{d^4}{dt^4}y(t) = \frac{d^2}{dt^2}y(t)$$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$$\frac{d^4}{dt^4}y(t) - \frac{d^2}{dt^2}y(t) = 0$$

- ☐ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(t)$

    $y_1(t) = y(t)$
  - Define new variable $y_2(t)$

    $y_2(t) = \frac{d}{dt}y(t)$
  - Define new variable $y_3(t)$

    $y_3(t) = \frac{d^2}{dt^2}y(t)$
  - Define new variable $y_4(t)$

    $y_4(t) = \frac{d^3}{dt^3}y(t)$
  - Isolate for $\frac{d}{dt}y_4(t)$ using original ODE

    $\frac{d}{dt}y_4(t) = y_3(t)$

    Convert linear ODE into a system of first order ODEs

    $\left[y_2(t) = \frac{d}{dt}y_1(t), y_3(t) = \frac{d}{dt}y_2(t), y_4(t) = \frac{d}{dt}y_3(t), \frac{d}{dt}y_4(t) = y_3(t)\right]$
- Define vector

$$\vec{y}(t) = \begin{bmatrix} y_1(t) \\ y_2(t) \\ y_3(t) \\ y_4(t) \end{bmatrix}$$

- System to solve

$$\frac{d}{dt}\vec{y}(t) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix} \cdot \vec{y}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$$

- Rewrite the system as

$\frac{d}{dt}\vec{y}(t) = A \cdot \vec{y}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[0, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{-t} \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 0, \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 0, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_4 = e^t \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{y} = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3 + c_4 \vec{y}_4$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 e^{-t} \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix} + c_4 e^t \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} c_2 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y(t) = -c_1 e^{-t} + c_4 e^t + c_2$$

- Change variables back using $t = \ln(x)$

$$y = -\frac{c_1}{x} + x c_4 + c_2$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup", "first order ode series method. Ordinary point", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y' + yx = 1}$$

With initial conditions

$$[y(0) = 0]$$

With the expansion point for the power series method at $x = 0$.

23.1.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = x$$
$$q(x) = 1$$

Hence the ode is

$$y' + yx = 1$$

The domain of $p(x) = x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

23.1.2 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor series

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0, y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0, y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f & (1) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f & (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2}\right) f & (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y)$ then the above can be written as

$$F_0 = f(x,y) \tag{4}$$

$$\begin{aligned} F_n &= \frac{d}{dx}(F_{n-1}) \\ &= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \end{aligned} \tag{5}$$

For example, for $n=1$ we see that

$$\begin{aligned} F_1 &= \frac{d}{dx}(F_0) \\ &= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\ &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \end{aligned}$$

Which is (1). And when $n=2$

$$\begin{aligned} F_2 &= \frac{d}{dx}(F_1) \\ &= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) F_0 \\ &= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) f \\ &= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} F_n\big|_{x_0,y_0} \tag{6}$$

Hence

$$
\begin{aligned}
F_0 &= 1 - yx \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} F_0 \\
&= yx^2 - y - x \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} F_1 \\
&= \left(-x^3 + 3x\right) y + x^2 - 2 \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} F_2 \\
&= \left(x^4 - 6x^2 + 3\right) y - x^3 + 5x \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} F_3 \\
&= \left(-x^5 + 10x^3 - 15x\right) y + x^4 - 9x^2 + 8
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = 0$ gives

$$
\begin{aligned}
F_0 &= 1 \\
F_1 &= 0 \\
F_2 &= -2 \\
F_3 &= 0 \\
F_4 &= 8
\end{aligned}
$$

Substituting all the above in (6) and simplifying gives the solution as

$$
y = x - \frac{x^3}{3} + \frac{x^5}{15} + O\left(x^6\right)
$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$
y(0) = y(0)
$$

Therefore the solution becomes

$$y = x - \frac{1}{3}x^3 + \frac{1}{15}x^5$$

Hence the solution can be written as

$$y = x - \frac{x^3}{3} + \frac{x^5}{15} + O(x^6)$$

which simplifies to

$$y = x - \frac{x^3}{3} + \frac{x^5}{15} + O(x^6)$$

Since $x = 0$ is also an ordinary point, then standard power series can also be used. Writing the ODE as

$$\begin{aligned} y' + q(x)y &= p(x) \\ y' + yx &= 1 \end{aligned}$$

Where

$$\begin{aligned} q(x) &= x \\ p(x) &= 1 \end{aligned}$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not. Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) x = 1 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \left(\sum_{n=0}^{\infty} x^{1+n} a_n\right) = 1 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (1+n) a_{1+n} x^n$$

$$\sum_{n=0}^{\infty} x^{1+n} a_n = \sum_{n=1}^{\infty} a_{n-1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (1+n) a_{1+n} x^n\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^n\right) = 1 \tag{3}$$

$n = 0$ gives

$$(a_1) 1 = 1$$
$$a_1 = 1$$

Or

$$a_1 = 1$$

For $1 \leq n$, the recurrence equation is

$$((1+n) a_{1+n} + a_{n-1}) x^n = 1 \tag{4}$$

For $n = 1$ the recurrence equation gives

$$(2a_2 + a_0) x = 0$$
$$2a_2 + a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_2 = -\frac{a_0}{2}$$

For $n = 2$ the recurrence equation gives

$$\begin{aligned}(3a_3 + a_1)\, x^2 &= 0\\ 3a_3 + a_1 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{1}{3}$$

For $n = 3$ the recurrence equation gives

$$\begin{aligned}(4a_4 + a_2)\, x^3 &= 0\\ 4a_4 + a_2 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{8}$$

For $n = 4$ the recurrence equation gives

$$\begin{aligned}(5a_5 + a_3)\, x^4 &= 0\\ 5a_5 + a_3 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{1}{15}$$

For $n = 5$ the recurrence equation gives

$$\begin{aligned}(6a_6 + a_4)\, x^5 &= 0\\ 6a_6 + a_4 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{a_0}{48}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + x - \frac{1}{2} a_0 x^2 - \frac{1}{3} x^3 + \frac{1}{8} a_0 x^4 + \frac{1}{15} x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{1}{2} x^2 + \frac{1}{8} x^4\right) a_0 + x - \frac{x^3}{3} + \frac{x^5}{15} + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y(0) = a_0$$

Therefore the solution in Eq(3) now can be written as

$$y = \left(1 - \frac{1}{2} x^2 + \frac{1}{8} x^4\right) y(0) + x - \frac{x^3}{3} + \frac{x^5}{15} + O(x^6)$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = 0$$

Therefore the solution becomes

$$y = x - \frac{1}{3} x^3 + \frac{1}{15} x^5$$

Hence the solution can be written as

$$y = x - \frac{x^3}{3} + \frac{x^5}{15} + O(x^6)$$

which simplifies to

$$y = x - \frac{x^3}{3} + \frac{x^5}{15} + O(x^6)$$

Summary

The solution(s) found are the following

$$y = x - \frac{x^3}{3} + \frac{x^5}{15} + O(x^6) \tag{1}$$
$$y = x - \frac{x^3}{3} + \frac{x^5}{15} + O(x^6) \tag{2}$$

Verification of solutions

$$y = x - \frac{x^3}{3} + \frac{x^5}{15} + O(x^6)$$

Verified OK.

$$y = x - \frac{x^3}{3} + \frac{x^5}{15} + O(x^6)$$

Verified OK.

Problem number: 725.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{y' - \frac{y - x}{y + x} = 0}$$

With initial conditions

$$[y(0) = 1]$$

With the expansion point for the power series method at $x = 0$.

23.2.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= \frac{y-x}{y+x} \end{aligned}$$

The x domain of $f(x,y)$ when $y=1$ is

$$\{x<-1\vee -1<x\}$$

And the point $x_0=0$ is inside this domain. The y domain of $f(x,y)$ when $x=0$ is

$$\{-\infty<y<\infty\}$$

And the point $y_0=1$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned} \frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{y-x}{y+x}\right) \\ &= \frac{1}{y+x}-\frac{y-x}{(y+x)^2} \end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y=1$ is

$$\{x<-1\vee -1<x\}$$

And the point $x_0=0$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x=0$ is

$$\{-\infty<y<\infty\}$$

And the point $y_0=1$ is inside this domain. Therefore solution exists and is unique.

23.2.2 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x,y)$$

Where $f(x,y)$ is analytic at expansion point x_0. We can always shift to $x_0=0$ if x_0 is not zero. So from now we assume $x_0=0$. Assume also that $y(x_0)=y_0$. Using Taylor series

$$
\begin{aligned}
y(x) &= y(x_0) + (x-x_0)\,y'(x_0) + \frac{(x-x_0)^2}{2}y''(x_0) + \frac{(x-x_0)^3}{3!}y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2}\frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!}\frac{d^2f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty}\frac{x^{n+1}}{(n+1)!}\frac{d^nf}{dx^n}\bigg|_{x_0,y_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f \qquad (1)\\
\frac{d^2f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)f \qquad (2)\\
\frac{d^3f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2f}{dx^2}\right)f \qquad (3)\\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0=f(x,y)$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y) \qquad (4)\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)F_0 \qquad (5)
\end{aligned}
$$

For example, for $n=1$ we see that

$$
\begin{aligned}
F_1 &= \frac{d}{dx}(F_0)\\
&= \frac{\partial}{\partial x}F_0 + \left(\frac{\partial F_0}{\partial y}\right)F_0\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f
\end{aligned}
$$

Which is (1). And when $n = 2$

$$
\begin{aligned}
F_2 &= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) F_0 \\
&= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) f \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f
\end{aligned}
$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$
y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} F_n|_{x_0, y_0} \tag{6}
$$

Hence

$$
\begin{aligned}
F_0 &= \frac{y-x}{y+x} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} F_0 \\
&= \frac{-2x^2-2y^2}{(y+x)^3} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} F_1 \\
&= -\frac{4(x-2y)\,(x^2+y^2)}{(y+x)^5} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} F_2 \\
&= -\frac{20(x^2+y^2)\,(x^2-2yx+3y^2)}{(y+x)^7} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} F_3 \\
&= \frac{40(16y^3-13y^2x+10yx^2-3x^3)\,(x^2+y^2)}{(y+x)^9}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x(0)=0$ and $y(0)=1$ gives

$$
\begin{aligned}
F_0 &= 1 \\
F_1 &= -2 \\
F_2 &= 8 \\
F_3 &= -60 \\
F_4 &= 640
\end{aligned}
$$

Substituting all the above in (6) and simplifying gives the solution as

$$
y = -x^2 + x + 1 + \frac{4x^3}{3} - \frac{5x^4}{2} + \frac{16x^5}{3} + O(x^6)
$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = y(0)$$

Therefore the solution becomes

$$y = -x^2 + x + 1 + \frac{4}{3}x^3 - \frac{5}{2}x^4 + \frac{16}{3}x^5$$

Hence the solution can be written as

$$y = -x^2 + x + 1 + \frac{4x^3}{3} - \frac{5x^4}{2} + \frac{16x^5}{3} + O(x^6)$$

which simplifies to

$$y = -x^2 + x + 1 + \frac{4x^3}{3} - \frac{5x^4}{2} + \frac{16x^5}{3} + O(x^6)$$

Unable to also solve using normal power series since not linear ode. Not currently supported.

Summary

The solution(s) found are the following

$$y = -x^2 + x + 1 + \frac{4x^3}{3} - \frac{5x^4}{2} + \frac{16x^5}{3} + O(x^6) \tag{1}$$

Verification of solutions

$$y = -x^2 + x + 1 + \frac{4x^3}{3} - \frac{5x^4}{2} + \frac{16x^5}{3} + O(x^6)$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 18.1 Integration of differential equation in series. Power series. Exercises page 171
Problem number: 726.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup", "first order ode series method. Ordinary point", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \sin(x)\, y = 0}$$

With initial conditions

$$[y(0) = 1]$$

With the expansion point for the power series method at $x = 0$.

23.3.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= -\sin(x)\\ q(x) &= 0\end{aligned}$$

Hence the ode is

$$y' - \sin(x)\, y = 0$$

The domain of $p(x) = -\sin(x)$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. Hence solution exists and is unique.

23.3.2 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor series

$$\begin{aligned}y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y''(x_0) + \cdots\\ &= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0,y_0} + \cdots\\ &= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0}\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \tag{1}$$

$$\begin{aligned}\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\ &= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \end{aligned} \tag{2}$$

$$\begin{aligned}\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\ &= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) f \end{aligned} \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y)$ then the above can be written as

$$F_0 = f(x,y) \tag{4}$$

$$\begin{aligned}F_n &= \frac{d}{dx}(F_{n-1}) \\ &= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \end{aligned} \tag{5}$$

For example, for $n = 1$ we see that

$$\begin{aligned}F_1 &= \frac{d}{dx}(F_0) \\ &= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\ &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \end{aligned}$$

Which is (1). And when $n = 2$

$$\begin{aligned}F_2 &= \frac{d}{dx}(F_1) \\ &= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) F_0 \\ &= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) f \\ &= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} F_n|_{x_0,y_0} \tag{6}$$

Hence

$$\begin{aligned}
F_0 &= \sin(x) y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} F_0 \\
&= y(\cos(x) + \sin(x)^2) \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} F_1 \\
&= -\sin(x)\cos(x)(\cos(x) - 3) y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} F_2 \\
&= (\cos(x)^4 - 6\cos(x)^3 + 5\cos(x)^2 + 5\cos(x) - 3) y \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} F_3 \\
&= \sin(x) y(\cos(x)^4 - 10\cos(x)^3 + 23\cos(x)^2 - 5\cos(x) - 8)
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = 1$ gives

$$\begin{aligned}
F_0 &= 0 \\
F_1 &= 1 \\
F_2 &= 0 \\
F_3 &= 2 \\
F_4 &= 0
\end{aligned}$$

Substituting all the above in (6) and simplifying gives the solution as

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{12} + O(x^6)$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = y(0)$$

Therefore the solution becomes

$$y = 1 + \frac{1}{2}x^2 + \frac{1}{12}x^4$$

Hence the solution can be written as

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{12} + O(x^6)$$

which simplifies to

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{12} + O(x^6)$$

Since $x = 0$ is also an ordinary point, then standard power series can also be used. Writing the ODE as

$$\begin{aligned} y' + q(x)y &= p(x) \\ y' - \sin(x)\, y &= 0 \end{aligned}$$

Where

$$\begin{aligned} q(x) &= -\sin(x) \\ p(x) &= 0 \end{aligned}$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not. Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - \sin\left(x\right) \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}$$

Expanding $-\sin\left(x\right)$ as Taylor series around $x = 0$ and keeping only the first 6 terms gives

$$\begin{aligned} -\sin\left(x\right) &= -x + \frac{1}{6}x^3 - \frac{1}{120}x^5 + \frac{1}{5040}x^7 + \dots \\ &= -x + \frac{1}{6}x^3 - \frac{1}{120}x^5 + \frac{1}{5040}x^7 \end{aligned}$$

Hence the ODE in Eq (1) becomes

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \left(-x + \frac{1}{6}x^3 - \frac{1}{120}x^5 + \frac{1}{5040}x^7\right) \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}$$

Expanding the second term in (1) gives

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + -x \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) + \frac{x^3}{6} \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) - \frac{x^5}{120} \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) + \frac{x^7}{5040} \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}$$

Which simplifies to

$$\begin{aligned} &\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \sum_{n=0}^{\infty} \left(-x^{1+n} a_n\right) + \left(\sum_{n=0}^{\infty} \frac{x^{n+3} a_n}{6}\right) \\ &+ \sum_{n=0}^{\infty} \left(-\frac{x^{n+5} a_n}{120}\right) + \left(\sum_{n=0}^{\infty} \frac{x^{n+7} a_n}{5040}\right) = 0 \end{aligned} \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (1+n) a_{1+n} x^n$$

$$\sum_{n=0}^{\infty} \left(-x^{1+n} a_n\right) = \sum_{n=1}^{\infty} (-a_{n-1} x^n)$$

$$\sum_{n=0}^{\infty} \frac{x^{n+3} a_n}{6} = \sum_{n=3}^{\infty} \frac{a_{n-3} x^n}{6}$$

$$\sum_{n=0}^{\infty} \left(-\frac{x^{n+5} a_n}{120}\right) = \sum_{n=5}^{\infty} \left(-\frac{a_{n-5} x^n}{120}\right)$$

$$\sum_{n=0}^{\infty} \frac{x^{n+7} a_n}{5040} = \sum_{n=7}^{\infty} \frac{a_{n-7} x^n}{5040}$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (1+n) a_{1+n} x^n\right) + \sum_{n=1}^{\infty} (-a_{n-1} x^n) + \left(\sum_{n=3}^{\infty} \frac{a_{n-3} x^n}{6}\right) + \sum_{n=5}^{\infty} \left(-\frac{a_{n-5} x^n}{120}\right) + \left(\sum_{n=7}^{\infty} \frac{a_{n-7} x^n}{5040}\right) = 0 \tag{3}$$

$n = 1$ gives

$$2a_2 - a_0 = 0$$

Which after substituting earlier equations, simplifies to

$$a_2 = \frac{a_0}{2}$$

$n = 2$ gives

$$3a_3 - a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$3a_3 = 0$$

Or

$$a_3 = 0$$

$n = 3$ gives

$$4a_4 - a_2 + \frac{a_0}{6} = 0$$

Which after substituting earlier equations, simplifies to

$$a_4 = \frac{a_0}{12}$$

$n = 4$ gives

$$5a_5 - a_3 + \frac{a_1}{6} = 0$$

Which after substituting earlier equations, simplifies to

$$5a_5 = 0$$

Or

$$a_5 = 0$$

$n = 5$ gives

$$6a_6 - a_4 + \frac{a_2}{6} - \frac{a_0}{120} = 0$$

Which after substituting earlier equations, simplifies to

$$a_6 = \frac{a_0}{720}$$

For $7 \leq n$, the recurrence equation is

$$(1+n)\, a_{1+n} - a_{n-1} + \frac{a_{n-3}}{6} - \frac{a_{n-5}}{120} + \frac{a_{n-7}}{5040} = 0 \tag{4}$$

Solving for a_{1+n}, gives

$$a_{1+n} = -\frac{-5040a_{n-1} + 840a_{n-3} - 42a_{n-5} + a_{n-7}}{5040\,(1+n)} \tag{5}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + \frac{1}{2}a_0x^2 + \frac{1}{12}a_0x^4 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + \frac{1}{2}x^2 + \frac{1}{12}x^4\right)a_0 + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y(0) = a_0$$

Therefore the solution in Eq(3) now can be written as

$$y = \left(1 + \frac{1}{2}x^2 + \frac{1}{12}x^4\right)y(0) + O(x^6)$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = 1$$

Therefore the solution becomes

$$y = 1 + \frac{1}{2}x^2 + \frac{1}{12}x^4$$

Hence the solution can be written as

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{12} + O(x^6)$$

which simplifies to

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{12} + O(x^6)$$

Summary
The solution(s) found are the following

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{12} + O(x^6) \tag{1}$$
$$y = 1 + \frac{x^2}{2} + \frac{x^4}{12} + O(x^6) \tag{2}$$

Verification of solutions

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{12} + O(x^6)$$

Verified OK.

$$y = 1 + \frac{x^2}{2} + \frac{x^4}{12} + O(x^6)$$

Verified OK.

23.3.3 Maple step by step solution

Let's solve

$[y' - \sin(x)\, y = 0, y(0) = 1]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = \sin(x)$

- Integrate both sides with respect to x

  $\int \frac{y'}{y} dx = \int \sin(x)\, dx + c_1$

- Evaluate integral

  $\ln(y) = -\cos(x) + c_1$

- Solve for y

  $y = e^{-\cos(x)+c_1}$

- Use initial condition $y(0) = 1$

  $1 = e^{c_1-1}$

- Solve for c_1

  $c_1 = 1$

- Substitute $c_1 = 1$ into general solution and simplify

  $y = e^{-\cos(x)+1}$

- Solution to the IVP

  $y = e^{-\cos(x)+1}$

The type(s) of ODE detected by this program : **"second_order_airy", "second_order_bessel_ode", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{y'' + yx = 0}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1]$$

With the expansion point for the power series method at $x = 0$.

23.4.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= x \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + yx = 0$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{1209}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{1210}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') &(4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f &(5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 &(6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \tag{7}$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -yx \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= -xy' - y \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= yx^2 - 2y' \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= x(xy' + 4y) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= -yx^3 + 6xy' + 4y
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = 0$ and $y'(0) = 1$ gives

$$
\begin{aligned}
F_0 &= 0 \\
F_1 &= 0 \\
F_2 &= -2 \\
F_3 &= 0 \\
F_4 &= 0
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = x - \frac{x^4}{12} + O(x^6)
$$

$$
y = x - \frac{x^4}{12} + O(x^6)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -\left(\sum_{n=0}^{\infty} a_n x^n\right) x \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=0}^{\infty} x^{1+n} a_n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^n$$
$$\sum_{n=0}^{\infty} x^{1+n} a_n = \sum_{n=1}^{\infty} a_{n-1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^n\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^n\right) = 0 \tag{3}$$

For $1 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(1+n) + a_{n-1} = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{a_{n-1}}{(n+2)(1+n)} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$6a_3 + a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{a_0}{6}$$

For $n = 2$ the recurrence equation gives

$$12a_4 + a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{a_1}{12}$$

For $n = 3$ the recurrence equation gives

$$20a_5 + a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = 0$$

For $n = 4$ the recurrence equation gives

$$30a_6 + a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_0}{180}$$

For $n = 5$ the recurrence equation gives

$$42a_7 + a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{a_1}{504}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x - \frac{1}{6} a_0 x^3 - \frac{1}{12} a_1 x^4 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{x^3}{6}\right) a_0 + \left(x - \frac{1}{12} x^4\right) a_1 + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{x^3}{6}\right) c_1 + \left(x - \frac{1}{12} x^4\right) c_2 + O(x^6)$$

$$y = x - \frac{x^4}{12} + O(x^6)$$

Summary

The solution(s) found are the following

$$y = x - \frac{x^4}{12} + O(x^6) \tag{1}$$
$$y = x - \frac{x^4}{12} + O(x^6) \tag{2}$$

Verification of solutions

$$y = x - \frac{x^4}{12} + O(x^6)$$

Verified OK.

$$y = x - \frac{x^4}{12} + O(x^6)$$

Verified OK.

23.4.2 Maple step by step solution

Let's solve

$$\left[y'' = -yx, y(0) = 0, y'\Big|_{\{x=0\}} = 1\right]$$

- Highest derivative means the order of the ODE is 2

$$y''$$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$$y'' + yx = 0$$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^k$$

□ Rewrite ODE with series expansions

  ◦ Convert $x \cdot y$ to series expansion

$$x \cdot y = \sum_{k=0}^{\infty} a_k x^{k+1}$$

  ◦ Shift index using $k- >k - 1$

$$x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^k$$

  ◦ Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

  ◦ Shift index using $k- >k + 2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite ODE with series expansions

$$2a_2 + \left(\sum_{k=1}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_{k-1}\right) x^k\right) = 0$$

- Each term must be 0

$$2a_2 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$\left(k^2 + 3k + 2\right) a_{k+2} + a_{k-1} = 0$$

- Shift index using $k- >k + 1$

$$\left((k+1)^2+3k+5\right) a_{k+3}+a_k=0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y=\sum_{k=0}^{\infty} a_k x^k, a_{k+3}=-\frac{a_k}{k^2+5k+6}, 2a_2=0\right]$$

Section: Chapter 2 (Higher order ODE's). Section 18.1 Integration of differential equation in series. Power series. Exercises page 171
Problem number: 728.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_y", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' - y' \sin(x) = 0}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1]$$

With the expansion point for the power series method at $x = 0$.

23.5.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -\sin(x) \\ q(x) &= 0 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - y' \sin(x) = 0$$

The domain of $p(x) = -\sin(x)$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. Hence solution exists and is unique.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned} y(x) &= y(x_0) + (x - x_0) y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\ &= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\ &= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0} \end{aligned}$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (1212)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (1213)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3)\\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= y' \sin(x) \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= y' \left(\sin(x)^2 + \cos(x)\right) \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= -\sin(x)\cos(x)\left(\cos(x) - 3\right) y' \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(\cos(x)^4 - 6\cos(x)^3 + 5\cos(x)^2 + 5\cos(x) - 3\right) y' \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= y' \sin(x)\left(\cos(x)^4 - 10\cos(x)^3 + 23\cos(x)^2 - 5\cos(x) - 8\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = 0$ and $y'(0) = 1$ gives

$$
\begin{aligned}
F_0 &= 0 \\
F_1 &= 1 \\
F_2 &= 0 \\
F_3 &= 2 \\
F_4 &= 0
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = x + \frac{x^3}{6} + \frac{x^5}{60} + O\left(x^6\right)
$$

$$
y = x + \frac{x^3}{6} + \frac{x^5}{60} + O\left(x^6\right)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) \sin(x) \tag{1}$$

Expanding $-\sin(x)$ as Taylor series around $x = 0$ and keeping only the first 6 terms gives

$$\begin{aligned} -\sin(x) &= -x + \frac{1}{6}x^3 - \frac{1}{120}x^5 + \frac{1}{5040}x^7 + \dots \\ &= -x + \frac{1}{6}x^3 - \frac{1}{120}x^5 + \frac{1}{5040}x^7 \end{aligned}$$

Hence the ODE in Eq (1) becomes

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(-x + \frac{1}{6}x^3 - \frac{1}{120}x^5 + \frac{1}{5040}x^7\right)\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) = 0$$

Expanding the second term in (1) gives

$$\begin{aligned} &\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + -x \cdot \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \frac{x^3}{6} \cdot \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) \\ &- \frac{x^5}{120} \cdot \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \frac{x^7}{5040} \cdot \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) = 0 \end{aligned}$$

Which simplifies to

$$\begin{aligned} &\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \sum_{n=1}^{\infty} (-n a_n x^n) + \left(\sum_{n=1}^{\infty} \frac{n\, x^{n+2} a_n}{6}\right) \\ &+ \sum_{n=1}^{\infty} \left(-\frac{n\, x^{n+4} a_n}{120}\right) + \left(\sum_{n=1}^{\infty} \frac{n\, x^{n+6} a_n}{5040}\right) = 0 \end{aligned} \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} &= \sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n \\
\sum_{n=1}^{\infty} \frac{n x^{n+2} a_n}{6} &= \sum_{n=3}^{\infty} \frac{(n-2) a_{n-2} x^n}{6} \\
\sum_{n=1}^{\infty} \left(-\frac{n x^{n+4} a_n}{120}\right) &= \sum_{n=5}^{\infty} \left(-\frac{(n-4) a_{n-4} x^n}{120}\right) \\
\sum_{n=1}^{\infty} \frac{n x^{n+6} a_n}{5040} &= \sum_{n=7}^{\infty} \frac{(n-6) a_{n-6} x^n}{5040}
\end{aligned}
$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n\right) + \sum_{n=1}^{\infty} (-n a_n x^n) + \left(\sum_{n=3}^{\infty} \frac{(n-2) a_{n-2} x^n}{6}\right) \\
&+ \sum_{n=5}^{\infty} \left(-\frac{(n-4) a_{n-4} x^n}{120}\right) + \left(\sum_{n=7}^{\infty} \frac{(n-6) a_{n-6} x^n}{5040}\right) = 0
\end{aligned} \tag{3}
$$

$n = 1$ gives

$$6a_3 - a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = \frac{a_1}{6}$$

$n = 2$ gives

$$12a_4 - 2a_2 = 0$$

Which after substituting earlier equations, simplifies to

$$12a_4 = 0$$

Or

$$a_4 = 0$$

$n = 3$ gives

$$20a_5 - 3a_3 + \frac{a_1}{6} = 0$$

Which after substituting earlier equations, simplifies to

$$a_5 = \frac{a_1}{60}$$

$n = 4$ gives

$$30a_6 - 4a_4 + \frac{a_2}{3} = 0$$

Which after substituting earlier equations, simplifies to

$$30a_6 = 0$$

Or

$$a_6 = 0$$

$n = 5$ gives

$$42a_7 - 5a_5 + \frac{a_3}{2} - \frac{a_1}{120} = 0$$

Which after substituting earlier equations, simplifies to

$$a_7 = \frac{a_1}{5040}$$

For $7 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(n+1) - n a_n + \frac{(n-2)\, a_{n-2}}{6} - \frac{(n-4)\, a_{n-4}}{120} + \frac{(n-6)\, a_{n-6}}{5040} = 0 \quad (4)$$

Solving for a_{n+2}, gives

$$a_{n+2} = \frac{5040 n a_n - n a_{n-6} + 42 n a_{n-4} - 840 n a_{n-2} + 6 a_{n-6} - 168 a_{n-4} + 1680 a_{n-2}}{5040\,(n+2)\,(n+1)} \quad (5)$$

$$= \frac{n a_n}{(n+2)\,(n+1)} + \frac{(-n+6)\, a_{n-6}}{5040\,(n+2)\,(n+1)} + \frac{(42n-168)\, a_{n-4}}{5040\,(n+2)\,(n+1)} + \frac{(-840n+1680)\, a_{n-2}}{5040\,(n+2)\,(n+1)}$$

And so on. Therefore the solution is

$$
\begin{aligned}
y &= \sum_{n=0}^{\infty} a_n x^n \\
&= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots
\end{aligned}
$$

Substituting the values for a_n found above, the solution becomes

$$
y = a_0 + a_1 x + \frac{1}{6} a_1 x^3 + \frac{1}{60} a_1 x^5 + \dots
$$

Collecting terms, the solution becomes

$$
y = a_0 + \left(x + \frac{1}{6} x^3 + \frac{1}{60} x^5\right) a_1 + O(x^6) \tag{3}
$$

At $x = 0$ the solution above becomes

$$
y = c_1 + \left(x + \frac{1}{6} x^3 + \frac{1}{60} x^5\right) c_2 + O(x^6)
$$

$$
y = x + \frac{x^3}{6} + \frac{x^5}{60} + O(x^6)
$$

Summary

The solution(s) found are the following

$$
y = x + \frac{x^3}{6} + \frac{x^5}{60} + O(x^6) \tag{1}
$$

$$
y = x + \frac{x^3}{6} + \frac{x^5}{60} + O(x^6) \tag{2}
$$

Verification of solutions

$$
y = x + \frac{x^3}{6} + \frac{x^5}{60} + O(x^6)
$$

Verified OK.

$$
y = x + \frac{x^3}{6} + \frac{x^5}{60} + O(x^6)
$$

Verified OK.

23.5.2 Maple step by step solution

Let's solve

$\left[y'' = y' \sin(x), y(0) = 0, y'\Big|_{\{x=0\}} = 1\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) = u(x)\sin(x)$

- Separate variables

  $\frac{u'(x)}{u(x)} = \sin(x)$

- Integrate both sides with respect to x

  $\int \frac{u'(x)}{u(x)}dx = \int \sin(x)\, dx + c_1$

- Evaluate integral

  $\ln(u(x)) = -\cos(x) + c_1$

- Solve for $u(x)$

  $u(x) = \mathrm{e}^{-\cos(x)+c_1}$

- Solve 1st ODE for $u(x)$

  $u(x) = \mathrm{e}^{-\cos(x)+c_1}$

- Make substitution $u = y'$

  $y' = \mathrm{e}^{-\cos(x)+c_1}$

- Integrate both sides to solve for y

  $\int y' dx = \int \mathrm{e}^{-\cos(x)+c_1} dx + c_2$

- Compute integrals

  $y = \int \mathrm{e}^{-\cos(x)+c_1} dx + c_2$

23.6.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$p(x) = 0$$
$$q(x) = \frac{\sin(x)}{x}$$
$$F = 1$$

Hence the ode is

$$y'' + \frac{\sin(x)\,y}{x} = 1$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = \pi$ is inside this domain. The domain of $q(x) = \frac{\sin(x)}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = \pi$ is also inside this domain. The domain of $F = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = \pi$ is also inside this domain. Hence solution exists and is unique.

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - \pi$$

The ode is converted to be in terms of the new independent variable t. This results in

$$(t+\pi)\left(\frac{d^2}{dt^2}y(t)\right) - \sin(t)\,y(t) = t + \pi$$

With its expansion point and initial conditions now at $t = 0$. With initial conditions now becoming

$$y(0) = 1$$
$$y'(0) = 0$$

The transformed ODE is now solved. Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (1216) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (1217) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}F_n|_{x_0,y_0,y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= \frac{\sin(t)\,y(t) + t + \pi}{t + \pi} \\
F_1 &= \frac{dF_0}{dt} \\
&= \frac{\partial F_0}{\partial t} + \frac{\partial F_0}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_0}{\partial \frac{d}{dt}y(t)}F_0 \\
&= \frac{\sin(t)\,(t+\pi)\left(\frac{d}{dt}y(t)\right) + (-\sin(t) + \cos(t)\,(t+\pi))\,y(t)}{(t+\pi)^2} \\
F_2 &= \frac{dF_1}{dt} \\
&= \frac{\partial F_1}{\partial t} + \frac{\partial F_1}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_1}{\partial \frac{d}{dt}y(t)}F_1 \\
&= \frac{2(t+\pi)\,(-\sin(t) + \cos(t)\,(t+\pi))\left(\frac{d}{dt}y(t)\right) + y(t)\,(t+\pi)\sin(t)^2 + \left((-\pi^2 - 2\pi t - t^2 + 2)\,y(t) + (t\right.}{(t+\pi)^3} \\
F_3 &= \frac{dF_2}{dt} \\
&= \frac{\partial F_2}{\partial t} + \frac{\partial F_2}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_2}{\partial \frac{d}{dt}y(t)}F_2 \\
&= \frac{-3(t+\pi)\left(\frac{(-t-\pi)\sin(t)^2}{3} + (\pi^2 + 2\pi t + t^2 - 2)\sin(t) + 2\cos(t)\,(t+\pi)\right)\left(\frac{d}{dt}y(t)\right) - 4y(t)\,(t+\pi)\sin(}{} \\
F_4 &= \frac{dF_3}{dt} \\
&= \frac{\partial F_3}{\partial t} + \frac{\partial F_3}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_3}{\partial \frac{d}{dt}y(t)}F_3 \\
&= \frac{-4\left(\frac{3(t+\pi)\sin(t)^2}{2} + 3\left(2 - \frac{(t+\pi)^2\cos(t)}{2} - t^2 - 2\pi t - \pi^2\right)\sin(t) + \cos(t)\,(t+\pi)\,(\pi^2 + 2\pi t + t^2 - 6)\right)(t}{}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $t = 0$ and $y(0) = 1$ and

$y'(0) = 0$ gives

$$
\begin{aligned}
F_0 &= 1 \\
F_1 &= \frac{1}{\pi} \\
F_2 &= -\frac{2}{\pi^2} \\
F_3 &= \frac{2\pi^2 + 6}{\pi^3} \\
F_4 &= \frac{-4\pi^2 - 24}{\pi^4}
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y(t) = 1 + \frac{t^2}{2} + \frac{t^3}{6\pi} - \frac{t^4}{12\pi^2} + \frac{t^5}{60\pi} + \frac{t^5}{20\pi^3} - \frac{t^6}{180\pi^2} - \frac{t^6}{30\pi^4} + O(t^6)
$$

$$
y(t) = 1 + \frac{t^2}{2} + \frac{t^3}{6\pi} - \frac{t^4}{12\pi^2} + \frac{t^5}{60\pi} + \frac{t^5}{20\pi^3} - \frac{t^6}{180\pi^2} - \frac{t^6}{30\pi^4} + O(t^6)
$$

Since the expansion point $t = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$
(t + \pi)\left(\frac{d^2}{dt^2}y(t)\right) - \sin(t)\, y(t) = t + \pi
$$

Let the solution be represented as power series of the form

$$
y(t) = \sum_{n=0}^{\infty} a_n t^n
$$

Then

$$
\begin{aligned}
\frac{d}{dt}y(t) &= \sum_{n=1}^{\infty} n a_n t^{n-1} \\
\frac{d^2}{dt^2}y(t) &= \sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
(t + \pi)\left(\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}\right) - \sin(t)\left(\sum_{n=0}^{\infty} a_n t^n\right) = t + \pi \tag{1}
$$

Expanding $-\sin(t)$ as Taylor series around $t=0$ and keeping only the first 6 terms gives

$$
\begin{aligned}
-\sin(t) &= -t+\frac{1}{6}t^3-\frac{1}{120}t^5+\frac{1}{5040}t^7+\dots\\
&= -t+\frac{1}{6}t^3-\frac{1}{120}t^5+\frac{1}{5040}t^7
\end{aligned}
$$

Expanding $t+\pi$ as Taylor series around $t=0$ and keeping only the first 6 terms gives

$$
\begin{aligned}
t+\pi &= t+\pi+\dots\\
&= t+\pi
\end{aligned}
$$

Hence the ODE in Eq (1) becomes

$$
(t+\pi)\left(\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}\right)+\left(-t+\frac{1}{6}t^3-\frac{1}{120}t^5+\frac{1}{5040}t^7\right)\left(\sum_{n=0}^{\infty} a_n t^n\right)=t+\pi
$$

Expanding the second term in (1) gives

$$
\begin{aligned}
&(t+\pi)\left(\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}\right)+-t\cdot\left(\sum_{n=0}^{\infty} a_n t^n\right)+\frac{t^3}{6}\\
&\cdot\left(\sum_{n=0}^{\infty} a_n t^n\right)-\frac{t^5}{120}\cdot\left(\sum_{n=0}^{\infty} a_n t^n\right)+\frac{t^7}{5040}\cdot\left(\sum_{n=0}^{\infty} a_n t^n\right)=t+\pi
\end{aligned}
$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=2}^{\infty} n\, t^{n-1} a_n (n-1)\right)+\left(\sum_{n=2}^{\infty} n\pi\, t^{n-2} a_n (n-1)\right)+\sum_{n=0}^{\infty}\left(-t^{1+n} a_n\right)\\
&+\left(\sum_{n=0}^{\infty}\frac{t^{n+3} a_n}{6}\right)+\sum_{n=0}^{\infty}\left(-\frac{t^{n+5} a_n}{120}\right)+\left(\sum_{n=0}^{\infty}\frac{t^{n+7} a_n}{5040}\right)=t+\pi
\end{aligned}
\tag{2}
$$

The next step is to make all powers of t be n in each summation term. Going over each summation term above with power of t in it which is not already t^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n\,t^{n-1} a_n (n-1) = \sum_{n=1}^{\infty} (1+n)\, a_{1+n} n\, t^{n}$$

$$\sum_{n=2}^{\infty} n\pi\, t^{n-2} a_n (n-1) = \sum_{n=0}^{\infty} \pi (n+2)\, a_{n+2} (1+n)\, t^{n}$$

$$\sum_{n=0}^{\infty} \left(-t^{1+n} a_n\right) = \sum_{n=1}^{\infty} \left(-a_{n-1} t^{n}\right)$$

$$\sum_{n=0}^{\infty} \frac{t^{n+3} a_n}{6} = \sum_{n=3}^{\infty} \frac{a_{n-3} t^{n}}{6}$$

$$\sum_{n=0}^{\infty} \left(-\frac{t^{n+5} a_n}{120}\right) = \sum_{n=5}^{\infty} \left(-\frac{a_{n-5} t^{n}}{120}\right)$$

$$\sum_{n=0}^{\infty} \frac{t^{n+7} a_n}{5040} = \sum_{n=7}^{\infty} \frac{a_{n-7} t^{n}}{5040}$$

Substituting all the above in Eq (2) gives the following equation where now all powers of t are the same and equal to n.

$$\left(\sum_{n=1}^{\infty} (1+n)\, a_{1+n} n\, t^{n}\right) + \left(\sum_{n=0}^{\infty} \pi (n+2)\, a_{n+2} (1+n)\, t^{n}\right) + \sum_{n=1}^{\infty} \left(-a_{n-1} t^{n}\right) + \left(\sum_{n=3}^{\infty} \frac{a_{n-3} t^{n}}{6}\right) + \sum_{n=5}^{\infty} \left(-\frac{a_{n-5} t^{n}}{120}\right) + \left(\sum_{n=7}^{\infty} \frac{a_{n-7} t^{n}}{5040}\right) = t + \pi \tag{3}$$

$n = 0$ gives

$$(2\pi a_2)\, 1 = \pi$$
$$2\pi a_2 = \pi$$

Or

$$a_2 = \frac{1}{2}$$

$n = 1$ gives

$$(6\pi a_3 - a_0 + 2a_2)\, t = t$$
$$6\pi a_3 - a_0 + 2a_2 = 1$$

Which after substituting earlier equations, simplifies to

$$a_3 = \frac{a_0}{6\pi}$$

$n = 2$ gives

$$12\pi a_4 - a_1 + 6a_3 = 0$$

Which after substituting earlier equations, simplifies to

$$a_4 = \frac{\pi a_1 - a_0}{12\pi^2}$$

$n = 3$ gives

$$20\pi a_5 - a_2 + 12a_4 + \frac{a_0}{6} = 0$$

Which after substituting earlier equations, simplifies to

$$a_5 = -\frac{\pi^2 a_0 - 3\pi^2 + 6\pi a_1 - 6a_0}{120\pi^3}$$

$n = 4$ gives

$$30\pi a_6 - a_3 + 20a_5 + \frac{a_1}{6} = 0$$

Which after substituting earlier equations, simplifies to

$$a_6 = -\frac{\pi^3 a_1 - 2\pi^2 a_0 + 3\pi^2 - 6\pi a_1 + 6a_0}{180\pi^4}$$

$n = 5$ gives

$$42\pi a_7 - a_4 + 30a_6 + \frac{a_2}{6} - \frac{a_0}{120} = 0$$

Which after substituting earlier equations, simplifies to

$$a_7 = \frac{\pi^4 a_0 - 10\pi^4 + 30\pi^3 a_1 - 50\pi^2 a_0 + 60\pi^2 - 120\pi a_1 + 120a_0}{5040\pi^5}$$

For $7 \leq n$, the recurrence equation is

$$\left((1+n)\, a_{1+n} n + \pi(n+2)\, a_{n+2}(1+n) - a_{n-1} + \frac{a_{n-3}}{6} - \frac{a_{n-5}}{120} + \frac{a_{n-7}}{5040}\right) t^n = t + \pi \quad (4)$$

And so on. Therefore the solution is

$$
\begin{aligned}
y(t) &= \sum_{n=0}^{\infty} a_n t^n \\
&= a_3 t^3 + a_2 t^2 + a_1 t + a_0 + \dots
\end{aligned}
$$

Substituting the values for a_n found above, the solution becomes

$$
y(t) = a_0 + a_1 t + \frac{t^2}{2} + \frac{a_0 t^3}{6\pi} + \frac{(\pi a_1 - a_0)\, t^4}{12\pi^2} - \frac{(\pi^2 a_0 - 3\pi^2 + 6\pi a_1 - 6a_0)\, t^5}{120\pi^3} + \dots
$$

Collecting terms, the solution becomes

$$
y(t) = \left(1+\frac{t^3}{6\pi}-\frac{t^4}{12\pi^2}-\frac{(\pi^2-6)\, t^5}{120\pi^3}\right) a_0+\left(t+\frac{t^4}{12\pi}-\frac{t^5}{20\pi^2}\right) a_1+\frac{t^2}{2}+\frac{t^5}{40\pi}+O(t^6) \quad (3)
$$

At $t = 0$ the solution above becomes

$$
y(t) = \left(1+\frac{t^3}{6\pi}-\frac{t^4}{12\pi^2}-\frac{(\pi^2-6)\, t^5}{120\pi^3}\right) c_1+\left(t+\frac{t^4}{12\pi}-\frac{t^5}{20\pi^2}\right) c_2+\frac{t^2}{2}+\frac{t^5}{40\pi}+O(t^6)
$$

$$
y(t) = 1 + \frac{t^3}{6\pi} - \frac{t^4}{12\pi^2} + \frac{t^5}{60\pi} + \frac{t^5}{20\pi^3} + \frac{t^2}{2} + O(t^6)
$$

Replacing t in the above with the original independent variable $x$susing $t = x - \pi$ results in

$$
\begin{aligned}
y = 1 &+ \frac{(x-\pi)^2}{2} + \frac{(x-\pi)^3}{6\pi} - \frac{(x-\pi)^4}{12\pi^2} + \frac{(x-\pi)^5}{60\pi} \\
&+ \frac{(x-\pi)^5}{20\pi^3} - \frac{(x-\pi)^6}{180\pi^2} - \frac{(x-\pi)^6}{30\pi^4} + O\left((x-\pi)^6\right)
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
\begin{aligned}
y = 1 &+ \frac{(x-\pi)^2}{2} + \frac{(x-\pi)^3}{6\pi} - \frac{(x-\pi)^4}{12\pi^2} + \frac{(x-\pi)^5}{60\pi} \\
&+ \frac{(x-\pi)^5}{20\pi^3} - \frac{(x-\pi)^6}{180\pi^2} - \frac{(x-\pi)^6}{30\pi^4} + O\left((x-\pi)^6\right)
\end{aligned} \quad (1)
$$

Verification of solutions

$$
y = 1 + \frac{(x-\pi)^2}{2} + \frac{(x-\pi)^3}{6\pi} - \frac{(x-\pi)^4}{12\pi^2} + \frac{(x-\pi)^5}{60\pi} + \frac{(x-\pi)^5}{20\pi^3} - \frac{(x-\pi)^6}{180\pi^2} - \frac{(x-\pi)^6}{30\pi^4} + O\left((x-\pi)^6\right)
$$

Verified OK.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{\ln(x)\, y'' - y\sin(x) = 0}$$

With initial conditions

$$[y(\mathrm{e}) = \mathrm{e}^{-1}, y'(\mathrm{e}) = 0]$$

With the expansion point for the power series method at $x = \mathrm{e}$.

23.7.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= -\frac{\sin(x)}{\ln(x)} \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - \frac{y \sin(x)}{\ln(x)} = 0$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = \mathrm{e}$ is inside this domain. The domain of $q(x) = -\frac{\sin(x)}{\ln(x)}$ is

$$\{0 < x < 1, 1 < x \leq \infty\}$$

And the point $x_0 = \mathrm{e}$ is also inside this domain. Hence solution exists and is unique.

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - \mathrm{e}$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\ln(t + \mathrm{e}) \left(\frac{d^2}{dt^2} y(t)\right) - y(t) \sin(t + \mathrm{e}) = 0$$

With its expansion point and initial conditions now at $t = 0$. With initial conditions now becoming

$$y(0) = \mathrm{e}^{-1}$$
$$y'(0) = 0$$

The transformed ODE is now solved. Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0,y_0,y'_0} + \frac{x^3}{3!} f'|_{x_0,y_0,y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y'_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (1219)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (1220)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3)\\
&\ \ \vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y'_0} \qquad (7)
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= \frac{y(t)\sin(t+\mathrm{e})}{\ln(t+\mathrm{e})}\\
F_1 &= \frac{dF_0}{dt}\\
&= \frac{\partial F_0}{\partial t}+\frac{\partial F_0}{\partial y}\frac{d}{dt}y(t)+\frac{\partial F_0}{\partial \frac{d}{dt}y(t)}F_0\\
&= \frac{\left(y(t)\cos(t+\mathrm{e})+\left(\frac{d}{dt}y(t)\right)\sin(t+\mathrm{e})\right)(t+\mathrm{e})\ln(t+\mathrm{e})-y(t)\sin(t+\mathrm{e})}{\ln(t+\mathrm{e})^2(t+\mathrm{e})}\\
F_2 &= \frac{dF_1}{dt}\\
&= \frac{\partial F_1}{\partial t}+\frac{\partial F_1}{\partial y}\frac{d}{dt}y(t)+\frac{\partial F_1}{\partial \frac{d}{dt}y(t)}F_1\\
&= \frac{-(t^2+2\,\mathrm{e}t+\mathrm{e}^2)\left(y(t)\sin(t+\mathrm{e})-2\left(\frac{d}{dt}y(t)\right)\cos(t+\mathrm{e})\right)\ln(t+\mathrm{e})^2+\left(y(t)(t^2+2\,\mathrm{e}t+\mathrm{e}^2)\sin(t+\mathrm{e}\right.}{\ln(t+\mathrm{e})^3}\\
F_3 &= \frac{dF_2}{dt}\\
&= \frac{\partial F_2}{\partial t}+\frac{\partial F_2}{\partial y}\frac{d}{dt}y(t)+\frac{\partial F_2}{\partial \frac{d}{dt}y(t)}F_2\\
&= \frac{-(t^3+3t^2\mathrm{e}+3\,\mathrm{e}^2t+\mathrm{e}^3)\left(y(t)\cos(t+\mathrm{e})+3\left(\frac{d}{dt}y(t)\right)\sin(t+\mathrm{e})\right)\ln(t+\mathrm{e})^3+\left(\left(\frac{d}{dt}y(t)\right)(t^3+3t^2\mathrm{e}+\right.}{}\\
F_4 &= \frac{dF_3}{dt}\\
&= \frac{\partial F_3}{\partial t}+\frac{\partial F_3}{\partial y}\frac{d}{dt}y(t)+\frac{\partial F_3}{\partial \frac{d}{dt}y(t)}F_3\\
&= \frac{(t^4+4t^3\mathrm{e}+6t^2\mathrm{e}^2+4t\,\mathrm{e}^3+\mathrm{e}^4)\left(y(t)\sin(t+\mathrm{e})-4\left(\frac{d}{dt}y(t)\right)\cos(t+\mathrm{e})\right)\ln(t+\mathrm{e})^4+\left(\left(6\left(\frac{d}{dt}y(t)\right)(t^4+\right.\right.}{}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $t=0$ and $y(0)=\mathrm{e}^{-1}$ and $y'(0)=0$ gives

$$
\begin{aligned}
F_0 &= \mathrm{e}^{-1}\sin(\mathrm{e})\\
F_1 &= -\mathrm{e}^{-2}\sin(\mathrm{e})+\cos(\mathrm{e})\,\mathrm{e}^{-1}\\
F_2 &= \sin(\mathrm{e})^2\,\mathrm{e}^{-1}+3\sin(\mathrm{e})\,\mathrm{e}^{-3}-\mathrm{e}^{-1}\sin(\mathrm{e})-2\,\mathrm{e}^{-2}\cos(\mathrm{e})\\
F_3 &= -4\sin(\mathrm{e})^2\,\mathrm{e}^{-2}+9\cos(\mathrm{e})\,\mathrm{e}^{-3}-\cos(\mathrm{e})\,\mathrm{e}^{-1}+2\sin(2\,\mathrm{e})\,\mathrm{e}^{-1}-14\sin(\mathrm{e})\,\mathrm{e}^{-4}+3\,\mathrm{e}^{-2}\sin(\mathrm{e})\\
F_4 &= 88\sin(\mathrm{e})\,\mathrm{e}^{-5}-56\,\mathrm{e}^{-4}\cos(\mathrm{e})+25\sin(\mathrm{e})^2\,\mathrm{e}^{-3}-18\sin(\mathrm{e})\,\mathrm{e}^{-3}+4\,\mathrm{e}^{-2}\cos(\mathrm{e})-11\sin(2\,\mathrm{e})\,\mathrm{e}^{-2}-\frac{\mathrm{e}^{-1}\mathrm{s}}{}
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y(t) = {} & \frac{t^{5} \mathrm{e}^{-1} \sin(\mathrm{e}) \cos(\mathrm{e})}{30} - \frac{t^{6} \sin(\mathrm{e}) \cos(\mathrm{e})^{2} \mathrm{e}^{-1}}{720} - \frac{11 t^{6} \mathrm{e}^{-2} \sin(\mathrm{e}) \cos(\mathrm{e})}{360} \\
& + \mathrm{e}^{-1} + \frac{\mathrm{e}^{-1} \sin(\mathrm{e}) t^{2}}{2} + O(t^{6}) - \frac{t^{3} \mathrm{e}^{-2} \sin(\mathrm{e})}{6} + \frac{t^{3} \cos(\mathrm{e}) \mathrm{e}^{-1}}{6} \\
& + \frac{t^{4} \sin(\mathrm{e})^{2} \mathrm{e}^{-1}}{24} + \frac{t^{4} \sin(\mathrm{e}) \mathrm{e}^{-3}}{8} - \frac{t^{4} \mathrm{e}^{-1} \sin(\mathrm{e})}{24} - \frac{t^{4} \mathrm{e}^{-2} \cos(\mathrm{e})}{12} \\
& - \frac{t^{5} \sin(\mathrm{e})^{2} \mathrm{e}^{-2}}{30} + \frac{3 t^{5} \cos(\mathrm{e}) \mathrm{e}^{-3}}{40} - \frac{t^{5} \cos(\mathrm{e}) \mathrm{e}^{-1}}{120} - \frac{7 t^{5} \sin(\mathrm{e}) \mathrm{e}^{-4}}{60} \\
& + \frac{t^{5} \mathrm{e}^{-2} \sin(\mathrm{e})}{40} + \frac{5 t^{6} \sin(\mathrm{e})^{2} \mathrm{e}^{-3}}{144} + \frac{11 t^{6} \mathrm{e}^{-1} \cos(\mathrm{e})^{2}}{720} + \frac{11 t^{6} \sin(\mathrm{e}) \mathrm{e}^{-5}}{90} \\
& - \frac{7 t^{6} \mathrm{e}^{-4} \cos(\mathrm{e})}{90} - \frac{t^{6} \sin(\mathrm{e}) \mathrm{e}^{-3}}{40} + \frac{t^{6} \mathrm{e}^{-2} \cos(\mathrm{e})}{180} + \frac{t^{6} \mathrm{e}^{-1} \sin(\mathrm{e})}{360} - \frac{7 t^{6} \mathrm{e}^{-1}}{720}
\end{aligned}
$$

$$
\begin{aligned}
y(t) = {} & \frac{t^{5} \mathrm{e}^{-1} \sin(\mathrm{e}) \cos(\mathrm{e})}{30} - \frac{t^{6} \sin(\mathrm{e}) \cos(\mathrm{e})^{2} \mathrm{e}^{-1}}{720} - \frac{11 t^{6} \mathrm{e}^{-2} \sin(\mathrm{e}) \cos(\mathrm{e})}{360} \\
& + \mathrm{e}^{-1} + \frac{\mathrm{e}^{-1} \sin(\mathrm{e}) t^{2}}{2} + O(t^{6}) - \frac{t^{3} \mathrm{e}^{-2} \sin(\mathrm{e})}{6} + \frac{t^{3} \cos(\mathrm{e}) \mathrm{e}^{-1}}{6} \\
& + \frac{t^{4} \sin(\mathrm{e})^{2} \mathrm{e}^{-1}}{24} + \frac{t^{4} \sin(\mathrm{e}) \mathrm{e}^{-3}}{8} - \frac{t^{4} \mathrm{e}^{-1} \sin(\mathrm{e})}{24} - \frac{t^{4} \mathrm{e}^{-2} \cos(\mathrm{e})}{12} \\
& - \frac{t^{5} \sin(\mathrm{e})^{2} \mathrm{e}^{-2}}{30} + \frac{3 t^{5} \cos(\mathrm{e}) \mathrm{e}^{-3}}{40} - \frac{t^{5} \cos(\mathrm{e}) \mathrm{e}^{-1}}{120} - \frac{7 t^{5} \sin(\mathrm{e}) \mathrm{e}^{-4}}{60} \\
& + \frac{t^{5} \mathrm{e}^{-2} \sin(\mathrm{e})}{40} + \frac{5 t^{6} \sin(\mathrm{e})^{2} \mathrm{e}^{-3}}{144} + \frac{11 t^{6} \mathrm{e}^{-1} \cos(\mathrm{e})^{2}}{720} + \frac{11 t^{6} \sin(\mathrm{e}) \mathrm{e}^{-5}}{90} \\
& - \frac{7 t^{6} \mathrm{e}^{-4} \cos(\mathrm{e})}{90} - \frac{t^{6} \sin(\mathrm{e}) \mathrm{e}^{-3}}{40} + \frac{t^{6} \mathrm{e}^{-2} \cos(\mathrm{e})}{180} + \frac{t^{6} \mathrm{e}^{-1} \sin(\mathrm{e})}{360} - \frac{7 t^{6} \mathrm{e}^{-1}}{720}
\end{aligned}
$$

Since the expansion point $t = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y(t) = \sum_{n=0}^{\infty} a_n t^n
$$

Then

$$
\begin{aligned}
\frac{d}{dt} y(t) &= \sum_{n=1}^{\infty} n a_n t^{n-1} \\
\frac{d^2}{dt^2} y(t) &= \sum_{n=2}^{\infty} n(n-1) a_n t^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2} = \frac{\left(\sum_{n=0}^{\infty} a_n t^n\right) \sin(t+\mathrm{e})}{\ln(t+\mathrm{e})} \tag{1}$$

Expanding $\ln(t+\mathrm{e})$ as Taylor series around $t=0$ and keeping only the first 6 terms gives

$$\begin{aligned}
\ln(t+\mathrm{e}) &= 1+\mathrm{e}^{-1}t-\frac{\mathrm{e}^{-2}t^2}{2}+\frac{\mathrm{e}^{-3}t^3}{3}-\frac{\mathrm{e}^{-4}t^4}{4}+\frac{\mathrm{e}^{-5}t^5}{5}-\frac{\mathrm{e}^{-6}t^6}{6}+\dots \\
&= 1+\mathrm{e}^{-1}t-\frac{\mathrm{e}^{-2}t^2}{2}+\frac{\mathrm{e}^{-3}t^3}{3}-\frac{\mathrm{e}^{-4}t^4}{4}+\frac{\mathrm{e}^{-5}t^5}{5}-\frac{\mathrm{e}^{-6}t^6}{6}
\end{aligned}$$

Expanding $-\sin(t+\mathrm{e})$ as Taylor series around $t=0$ and keeping only the first 6 terms gives

$$\begin{aligned}
-\sin(t+\mathrm{e}) &= -\sin(\mathrm{e})-\cos(\mathrm{e})\,t+\frac{\sin(\mathrm{e})\,t^2}{2}+\frac{\cos(\mathrm{e})\,t^3}{6}-\frac{\sin(\mathrm{e})\,t^4}{24}-\frac{\cos(\mathrm{e})\,t^5}{120}+\frac{\sin(\mathrm{e})\,t^6}{720}+\dots \\
&= -\sin(\mathrm{e})-\cos(\mathrm{e})\,t+\frac{\sin(\mathrm{e})\,t^2}{2}+\frac{\cos(\mathrm{e})\,t^3}{6}-\frac{\sin(\mathrm{e})\,t^4}{24}-\frac{\cos(\mathrm{e})\,t^5}{120}+\frac{\sin(\mathrm{e})\,t^6}{720}
\end{aligned}$$

Hence the ODE in Eq (1) becomes

$$\begin{aligned}
&\left(1+\mathrm{e}^{-1}t-\frac{\mathrm{e}^{-2}t^2}{2}+\frac{\mathrm{e}^{-3}t^3}{3}-\frac{\mathrm{e}^{-4}t^4}{4}+\frac{\mathrm{e}^{-5}t^5}{5}-\frac{\mathrm{e}^{-6}t^6}{6}\right)\left(\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}\right) \\
&+\left(-\sin(\mathrm{e})-\cos(\mathrm{e})\,t+\frac{\sin(\mathrm{e})\,t^2}{2}+\frac{\cos(\mathrm{e})\,t^3}{6}\right. \\
&\left.-\frac{\sin(\mathrm{e})\,t^4}{24}-\frac{\cos(\mathrm{e})\,t^5}{120}+\frac{\sin(\mathrm{e})\,t^6}{720}\right)\left(\sum_{n=0}^{\infty} a_n t^n\right) = 0
\end{aligned}$$

Expanding the first term in (1) gives

$$\begin{aligned}
&1\cdot\left(\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}\right)+\frac{t}{\mathrm{e}}\cdot\left(\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}\right)-\frac{t^2}{2\left(\mathrm{e}\right)^2} \\
&\cdot\left(\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}\right)+\frac{t^3}{3\left(\mathrm{e}\right)^3}\cdot\left(\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}\right)-\frac{t^4}{4\left(\mathrm{e}\right)^4} \\
&\cdot\left(\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}\right)+\frac{t^5}{5\left(\mathrm{e}\right)^5}\cdot\left(\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}\right)-\frac{t^6}{6\left(\mathrm{e}\right)^6} \\
&\cdot\left(\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}\right)+\left(-\sin(\mathrm{e})-\cos(\mathrm{e})\,t+\frac{\sin(\mathrm{e})\,t^2}{2}\right. \\
&\left.+\frac{\cos(\mathrm{e})\,t^3}{6}-\frac{\sin(\mathrm{e})\,t^4}{24}-\frac{\cos(\mathrm{e})\,t^5}{120}+\frac{\sin(\mathrm{e})\,t^6}{720}\right)\left(\sum_{n=0}^{\infty} a_n t^n\right) = 0
\end{aligned}$$

Expanding the second term in (1) gives

Expression too large to display

Which simplifies to

$$
\begin{aligned}
&\sum_{n=2}^{\infty} \left(-\frac{n\,t^{n+4} a_n (n-1)\,\mathrm{e}^{-6}}{6}\right) + \left(\sum_{n=2}^{\infty} \frac{n\,t^{n+3} a_n (n-1)\,\mathrm{e}^{-5}}{5}\right) \\
&+ \sum_{n=2}^{\infty} \left(-\frac{n\,t^{n+2} a_n (n-1)\,\mathrm{e}^{-4}}{4}\right) + \left(\sum_{n=2}^{\infty} \frac{n\,t^{1+n} a_n (n-1)\,\mathrm{e}^{-3}}{3}\right) \\
&+ \sum_{n=2}^{\infty} \left(-\frac{n a_n t^n (n-1)\,\mathrm{e}^{-2}}{2}\right) + \left(\sum_{n=2}^{\infty} n\,t^{n-1} a_n (n-1)\,\mathrm{e}^{-1}\right) \\
&+ \left(\sum_{n=2}^{\infty} n(n-1)\,a_n t^{n-2}\right) + \sum_{n=0}^{\infty} \left(-a_n t^n \sin\left(\mathrm{e}\right)\right) \\
&+ \sum_{n=0}^{\infty} \left(-t^{1+n} a_n \cos\left(\mathrm{e}\right)\right) + \left(\sum_{n=0}^{\infty} \frac{t^{n+2} a_n \sin\left(\mathrm{e}\right)}{2}\right) \\
&+ \left(\sum_{n=0}^{\infty} \frac{t^{n+3} a_n \cos\left(\mathrm{e}\right)}{6}\right) + \sum_{n=0}^{\infty} \left(-\frac{t^{n+4} a_n \sin\left(\mathrm{e}\right)}{24}\right) \\
&+ \sum_{n=0}^{\infty} \left(-\frac{t^{n+5} a_n \cos\left(\mathrm{e}\right)}{120}\right) + \left(\sum_{n=0}^{\infty} \frac{t^{n+6} a_n \sin\left(\mathrm{e}\right)}{720}\right) = 0
\end{aligned}
\tag{2}
$$

The next step is to make all powers of t be n in each summation term. Going over each summation term above with power of t in it which is not already t^n and adjusting the power and the corresponding index gives

$$
\sum_{n=2}^{\infty} \left(-\frac{n\,t^{n+4} a_n (n-1)\,\mathrm{e}^{-6}}{6}\right) = \sum_{n=6}^{\infty} \left(-\frac{(n-4)\,a_{n-4} (n-5)\,\mathrm{e}^{-6} t^n}{6}\right)
$$

$$
\sum_{n=2}^{\infty} \frac{n\,t^{n+3} a_n (n-1)\,\mathrm{e}^{-5}}{5} = \sum_{n=5}^{\infty} \frac{(n-3)\,a_{n-3} (n-4)\,\mathrm{e}^{-5} t^n}{5}
$$

$$
\sum_{n=2}^{\infty} \left(-\frac{n\,t^{n+2} a_n (n-1)\,\mathrm{e}^{-4}}{4}\right) = \sum_{n=4}^{\infty} \left(-\frac{(n-2)\,a_{n-2} (n-3)\,\mathrm{e}^{-4} t^n}{4}\right)
$$

$$
\sum_{n=2}^{\infty} \frac{n\,t^{1+n} a_n (n-1)\,\mathrm{e}^{-3}}{3} = \sum_{n=3}^{\infty} \frac{(n-1)\,a_{n-1} (n-2)\,\mathrm{e}^{-3} t^n}{3}
$$

$$\sum_{n=2}^{\infty} n\, t^{n-1} a_n (n-1)\, \mathrm{e}^{-1} = \sum_{n=1}^{\infty} (1+n)\, a_{1+n} n\, \mathrm{e}^{-1} t^n$$

$$\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2} (1+n)\, t^n$$

$$\sum_{n=0}^{\infty} \left(-t^{1+n} a_n \cos(\mathrm{e})\right) = \sum_{n=1}^{\infty} \left(-a_{n-1} \cos(\mathrm{e})\, t^n\right)$$

$$\sum_{n=0}^{\infty} \frac{t^{n+2} a_n \sin(\mathrm{e})}{2} = \sum_{n=2}^{\infty} \frac{a_{n-2} \sin(\mathrm{e})\, t^n}{2}$$

$$\sum_{n=0}^{\infty} \frac{t^{n+3} a_n \cos(\mathrm{e})}{6} = \sum_{n=3}^{\infty} \frac{a_{n-3} \cos(\mathrm{e})\, t^n}{6}$$

$$\sum_{n=0}^{\infty} \left(-\frac{t^{n+4} a_n \sin(\mathrm{e})}{24}\right) = \sum_{n=4}^{\infty} \left(-\frac{a_{n-4} \sin(\mathrm{e})\, t^n}{24}\right)$$

$$\sum_{n=0}^{\infty} \left(-\frac{t^{n+5} a_n \cos(\mathrm{e})}{120}\right) = \sum_{n=5}^{\infty} \left(-\frac{a_{n-5} \cos(\mathrm{e})\, t^n}{120}\right)$$

$$\sum_{n=0}^{\infty} \frac{t^{n+6} a_n \sin(\mathrm{e})}{720} = \sum_{n=6}^{\infty} \frac{a_{n-6} \sin(\mathrm{e})\, t^n}{720}$$

Substituting all the above in Eq (2) gives the following equation where now all powers of t are the same and equal to n.

$$\sum_{n=6}^{\infty}\left(-\frac{(n-4)\, a_{n-4}(n-5)\, \mathrm{e}^{-6} t^{n}}{6}\right)+\left(\sum_{n=5}^{\infty}\frac{(n-3)\, a_{n-3}(n-4)\, \mathrm{e}^{-5} t^{n}}{5}\right)$$
$$+\sum_{n=4}^{\infty}\left(-\frac{(n-2)\, a_{n-2}(n-3)\, \mathrm{e}^{-4} t^{n}}{4}\right)$$
$$+\left(\sum_{n=3}^{\infty}\frac{(n-1)\, a_{n-1}(n-2)\, \mathrm{e}^{-3} t^{n}}{3}\right)+\sum_{n=2}^{\infty}\left(-\frac{n a_{n} t^{n}(n-1)\, \mathrm{e}^{-2}}{2}\right)$$
$$+\left(\sum_{n=1}^{\infty}(1+n)\, a_{1+n} n\, \mathrm{e}^{-1} t^{n}\right)+\left(\sum_{n=0}^{\infty}(n+2)\, a_{n+2}(1+n)\, t^{n}\right) \tag{3}$$
$$+\sum_{n=0}^{\infty}\left(-a_{n} t^{n} \sin(\mathrm{e})\right)+\sum_{n=1}^{\infty}\left(-a_{n-1}\cos(\mathrm{e})\, t^{n}\right)+\left(\sum_{n=2}^{\infty}\frac{a_{n-2}\sin(\mathrm{e})\, t^{n}}{2}\right)$$
$$+\left(\sum_{n=3}^{\infty}\frac{a_{n-3}\cos(\mathrm{e})\, t^{n}}{6}\right)+\sum_{n=4}^{\infty}\left(-\frac{a_{n-4}\sin(\mathrm{e})\, t^{n}}{24}\right)$$
$$+\sum_{n=5}^{\infty}\left(-\frac{a_{n-5}\cos(\mathrm{e})\, t^{n}}{120}\right)+\left(\sum_{n=6}^{\infty}\frac{a_{n-6}\sin(\mathrm{e})\, t^{n}}{720}\right)=0$$

$n=0$ gives

$$2a_2 - a_0\sin(\mathrm{e}) = 0$$

$$a_2 = \frac{a_0\sin(\mathrm{e})}{2}$$

$n=1$ gives

$$2a_2\mathrm{e}^{-1} + 6a_3 - a_1\sin(\mathrm{e}) - a_0\cos(\mathrm{e}) = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -\frac{a_0\sin(\mathrm{e})\,\mathrm{e}^{-1}}{6} + \frac{a_0\cos(\mathrm{e})}{6} + \frac{a_1\sin(\mathrm{e})}{6}$$

$n=2$ gives

$$-a_2\mathrm{e}^{-2} + 6a_3\mathrm{e}^{-1} + 12a_4 - a_2\sin(\mathrm{e}) - a_1\cos(\mathrm{e}) + \frac{a_0\sin(\mathrm{e})}{2} = 0$$

Which after substituting earlier equations, simplifies to

$$a_4 = \frac{a_0 \sin(e) e^{-2}}{8} - \frac{e^{-1} a_0 \cos(e)}{12} + \frac{a_0 \sin(e)^2}{24} - \frac{a_0 \sin(e)}{24} - \frac{e^{-1} a_1 \sin(e)}{12} + \frac{a_1 \cos(e)}{12}$$

$n = 3$ gives

$$\frac{2a_2 e^{-3}}{3} - 3a_3 e^{-2} + 12a_4 e^{-1} + 20a_5 - a_3 \sin(e) - a_2 \cos(e) + \frac{a_1 \sin(e)}{2} + \frac{a_0 \cos(e)}{6} = 0$$

Which after substituting earlier equations, simplifies to

$$\begin{aligned} a_5 = &-\frac{a_0 \sin(e) e^{-3}}{15} - \frac{e^{-2} a_0 \sin(e) e^{-1}}{20} + \frac{3 e^{-2} a_0 \cos(e)}{40} \\ &- \frac{e^{-1} a_0 \sin(e)^2}{30} + \frac{a_0 \sin(e) e^{-1}}{40} + \frac{a_0 \sin(e) \cos(e)}{30} - \frac{a_0 \cos(e)}{120} \\ &+ \frac{3 e^{-2} a_1 \sin(e)}{40} - \frac{e^{-1} a_1 \cos(e)}{20} + \frac{a_1 \sin(e)^2}{120} - \frac{a_1 \sin(e)}{40} \end{aligned}$$

$n = 4$ gives

$$\begin{aligned} &-\frac{a_2 e^{-4}}{2} + 2a_3 e^{-3} - 6a_4 e^{-2} + 20a_5 e^{-1} + 30a_6 - a_4 \sin(e) \\ &- a_3 \cos(e) + \frac{a_2 \sin(e)}{2} + \frac{a_1 \cos(e)}{6} - \frac{a_0 \sin(e)}{24} = 0 \end{aligned}$$

Which after substituting earlier equations, simplifies to

$$\begin{aligned} a_6 = &\frac{a_0 \sin(e)^3}{720} + \frac{a_0 \cos(e)^2}{180} + \frac{e^{-1} a_0 \cos(e)}{180} + \frac{e^{-1} a_1 \sin(e)}{60} \\ &+ \frac{a_0 \sin(e) e^{-4}}{20} - \frac{2 e^{-3} a_0 \cos(e)}{45} - \frac{2 e^{-3} a_1 \sin(e)}{45} + \frac{a_0 \sin(e) (e^{-2})^2}{20} \\ &+ \frac{5 e^{-2} a_0 \sin(e)^2}{144} + \frac{e^{-2} a_1 \cos(e)}{20} - \frac{e^{-1} a_1 \sin(e)^2}{120} + \frac{\sin(e) a_1 \cos(e)}{120} \\ &- \frac{a_0 \sin(e) e^{-2}}{40} - \frac{7 a_0 \sin(e)^2}{720} - \frac{e^{-2} e^{-1} a_0 \cos(e)}{30} - \frac{e^{-2} e^{-1} a_1 \sin(e)}{30} \\ &- \frac{11 e^{-1} a_0 \sin(e) \cos(e)}{360} + \frac{e^{-3} a_0 \sin(e) e^{-1}}{45} + \frac{a_0 \sin(e)}{720} - \frac{a_1 \cos(e)}{180} \end{aligned}$$

$n = 5$ gives

$$\begin{aligned} &\frac{2a_2 e^{-5}}{5} - \frac{3a_3 e^{-4}}{2} + 4a_4 e^{-3} - 10a_5 e^{-2} + 30a_6 e^{-1} + 42a_7 - a_5 \sin(e) \\ &- a_4 \cos(e) + \frac{a_3 \sin(e)}{2} + \frac{a_2 \cos(e)}{6} - \frac{a_1 \sin(e)}{24} - \frac{a_0 \cos(e)}{120} = 0 \end{aligned}$$

Which after substituting earlier equations, simplifies to

$$
\begin{aligned}
a_7 = &-\frac{a_0 \sin(\mathrm{e})\,\mathrm{e}^{-5}}{35} + \frac{\mathrm{e}^{-4} a_0 \cos(\mathrm{e})}{28} + \frac{\mathrm{e}^{-4} a_1 \sin(\mathrm{e})}{28} - \frac{59\,\mathrm{e}^{-3} a_0 \sin(\mathrm{e})^2}{2520} \\
&- \frac{2\,\mathrm{e}^{-3} a_1 \cos(\mathrm{e})}{63} + \frac{\left(\mathrm{e}^{-2}\right)^2 a_0 \cos(\mathrm{e})}{28} + \frac{\left(\mathrm{e}^{-2}\right)^2 a_1 \sin(\mathrm{e})}{28} + \frac{7\,\mathrm{e}^{-2} a_1 \sin(\mathrm{e})^2}{720} \\
&- \frac{\mathrm{e}^{-1} a_0 \sin(\mathrm{e})^3}{560} - \frac{\mathrm{e}^{-1} a_0 \cos(\mathrm{e})^2}{168} + \frac{a_0 \sin(\mathrm{e})^2 \cos(\mathrm{e})}{560} - \frac{13 a_1 \sin(\mathrm{e})^2}{5040} \\
&+ \frac{a_1 \sin(\mathrm{e})^3}{5040} + \frac{a_1 \cos(\mathrm{e})^2}{504} - \frac{a_0 \sin(\mathrm{e})\,\mathrm{e}^{-1}}{1008} - \frac{5\,\mathrm{e}^{-4} a_0 \sin(\mathrm{e})\,\mathrm{e}^{-1}}{168} \\
&- \frac{5\,\mathrm{e}^{-3} a_0 \sin(\mathrm{e})\,\mathrm{e}^{-2}}{63} + \frac{\mathrm{e}^{-3}\mathrm{e}^{-1} a_0 \cos(\mathrm{e})}{63} + \frac{\mathrm{e}^{-3}\mathrm{e}^{-1} a_1 \sin(\mathrm{e})}{63} - \frac{9\,\mathrm{e}^{-2}\mathrm{e}^{-1} a_0 \sin(\mathrm{e})^2}{560} \\
&+ \frac{29\,\mathrm{e}^{-2} a_0 \sin(\mathrm{e}) \cos(\mathrm{e})}{840} - \frac{\mathrm{e}^{-2}\mathrm{e}^{-1} a_1 \cos(\mathrm{e})}{42} - \frac{23\,\mathrm{e}^{-1} \sin(\mathrm{e})\, a_1 \cos(\mathrm{e})}{2520} \\
&- \frac{\mathrm{e}^{-2} a_0 \cos(\mathrm{e})}{168} - \frac{\mathrm{e}^{-2} a_1 \sin(\mathrm{e})}{56} + \frac{\mathrm{e}^{-1} a_0 \sin(\mathrm{e})^2}{105} + \frac{\mathrm{e}^{-1} a_1 \cos(\mathrm{e})}{252} + \frac{a_0 \sin(\mathrm{e})\,\mathrm{e}^{-3}}{63} \\
&- \frac{13 a_0 \sin(\mathrm{e}) \cos(\mathrm{e})}{2520} + \frac{\mathrm{e}^{-2} a_0 \sin(\mathrm{e})\,\mathrm{e}^{-1}}{84} + \frac{a_0 \cos(\mathrm{e})}{5040} + \frac{a_1 \sin(\mathrm{e})}{1008}
\end{aligned}
$$

For $6 \leq n$, the recurrence equation is

$$
\begin{aligned}
&-\frac{(n-4)\, a_{n-4}(n-5)\,\mathrm{e}^{-6}}{6} + \frac{(n-3)\, a_{n-3}(n-4)\,\mathrm{e}^{-5}}{5} \\
&- \frac{(n-2)\, a_{n-2}(n-3)\,\mathrm{e}^{-4}}{4} + \frac{(n-1)\, a_{n-1}(n-2)\,\mathrm{e}^{-3}}{3} - \frac{n a_n (n-1)\,\mathrm{e}^{-2}}{2} \\
&+ (1+n)\, a_{1+n} n\,\mathrm{e}^{-1} + (n+2)\, a_{n+2}(1+n) - a_n \sin(\mathrm{e}) - a_{n-1} \cos(\mathrm{e}) \\
&+ \frac{a_{n-2} \sin(\mathrm{e})}{2} + \frac{a_{n-3} \cos(\mathrm{e})}{6} - \frac{a_{n-4} \sin(\mathrm{e})}{24} - \frac{a_{n-5} \cos(\mathrm{e})}{120} + \frac{a_{n-6} \sin(\mathrm{e})}{720} = 0
\end{aligned} \tag{4}
$$

Solving for a_{n+2}, gives

$$
a_{n+2} = \tag{5}
$$

$$
-\frac{144\,\mathrm{e}^{-5} n^2 a_{n-3} - 120\,\mathrm{e}^{-6} n^2 a_{n-4} + 720 a_{1+n} n^2 \mathrm{e}^{-1} + 240\,\mathrm{e}^{-3} n^2 a_{n-1} - 360 n^2 a_n \mathrm{e}^{-2} - 180\,\mathrm{e}^{-4} n^2 a_{n-2} - 1}{}
$$

$$
\begin{aligned}
&= -\frac{\left(-360\,\mathrm{e}^{-2} n^{2}+360\,\mathrm{e}^{-2} n -720 \sin \left(\mathrm{e}\right)\right) a_{n}}{720 \left(n +2\right) \left(1+n \right)}-\frac{\left(720\,\mathrm{e}^{-1} n^{2}+720\,\mathrm{e}^{-1} n \right) a_{1+n}}{720 \left(n +2\right) \left(1+n \right)}\\
&\quad -\frac{\sin \left(\mathrm{e}\right) a_{n -6}}{720 \left(n +2\right) \left(1+n \right)}+\frac{\cos \left(\mathrm{e}\right) a_{n -5}}{120 \left(n +2\right) \left(1+n \right)}\\
&\quad -\frac{\left(-120\,\mathrm{e}^{-6} n^{2}+1080\,\mathrm{e}^{-6} n -30 \sin \left(\mathrm{e}\right)-2400\,\mathrm{e}^{-6}\right) a_{n -4}}{720 \left(n +2\right) \left(1+n \right)}\\
&\quad -\frac{\left(144\,\mathrm{e}^{-5} n^{2}-1008\,\mathrm{e}^{-5} n +1728\,\mathrm{e}^{-5}+120 \cos \left(\mathrm{e}\right)\right) a_{n -3}}{720 \left(n +2\right) \left(1+n \right)}\\
&\quad -\frac{\left(-180\,\mathrm{e}^{-4} n^{2}+900\,\mathrm{e}^{-4} n +360 \sin \left(\mathrm{e}\right)-1080\,\mathrm{e}^{-4}\right) a_{n -2}}{720 \left(n +2\right) \left(1+n \right)}\\
&\quad -\frac{\left(240\,\mathrm{e}^{-3} n^{2}-720\,\mathrm{e}^{-3} n -720 \cos \left(\mathrm{e}\right)+480\,\mathrm{e}^{-3}\right) a_{n -1}}{720 \left(n +2\right) \left(1+n \right)}
\end{aligned}
$$

And so on. Therefore the solution is

$$
\begin{aligned}
y(t) &= \sum_{n=0}^{\infty} a_{n} t^{n}\\
&= a_{3} t^{3}+a_{2} t^{2}+a_{1} t +a_{0}+\dots
\end{aligned}
$$

Substituting the values for a_n found above, the solution becomes

$$
\begin{aligned}
y(t) &= a_{0}+a_{1} t +\frac{a_{0} \sin \left(\mathrm{e}\right) t^{2}}{2}+\left(-\frac{a_{0} \sin \left(\mathrm{e}\right) \mathrm{e}^{-1}}{6}+\frac{a_{0} \cos \left(\mathrm{e}\right)}{6}+\frac{a_{1} \sin \left(\mathrm{e}\right)}{6}\right) t^{3}\\
&\quad +\left(\frac{a_{0} \sin \left(\mathrm{e}\right) \mathrm{e}^{-2}}{8}-\frac{\mathrm{e}^{-1} a_{0} \cos \left(\mathrm{e}\right)}{12}+\frac{a_{0} \sin \left(\mathrm{e}\right)^{2}}{24}-\frac{a_{0} \sin \left(\mathrm{e}\right)}{24}-\frac{\mathrm{e}^{-1} a_{1} \sin \left(\mathrm{e}\right)}{12}\right.\\
&\quad \left.+\frac{a_{1} \cos \left(\mathrm{e}\right)}{12}\right) t^{4}+\left(-\frac{a_{0} \sin \left(\mathrm{e}\right) \mathrm{e}^{-3}}{15}-\frac{\mathrm{e}^{-2} a_{0} \sin \left(\mathrm{e}\right) \mathrm{e}^{-1}}{20}+\frac{3\,\mathrm{e}^{-2} a_{0} \cos \left(\mathrm{e}\right)}{40}\right.\\
&\quad -\frac{\mathrm{e}^{-1} a_{0} \sin \left(\mathrm{e}\right)^{2}}{30}+\frac{a_{0} \sin \left(\mathrm{e}\right) \mathrm{e}^{-1}}{40}+\frac{a_{0} \sin \left(\mathrm{e}\right) \cos \left(\mathrm{e}\right)}{30}-\frac{a_{0} \cos \left(\mathrm{e}\right)}{120}+\frac{3\,\mathrm{e}^{-2} a_{1} \sin \left(\mathrm{e}\right)}{40}\\
&\quad \left.-\frac{\mathrm{e}^{-1} a_{1} \cos \left(\mathrm{e}\right)}{20}+\frac{a_{1} \sin \left(\mathrm{e}\right)^{2}}{120}-\frac{a_{1} \sin \left(\mathrm{e}\right)}{40}\right) t^{5}+\dots
\end{aligned}
$$

Collecting terms, the solution becomes

$$
\begin{aligned}
y(t) = {} & \left(1+\frac{\sin(\mathrm{e})\, t^2}{2}+\left(-\frac{\mathrm{e}^{-1}\sin(\mathrm{e})}{6}+\frac{\cos(\mathrm{e})}{6}\right)t^3\right. \\
& +\left(\frac{\mathrm{e}^{-2}\sin(\mathrm{e})}{8}-\frac{\cos(\mathrm{e})\,\mathrm{e}^{-1}}{12}+\frac{\sin(\mathrm{e})^2}{24}-\frac{\sin(\mathrm{e})}{24}\right)t^4 \\
& +\left(-\frac{\sin(\mathrm{e})\,\mathrm{e}^{-3}}{15}-\frac{\mathrm{e}^{-2}\sin(\mathrm{e})\,\mathrm{e}^{-1}}{20}+\frac{3\,\mathrm{e}^{-2}\cos(\mathrm{e})}{40}-\frac{\sin(\mathrm{e})^2\,\mathrm{e}^{-1}}{30}+\frac{\mathrm{e}^{-1}\sin(\mathrm{e})}{40}\right. \\
& \left.\left.+\frac{\sin(\mathrm{e})\cos(\mathrm{e})}{30}-\frac{\cos(\mathrm{e})}{120}\right)t^5\right)a_0+\left(t+\frac{\sin(\mathrm{e})\, t^3}{6}+\left(-\frac{\mathrm{e}^{-1}\sin(\mathrm{e})}{12}+\frac{\cos(\mathrm{e})}{12}\right)t^4\right. \\
& \left.+\left(\frac{3\,\mathrm{e}^{-2}\sin(\mathrm{e})}{40}-\frac{\cos(\mathrm{e})\,\mathrm{e}^{-1}}{20}+\frac{\sin(\mathrm{e})^2}{120}-\frac{\sin(\mathrm{e})}{40}\right)t^5\right)a_1+O(t^6)
\end{aligned} \tag{3}
$$

At $t=0$ the solution above becomes

$$
\begin{aligned}
y(t) = {} & \left(1+\frac{\sin(\mathrm{e})\, t^2}{2}+\left(-\frac{\mathrm{e}^{-1}\sin(\mathrm{e})}{6}+\frac{\cos(\mathrm{e})}{6}\right)t^3\right. \\
& +\left(\frac{\mathrm{e}^{-2}\sin(\mathrm{e})}{8}-\frac{\cos(\mathrm{e})\,\mathrm{e}^{-1}}{12}+\frac{\sin(\mathrm{e})^2}{24}-\frac{\sin(\mathrm{e})}{24}\right)t^4 \\
& +\left(-\frac{\sin(\mathrm{e})\,\mathrm{e}^{-3}}{15}-\frac{\mathrm{e}^{-2}\sin(\mathrm{e})\,\mathrm{e}^{-1}}{20}+\frac{3\,\mathrm{e}^{-2}\cos(\mathrm{e})}{40}-\frac{\sin(\mathrm{e})^2\,\mathrm{e}^{-1}}{30}+\frac{\mathrm{e}^{-1}\sin(\mathrm{e})}{40}\right. \\
& \left.\left.+\frac{\sin(\mathrm{e})\cos(\mathrm{e})}{30}-\frac{\cos(\mathrm{e})}{120}\right)t^5\right)c_1+\left(t+\frac{\sin(\mathrm{e})\, t^3}{6}+\left(-\frac{\mathrm{e}^{-1}\sin(\mathrm{e})}{12}+\frac{\cos(\mathrm{e})}{12}\right)t^4\right. \\
& \left.+\left(\frac{3\,\mathrm{e}^{-2}\sin(\mathrm{e})}{40}-\frac{\cos(\mathrm{e})\,\mathrm{e}^{-1}}{20}+\frac{\sin(\mathrm{e})^2}{120}-\frac{\sin(\mathrm{e})}{40}\right)t^5\right)c_2+O(t^6)
\end{aligned}
$$

$$
\begin{aligned}
y(t) = {} & \mathrm{e}^{-1}+\frac{\mathrm{e}^{-1}\sin(\mathrm{e})\, t^2}{2}-\frac{(\mathrm{e}^{-1})^2\, t^3\sin(\mathrm{e})}{6}+\frac{t^3\cos(\mathrm{e})\,\mathrm{e}^{-1}}{6}+\frac{\mathrm{e}^{-1}t^4\mathrm{e}^{-2}\sin(\mathrm{e})}{8} \\
& -\frac{(\mathrm{e}^{-1})^2\, t^4\cos(\mathrm{e})}{12}+\frac{t^4\sin(\mathrm{e})^2\,\mathrm{e}^{-1}}{24}-\frac{t^4\mathrm{e}^{-1}\sin(\mathrm{e})}{24}-\frac{\mathrm{e}^{-1}t^5\sin(\mathrm{e})\,\mathrm{e}^{-3}}{15} \\
& -\frac{(\mathrm{e}^{-1})^2\, t^5\mathrm{e}^{-2}\sin(\mathrm{e})}{20}+\frac{3\,\mathrm{e}^{-1}t^5\mathrm{e}^{-2}\cos(\mathrm{e})}{40}-\frac{(\mathrm{e}^{-1})^2\, t^5\sin(\mathrm{e})^2}{30} \\
& +\frac{(\mathrm{e}^{-1})^2\, t^5\sin(\mathrm{e})}{40}+\frac{t^5\mathrm{e}^{-1}\sin(\mathrm{e})\cos(\mathrm{e})}{30}-\frac{t^5\cos(\mathrm{e})\,\mathrm{e}^{-1}}{120}+O(t^6)
\end{aligned}
$$

Replacing t in the above with the original independent variable $x$susing $t = x-\mathrm{e}$ results in

$$
\begin{aligned}
y = \mathrm{e}^{-1}+O\left(\left(x-\mathrm{e}\right)^{6}\right)+\frac{\mathrm{e}^{-1} \sin \left(\mathrm{e}\right) \left(x-\mathrm{e}\right)^{2}}{2}-\frac{\left(x-\mathrm{e}\right)^{3} \mathrm{e}^{-2} \sin \left(\mathrm{e}\right)}{6}+\frac{\left(x-\mathrm{e}\right)^{3} \cos \left(\mathrm{e}\right) \mathrm{e}^{-1}}{6} \\
+\frac{\left(x-\mathrm{e}\right)^{4} \sin \left(\mathrm{e}\right)^{2} \mathrm{e}^{-1}}{24}+\frac{\left(x-\mathrm{e}\right)^{4} \sin \left(\mathrm{e}\right) \mathrm{e}^{-3}}{8}-\frac{\left(x-\mathrm{e}\right)^{4} \mathrm{e}^{-1} \sin \left(\mathrm{e}\right)}{24} \\
-\frac{\left(x-\mathrm{e}\right)^{4} \mathrm{e}^{-2} \cos \left(\mathrm{e}\right)}{12}-\frac{\left(x-\mathrm{e}\right)^{5} \sin \left(\mathrm{e}\right)^{2} \mathrm{e}^{-2}}{30}+\frac{3\left(x-\mathrm{e}\right)^{5} \cos \left(\mathrm{e}\right) \mathrm{e}^{-3}}{40} \\
-\frac{\left(x-\mathrm{e}\right)^{5} \cos \left(\mathrm{e}\right) \mathrm{e}^{-1}}{120}-\frac{7\left(x-\mathrm{e}\right)^{5} \sin \left(\mathrm{e}\right) \mathrm{e}^{-4}}{60}+\frac{\left(x-\mathrm{e}\right)^{5} \mathrm{e}^{-2} \sin \left(\mathrm{e}\right)}{40} \\
+\frac{5\left(x-\mathrm{e}\right)^{6} \sin \left(\mathrm{e}\right)^{2} \mathrm{e}^{-3}}{144}+\frac{11\left(x-\mathrm{e}\right)^{6} \mathrm{e}^{-1} \cos \left(\mathrm{e}\right)^{2}}{720}+\frac{11\left(x-\mathrm{e}\right)^{6} \sin \left(\mathrm{e}\right) \mathrm{e}^{-5}}{90} \\
-\frac{7\left(x-\mathrm{e}\right)^{6} \mathrm{e}^{-4} \cos \left(\mathrm{e}\right)}{90}-\frac{\left(x-\mathrm{e}\right)^{6} \sin \left(\mathrm{e}\right) \mathrm{e}^{-3}}{40}+\frac{\left(x-\mathrm{e}\right)^{6} \mathrm{e}^{-2} \cos \left(\mathrm{e}\right)}{180} \\
+\frac{\left(x-\mathrm{e}\right)^{6} \mathrm{e}^{-1} \sin \left(\mathrm{e}\right)}{360}-\frac{7\left(x-\mathrm{e}\right)^{6} \mathrm{e}^{-1}}{720}+\frac{\left(x-\mathrm{e}\right)^{5} \mathrm{e}^{-1} \sin \left(\mathrm{e}\right) \cos \left(\mathrm{e}\right)}{30} \\
-\frac{\left(x-\mathrm{e}\right)^{6} \sin \left(\mathrm{e}\right) \cos \left(\mathrm{e}\right)^{2} \mathrm{e}^{-1}}{720}-\frac{11\left(x-\mathrm{e}\right)^{6} \mathrm{e}^{-2} \sin \left(\mathrm{e}\right) \cos \left(\mathrm{e}\right)}{360}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = \mathrm{e}^{-1}+O\left(\left(x-\mathrm{e}\right)^{6}\right)+\frac{\mathrm{e}^{-1} \sin \left(\mathrm{e}\right) \left(x-\mathrm{e}\right)^{2}}{2}-\frac{\left(x-\mathrm{e}\right)^{3} \mathrm{e}^{-2} \sin \left(\mathrm{e}\right)}{6} \\
+\frac{\left(x-\mathrm{e}\right)^{3} \cos \left(\mathrm{e}\right) \mathrm{e}^{-1}}{6}+\frac{\left(x-\mathrm{e}\right)^{4} \sin \left(\mathrm{e}\right)^{2} \mathrm{e}^{-1}}{24}+\frac{\left(x-\mathrm{e}\right)^{4} \sin \left(\mathrm{e}\right) \mathrm{e}^{-3}}{8} \\
-\frac{\left(x-\mathrm{e}\right)^{4} \mathrm{e}^{-1} \sin \left(\mathrm{e}\right)}{24}-\frac{\left(x-\mathrm{e}\right)^{4} \mathrm{e}^{-2} \cos \left(\mathrm{e}\right)}{12}-\frac{\left(x-\mathrm{e}\right)^{5} \sin \left(\mathrm{e}\right)^{2} \mathrm{e}^{-2}}{30} \\
+\frac{3\left(x-\mathrm{e}\right)^{5} \cos \left(\mathrm{e}\right) \mathrm{e}^{-3}}{40}-\frac{\left(x-\mathrm{e}\right)^{5} \cos \left(\mathrm{e}\right) \mathrm{e}^{-1}}{120}-\frac{7\left(x-\mathrm{e}\right)^{5} \sin \left(\mathrm{e}\right) \mathrm{e}^{-4}}{60} \\
+\frac{\left(x-\mathrm{e}\right)^{5} \mathrm{e}^{-2} \sin \left(\mathrm{e}\right)}{40}+\frac{5\left(x-\mathrm{e}\right)^{6} \sin \left(\mathrm{e}\right)^{2} \mathrm{e}^{-3}}{144} \\
+\frac{11\left(x-\mathrm{e}\right)^{6} \mathrm{e}^{-1} \cos \left(\mathrm{e}\right)^{2}}{720}+\frac{11\left(x-\mathrm{e}\right)^{6} \sin \left(\mathrm{e}\right) \mathrm{e}^{-5}}{90} \\
-\frac{7\left(x-\mathrm{e}\right)^{6} \mathrm{e}^{-4} \cos \left(\mathrm{e}\right)}{90}-\frac{\left(x-\mathrm{e}\right)^{6} \sin \left(\mathrm{e}\right) \mathrm{e}^{-3}}{40}+\frac{\left(x-\mathrm{e}\right)^{6} \mathrm{e}^{-2} \cos \left(\mathrm{e}\right)}{180} \\
+\frac{\left(x-\mathrm{e}\right)^{6} \mathrm{e}^{-1} \sin \left(\mathrm{e}\right)}{360}-\frac{7\left(x-\mathrm{e}\right)^{6} \mathrm{e}^{-1}}{720}+\frac{\left(x-\mathrm{e}\right)^{5} \mathrm{e}^{-1} \sin \left(\mathrm{e}\right) \cos \left(\mathrm{e}\right)}{30} \\
-\frac{\left(x-\mathrm{e}\right)^{6} \sin \left(\mathrm{e}\right) \cos \left(\mathrm{e}\right)^{2} \mathrm{e}^{-1}}{720}-\frac{11\left(x-\mathrm{e}\right)^{6} \mathrm{e}^{-2} \sin \left(\mathrm{e}\right) \cos \left(\mathrm{e}\right)}{360}
\end{aligned} \tag{1}
$$

Verification of solutions

$$
y = \mathrm{e}^{-1} + O\left((x-\mathrm{e})^{6}\right) + \frac{\mathrm{e}^{-1}\sin(\mathrm{e})(x-\mathrm{e})^{2}}{2} - \frac{(x-\mathrm{e})^{3}\mathrm{e}^{-2}\sin(\mathrm{e})}{6} + \frac{(x-\mathrm{e})^{3}\cos(\mathrm{e})\mathrm{e}^{-1}}{6} + \frac{(x-\mathrm{e})^{4}\sin(\mathrm{e})^{2}\mathrm{e}^{-1}}{24} + \frac{(x-\mathrm{e})^{4}\sin(\mathrm{e})\mathrm{e}^{-3}}{8} - \frac{(x-\mathrm{e})^{4}\mathrm{e}^{-1}\sin(\mathrm{e})}{24} - \frac{(x-\mathrm{e})^{4}\mathrm{e}^{-2}\cos(\mathrm{e})}{12} - \frac{(x-\mathrm{e})^{5}\sin(\mathrm{e})^{2}\mathrm{e}^{-2}}{30} + \frac{3(x-\mathrm{e})^{5}\cos(\mathrm{e})\mathrm{e}^{-3}}{40} - \frac{(x-\mathrm{e})^{5}\cos(\mathrm{e})\mathrm{e}^{-1}}{120} - \frac{7(x-\mathrm{e})^{5}\sin(\mathrm{e})\mathrm{e}^{-4}}{60} + \frac{(x-\mathrm{e})^{5}\mathrm{e}^{-2}\sin(\mathrm{e})}{40} + \frac{5(x-\mathrm{e})^{6}\sin(\mathrm{e})^{2}\mathrm{e}^{-3}}{144} + \frac{11(x-\mathrm{e})^{6}\mathrm{e}^{-1}\cos(\mathrm{e})^{2}}{720} + \frac{11(x-\mathrm{e})^{6}\sin(\mathrm{e})\mathrm{e}^{-5}}{90} - \frac{7(x-\mathrm{e})^{6}\mathrm{e}^{-4}\cos(\mathrm{e})}{90} - \frac{(x-\mathrm{e})^{6}\sin(\mathrm{e})\mathrm{e}^{-3}}{40} + \frac{(x-\mathrm{e})^{6}\mathrm{e}^{-2}\cos(\mathrm{e})}{180} + \frac{(x-\mathrm{e})^{6}\mathrm{e}^{-1}\sin(\mathrm{e})}{360} - \frac{7(x-\mathrm{e})^{6}\mathrm{e}^{-1}}{720} + \frac{(x-\mathrm{e})^{5}\mathrm{e}^{-1}\sin(\mathrm{e})\cos(\mathrm{e})}{30} - \frac{(x-\mathrm{e})^{6}\sin(\mathrm{e})\cos(\mathrm{e})^{2}\mathrm{e}^{-1}}{720} - \frac{11(x-\mathrm{e})^{6}\mathrm{e}^{-2}\sin(\mathrm{e})\cos(\mathrm{e})}{360}
$$

Verified OK.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup", "first order ode series method. Ordinary point", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - 2yx = 0}$$

With initial conditions

$$[y(0) = 1]$$

With the expansion point for the power series method at $x = 0$.

23.9.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -2x \\ q(x) &= 0 \end{aligned}$$

Hence the ode is

$$y' - 2yx = 0$$

The domain of $p(x) = -2x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. Hence solution exists and is unique.

23.9.2 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor series

$$\begin{aligned} y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y''(x_0) + \cdots \\ &= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\ &= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0} \end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \tag{1}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y)$ then the above can be written as

$$F_0 = f(x,y) \tag{4}$$

$$F_n = \frac{d}{dx}(F_{n-1})$$

$$= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \tag{5}$$

For example, for $n = 1$ we see that

$$\begin{aligned} F_1 &= \frac{d}{dx}(F_0) \\ &= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\ &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \end{aligned}$$

Which is (1). And when $n = 2$

$$\begin{aligned} F_2 &= \frac{d}{dx}(F_1) \\ &= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) F_0 \\ &= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) f \\ &= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} F_n|_{x_0,y_0} \tag{6}$$

Hence

$$\begin{aligned}
F_0 &= 2yx \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} F_0 \\
&= (4x^2+2)\, y \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} F_1 \\
&= (8x^3+12x)\, y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} F_2 \\
&= 4y(4x^4+12x^2+3) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} F_3 \\
&= 32yx\left(x^4+5x^2+\frac{15}{4}\right)
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = 1$ gives

$$\begin{aligned}
F_0 &= 0 \\
F_1 &= 2 \\
F_2 &= 0 \\
F_3 &= 12 \\
F_4 &= 0
\end{aligned}$$

Substituting all the above in (6) and simplifying gives the solution as

$$y = x^2 + 1 + \frac{x^4}{2} + O(x^6)$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = y(0)$$

Therefore the solution becomes

$$y = x^2 + 1 + \frac{1}{2}x^4$$

Hence the solution can be written as

$$y = x^2 + 1 + \frac{x^4}{2} + O(x^6)$$

which simplifies to

$$y = x^2 + 1 + \frac{x^4}{2} + O(x^6)$$

Since $x = 0$ is also an ordinary point, then standard power series can also be used. Writing the ODE as

$$\begin{aligned} y' + q(x)y &= p(x) \\ y' - 2yx &= 0 \end{aligned}$$

Where

$$\begin{aligned} q(x) &= -2x \\ p(x) &= 0 \end{aligned}$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not. Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$
y' = \sum_{n=1}^{\infty} n a_n x^{n-1}
$$

Substituting the above back into the ode gives

$$
\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - 2\left(\sum_{n=0}^{\infty} a_n x^n\right) x = 0 \tag{1}
$$

Which simplifies to

$$
\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \sum_{n=0}^{\infty} \left(-2x^{1+n} a_n\right) = 0 \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=1}^{\infty} n a_n x^{n-1} &= \sum_{n=0}^{\infty} (1+n) a_{1+n} x^n \\
\sum_{n=0}^{\infty} \left(-2x^{1+n} a_n\right) &= \sum_{n=1}^{\infty} \left(-2a_{n-1} x^n\right)
\end{aligned}
$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$
\left(\sum_{n=0}^{\infty} (1+n) a_{1+n} x^n\right) + \sum_{n=1}^{\infty} \left(-2a_{n-1} x^n\right) = 0 \tag{3}
$$

For $1 \leq n$, the recurrence equation is

$$
(1+n) a_{1+n} - 2a_{n-1} = 0 \tag{4}
$$

Solving for a_{1+n}, gives

$$
a_{1+n} = \frac{2a_{n-1}}{1+n} \tag{5}
$$

For $n = 1$ the recurrence equation gives

$$2a_2 - 2a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_2 = a_0$$

For $n = 2$ the recurrence equation gives

$$3a_3 - 2a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = 0$$

For $n = 3$ the recurrence equation gives

$$4a_4 - 2a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{2}$$

For $n = 4$ the recurrence equation gives

$$5a_5 - 2a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = 0$$

For $n = 5$ the recurrence equation gives

$$6a_6 - 2a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_0}{6}$$

And so on. Therefore the solution is

$$
\begin{aligned}
y &= \sum_{n=0}^{\infty} a_n x^n \\
&= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots
\end{aligned}
$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_0 x^2 + \frac{1}{2} a_0 x^4 + \dots$$

Collecting terms, the solution becomes

$$y = \left(x^2 + 1 + \frac{1}{2} x^4\right) a_0 + O\left(x^6\right) \tag{3}$$

At $x = 0$ the solution above becomes

$$y(0) = a_0$$

Therefore the solution in Eq(3) now can be written as

$$y = \left(x^2 + 1 + \frac{1}{2} x^4\right) y(0) + O\left(x^6\right)$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = 1$$

Therefore the solution becomes

$$y = x^2 + 1 + \frac{1}{2} x^4$$

Hence the solution can be written as

$$y = x^2 + 1 + \frac{x^4}{2} + O\left(x^6\right)$$

which simplifies to

$$y = x^2 + 1 + \frac{x^4}{2} + O\left(x^6\right)$$

Summary
The solution(s) found are the following

$$y = x^2 + 1 + \frac{x^4}{2} + O(x^6) \tag{1}$$
$$y = x^2 + 1 + \frac{x^4}{2} + O(x^6) \tag{2}$$

Verification of solutions

$$y = x^2 + 1 + \frac{x^4}{2} + O(x^6)$$

Verified OK.

$$y = x^2 + 1 + \frac{x^4}{2} + O(x^6)$$

Verified OK.

23.9.3 Maple step by step solution

Let's solve

$[y' - 2yx = 0, y(0) = 1]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = 2x$

- Integrate both sides with respect to x

  $\int \frac{y'}{y} dx = \int 2x dx + c_1$

- Evaluate integral

  $\ln(y) = x^2 + c_1$

- Solve for y

  $y = e^{x^2 + c_1}$

- Use initial condition $y(0) = 1$

  $1 = e^{c_1}$

- Solve for c_1

  $c_1 = 0$

- Substitute $c_1 = 0$ into general solution and simplify

  $y = e^{x^2}$

- Solution to the IVP

  $y = e^{x^2}$

Section: Chapter 2 (Higher order ODE's). Section 18.1 Integration of differential equation in series. Power series. Exercises page 171
Problem number: 733.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{y'' + y'x + y = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using

Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0, y_0, y_0'} + \frac{x^3}{3!} f'|_{x_0, y_0, y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left. \frac{d^n f}{dx^n} \right|_{x_0, y_0, y_0'}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} \frac{dx}{dx} + \frac{\partial f}{\partial y} \frac{dy}{dx} + \frac{\partial f}{\partial y'} \frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (1224) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (1225) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx} \left(\frac{df}{dx} \right) \\
&= \frac{\partial}{\partial x} \left(\frac{df}{dx} \right) + \frac{\partial}{\partial y} \left(\frac{df}{dx} \right) y' + \frac{\partial}{\partial y'} \left(\frac{df}{dx} \right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx} \left(\frac{d^2 f}{dx^2} \right) \\
&= \frac{\partial}{\partial x} \left(\frac{d^2 f}{dx^2} \right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2} \right) y' + \frac{\partial}{\partial y'} \left(\frac{d^2 f}{dx^2} \right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x, y, y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \tag{7}$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -y'x - y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= y'x^2 + yx - 2y' \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= -y'x^3 - yx^2 + 5y'x + 3y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(x^4 - 9x^2 + 8\right) y' + yx\left(x^2 - 7\right) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(-x^5 + 14x^3 - 33x\right) y' - y\left(x^4 - 12x^2 + 15\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=y(0)$ and $y'(0)=y'(0)$ gives

$$
\begin{aligned}
F_0 &= -y(0) \\
F_1 &= -2y'(0) \\
F_2 &= 3y(0) \\
F_3 &= 8y'(0) \\
F_4 &= -15y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6\right) y(0) + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5\right) y'(0) + O\left(x^6\right)
$$

Since the expansion point $x=0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x - \left(\sum_{n=0}^{\infty} a_n x^n\right) \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + a_0 = 0$$

$$a_2 = -\frac{a_0}{2}$$

For $1 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(n+1) + n a_n + a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{a_n}{n+2} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$6a_3 + 2a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{a_1}{3}$$

For $n = 2$ the recurrence equation gives

$$12a_4 + 3a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{8}$$

For $n = 3$ the recurrence equation gives

$$20a_5 + 4a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_1}{15}$$

For $n = 4$ the recurrence equation gives

$$30a_6 + 5a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{a_0}{48}$$

For $n = 5$ the recurrence equation gives

$$42a_7 + 6a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{a_1}{105}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x - \frac{1}{2} a_0 x^2 - \frac{1}{3} a_1 x^3 + \frac{1}{8} a_0 x^4 + \frac{1}{15} a_1 x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4\right) a_0 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5\right) a_1 + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4\right) c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5\right) c_2 + O(x^6)$$

Summary

The solution(s) found are the following

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6\right) y(0) + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5\right) y'(0) + O(x^6) \tag{1}$$

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4\right) c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5\right) c_2 + O(x^6) \tag{2}$$

Verification of solutions

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6\right) y(0) + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5\right) y'(0) + O(x^6)$$

Verified OK.

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4\right) c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5\right) c_2 + O(x^6)$$

Verified OK.

23.10.1 Maple step by step solution

Let's solve

$y'' = -y'x - y$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + y'x + y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  ◦ Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert y'' to series expansion

  $y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k- >k+2$

  $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_k(k+1)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k+1)\left(a_{k+2}(k+2) + a_k\right) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k}{k+2}\right]$

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second_order_change_of_variable_on_y_method_2", "second order series method. Taylor series method", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - y'x + y = 1}$$

With initial conditions

$$[y(0) = 0, y'(0) = 0]$$

With the expansion point for the power series method at $x = 0$.

23.11.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -x \\ q(x) &= 1 \\ F &= 1 \end{aligned}$$

Hence the ode is

$$y'' - y'x + y = 1$$

The domain of $p(x) = -x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (1227)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (1228)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3)\\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{align*}
F_0 &= f(x, y, y') \tag{4}\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{5}\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \tag{6}
\end{align*}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \tag{7}
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= y'x - y + 1 \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= (y'x - y + 1)\, x \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \left(x^2 + 1\right)(y'x - y + 1) \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= x\left(x^2 + 3\right)(y'x - y + 1) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= (y'x - y + 1)\left(x^4 + 6x^2 + 3\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = 0$ and $y'(0) = 0$ gives

$$
\begin{aligned}
F_0 &= 1 \\
F_1 &= 0 \\
F_2 &= 1 \\
F_3 &= 0 \\
F_4 &= 3
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \frac{x^2}{2} + \frac{x^4}{24} + \frac{x^6}{240} + O\left(x^6\right)
$$

$$
y = \frac{x^2}{2} + \frac{x^4}{24} + \frac{x^6}{240} + O\left(x^6\right)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x - \left(\sum_{n=0}^{\infty} a_n x^n\right) + 1 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + \sum_{n=1}^{\infty} (-n\, x^n a_n) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 1 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n\right) + \sum_{n=1}^{\infty} (-n\, x^n a_n) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 1 \tag{3}$$

$n = 0$ gives

$$(2a_2 + a_0) x^0 = 1$$
$$2a_2 + a_0 = 1$$

$$a_2 = -\frac{a_0}{2} + \frac{1}{2}$$

For $1 \leq n$, the recurrence equation is

$$\left(\left(n+2\right) a_{n+2}\left(n+1\right)-n a_{n}+a_{n}\right) x^{n} = 1 \tag{4}$$

For $n = 1$ the recurrence equation gives

$$\begin{aligned}(6a_3)\, x &= 0\\ 6a_3 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_3 = 0$$

For $n = 2$ the recurrence equation gives

$$\begin{aligned}(12a_4 - a_2)\, x^2 &= 0\\ 12a_4 - a_2 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{1}{24} - \frac{a_0}{24}$$

For $n = 3$ the recurrence equation gives

$$\begin{aligned}(20a_5 - 2a_3)\, x^3 &= 0\\ 20a_5 - 2a_3 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_5 = 0$$

For $n = 4$ the recurrence equation gives

$$\begin{aligned}(30a_6 - 3a_4)\, x^4 &= 0\\ 30a_6 - 3a_4 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{1}{240} - \frac{a_0}{240}$$

For $n = 5$ the recurrence equation gives

$$\begin{aligned}(42a_7 - 4a_5)\, x^5 &= 0 \\ 42a_7 - 4a_5 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_7 = 0$$

And so on. Therefore the solution is

$$\begin{aligned}y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots\end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + \left(-\frac{a_0}{2} + \frac{1}{2}\right) x^2 + \left(\frac{1}{24} - \frac{a_0}{24}\right) x^4 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{1}{2}x^2 - \frac{1}{24}x^4\right) a_0 + a_1 x + \frac{x^2}{2} + \frac{x^4}{24} + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{1}{2}x^2 - \frac{1}{24}x^4\right) c_1 + c_2 x + \frac{x^2}{2} + \frac{x^4}{24} + O(x^6)$$

$$y = \frac{x^2}{2} + \frac{x^4}{24} + O(x^6)$$

Summary
The solution(s) found are the following

$$y = \frac{x^2}{2} + \frac{x^4}{24} + \frac{x^6}{240} + O(x^6) \tag{1}$$

$$y = \frac{x^2}{2} + \frac{x^4}{24} + O(x^6) \tag{2}$$

Verification of solutions

$$y = \frac{x^2}{2} + \frac{x^4}{24} + \frac{x^6}{240} + O(x^6)$$

Verified OK.

$$y = \frac{x^2}{2} + \frac{x^4}{24} + O(x^6)$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - (x^2 + 1)\, y = 0}$$

With initial conditions

$$[y(0) = -2, y'(0) = 2]$$

With the expansion point for the power series method at $x = 0$.

23.12.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= -x^2 - 1 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + (-x^2 - 1)\,y = 0$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -x^2 - 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\,y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{1230}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{1231}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} F_n|_{x_0,y_0,y_0'} \tag{7}$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= \left(x^2+1\right) y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= 2yx + \left(x^2+1\right) y' \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= 4y'x + y\left(x^4+2x^2+3\right) \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= 8yx\left(x^2+1\right) + \left(x^4+2x^2+7\right) y' \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= 12\left(x^3+x\right) y' + y\left(x^6+3x^4+33x^2+15\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=-2$ and $y'(0)=2$ gives

$$
\begin{aligned}
F_0 &= -2 \\
F_1 &= 2 \\
F_2 &= -6 \\
F_3 &= 14 \\
F_4 &= -30
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = -x^2 + 2x - 2 + \frac{x^3}{3} - \frac{x^4}{4} + \frac{7x^5}{60} - \frac{x^6}{24} + O\left(x^6\right)
$$

$$
y = -x^2 + 2x - 2 + \frac{x^3}{3} - \frac{x^4}{4} + \frac{7x^5}{60} - \frac{x^6}{24} + O\left(x^6\right)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = (x^2+1) \left(\sum_{n=0}^{\infty} a_n x^n \right) \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} \right) + \sum_{n=0}^{\infty} \left(-x^{n+2} a_n\right) + \sum_{n=0}^{\infty} \left(-a_n x^n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n$$
$$\sum_{n=0}^{\infty} \left(-x^{n+2} a_n\right) = \sum_{n=2}^{\infty} \left(-a_{n-2} x^n\right)$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n \right) + \sum_{n=2}^{\infty} \left(-a_{n-2} x^n\right) + \sum_{n=0}^{\infty} \left(-a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 - a_0 = 0$$

$$a_2 = \frac{a_0}{2}$$

$n = 1$ gives

$$6a_3 - a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = \frac{a_1}{6}$$

For $2 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(n+1) - a_{n-2} - a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= \frac{a_{n-2} + a_n}{(n+2)\,(n+1)} \\ &= \frac{a_n}{(n+2)\,(n+1)} + \frac{a_{n-2}}{(n+2)\,(n+1)} \end{aligned} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$12a_4 - a_0 - a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{8}$$

For $n = 3$ the recurrence equation gives

$$20a_5 - a_1 - a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{7a_1}{120}$$

For $n = 4$ the recurrence equation gives

$$30a_6 - a_2 - a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_0}{48}$$

For $n = 5$ the recurrence equation gives

$$42a_7 - a_3 - a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{3a_1}{560}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + \frac{1}{2} a_0 x^2 + \frac{1}{6} a_1 x^3 + \frac{1}{8} a_0 x^4 + \frac{7}{120} a_1 x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + \frac{1}{2}x^2 + \frac{1}{8}x^4\right) a_0 + \left(x + \frac{1}{6}x^3 + \frac{7}{120}x^5\right) a_1 + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 + \frac{1}{2}x^2 + \frac{1}{8}x^4\right) c_1 + \left(x + \frac{1}{6}x^3 + \frac{7}{120}x^5\right) c_2 + O(x^6)$$

$$y = -2 - x^2 - \frac{x^4}{4} + 2x + \frac{x^3}{3} + \frac{7x^5}{60} + O(x^6)$$

<u>Summary</u>
The solution(s) found are the following

$$y = -x^2 + 2x - 2 + \frac{x^3}{3} - \frac{x^4}{4} + \frac{7x^5}{60} - \frac{x^6}{24} + O(x^6) \tag{1}$$

$$y = -2 - x^2 - \frac{x^4}{4} + 2x + \frac{x^3}{3} + \frac{7x^5}{60} + O(x^6) \tag{2}$$

Verification of solutions

$$y = -x^2 + 2x - 2 + \frac{x^3}{3} - \frac{x^4}{4} + \frac{7x^5}{60} - \frac{x^6}{24} + O(x^6)$$

Verified OK.

$$y = -2 - x^2 - \frac{x^4}{4} + 2x + \frac{x^3}{3} + \frac{7x^5}{60} + O(x^6)$$

Verified OK.

23.12.2 Maple step by step solution

Let's solve

$\left[y'' = (x^2+1)\, y, y(0) = -2, y'\Big|_{\{x=0\}} = 2\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + (-x^2 - 1)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  - Shift index using $k->k-m$

    $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  - Convert y'' to series expansion

    $y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  - Shift index using $k->k+2$

    $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

Rewrite ODE with series expansions

$$2a_2 - a_0 + (6a_3 - a_1)x + \left(\sum_{k=2}^{\infty} (a_{k+2}(k+2)(k+1) - a_k - a_{k-2})x^k\right) = 0$$

- The coefficients of each power of x must be 0

  $[2a_2 - a_0 = 0, 6a_3 - a_1 = 0]$

- Solve for the dependent coefficient(s)

  $\left\{a_2 = \frac{a_0}{2}, a_3 = \frac{a_1}{6}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $(k^2 + 3k + 2)a_{k+2} - a_k - a_{k-2} = 0$

- Shift index using $k- >k + 2$

  $\left((k+2)^2 + 3k + 8\right)a_{k+4} - a_{k+2} - a_k = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = \frac{a_{k+2}+a_k}{k^2+7k+12}, a_2 = \frac{a_0}{2}, a_3 = \frac{a_1}{6}\right]$

Section: Chapter 2 (Higher order ODE's). Section 18.1 Integration of differential equation in series. Power series. Exercises page 171
Problem number: 736.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - yx^2 + y' = 0}$$

With initial conditions

$$[y(0) = 1, y'(0) = 0]$$

With the expansion point for the power series method at $x = 0$.

23.13.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 1 \\ q(x) &= -x^2 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - yx^2 + y' = 0$$

The domain of $p(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -x^2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned} y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\ &= y_0 + xy'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\ &= y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0} \end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{1234}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{1235}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= yx^2 - y' \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \left(x^2+1\right) y' - yx(x-2) \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \left(-2x^2+4x-1\right) y' + y\left(x^4+x^2-2x+2\right) \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(x^4+3x^2-10x+7\right) y' - 2y\left(x^4-4x^3+\frac{1}{2}x^2-x+1\right) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(-3x^4+12x^3-4x^2+18x-19\right) y' + y\left(x^6+3x^4-18x^3+31x^2-2x+2\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=1$ and $y'(0)=0$ gives

$$
\begin{aligned}
F_0 &= 0 \\
F_1 &= 0 \\
F_2 &= 2 \\
F_3 &= -2 \\
F_4 &= 2
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = 1 + \frac{x^4}{12} - \frac{x^5}{60} + \frac{x^6}{360} + O\left(x^6\right)
$$

$$
y = 1 + \frac{x^4}{12} - \frac{x^5}{60} + \frac{x^6}{360} + O\left(x^6\right)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \left(\sum_{n=0}^{\infty} a_n x^n\right) x^2 - \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \sum_{n=0}^{\infty} \left(-x^{n+2} a_n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n$$
$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n$$
$$\sum_{n=0}^{\infty} \left(-x^{n+2} a_n\right) = \sum_{n=2}^{\infty} \left(-a_{n-2} x^n\right)$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n\right) + \left(\sum_{n=0}^{\infty} (n+1) a_{n+1} x^n\right) + \sum_{n=2}^{\infty} \left(-a_{n-2} x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + a_1 = 0$$

$$a_2 = -\frac{a_1}{2}$$

$n = 1$ gives

$$6a_3 + 2a_2 = 0$$

Which after substituting earlier equations, simplifies to

$$6a_3 - a_1 = 0$$

Or

$$a_3 = \frac{a_1}{6}$$

For $2 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(n+1) + (n+1)\, a_{n+1} - a_{n-2} = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{n a_{n+1} - a_{n-2} + a_{n+1}}{(n+2)\,(n+1)} \\ &= \frac{a_{n-2}}{(n+2)\,(n+1)} - \frac{a_{n+1}}{n+2} \end{aligned} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$12a_4 + 3a_3 - a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{a_1}{24} + \frac{a_0}{12}$$

For $n = 3$ the recurrence equation gives

$$20a_5 + 4a_4 - a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{7a_1}{120} - \frac{a_0}{60}$$

For $n = 4$ the recurrence equation gives

$$30a_6 + 5a_5 - a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{19a_1}{720} + \frac{a_0}{360}$$

For $n = 5$ the recurrence equation gives

$$42a_7 + 6a_6 - a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{13a_1}{1680} - \frac{a_0}{2520}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x - \frac{a_1 x^2}{2} + \frac{a_1 x^3}{6} + \left(-\frac{a_1}{24} + \frac{a_0}{12}\right) x^4 + \left(\frac{7a_1}{120} - \frac{a_0}{60}\right) x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + \frac{1}{12}x^4 - \frac{1}{60}x^5\right) a_0 + \left(x - \frac{1}{2}x^2 + \frac{1}{6}x^3 - \frac{1}{24}x^4 + \frac{7}{120}x^5\right) a_1 + O(x^6) \quad (3)$$

At $x = 0$ the solution above becomes

$$y = \left(1 + \frac{1}{12}x^4 - \frac{1}{60}x^5\right) c_1 + \left(x - \frac{1}{2}x^2 + \frac{1}{6}x^3 - \frac{1}{24}x^4 + \frac{7}{120}x^5\right) c_2 + O(x^6)$$

$$y = 1 + \frac{x^4}{12} - \frac{x^5}{60} + O(x^6)$$

<u>Summary</u>

The solution(s) found are the following

$$y = 1 + \frac{x^4}{12} - \frac{x^5}{60} + \frac{x^6}{360} + O(x^6) \tag{1}$$

$$y = 1 + \frac{x^4}{12} - \frac{x^5}{60} + O(x^6) \tag{2}$$

<u>Verification of solutions</u>

$$y = 1 + \frac{x^4}{12} - \frac{x^5}{60} + \frac{x^6}{360} + O(x^6)$$

Verified OK.

$$y = 1 + \frac{x^4}{12} - \frac{x^5}{60} + O(x^6)$$

Verified OK.

23.13.2 Maple step by step solution

Let's solve

$$\left[y'' = yx^2 - y', y(0) = 1, y'\Big|_{\{x=0\}} = 0\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - yx^2 + y' = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ◦ Convert $x^2 \cdot y$ to series expansion

    $x^2 \cdot y = \sum_{k=0}^{\infty} a_k x^{k+2}$

  ◦ Shift index using $k- >k-2$

$$x^2 \cdot y = \sum_{k=2}^{\infty} a_{k-2} x^k$$

- Convert y' to series expansion

$$y' = \sum_{k=1}^{\infty} a_k k\, x^{k-1}$$

- Shift index using $k- >k+1$

$$y' = \sum_{k=0}^{\infty} a_{k+1}(k+1)\, x^k$$

- Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k- >k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite ODE with series expansions

$$2a_2 + a_1 + (6a_3 + 2a_2)\, x + \left(\sum_{k=2}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_{k+1}(k+1) - a_{k-2}\right) x^k\right) = 0$$

- The coefficients of each power of x must be 0

$$[2a_2 + a_1 = 0, 6a_3 + 2a_2 = 0]$$

- Solve for the dependent coefficient(s)

$$\left\{a_2 = -\frac{a_1}{2}, a_3 = \frac{a_1}{6}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$(k^2 + 3k + 2)\, a_{k+2} + a_{k+1} k - a_{k-2} + a_{k+1} = 0$$

- Shift index using $k- >k+2$

$$\left((k+2)^2 + 3k + 8\right) a_{k+4} + a_{k+3}(k+2) - a_k + a_{k+3} = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{k a_{k+3} - a_k + 3a_{k+3}}{k^2 + 7k + 12}, a_2 = -\frac{a_1}{2}, a_3 = \frac{a_1}{6}\right]$$

Problem number: 737.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode_form_A", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y'' - y\,e^{x} = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\,y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + xy'_0 + \frac{x^2}{2} f|_{x_0,y_0,y'_0} + \frac{x^3}{3!} f'|_{x_0,y_0,y'_0} + \cdots \\
&= y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y'_0}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{1238}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{1239}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy'_0 + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}F_n|_{x_0,y_0,y'_0} \qquad (7)
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= y\,\mathrm{e}^x \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \mathrm{e}^x (y' + y) \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \mathrm{e}^x (y\,\mathrm{e}^x + y + 2y') \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= (4y + y')\,\mathrm{e}^{2x} + \mathrm{e}^x (y + 3y') \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= (11y + 6y')\,\mathrm{e}^{2x} + y\,\mathrm{e}^{3x} + \mathrm{e}^x (y + 4y')
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= y(0) \\
F_1 &= y'(0) + y(0) \\
F_2 &= 2y(0) + 2y'(0) \\
F_3 &= 5y(0) + 4y'(0) \\
F_4 &= 13y(0) + 10y'(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = {} & \left(1 + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{12}x^4 + \frac{1}{24}x^5 + \frac{13}{720}x^6\right) y(0) \\
& + \left(x + \frac{1}{6}x^3 + \frac{1}{12}x^4 + \frac{1}{30}x^5 + \frac{1}{72}x^6\right) y'(0) + O(x^6)
\end{aligned}
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \left(\sum_{n=0}^{\infty} a_n x^n\right) \mathrm{e}^{x} \tag{1}$$

Expanding $-\mathrm{e}^{x}$ as Taylor series around $x = 0$ and keeping only the first 6 terms gives

$$\begin{aligned} -\mathrm{e}^{x} &= -1 - x - \frac{1}{2}x^2 - \frac{1}{6}x^3 - \frac{1}{24}x^4 - \frac{1}{120}x^5 - \frac{1}{720}x^6 + \dots \\ &= -1 - x - \frac{1}{2}x^2 - \frac{1}{6}x^3 - \frac{1}{24}x^4 - \frac{1}{120}x^5 - \frac{1}{720}x^6 \end{aligned}$$

Hence the ODE in Eq (1) becomes

$$\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + \left(-1 - x - \frac{1}{2}x^2 - \frac{1}{6}x^3 - \frac{1}{24}x^4 - \frac{1}{120}x^5 - \frac{1}{720}x^6\right)\left(\sum_{n=0}^{\infty} a_n x^n\right) = 0$$

Expanding the second term in (1) gives

$$\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + -1 \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) - x \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) - \frac{x^2}{2} \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) - \frac{x^3}{6} \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) - \frac{x^4}{24} \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) - \frac{x^5}{120} \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) - \frac{x^6}{720} \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \sum_{n\,=0}^{\infty} \left(-a_n x^n\right) + \sum_{n\,=0}^{\infty} \left(-x^{1+n} a_n\right) \\
&\quad + \sum_{n\,=0}^{\infty} \left(-\frac{x^{n+2} a_n}{2}\right) + \sum_{n\,=0}^{\infty} \left(-\frac{x^{n+3} a_n}{6}\right) + \sum_{n\,=0}^{\infty} \left(-\frac{x^{n+4} a_n}{24}\right) \\
&\quad + \sum_{n\,=0}^{\infty} \left(-\frac{x^{n+5} a_n}{120}\right) + \sum_{n\,=0}^{\infty} \left(-\frac{x^{n+6} a_n}{720}\right) = 0
\end{aligned} \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n\,=2}^{\infty} n(n-1)\, a_n x^{n-2} &= \sum_{n=0}^{\infty} (n+2)\, a_{n+2} (1+n)\, x^n \\
\sum_{n\,=0}^{\infty} \left(-x^{1+n} a_n\right) &= \sum_{n=1}^{\infty} \left(-a_{n-1} x^n\right) \\
\sum_{n\,=0}^{\infty} \left(-\frac{x^{n+2} a_n}{2}\right) &= \sum_{n=2}^{\infty} \left(-\frac{a_{n-2} x^n}{2}\right) \\
\sum_{n\,=0}^{\infty} \left(-\frac{x^{n+3} a_n}{6}\right) &= \sum_{n=3}^{\infty} \left(-\frac{a_{n-3} x^n}{6}\right) \\
\sum_{n\,=0}^{\infty} \left(-\frac{x^{n+4} a_n}{24}\right) &= \sum_{n=4}^{\infty} \left(-\frac{a_{n-4} x^n}{24}\right) \\
\sum_{n\,=0}^{\infty} \left(-\frac{x^{n+5} a_n}{120}\right) &= \sum_{n=5}^{\infty} \left(-\frac{a_{n-5} x^n}{120}\right) \\
\sum_{n\,=0}^{\infty} \left(-\frac{x^{n+6} a_n}{720}\right) &= \sum_{n=6}^{\infty} \left(-\frac{a_{n-6} x^n}{720}\right)
\end{aligned}
$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^n\right) + \sum_{n=0}^{\infty} (-a_n x^n) + \sum_{n=1}^{\infty} (-a_{n-1} x^n) + \sum_{n=2}^{\infty} \left(-\frac{a_{n-2} x^n}{2}\right) + \sum_{n=3}^{\infty} \left(-\frac{a_{n-3} x^n}{6}\right) + \sum_{n=4}^{\infty} \left(-\frac{a_{n-4} x^n}{24}\right) + \sum_{n=5}^{\infty} \left(-\frac{a_{n-5} x^n}{120}\right) + \sum_{n=6}^{\infty} \left(-\frac{a_{n-6} x^n}{720}\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 - a_0 = 0$$

$$a_2 = \frac{a_0}{2}$$

$n = 1$ gives

$$6a_3 - a_1 - a_0 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = \frac{a_0}{6} + \frac{a_1}{6}$$

$n = 2$ gives

$$12a_4 - a_2 - a_1 - \frac{a_0}{2} = 0$$

Which after substituting earlier equations, simplifies to

$$a_4 = \frac{a_0}{12} + \frac{a_1}{12}$$

$n = 3$ gives

$$20a_5 - a_3 - a_2 - \frac{a_1}{2} - \frac{a_0}{6} = 0$$

Which after substituting earlier equations, simplifies to

$$a_5 = \frac{a_0}{24} + \frac{a_1}{30}$$

$n = 4$ gives

$$30a_6 - a_4 - a_3 - \frac{a_2}{2} - \frac{a_1}{6} - \frac{a_0}{24} = 0$$

Which after substituting earlier equations, simplifies to

$$a_6 = \frac{13a_0}{720} + \frac{a_1}{72}$$

$n = 5$ gives

$$42a_7 - a_5 - a_4 - \frac{a_3}{2} - \frac{a_2}{6} - \frac{a_1}{24} - \frac{a_0}{120} = 0$$

Which after substituting earlier equations, simplifies to

$$a_7 = \frac{a_0}{140} + \frac{29a_1}{5040}$$

For $6 \leq n$, the recurrence equation is

$$(n+2)\,a_{n+2}(1+n) - a_n - a_{n-1} - \frac{a_{n-2}}{2} - \frac{a_{n-3}}{6} - \frac{a_{n-4}}{24} - \frac{a_{n-5}}{120} - \frac{a_{n-6}}{720} = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= \frac{720a_n + 720a_{n-1} + 360a_{n-2} + 120a_{n-3} + 30a_{n-4} + 6a_{n-5} + a_{n-6}}{720\,(n+2)\,(1+n)} \qquad (5) \\ &= \frac{a_n}{(n+2)\,(1+n)} + \frac{a_{n-6}}{720\,(n+2)\,(1+n)} + \frac{a_{n-5}}{120\,(n+2)\,(1+n)} \\ &\quad + \frac{a_{n-4}}{24\,(n+2)\,(1+n)} + \frac{a_{n-3}}{6\,(n+2)\,(1+n)} + \frac{a_{n-2}}{2\,(n+2)\,(1+n)} + \frac{a_{n-1}}{(n+2)\,(1+n)} \end{aligned}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3x^3 + a_2x^2 + a_1x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1x + \frac{a_0x^2}{2} + \left(\frac{a_0}{6} + \frac{a_1}{6}\right)x^3 + \left(\frac{a_0}{12} + \frac{a_1}{12}\right)x^4 + \left(\frac{a_0}{24} + \frac{a_1}{30}\right)x^5 + \dots$$

Collecting terms, the solution becomes

$$y=\left(1+\frac{1}{2}x^{2}+\frac{1}{6}x^{3}+\frac{1}{12}x^{4}+\frac{1}{24}x^{5}\right)a_{0}+\left(x+\frac{1}{6}x^{3}+\frac{1}{12}x^{4}+\frac{1}{30}x^{5}\right)a_{1}+O\left(x^{6}\right) \quad (3)$$

At $x=0$ the solution above becomes

$$y=\left(1+\frac{1}{2}x^{2}+\frac{1}{6}x^{3}+\frac{1}{12}x^{4}+\frac{1}{24}x^{5}\right)c_{1}+\left(x+\frac{1}{6}x^{3}+\frac{1}{12}x^{4}+\frac{1}{30}x^{5}\right)c_{2}+O\left(x^{6}\right)$$

Summary

The solution(s) found are the following

$$\begin{aligned}y&=\left(1+\frac{1}{2}x^{2}+\frac{1}{6}x^{3}+\frac{1}{12}x^{4}+\frac{1}{24}x^{5}+\frac{13}{720}x^{6}\right)y(0)\\&+\left(x+\frac{1}{6}x^{3}+\frac{1}{12}x^{4}+\frac{1}{30}x^{5}+\frac{1}{72}x^{6}\right)y'(0)+O\left(x^{6}\right)\end{aligned} \quad (1)$$

$$y=\left(1+\frac{1}{2}x^{2}+\frac{1}{6}x^{3}+\frac{1}{12}x^{4}+\frac{1}{24}x^{5}\right)c_{1}+\left(x+\frac{1}{6}x^{3}+\frac{1}{12}x^{4}+\frac{1}{30}x^{5}\right)c_{2}+O\left(x^{6}\right) \quad (2)$$

Verification of solutions

$$\begin{aligned}y&=\left(1+\frac{1}{2}x^{2}+\frac{1}{6}x^{3}+\frac{1}{12}x^{4}+\frac{1}{24}x^{5}+\frac{13}{720}x^{6}\right)y(0)\\&+\left(x+\frac{1}{6}x^{3}+\frac{1}{12}x^{4}+\frac{1}{30}x^{5}+\frac{1}{72}x^{6}\right)y'(0)+O\left(x^{6}\right)\end{aligned}$$

Verified OK.

$$y=\left(1+\frac{1}{2}x^{2}+\frac{1}{6}x^{3}+\frac{1}{12}x^{4}+\frac{1}{24}x^{5}\right)c_{1}+\left(x+\frac{1}{6}x^{3}+\frac{1}{12}x^{4}+\frac{1}{30}x^{5}\right)c_{2}+O\left(x^{6}\right)$$

Verified OK.

The type(s) of ODE detected by this program : **"first order ode series method. Taylor series method"**

Maple gives the following as the ode type

```
[`y=_G(x,y')`]
```

$$\boxed{y' - e^{y} - yx = 0}$$

With initial conditions

$$[y(0) = 0]$$

With the expansion point for the power series method at $x = 0$.

23.15.1 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor series

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\,y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0}
\end{aligned}
$$

But

$$
\frac{df}{dx} = \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \tag{1}
$$

$$
\begin{aligned}
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f
\end{aligned} \tag{2}
$$

$$
\begin{aligned}
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2}\right) f
\end{aligned} \tag{3}
$$

$$
\vdots
$$

And so on. Hence if we name $F_0 = f(x,y)$ then the above can be written as

$$
F_0 = f(x,y) \tag{4}
$$

$$
\begin{aligned}
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0
\end{aligned} \tag{5}
$$

For example, for $n = 1$ we see that

$$
\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f
\end{aligned}
$$

Which is (1). And when $n = 2$

$$\begin{aligned}
F_2 &= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)F_0 \\
&= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right)f \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)f
\end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} F_n|_{x_0,y_0} \tag{6}$$

Hence

$$\begin{aligned}
F_0 &= e^{y} + yx \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}F_0 \\
&= e^{2y} + (y+1)\,x\,e^{y} + \left(x^2+1\right)y \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y}F_1 \\
&= x(3y+2)\,e^{2y} + 2\,e^{3y} + \left(x^2y^2 + y\left(2x^2+1\right) + x^2 + 2\right)e^{y} + \left(x^3+3x\right)y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y}F_2 \\
&= \left(7x^2y^2 + 11yx^2 + 3x^2 + 4y + 5\right)e^{2y} + x(12y+7)\,e^{3y} + 6\,e^{4y} + \left(x^3y^3 + \left(4x^3+3x\right)y^2 + \left(3x^3+7x\right)y \right. \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y}F_3 \\
&= \left(15x^3y^3 + \left(43x^3+25x\right)y^2 + 7\left(4x^3+7x\right)y + 4x^3 + 18x\right)e^{2y} + \left(50x^2y^2 + 69yx^2 + 17x^2 + 20y + 21\right.
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = 0$ gives

$$\begin{aligned} F_0 &= 1 \\ F_1 &= 1 \\ F_2 &= 4 \\ F_3 &= 11 \\ F_4 &= 53 \end{aligned}$$

Substituting all the above in (6) and simplifying gives the solution as

$$y = x + \frac{x^2}{2} + \frac{2x^3}{3} + \frac{11x^4}{24} + \frac{53x^5}{120} + O(x^6)$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = y(0)$$

Therefore the solution becomes

$$y = x + \frac{1}{2}x^2 + \frac{2}{3}x^3 + \frac{11}{24}x^4 + \frac{53}{120}x^5$$

Hence the solution can be written as

$$y = x + \frac{x^2}{2} + \frac{2x^3}{3} + \frac{11x^4}{24} + \frac{53x^5}{120} + O(x^6)$$

which simplifies to

$$y = x + \frac{x^2}{2} + \frac{2x^3}{3} + \frac{11x^4}{24} + \frac{53x^5}{120} + O(x^6)$$

Unable to also solve using normal power series since not linear ode. Not currently supported.

Summary

The solution(s) found are the following

$$y = x + \frac{x^2}{2} + \frac{2x^3}{3} + \frac{11x^4}{24} + \frac{53x^5}{120} + O(x^6) \tag{1}$$

Verification of solutions

$$y = x + \frac{x^2}{2} + \frac{2x^3}{3} + \frac{11x^4}{24} + \frac{53x^5}{120} + O(x^6)$$

Verified OK.

ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler], [_2nd_order, _linear, `_with_symmetry_[0,F(
   x)]`]]
```

$$\boxed{4xy'' + 2y' + y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$4xy'' + 2y' + y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1}{2x}$$
$$q(x) = \frac{1}{4x}$$

Table 715: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{2x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{1}{4x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$4xy'' + 2y' + y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$4\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x + 2\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 4x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} a_n x^{n+r} = \sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} 4x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$4x^{n+r-1} a_n (n+r)(n+r-1) + 2(n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$4x^{-1+r} a_0 r(-1+r) + 2r a_0 x^{-1+r} = 0$$

Or

$$\left(4x^{-1+r} r(-1+r) + 2r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(4r^2 - 2r\right) x^{-1+r} = 0$$

Since the above is true for all x then the indicial equation becomes

$$4r^2 - 2r = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{2}$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(4r^2 - 2r\right) x^{-1+r} = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{2}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^n$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$4a_n(n+r)(n+r-1) + 2a_n(n+r) + a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}}{2(2n^2 + 4nr + 2r^2 - n - r)} \tag{4}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_n = -\frac{a_{n-1}}{4n^2 + 2n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{1}{4r^2 + 6r + 2}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_1 = -\frac{1}{6}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{4r^2+6r+2}$	$-\frac{1}{6}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{16r^4 + 80r^3 + 140r^2 + 100r + 24}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_2 = \frac{1}{120}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{4r^2+6r+2}$	$-\frac{1}{6}$
a_2	$\frac{1}{16r^4+80r^3+140r^2+100r+24}$	$\frac{1}{120}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{1}{64r^6 + 672r^5 + 2800r^4 + 5880r^3 + 6496r^2 + 3528r + 720}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_3 = -\frac{1}{5040}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{4r^2+6r+2}$	$-\frac{1}{6}$
a_2	$\frac{1}{16r^4+80r^3+140r^2+100r+24}$	$\frac{1}{120}$
a_3	$-\frac{1}{64r^6+672r^5+2800r^4+5880r^3+6496r^2+3528r+720}$	$-\frac{1}{5040}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{16 (8r^6 + 84r^5 + 350r^4 + 735r^3 + 812r^2 + 441r + 90) (2r^2 + 15r + 28)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_4 = \frac{1}{362880}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{4r^2+6r+2}$	$-\frac{1}{6}$
a_2	$\frac{1}{16r^4+80r^3+140r^2+100r+24}$	$\frac{1}{120}$
a_3	$-\frac{1}{64r^6+672r^5+2800r^4+5880r^3+6496r^2+3528r+720}$	$-\frac{1}{5040}$
a_4	$\frac{1}{16(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r^2+15r+28)}$	$\frac{1}{362880}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1}{32 (8r^6 + 84r^5 + 350r^4 + 735r^3 + 812r^2 + 441r + 90) (2r^2 + 15r + 28) (2r^2 + 19r + 45)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_5 = -\frac{1}{39916800}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{4r^2+6r+2}$	$-\frac{1}{6}$
a_2	$\frac{1}{16r^4+80r^3+140r^2+100r+24}$	$\frac{1}{120}$
a_3	$-\frac{1}{64r^6+672r^5+2800r^4+5880r^3+6496r^2+3528r+720}$	$-\frac{1}{5040}$
a_4	$\frac{1}{16(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r^2+15r+28)}$	$\frac{1}{362880}$
a_5	$-\frac{1}{32(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r^2+15r+28)(2r^2+19r+45)}$	$-\frac{1}{39916800}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= \sqrt{x}\,(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots) \\ &= \sqrt{x}\left(1 - \frac{x}{6} + \frac{x^2}{120} - \frac{x^3}{5040} + \frac{x^4}{362880} - \frac{x^5}{39916800} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$4b_n(n+r)(n+r-1) + 2(n+r)\,b_n + b_{n-1} = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{b_{n-1}}{2(2n^2 + 4nr + 2r^2 - n - r)} \tag{4}$$

Which for the root $r = 0$ becomes

$$b_n = -\frac{b_{n-1}}{4n^2 - 2n} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = -\frac{1}{4r^2 + 6r + 2}$$

Which for the root $r = 0$ becomes

$$b_1 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{4r^2+6r+2}$	$-\frac{1}{2}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{1}{16r^4 + 80r^3 + 140r^2 + 100r + 24}$$

Which for the root $r = 0$ becomes

$$b_2 = \frac{1}{24}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{4r^2+6r+2}$	$-\frac{1}{2}$
b_2	$\frac{1}{16r^4+80r^3+140r^2+100r+24}$	$\frac{1}{24}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{1}{64r^6 + 672r^5 + 2800r^4 + 5880r^3 + 6496r^2 + 3528r + 720}$$

Which for the root $r = 0$ becomes

$$b_3 = -\frac{1}{720}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{4r^2+6r+2}$	$-\frac{1}{2}$
b_2	$\frac{1}{16r^4+80r^3+140r^2+100r+24}$	$\frac{1}{24}$
b_3	$-\frac{1}{64r^6+672r^5+2800r^4+5880r^3+6496r^2+3528r+720}$	$-\frac{1}{720}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{16\left(8r^6 + 84r^5 + 350r^4 + 735r^3 + 812r^2 + 441r + 90\right)\left(2r^2 + 15r + 28\right)}$$

Which for the root $r = 0$ becomes

$$b_4 = \frac{1}{40320}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{4r^2+6r+2}$	$-\frac{1}{2}$
b_2	$\frac{1}{16r^4+80r^3+140r^2+100r+24}$	$\frac{1}{24}$
b_3	$-\frac{1}{64r^6+672r^5+2800r^4+5880r^3+6496r^2+3528r+720}$	$-\frac{1}{720}$
b_4	$\frac{1}{16(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r^2+15r+28)}$	$\frac{1}{40320}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{1}{32 \left(8r^6 + 84r^5 + 350r^4 + 735r^3 + 812r^2 + 441r + 90\right) \left(2r^2 + 15r + 28\right) \left(2r^2 + 19r + 45\right)}$$

Which for the root $r = 0$ becomes

$$b_5 = -\frac{1}{3628800}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{4r^2+6r+2}$	$-\frac{1}{2}$
b_2	$\frac{1}{16r^4+80r^3+140r^2+100r+24}$	$\frac{1}{24}$
b_3	$-\frac{1}{64r^6+672r^5+2800r^4+5880r^3+6496r^2+3528r+720}$	$-\frac{1}{720}$
b_4	$\frac{1}{16(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r^2+15r+28)}$	$\frac{1}{40320}$
b_5	$-\frac{1}{32(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r^2+15r+28)(2r^2+19r+45)}$	$-\frac{1}{3628800}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots \\ &= 1 - \frac{x}{2} + \frac{x^2}{24} - \frac{x^3}{720} + \frac{x^4}{40320} - \frac{x^5}{3628800} + O\left(x^6\right) \end{aligned}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1\sqrt{x}\left(1-\frac{x}{6}+\frac{x^2}{120}-\frac{x^3}{5040}+\frac{x^4}{362880}-\frac{x^5}{39916800}+O\left(x^6\right)\right) \\
&\quad + c_2\left(1-\frac{x}{2}+\frac{x^2}{24}-\frac{x^3}{720}+\frac{x^4}{40320}-\frac{x^5}{3628800}+O\left(x^6\right)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1\sqrt{x}\left(1-\frac{x}{6}+\frac{x^2}{120}-\frac{x^3}{5040}+\frac{x^4}{362880}-\frac{x^5}{39916800}+O\left(x^6\right)\right) \\
&\quad + c_2\left(1-\frac{x}{2}+\frac{x^2}{24}-\frac{x^3}{720}+\frac{x^4}{40320}-\frac{x^5}{3628800}+O\left(x^6\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1\sqrt{x}\left(1-\frac{x}{6}+\frac{x^2}{120}-\frac{x^3}{5040}+\frac{x^4}{362880}-\frac{x^5}{39916800}+O\left(x^6\right)\right) \\
&\quad + c_2\left(1-\frac{x}{2}+\frac{x^2}{24}-\frac{x^3}{720}+\frac{x^4}{40320}-\frac{x^5}{3628800}+O\left(x^6\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1\sqrt{x}\left(1-\frac{x}{6}+\frac{x^2}{120}-\frac{x^3}{5040}+\frac{x^4}{362880}-\frac{x^5}{39916800}+O\left(x^6\right)\right) \\
&\quad + c_2\left(1-\frac{x}{2}+\frac{x^2}{24}-\frac{x^3}{720}+\frac{x^4}{40320}-\frac{x^5}{3628800}+O\left(x^6\right)\right)
\end{aligned}
$$

Verified OK.

24.1.1 Maple step by step solution

Let's solve

$4y''x + 2y' + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y}{4x} - \frac{y'}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{2x} + \frac{y}{4x} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{1}{2x}, P_3(x) = \frac{1}{4x}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = \frac{1}{2}$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 0$

  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $4y''x + 2y' + y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert y' to series expansion

    $y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r-1}$

  - Shift index using $k- >k + 1$

$$y' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, x^{k+r}$$

- Convert $x \cdot y''$ to series expansion

$$x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$$

- Shift index using $k->k+1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$2a_0 r(-1+2r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} (2a_{k+1}(k+1+r)\,(2k+1+2r) + a_k)\, x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$2r(-1+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, \frac{1}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$4\left(k+\frac{1}{2}+r\right)(k+1+r)\, a_{k+1} + a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{a_k}{2(2k+1+2r)(k+1+r)}$$

- Recursion relation for $r = 0$

$$a_{k+1} = -\frac{a_k}{2(2k+1)(k+1)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = -\frac{a_k}{2(2k+1)(k+1)}\right]$$

- Recursion relation for $r = \frac{1}{2}$

$$a_{k+1} = -\frac{a_k}{2(2k+2)\left(k+\frac{3}{2}\right)}$$

- Solution for $r = \frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = -\frac{a_k}{2(2k+2)\left(k+\frac{3}{2}\right)}\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}a_kx^k\right)+\left(\sum_{k=0}^{\infty}b_kx^{k+\frac{1}{2}}\right),a_{k+1}=-\frac{a_k}{2(2k+1)(k+1)},b_{k+1}=-\frac{b_k}{2(2k+2)\left(k+\frac{3}{2}\right)}\right]$$

Section: Chapter 2 (Higher order ODE's). Section 18.2. Expanding a solution in generalized power series. Bessels equation. Exercises page 177
Problem number: 740.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Ordinary point", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{(x+1)\,y'-ny=0}$$

With the expansion point for the power series method at $x=0$.

24.2.1 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y'=f(x,y)$$

Where $f(x,y)$ is analytic at expansion point x_0. We can always shift to $x_0=0$ if x_0 is not zero. So from now we assume $x_0=0$. Assume also that $y(x_0)=y_0$. Using Taylor series

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \qquad (1) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \qquad (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) f \qquad (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y)$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y) \qquad (4) \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \qquad (5)
\end{aligned}$$

For example, for $n = 1$ we see that

$$\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f
\end{aligned}$$

Which is (1). And when $n=2$

$$\begin{aligned}
F_2 &= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)F_0\\
&= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right)f\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)f
\end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty}\frac{x^{n+1}}{(n+1)!}F_n|_{x_0,y_0} \tag{6}$$

Hence

$$\begin{aligned}
F_0 &= \frac{ny}{x+1}\\
F_1 &= \frac{dF_0}{dx}\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}F_0\\
&= \frac{ny(-1+n)}{(x+1)^2}\\
F_2 &= \frac{dF_1}{dx}\\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y}F_1\\
&= \frac{ny(-2+n)(-1+n)}{(x+1)^3}\\
F_3 &= \frac{dF_2}{dx}\\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y}F_2\\
&= \frac{y(-3+n)(-2+n)n(-1+n)}{(x+1)^4}\\
F_4 &= \frac{dF_3}{dx}\\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y}F_3\\
&= \frac{y(-4+n)(-2+n)n(-3+n)(-1+n)}{(x+1)^5}
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = y(0)$ gives

$$
\begin{aligned}
F_0 &= y(0)\,n \\
F_1 &= y(0)\,n(-1+n) \\
F_2 &= y(0)\,n\left(n^2-3n+2\right) \\
F_3 &= y(0)\,n\left(n^3-6n^2+11n-6\right) \\
F_4 &= y(0)\,n\left(n^4-10n^3+35n^2-50n+24\right)
\end{aligned}
$$

Substituting all the above in (6) and simplifying gives the solution as

$$
\begin{aligned}
y = \bigg(&1+nx-\frac{1}{2}n\,x^2+\frac{1}{2}n^2x^2+\frac{1}{6}n^3x^3-\frac{1}{2}n^2x^3+\frac{1}{3}n\,x^3+\frac{1}{24}n^4x^4-\frac{1}{4}n^3x^4+\frac{11}{24}n^2x^4 \\
&-\frac{1}{4}n\,x^4+\frac{1}{120}n^5x^5-\frac{1}{12}n^4x^5+\frac{7}{24}n^3x^5-\frac{5}{12}n^2x^5+\frac{1}{5}n\,x^5\bigg)\,y(0)+O\left(x^6\right)
\end{aligned}
$$

Since $x = 0$ is also an ordinary point, then standard power series can also be used. Writing the ODE as

$$
\begin{aligned}
y'+q(x)y &= p(x) \\
y'-\frac{ny}{x+1} &= 0
\end{aligned}
$$

Where

$$
\begin{aligned}
q(x) &= -\frac{n}{x+1} \\
p(x) &= 0
\end{aligned}
$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not. Now the ode is normalized by writing it as

$$
(x+1)\,y'-ny = 0
$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$

Substituting the above back into the ode gives

$$(x+1)\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - n\left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=1}^{\infty} n a_n x^n\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \sum_{n=0}^{\infty} (-n a_n x^n) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=1}^{\infty} n a_n x^n\right) + \left(\sum_{n=0}^{\infty} (n+1) a_{n+1} x^n\right) + \sum_{n=0}^{\infty} (-n a_n x^n) = 0 \tag{3}$$

$n = 0$ gives

$$\begin{aligned} -n a_0 + a_1 &= 0 \\ a_1 &= n a_0 \end{aligned}$$

For $1 \leq n$, the recurrence equation is

$$n a_n + (n+1) a_{n+1} - n a_n = 0 \tag{4}$$

Solving for a_{n+1}, gives

$$a_{n+1} = \frac{a_n(n-n)}{n+1} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$-na_1 + a_1 + 2a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_2 = \frac{1}{2}n^2 a_0 - \frac{1}{2}na_0$$

For $n = 2$ the recurrence equation gives

$$-na_2 + 2a_2 + 3a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{1}{6}n^3 a_0 - \frac{1}{2}n^2 a_0 + \frac{1}{3}na_0$$

For $n = 3$ the recurrence equation gives

$$-na_3 + 3a_3 + 4a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{1}{24}n^4 a_0 - \frac{1}{4}n^3 a_0 + \frac{11}{24}n^2 a_0 - \frac{1}{4}na_0$$

For $n = 4$ the recurrence equation gives

$$-na_4 + 4a_4 + 5a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{1}{120}n^5 a_0 - \frac{1}{12}n^4 a_0 + \frac{7}{24}n^3 a_0 - \frac{5}{12}n^2 a_0 + \frac{1}{5}na_0$$

For $n = 5$ the recurrence equation gives

$$-na_5 + 5a_5 + 6a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{1}{720}n^6 a_0 - \frac{1}{48}n^5 a_0 + \frac{17}{144}n^4 a_0 - \frac{5}{16}n^3 a_0 + \frac{137}{360}n^2 a_0 - \frac{1}{6}n a_0$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned} y = a_0 + n a_0 x &+ \left(\frac{1}{2}n^2 a_0 - \frac{1}{2}n a_0\right) x^2 + \left(\frac{1}{6}n^3 a_0 - \frac{1}{2}n^2 a_0 + \frac{1}{3}n a_0\right) x^3 \\ &+ \left(\frac{1}{24}n^4 a_0 - \frac{1}{4}n^3 a_0 + \frac{11}{24}n^2 a_0 - \frac{1}{4}n a_0\right) x^4 \\ &+ \left(\frac{1}{120}n^5 a_0 - \frac{1}{12}n^4 a_0 + \frac{7}{24}n^3 a_0 - \frac{5}{12}n^2 a_0 + \frac{1}{5}n a_0\right) x^5 + \dots \end{aligned}$$

Collecting terms, the solution becomes

$$\begin{aligned} y = \Bigg(1 + nx + \left(\frac{1}{2}n^2 - \frac{1}{2}n\right) x^2 + \left(\frac{1}{6}n^3 - \frac{1}{2}n^2 + \frac{1}{3}n\right) x^3 + \left(\frac{1}{24}n^4 - \frac{1}{4}n^3 + \frac{11}{24}n^2 - \frac{1}{4}n\right) x^4 \\ + \left(\frac{1}{120}n^5 - \frac{1}{12}n^4 + \frac{7}{24}n^3 - \frac{5}{12}n^2 + \frac{1}{5}n\right) x^5\Bigg) a_0 + O(x^6) \end{aligned} \tag{3}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = \Bigg(1 + nx - \frac{1}{2}n\,x^2 + \frac{1}{2}n^2 x^2 + \frac{1}{6}n^3 x^3 - \frac{1}{2}n^2 x^3 + \frac{1}{3}n\,x^3 + \frac{1}{24}n^4 x^4 - \frac{1}{4}n^3 x^4 + \frac{11}{24}n^2 x^4 \\ - \frac{1}{4}n\,x^4 + \frac{1}{120}n^5 x^5 - \frac{1}{12}n^4 x^5 + \frac{7}{24}n^3 x^5 - \frac{5}{12}n^2 x^5 + \frac{1}{5}n\,x^5\Bigg) y(0) + O(x^6) \end{aligned} \tag{1}$$

$$\begin{aligned} y = \Bigg(1 + nx + \left(\frac{1}{2}n^2 - \frac{1}{2}n\right) x^2 + \left(\frac{1}{6}n^3 - \frac{1}{2}n^2 + \frac{1}{3}n\right) x^3 + \left(\frac{1}{24}n^4 - \frac{1}{4}n^3 + \frac{11}{24}n^2 - \frac{1}{4}n\right) x^4 \\ + \left(\frac{1}{120}n^5 - \frac{1}{12}n^4 + \frac{7}{24}n^3 - \frac{5}{12}n^2 + \frac{1}{5}n\right) x^5\Bigg) c_1 + O(x^6) \end{aligned} \tag{2}$$

Verification of solutions

$$y = \left(1 + nx - \frac{1}{2} n\, x^2 + \frac{1}{2} n^2 x^2 + \frac{1}{6} n^3 x^3 - \frac{1}{2} n^2 x^3 + \frac{1}{3} n\, x^3 + \frac{1}{24} n^4 x^4 - \frac{1}{4} n^3 x^4 + \frac{11}{24} n^2 x^4 - \frac{1}{4} n\, x^4 + \frac{1}{120} n^5 x^5 - \frac{1}{12} n^4 x^5 + \frac{7}{24} n^3 x^5 - \frac{5}{12} n^2 x^5 + \frac{1}{5} n\, x^5\right) y(0) + O(x^6)$$

Verified OK.

$$y = \left(1+nx+\left(\frac{1}{2} n^2 - \frac{1}{2} n\right) x^2 + \left(\frac{1}{6} n^3 - \frac{1}{2} n^2 + \frac{1}{3} n\right) x^3 + \left(\frac{1}{24} n^4 - \frac{1}{4} n^3 + \frac{11}{24} n^2 - \frac{1}{4} n\right) x^4 + \left(\frac{1}{120} n^5 - \frac{1}{12} n^4 + \frac{7}{24} n^3 - \frac{5}{12} n^2 + \frac{1}{5} n\right) x^5\right) c_1 + O(x^6)$$

Verified OK.

24.2.2 Maple step by step solution

Let's solve

$(x+1)\, y' - ny = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = \frac{n}{x+1}$

- Integrate both sides with respect to x

  $\int \frac{y'}{y} dx = \int \frac{n}{x+1} dx + c_1$

- Evaluate integral

  $\ln(y) = n \ln(x+1) + c_1$

- Solve for y

  $y = \mathrm{e}^{n \ln(x+1) + c_1}$

Section: Chapter 2 (Higher order ODE's). Section 18.2. Expanding a solution in generalized power series. Bessels equation. Exercises page 177
Problem number: 741.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

`[_Jacobi]`

$$\boxed{9x(1-x)\,y''-12y'+4y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(-9x^2+9x\right)y''-12y'+4y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=\frac{4}{3x\,(x-1)}$$
$$q(x)=-\frac{4}{9x\,(x-1)}$$

Table 718: Table $p(x), q(x)$ singularites.

$p(x) = \frac{4}{3x(x-1)}$	
singularity	type
$x = 0$	"regular"
$x = 1$	"regular"

$q(x) = -\frac{4}{9x(x-1)}$	
singularity	type
$x = 0$	"regular"
$x = 1$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, 1, \infty]$

Irregular singular points : []

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$-9y''x(x-1) - 12y' + 4y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$-9\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x(x-1) - 12\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + 4\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\sum_{n=0}^{\infty}\left(-9x^{n+r}a_n(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty}9x^{n+r-1}a_n(n+r)(n+r-1)\right) \\ +\sum_{n=0}^{\infty}\left(-12(n+r)a_n x^{n+r-1}\right)+\left(\sum_{n=0}^{\infty}4a_n x^{n+r}\right)=0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty}\left(-9x^{n+r}a_n(n+r)(n+r-1)\right)=\sum_{n=1}^{\infty}\left(-9a_{n-1}(n+r-1)(n+r-2)x^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty}4a_n x^{n+r}=\sum_{n=1}^{\infty}4a_{n-1}x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\sum_{n=1}^{\infty}\left(-9a_{n-1}(n+r-1)(n+r-2)x^{n+r-1}\right) \\ +\left(\sum_{n=0}^{\infty}9x^{n+r-1}a_n(n+r)(n+r-1)\right) \\ +\sum_{n=0}^{\infty}\left(-12(n+r)a_n x^{n+r-1}\right)+\left(\sum_{n=1}^{\infty}4a_{n-1}x^{n+r-1}\right)=0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$9x^{n+r-1}a_n(n+r)(n+r-1)-12(n+r)a_n x^{n+r-1}=0$$

When $n=0$ the above becomes

$$9x^{-1+r}a_0r(-1+r)-12ra_0x^{-1+r}=0$$

Or

$$\left(9x^{-1+r}r(-1+r)-12r\,x^{-1+r}\right)a_0=0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(9r^2 - 21r\right) x^{-1+r} = 0$$

Since the above is true for all x then the indicial equation becomes

$$9r^2 - 21r = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{7}{3}$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(9r^2 - 21r\right) x^{-1+r} = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{7}{3}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{7}{3}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^n$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$-9a_{n-1}(n+r-1)(n+r-2) + 9a_n(n+r)(n+r-1) - 12a_n(n+r) + 4a_{n-1} = 0 \quad (3)$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{(3n+3r-2)\, a_{n-1}}{3n+3r} \quad (4)$$

Which for the root $r = \frac{7}{3}$ becomes

$$a_n = \frac{(3n+5)\, a_{n-1}}{3n+7} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{7}{3}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{1+3r}{3+3r}$$

Which for the root $r = \frac{7}{3}$ becomes

$$a_1 = \frac{4}{5}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1+3r}{3+3r}$	$\frac{4}{5}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{9r^2+15r+4}{9(1+r)(2+r)}$$

Which for the root $r = \frac{7}{3}$ becomes

$$a_2 = \frac{44}{65}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1+3r}{3+3r}$	$\frac{4}{5}$
a_2	$\frac{9r^2+15r+4}{9(1+r)(2+r)}$	$\frac{44}{65}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{27r^3 + 108r^2 + 117r + 28}{27 (1 + r) (2 + r) (3 + r)}$$

Which for the root $r = \frac{7}{3}$ becomes

$$a_3 = \frac{77}{130}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1+3r}{3+3r}$	$\frac{4}{5}$
a_2	$\frac{9r^2+15r+4}{9(1+r)(2+r)}$	$\frac{44}{65}$
a_3	$\frac{27r^3+108r^2+117r+28}{27(1+r)(2+r)(3+r)}$	$\frac{77}{130}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{81r^4 + 594r^3 + 1431r^2 + 1254r + 280}{81 (1 + r) (2 + r) (3 + r) (4 + r)}$$

Which for the root $r = \frac{7}{3}$ becomes

$$a_4 = \frac{1309}{2470}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1+3r}{3+3r}$	$\frac{4}{5}$
a_2	$\frac{9r^2+15r+4}{9(1+r)(2+r)}$	$\frac{44}{65}$
a_3	$\frac{27r^3+108r^2+117r+28}{27(1+r)(2+r)(3+r)}$	$\frac{77}{130}$
a_4	$\frac{81r^4+594r^3+1431r^2+1254r+280}{81(1+r)(2+r)(3+r)(4+r)}$	$\frac{1309}{2470}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{243r^5 + 2835r^4 + 12015r^3 + 22365r^2 + 17142r + 3640}{243 (1 + r) (2 + r) (3 + r) (4 + r) (5 + r)}$$

Which for the root $r = \frac{7}{3}$ becomes

$$a_5 = \frac{119}{247}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1+3r}{3+3r}$	$\frac{4}{5}$
a_2	$\frac{9r^2+15r+4}{9(1+r)(2+r)}$	$\frac{44}{65}$
a_3	$\frac{27r^3+108r^2+117r+28}{27(1+r)(2+r)(3+r)}$	$\frac{77}{130}$
a_4	$\frac{81r^4+594r^3+1431r^2+1254r+280}{81(1+r)(2+r)(3+r)(4+r)}$	$\frac{1309}{2470}$
a_5	$\frac{243r^5+2835r^4+12015r^3+22365r^2+17142r+3640}{243(1+r)(2+r)(3+r)(4+r)(5+r)}$	$\frac{119}{247}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{7}{3}} \left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^{\frac{7}{3}} \left(1 + \frac{4x}{5} + \frac{44x^2}{65} + \frac{77x^3}{130} + \frac{1309x^4}{2470} + \frac{119x^5}{247} + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$-9b_{n-1}(n+r-1)(n+r-2) + 9b_n(n+r)(n+r-1) - 12(n+r)b_n + 4b_{n-1} = 0 \quad (3)$$

Solving for b_n from recursive equation (4) gives

$$b_n = \frac{(3n+3r-2)\, b_{n-1}}{3n+3r} \quad (4)$$

Which for the root $r = 0$ becomes

$$b_n = \frac{(3n-2)\, b_{n-1}}{3n} \quad (5)$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{1 + 3r}{3 + 3r}$$

Which for the root $r = 0$ becomes

$$b_1 = \frac{1}{3}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1+3r}{3+3r}$	$\frac{1}{3}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{9r^2 + 15r + 4}{9\,(1 + r)\,(2 + r)}$$

Which for the root $r = 0$ becomes

$$b_2 = \frac{2}{9}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1+3r}{3+3r}$	$\frac{1}{3}$
b_2	$\frac{9r^2+15r+4}{9(1+r)(2+r)}$	$\frac{2}{9}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{27r^3 + 108r^2 + 117r + 28}{27\,(1 + r)\,(2 + r)\,(3 + r)}$$

Which for the root $r = 0$ becomes

$$b_3 = \frac{14}{81}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1+3r}{3+3r}$	$\frac{1}{3}$
b_2	$\frac{9r^2+15r+4}{9(1+r)(2+r)}$	$\frac{2}{9}$
b_3	$\frac{27r^3+108r^2+117r+28}{27(1+r)(2+r)(3+r)}$	$\frac{14}{81}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{81r^4 + 594r^3 + 1431r^2 + 1254r + 280}{81\left(1+r\right)\left(2+r\right)\left(3+r\right)\left(4+r\right)}$$

Which for the root $r = 0$ becomes

$$b_4 = \frac{35}{243}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1+3r}{3+3r}$	$\frac{1}{3}$
b_2	$\frac{9r^2+15r+4}{9(1+r)(2+r)}$	$\frac{2}{9}$
b_3	$\frac{27r^3+108r^2+117r+28}{27(1+r)(2+r)(3+r)}$	$\frac{14}{81}$
b_4	$\frac{81r^4+594r^3+1431r^2+1254r+280}{81(1+r)(2+r)(3+r)(4+r)}$	$\frac{35}{243}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{243r^5 + 2835r^4 + 12015r^3 + 22365r^2 + 17142r + 3640}{243\left(1+r\right)\left(2+r\right)\left(3+r\right)\left(4+r\right)\left(5+r\right)}$$

Which for the root $r = 0$ becomes

$$b_5 = \frac{91}{729}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1+3r}{3+3r}$	$\frac{1}{3}$
b_2	$\frac{9r^2+15r+4}{9(1+r)(2+r)}$	$\frac{2}{9}$
b_3	$\frac{27r^3+108r^2+117r+28}{27(1+r)(2+r)(3+r)}$	$\frac{14}{81}$
b_4	$\frac{81r^4+594r^3+1431r^2+1254r+280}{81(1+r)(2+r)(3+r)(4+r)}$	$\frac{35}{243}$
b_5	$\frac{243r^5+2835r^4+12015r^3+22365r^2+17142r+3640}{243(1+r)(2+r)(3+r)(4+r)(5+r)}$	$\frac{91}{729}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots \\
&= 1 + \frac{x}{3} + \frac{2x^2}{9} + \frac{14x^3}{81} + \frac{35x^4}{243} + \frac{91x^5}{729} + O(x^6)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{\frac{7}{3}} \left(1 + \frac{4x}{5} + \frac{44x^2}{65} + \frac{77x^3}{130} + \frac{1309x^4}{2470} + \frac{119x^5}{247} + O(x^6)\right) \\
&\quad + c_2 \left(1 + \frac{x}{3} + \frac{2x^2}{9} + \frac{14x^3}{81} + \frac{35x^4}{243} + \frac{91x^5}{729} + O(x^6)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{\frac{7}{3}} \left(1 + \frac{4x}{5} + \frac{44x^2}{65} + \frac{77x^3}{130} + \frac{1309x^4}{2470} + \frac{119x^5}{247} + O(x^6)\right) \\
&\quad + c_2 \left(1 + \frac{x}{3} + \frac{2x^2}{9} + \frac{14x^3}{81} + \frac{35x^4}{243} + \frac{91x^5}{729} + O(x^6)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x^{\frac{7}{3}} \left(1 + \frac{4x}{5} + \frac{44x^2}{65} + \frac{77x^3}{130} + \frac{1309x^4}{2470} + \frac{119x^5}{247} + O(x^6)\right) \\
&\quad + c_2 \left(1 + \frac{x}{3} + \frac{2x^2}{9} + \frac{14x^3}{81} + \frac{35x^4}{243} + \frac{91x^5}{729} + O(x^6)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
y = c_1 x^{\frac{7}{3}} \left(1+\frac{4x}{5}+\frac{44x^2}{65}+\frac{77x^3}{130}+\frac{1309x^4}{2470}+\frac{119x^5}{247}+O(x^6)\right) + c_2 \left(1+\frac{x}{3}+\frac{2x^2}{9}+\frac{14x^3}{81}+\frac{35x^4}{243}+\frac{91x^5}{729}+O(x^6)\right)
$$

Verified OK.

24.3.1 Maple step by step solution

Let's solve

$-9y''x(x-1)-12y'+4y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{4y}{9x(x-1)}-\frac{4y'}{3x(x-1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{4y'}{3x(x-1)}-\frac{4y}{9x(x-1)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{4}{3x(x-1)}, P_3(x)=-\frac{4}{9x(x-1)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x=0$

  $\left.(x \cdot P_2(x))\right|_{x=0}=-\frac{4}{3}$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x=0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0}=0$

  ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $9y''x(x-1)+12y'-4y=0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert y' to series expansion

    $y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1}$

  - Shift index using $k->k+1$

    $y' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, x^{k+r}$

  - Convert $x^m \cdot y''$ to series expansion for $m = 1..2$

    $x^m \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$

  - Shift index using $k->k+2-m$

    $x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $-3a_0r(-7+3r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} (-3a_{k+1}(k+1+r)\,(3k+3r-4) + a_k(3k+3r+1)\,(3k+3r-4$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-3r(-7+3r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, \frac{7}{3}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $9\left((-k-r-1)\, a_{k+1} + a_k\left(k+r+\frac{1}{3}\right)\right)\left(k+r-\frac{4}{3}\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(3k+3r+1)}{3(k+1+r)}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{a_k(3k+1)}{3(k+1)}$

- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = \frac{a_k(3k+1)}{3(k+1)}\right]$

- Recursion relation for $r = \frac{7}{3}$

  $a_{k+1} = \frac{a_k(3k+8)}{3(k+\frac{10}{3})}$
- Solution for $r = \frac{7}{3}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{7}{3}}, a_{k+1} = \frac{a_k(3k+8)}{3(k+\frac{10}{3})}\right]$
- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{7}{3}}\right), a_{k+1} = \frac{a_k(3k+1)}{3(k+1)}, b_{k+1} = \frac{b_k(3k+8)}{3(k+\frac{10}{3})}\right]$

Problem number: 744.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2y'' + y'x + \left(4x^2 - \frac{1}{9}\right)y = 0}$$

24.4.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + y'x + \left(4x^2 - \frac{1}{9}\right)y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right)y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$
\begin{aligned}
\alpha &= 0 \\
\beta &= 2 \\
n &= -\frac{1}{3} \\
\gamma &= 1
\end{aligned}
$$

Substituting all the above into (4) gives the solution as

$$
y = c_1 \operatorname{BesselJ}\left(-\frac{1}{3}, 2x\right) + c_2 \operatorname{BesselY}\left(-\frac{1}{3}, 2x\right)
$$

Summary

The solution(s) found are the following

$$
y = c_1 \operatorname{BesselJ}\left(-\frac{1}{3}, 2x\right) + c_2 \operatorname{BesselY}\left(-\frac{1}{3}, 2x\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 \operatorname{BesselJ}\left(-\frac{1}{3}, 2x\right) + c_2 \operatorname{BesselY}\left(-\frac{1}{3}, 2x\right)
$$

Verified OK.

24.4.2 Maple step by step solution

Let's solve

$y''x^2 + y'x + \left(4x^2 - \frac{1}{9}\right) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(36x^2-1)y}{9x^2} - \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + \frac{(36x^2-1)y}{9x^2} = 0$

- Simplify ODE

  $y''x^2 + y'x + 4yx^2 - \frac{y}{9} = 0$

- Make a change of variables

$$t = 2x$$

- Compute y'

$$y' = 2\frac{d}{dt}y(t)$$

- Compute second derivative

$$y'' = 4\frac{d^2}{dt^2}y(t)$$

- Apply change of variables to the ODE

$$\left(\frac{d^2}{dt^2}y(t)\right)t^2 + \left(\frac{d}{dt}y(t)\right)t + y(t)\,t^2 - \frac{y(t)}{9} = 0$$

- ODE is now of the Bessel form
- Solution to Bessel ODE

$$y(t) = c_1 BesselJ\left(\frac{1}{3}, t\right) + c_2 BesselY\left(\frac{1}{3}, t\right)$$

- Make the change from t back to x

$$y = c_1 BesselJ\left(\frac{1}{3}, 2x\right) + c_2 BesselY\left(\frac{1}{3}, 2x\right)$$

Problem number: 745.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode", "second_order_change_of_variable_on_y_method_1"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2y'' + y'x + \left(x^2 - \frac{1}{4}\right)y = 0}$$

24.5.1 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= \frac{x^2 - \frac{1}{4}}{x^2} \end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{x^2 - \frac{1}{4}}{x^2} - \frac{\left(\frac{1}{x}\right)'}{2} - \frac{\left(\frac{1}{x}\right)^2}{4} \\
&= \frac{x^2 - \frac{1}{4}}{x^2} - \frac{\left(-\frac{1}{x^2}\right)}{2} - \frac{\left(\frac{1}{x^2}\right)}{4} \\
&= \frac{x^2 - \frac{1}{4}}{x^2} - \left(-\frac{1}{2x^2}\right) - \frac{1}{4x^2} \\
&= 1
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\, z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{\frac{1}{x}}{2}} \\
&= \frac{1}{\sqrt{x}}
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = \frac{v(x)}{\sqrt{x}} \tag{4}
$$

Applying this change of variable to the original ode results in

$$
x^{\frac{3}{2}}(v''(x) + v(x)) = 0
$$

Which is now solved for $v(x)$ This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$
Av''(x) + Bv'(x) + Cv(x) = 0
$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$
\lambda^2 \mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}
$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$v(x) = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$v(x) = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$v(x) = c_1 \cos(x) + c_2 \sin(x)$$

Now that $v(x)$ is known, then

$$\begin{aligned}y &= v(x)\, z(x) \\ &= (c_1 \cos(x) + c_2 \sin(x))\,(z(x))\end{aligned} \tag{7}$$

But from (5)

$$z(x) = \frac{1}{\sqrt{x}}$$

Hence (7) becomes

$$y = \frac{c_1 \cos(x) + c_2 \sin(x)}{\sqrt{x}}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 \cos(x) + c_2 \sin(x)}{\sqrt{x}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \cos(x) + c_2 \sin(x)}{\sqrt{x}}$$

Verified OK.

24.5.2 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + y'x + \left(x^2 - \frac{1}{4}\right)y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + (-n^2 + x^2)\,y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = 0$$
$$\beta = 1$$
$$n = -\frac{1}{2}$$
$$\gamma = 1$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1\sqrt{2}\,\cos(x)}{\sqrt{\pi}\,\sqrt{x}} + \frac{c_2\sqrt{2}\,\sin(x)}{\sqrt{\pi}\,\sqrt{x}}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1\sqrt{2}\,\cos(x)}{\sqrt{\pi}\,\sqrt{x}} + \frac{c_2\sqrt{2}\,\sin(x)}{\sqrt{\pi}\,\sqrt{x}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1\sqrt{2}\,\cos(x)}{\sqrt{\pi}\,\sqrt{x}} + \frac{c_2\sqrt{2}\,\sin(x)}{\sqrt{\pi}\,\sqrt{x}}$$

Verified OK.

24.5.3 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + y'x + \left(x^2 - \frac{1}{4}\right)y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= x^2 - \frac{1}{4} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 721: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2}\,dx} \\
&= z_1 e^{-\frac{\ln(x)}{2}} \\
&= z_1\left(\frac{1}{\sqrt{x}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\cos(x)}{\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(\tan(x))
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\cos(x)}{\sqrt{x}}\right) + c_2 \left(\frac{\cos(x)}{\sqrt{x}} (\tan(x))\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1 \cos(x)}{\sqrt{x}} + \frac{c_2 \sin(x)}{\sqrt{x}} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1 \cos(x)}{\sqrt{x}} + \frac{c_2 \sin(x)}{\sqrt{x}}
$$

Verified OK.

24.5.4 Maple step by step solution

Let's solve

$y''x^2 + y'x + \left(x^2 - \frac{1}{4}\right) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(4x^2-1)y}{4x^2} - \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + \frac{(4x^2-1)y}{4x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{1}{x}, P_3(x) = \frac{4x^2-1}{4x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\Big|_{x=0} = 1$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\Big|_{x=0} = -\frac{1}{4}$

- $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $4y''x^2+4y'x+(4x^2-1)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m=0..2$

    $x^m \cdot y=\sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k->k-m$

    $x^m \cdot y=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x \cdot y'$ to series expansion

    $x \cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r}$

  - Convert $x^2 \cdot y''$ to series expansion

    $x^2 \cdot y''=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+2r)\,(-1+2r)\,x^r+a_1(3+2r)\,(1+2r)\,x^{1+r}+\left(\sum_{k=2}^{\infty} (a_k(2k+2r+1)\,(2k+2r-1)+4a_{k-}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+2r)\,(-1+2r)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{-\frac{1}{2},\frac{1}{2}\right\}$

- Each term must be 0

  $a_1(3+2r)\,(1+2r)=0$

- Solve for the dependent coefficient(s)

  $a_1=0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(4k^2+8kr+4r^2-1)+4a_{k-2}=0$

- Shift index using $k->k+2$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 18.2. Expanding a solution in generalized power series. Bessels equation. Exercises page 177
Problem number: 746.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + \frac{y'}{x} + \frac{y}{9} = 0}$$

24.6.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2 y'' + y' x + \frac{y x^2}{9} = 0 \tag{1}$$

Bessel ode has the form

$$x^2 y'' + y' x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2 y'' + (1 - 2\alpha) x y' + \left(\beta^2 \gamma^2 x^{2\gamma} - n^2 \gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha (c_1 \operatorname{BesselJ}(n, \beta x^\gamma) + c_2 \operatorname{BesselY}(n, \beta x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = 0$$
$$\beta = \frac{1}{3}$$
$$n = 0$$
$$\gamma = 1$$

Substituting all the above into (4) gives the solution as

$$y = c_1 \text{BesselJ}\left(0, \frac{x}{3}\right) + c_2 \text{BesselY}\left(0, \frac{x}{3}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \text{BesselJ}\left(0, \frac{x}{3}\right) + c_2 \text{BesselY}\left(0, \frac{x}{3}\right) \tag{1}$$

Verification of solutions

$$y = c_1 \text{BesselJ}\left(0, \frac{x}{3}\right) + c_2 \text{BesselY}\left(0, \frac{x}{3}\right)$$

Verified OK.

24.6.2 Maple step by step solution

Let's solve

$9y''x + yx + 9y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y'}{x} - \frac{y}{9}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + \frac{y}{9} = 0$

- Simplify ODE

  $y''x^2 + y'x + \frac{yx^2}{9} = 0$

- Make a change of variables

  $t = \frac{x}{3}$

- Compute y'

  $y' = \frac{\frac{d}{dt}y(t)}{3}$
- Compute second derivative

  $y'' = \frac{\frac{d^2}{dt^2}y(t)}{9}$
- Apply change of variables to the ODE

  $\left(\frac{d^2}{dt^2}y(t)\right)t^2 + \left(\frac{d}{dt}y(t)\right)t + y(t)\,t^2 = 0$
- ODE is now of the Bessel form
- Solution to Bessel ODE

  $y(t) = c_1 \mathit{BesselJ}(0, t) + c_2 \mathit{BesselY}(0, t)$
- Make the change from t back to x

  $y = c_1 \mathit{BesselJ}\left(0, \frac{x}{3}\right) + c_2 \mathit{BesselY}\left(0, \frac{x}{3}\right)$

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + \frac{y'}{x} + 4y = 0}$$

24.7.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2 y'' + y' x + 4y x^2 = 0 \tag{1}$$

Bessel ode has the form

$$x^2 y'' + y' x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2 y'' + (1 - 2\alpha) x y' + \left(\beta^2 \gamma^2 x^{2\gamma} - n^2 \gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha (c_1 \operatorname{BesselJ}(n, \beta x^\gamma) + c_2 \operatorname{BesselY}(n, \beta x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = 0$$
$$\beta = 2$$
$$n = 0$$
$$\gamma = 1$$

Substituting all the above into (4) gives the solution as

$$y = c_1 \operatorname{BesselJ}(0, 2x) + c_2 \operatorname{BesselY}(0, 2x)$$

Summary

The solution(s) found are the following

$$y = c_1 \operatorname{BesselJ}(0, 2x) + c_2 \operatorname{BesselY}(0, 2x) \tag{1}$$

Verification of solutions

$$y = c_1 \operatorname{BesselJ}(0, 2x) + c_2 \operatorname{BesselY}(0, 2x)$$

Verified OK.

Problem number: 748.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - 2y'x + 4\left(x^4 - 1\right)y = 0}$$

24.8.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' - 2y'x + \left(4x^4 - 4\right)y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right)y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$
\begin{aligned}
\alpha &= \frac{3}{2} \\
\beta &= 1 \\
n &= -\frac{5}{4} \\
\gamma &= 2
\end{aligned}
$$

Substituting all the above into (4) gives the solution as

$$
y = c_1 x^{\frac{3}{2}} \operatorname{BesselJ}\left(-\frac{5}{4}, x^2\right) + c_2 x^{\frac{3}{2}} \operatorname{BesselY}\left(-\frac{5}{4}, x^2\right)
$$

Summary

The solution(s) found are the following

$$
y = c_1 x^{\frac{3}{2}} \operatorname{BesselJ}\left(-\frac{5}{4}, x^2\right) + c_2 x^{\frac{3}{2}} \operatorname{BesselY}\left(-\frac{5}{4}, x^2\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 x^{\frac{3}{2}} \operatorname{BesselJ}\left(-\frac{5}{4}, x^2\right) + c_2 x^{\frac{3}{2}} \operatorname{BesselY}\left(-\frac{5}{4}, x^2\right)
$$

Verified OK.

24.8.2 Maple step by step solution

Let's solve

$y''x^2 - 2y'x + (4x^4 - 4)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{4(x^4-1)y}{x^2} + \frac{2y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{2y'}{x} + \frac{4(x^4-1)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ○ Define functions

$\left[P_2(x) = -\frac{2}{x}, P_3(x) = \frac{4(x^4-1)}{x^2}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\bigg|_{x=0} = -2$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = -4$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x^2 - 2y'x + (4x^4 - 4)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..4$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$

- Convert $x^2 \cdot y''$ to series expansion

  $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)\,(-4+r)\,x^r + a_1(2+r)\,(-3+r)\,x^{1+r} + a_2(3+r)\,(-2+r)\,x^{2+r} + a_3(4+r)\,(-1+r)\,x$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(1+r)(-4+r)=0$

- Values of r that satisfy the indicial equation

  $r \in \{-1, 4\}$
- The coefficients of each power of x must be 0

  $[a_1(2+r)(-3+r)=0, a_2(3+r)(-2+r)=0, a_3(4+r)(-1+r)=0]$
- Solve for the dependent coefficient(s)

  $\{a_1=0, a_2=0, a_3=0\}$
- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+1)(k+r-4)+4a_{k-4}=0$
- Shift index using $k->k+4$

  $a_{k+4}(k+5+r)(k+r)+4a_k=0$
- Recursion relation that defines series solution to ODE

  $a_{k+4}=-\frac{4a_k}{(k+5+r)(k+r)}$
- Recursion relation for $r=-1$

  $a_{k+4}=-\frac{4a_k}{(k+4)(k-1)}$
- Solution for $r=-1$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+4}=-\frac{4a_k}{(k+4)(k-1)}, a_1=0, a_2=0, a_3=0\right]$
- Recursion relation for $r=4$

  $a_{k+4}=-\frac{4a_k}{(k+9)(k+4)}$
- Solution for $r=4$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k+4}, a_{k+4}=-\frac{4a_k}{(k+9)(k+4)}, a_1=0, a_2=0, a_3=0\right]$
- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty} a_k x^{k-1}\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+4}\right), a_{k+4}=-\frac{4a_k}{(k+4)(k-1)}, a_1=0, a_2=0, a_3=0, b_{k+4}=-\frac{4b_k}{(k+9)(k+\right.$

The type(s) of ODE detected by this program : **"kovacic", "second__order__bessel__ode", "second__order__change__of__variable__on__x__method__1", "second__order__change__of__variable__on__x__method__2"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler], [_2nd_order, _linear, `_with_symmetry_[0,F(
   x)]`]]
```

$$\boxed{y''x + \frac{y'}{2} + \frac{y}{4} = 0}$$

24.9.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$y''x + \frac{y'}{2} + \frac{y}{4} = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= \frac{1}{2x} \\
q(x) &= \frac{1}{4x}
\end{aligned}
$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$
\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau) \right) + q_1 y(\tau) = 0 \tag{3}
$$

Where τ is the new independent variable, and

$$
p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}
$$

$$
q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}
$$

Let $p_1 = 0$. Eq (4) simplifies to

$$
\tau''(x) + p(x)\,\tau'(x) = 0
$$

This ode is solved resulting in

$$
\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\
&= \int \mathrm{e}^{-\left(\int \frac{1}{2x} dx\right)} dx \\
&= \int e^{-\frac{\ln(x)}{2}} dx \\
&= \int \frac{1}{\sqrt{x}} dx \\
&= 2\sqrt{x}
\end{aligned} \tag{6}
$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{1}{4x}}{\frac{1}{x}} \\
&= \frac{1}{4}
\end{aligned} \tag{7}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{4} = 0$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = \frac{1}{4}$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda\tau} + \frac{e^{\lambda\tau}}{4} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 + \frac{1}{4} = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = \frac{1}{4}$ into the above gives

$$\lambda_{1,2} = \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)\left(\frac{1}{4}\right)}$$
$$= \pm\frac{i}{2}$$

Hence

$$\lambda_1 = +\frac{i}{2}$$
$$\lambda_2 = -\frac{i}{2}$$

Which simplifies to

$$\lambda_1 = \frac{i}{2}$$
$$\lambda_2 = -\frac{i}{2}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = \frac{1}{2}$. Therefore the final solution, when using Euler relation, can be written as

$$y(\tau) = e^{\alpha\tau}(c_1 \cos(\beta\tau) + c_2 \sin(\beta\tau))$$

Which becomes

$$y(\tau) = e^{0}\left(c_1 \cos\left(\frac{\tau}{2}\right) + c_2 \sin\left(\frac{\tau}{2}\right)\right)$$

Or

$$y(\tau) = c_1 \cos\left(\frac{\tau}{2}\right) + c_2 \sin\left(\frac{\tau}{2}\right)$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right) \tag{1}$$

Verification of solutions

$$y = c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right)$$

Verified OK.

24.9.2 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$y''x + \frac{y'}{2} + \frac{y}{4} = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = \frac{1}{2x}$$
$$q(x) = \frac{1}{4x}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{\frac{1}{x}}}{2c} \\ \tau'' &= -\frac{1}{4c\sqrt{\frac{1}{x}}\,x^2} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{1}{4c\sqrt{\frac{1}{x}}\,x^2} + \frac{1}{2x}\frac{\sqrt{\frac{1}{x}}}{2c}}{\left(\frac{\sqrt{\frac{1}{x}}}{2c}\right)^2} \\ &= 0 \end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned} y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0 \end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$\begin{aligned}\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int \frac{\sqrt{\frac{1}{x}}}{2}dx}{c} \\ &= \frac{x\sqrt{\frac{1}{x}}}{c}\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right) \tag{1}$$

Verification of solutions

$$y = c_1 \cos\left(\sqrt{x}\right) + c_2 \sin\left(\sqrt{x}\right)$$

Verified OK.

24.9.3 Solving as second order bessel ode ode

Writing the ode as

$$x^2 y'' + \frac{y'x}{2} + \frac{yx}{4} = 0 \tag{1}$$

Bessel ode has the form

$$x^2 y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2 y'' + (1 - 2\alpha)\, x y' + \left(\beta^2 \gamma^2 x^{2\gamma} - n^2 \gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{4}$$
$$\beta = 1$$
$$n = \frac{1}{2}$$
$$\gamma = \frac{1}{2}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1\sqrt{2}\,\sin\left(\sqrt{x}\right)}{\sqrt{\pi}} - \frac{c_2\sqrt{2}\,\cos\left(\sqrt{x}\right)}{\sqrt{\pi}}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1\sqrt{2}\,\sin\left(\sqrt{x}\right)}{\sqrt{\pi}} - \frac{c_2\sqrt{2}\,\cos\left(\sqrt{x}\right)}{\sqrt{\pi}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1\sqrt{2}\,\sin\left(\sqrt{x}\right)}{\sqrt{\pi}} - \frac{c_2\sqrt{2}\,\cos\left(\sqrt{x}\right)}{\sqrt{\pi}}$$

Verified OK.

24.9.4 Solving using Kovacic algorithm

Writing the ode as

$$y''x + \frac{y'}{2} + \frac{y}{4} = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$A = x$$
$$B = \frac{1}{2} \tag{3}$$
$$C = \frac{1}{4}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4x - 3}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4x - 3 \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-4x - 3}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 726: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 1 \\ &= 1 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [2]$$

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16x^2} - \frac{1}{4x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is $1 < 2$ then

$$E_\infty = \{1\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{1, 2, 3\}$

Order of r at ∞	E_∞
1	$\{1\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 1, \; e_\infty = 1$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(1-(1)) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{1}{(x-(0))}\right) \\ &= \frac{1}{2x} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d=0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d=0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned} \phi &= \theta + \frac{p'}{p} \\ &= \frac{1}{2x} \end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \frac{w}{2x} + \frac{1+4x}{16x^2} = 0$$

Solving for ω gives

$$\omega = \frac{1+2\sqrt{-x}}{4x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{1+2\sqrt{-x}}{4x} dx} \\ &= x^{\frac{1}{4}} \mathrm{e}^{\sqrt{-x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{\frac{1}{2}}{x} \, dx} \\ &= z_1 e^{-\frac{\ln(x)}{4}} \\ &= z_1 \left(\frac{1}{x^{\frac{1}{4}}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\sqrt{-x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{\frac{1}{2}}{x} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-\frac{\ln(x)}{2}}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{\sqrt{-x}\left(-1+\mathrm{e}^{-2\sqrt{-x}}\right)}{\sqrt{x}}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(e^{\sqrt{-x}}\right) + c_2\left(e^{\sqrt{-x}}\left(\frac{\sqrt{-x}\left(-1+e^{-2\sqrt{-x}}\right)}{\sqrt{x}}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^{\sqrt{-x}} - \frac{c_2\sqrt{-x}\left(e^{\sqrt{-x}} - e^{-\sqrt{-x}}\right)}{\sqrt{x}} \tag{1}
$$

Verification of solutions

$$
y = c_1 e^{\sqrt{-x}} - \frac{c_2\sqrt{-x}\left(e^{\sqrt{-x}} - e^{-\sqrt{-x}}\right)}{\sqrt{x}}
$$

Verified OK.

24.9.5 Maple step by step solution

Let's solve

$y''x + \frac{y'}{2} + \frac{y}{4} = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y}{4x} - \frac{y'}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{2x} + \frac{y}{4x} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

- ◦ Define functions

  $\left[P_2(x) = \frac{1}{2x}, P_3(x) = \frac{1}{4x}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = \frac{1}{2}$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 0$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4y''x + 2y' + y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions

  - Convert y' to series expansion

    $y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1}$

  - Shift index using $k- >k+1$

    $y' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, x^{k+r}$

  - Convert $x \cdot y''$ to series expansion

    $x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$

  - Shift index using $k- >k+1$

    $x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $2a_0r(-1+2r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} (2a_{k+1}(k+1+r)\,(2k+1+2r) + a_k)\, x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $2r(-1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, \frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

$$4\left(k+\frac{1}{2}+r\right)\left(k+1+r\right)a_{k+1}+a_k=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=-\frac{a_k}{2(2k+1+2r)(k+1+r)}$$

- Recursion relation for $r=0$

$$a_{k+1}=-\frac{a_k}{2(2k+1)(k+1)}$$

- Solution for $r=0$

$$\left[y=\sum_{k=0}^{\infty}a_k x^k, a_{k+1}=-\frac{a_k}{2(2k+1)(k+1)}\right]$$

- Recursion relation for $r=\frac{1}{2}$

$$a_{k+1}=-\frac{a_k}{2(2k+2)\left(k+\frac{3}{2}\right)}$$

- Solution for $r=\frac{1}{2}$

$$\left[y=\sum_{k=0}^{\infty}a_k x^{k+\frac{1}{2}}, a_{k+1}=-\frac{a_k}{2(2k+2)\left(k+\frac{3}{2}\right)}\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}a_k x^k\right)+\left(\sum_{k=0}^{\infty}b_k x^{k+\frac{1}{2}}\right), a_{k+1}=-\frac{a_k}{2(2k+1)(k+1)}, b_{k+1}=-\frac{b_k}{2(2k+2)\left(k+\frac{3}{2}\right)}\right]$$

Problem number: 750.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

`[_Lienard]`

$$\boxed{y'' + \frac{5y'}{x} + y = 0}$$

24.10.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + 5y'x + yx^2 = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\, xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}\left(n, \beta\, x^{\gamma}\right) + c_2 \operatorname{BesselY}\left(n, \beta\, x^{\gamma}\right)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}\alpha &= -2\\ \beta &= 1\\ n &= 2\\ \gamma &= 1\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1 \operatorname{BesselJ}(2, x)}{x^2} + \frac{c_2 \operatorname{BesselY}(2, x)}{x^2}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 \operatorname{BesselJ}(2, x)}{x^2} + \frac{c_2 \operatorname{BesselY}(2, x)}{x^2} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \operatorname{BesselJ}(2, x)}{x^2} + \frac{c_2 \operatorname{BesselY}(2, x)}{x^2}$$

Verified OK.

24.10.2 Maple step by step solution

Let's solve

$y''x + yx + 5y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{5y'}{x} - y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{5y'}{x} + y = 0$

- Simplify ODE

  $y''x^2 + 5y'x + yx^2 = 0$

- Make a change of variables

  $y = \frac{u(x)}{x^2}$

- Compute y'

  $y' = -\frac{2u(x)}{x^3} + \frac{u'(x)}{x^2}$

- Compute y''

  $y'' = \frac{6u(x)}{x^4} - \frac{4u'(x)}{x^3} + \frac{u''(x)}{x^2}$

- Apply change of variables to the ODE

  $u(x)\, x^2 + u''(x)\, x^2 + u'(x)\, x - 4u(x) = 0$

- ODE is now of the Bessel form
- Solution to Bessel ODE

  $u(x) = c_1 BesselJ(2, x) + c_2 BesselY(2, x)$

- Make the change from y back to y

  $y = \frac{c_1 BesselJ(2,x) + c_2 BesselY(2,x)}{x^2}$

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y'' + \frac{3y'}{x} + 4y = 0}$$

24.11.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + 3y'x + 4yx^2 = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\, xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = -1$$
$$\beta = 2$$
$$n = 1$$
$$\gamma = 1$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1 \operatorname{BesselJ}(1, 2x)}{x} + \frac{c_2 \operatorname{BesselY}(1, 2x)}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 \operatorname{BesselJ}(1, 2x)}{x} + \frac{c_2 \operatorname{BesselY}(1, 2x)}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \operatorname{BesselJ}(1, 2x)}{x} + \frac{c_2 \operatorname{BesselY}(1, 2x)}{x}$$

Verified OK.

24.11.2 Maple step by step solution

Let's solve

$y''x + 4yx + 3y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{3y'}{x} - 4y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{3y'}{x} + 4y = 0$

- Simplify ODE

  $y''x^2 + 3y'x + 4yx^2 = 0$

- Make a change of variables

  $t = 2x$

- Compute y'

  $y' = 2\frac{d}{dt}y(t)$
- Compute second derivative

  $y'' = 4\frac{d^2}{dt^2}y(t)$
- Apply change of variables to the ODE

  $\left(\frac{d^2}{dt^2}y(t)\right)t^2 + 3\left(\frac{d}{dt}y(t)\right)t + y(t)\,t^2 = 0$
- Make a change of variables

  $y(t) = \frac{u(t)}{t}$
- Compute $\frac{d}{dt}y(t)$

  $\frac{d}{dt}y(t) = -\frac{u(t)}{t^2} + \frac{\frac{d}{dt}u(t)}{t}$
- Compute $\frac{d^2}{dt^2}y(t)$

  $\frac{d^2}{dt^2}y(t) = \frac{2u(t)}{t^3} - \frac{2\left(\frac{d}{dt}u(t)\right)}{t^2} + \frac{\frac{d^2}{dt^2}u(t)}{t}$
- Apply change of variables to the ODE

  $t^2u(t) + \left(\frac{d^2}{dt^2}u(t)\right)t^2 + \left(\frac{d}{dt}u(t)\right)t - u(t) = 0$
- ODE is now of the Bessel form
- Solution to Bessel ODE

  $u(t) = c_1 BesselJ(1, t) + c_2 BesselY(1, t)$
- Make the change from y back to $y(t)$

  $y(t) = \frac{c_1 BesselJ(1,t)+c_2 BesselY(1,t)}{t}$
- Make the change from t back to x

  $y = \frac{c_1 BesselJ(1,2x)+c_2 BesselY(1,2x)}{2x}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 4y = \cos(x)^2}$$

25.1.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 4, f(x) = \cos(x)^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(4)} \\ &= \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2i \\ \lambda_2 &= -2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2i \\ \lambda_2 &= -2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(2x) + c_2 \sin(2x))$$

Or

$$y = c_1 \cos(2x) + c_2 \sin(2x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(2x) + c_2 \sin(2x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(x)^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(2x), \sin(2x)\}$$

Since $\cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{1\}, \{x\cos(2x), x\sin(2x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 + A_2 x\cos(2x) + A_3 x\sin(2x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_2 \sin(2x) + 4A_3 \cos(2x) + 4A_1 = \cos(x)^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{8}, A_2 = 0, A_3 = \frac{1}{8}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{8} + \frac{x \sin(2x)}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(2x) + c_2 \sin(2x)) + \left(\frac{1}{8} + \frac{x \sin(2x)}{8}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(2x) + c_2 \sin(2x) + \frac{1}{8} + \frac{x \sin(2x)}{8} \tag{1}$$

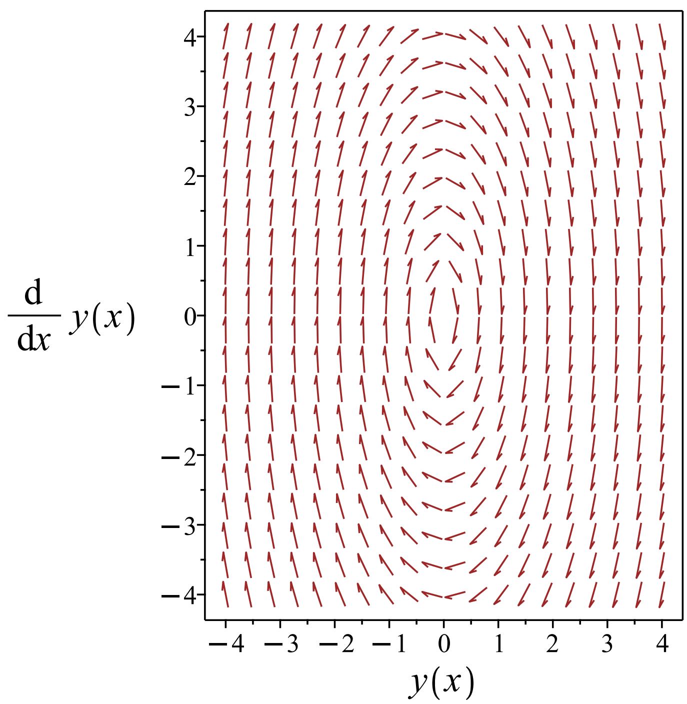

Figure 827: Slope field plot

Verification of solutions

$$y = c_1 \cos(2x) + c_2 \sin(2x) + \frac{1}{8} + \frac{x \sin(2x)}{8}$$

Verified OK.

25.1.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 730: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(2x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(2x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \cos(2x) \int \frac{1}{\cos(2x)^2}\, dx \\ &= \cos(2x) \left(\frac{\tan(2x)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(2x)) + c_2\left(\cos(2x)\left(\frac{\tan(2x)}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(x)^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sin(2x)}{2}, \cos(2x)\right\}$$

Since $\cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{1\}, \{x\cos(2x), x\sin(2x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 + A_2 x\cos(2x) + A_3 x\sin(2x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_2 \sin(2x) + 4A_3 \cos(2x) + 4A_1 = \cos(x)^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{8}, A_2 = 0, A_3 = \frac{1}{8}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{8} + \frac{x\sin(2x)}{8}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2}\right) + \left(\frac{1}{8} + \frac{x \sin(2x)}{8}\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2} + \frac{1}{8} + \frac{x \sin(2x)}{8} \tag{1}
$$

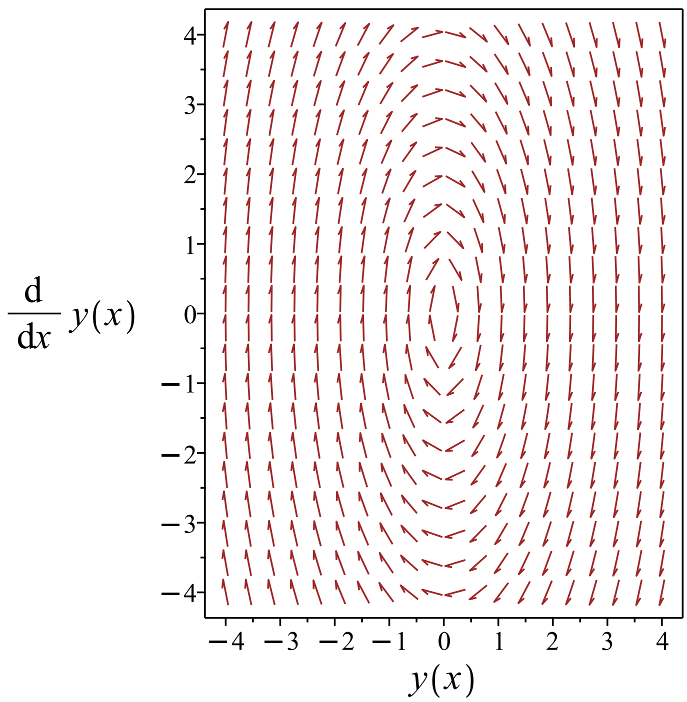

Figure 828: Slope field plot

Verification of solutions

$$
y = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2} + \frac{1}{8} + \frac{x \sin(2x)}{8}
$$

Verified OK.

25.1.3 Maple step by step solution

Let's solve

$y'' + 4y = \cos(x)^2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r = (-2\,\mathrm{I}, 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(2x) + c_2 \sin(2x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \cos(x)^2\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(2x) & \sin(2x) \\ -2\sin(2x) & 2\cos(2x) \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2$

- ○ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{\cos(2x)\left(\int \sin(2x)\cos(x)^2 dx\right)}{2} + \frac{\sin(2x)\left(\int \cos(2x)\cos(x)^2 dx\right)}{2}$$

- Compute integrals

$$y_p(x) = \frac{x\sin(2x)}{8} + \frac{\cos(2x)}{8} + \frac{1}{8}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 \cos(2x) + c_2 \sin(2x) + \frac{x\sin(2x)}{8} + \frac{\cos(2x)}{8} + \frac{1}{8}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 4y' + 4y = \pi^2 - x^2}$$

25.2.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 4, f(x) = \pi^2 - x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 4\lambda \, \mathrm{e}^{\lambda x} + 4 \, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-4)^2 - (4)(1)(4)} \\ &= 2\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -2$. Therefore the solution is

$$y = c_1 \mathrm{e}^{2x} + c_2 x \, \mathrm{e}^{2x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{2x} + c_2 x \, \mathrm{e}^{2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 + 1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x \, \mathrm{e}^{2x}, \mathrm{e}^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_3x^2 + A_2x + A_1$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_3x^2 + 4A_2x - 8xA_3 + 4A_1 - 4A_2 + 2A_3 = \pi^2 - x^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{\pi^2}{4} - \frac{3}{8}, A_2 = -\frac{1}{2}, A_3 = -\frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{1}{4}x^2 - \frac{1}{2}x + \frac{1}{4}\pi^2 - \frac{3}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{2x} + c_2 x\, \mathrm{e}^{2x}\right) + \left(-\frac{1}{4}x^2 - \frac{1}{2}x + \frac{1}{4}\pi^2 - \frac{3}{8}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{2x}(c_2x + c_1) - \frac{x^2}{4} - \frac{x}{2} + \frac{\pi^2}{4} - \frac{3}{8}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{2x}(c_2x + c_1) - \frac{x^2}{4} - \frac{x}{2} + \frac{\pi^2}{4} - \frac{3}{8} \tag{1}$$

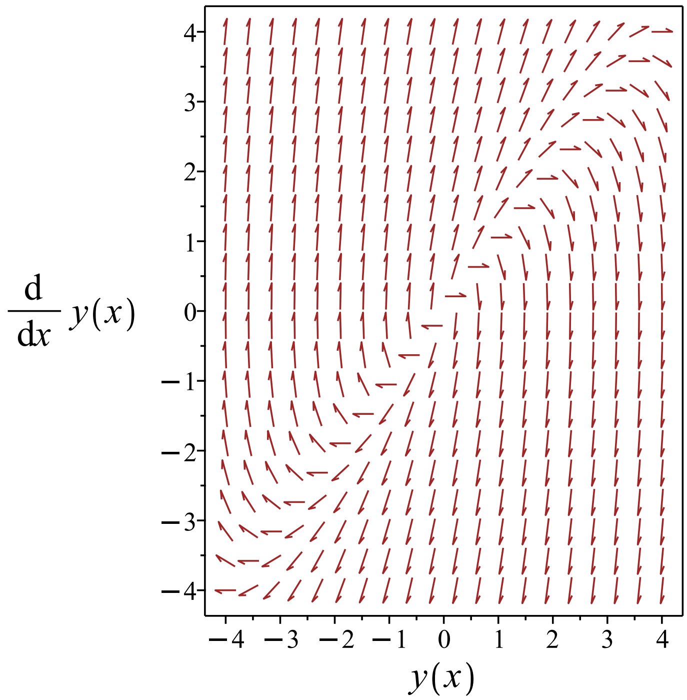

Figure 829: Slope field plot

Verification of solutions

$$y = e^{2x}(c_2 x + c_1) - \frac{x^2}{4} - \frac{x}{2} + \frac{\pi^2}{4} - \frac{3}{8}$$

Verified OK.

25.2.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -4$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int -4\, dx} \\ &= e^{-2x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= e^{-2x}(\pi^2 - x^2) \\
(e^{-2x}y)'' &= e^{-2x}(\pi^2 - x^2)
\end{aligned}
$$

Integrating once gives

$$
(e^{-2x}y)' = -\frac{e^{-2x}(2\pi^2 - 2x^2 - 2x - 1)}{4} + c_1
$$

Integrating again gives

$$
(e^{-2x}y) = \frac{(2\pi^2 - 2x^2 - 4x - 3)\, e^{-2x}}{8} + c_1 x + c_2
$$

Hence the solution is

$$
y = \frac{\frac{(2\pi^2 - 2x^2 - 4x - 3)\, e^{-2x}}{8} + c_1 x + c_2}{e^{-2x}}
$$

Or

$$
y = c_1 x\, e^{2x} + e^{2x} c_2 - \frac{x^2}{4} - \frac{x}{2} + \frac{\pi^2}{4} - \frac{3}{8}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x\, e^{2x} + e^{2x} c_2 - \frac{x^2}{4} - \frac{x}{2} + \frac{\pi^2}{4} - \frac{3}{8} \tag{1}
$$

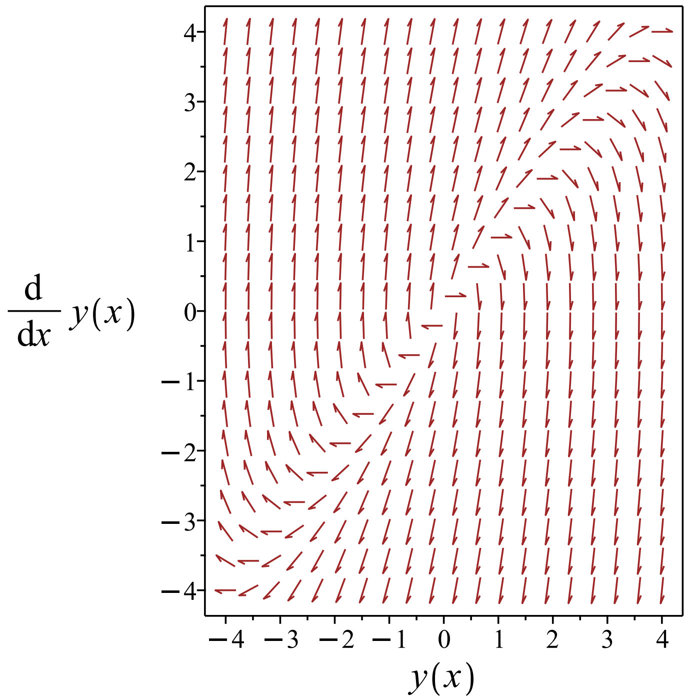

Figure 830: Slope field plot

Verification of solutions

$$y = c_1 x\,e^{2x} + e^{2x} c_2 - \frac{x^2}{4} - \frac{x}{2} + \frac{\pi^2}{4} - \frac{3}{8}$$

Verified OK.

25.2.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 732: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx} \\ &= z_1 e^{2x} \\ &= z_1 \left(\mathrm{e}^{2x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{4x}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{2x}\right) + c_2\left(\mathrm{e}^{2x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
y'' - 4y' + 4y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{2x} + c_2 x\,\mathrm{e}^{2x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
x^2 + 1
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{1, x, x^2\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{x\,\mathrm{e}^{2x}, \mathrm{e}^{2x}\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_3 x^2 + A_2 x + A_1
$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
4A_3x^2 + 4A_2x - 8xA_3 + 4A_1 - 4A_2 + 2A_3 = \pi^2 - x^2
$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{\pi^2}{4} - \frac{3}{8}, A_2 = -\frac{1}{2}, A_3 = -\frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{1}{4}x^2 - \frac{1}{2}x + \frac{1}{4}\pi^2 - \frac{3}{8}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{2x} + c_2 x\, \mathrm{e}^{2x}\right) + \left(-\frac{1}{4}x^2 - \frac{1}{2}x + \frac{1}{4}\pi^2 - \frac{3}{8}\right)\end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{2x}(c_2 x + c_1) - \frac{x^2}{4} - \frac{x}{2} + \frac{\pi^2}{4} - \frac{3}{8}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{2x}(c_2 x + c_1) - \frac{x^2}{4} - \frac{x}{2} + \frac{\pi^2}{4} - \frac{3}{8} \tag{1}$$

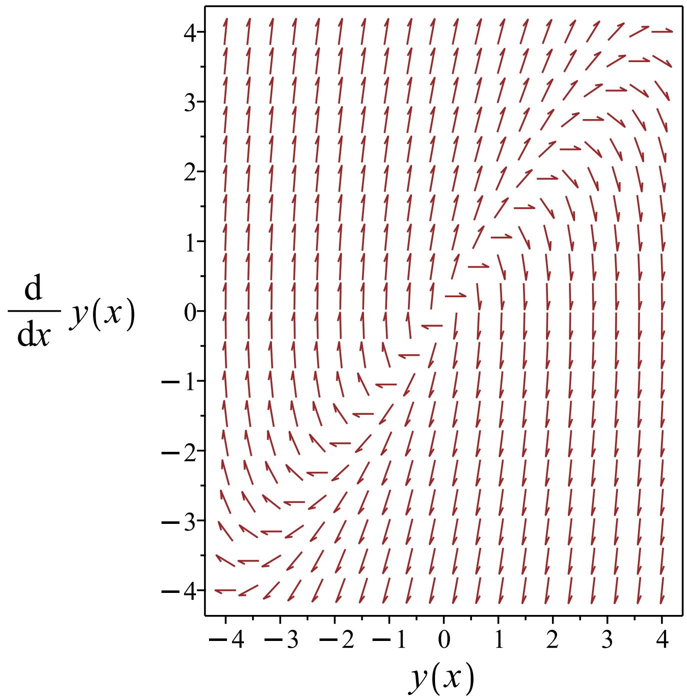

Figure 831: Slope field plot

Verification of solutions

$$y = e^{2x}(c_2x + c_1) - \frac{x^2}{4} - \frac{x}{2} + \frac{\pi^2}{4} - \frac{3}{8}$$

Verified OK.

25.2.4 Maple step by step solution

Let's solve

$y'' - 4y' + 4y = \pi^2 - x^2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 4r + 4 = 0$

- Factor the characteristic polynomial

  $(r-2)^2 = 0$

- Root of the characteristic polynomial

$r = 2$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{2x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,\mathrm{e}^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{2x} + c_2 x\,\mathrm{e}^{2x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \pi^2 - x^2\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{2x} & x\,\mathrm{e}^{2x} \\ 2\,\mathrm{e}^{2x} & \mathrm{e}^{2x} + 2x\,\mathrm{e}^{2x} \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = \mathrm{e}^{4x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = \mathrm{e}^{2x}\left(-\left(\int x\,\mathrm{e}^{-2x}(\pi^2 - x^2)\,dx\right) + \left(\int \mathrm{e}^{-2x}(\pi^2 - x^2)\,dx\right)x\right)$

  ◦ Compute integrals

  $y_p(x) = -\frac{1}{4}x^2 - \frac{1}{2}x + \frac{1}{4}\pi^2 - \frac{3}{8}$

- Substitute particular solution into general solution to ODE

  $y = c_2 x\,\mathrm{e}^{2x} + c_1 \mathrm{e}^{2x} - \frac{x^2}{4} - \frac{x}{2} + \frac{\pi^2}{4} - \frac{3}{8}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 4y = \cos(\pi x)}$$

25.3.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = -4, f(x) = \cos(\pi x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = -4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 4 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-4)} \\ &= \pm 2\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2 \\ \lambda_2 &= -2\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2 \\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(2)x} + c_2 e^{(-2)x}\end{aligned}$$

Or

$$y = c_1 e^{2x} + c_2 e^{-2x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{2x} + c_2 e^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(\pi x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(\pi x), \sin(\pi x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-2x}, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(\pi x) + A_2 \sin(\pi x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1\pi^2 \cos(\pi x) - A_2\pi^2 \sin(\pi x) - 4A_1 \cos(\pi x) - 4A_2 \sin(\pi x) = \cos(\pi x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{\pi^2 + 4}, A_2 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{\cos(\pi x)}{\pi^2 + 4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{2x} + c_2 e^{-2x}\right) + \left(-\frac{\cos(\pi x)}{\pi^2 + 4}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{2x} + c_2 e^{-2x} - \frac{\cos(\pi x)}{\pi^2 + 4} \tag{1}$$

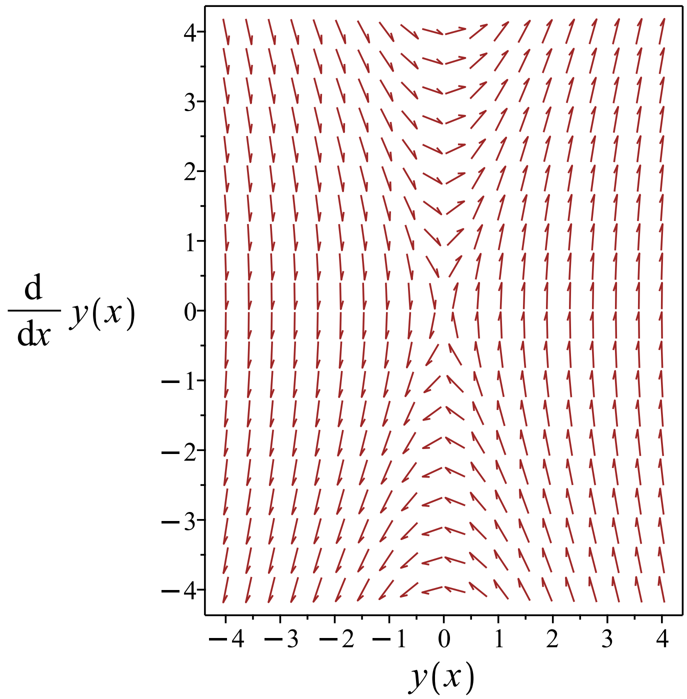

Figure 832: Slope field plot

Verification of solutions

$$y = c_1 e^{2x} + c_2 e^{-2x} - \frac{\cos(\pi x)}{\pi^2 + 4}$$

Verified OK.

25.3.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 0 \\
C &= -4
\end{aligned}
\tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A}\,dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
\tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{4}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 4 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = 4z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\,dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 734: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-2x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}
y_1 &= z_1 \\
&= \mathrm{e}^{-2x}
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2} \, dx \\ &= \mathrm{e}^{-2x} \int \frac{1}{\mathrm{e}^{-4x}} \, dx \\ &= \mathrm{e}^{-2x} \left(\frac{\mathrm{e}^{4x}}{4} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-2x} \right) + c_2 \left(\mathrm{e}^{-2x} \left(\frac{\mathrm{e}^{4x}}{4} \right) \right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-2x} + \frac{\mathrm{e}^{2x} c_2}{4}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(\pi x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(\pi x), \sin(\pi x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{e^{2x}}{4}, e^{-2x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(\pi x) + A_2 \sin(\pi x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1\pi^2 \cos(\pi x) - A_2\pi^2 \sin(\pi x) - 4A_1 \cos(\pi x) - 4A_2 \sin(\pi x) = \cos(\pi x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{\pi^2 + 4}, A_2 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{\cos(\pi x)}{\pi^2 + 4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-2x} + \frac{e^{2x} c_2}{4}\right) + \left(-\frac{\cos(\pi x)}{\pi^2 + 4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-2x} + \frac{e^{2x} c_2}{4} - \frac{\cos(\pi x)}{\pi^2 + 4} \tag{1}$$

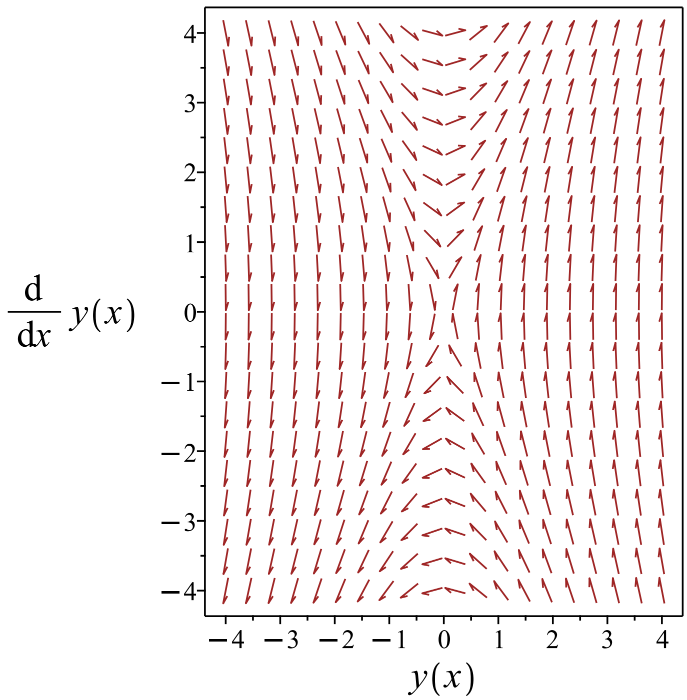

Figure 833: Slope field plot

Verification of solutions

$$y = c_1 e^{-2x} + \frac{e^{2x} c_2}{4} - \frac{\cos(\pi x)}{\pi^2 + 4}$$

Verified OK.

25.3.3 Maple step by step solution

Let's solve

$y'' - 4y = \cos(\pi x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 - 4 = 0$

- Factor the characteristic polynomial

  $(r-2)(r+2) = 0$
- Roots of the characteristic polynomial

  $r = (-2, 2)$
- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-2x}$
- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{2x}$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-2x} + e^{2x} c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \cos(\pi x)\right]$
  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-2x} & e^{2x} \\ -2 e^{-2x} & 2 e^{2x} \end{bmatrix}$
  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 4$
  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\frac{e^{-2x}\left(\int e^{2x} \cos(\pi x) dx\right)}{4} + \frac{e^{2x}\left(\int e^{-2x} \cos(\pi x) dx\right)}{4}$
  - Compute integrals

    $y_p(x) = -\frac{\cos(\pi x)}{\pi^2 + 4}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-2x} + e^{2x} c_2 - \frac{\cos(\pi x)}{\pi^2 + 4}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' - 4y' + 4y = \arcsin(\sin(x))}$$

25.4.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 4, f(x) = \arcsin(\sin(x))$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 4\lambda\, e^{\lambda x} + 4\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{(-4)^2 - (4)\,(1)\,(4)}\\ &= 2\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -2$. Therefore the solution is

$$y = c_1 e^{2x} + c_2 x\, e^{2x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{2x} + c_2 x\, e^{2x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}y_1 &= e^{2x}\\ y_2 &= x\, e^{2x}\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{2x} & x\,e^{2x} \\ \frac{d}{dx}(e^{2x}) & \frac{d}{dx}(x\,e^{2x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{2x} & x\,e^{2x} \\ 2\,e^{2x} & e^{2x} + 2x\,e^{2x} \end{vmatrix}$$

Therefore

$$W = (e^{2x})\left(e^{2x} + 2x\,e^{2x}\right) - \left(x\,e^{2x}\right)\left(2\,e^{2x}\right)$$

Which simplifies to

$$W = e^{4x}$$

Which simplifies to

$$W = e^{4x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x\,e^{2x} \arcsin(\sin(x))}{e^{4x}}\,dx$$

Which simplifies to

$$u_1 = -\int \arcsin(\sin(x))\,x\,e^{-2x}dx$$

Hence

$$u_1 = -\left(\int_0^x \arcsin(\sin(\alpha))\, \alpha\, \mathrm{e}^{-2\alpha} d\alpha\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\mathrm{e}^{2x} \arcsin(\sin(x))}{\mathrm{e}^{4x}} dx$$

Which simplifies to

$$u_2 = \int \arcsin(\sin(x))\, \mathrm{e}^{-2x} dx$$

Hence

$$u_2 = \int_0^x \arcsin(\sin(\alpha))\, \mathrm{e}^{-2\alpha} d\alpha$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\left(\int_0^x \arcsin(\sin(\alpha))\, \alpha\, \mathrm{e}^{-2\alpha} d\alpha\right) \mathrm{e}^{2x} + \left(\int_0^x \arcsin(\sin(\alpha))\, \mathrm{e}^{-2\alpha} d\alpha\right) x\, \mathrm{e}^{2x}$$

Which simplifies to

$$y_p(x) = \mathrm{e}^{2x}\left(-\left(\int_0^x \arcsin(\sin(\alpha))\, \alpha\, \mathrm{e}^{-2\alpha} d\alpha\right) + \left(\int_0^x \arcsin(\sin(\alpha))\, \mathrm{e}^{-2\alpha} d\alpha\right) x\right)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \mathrm{e}^{2x} + c_2 x\, \mathrm{e}^{2x}) \\ &\quad + \left(\mathrm{e}^{2x}\left(-\left(\int_0^x \arcsin(\sin(\alpha))\, \alpha\, \mathrm{e}^{-2\alpha} d\alpha\right) + \left(\int_0^x \arcsin(\sin(\alpha))\, \mathrm{e}^{-2\alpha} d\alpha\right) x\right)\right) \end{aligned}$$

Which simplifies to

$$\begin{aligned} y &= \mathrm{e}^{2x}(c_2 x + c_1) \\ &\quad + \mathrm{e}^{2x}\left(-\left(\int_0^x \arcsin(\sin(\alpha))\, \alpha\, \mathrm{e}^{-2\alpha} d\alpha\right) + \left(\int_0^x \arcsin(\sin(\alpha))\, \mathrm{e}^{-2\alpha} d\alpha\right) x\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{2x}(c_2 x + c_1) + e^{2x}\left(-\left(\int_0^x \arcsin(\sin(\alpha))\,\alpha\, e^{-2\alpha} d\alpha\right) + \left(\int_0^x \arcsin(\sin(\alpha))\, e^{-2\alpha} d\alpha\right) x\right) \tag{1}$$

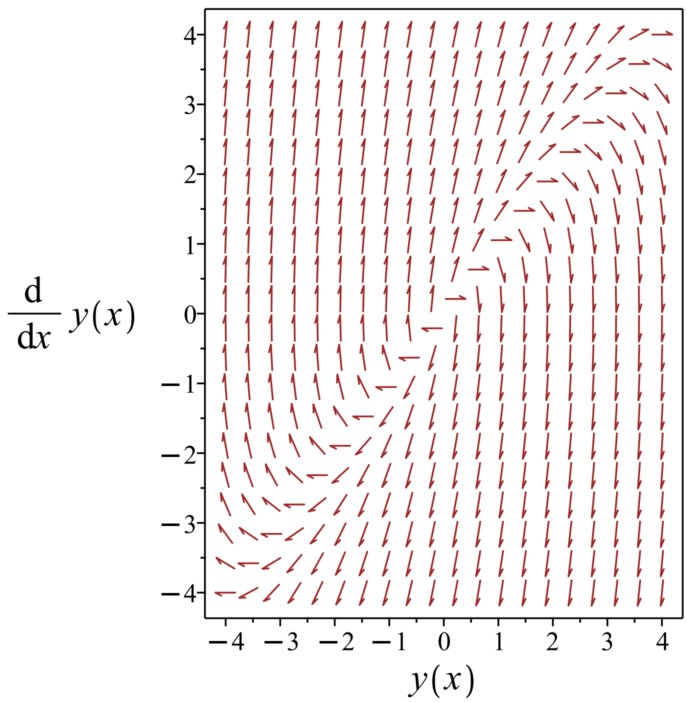

Figure 834: Slope field plot

Verification of solutions

$$y = e^{2x}(c_2 x + c_1) + e^{2x}\left(-\left(\int_0^x \arcsin(\sin(\alpha))\,\alpha\, e^{-2\alpha} d\alpha\right) + \left(\int_0^x \arcsin(\sin(\alpha))\, e^{-2\alpha} d\alpha\right) x\right)$$

Verified OK.

25.4.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -4$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int -4\, dx} \\ &= \mathrm{e}^{-2x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= \arcsin\left(\sin\left(x\right)\right) \mathrm{e}^{-2x} \\ \left(\mathrm{e}^{-2x}y\right)'' &= \arcsin\left(\sin\left(x\right)\right) \mathrm{e}^{-2x} \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{-2x}y\right)' = \int \arcsin\left(\sin\left(x\right)\right) \mathrm{e}^{-2x} dx + c_1$$

Integrating again gives

$$\left(\mathrm{e}^{-2x}y\right) = \int \left(\int \arcsin\left(\sin\left(x\right)\right) \mathrm{e}^{-2x} dx + c_1\right) dx + c_2$$

Hence the solution is

$$y = \frac{\int \left(\int \arcsin\left(\sin\left(x\right)\right) \mathrm{e}^{-2x} dx + c_1\right) dx + c_2}{\mathrm{e}^{-2x}}$$

Or

$$y = c_1 x\, \mathrm{e}^{2x} + \mathrm{e}^{2x} c_2 + \mathrm{e}^{2x} \left(\int \int \arcsin\left(\sin\left(x\right)\right) \mathrm{e}^{-2x} dx dx\right)$$

Summary

The solution(s) found are the following

$$y = c_1 x\, \mathrm{e}^{2x} + \mathrm{e}^{2x} c_2 + \mathrm{e}^{2x} \left(\int \int \arcsin\left(\sin\left(x\right)\right) \mathrm{e}^{-2x} dx dx\right) \tag{1}$$

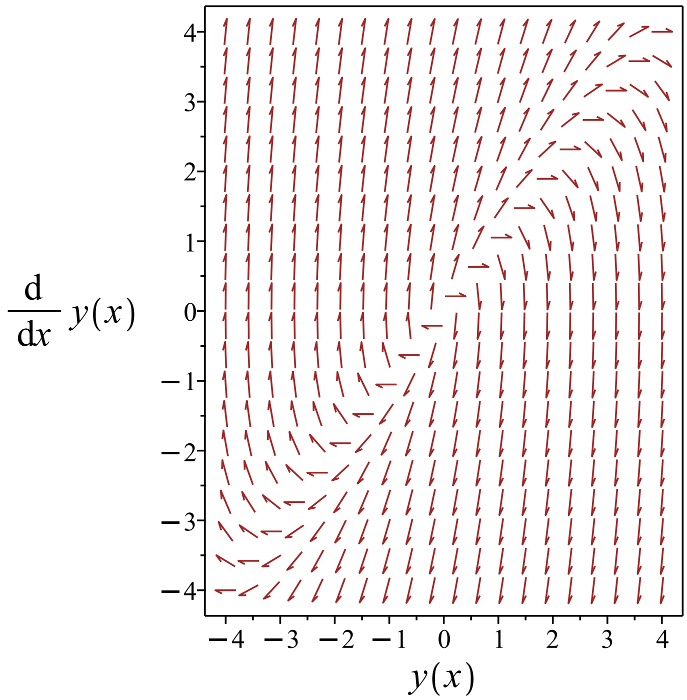

Figure 835: Slope field plot

Verification of solutions

$$y = c_1 x\,\mathrm{e}^{2x} + \mathrm{e}^{2x} c_2 + \mathrm{e}^{2x}\left(\int\int \arcsin\left(\sin\left(x\right)\right)\mathrm{e}^{-2x} dx dx\right)$$

Verified OK.

25.4.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 736: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx} \\ &= z_1 e^{2x} \\ &= z_1 \left(\mathrm{e}^{2x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{4x}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{2x}\right) + c_2 \left(\mathrm{e}^{2x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 4y' + 4y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{2x} + c_2 x \,\mathrm{e}^{2x}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \mathrm{e}^{2x} \\
y_2 &= x \,\mathrm{e}^{2x}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{2x} & x\,e^{2x} \\ \frac{d}{dx}\left(e^{2x}\right) & \frac{d}{dx}\left(x\,e^{2x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{2x} & x\,e^{2x} \\ 2\,e^{2x} & e^{2x} + 2x\,e^{2x} \end{vmatrix}$$

Therefore

$$W = \left(e^{2x}\right)\left(e^{2x} + 2x\,e^{2x}\right) - \left(x\,e^{2x}\right)\left(2\,e^{2x}\right)$$

Which simplifies to

$$W = e^{4x}$$

Which simplifies to

$$W = e^{4x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x\,e^{2x} \arcsin\left(\sin\left(x\right)\right)}{e^{4x}}\,dx$$

Which simplifies to

$$u_1 = -\int \arcsin\left(\sin\left(x\right)\right) x\,e^{-2x} dx$$

Hence

$$u_1 = -\left(\int_0^x \arcsin\left(\sin\left(\alpha\right)\right) \alpha\,e^{-2\alpha} d\alpha\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{2x} \arcsin\left(\sin\left(x\right)\right)}{e^{4x}}\,dx$$

Which simplifies to

$$u_2 = \int \arcsin(\sin(x))\,\mathrm{e}^{-2x} dx$$

Hence

$$u_2 = \int_0^x \arcsin(\sin(\alpha))\,\mathrm{e}^{-2\alpha} d\alpha$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\left(\int_0^x \arcsin(\sin(\alpha))\,\alpha\,\mathrm{e}^{-2\alpha} d\alpha\right)\mathrm{e}^{2x} + \left(\int_0^x \arcsin(\sin(\alpha))\,\mathrm{e}^{-2\alpha} d\alpha\right) x\,\mathrm{e}^{2x}$$

Which simplifies to

$$y_p(x) = \mathrm{e}^{2x}\left(-\left(\int_0^x \arcsin(\sin(\alpha))\,\alpha\,\mathrm{e}^{-2\alpha} d\alpha\right) + \left(\int_0^x \arcsin(\sin(\alpha))\,\mathrm{e}^{-2\alpha} d\alpha\right) x\right)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{2x} + c_2 x\,\mathrm{e}^{2x}\right) \\ &\quad + \left(\mathrm{e}^{2x}\left(-\left(\int_0^x \arcsin(\sin(\alpha))\,\alpha\,\mathrm{e}^{-2\alpha} d\alpha\right) + \left(\int_0^x \arcsin(\sin(\alpha))\,\mathrm{e}^{-2\alpha} d\alpha\right) x\right)\right) \end{aligned}$$

Which simplifies to

$$\begin{aligned} y &= \mathrm{e}^{2x}(c_2 x + c_1) \\ &\quad + \mathrm{e}^{2x}\left(-\left(\int_0^x \arcsin(\sin(\alpha))\,\alpha\,\mathrm{e}^{-2\alpha} d\alpha\right) + \left(\int_0^x \arcsin(\sin(\alpha))\,\mathrm{e}^{-2\alpha} d\alpha\right) x\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y &= \mathrm{e}^{2x}(c_2 x + c_1) \\ &\quad + \mathrm{e}^{2x}\left(-\left(\int_0^x \arcsin(\sin(\alpha))\,\alpha\,\mathrm{e}^{-2\alpha} d\alpha\right) + \left(\int_0^x \arcsin(\sin(\alpha))\,\mathrm{e}^{-2\alpha} d\alpha\right) x\right) \end{aligned} \tag{1}$$

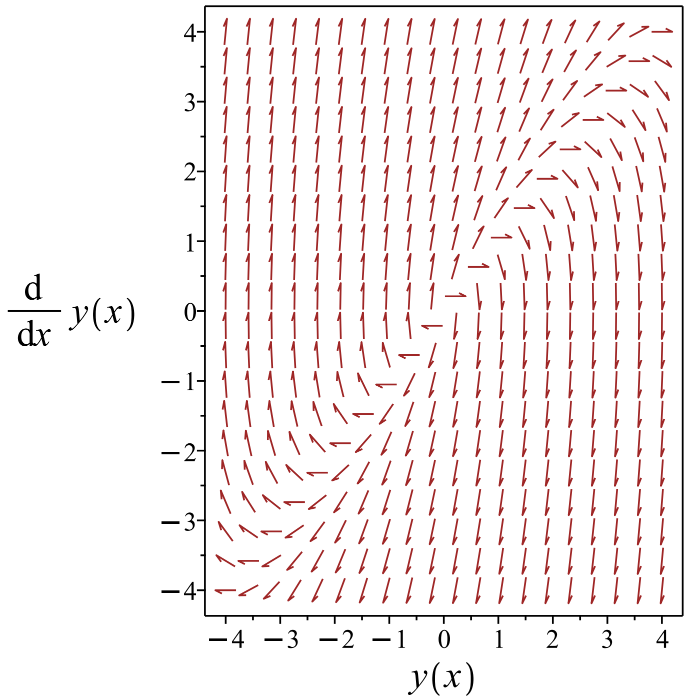

Figure 836: Slope field plot

Verification of solutions

$$y = e^{2x}(c_2 x + c_1) + e^{2x}\left(-\left(\int_0^x \arcsin(\sin(\alpha))\,\alpha\, e^{-2\alpha} d\alpha\right) + \left(\int_0^x \arcsin(\sin(\alpha))\, e^{-2\alpha} d\alpha\right) x\right)$$

Verified OK.

25.4.4 Maple step by step solution

Let's solve

$y'' - 4y' + 4y = \arcsin(\sin(x))$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 4r + 4 = 0$

- Factor the characteristic polynomial

  $(r-2)^2 = 0$

- Root of the characteristic polynomial

  $r = 2$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{2x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{2x} + c_2 x\,e^{2x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \arcsin(\sin(x))\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{2x} & x\,e^{2x} \\ 2\,e^{2x} & e^{2x} + 2x\,e^{2x} \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{4x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = e^{2x}\left(-\left(\int \arcsin(\sin(x))\,x\,e^{-2x} dx\right) + x\left(\int \arcsin(\sin(x))\,e^{-2x} dx\right)\right)$

  ◦ Compute integrals

  $y_p(x) = e^{2x}\left(-\left(\int \arcsin(\sin(x))\,x\,e^{-2x} dx\right) + \left(\int \arcsin(\sin(x))\,e^{-2x} dx\right) x\right)$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{2x} + c_2 x\,e^{2x} + e^{2x}\left(-\left(\int \arcsin(\sin(x))\,x\,e^{-2x} dx\right) + \left(\int \arcsin(\sin(x))\,e^{-2x} dx\right) x\right)$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 9y = \sin(x)^3}$$

25.5.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 9, f(x) = \sin(x)^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 9y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 9 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(9)}\\ &= \pm 3i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +3i\\ \lambda_2 &= -3i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 3i\\ \lambda_2 &= -3i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 3$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(3x) + c_2 \sin(3x))$$

Or

$$y = c_1 \cos(3x) + c_2 \sin(3x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(3x) + c_2 \sin(3x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)^3$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}, \{\cos(3x), \sin(3x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(3x), \sin(3x)\}$$

Since $\cos(3x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{\cos(x), \sin(x)\}, \{x\cos(3x), x\sin(3x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x) + A_3 x \cos(3x) + A_4 x \sin(3x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$8A_1 \cos(x) + 8A_2 \sin(x) - 6A_3 \sin(3x) + 6A_4 \cos(3x) = \sin(x)^3$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{3}{32}, A_3 = \frac{1}{24}, A_4 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{3\sin(x)}{32} + \frac{x\cos(3x)}{24}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(3x) + c_2 \sin(3x)) + \left(\frac{3\sin(x)}{32} + \frac{x\cos(3x)}{24}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(3x) + c_2 \sin(3x) + \frac{3\sin(x)}{32} + \frac{x\cos(3x)}{24} \tag{1}$$

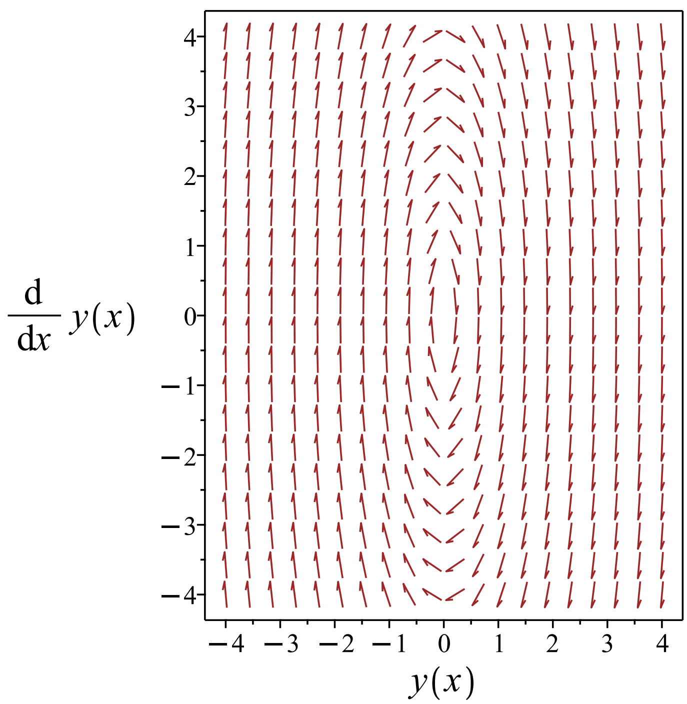

Figure 837: Slope field plot

Verification of solutions

$$y = c_1 \cos(3x) + c_2 \sin(3x) + \frac{3\sin(x)}{32} + \frac{x\cos(3x)}{24}$$

Verified OK.

25.5.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-9}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -9 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -9z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 738: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -9$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(3x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(3x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(3x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2} \, dx \\ &= \cos(3x) \int \frac{1}{\cos(3x)^2} \, dx \\ &= \cos(3x) \left(\frac{\tan(3x)}{3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(3x)) + c_2 \left(\cos(3x) \left(\frac{\tan(3x)}{3}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 9y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)^3$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}, \{\cos(3x), \sin(3x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sin(3x)}{3}, \cos(3x)\right\}$$

Since $\cos(3x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{\cos(x), \sin(x)\}, \{x\cos(3x), x\sin(3x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x) + A_3 x \cos(3x) + A_4 x \sin(3x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$8A_1 \cos(x) + 8A_2 \sin(x) - 6A_3 \sin(3x) + 6A_4 \cos(3x) = \sin(x)^3$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{3}{32}, A_3 = \frac{1}{24}, A_4 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{3\sin(x)}{32} + \frac{x\cos(3x)}{24}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3}\right) + \left(\frac{3\sin(x)}{32} + \frac{x\cos(3x)}{24}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3} + \frac{3\sin(x)}{32} + \frac{x\cos(3x)}{24} \tag{1}
$$

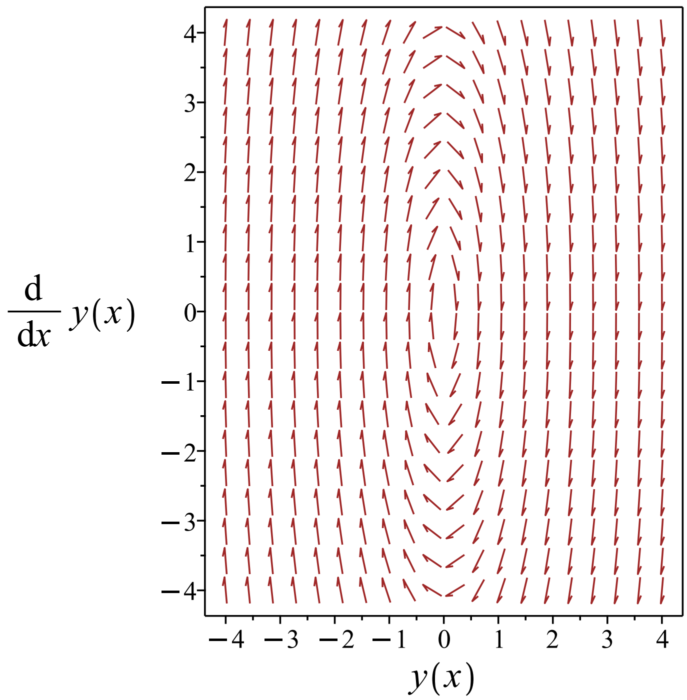

Figure 838: Slope field plot

Verification of solutions

$$
y = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3} + \frac{3\sin(x)}{32} + \frac{x\cos(3x)}{24}
$$

Verified OK.

25.5.3 Maple step by step solution

Let's solve

$y'' + 9y = \sin(x)^3$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 9 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-36})}{2}$

- Roots of the characteristic polynomial

  $r = (-3\,\mathrm{I}, 3\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(3x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(3x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(3x) + c_2 \sin(3x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ∘ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \sin(x)^3\right]$

- ∘ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(3x) & \sin(3x) \\ -3\sin(3x) & 3\cos(3x) \end{bmatrix}$

- ∘ Compute Wronskian

  $W(y_1(x), y_2(x)) = 3$

- ∘ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{\cos(3x)\left(\int \sin(3x)\sin(x)^3 dx\right)}{3} + \frac{\sin(3x)\left(\int \cos(3x)\sin(x)^3 dx\right)}{3}$$

- Compute integrals

$$y_p(x) = -\frac{\cos(x)^2 \sin(x)}{36} + \frac{29\sin(x)}{288} + \frac{\cos(x)^3 x}{6} - \frac{\cos(x)x}{8}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 \cos(3x) + c_2 \sin(3x) - \frac{\cos(x)^2 \sin(x)}{36} + \frac{29\sin(x)}{288} + \frac{\cos(x)^3 x}{6} - \frac{\cos(x)x}{8}$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= -9y(t) \\
y'(t) &= x(t)
\end{aligned}
$$

27.1.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & -9 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

For the above matrix A, the matrix exponential can be found to be

$$
e^{At} = \begin{bmatrix} \cos(3t) & -3\sin(3t) \\ \frac{\sin(3t)}{3} & \cos(3t) \end{bmatrix}
$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \cos(3t) & -3\sin(3t) \\ \frac{\sin(3t)}{3} & \cos(3t) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \cos(3t)\, c_1 - 3\sin(3t)\, c_2 \\ \frac{\sin(3t)c_1}{3} + \cos(3t)\, c_2 \end{bmatrix}
\end{aligned}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

27.1.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & -9 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 0 & -9 \\ 1 & 0 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -\lambda & -9 \\ 1 & -\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 9 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 3i$$
$$\lambda_2 = -3i$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$3i$	1	complex eigenvalue
$-3i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -3i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & -9 \\ 1 & 0 \end{bmatrix} - (-3i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 3i & -9 \\ 1 & 3i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 3i & -9 & 0 \\ 1 & 3i & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{iR_1}{3} \Longrightarrow \left[\begin{array}{cc|c} 3i & -9 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 3i & -9 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -3it\}$

Hence the solution is

$$\begin{bmatrix} -3\,\mathrm{I}\,t \\ t \end{bmatrix} = \begin{bmatrix} -3it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -3\,\mathrm{I}\,t \\ t \end{bmatrix} = t \begin{bmatrix} -3i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -3\,\mathrm{I}\,t \\ t \end{bmatrix} = \begin{bmatrix} -3i \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 3i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & -9 \\ 1 & 0 \end{bmatrix} - (3i) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -3i & -9 \\ 1 & -3i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -3i & -9 & 0 \\ 1 & -3i & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{iR_1}{3} \Longrightarrow \left[\begin{array}{cc|c} -3i & -9 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -3i & -9 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 3it\}$

Hence the solution is

$$\begin{bmatrix} 3\,\mathrm{I}\,t \\ t \end{bmatrix} = \begin{bmatrix} 3it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 3\,\mathrm{I}\,t \\ t \end{bmatrix} = t \begin{bmatrix} 3i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 3\,\mathrm{I}\,t \\ t \end{bmatrix} = \begin{bmatrix} 3i \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
$3i$	1	1	No	$\begin{bmatrix} 3i \\ 1 \end{bmatrix}$
$-3i$	1	1	No	$\begin{bmatrix} -3i \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the final solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} 3i\mathrm{e}^{3it} \\ \mathrm{e}^{3it} \end{bmatrix} + c_2 \begin{bmatrix} -3i\mathrm{e}^{-3it} \\ \mathrm{e}^{-3it} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} 3i(c_1 e^{3it} - c_2 e^{-3it}) \\ c_1 e^{3it} + c_2 e^{-3it} \end{bmatrix}$$

The following is the phase plot of the system.

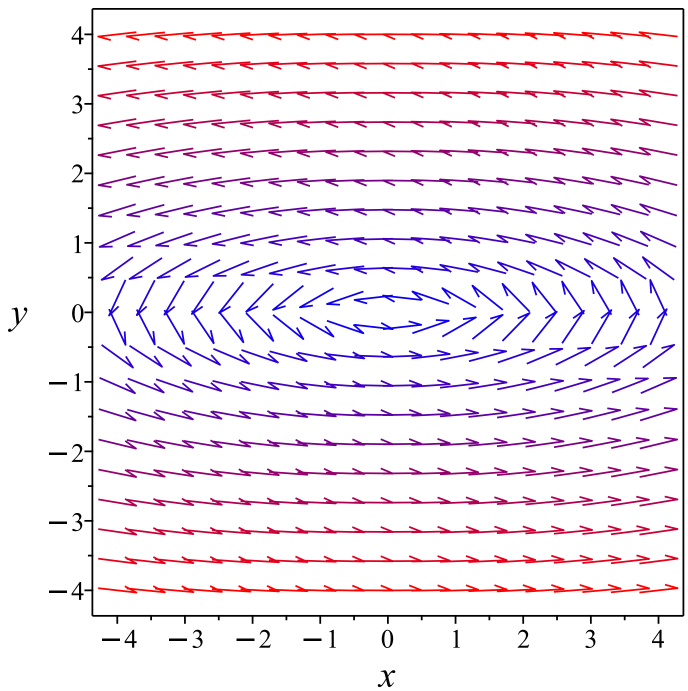

Figure 841: Phase plot

27.1.3 Maple step by step solution

Let's solve

$[x'(t) = -9y(t), y'(t) = x(t)]$

- Define vector

$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 0 & -9 \\ 1 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 0 & -9 \\ 1 & 0 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & -9 \\ 1 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-3\,\mathrm{I}, \begin{bmatrix} -3\,\mathrm{I} \\ 1 \end{bmatrix}\right], \left[3\,\mathrm{I}, \begin{bmatrix} 3\,\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-3\,\mathrm{I}, \begin{bmatrix} -3\,\mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$\mathrm{e}^{-3\,\mathrm{I}t} \cdot \begin{bmatrix} -3\,\mathrm{I} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(3t) - \mathrm{I}\sin(3t)) \cdot \begin{bmatrix} -3\,\mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -3\,\mathrm{I}(\cos(3t) - \mathrm{I}\sin(3t)) \\ \cos(3t) - \mathrm{I}\sin(3t) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{x}_1(t) = \begin{bmatrix} -3\sin(3t) \\ \cos(3t) \end{bmatrix}, \vec{x}_2(t) = \begin{bmatrix} -3\cos(3t) \\ -\sin(3t) \end{bmatrix}\right]$$

- General solution to the system of ODEs

  $\vec{x} = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$
- Substitute solutions into the general solution

  $$\vec{x} = \begin{bmatrix} -3c_2\cos(3t) - 3c_1\sin(3t) \\ -c_2\sin(3t) + c_1\cos(3t) \end{bmatrix}$$
- Substitute in vector of dependent variables

  $$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -3c_2\cos(3t) - 3c_1\sin(3t) \\ -c_2\sin(3t) + c_1\cos(3t) \end{bmatrix}$$
- Solution to the system of ODEs

  $\{x(t) = -3c_2\cos(3t) - 3c_1\sin(3t), y(t) = -c_2\sin(3t) + c_1\cos(3t)\}$

✓ Solution by Maple

Time used: 0.015 (sec). Leaf size: 36

```
dsolve([diff(x(t),t)=-9*y(t),diff(y(t),t)=x(t)],singsol=all)
```

$$x(t) = c_1\sin(3t) + c_2\cos(3t)$$
$$y(t) = -\frac{c_1\cos(3t)}{3} + \frac{c_2\sin(3t)}{3}$$

✓ Solution by Mathematica

Time used: 0.015 (sec). Leaf size: 42

```
DSolve[{x'[t]==-9*y[t],y'[t]==x[t]},{x[t],y[t]},t,IncludeSingularSolutions -> True]
```

$$x(t) \to c_1\cos(3t) - 3c_2\sin(3t)$$
$$y(t) \to c_2\cos(3t) + \frac{1}{3}c_1\sin(3t)$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= y(t) + t \\
y'(t) &= x(t) - t
\end{aligned}
$$

27.2.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} t \\ -t \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{e^{-t}}{2} + \frac{e^t}{2} & \frac{e^t}{2} - \frac{e^{-t}}{2} \\ \frac{e^t}{2} - \frac{e^{-t}}{2} & \frac{e^{-t}}{2} + \frac{e^t}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{e^{-t}}{2} + \frac{e^t}{2} & \frac{e^t}{2} - \frac{e^{-t}}{2} \\ \frac{e^t}{2} - \frac{e^{-t}}{2} & \frac{e^{-t}}{2} + \frac{e^t}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{e^{-t}}{2} + \frac{e^t}{2}\right) c_1 + \left(\frac{e^t}{2} - \frac{e^{-t}}{2}\right) c_2 \\ \left(\frac{e^t}{2} - \frac{e^{-t}}{2}\right) c_1 + \left(\frac{e^{-t}}{2} + \frac{e^t}{2}\right) c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(c_1 - c_2)e^{-t}}{2} + \frac{e^t(c_2 + c_1)}{2} \\ \frac{(-c_1 + c_2)e^{-t}}{2} + \frac{e^t(c_2 + c_1)}{2} \end{bmatrix}
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\, dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \begin{bmatrix} \frac{e^{-t}}{2} + \frac{e^t}{2} & -\frac{e^t}{2} + \frac{e^{-t}}{2} \\ -\frac{e^t}{2} + \frac{e^{-t}}{2} & \frac{e^{-t}}{2} + \frac{e^t}{2} \end{bmatrix}
\end{aligned}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \frac{e^{-t}}{2} + \frac{e^t}{2} & \frac{e^t}{2} - \frac{e^{-t}}{2} \\ \frac{e^t}{2} - \frac{e^{-t}}{2} & \frac{e^{-t}}{2} + \frac{e^t}{2} \end{bmatrix} \int \begin{bmatrix} \frac{e^{-t}}{2} + \frac{e^t}{2} & -\frac{e^t}{2} + \frac{e^{-t}}{2} \\ -\frac{e^t}{2} + \frac{e^{-t}}{2} & \frac{e^{-t}}{2} + \frac{e^t}{2} \end{bmatrix} \begin{bmatrix} t \\ -t \end{bmatrix} dt \\
&= \begin{bmatrix} \frac{e^{-t}}{2} + \frac{e^t}{2} & \frac{e^t}{2} - \frac{e^{-t}}{2} \\ \frac{e^t}{2} - \frac{e^{-t}}{2} & \frac{e^{-t}}{2} + \frac{e^t}{2} \end{bmatrix} \begin{bmatrix} (t-1)\, e^t \\ -(t-1)\, e^t \end{bmatrix} \\
&= \begin{bmatrix} t - 1 \\ -t + 1 \end{bmatrix}
\end{aligned}$$

Hence the complete solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$= \begin{bmatrix} \frac{(c_1-c_2)\mathrm{e}^{-t}}{2} + \frac{\mathrm{e}^{t}(c_2+c_1)}{2} + t - 1 \\ \frac{(-c_1+c_2)\mathrm{e}^{-t}}{2} + \frac{\mathrm{e}^{t}(c_2+c_1)}{2} - t + 1 \end{bmatrix}$$

27.2.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} t \\ -t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -\lambda & 1 \\ 1 & -\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 1 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 1$$
$$\lambda_2 = -1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
1	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} - (-1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 & 1 & 0 \\ 1 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -1 & 1 & 0 \\ 1 & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} -1 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
1	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$
-1	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{t} \\ &= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{t} \end{aligned}$$

Since eigenvalue -1 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{-t}$$
$$= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{-t}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} e^t \\ e^t \end{bmatrix} + c_2 \begin{bmatrix} -e^{-t} \\ e^{-t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} e^t & -e^{-t} \\ e^t & e^{-t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{e^{-t}}{2} & \frac{e^{-t}}{2} \\ -\frac{e^t}{2} & \frac{e^t}{2} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} e^t & -e^{-t} \\ e^t & e^{-t} \end{bmatrix} \int \begin{bmatrix} \frac{e^{-t}}{2} & \frac{e^{-t}}{2} \\ -\frac{e^t}{2} & \frac{e^t}{2} \end{bmatrix} \begin{bmatrix} t \\ -t \end{bmatrix} dt$$

$$= \begin{bmatrix} e^t & -e^{-t} \\ e^t & e^{-t} \end{bmatrix} \int \begin{bmatrix} 0 \\ -t\, e^t \end{bmatrix} dt$$

$$= \begin{bmatrix} e^t & -e^{-t} \\ e^t & e^{-t} \end{bmatrix} \begin{bmatrix} 0 \\ -(t-1)\, e^t \end{bmatrix}$$

$$= \begin{bmatrix} t-1 \\ -t+1 \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 e^t \\ c_1 e^t \end{bmatrix} + \begin{bmatrix} -c_2 e^{-t} \\ c_2 e^{-t} \end{bmatrix} + \begin{bmatrix} t-1 \\ -t+1 \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 e^t - c_2 e^{-t} + t - 1 \\ c_1 e^t + c_2 e^{-t} - t + 1 \end{bmatrix}$$

27.2.3 Maple step by step solution

Let's solve

$[x'(t) = y(t) + t, y'(t) = x(t) - t]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} t \\ -t \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} t \\ -t \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} t \\ -t \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^{-t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \mathrm{e}^{t} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

  $\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \vec{x}_p(t)$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

  $\phi(t) = \begin{bmatrix} -e^{-t} & e^t \\ e^{-t} & e^t \end{bmatrix}$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

  $\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(t)$ and $\phi(0)$

  $\Phi(t) = \begin{bmatrix} -e^{-t} & e^t \\ e^{-t} & e^t \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -1 & 1 \\ 1 & 1 \end{bmatrix}}$

- Evaluate and simplify to get the fundamental matrix

  $\Phi(t) = \begin{bmatrix} \frac{e^{-t}}{2} + \frac{e^t}{2} & \frac{e^t}{2} - \frac{e^{-t}}{2} \\ \frac{e^t}{2} - \frac{e^{-t}}{2} & \frac{e^{-t}}{2} + \frac{e^t}{2} \end{bmatrix}$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

  $\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$

- Take the derivative of the particular solution

  $\vec{x}_p'(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$

- Cancel like terms

  $\Phi(t) \cdot \vec{v}'(t) = \vec{f}(t)$

- Multiply by the inverse of the fundamental matrix

$\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$

- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{x}_p(t) = \begin{bmatrix} \mathrm{e}^{-t} + t - 1 \\ -\mathrm{e}^{-t} - t + 1 \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{x}(t) = c_1 \vec{x}_1 + c_2 \vec{x}_2 + \begin{bmatrix} \mathrm{e}^{-t} + t - 1 \\ -\mathrm{e}^{-t} - t + 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -c_1 \mathrm{e}^{-t} + c_2 \mathrm{e}^{t} + \mathrm{e}^{-t} + t - 1 \\ (c_1 - 1)\,\mathrm{e}^{-t} + c_2 \mathrm{e}^{t} - t + 1 \end{bmatrix}$$

- Solution to the system of ODEs

$$\{x(t) = -c_1 \mathrm{e}^{-t} + c_2 \mathrm{e}^{t} + \mathrm{e}^{-t} + t - 1, y(t) = (c_1 - 1)\,\mathrm{e}^{-t} + c_2 \mathrm{e}^{t} - t + 1\}$$

✓ Solution by Maple

Time used: 0.031 (sec). Leaf size: 37

```
dsolve([diff(x(t),t)=y(t)+t,diff(y(t),t)=x(t)-t],singsol=all)
```

$$x(t) = c_2 \mathrm{e}^{t} + \mathrm{e}^{-t} c_1 + t - 1$$
$$y(t) = c_2 \mathrm{e}^{t} - \mathrm{e}^{-t} c_1 + 1 - t$$

✓ Solution by Mathematica

Time used: 0.014 (sec). Leaf size: 78

```
DSolve[{x'[t]==y[t]+t,y'[t]==x[t]-t},{x[t],y[t]},t,IncludeSingularSolutions -> True]
```

$$x(t) \to \frac{1}{2}e^{-t}\left(2e^{t}(t-1)+(c_1+c_2)e^{2t}+c_1-c_2\right)$$
$$y(t) \to \frac{1}{2}e^{-t}\left(-2e^{t}(t-1)+(c_1+c_2)e^{2t}-c_1+c_2\right)$$

Problem number: 778.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = -3x(t) - 4y(t)$$
$$y'(t) = -2x(t) - 5y(t)$$

With initial conditions

$$[x(0) = 1, y(0) = 4]$$

27.3.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -3 & -4 \\ -2 & -5 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{e^{-7t}}{3} + \frac{2\,e^{-t}}{3} & -\frac{2\,e^{-t}}{3} + \frac{2\,e^{-7t}}{3} \\ -\frac{e^{-t}}{3} + \frac{e^{-7t}}{3} & \frac{2\,e^{-7t}}{3} + \frac{e^{-t}}{3} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{x}_0 \\
&= \begin{bmatrix} \frac{e^{-7t}}{3} + \frac{2\,e^{-t}}{3} & -\frac{2\,e^{-t}}{3} + \frac{2\,e^{-7t}}{3} \\ -\frac{e^{-t}}{3} + \frac{e^{-7t}}{3} & \frac{2\,e^{-7t}}{3} + \frac{e^{-t}}{3} \end{bmatrix} \begin{bmatrix} 1 \\ 4 \end{bmatrix} \\
&= \begin{bmatrix} 3\,e^{-7t} - 2\,e^{-t} \\ e^{-t} + 3\,e^{-7t} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

27.3.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -3 & -4 \\ -2 & -5 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$
\det(A - \lambda I) = 0
$$

Expanding gives

$$
\det\left(\begin{bmatrix} -3 & -4 \\ -2 & -5 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0
$$

Therefore

$$
\det\left(\begin{bmatrix} -3-\lambda & -4 \\ -2 & -5-\lambda \end{bmatrix}\right) = 0
$$

Which gives the characteristic equation

$$
\lambda^2 + 8\lambda + 7 = 0
$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -7$$
$$\lambda_2 = -1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
-7	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -7$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -3 & -4 \\ -2 & -5 \end{bmatrix} - (-7)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 4 & -4 \\ -2 & 2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 4 & -4 & 0 \\ -2 & 2 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{2} \Longrightarrow \left[\begin{array}{cc|c} 4 & -4 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 4 & -4 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -3 & -4 \\ -2 & -5 \end{bmatrix} - (-1) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} -2 & -4 \\ -2 & -4 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -2 & -4 & 0 \\ -2 & -4 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} -2 & -4 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & -4 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -2t\}$

Hence the solution is

$$\begin{bmatrix} -2t \\ t \end{bmatrix} = \begin{bmatrix} -2t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -2t \\ t \end{bmatrix} = t \begin{bmatrix} -2 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -2t \\ t \end{bmatrix} = \begin{bmatrix} -2 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-7	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$
-1	1	1	No	$\begin{bmatrix} -2 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -7 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{-7t} \\ &= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{-7t} \end{aligned}$$

Since eigenvalue -1 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{-t}$$
$$= \begin{bmatrix} -2 \\ 1 \end{bmatrix} e^{-t}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} e^{-7t} \\ e^{-7t} \end{bmatrix} + c_2 \begin{bmatrix} -2\,e^{-t} \\ e^{-t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 e^{-7t} - 2c_2 e^{-t} \\ c_1 e^{-7t} + c_2 e^{-t} \end{bmatrix}$$

Since initial conditions are given, the solution above needs to be updated by solving for the constants of integrations using the given initial conditions

$$\begin{bmatrix} x(0) = 1 \\ y(0) = 4 \end{bmatrix} \tag{1}$$

Substituting initial conditions into the above solution at $t = 0$ gives

$$\begin{bmatrix} 1 \\ 4 \end{bmatrix} = \begin{bmatrix} c_1 - 2c_2 \\ c_1 + c_2 \end{bmatrix}$$

Solving for the constants of integrations gives

$$\begin{bmatrix} c_1 = 3 \\ c_2 = 1 \end{bmatrix}$$

Substituting these constants back in original solution in Eq. (1) gives

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} 3\,e^{-7t} - 2\,e^{-t} \\ e^{-t} + 3\,e^{-7t} \end{bmatrix}$$

The following is the phase plot of the system.

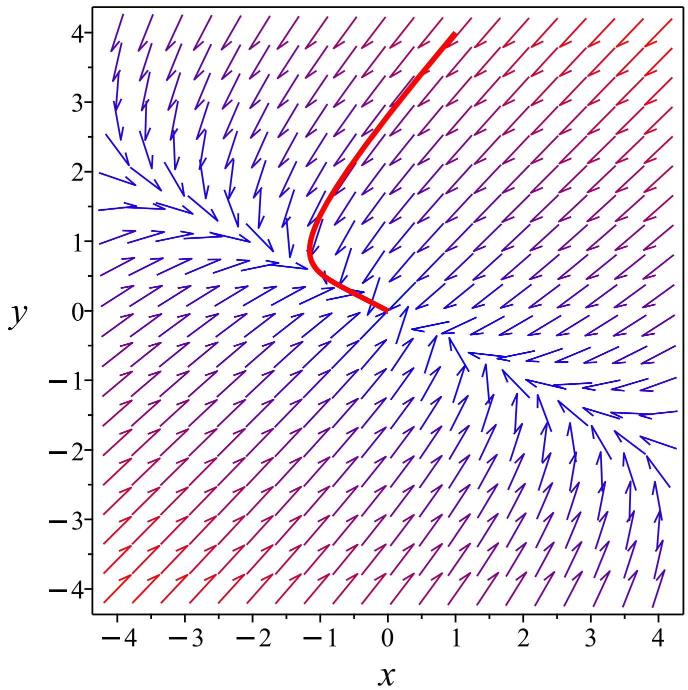

Figure 842: Phase plot

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= x(t) + 5y(t) \\
y'(t) &= -x(t) - 3y(t)
\end{aligned}
$$

With initial conditions

$$
[x(0) = -2, y(0) = 1]
$$

27.4.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 5 \\ -1 & -3 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} e^{-t}\cos(t) + 2\,e^{-t}\sin(t) & 5\,e^{-t}\sin(t) \\ -e^{-t}\sin(t) & e^{-t}\cos(t) - 2\,e^{-t}\sin(t) \end{bmatrix}$$

$$= \begin{bmatrix} e^{-t}(\cos(t) + 2\sin(t)) & 5\,e^{-t}\sin(t) \\ -e^{-t}\sin(t) & e^{-t}(\cos(t) - 2\sin(t)) \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{x}_0 \\
&= \begin{bmatrix} e^{-t}(\cos(t) + 2\sin(t)) & 5\,e^{-t}\sin(t) \\ -e^{-t}\sin(t) & e^{-t}(\cos(t) - 2\sin(t)) \end{bmatrix} \begin{bmatrix} -2 \\ 1 \end{bmatrix} \\
&= \begin{bmatrix} -2\,e^{-t}(\cos(t) + 2\sin(t)) + 5\,e^{-t}\sin(t) \\ 2\,e^{-t}\sin(t) + e^{-t}(\cos(t) - 2\sin(t)) \end{bmatrix} \\
&= \begin{bmatrix} e^{-t}(-2\cos(t) + \sin(t)) \\ e^{-t}\cos(t) \end{bmatrix}
\end{aligned}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

27.4.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 5 \\ -1 & -3 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & 5 \\ -1 & -3 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & 5 \\ -1 & -3-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 2\lambda + 2 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -1+i$$
$$\lambda_2 = -1-i$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$-1+i$	1	complex eigenvalue
$-1-i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1-i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A-\lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 5 \\ -1 & -3 \end{bmatrix} - (-1-i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 2+i & 5 \\ -1 & -2+i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2+i & 5 & 0 \\ -1 & -2+i & 0 \end{array}\right]$$

$$R_2 = R_2 + \left(\frac{2}{5} - \frac{i}{5}\right)R_1 \Longrightarrow \left[\begin{array}{cc|c} 2+i & 5 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2+i & 5 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = (-2+i)\,t\}$

Hence the solution is

$$\begin{bmatrix} (-2+\mathrm{I})\,t \\ t \end{bmatrix} = \begin{bmatrix} (-2+i)\,t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} (-2+\mathrm{I})\,t \\ t \end{bmatrix} = t \begin{bmatrix} -2+i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} (-2+\mathrm{I})\,t \\ t \end{bmatrix} = \begin{bmatrix} -2+i \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = -1+i$

We need to solve $A\vec{v} = \lambda \vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 5 \\ -1 & -3 \end{bmatrix} - (-1+i) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 2-i & 5 \\ -1 & -2-i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2-i & 5 & 0 \\ -1 & -2-i & 0 \end{array}\right]$$

$$R_2 = R_2 + \left(\frac{2}{5} + \frac{i}{5}\right) R_1 \Longrightarrow \left[\begin{array}{cc|c} 2-i & 5 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2-i & 5 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = (-2-i)\,t\}$

Hence the solution is

$$\begin{bmatrix} (-2-\mathrm{I})\,t \\ t \end{bmatrix} = \begin{bmatrix} (-2-i)\,t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} (-2-\mathrm{I})\,t \\ t \end{bmatrix} = t \begin{bmatrix} -2-i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} (-2-\mathrm{I})\,t \\ t \end{bmatrix} = \begin{bmatrix} -2-i \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m-k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
$-1+i$	1	1	No	$\begin{bmatrix} -2-i \\ 1 \end{bmatrix}$
$-1-i$	1	1	No	$\begin{bmatrix} -2+i \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} (-2-i)\,\mathrm{e}^{(-1+i)t} \\ \mathrm{e}^{(-1+i)t} \end{bmatrix} + c_2 \begin{bmatrix} (-2+i)\,\mathrm{e}^{(-1-i)t} \\ \mathrm{e}^{(-1-i)t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} (-2-i)\,c_1 \mathrm{e}^{(-1+i)t} + (-2+i)\,c_2 \mathrm{e}^{(-1-i)t} \\ c_1 \mathrm{e}^{(-1+i)t} + c_2 \mathrm{e}^{(-1-i)t} \end{bmatrix}$$

Since initial conditions are given, the solution above needs to be updated by solving for the constants of integrations using the given initial conditions

$$\begin{bmatrix} x(0) = -2 \\ y(0) = 1 \end{bmatrix} \tag{1}$$

Substituting initial conditions into the above solution at $t = 0$ gives

$$\begin{bmatrix} -2 \\ 1 \end{bmatrix} = \begin{bmatrix} (-2-i)\,c_1 + (-2+i)\,c_2 \\ c_1 + c_2 \end{bmatrix}$$

Solving for the constants of integrations gives

$$\begin{bmatrix} c_1 = \frac{1}{2} \\ c_2 = \frac{1}{2} \end{bmatrix}$$

Substituting these constants back in original solution in Eq. (1) gives

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \left(-1 - \frac{i}{2}\right) \mathrm{e}^{(-1+i)t} + \left(-1 + \frac{i}{2}\right) \mathrm{e}^{(-1-i)t} \\ \frac{\mathrm{e}^{(-1+i)t}}{2} + \frac{\mathrm{e}^{(-1-i)t}}{2} \end{bmatrix}$$

The following is the phase plot of the system.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= -y(t) + \cos(t) \\
y'(t) &= -4y(t) + 4\cos(t) + 3x(t) - \sin(t)
\end{aligned}
$$

27.5.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & -1 \\ 3 & -4 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \cos(t) \\ 4\cos(t) - \sin(t) \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} -\frac{e^{-3t}}{2}+\frac{3\,e^{-t}}{2} & -\frac{e^{-t}}{2}+\frac{e^{-3t}}{2} \\ \frac{3\,e^{-t}}{2}-\frac{3\,e^{-3t}}{2} & \frac{3\,e^{-3t}}{2}-\frac{e^{-t}}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} -\frac{e^{-3t}}{2}+\frac{3\,e^{-t}}{2} & -\frac{e^{-t}}{2}+\frac{e^{-3t}}{2} \\ \frac{3\,e^{-t}}{2}-\frac{3\,e^{-3t}}{2} & \frac{3\,e^{-3t}}{2}-\frac{e^{-t}}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(-\frac{e^{-3t}}{2}+\frac{3\,e^{-t}}{2}\right)c_1+\left(-\frac{e^{-t}}{2}+\frac{e^{-3t}}{2}\right)c_2 \\ \left(\frac{3\,e^{-t}}{2}-\frac{3\,e^{-3t}}{2}\right)c_1+\left(\frac{3\,e^{-3t}}{2}-\frac{e^{-t}}{2}\right)c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(-c_1+c_2)e^{-3t}}{2}+\frac{3\left(c_1-\frac{c_2}{3}\right)e^{-t}}{2} \\ \frac{(-3c_1+3c_2)e^{-3t}}{2}+\frac{3\left(c_1-\frac{c_2}{3}\right)e^{-t}}{2} \end{bmatrix}
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At}\int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \begin{bmatrix} -\frac{(e^{2t}-3)e^{t}}{2} & \frac{(e^{2t}-1)e^{t}}{2} \\ -\frac{3(e^{2t}-1)e^{t}}{2} & \frac{(3\,e^{2t}-1)e^{t}}{2} \end{bmatrix}
\end{aligned}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} -\frac{e^{-3t}}{2}+\frac{3\,e^{-t}}{2} & -\frac{e^{-t}}{2}+\frac{e^{-3t}}{2} \\ \frac{3\,e^{-t}}{2}-\frac{3\,e^{-3t}}{2} & \frac{3\,e^{-3t}}{2}-\frac{e^{-t}}{2} \end{bmatrix} \int \begin{bmatrix} -\frac{(e^{2t}-3)e^{t}}{2} & \frac{(e^{2t}-1)e^{t}}{2} \\ -\frac{3(e^{2t}-1)e^{t}}{2} & \frac{(3\,e^{2t}-1)e^{t}}{2} \end{bmatrix} \begin{bmatrix} \cos(t) \\ 4\cos(t)-\sin(t) \end{bmatrix} dt \\
&= \begin{bmatrix} -\frac{e^{-3t}}{2}+\frac{3\,e^{-t}}{2} & -\frac{e^{-t}}{2}+\frac{e^{-3t}}{2} \\ \frac{3\,e^{-t}}{2}-\frac{3\,e^{-3t}}{2} & \frac{3\,e^{-3t}}{2}-\frac{e^{-t}}{2} \end{bmatrix} \begin{bmatrix} \frac{(e^{2t}-1)e^{t}\cos(t)}{2} \\ \frac{\cos(t)(3\,e^{2t}-1)e^{t}}{2} \end{bmatrix} \\
&= \begin{bmatrix} 0 \\ \cos(t) \end{bmatrix}
\end{aligned}$$

Hence the complete solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$= \begin{bmatrix} \frac{(-c_1+c_2)e^{-3t}}{2} + \frac{3\left(c_1-\frac{c_2}{3}\right)e^{-t}}{2} \\ \frac{(-3c_1+3c_2)e^{-3t}}{2} + \frac{(3c_1-c_2)e^{-t}}{2} + \cos(t) \end{bmatrix}$$

27.5.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & -1 \\ 3 & -4 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \cos(t) \\ 4\cos(t) - \sin(t) \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 0 & -1 \\ 3 & -4 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -\lambda & -1 \\ 3 & -4-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 4\lambda + 3 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -1$$
$$\lambda_2 = -3$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
-3	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & -1 \\ 3 & -4 \end{bmatrix} - (-3)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 3 & -1 \\ 3 & -1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 3 & -1 & 0 \\ 3 & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 3 & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 3 & -1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{t}{3}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 3 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & -1 \\ 3 & -4 \end{bmatrix} - (-1) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 1 & -1 \\ 3 & -3 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 & -1 & 0 \\ 3 & -3 & 0 \end{array}\right]$$

$$R_2 = R_2 - 3R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & -1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-1	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$
-3	1	1	No	$\begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -1 is real and distinct then the

corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^{-t} \\ &= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{-t}\end{aligned}$$

Since eigenvalue -3 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{-3t} \\ &= \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix} e^{-3t}\end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \mathrm{e}^{-t} \\ \mathrm{e}^{-t} \end{bmatrix} + c_2 \begin{bmatrix} \frac{\mathrm{e}^{-3t}}{3} \\ \mathrm{e}^{-3t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} \mathrm{e}^{-t} & \frac{\mathrm{e}^{-3t}}{3} \\ \mathrm{e}^{-t} & \mathrm{e}^{-3t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{3\,\mathrm{e}^{t}}{2} & -\frac{\mathrm{e}^{t}}{2} \\ -\frac{3\,\mathrm{e}^{3t}}{2} & \frac{3\,\mathrm{e}^{3t}}{2} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} e^{-t} & \frac{e^{-3t}}{3} \\ e^{-t} & e^{-3t} \end{bmatrix} \int \begin{bmatrix} \frac{3\,e^{t}}{2} & -\frac{e^{t}}{2} \\ -\frac{3\,e^{3t}}{2} & \frac{3\,e^{3t}}{2} \end{bmatrix} \begin{bmatrix} \cos(t) \\ 4\cos(t) - \sin(t) \end{bmatrix} dt$$

$$= \begin{bmatrix} e^{-t} & \frac{e^{-3t}}{3} \\ e^{-t} & e^{-3t} \end{bmatrix} \int \begin{bmatrix} -\frac{e^{t}(\cos(t)-\sin(t))}{2} \\ \frac{3\,e^{3t}(3\cos(t)-\sin(t))}{2} \end{bmatrix} dt$$

$$= \begin{bmatrix} e^{-t} & \frac{e^{-3t}}{3} \\ e^{-t} & e^{-3t} \end{bmatrix} \begin{bmatrix} -\frac{e^{t}\cos(t)}{2} \\ \frac{3\,e^{3t}\cos(t)}{2} \end{bmatrix}$$

$$= \begin{bmatrix} 0 \\ \cos(t) \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 e^{-t} \\ c_1 e^{-t} \end{bmatrix} + \begin{bmatrix} \frac{c_2 e^{-3t}}{3} \\ c_2 e^{-3t} \end{bmatrix} + \begin{bmatrix} 0 \\ \cos(t) \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 e^{-t} + \frac{c_2 e^{-3t}}{3} \\ c_1 e^{-t} + c_2 e^{-3t} + \cos(t) \end{bmatrix}$$

27.5.3 Maple step by step solution

Let's solve

$[x'(t) = -y(t) + \cos(t), y'(t) = -4y(t) + 4\cos(t) + 3x(t) - \sin(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 0 & -1 \\ 3 & -4 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} \cos(t) \\ 4\cos(t) - \sin(t) \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 0 & -1 \\ 3 & -4 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} \cos(t) \\ 4\cos(t) - \sin(t) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} \cos(t) \\ 4\cos(t) - \sin(t) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & -1 \\ 3 & -4 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-3, \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}\right], \left[-1, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-3, \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^{-3t} \cdot \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \mathrm{e}^{-t} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{x}_p($

  $\overrightarrow{x}(t) = c_1 \overrightarrow{x}_1 + c_2 \overrightarrow{x}_2 + \overrightarrow{x}_p(t)$

☐ Fundamental matrix

  - Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

    $\phi(t) = \begin{bmatrix} \frac{e^{-3t}}{3} & e^{-t} \\ e^{-3t} & e^{-t} \end{bmatrix}$

  - The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

    $\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$

  - Substitute the value of $\phi(t)$ and $\phi(0)$

    $\Phi(t) = \begin{bmatrix} \frac{e^{-3t}}{3} & e^{-t} \\ e^{-3t} & e^{-t} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} \frac{1}{3} & 1 \\ 1 & 1 \end{bmatrix}}$

  - Evaluate and simplify to get the fundamental matrix

    $\Phi(t) = \begin{bmatrix} -\frac{e^{-3t}}{2} + \frac{3\,e^{-t}}{2} & -\frac{e^{-t}}{2} + \frac{e^{-3t}}{2} \\ \frac{3\,e^{-t}}{2} - \frac{3\,e^{-3t}}{2} & \frac{3\,e^{-3t}}{2} - \frac{e^{-t}}{2} \end{bmatrix}$

☐ Find a particular solution of the system of ODEs using variation of parameters

  - Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

    $\overrightarrow{x}_p(t) = \Phi(t) \cdot \overrightarrow{v}(t)$

  - Take the derivative of the particular solution

    $\overrightarrow{x}'_p(t) = \Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t)$

  - Substitute particular solution and its derivative into the system of ODEs

    $\Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

  - The fundamental matrix has columns that are solutions to the homogeneous system so its der

    $A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

  - Cancel like terms

    $\Phi(t) \cdot \overrightarrow{v}'(t) = \overrightarrow{f}(t)$

  - Multiply by the inverse of the fundamental matrix

$\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$

- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\vec{x}_p(t) = \left[\begin{array}{c} \frac{e^{-t}}{2} - \frac{e^{-3t}}{2} \\ \cos(t) - \frac{3\,e^{-3t}}{2} + \frac{e^{-t}}{2} \end{array}\right]$$

- Plug particular solution back into general solution

  $$\vec{x}(t) = c_1 \vec{x}_1 + c_2 \vec{x}_2 + \left[\begin{array}{c} \frac{e^{-t}}{2} - \frac{e^{-3t}}{2} \\ \cos(t) - \frac{3\,e^{-3t}}{2} + \frac{e^{-t}}{2} \end{array}\right]$$

- Substitute in vector of dependent variables

  $$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} \frac{(2c_1-3)e^{-3t}}{6} + \frac{(6c_2+3)e^{-t}}{6} \\ \frac{(2c_1-3)e^{-3t}}{2} + \frac{(2c_2+1)e^{-t}}{2} + \cos(t) \end{array}\right]$$

- Solution to the system of ODEs

  $$\left\{x(t) = \frac{(2c_1-3)e^{-3t}}{6} + \frac{(6c_2+3)e^{-t}}{6}, y(t) = \frac{(2c_1-3)e^{-3t}}{2} + \frac{(2c_2+1)e^{-t}}{2} + \cos(t)\right\}$$

✓ Solution by Maple

Problem number: 781.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= -y(t) + z(t) \\
y'(t) &= z(t) \\
z'(t) &= -x(t) + z(t)
\end{aligned}
$$

27.6.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 0 & -1 & 1 \\ 0 & 0 & 1 \\ -1 & 0 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}
$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \cos(t) & -\sin(t) & \sin(t) \\ -\frac{e^t}{2} + \frac{\cos(t)}{2} + \frac{\sin(t)}{2} & \frac{e^t}{2} + \frac{\cos(t)}{2} - \frac{\sin(t)}{2} & \frac{e^t}{2} - \frac{\cos(t)}{2} + \frac{\sin(t)}{2} \\ -\frac{e^t}{2} + \frac{\cos(t)}{2} - \frac{\sin(t)}{2} & \frac{e^t}{2} - \frac{\cos(t)}{2} - \frac{\sin(t)}{2} & \frac{e^t}{2} + \frac{\cos(t)}{2} + \frac{\sin(t)}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \cos(t) & -\sin(t) & \sin(t) \\ -\frac{e^t}{2} + \frac{\cos(t)}{2} + \frac{\sin(t)}{2} & \frac{e^t}{2} + \frac{\cos(t)}{2} - \frac{\sin(t)}{2} & \frac{e^t}{2} - \frac{\cos(t)}{2} + \frac{\sin(t)}{2} \\ -\frac{e^t}{2} + \frac{\cos(t)}{2} - \frac{\sin(t)}{2} & \frac{e^t}{2} - \frac{\cos(t)}{2} - \frac{\sin(t)}{2} & \frac{e^t}{2} + \frac{\cos(t)}{2} + \frac{\sin(t)}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ c_3 \end{bmatrix} \\
&= \begin{bmatrix} \cos(t)\,c_1 - \sin(t)\,c_2 + \sin(t)\,c_3 \\ \left(-\frac{e^t}{2} + \frac{\cos(t)}{2} + \frac{\sin(t)}{2}\right)c_1 + \left(\frac{e^t}{2} + \frac{\cos(t)}{2} - \frac{\sin(t)}{2}\right)c_2 + \left(\frac{e^t}{2} - \frac{\cos(t)}{2} + \frac{\sin(t)}{2}\right)c_3 \\ \left(-\frac{e^t}{2} + \frac{\cos(t)}{2} - \frac{\sin(t)}{2}\right)c_1 + \left(\frac{e^t}{2} - \frac{\cos(t)}{2} - \frac{\sin(t)}{2}\right)c_2 + \left(\frac{e^t}{2} + \frac{\cos(t)}{2} + \frac{\sin(t)}{2}\right)c_3 \end{bmatrix} \\
&= \begin{bmatrix} (-c_2 + c_3)\sin(t) + \cos(t)\,c_1 \\ \frac{(c_2+c_1-c_3)\cos(t)}{2} + \frac{(c_2-c_1+c_3)e^t}{2} + \frac{\sin(t)(-c_2+c_1+c_3)}{2} \\ \frac{(-c_2+c_1+c_3)\cos(t)}{2} + \frac{(c_2-c_1+c_3)e^t}{2} - \frac{\sin(t)(c_2+c_1-c_3)}{2} \end{bmatrix}
\end{aligned}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

27.6.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 0 & -1 & 1 \\ 0 & 0 & 1 \\ -1 & 0 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 0 & -1 & 1 \\ 0 & 0 & 1 \\ -1 & 0 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -\lambda & -1 & 1 \\ 0 & -\lambda & 1 \\ -1 & 0 & 1-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^3 - \lambda^2 + \lambda - 1 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = i$$
$$\lambda_2 = -i$$
$$\lambda_3 = 1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue
i	1	complex eigenvalue
$-i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & -1 & 1 \\ 0 & 0 & 1 \\ -1 & 0 & 1 \end{bmatrix} - (1)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -1 & -1 & 1 \\ 0 & -1 & 1 \\ -1 & 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} -1 & -1 & 1 & 0 \\ 0 & -1 & 1 & 0 \\ -1 & 0 & 0 & 0 \end{array}\right]$$

$$R_3 = R_3 - R_1 \Longrightarrow \left[\begin{array}{ccc|c} -1 & -1 & 1 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & 1 & -1 & 0 \end{array}\right]$$

$$R_3 = R_3 + R_2 \Longrightarrow \left[\begin{array}{ccc|c} -1 & -1 & 1 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & -1 & 1 \\ 0 & -1 & 1 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 0, v_2 = t\}$

Hence the solution is

$$\begin{bmatrix} 0 \\ t \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 0 \\ t \\ t \end{bmatrix} = t \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 0 \\ t \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = -i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & -1 & 1 \\ 0 & 0 & 1 \\ -1 & 0 & 1 \end{bmatrix} - (-i) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} i & -1 & 1 \\ 0 & i & 1 \\ -1 & 0 & 1+i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} i & -1 & 1 & 0 \\ 0 & i & 1 & 0 \\ -1 & 0 & 1+i & 0 \end{array}\right]$$

$$R_3 = -iR_1 + R_3 \Longrightarrow \left[\begin{array}{ccc|c} i & -1 & 1 & 0 \\ 0 & i & 1 & 0 \\ 0 & i & 1 & 0 \end{array}\right]$$

$$R_3 = R_3 - R_2 \Longrightarrow \left[\begin{array}{ccc|c} i & -1 & 1 & 0 \\ 0 & i & 1 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} i & -1 & 1 \\ 0 & i & 1 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = (1+i)\,t, v_2 = it\}$

Hence the solution is

$$\begin{bmatrix} (1+\mathrm{I})\,t \\ \mathrm{I}\,t \\ t \end{bmatrix} = \begin{bmatrix} (1+i)\,t \\ it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} (1+\mathrm{I})\,t \\ \mathrm{I}\,t \\ t \end{bmatrix} = t \begin{bmatrix} 1+i \\ i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} (1+\mathrm{I})\,t \\ \mathrm{I}\,t \\ t \end{bmatrix} = \begin{bmatrix} 1+i \\ i \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_3 = i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & -1 & 1 \\ 0 & 0 & 1 \\ -1 & 0 & 1 \end{bmatrix} - (i) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -i & -1 & 1 \\ 0 & -i & 1 \\ -1 & 0 & 1-i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} -i & -1 & 1 & 0 \\ 0 & -i & 1 & 0 \\ -1 & 0 & 1-i & 0 \end{array}\right]$$

$$R_3 = iR_1 + R_3 \Longrightarrow \left[\begin{array}{ccc|c} -i & -1 & 1 & 0 \\ 0 & -i & 1 & 0 \\ 0 & -i & 1 & 0 \end{array}\right]$$

$$R_3 = R_3 - R_2 \Longrightarrow \left[\begin{array}{ccc|c} -i & -1 & 1 & 0 \\ 0 & -i & 1 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -i & -1 & 1 \\ 0 & -i & 1 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = (1-i)\,t, v_2 = -it\}$

Hence the solution is

$$\begin{bmatrix} (1-\mathrm{I})\,t \\ \text{-I}\,t \\ t \end{bmatrix} = \begin{bmatrix} (1-i)\,t \\ -it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} (1-\mathrm{I})\,t \\ \text{-I}\,t \\ t \end{bmatrix} = t \begin{bmatrix} 1-i \\ -i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} (1-\mathrm{I})\,t \\ \text{-I}\,t \\ t \end{bmatrix} = \begin{bmatrix} 1-i \\ -i \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m-k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
i	1	1	No	$\begin{bmatrix} 1-i \\ -i \\ 1 \end{bmatrix}$
$-i$	1	1	No	$\begin{bmatrix} 1+i \\ i \\ 1 \end{bmatrix}$
1	1	1	No	$\begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^t \\ &= \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix} e^t \end{aligned}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + c_3\vec{x}_3(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = c_1 \begin{bmatrix} (1-i)\,\mathrm{e}^{it} \\ -i\mathrm{e}^{it} \\ \mathrm{e}^{it} \end{bmatrix} + c_2 \begin{bmatrix} (1+i)\,\mathrm{e}^{-it} \\ i\mathrm{e}^{-it} \\ \mathrm{e}^{-it} \end{bmatrix} + c_3 \begin{bmatrix} 0 \\ \mathrm{e}^{t} \\ \mathrm{e}^{t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} (1-i)\, c_1 \mathrm{e}^{it} + (1+i)\, c_2 \mathrm{e}^{-it} \\ -i c_1 \mathrm{e}^{it} + i c_2 \mathrm{e}^{-it} + c_3 \mathrm{e}^{t} \\ c_1 \mathrm{e}^{it} + c_2 \mathrm{e}^{-it} + c_3 \mathrm{e}^{t} \end{bmatrix}$$

27.6.3 Maple step by step solution

Let's solve

$[x'(t) = -y(t) + z(t)\,, y'(t) = z(t)\,, z'(t) = -x(t) + z(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 0 & -1 & 1 \\ 0 & 0 & 1 \\ -1 & 0 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 0 & -1 & 1 \\ 0 & 0 & 1 \\ -1 & 0 & 1 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & -1 & 1 \\ 0 & 0 & 1 \\ -1 & 0 & 1 \end{bmatrix}$$

- Rewrite the system as

$\vec{x}'(t) = A \cdot \vec{x}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} 1+\mathrm{I} \\ \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} 1-\mathrm{I} \\ -\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^t \cdot \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} 1+\mathrm{I} \\ \mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$\mathrm{e}^{-\mathrm{I}t} \cdot \begin{bmatrix} 1+\mathrm{I} \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(t) - \mathrm{I}\sin(t)) \cdot \begin{bmatrix} 1+\mathrm{I} \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} (1+\mathrm{I})(\cos(t) - \mathrm{I}\sin(t)) \\ \mathrm{I}(\cos(t) - \mathrm{I}\sin(t)) \\ \cos(t) - \mathrm{I}\sin(t) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{x}_2(t) = \begin{bmatrix} \cos(t) + \sin(t) \\ \sin(t) \\ \cos(t) \end{bmatrix}, \vec{x}_3(t) = \begin{bmatrix} \cos(t) - \sin(t) \\ \cos(t) \\ -\sin(t) \end{bmatrix}\right]$$

- General solution to the system of ODEs
$$\vec{x} = c_1\vec{x}_1 + c_2\vec{x}_2(t) + c_3\vec{x}_3(t)$$
- Substitute solutions into the general solution
$$\vec{x} = c_1 e^t \cdot \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} c_3(\cos(t) - \sin(t)) + c_2(\cos(t) + \sin(t)) \\ c_2\sin(t) + c_3\cos(t) \\ c_2\cos(t) - c_3\sin(t) \end{bmatrix}$$
- Substitute in vector of dependent variables
$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} \cos(t)(c_2 + c_3) + (c_2 - c_3)\sin(t) \\ c_1 e^t + c_3\cos(t) + c_2\sin(t) \\ c_1 e^t - c_3\sin(t) + c_2\cos(t) \end{bmatrix}$$
- Solution to the system of ODEs
$$\{x(t) = \cos(t)(c_2 + c_3) + (c_2 - c_3)\sin(t), y(t) = c_1 e^t + c_3\cos(t) + c_2\sin(t), z(t) = c_1 e^t - c_3\sin($$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= y(t) + z(t) \\
y'(t) &= x(t) + z(t) \\
z'(t) &= x(t) + y(t)
\end{aligned}
$$

27.7.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}
$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{2\,\mathrm{e}^{-t}}{3}+\frac{\mathrm{e}^{2t}}{3} & \frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3} & \frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3} \\ \frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3} & \frac{2\,\mathrm{e}^{-t}}{3}+\frac{\mathrm{e}^{2t}}{3} & \frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3} \\ \frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3} & \frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3} & \frac{2\,\mathrm{e}^{-t}}{3}+\frac{\mathrm{e}^{2t}}{3} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{2\,\mathrm{e}^{-t}}{3}+\frac{\mathrm{e}^{2t}}{3} & \frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3} & \frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3} \\ \frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3} & \frac{2\,\mathrm{e}^{-t}}{3}+\frac{\mathrm{e}^{2t}}{3} & \frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3} \\ \frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3} & \frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3} & \frac{2\,\mathrm{e}^{-t}}{3}+\frac{\mathrm{e}^{2t}}{3} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ c_3 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{2\,\mathrm{e}^{-t}}{3}+\frac{\mathrm{e}^{2t}}{3}\right)c_1+\left(\frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3}\right)c_2+\left(\frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3}\right)c_3 \\ \left(\frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3}\right)c_1+\left(\frac{2\,\mathrm{e}^{-t}}{3}+\frac{\mathrm{e}^{2t}}{3}\right)c_2+\left(\frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3}\right)c_3 \\ \left(\frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3}\right)c_1+\left(\frac{\mathrm{e}^{2t}}{3}-\frac{\mathrm{e}^{-t}}{3}\right)c_2+\left(\frac{2\,\mathrm{e}^{-t}}{3}+\frac{\mathrm{e}^{2t}}{3}\right)c_3 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(2c_1-c_2-c_3)\mathrm{e}^{-t}}{3}+\frac{\mathrm{e}^{2t}(c_2+c_1+c_3)}{3} \\ \frac{(-c_1+2c_2-c_3)\mathrm{e}^{-t}}{3}+\frac{\mathrm{e}^{2t}(c_2+c_1+c_3)}{3} \\ \frac{(-c_1-c_2+2c_3)\mathrm{e}^{-t}}{3}+\frac{\mathrm{e}^{2t}(c_2+c_1+c_3)}{3} \end{bmatrix}
\end{aligned}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

27.7.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A-\lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -\lambda & 1 & 1 \\ 1 & -\lambda & 1 \\ 1 & 1 & -\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^3 - 3\lambda - 2 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -1$$
$$\lambda_2 = 2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
2	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix} - (-1) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{ccc|c} 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 0 \end{array}\right]$$

$$R_3 = R_3 - R_1 \Longrightarrow \left[\begin{array}{ccc|c} 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2, v_3\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Let $v_3 = s$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t - s\}$

Hence the solution is

$$\begin{bmatrix} -t - s \\ t \\ s \end{bmatrix} = \begin{bmatrix} -t - s \\ t \\ s \end{bmatrix}$$

Since there are two free Variable, we have found two eigenvectors associated with this eigenvalue. The above can be written as

$$\begin{aligned} \begin{bmatrix} -t - s \\ t \\ s \end{bmatrix} &= \begin{bmatrix} -t \\ t \\ 0 \end{bmatrix} + \begin{bmatrix} -s \\ 0 \\ s \end{bmatrix} \\ &= t \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix} + s \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} \end{aligned}$$

By letting $t = 1$ and $s = 1$ then the above becomes

$$\begin{bmatrix} -t-s \\ t \\ s \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$$

Hence the two eigenvectors associated with this eigenvalue are

$$\left(\begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}, \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} \right)$$

Considering the eigenvalue $\lambda_2 = 2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix} - (2) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -2 & 1 & 1 \\ 1 & -2 & 1 \\ 1 & 1 & -2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} -2 & 1 & 1 & 0 \\ 1 & -2 & 1 & 0 \\ 1 & 1 & -2 & 0 \end{array} \right]$$

$$R_2 = R_2 + \frac{R_1}{2} \Longrightarrow \left[\begin{array}{ccc|c} -2 & 1 & 1 & 0 \\ 0 & -\frac{3}{2} & \frac{3}{2} & 0 \\ 1 & 1 & -2 & 0 \end{array} \right]$$

$$R_3 = R_3 + \frac{R_1}{2} \Longrightarrow \left[\begin{array}{ccc|c} -2 & 1 & 1 & 0 \\ 0 & -\frac{3}{2} & \frac{3}{2} & 0 \\ 0 & \frac{3}{2} & -\frac{3}{2} & 0 \end{array} \right]$$

$$R_3 = R_3 + R_2 \Longrightarrow \left[\begin{array}{ccc|c} -2 & 1 & 1 & 0 \\ 0 & -\frac{3}{2} & \frac{3}{2} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & 1 & 1 \\ 0 & -\frac{3}{2} & \frac{3}{2} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t, v_2 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
-1	2	2	No	$\begin{bmatrix} -1 & -1 \\ 0 & 1 \\ 1 & 0 \end{bmatrix}$
2	1	1	No	$\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. eigenvalue -1 is real and repated eigenvalue of multiplicity 2.There are two possible cases that can happen. This is illustrated in this diagram

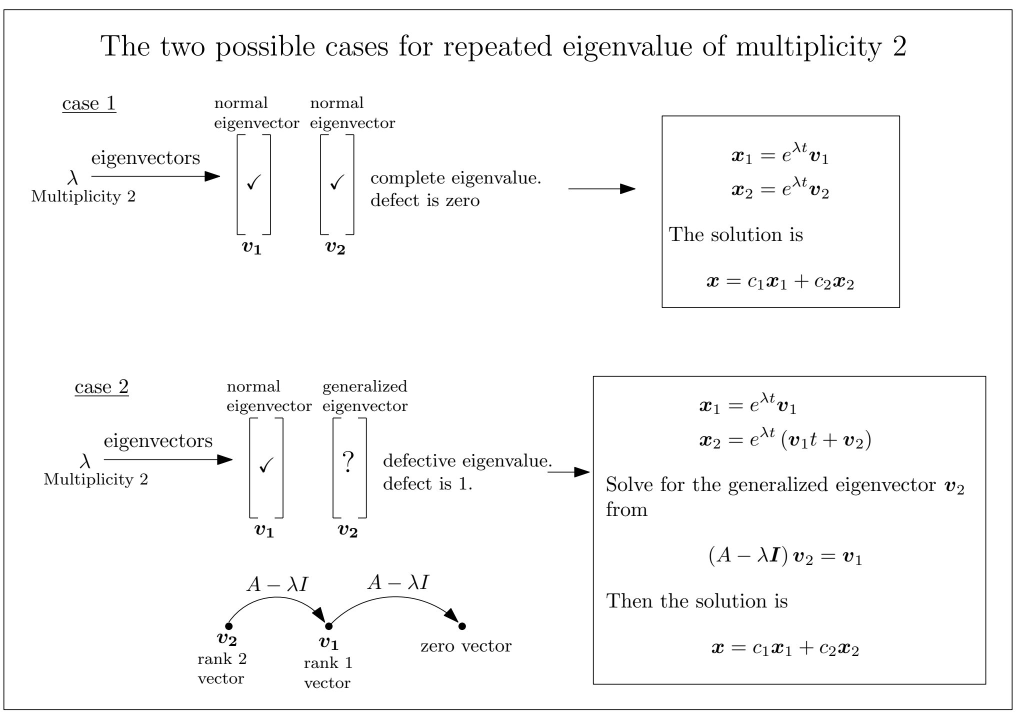

Figure 844: Possible case for repeated λ of multiplicity 2

This eigenvalue has algebraic multiplicity of 2 which is the same as its geometric multiplicity 2, then it is complete eigenvalue and this falls into case 1 shown above. Hence the corresponding eigenvector basis are

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^{-t} \\ &= \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} e^{-t}\end{aligned}$$

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{-t} \\ &= \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix} e^{-t}\end{aligned}$$

Since eigenvalue 2 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_3(t) &= \vec{v}_3 e^{2t} \\ &= \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} e^{2t}\end{aligned}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t) + c_3 \vec{x}_3(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = c_1 \begin{bmatrix} -\mathrm{e}^{-t} \\ 0 \\ \mathrm{e}^{-t} \end{bmatrix} + c_2 \begin{bmatrix} -\mathrm{e}^{-t} \\ \mathrm{e}^{-t} \\ 0 \end{bmatrix} + c_3 \begin{bmatrix} \mathrm{e}^{2t} \\ \mathrm{e}^{2t} \\ \mathrm{e}^{2t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} (-c_1 - c_2)\,\mathrm{e}^{-t} + c_3 \mathrm{e}^{2t} \\ c_2 \mathrm{e}^{-t} + c_3 \mathrm{e}^{2t} \\ c_1 \mathrm{e}^{-t} + c_3 \mathrm{e}^{2t} \end{bmatrix}$$

27.7.3 Maple step by step solution

Let's solve

$[x'(t) = y(t) + z(t), y'(t) = x(t) + z(t), z'(t) = x(t) + y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix}$$

- Rewrite the system as

$\vec{x}'(t) = A \cdot \vec{x}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}\right], \left[-1, \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}\right], \left[2, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[-1, \left[\begin{array}{c} -1 \\ 0 \\ 1 \end{array}\right]\right]$$

- First solution from eigenvalue -1

$$\overrightarrow{x}_1(t) = \mathrm{e}^{-t} \cdot \left[\begin{array}{c} -1 \\ 0 \\ 1 \end{array}\right]$$

- Form of the 2nd homogeneous solution where $\overrightarrow{p}$ is to be solved for, $\lambda = -1$ is the eigenvalue, an

$$\overrightarrow{x}_2(t) = \mathrm{e}^{\lambda t}\left(t\overrightarrow{v} + \overrightarrow{p}\right)$$

- Note that the t multiplying $\overrightarrow{v}$ makes this solution linearly independent to the 1st solution obtai
- Substitute $\overrightarrow{x}_2(t)$ into the homogeneous system

$$\lambda\,\mathrm{e}^{\lambda t}\left(t\overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda t}\overrightarrow{v} = \left(\mathrm{e}^{\lambda t} A\right) \cdot \left(t\overrightarrow{v} + \overrightarrow{p}\right)$$

- Use the fact that $\overrightarrow{v}$ is an eigenvector of A

$$\lambda\,\mathrm{e}^{\lambda t}\left(t\overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda t}\overrightarrow{v} = \mathrm{e}^{\lambda t}\left(\lambda t\overrightarrow{v} + A \cdot \overrightarrow{p}\right)$$

- Simplify equation

$$\lambda\overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$$

- Make use of the identity matrix I

$$(\lambda \cdot I) \cdot \overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$$

- Condition $\overrightarrow{p}$ must meet for $\overrightarrow{x}_2(t)$ to be a solution to the homogeneous system

$$(A - \lambda \cdot I) \cdot \overrightarrow{p} = \overrightarrow{v}$$

- Choose $\overrightarrow{p}$ to use in the second solution to the homogeneous system from eigenvalue -1

$$\left(\left[\begin{array}{ccc} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{array}\right] - (-1) \cdot \left[\begin{array}{ccc} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{array}\right]\right) \cdot \overrightarrow{p} = \left[\begin{array}{c} -1 \\ 0 \\ 1 \end{array}\right]$$

- Choice of $\overrightarrow{p}$

$$\vec{p} = \begin{bmatrix} -1 \\ 0 \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue -1

$$\vec{x}_2(t) = e^{-t} \cdot \left(t \cdot \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \end{bmatrix}\right)$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_3 = e^{2t} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{x} = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t) + c_3 \vec{x}_3$$

- Substitute solutions into the general solution

$$\vec{x} = c_1 e^{-t} \cdot \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} + c_2 e^{-t} \cdot \left(t \cdot \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \end{bmatrix}\right) + c_3 e^{2t} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} ((-t-1) c_2 - c_1) e^{-t} + c_3 e^{2t} \\ c_3 e^{2t} \\ (c_2 t + c_1) e^{-t} + c_3 e^{2t} \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = ((-t-1) c_2 - c_1) e^{-t} + c_3 e^{2t}, y(t) = c_3 e^{2t}, z(t) = (c_2 t + c_1) e^{-t} + c_3 e^{2t}\right\}$$

Problem number: 802.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 8y(t) - x(t) \\
y'(t) &= x(t) + y(t)
\end{aligned}
$$

29.1.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -1 & 8 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

For the above matrix A, the matrix exponential can be found to be

$$
e^{At} = \begin{bmatrix} \frac{2\,\mathrm{e}^{-3t}}{3} + \frac{\mathrm{e}^{3t}}{3} & \frac{4\,\mathrm{e}^{3t}}{3} - \frac{4\,\mathrm{e}^{-3t}}{3} \\ \frac{\mathrm{e}^{3t}}{6} - \frac{\mathrm{e}^{-3t}}{6} & \frac{\mathrm{e}^{-3t}}{3} + \frac{2\,\mathrm{e}^{3t}}{3} \end{bmatrix}
$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{2\,e^{-3t}}{3}+\frac{e^{3t}}{3} & \frac{4\,e^{3t}}{3}-\frac{4\,e^{-3t}}{3} \\ \frac{e^{3t}}{6}-\frac{e^{-3t}}{6} & \frac{e^{-3t}}{3}+\frac{2\,e^{3t}}{3} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{2\,e^{-3t}}{3}+\frac{e^{3t}}{3}\right) c_1 + \left(\frac{4\,e^{3t}}{3}-\frac{4\,e^{-3t}}{3}\right) c_2 \\ \left(\frac{e^{3t}}{6}-\frac{e^{-3t}}{6}\right) c_1 + \left(\frac{e^{-3t}}{3}+\frac{2\,e^{3t}}{3}\right) c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(2c_1-4c_2)e^{-3t}}{3}+\frac{e^{3t}(c_1+4c_2)}{3} \\ \frac{(-c_1+2c_2)e^{-3t}}{6}+\frac{e^{3t}(c_1+4c_2)}{6} \end{bmatrix}
\end{aligned}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.1.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -1 & 8 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} -1 & 8 \\ 1 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -1-\lambda & 8 \\ 1 & 1-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 9 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 3$$
$$\lambda_2 = -3$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-3	1	real eigenvalue
3	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -1 & 8 \\ 1 & 1 \end{bmatrix} - (-3)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 2 & 8 \\ 1 & 4 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2 & 8 & 0 \\ 1 & 4 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{2} \Longrightarrow \left[\begin{array}{cc|c} 2 & 8 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & 8 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -4t\}$

Hence the solution is

$$\begin{bmatrix} -4t \\ t \end{bmatrix} = \begin{bmatrix} -4t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -4t \\ t \end{bmatrix} = t \begin{bmatrix} -4 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -4t \\ t \end{bmatrix} = \begin{bmatrix} -4 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -1 & 8 \\ 1 & 1 \end{bmatrix} - (3) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -4 & 8 \\ 1 & -2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -4 & 8 & 0 \\ 1 & -2 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{4} \Longrightarrow \left[\begin{array}{cc|c} -4 & 8 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -4 & 8 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 2t\}$

Hence the solution is

$$\begin{bmatrix} 2t \\ t \end{bmatrix} = \begin{bmatrix} 2t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 2t \\ t \end{bmatrix} = t \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 2t \\ t \end{bmatrix} = \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
3	1	1	No	$\begin{bmatrix} 2 \\ 1 \end{bmatrix}$
-3	1	1	No	$\begin{bmatrix} -4 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 3 is real and distinct then the

corresponding eigenvector solution is

$$\vec{x}_1(t) = \vec{v}_1 e^{3t}$$
$$= \begin{bmatrix} 2 \\ 1 \end{bmatrix} e^{3t}$$

Since eigenvalue -3 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{-3t}$$
$$= \begin{bmatrix} -4 \\ 1 \end{bmatrix} e^{-3t}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} 2\,\mathrm{e}^{3t} \\ \mathrm{e}^{3t} \end{bmatrix} + c_2 \begin{bmatrix} -4\,\mathrm{e}^{-3t} \\ \mathrm{e}^{-3t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} 2c_1 \mathrm{e}^{3t} - 4c_2 \mathrm{e}^{-3t} \\ c_1 \mathrm{e}^{3t} + c_2 \mathrm{e}^{-3t} \end{bmatrix}$$

The following is the phase plot of the system.

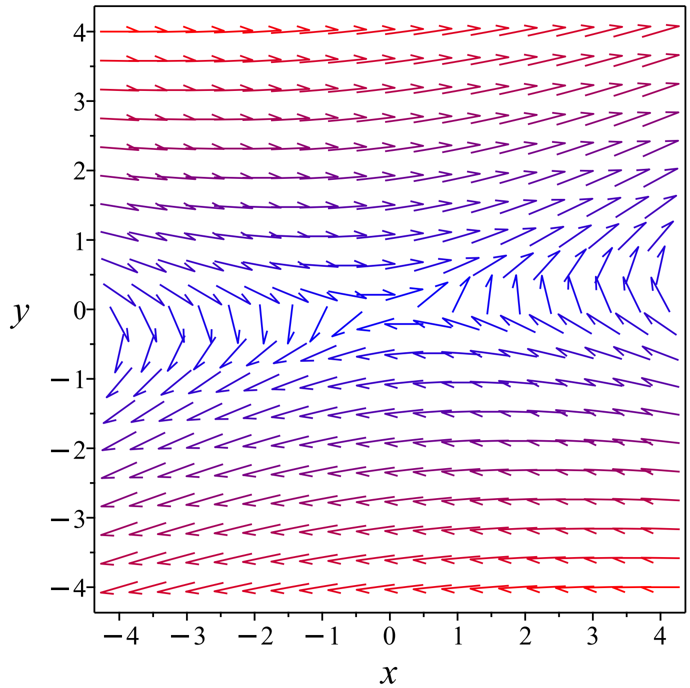

Figure 851: Phase plot

29.1.3 Maple step by step solution

Let's solve

$[x'(t) = 8y(t) - x(t), y'(t) = x(t) + y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} -1 & 8 \\ 1 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} -1 & 8 \\ 1 & 1 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} -1 & 8 \\ 1 & 1 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-3, \begin{bmatrix} -4 \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} 2 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-3, \begin{bmatrix} -4 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{x}_1 = e^{-3t} \cdot \begin{bmatrix} -4 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[3, \begin{bmatrix} 2 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{x}_2 = e^{3t} \cdot \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\overrightarrow{x} = c_1 \overrightarrow{x}_1 + c_2 \overrightarrow{x}_2$$

- Substitute solutions into the general solution

$$\overrightarrow{x} = c_1 e^{-3t} \cdot \begin{bmatrix} -4 \\ 1 \end{bmatrix} + c_2 e^{3t} \cdot \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -4c_1 \mathrm{e}^{-3t} + 2c_2 \mathrm{e}^{3t} \\ c_1 \mathrm{e}^{-3t} + c_2 \mathrm{e}^{3t} \end{bmatrix}$$

- Solution to the system of ODEs

  $\{x(t) = -4c_1 \mathrm{e}^{-3t} + 2c_2 \mathrm{e}^{3t}, y(t) = c_1 \mathrm{e}^{-3t} + c_2 \mathrm{e}^{3t}\}$

✓ Solution by Maple

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= x(t) - y(t) \\
y'(t) &= y(t) - x(t)
\end{aligned}
$$

29.2.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

For the above matrix A, the matrix exponential can be found to be

$$
e^{At} = \begin{bmatrix} \frac{1}{2} + \frac{e^{2t}}{2} & -\frac{e^{2t}}{2} + \frac{1}{2} \\ -\frac{e^{2t}}{2} + \frac{1}{2} & \frac{1}{2} + \frac{e^{2t}}{2} \end{bmatrix}
$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{1}{2}+\frac{e^{2t}}{2} & -\frac{e^{2t}}{2}+\frac{1}{2} \\ -\frac{e^{2t}}{2}+\frac{1}{2} & \frac{1}{2}+\frac{e^{2t}}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{1}{2}+\frac{e^{2t}}{2}\right)c_1 + \left(-\frac{e^{2t}}{2}+\frac{1}{2}\right)c_2 \\ \left(-\frac{e^{2t}}{2}+\frac{1}{2}\right)c_1 + \left(\frac{1}{2}+\frac{e^{2t}}{2}\right)c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(c_1-c_2)e^{2t}}{2}+\frac{c_2}{2}+\frac{c_1}{2} \\ \frac{(-c_1+c_2)e^{2t}}{2}+\frac{c_2}{2}+\frac{c_1}{2} \end{bmatrix}
\end{aligned}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.2.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & -1 \\ -1 & 1-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 2\lambda = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 0$$
$$\lambda_2 = 2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
0	1	real eigenvalue
2	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 0$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} - (0)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 & -1 & 0 \\ -1 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & -1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} - (2) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -1 & -1 \\ -1 & -1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -1 & -1 & 0 \\ -1 & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} -1 & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & -1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
0	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$
2	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 0 is real and distinct then the

corresponding eigenvector solution is

$$\vec{x}_1(t) = \vec{v}_1 e^0$$
$$= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^0$$

Since eigenvalue 2 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{2t}$$
$$= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{2t}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} 1 \\ 1 \end{bmatrix} + c_2 \begin{bmatrix} -\mathrm{e}^{2t} \\ \mathrm{e}^{2t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 - c_2 \mathrm{e}^{2t} \\ c_1 + c_2 \mathrm{e}^{2t} \end{bmatrix}$$

The following is the phase plot of the system.

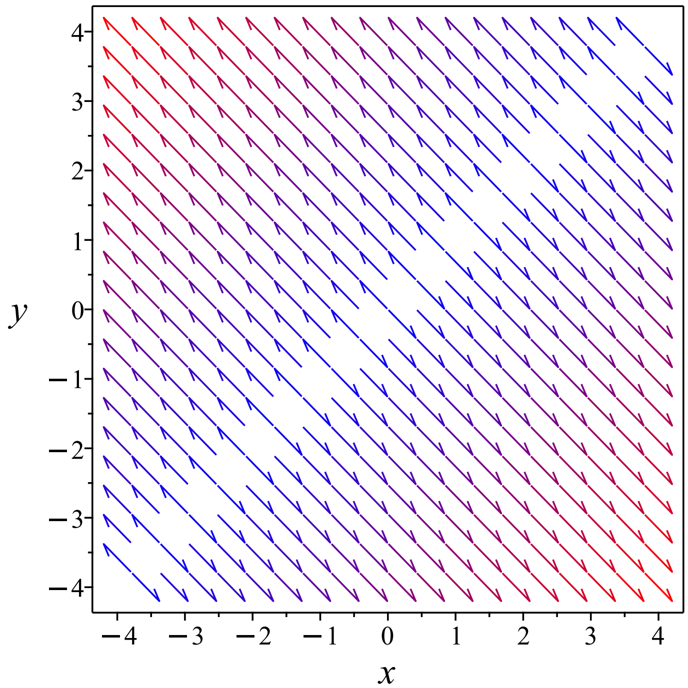

Figure 852: Phase plot

29.2.3 Maple step by step solution

Let's solve

$[x'(t) = x(t) - y(t), y'(t) = y(t) - x(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right], \left[2, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \mathrm{e}^{2t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{x} = c_1 \vec{x}_1 + c_2 \vec{x}_2$$

- Substitute solutions into the general solution

$$\vec{x} = c_2 \mathrm{e}^{2t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix} + \begin{bmatrix} c_1 \\ c_1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 - c_2 e^{2t} \\ c_1 + c_2 e^{2t} \end{bmatrix}$$

- Solution to the system of ODEs

  $\{x(t) = c_1 - c_2 e^{2t}, y(t) = c_1 + c_2 e^{2t}\}$

✓ Solution by Maple

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = 2x(t) + y(t)$$
$$y'(t) = x(t) - 3y(t)$$

With initial conditions

$$[x(0) = 0, y(0) = 0]$$

29.3.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 2 & 1 \\ 1 & -3 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{\left(5\sqrt{29}+29\right)e^{\frac{\left(-1+\sqrt{29}\right)t}{2}}}{58} + \frac{\left(-5\sqrt{29}+29\right)e^{-\frac{\left(1+\sqrt{29}\right)t}{2}}}{58} & -\frac{\left(-e^{\frac{\left(-1+\sqrt{29}\right)t}{2}}+e^{-\frac{\left(1+\sqrt{29}\right)t}{2}}\right)\sqrt{29}}{29} \\ -\frac{\left(-e^{\frac{\left(-1+\sqrt{29}\right)t}{2}}+e^{-\frac{\left(1+\sqrt{29}\right)t}{2}}\right)\sqrt{29}}{29} & \frac{\left(-5\sqrt{29}+29\right)e^{\frac{\left(-1+\sqrt{29}\right)t}{2}}}{58} + \frac{e^{-\frac{\left(1+\sqrt{29}\right)t}{2}}\left(5\sqrt{29}+29\right)}{58} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{x}_0 \\ &= \begin{bmatrix} \frac{\left(5\sqrt{29}+29\right)e^{\frac{\left(-1+\sqrt{29}\right)t}{2}}}{58} + \frac{\left(-5\sqrt{29}+29\right)e^{-\frac{\left(1+\sqrt{29}\right)t}{2}}}{58} & -\frac{\left(-e^{\frac{\left(-1+\sqrt{29}\right)t}{2}}+e^{-\frac{\left(1+\sqrt{29}\right)t}{2}}\right)\sqrt{29}}{29} \\ -\frac{\left(-e^{\frac{\left(-1+\sqrt{29}\right)t}{2}}+e^{-\frac{\left(1+\sqrt{29}\right)t}{2}}\right)\sqrt{29}}{29} & \frac{\left(-5\sqrt{29}+29\right)e^{\frac{\left(-1+\sqrt{29}\right)t}{2}}}{58} + \frac{e^{-\frac{\left(1+\sqrt{29}\right)t}{2}}\left(5\sqrt{29}+29\right)}{58} \end{bmatrix} \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \end{aligned}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.3.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 2 & 1 \\ 1 & -3 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 2 & 1 \\ 1 & -3 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 2-\lambda & 1 \\ 1 & -3-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + \lambda - 7 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -\frac{1}{2} + \frac{\sqrt{29}}{2}$$
$$\lambda_2 = -\frac{1}{2} - \frac{\sqrt{29}}{2}$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$-\frac{1}{2} + \frac{\sqrt{29}}{2}$	1	real eigenvalue
$-\frac{1}{2} - \frac{\sqrt{29}}{2}$	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -\frac{1}{2} - \frac{\sqrt{29}}{2}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & 1 \\ 1 & -3 \end{bmatrix} - \left(-\frac{1}{2} - \frac{\sqrt{29}}{2}\right)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} \frac{5}{2} + \frac{\sqrt{29}}{2} & 1 \\ 1 & -\frac{5}{2} + \frac{\sqrt{29}}{2} \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} \frac{5}{2} + \frac{\sqrt{29}}{2} & 1 & 0 \\ 1 & -\frac{5}{2} + \frac{\sqrt{29}}{2} & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{\frac{5}{2} + \frac{\sqrt{29}}{2}} \Longrightarrow \left[\begin{array}{cc|c} \frac{5}{2} + \frac{\sqrt{29}}{2} & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} \frac{5}{2}+\frac{\sqrt{29}}{2} & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix}=\begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{2t}{5+\sqrt{29}}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{2t}{5+\sqrt{29}} \\ t \end{bmatrix}=\begin{bmatrix} -\frac{2t}{5+\sqrt{29}} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{2t}{5+\sqrt{29}} \\ t \end{bmatrix}=t\begin{bmatrix} -\frac{2}{5+\sqrt{29}} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{2t}{5+\sqrt{29}} \\ t \end{bmatrix}=\begin{bmatrix} -\frac{2}{5+\sqrt{29}} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{2t}{5+\sqrt{29}} \\ t \end{bmatrix}=\begin{bmatrix} -\frac{2}{5+\sqrt{29}} \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = -\frac{1}{2}+\frac{\sqrt{29}}{2}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A-\lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & 1 \\ 1 & -3 \end{bmatrix}-\left(-\frac{1}{2}+\frac{\sqrt{29}}{2}\right)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix}=\begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} \frac{5}{2}-\frac{\sqrt{29}}{2} & 1 \\ 1 & -\frac{5}{2}-\frac{\sqrt{29}}{2} \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix}=\begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} \frac{5}{2}-\frac{\sqrt{29}}{2} & 1 & 0 \\ 1 & -\frac{5}{2}-\frac{\sqrt{29}}{2} & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{\frac{5}{2} - \frac{\sqrt{29}}{2}} \Longrightarrow \left[\begin{array}{cc|c} \frac{5}{2} - \frac{\sqrt{29}}{2} & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} \frac{5}{2} - \frac{\sqrt{29}}{2} & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{2t}{-5+\sqrt{29}}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{2t}{-5+\sqrt{29}} \\ t \end{bmatrix} = \begin{bmatrix} \frac{2t}{-5+\sqrt{29}} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{2t}{-5+\sqrt{29}} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{2}{-5+\sqrt{29}} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{2t}{-5+\sqrt{29}} \\ t \end{bmatrix} = \begin{bmatrix} \frac{2}{-5+\sqrt{29}} \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
$-\frac{1}{2}+\frac{\sqrt{29}}{2}$	1	1	No	$\left[\begin{array}{c}\frac{1}{-\frac{5}{2}+\frac{\sqrt{29}}{2}}\\ 1\end{array}\right]$
$-\frac{1}{2}-\frac{\sqrt{29}}{2}$	1	1	No	$\left[\begin{array}{c}\frac{1}{-\frac{5}{2}-\frac{\sqrt{29}}{2}}\\ 1\end{array}\right]$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue $-\frac{1}{2}+\frac{\sqrt{29}}{2}$ is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^{\left(-\frac{1}{2}+\frac{\sqrt{29}}{2}\right)t}\\ &= \left[\begin{array}{c}\frac{1}{-\frac{5}{2}+\frac{\sqrt{29}}{2}}\\ 1\end{array}\right] e^{\left(-\frac{1}{2}+\frac{\sqrt{29}}{2}\right)t}\end{aligned}$$

Since eigenvalue $-\frac{1}{2}-\frac{\sqrt{29}}{2}$ is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{\left(-\frac{1}{2}-\frac{\sqrt{29}}{2}\right)t}\\ &= \left[\begin{array}{c}\frac{1}{-\frac{5}{2}-\frac{\sqrt{29}}{2}}\\ 1\end{array}\right] e^{\left(-\frac{1}{2}-\frac{\sqrt{29}}{2}\right)t}\end{aligned}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

Which is written as

$$\left[\begin{array}{c}x(t)\\ y(t)\end{array}\right] = c_1\left[\begin{array}{c}\frac{\mathrm{e}^{\left(-\frac{1}{2}+\frac{\sqrt{29}}{2}\right)t}}{-\frac{5}{2}+\frac{\sqrt{29}}{2}}\\ \mathrm{e}^{\left(-\frac{1}{2}+\frac{\sqrt{29}}{2}\right)t}\end{array}\right] + c_2\left[\begin{array}{c}\frac{\mathrm{e}^{\left(-\frac{1}{2}-\frac{\sqrt{29}}{2}\right)t}}{-\frac{5}{2}-\frac{\sqrt{29}}{2}}\\ \mathrm{e}^{\left(-\frac{1}{2}-\frac{\sqrt{29}}{2}\right)t}\end{array}\right]$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{c_1\left(5+\sqrt{29}\right)e^{\frac{\left(-1+\sqrt{29}\right)t}{2}}}{2} - \frac{c_2 e^{-\frac{\left(1+\sqrt{29}\right)t}{2}}\left(-5+\sqrt{29}\right)}{2} \\ c_1 e^{\frac{\left(-1+\sqrt{29}\right)t}{2}} + c_2 e^{-\frac{\left(1+\sqrt{29}\right)t}{2}} \end{bmatrix}$$

Since initial conditions are given, the solution above needs to be updated by solving for the constants of integrations using the given initial conditions

$$\begin{bmatrix} x(0) = 0 \\ y(0) = 0 \end{bmatrix} \tag{1}$$

Substituting initial conditions into the above solution at $t = 0$ gives

$$\begin{bmatrix} 0 \\ 0 \end{bmatrix} = \begin{bmatrix} \frac{(c_1-c_2)\sqrt{29}}{2} + \frac{5c_1}{2} + \frac{5c_2}{2} \\ c_1 + c_2 \end{bmatrix}$$

Solving for the constants of integrations gives

$$\begin{bmatrix} c_1 = 0 \\ c_2 = 0 \end{bmatrix}$$

Substituting these constants back in original solution in Eq. (1) gives

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The following is the phase plot of the system.

Problem number: 805.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = x(t) + y(t)$$
$$y'(t) = 4y(t) - 2x(t)$$

With initial conditions

$$[x(0) = 0, y(0) = -1]$$

29.4.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ -2 & 4 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} 2\,\mathrm{e}^{2t} - \mathrm{e}^{3t} & \mathrm{e}^{3t} - \mathrm{e}^{2t} \\ -2\,\mathrm{e}^{3t} + 2\,\mathrm{e}^{2t} & -\mathrm{e}^{2t} + 2\,\mathrm{e}^{3t} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{x}_0 \\
&= \begin{bmatrix} 2\,\mathrm{e}^{2t}-\mathrm{e}^{3t} & \mathrm{e}^{3t}-\mathrm{e}^{2t} \\ -2\,\mathrm{e}^{3t}+2\,\mathrm{e}^{2t} & -\mathrm{e}^{2t}+2\,\mathrm{e}^{3t} \end{bmatrix} \begin{bmatrix} 0 \\ -1 \end{bmatrix} \\
&= \begin{bmatrix} -\mathrm{e}^{3t}+\mathrm{e}^{2t} \\ \mathrm{e}^{2t}-2\,\mathrm{e}^{3t} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.4.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ -2 & 4 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$
\det(A-\lambda I) = 0
$$

Expanding gives

$$
\det\left(\begin{bmatrix} 1 & 1 \\ -2 & 4 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0
$$

Therefore

$$
\det\left(\begin{bmatrix} 1-\lambda & 1 \\ -2 & 4-\lambda \end{bmatrix}\right) = 0
$$

Which gives the characteristic equation

$$
\lambda^2 - 5\lambda + 6 = 0
$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 3$$
$$\lambda_2 = 2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
2	1	real eigenvalue
3	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 \\ -2 & 4 \end{bmatrix} - (2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} -1 & 1 \\ -2 & 2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -1 & 1 & 0 \\ -2 & 2 & 0 \end{array}\right]$$

$$R_2 = R_2 - 2R_1 \Longrightarrow \left[\begin{array}{cc|c} -1 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 3$

We need to solve $A\vec{v} = \lambda \vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 \\ -2 & 4 \end{bmatrix} - (3) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -2 & 1 \\ -2 & 1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -2 & 1 & 0 \\ -2 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} -2 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 2 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
3	1	1	No	$\begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$
2	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 3 is real and distinct then the

corresponding eigenvector solution is

$$\vec{x}_1(t) = \vec{v}_1 e^{3t}$$
$$= \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix} e^{3t}$$

Since eigenvalue 2 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{2t}$$
$$= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{2t}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \frac{e^{3t}}{2} \\ e^{3t} \end{bmatrix} + c_2 \begin{bmatrix} e^{2t} \\ e^{2t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{c_1 e^{3t}}{2} + c_2 e^{2t} \\ c_1 e^{3t} + c_2 e^{2t} \end{bmatrix}$$

Since initial conditions are given, the solution above needs to be updated by solving for the constants of integrations using the given initial conditions

$$\begin{bmatrix} x(0) = 0 \\ y(0) = -1 \end{bmatrix} \tag{1}$$

Substituting initial conditions into the above solution at $t = 0$ gives

$$\begin{bmatrix} 0 \\ -1 \end{bmatrix} = \begin{bmatrix} \frac{c_1}{2} + c_2 \\ c_1 + c_2 \end{bmatrix}$$

Solving for the constants of integrations gives

$$\begin{bmatrix} c_1 = -2 \\ c_2 = 1 \end{bmatrix}$$

Substituting these constants back in original solution in Eq. (1) gives

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -e^{3t} + e^{2t} \\ e^{2t} - 2\,e^{3t} \end{bmatrix}$$

The following is the phase plot of the system.

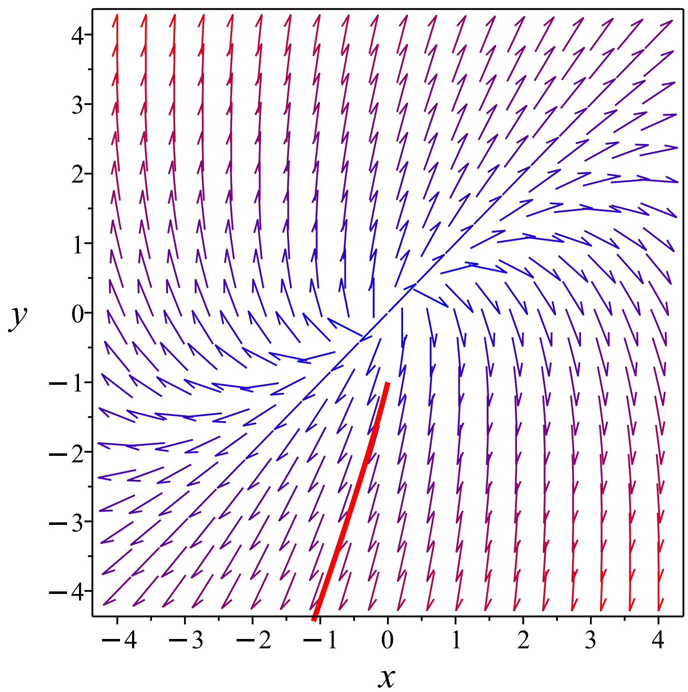

Figure 854: Phase plot

Problem number: 806.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 4x(t) - 5y(t) \\
y'(t) &= x(t)
\end{aligned}
$$

With initial conditions

$$[x(0) = 0, y(0) = 1]$$

29.5.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 4 & -5 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$
\begin{aligned}
e^{At} &= \begin{bmatrix} e^{2t}\cos(t) + 2\,e^{2t}\sin(t) & -5\,e^{2t}\sin(t) \\ e^{2t}\sin(t) & e^{2t}\cos(t) - 2\,e^{2t}\sin(t) \end{bmatrix} \\
&= \begin{bmatrix} e^{2t}(\cos(t) + 2\sin(t)) & -5\,e^{2t}\sin(t) \\ e^{2t}\sin(t) & e^{2t}(\cos(t) - 2\sin(t)) \end{bmatrix}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{x}_0 \\
&= \begin{bmatrix} e^{2t}(\cos(t) + 2\sin(t)) & -5\,e^{2t}\sin(t) \\ e^{2t}\sin(t) & e^{2t}(\cos(t) - 2\sin(t)) \end{bmatrix} \begin{bmatrix} 0 \\ 1 \end{bmatrix} \\
&= \begin{bmatrix} -5\,e^{2t}\sin(t) \\ e^{2t}(\cos(t) - 2\sin(t)) \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.5.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 4 & -5 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 4 & -5 \\ 1 & 0 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 4-\lambda & -5 \\ 1 & -\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 4\lambda + 5 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 2+i$$
$$\lambda_2 = 2-i$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$2+i$	1	complex eigenvalue
$2-i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 2-i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A-\lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 4 & -5 \\ 1 & 0 \end{bmatrix} - (2-i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 2+i & -5 \\ 1 & -2+i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2+i & -5 & 0 \\ 1 & -2+i & 0 \end{array}\right]$$

$$R_2 = R_2 + \left(-\frac{2}{5} + \frac{i}{5}\right) R_1 \Longrightarrow \left[\begin{array}{cc|c} 2+i & -5 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2+i & -5 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = (2-i)\,t\}$

Hence the solution is

$$\begin{bmatrix} (2-\mathrm{I})\,t \\ t \end{bmatrix} = \begin{bmatrix} (2-i)\,t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} (2-\mathrm{I})\,t \\ t \end{bmatrix} = t \begin{bmatrix} 2-i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} (2-\mathrm{I})\,t \\ t \end{bmatrix} = \begin{bmatrix} 2-i \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 2+i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A-\lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 4 & -5 \\ 1 & 0 \end{bmatrix} - (2+i) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 2-i & -5 \\ 1 & -2-i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2-i & -5 & 0 \\ 1 & -2-i & 0 \end{array}\right]$$

$$R_2 = R_2 + \left(-\frac{2}{5} - \frac{i}{5}\right) R_1 \Longrightarrow \left[\begin{array}{cc|c} 2-i & -5 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$
\begin{bmatrix} 2-i & -5 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}
$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = (2+i)\,t\}$

Hence the solution is

$$
\begin{bmatrix} (2+\mathrm{I})\,t \\ t \end{bmatrix} = \begin{bmatrix} (2+i)\,t \\ t \end{bmatrix}
$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$
\begin{bmatrix} (2+\mathrm{I})\,t \\ t \end{bmatrix} = t \begin{bmatrix} 2+i \\ 1 \end{bmatrix}
$$

Let $t = 1$ the eigenvector becomes

$$
\begin{bmatrix} (2+\mathrm{I})\,t \\ t \end{bmatrix} = \begin{bmatrix} 2+i \\ 1 \end{bmatrix}
$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
$2+i$	1	1	No	$\begin{bmatrix} 2+i \\ 1 \end{bmatrix}$
$2-i$	1	1	No	$\begin{bmatrix} 2-i \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} (2+i)\,\mathrm{e}^{(2+i)t} \\ \mathrm{e}^{(2+i)t} \end{bmatrix} + c_2 \begin{bmatrix} (2-i)\,\mathrm{e}^{(2-i)t} \\ \mathrm{e}^{(2-i)t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} (2+i)\,c_1 \mathrm{e}^{(2+i)t} + (2-i)\,c_2 \mathrm{e}^{(2-i)t} \\ c_1 \mathrm{e}^{(2+i)t} + c_2 \mathrm{e}^{(2-i)t} \end{bmatrix}$$

Since initial conditions are given, the solution above needs to be updated by solving for the constants of integrations using the given initial conditions

$$\begin{bmatrix} x(0) = 0 \\ y(0) = 1 \end{bmatrix} \tag{1}$$

Substituting initial conditions into the above solution at $t = 0$ gives

$$\begin{bmatrix} 0 \\ 1 \end{bmatrix} = \begin{bmatrix} (2+i)\,c_1 + (2-i)\,c_2 \\ c_1 + c_2 \end{bmatrix}$$

Solving for the constants of integrations gives

$$\begin{bmatrix} c_1 = \frac{1}{2} + i \\ c_2 = \frac{1}{2} - i \end{bmatrix}$$

Substituting these constants back in original solution in Eq. (1) gives

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{5i\mathrm{e}^{(2-i)t}}{2} + \frac{5i\mathrm{e}^{(2+i)t}}{2} \\ \left(\frac{1}{2} - i\right) \mathrm{e}^{(2-i)t} + \left(\frac{1}{2} + i\right) \mathrm{e}^{(2+i)t} \end{bmatrix}$$

The following is the phase plot of the system.

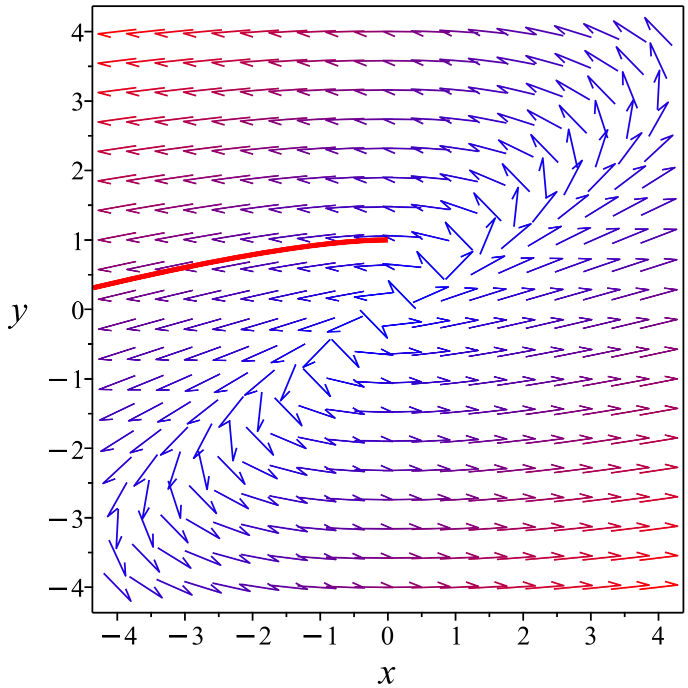

Figure 855: Phase plot

The following are plots of each solution.

✓ Solution by Maple

Problem number: 807.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$\begin{aligned} x'(t) &= -x(t) + y(t) + z(t) \\ y'(t) &= x(t) - y(t) + z(t) \\ z'(t) &= x(t) + y(t) - z(t) \end{aligned}$$

29.6.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{(e^{3t}+2)e^{-2t}}{3} & \frac{(e^{3t}-1)e^{-2t}}{3} & \frac{(e^{3t}-1)e^{-2t}}{3} \\ \frac{(e^{3t}-1)e^{-2t}}{3} & \frac{(e^{3t}+2)e^{-2t}}{3} & \frac{(e^{3t}-1)e^{-2t}}{3} \\ \frac{(e^{3t}-1)e^{-2t}}{3} & \frac{(e^{3t}-1)e^{-2t}}{3} & \frac{(e^{3t}+2)e^{-2t}}{3} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} \frac{(e^{3t}+2)e^{-2t}}{3} & \frac{(e^{3t}-1)e^{-2t}}{3} & \frac{(e^{3t}-1)e^{-2t}}{3} \\ \frac{(e^{3t}-1)e^{-2t}}{3} & \frac{(e^{3t}+2)e^{-2t}}{3} & \frac{(e^{3t}-1)e^{-2t}}{3} \\ \frac{(e^{3t}-1)e^{-2t}}{3} & \frac{(e^{3t}-1)e^{-2t}}{3} & \frac{(e^{3t}+2)e^{-2t}}{3} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ c_3 \end{bmatrix} \\ &= \begin{bmatrix} \frac{(e^{3t}+2)e^{-2t}c_1}{3} + \frac{(e^{3t}-1)e^{-2t}c_2}{3} + \frac{(e^{3t}-1)e^{-2t}c_3}{3} \\ \frac{(e^{3t}-1)e^{-2t}c_1}{3} + \frac{(e^{3t}+2)e^{-2t}c_2}{3} + \frac{(e^{3t}-1)e^{-2t}c_3}{3} \\ \frac{(e^{3t}-1)e^{-2t}c_1}{3} + \frac{(e^{3t}-1)e^{-2t}c_2}{3} + \frac{(e^{3t}+2)e^{-2t}c_3}{3} \end{bmatrix} \\ &= \begin{bmatrix} \frac{e^{-2t}(e^{3t}(c_2+c_1+c_3)+2c_1-c_2-c_3)}{3} \\ \frac{(e^{3t}(c_2+c_1+c_3)-c_1+2c_2-c_3)e^{-2t}}{3} \\ \frac{(e^{3t}(c_2+c_1+c_3)-c_1-c_2+2c_3)e^{-2t}}{3} \end{bmatrix} \end{aligned}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.6.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix}-1 & 1 & 1\\ 1 & -1 & 1\\ 1 & 1 & -1\end{bmatrix} - \lambda\begin{bmatrix}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix}-1-\lambda & 1 & 1\\ 1 & -1-\lambda & 1\\ 1 & 1 & -1-\lambda\end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^3 + 3\lambda^2 - 4 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 1$$
$$\lambda_2 = -2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-2	1	real eigenvalue
1	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix}-1 & 1 & 1\\ 1 & -1 & 1\\ 1 & 1 & -1\end{bmatrix} - (-2)\begin{bmatrix}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{bmatrix}\right)\begin{bmatrix}v_1\\ v_2\\ v_3\end{bmatrix} = \begin{bmatrix}0\\ 0\\ 0\end{bmatrix}$$

$$\begin{bmatrix}1 & 1 & 1\\ 1 & 1 & 1\\ 1 & 1 & 1\end{bmatrix}\begin{bmatrix}v_1\\ v_2\\ v_3\end{bmatrix} = \begin{bmatrix}0\\ 0\\ 0\end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{ccc|c} 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 0 \end{array}\right]$$

$$R_3 = R_3 - R_1 \Longrightarrow \left[\begin{array}{ccc|c} 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2, v_3\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Let $v_3 = s$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t - s\}$

Hence the solution is

$$\begin{bmatrix} -t - s \\ t \\ s \end{bmatrix} = \begin{bmatrix} -t - s \\ t \\ s \end{bmatrix}$$

Since there are two free Variable, we have found two eigenvectors associated with this eigenvalue. The above can be written as

$$\begin{aligned} \begin{bmatrix} -t - s \\ t \\ s \end{bmatrix} &= \begin{bmatrix} -t \\ t \\ 0 \end{bmatrix} + \begin{bmatrix} -s \\ 0 \\ s \end{bmatrix} \\ &= t \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix} + s \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} \end{aligned}$$

By letting $t = 1$ and $s = 1$ then the above becomes

$$\begin{bmatrix} -t-s \\ t \\ s \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$$

Hence the two eigenvectors associated with this eigenvalue are

$$\left(\begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}, \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} \right)$$

Considering the eigenvalue $\lambda_2 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -2 & 1 & 1 \\ 1 & -2 & 1 \\ 1 & 1 & -2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} -2 & 1 & 1 & 0 \\ 1 & -2 & 1 & 0 \\ 1 & 1 & -2 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{2} \Longrightarrow \left[\begin{array}{ccc|c} -2 & 1 & 1 & 0 \\ 0 & -\frac{3}{2} & \frac{3}{2} & 0 \\ 1 & 1 & -2 & 0 \end{array}\right]$$

$$R_3 = R_3 + \frac{R_1}{2} \Longrightarrow \left[\begin{array}{ccc|c} -2 & 1 & 1 & 0 \\ 0 & -\frac{3}{2} & \frac{3}{2} & 0 \\ 0 & \frac{3}{2} & -\frac{3}{2} & 0 \end{array}\right]$$

$$R_3 = R_3 + R_2 \Longrightarrow \left[\begin{array}{ccc|c} -2 & 1 & 1 & 0 \\ 0 & -\frac{3}{2} & \frac{3}{2} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & 1 & 1 \\ 0 & -\frac{3}{2} & \frac{3}{2} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t, v_2 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
1	1	1	No	$\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$
-2	2	2	No	$\begin{bmatrix} -1 & -1 \\ 0 & 1 \\ 1 & 0 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^{t} \\
&= \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} e^{t}
\end{aligned}
$$

eigenvalue -2 is real and repated eigenvalue of multiplicity 2.There are two possible cases that can happen. This is illustrated in this diagram

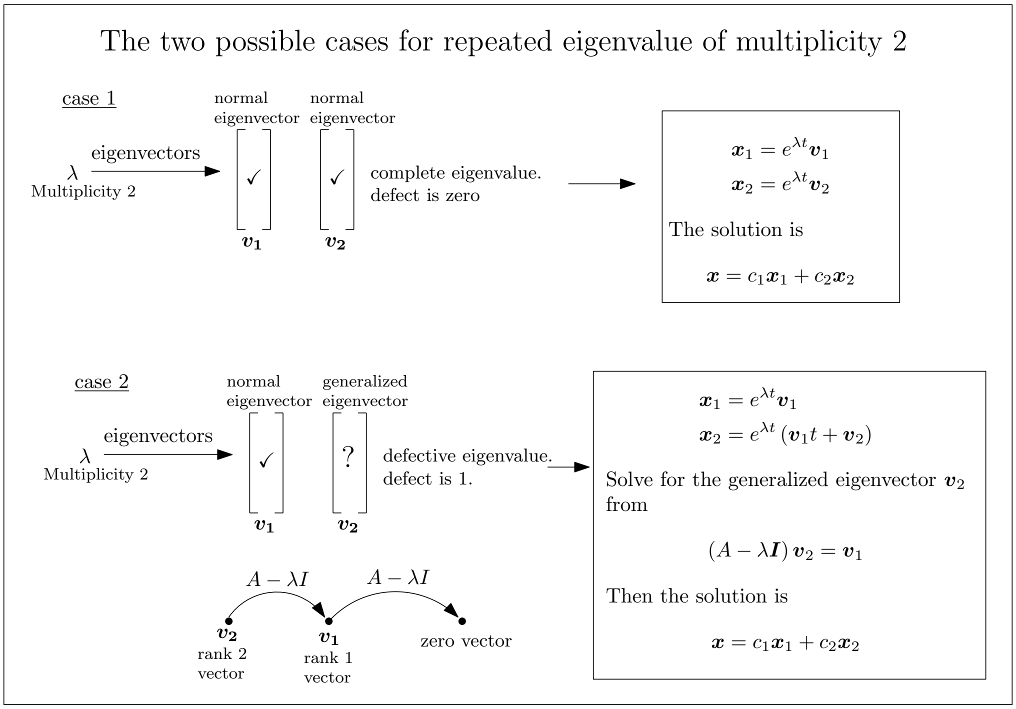

Figure 856: Possible case for repeated λ of multiplicity 2

This eigenvalue has algebraic multiplicity of 2 which is the same as its geometric multiplicity 2, then it is complete eigenvalue and this falls into case 1 shown above. Hence the corresponding eigenvector basis are

$$
\begin{aligned}
\vec{x}_2(t) &= \vec{v}_2 e^{-2t} \\
&= \left[\begin{array}{c} -1 \\ 0 \\ 1 \end{array}\right] e^{-2t}
\end{aligned}
$$

$$
\begin{aligned}
\vec{x}_3(t) &= \vec{v}_3 e^{-2t} \\
&= \left[\begin{array}{c} -1 \\ 1 \\ 0 \end{array}\right] e^{-2t}
\end{aligned}
$$

Therefore the final solution is

$$
\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t) + c_3 \vec{x}_3(t)
$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = c_1 \begin{bmatrix} e^t \\ e^t \\ e^t \end{bmatrix} + c_2 \begin{bmatrix} -e^{-2t} \\ 0 \\ e^{-2t} \end{bmatrix} + c_3 \begin{bmatrix} -e^{-2t} \\ e^{-2t} \\ 0 \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} (c_1 e^{3t} - c_2 - c_3)\, e^{-2t} \\ (c_1 e^{3t} + c_3)\, e^{-2t} \\ (c_1 e^{3t} + c_2)\, e^{-2t} \end{bmatrix}$$

29.6.3 Maple step by step solution

Let's solve

$[x'(t) = -x(t) + y(t) + z(t)\,, y'(t) = x(t) - y(t) + z(t)\,, z'(t) = x(t) + y(t) - z(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \end{bmatrix}$$

- Rewrite the system as

$\vec{x}'(t) = A \cdot \vec{x}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2, \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}\right], \left[-2, \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[-2, \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}\right]$$

- First solution from eigenvalue -2

$$\vec{x}_1(t) = e^{-2t} \cdot \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\vec{p}$ is to be solved for, $\lambda = -2$ is the eigenvalue, an

$\vec{x}_2(t) = e^{\lambda t}\left(t\vec{v} + \vec{p}\right)$

- Note that the t multiplying $\vec{v}$ makes this solution linearly independent to the 1st solution obtai
- Substitute $\vec{x}_2(t)$ into the homogeneous system

$\lambda e^{\lambda t}\left(t\vec{v} + \vec{p}\right) + e^{\lambda t}\vec{v} = \left(e^{\lambda t}A\right) \cdot \left(t\vec{v} + \vec{p}\right)$

- Use the fact that $\vec{v}$ is an eigenvector of A

$\lambda e^{\lambda t}\left(t\vec{v} + \vec{p}\right) + e^{\lambda t}\vec{v} = e^{\lambda t}\left(\lambda t\vec{v} + A \cdot \vec{p}\right)$

- Simplify equation

$\lambda\vec{p} + \vec{v} = A \cdot \vec{p}$

- Make use of the identity matrix I

  $(\lambda \cdot I) \cdot \vec{p} + \vec{v} = A \cdot \vec{p}$
- Condition $\vec{p}$ must meet for $\vec{x}_2(t)$ to be a solution to the homogeneous system

  $(A - \lambda \cdot I) \cdot \vec{p} = \vec{v}$
- Choose $\vec{p}$ to use in the second solution to the homogeneous system from eigenvalue -2

  $$\left(\begin{bmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \end{bmatrix} - (-2) \cdot \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) \cdot \vec{p} = \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$$
- Choice of $\vec{p}$

  $$\vec{p} = \begin{bmatrix} -1 \\ 0 \\ 0 \end{bmatrix}$$
- Second solution from eigenvalue -2

  $$\vec{x}_2(t) = \mathrm{e}^{-2t} \cdot \left(t \cdot \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \end{bmatrix}\right)$$
- Consider eigenpair

  $$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$
- Solution to homogeneous system from eigenpair

  $$\vec{x}_3 = \mathrm{e}^{t} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$
- General solution to the system of ODEs

  $\vec{x} = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t) + c_3 \vec{x}_3$
- Substitute solutions into the general solution

$$\vec{x} = c_1 e^{-2t} \cdot \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} + c_2 e^{-2t} \cdot \left(t \cdot \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \end{bmatrix} \right) + c_3 e^{t} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} -e^{-2t}(-c_3 e^{3t} + c_2(t+1) + c_1) \\ c_3 e^{t} \\ (c_3 e^{3t} + c_2 t + c_1)\, e^{-2t} \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = -e^{-2t}(-c_3 e^{3t} + c_2(t+1) + c_1)\,, y(t) = c_3 e^{t}, z(t) = (c_3 e^{3t} + c_2 t + c_1)\, e^{-2t}\right\}$$

✓ Solution by Maple

Problem number: 808.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$\begin{aligned} x'(t) &= 2x(t) - y(t) + z(t) \\ y'(t) &= x(t) + 2y(t) - z(t) \\ z'(t) &= x(t) - y(t) + 2z(t) \end{aligned}$$

29.7.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 2 & -1 & 1 \\ 1 & 2 & -1 \\ 1 & -1 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} e^{2t} & -e^{3t} + e^{2t} & e^{3t} - e^{2t} \\ e^{2t} - e^{t} & e^{2t} & -e^{2t} + e^{t} \\ e^{2t} - e^{t} & -e^{3t} + e^{2t} & e^{t} + e^{3t} - e^{2t} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} e^{2t} & -e^{3t}+e^{2t} & e^{3t}-e^{2t} \\ e^{2t}-e^{t} & e^{2t} & -e^{2t}+e^{t} \\ e^{2t}-e^{t} & -e^{3t}+e^{2t} & e^{t}+e^{3t}-e^{2t} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ c_3 \end{bmatrix} \\
&= \begin{bmatrix} e^{2t}c_1 + (-e^{3t}+e^{2t})\, c_2 + (e^{3t}-e^{2t})\, c_3 \\ (e^{2t}-e^{t})\, c_1 + e^{2t}c_2 + (-e^{2t}+e^{t})\, c_3 \\ (e^{2t}-e^{t})\, c_1 + (-e^{3t}+e^{2t})\, c_2 + (e^{t}+e^{3t}-e^{2t})\, c_3 \end{bmatrix} \\
&= \begin{bmatrix} (c_2+c_1-c_3)\, e^{2t} - e^{3t}(c_2-c_3) \\ (c_2+c_1-c_3)\, e^{2t} - e^{t}(c_1-c_3) \\ (c_2+c_1-c_3)\, e^{2t} + (-c_2+c_3)\, e^{3t} - e^{t}(c_1-c_3) \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.7.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 2 & -1 & 1 \\ 1 & 2 & -1 \\ 1 & -1 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}
$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$
\det(A - \lambda I) = 0
$$

Expanding gives

$$
\det\left(\begin{bmatrix} 2 & -1 & 1 \\ 1 & 2 & -1 \\ 1 & -1 & 2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) = 0
$$

Therefore

$$\det\left(\begin{bmatrix} 2-\lambda & -1 & 1 \\ 1 & 2-\lambda & -1 \\ 1 & -1 & 2-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^3 - 6\lambda^2 + 11\lambda - 6 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 1$$
$$\lambda_2 = 3$$
$$\lambda_3 = 2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue
2	1	real eigenvalue
3	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & -1 & 1 \\ 1 & 2 & -1 \\ 1 & -1 & 2 \end{bmatrix} - (1)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 1 & -1 & 1 \\ 1 & 1 & -1 \\ 1 & -1 & 1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 1 & -1 & 1 & 0 \\ 1 & 1 & -1 & 0 \\ 1 & -1 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{ccc|c} 1 & -1 & 1 & 0 \\ 0 & 2 & -2 & 0 \\ 1 & -1 & 1 & 0 \end{array}\right]$$

$$R_3 = R_3 - R_1 \Longrightarrow \left[\begin{array}{ccc|c} 1 & -1 & 1 & 0 \\ 0 & 2 & -2 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & -1 & 1 \\ 0 & 2 & -2 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 0, v_2 = t\}$

Hence the solution is

$$\begin{bmatrix} 0 \\ t \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 0 \\ t \\ t \end{bmatrix} = t \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 0 \\ t \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & -1 & 1 \\ 1 & 2 & -1 \\ 1 & -1 & 2 \end{bmatrix} - (2)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 0 & -1 & 1 \\ 1 & 0 & -1 \\ 1 & -1 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 0 & -1 & 1 & 0 \\ 1 & 0 & -1 & 0 \\ 1 & -1 & 0 & 0 \end{array}\right]$$

Since the current pivot $A(1,1)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 1 and row 2 gives

$$\left[\begin{array}{ccc|c} 1 & 0 & -1 & 0 \\ 0 & -1 & 1 & 0 \\ 1 & -1 & 0 & 0 \end{array}\right]$$

$$R_3 = R_3 - R_1 \Longrightarrow \left[\begin{array}{ccc|c} 1 & 0 & -1 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & -1 & 1 & 0 \end{array}\right]$$

$$R_3 = R_3 - R_2 \Longrightarrow \left[\begin{array}{ccc|c} 1 & 0 & -1 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & 0 & -1 \\ 0 & -1 & 1 \\ 0 & 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t, v_2 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_3 = 3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & -1 & 1 \\ 1 & 2 & -1 \\ 1 & -1 & 2 \end{bmatrix} - (3) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -1 & -1 & 1 \\ 1 & -1 & -1 \\ 1 & -1 & -1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} -1 & -1 & 1 & 0 \\ 1 & -1 & -1 & 0 \\ 1 & -1 & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{ccc|c} -1 & -1 & 1 & 0 \\ 0 & -2 & 0 & 0 \\ 1 & -1 & -1 & 0 \end{array}\right]$$

$$R_3 = R_3 + R_1 \Longrightarrow \left[\begin{array}{ccc|c} -1 & -1 & 1 & 0 \\ 0 & -2 & 0 & 0 \\ 0 & -2 & 0 & 0 \end{array}\right]$$

$$R_3 = R_3 - R_2 \Longrightarrow \left[\begin{array}{ccc|c} -1 & -1 & 1 & 0 \\ 0 & -2 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & -1 & 1 \\ 0 & -2 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t, v_2 = 0\}$

Hence the solution is

$$\begin{bmatrix} t \\ 0 \\ t \end{bmatrix} = \begin{bmatrix} t \\ 0 \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ 0 \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ 0 \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
1	1	1	No	$\begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}$
3	1	1	No	$\begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$
2	1	1	No	$\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^t \\
&= \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix} e^t
\end{aligned}
$$

Since eigenvalue 3 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{3t}$$
$$= \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} e^{3t}$$

Since eigenvalue 2 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_3(t) = \vec{v}_3 e^{2t}$$
$$= \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} e^{2t}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t) + c_3 \vec{x}_3(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = c_1 \begin{bmatrix} 0 \\ \mathrm{e}^t \\ \mathrm{e}^t \end{bmatrix} + c_2 \begin{bmatrix} \mathrm{e}^{3t} \\ 0 \\ \mathrm{e}^{3t} \end{bmatrix} + c_3 \begin{bmatrix} \mathrm{e}^{2t} \\ \mathrm{e}^{2t} \\ \mathrm{e}^{2t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} c_2 \mathrm{e}^{3t} + c_3 \mathrm{e}^{2t} \\ c_1 \mathrm{e}^t + c_3 \mathrm{e}^{2t} \\ c_1 \mathrm{e}^t + c_2 \mathrm{e}^{3t} + c_3 \mathrm{e}^{2t} \end{bmatrix}$$

29.7.3 Maple step by step solution

Let's solve

$[x'(t) = 2x(t) - y(t) + z(t), y'(t) = x(t) + 2y(t) - z(t), z'(t) = x(t) - y(t) + 2z(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 2 & -1 & 1 \\ 1 & 2 & -1 \\ 1 & -1 & 2 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 2 & -1 & 1 \\ 1 & 2 & -1 \\ 1 & -1 & 2 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 2 & -1 & 1 \\ 1 & 2 & -1 \\ 1 & -1 & 2 \end{bmatrix}$$

- Rewrite the system as

$\vec{x}'(t) = A \cdot \vec{x}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}\right], \left[2, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = e^t \cdot \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 2, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = e^{2t} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 3, \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_3 = e^{3t} \cdot \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$\vec{x} = c_1 \vec{x}_1 + c_2 \vec{x}_2 + c_3 \vec{x}_3$

- Substitute solutions into the general solution

$$\vec{x} = c_1 e^t \cdot \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix} + c_2 e^{2t} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + c_3 e^{3t} \cdot \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} c_2 e^{2t} + c_3 e^{3t} \\ c_1 e^t + c_2 e^{2t} \\ c_1 e^t + c_2 e^{2t} + c_3 e^{3t} \end{bmatrix}$$

- Solution to the system of ODEs

  $\{x(t) = c_2 e^{2t} + c_3 e^{3t}, y(t) = c_1 e^t + c_2 e^{2t}, z(t) = c_1 e^t + c_2 e^{2t} + c_3 e^{3t}\}$

✓ Solution by Maple

ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 2x(t) - y(t) + z(t) \\
y'(t) &= x(t) + z(t) \\
z'(t) &= y(t) - 2z(t) - 3x(t)
\end{aligned}
$$

With initial conditions

$$
[x(0) = 0, y(0) = 0, z(0) = 1]
$$

29.8.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 2 & -1 & 1 \\ 1 & 0 & 1 \\ -3 & 1 & -2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}
$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} -e^{-t} + e^{t} + 1 & -e^{t} + 1 & 1 - e^{-t} \\ 1 - e^{-t} & 1 & 1 - e^{-t} \\ -e^{t} - 1 + 2e^{-t} & e^{t} - 1 & -1 + 2e^{-t} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{x}_0 \\ &= \begin{bmatrix} -e^{-t} + e^{t} + 1 & -e^{t} + 1 & 1 - e^{-t} \\ 1 - e^{-t} & 1 & 1 - e^{-t} \\ -e^{t} - 1 + 2e^{-t} & e^{t} - 1 & -1 + 2e^{-t} \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} \\ &= \begin{bmatrix} 1 - e^{-t} \\ 1 - e^{-t} \\ -1 + 2e^{-t} \end{bmatrix} \end{aligned}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.8.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 2 & -1 & 1 \\ 1 & 0 & 1 \\ -3 & 1 & -2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 2 & -1 & 1 \\ 1 & 0 & 1 \\ -3 & 1 & -2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 2-\lambda & -1 & 1 \\ 1 & -\lambda & 1 \\ -3 & 1 & -2-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^3 - \lambda = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -1$$
$$\lambda_2 = 0$$
$$\lambda_3 = 1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
0	1	real eigenvalue
1	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & -1 & 1 \\ 1 & 0 & 1 \\ -3 & 1 & -2 \end{bmatrix} - (-1)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 3 & -1 & 1 \\ 1 & 1 & 1 \\ -3 & 1 & -1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 3 & -1 & 1 & 0 \\ 1 & 1 & 1 & 0 \\ -3 & 1 & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{3} \Longrightarrow \left[\begin{array}{ccc|c} 3 & -1 & 1 & 0 \\ 0 & \frac{4}{3} & \frac{2}{3} & 0 \\ -3 & 1 & -1 & 0 \end{array}\right]$$

$$R_3 = R_3 + R_1 \Longrightarrow \left[\begin{array}{ccc|c} 3 & -1 & 1 & 0 \\ 0 & \frac{4}{3} & \frac{2}{3} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 3 & -1 & 1 \\ 0 & \frac{4}{3} & \frac{2}{3} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{t}{2}, v_2 = -\frac{t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{t}{2} \\ -\frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{t}{2} \\ -\frac{t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{t}{2} \\ -\frac{t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{2} \\ -\frac{1}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{t}{2} \\ -\frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{2} \\ -\frac{1}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{t}{2} \\ -\frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ -1 \\ 2 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 0$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & -1 & 1 \\ 1 & 0 & 1 \\ -3 & 1 & -2 \end{bmatrix} - (0) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 2 & -1 & 1 \\ 1 & 0 & 1 \\ -3 & 1 & -2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 2 & -1 & 1 & 0 \\ 1 & 0 & 1 & 0 \\ -3 & 1 & -2 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{2} \Longrightarrow \left[\begin{array}{ccc|c} 2 & -1 & 1 & 0 \\ 0 & \frac{1}{2} & \frac{1}{2} & 0 \\ -3 & 1 & -2 & 0 \end{array}\right]$$

$$R_3 = R_3 + \frac{3R_1}{2} \Longrightarrow \left[\begin{array}{ccc|c} 2 & -1 & 1 & 0 \\ 0 & \frac{1}{2} & \frac{1}{2} & 0 \\ 0 & -\frac{1}{2} & -\frac{1}{2} & 0 \end{array}\right]$$

$$R_3 = R_3 + R_2 \Longrightarrow \left[\begin{array}{ccc|c} 2 & -1 & 1 & 0 \\ 0 & \frac{1}{2} & \frac{1}{2} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & -1 & 1 \\ 0 & \frac{1}{2} & \frac{1}{2} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t, v_2 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ -1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_3 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & -1 & 1 \\ 1 & 0 & 1 \\ -3 & 1 & -2 \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 1 & -1 & 1 \\ 1 & -1 & 1 \\ -3 & 1 & -3 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 1 & -1 & 1 & 0 \\ 1 & -1 & 1 & 0 \\ -3 & 1 & -3 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{ccc|c} 1 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ -3 & 1 & -3 & 0 \end{array}\right]$$

$$R_3 = R_3 + 3R_1 \Longrightarrow \left[\begin{array}{ccc|c} 1 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & -2 & 0 & 0 \end{array}\right]$$

Since the current pivot $A(2,2)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 2 and row 3 gives

$$\left[\begin{array}{ccc|c} 1 & -1 & 1 & 0 \\ 0 & -2 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & -1 & 1 \\ 0 & -2 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t, v_2 = 0\}$

Hence the solution is

$$\begin{bmatrix} -t \\ 0 \\ t \end{bmatrix} = \begin{bmatrix} -t \\ 0 \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ 0 \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ 0 \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-1	1	1	No	$\begin{bmatrix} -\frac{1}{2} \\ -\frac{1}{2} \\ 1 \end{bmatrix}$
0	1	1	No	$\begin{bmatrix} -1 \\ -1 \\ 1 \end{bmatrix}$
1	1	1	No	$\begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^{-t} \\ &= \begin{bmatrix} -\frac{1}{2} \\ -\frac{1}{2} \\ 1 \end{bmatrix} e^{-t}\end{aligned}$$

Since eigenvalue 0 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{0} \\ &= \begin{bmatrix} -1 \\ -1 \\ 1 \end{bmatrix} e^{0}\end{aligned}$$

Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_3(t) &= \vec{v}_3 e^{t} \\ &= \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} e^{t}\end{aligned}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t) + c_3 \vec{x}_3(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = c_1 \begin{bmatrix} -\frac{\mathrm{e}^{-t}}{2} \\ -\frac{\mathrm{e}^{-t}}{2} \\ \mathrm{e}^{-t} \end{bmatrix} + c_2 \begin{bmatrix} -1 \\ -1 \\ 1 \end{bmatrix} + c_3 \begin{bmatrix} -\mathrm{e}^{t} \\ 0 \\ \mathrm{e}^{t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} -\frac{c_1 \mathrm{e}^{-t}}{2} - c_2 - c_3 \mathrm{e}^{t} \\ -\frac{c_1 \mathrm{e}^{-t}}{2} - c_2 \\ c_1 \mathrm{e}^{-t} + c_2 + c_3 \mathrm{e}^{t} \end{bmatrix}$$

Since initial conditions are given, the solution above needs to be updated by solving for the constants of integrations using the given initial conditions

$$\begin{bmatrix} x(0) = 0 \\ y(0) = 0 \\ z(0) = 1 \end{bmatrix} \tag{1}$$

Substituting initial conditions into the above solution at $t = 0$ gives

$$\begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} = \begin{bmatrix} -\frac{c_1}{2} - c_2 - c_3 \\ -\frac{c_1}{2} - c_2 \\ c_1 + c_2 + c_3 \end{bmatrix}$$

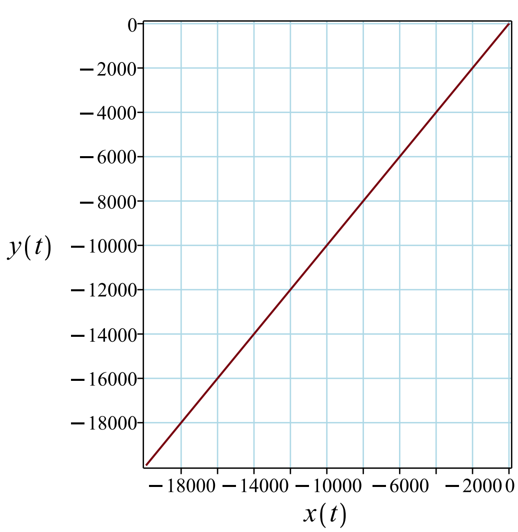
Solving for the constants of integrations gives

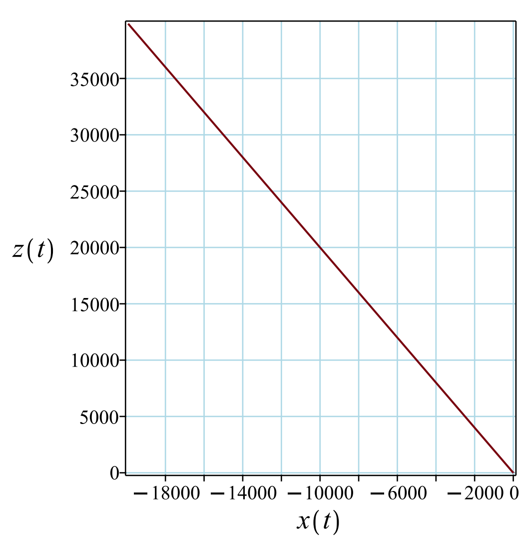
$$\begin{bmatrix} c_1 = 2 \\ c_2 = -1 \\ c_3 = 0 \end{bmatrix}$$

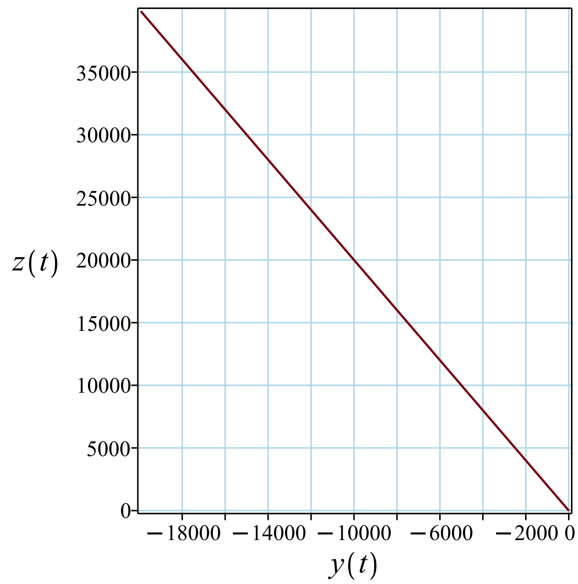
Substituting these constants back in original solution in Eq. (1) gives

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} 1 - \mathrm{e}^{-t} \\ 1 - \mathrm{e}^{-t} \\ -1 + 2\,\mathrm{e}^{-t} \end{bmatrix}$$

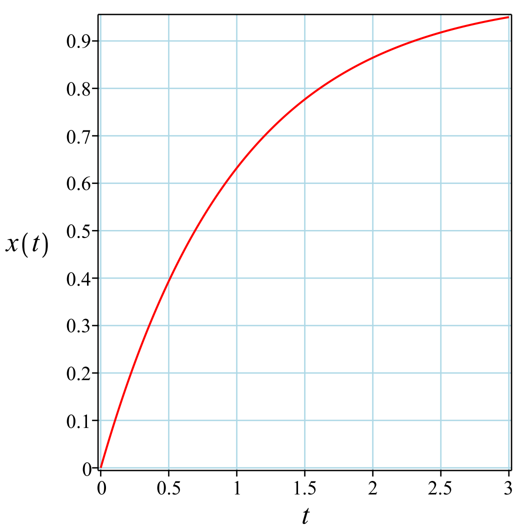
The following are plots of each solution against another.

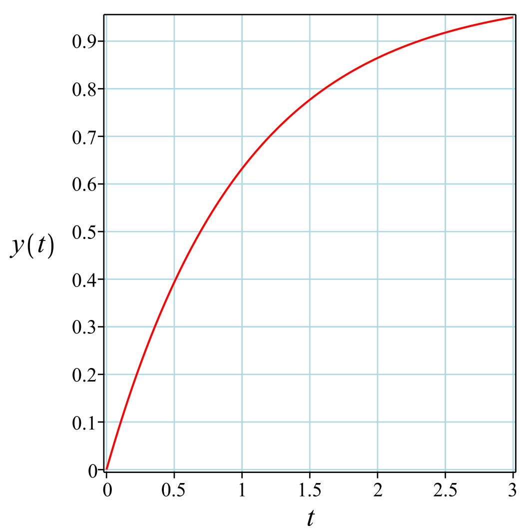


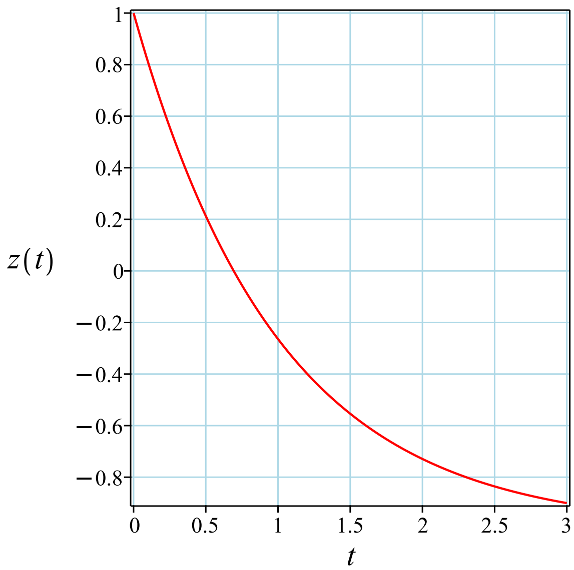




The following are plots of each solution.







✓ Solution by Maple

Time used: 0.031 (sec). Leaf size: 35

```
dsolve([diff(x(t),t) = 2*x(t)-y(t)+z(t), diff(y(t),t) = x(t)+z(t), diff(z(t),t) = y(t)-2*z(t
```

$$x(t) = 1 - e^{-t}$$
$$y(t) = 1 - e^{-t}$$
$$z(t) = 2\, e^{-t} - 1$$

✓ Solution by Mathematica

Time used: 0.01 (sec). Leaf size: 38

```
DSolve[{x'[t]==2*x[t]-y[t]+z[t],y'[t]==x[t]+z[t],z'[t]==y[t]-2*z[t]-3*x[t]},{x[0]==0,y[0]==0
```

$$x(t) \to 1 - e^{-t}$$
$$y(t) \to 1 - e^{-t}$$
$$z(t) \to 2e^{-t} - 1$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = -2x(t) + y(t) - e^{2t}$$
$$y'(t) = -3x(t) + 2y(t) + 6\,e^{2t}$$

30.1.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -2 & 1 \\ -3 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -e^{2t} \\ 6\,e^{2t} \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{3\,e^{-t}}{2} - \frac{e^{t}}{2} & \frac{e^{t}}{2} - \frac{e^{-t}}{2} \\ -\frac{3\,e^{t}}{2} + \frac{3\,e^{-t}}{2} & -\frac{e^{-t}}{2} + \frac{3\,e^{t}}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} \frac{3\,e^{-t}}{2} - \frac{e^{t}}{2} & \frac{e^{t}}{2} - \frac{e^{-t}}{2} \\ -\frac{3\,e^{t}}{2} + \frac{3\,e^{-t}}{2} & -\frac{e^{-t}}{2} + \frac{3\,e^{t}}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} \left(\frac{3\,e^{-t}}{2} - \frac{e^{t}}{2}\right) c_1 + \left(\frac{e^{t}}{2} - \frac{e^{-t}}{2}\right) c_2 \\ \left(-\frac{3\,e^{t}}{2} + \frac{3\,e^{-t}}{2}\right) c_1 + \left(-\frac{e^{-t}}{2} + \frac{3\,e^{t}}{2}\right) c_2 \end{bmatrix} \\ &= \begin{bmatrix} \frac{(-c_2+3c_1)e^{-t}}{2} - \frac{e^{t}(c_1-c_2)}{2} \\ \frac{(-c_2+3c_1)e^{-t}}{2} - \frac{3\,e^{t}(c_1-c_2)}{2} \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned} e^{-At} &= \left(e^{At}\right)^{-1} \\ &= \begin{bmatrix} -\frac{e^{-t}}{2} + \frac{3\,e^{t}}{2} & -\frac{e^{t}}{2} + \frac{e^{-t}}{2} \\ \frac{3\,e^{t}}{2} - \frac{3\,e^{-t}}{2} & \frac{3\,e^{-t}}{2} - \frac{e^{t}}{2} \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} \frac{3\,e^{-t}}{2} - \frac{e^{t}}{2} & \frac{e^{t}}{2} - \frac{e^{-t}}{2} \\ -\frac{3\,e^{t}}{2} + \frac{3\,e^{-t}}{2} & -\frac{e^{-t}}{2} + \frac{3\,e^{t}}{2} \end{bmatrix} \int \begin{bmatrix} -\frac{e^{-t}}{2} + \frac{3\,e^{t}}{2} & -\frac{e^{t}}{2} + \frac{e^{-t}}{2} \\ \frac{3\,e^{t}}{2} - \frac{3\,e^{-t}}{2} & \frac{3\,e^{-t}}{2} - \frac{e^{t}}{2} \end{bmatrix} \begin{bmatrix} -e^{2t} \\ 6\,e^{2t} \end{bmatrix} dt \\ &= \begin{bmatrix} \frac{3\,e^{-t}}{2} - \frac{e^{t}}{2} & \frac{e^{t}}{2} - \frac{e^{-t}}{2} \\ -\frac{3\,e^{t}}{2} + \frac{3\,e^{-t}}{2} & -\frac{e^{-t}}{2} + \frac{3\,e^{t}}{2} \end{bmatrix} \begin{bmatrix} -\frac{3\,e^{3t}}{2} + \frac{7\,e^{t}}{2} \\ -\frac{3\,e^{3t}}{2} + \frac{21\,e^{t}}{2} \end{bmatrix} \\ &= \begin{bmatrix} 2\,e^{2t} \\ 9\,e^{2t} \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$
\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
&= \begin{bmatrix} \frac{(-c_2+3c_1)e^{-t}}{2} + 2\,e^{2t} + \frac{(-c_1+c_2)e^{t}}{2} \\ \frac{(-c_2+3c_1)e^{-t}}{2} + 9\,e^{2t} + \frac{(-3c_1+3c_2)e^{t}}{2} \end{bmatrix}
\end{aligned}
$$

30.1.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -2 & 1 \\ -3 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -e^{2t} \\ 6\,e^{2t} \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} -2 & 1 \\ -3 & 2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -2-\lambda & 1 \\ -3 & 2-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 1 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 1$$
$$\lambda_2 = -1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
1	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -2 & 1 \\ -3 & 2 \end{bmatrix} - (-1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} -1 & 1 \\ -3 & 3 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -1 & 1 & 0 \\ -3 & 3 & 0 \end{array}\right]$$

$$R_2 = R_2 - 3R_1 \Longrightarrow \left[\begin{array}{cc|c} -1 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -2 & 1 \\ -3 & 2 \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -3 & 1 \\ -3 & 1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -3 & 1 & 0 \\ -3 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} -3 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -3 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{t}{3}\right\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} \frac{t}{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 3 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
1	1	1	No	$\begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}$
-1	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 1 is real and distinct then the

corresponding eigenvector solution is

$$\vec{x}_1(t) = \vec{v}_1 e^{t} = \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix} e^{t}$$

Since eigenvalue -1 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{-t} = \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{-t}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \frac{e^{t}}{3} \\ e^{t} \end{bmatrix} + c_2 \begin{bmatrix} e^{-t} \\ e^{-t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} \frac{e^{t}}{3} & e^{-t} \\ e^{t} & e^{-t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{3 e^{-t}}{2} & \frac{3 e^{-t}}{2} \\ \frac{3 e^{t}}{2} & -\frac{e^{t}}{2} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} \frac{e^t}{3} & e^{-t} \\ e^t & e^{-t} \end{bmatrix} \int \begin{bmatrix} -\frac{3\,e^{-t}}{2} & \frac{3\,e^{-t}}{2} \\ \frac{3\,e^t}{2} & -\frac{e^t}{2} \end{bmatrix} \begin{bmatrix} -e^{2t} \\ 6\,e^{2t} \end{bmatrix} dt$$
$$= \begin{bmatrix} \frac{e^t}{3} & e^{-t} \\ e^t & e^{-t} \end{bmatrix} \int \begin{bmatrix} \frac{21\,e^t}{2} \\ -\frac{9\,e^{3t}}{2} \end{bmatrix} dt$$
$$= \begin{bmatrix} \frac{e^t}{3} & e^{-t} \\ e^t & e^{-t} \end{bmatrix} \begin{bmatrix} \frac{21\,e^t}{2} \\ -\frac{3\,e^{3t}}{2} \end{bmatrix}$$
$$= \begin{bmatrix} 2\,e^{2t} \\ 9\,e^{2t} \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{c_1 e^t}{3} \\ c_1 e^t \end{bmatrix} + \begin{bmatrix} c_2 e^{-t} \\ c_2 e^{-t} \end{bmatrix} + \begin{bmatrix} 2\,e^{2t} \\ 9\,e^{2t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{c_1 e^t}{3} + c_2 e^{-t} + 2\,e^{2t} \\ c_1 e^t + c_2 e^{-t} + 9\,e^{2t} \end{bmatrix}$$

30.1.3 Maple step by step solution

Let's solve

$$\left[x'(t) = -2x(t) + y(t) - (e^t)^2, y'(t) = -3x(t) + 2y(t) + 6(e^t)^2\right]$$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} -2 & 1 \\ -3 & 2 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} -(e^t)^2 \\ 6(e^t)^2 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} -2 & 1 \\ -3 & 2 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} -(\mathrm{e}^t)^2 \\ 6(\mathrm{e}^t)^2 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} -(\mathrm{e}^t)^2 \\ 6(\mathrm{e}^t)^2 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} -2 & 1 \\ -3 & 2 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^{-t} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \mathrm{e}^{t} \cdot \begin{bmatrix} \frac{1}{3} \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{x}_p($

$\overrightarrow{x}(t) = c_1\overrightarrow{x}_1 + c_2\overrightarrow{x}_2 + \overrightarrow{x}_p(t)$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(t) = \begin{bmatrix} e^{-t} & \frac{e^t}{3} \\ e^{-t} & e^t \end{bmatrix}$$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$\Phi(t) = \phi(t) \cdot \phi(0)^{-1}$

- Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} e^{-t} & \frac{e^t}{3} \\ e^{-t} & e^t \end{bmatrix} \cdot \begin{bmatrix} 1 & \frac{1}{3} \\ 1 & 1 \end{bmatrix}^{-1}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} \frac{3\,e^{-t}}{2} - \frac{e^t}{2} & \frac{e^t}{2} - \frac{e^{-t}}{2} \\ -\frac{3\,e^t}{2} + \frac{3\,e^{-t}}{2} & -\frac{e^{-t}}{2} + \frac{3\,e^t}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

$\overrightarrow{x}_p(t) = \Phi(t) \cdot \overrightarrow{v}(t)$

- Take the derivative of the particular solution

$\overrightarrow{x}'_p(t) = \Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

$\Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- Cancel like terms

$\Phi(t) \cdot \overrightarrow{v}'(t) = \overrightarrow{f}(t)$

- Multiply by the inverse of the fundamental matrix

$\overrightarrow{v}'(t) = \Phi(t)^{-1} \cdot \overrightarrow{f}(t)$

- Integrate to solve for $\overrightarrow{v}(t)$

$\vec{v}(t) = \int_0^t \Phi(s)^{-1} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \Phi(s)^{-1} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{x}_p(t) = \begin{bmatrix} \frac{3\,e^{-t}}{2} + 2\,e^{2t} - \frac{7\,e^{t}}{2} \\ -\frac{21\,e^{t}}{2} + 9\,e^{2t} + \frac{3\,e^{-t}}{2} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{x}(t) = c_1 \vec{x}_1 + c_2 \vec{x}_2 + \begin{bmatrix} \frac{3\,e^{-t}}{2} + 2\,e^{2t} - \frac{7\,e^{t}}{2} \\ -\frac{21\,e^{t}}{2} + 9\,e^{2t} + \frac{3\,e^{-t}}{2} \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 e^{-t} + \frac{c_2 e^{t}}{3} + \frac{3\,e^{-t}}{2} + 2\,e^{2t} - \frac{7\,e^{t}}{2} \\ c_1 e^{-t} + c_2 e^{t} - \frac{21\,e^{t}}{2} + 9\,e^{2t} + \frac{3\,e^{-t}}{2} \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = c_1 e^{-t} + \frac{c_2 e^{t}}{3} + \frac{3\,e^{-t}}{2} + 2\,e^{2t} - \frac{7\,e^{t}}{2}, y(t) = c_1 e^{-t} + c_2 e^{t} - \frac{21\,e^{t}}{2} + 9\,e^{2t} + \frac{3\,e^{-t}}{2}\right\}$$

✓ Solution by Maple

Time used: 0.031 (sec). Leaf size: 43

```
dsolve([diff(x(t),t)+2*x(t)-y(t)=-exp(2*t),diff(y(t),t)+3*x(t)-2*y(t)=6*exp(2*t)],singsol=al
```

$$x(t) = c_2 e^{t} + e^{-t} c_1 + 2\,e^{2t}$$
$$y(t) = 3c_2 e^{t} + e^{-t} c_1 + 9\,e^{2t}$$

✓ Solution by Mathematica

Problem number: 811.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= x(t) + y(t) - \cos(t) \\
y'(t) &= -y(t) - 2x(t) + \cos(t) + \sin(t)
\end{aligned}
$$

With initial conditions

$$
[x(0) = 1, y(0) = -2]
$$

30.2.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ -2 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -\cos(t) \\ \cos(t) + \sin(t) \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \cos(t) + \sin(t) & \sin(t) \\ -2\sin(t) & \cos(t) - \sin(t) \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{x}_0 \\
&= \begin{bmatrix} \cos(t) + \sin(t) & \sin(t) \\ -2\sin(t) & \cos(t) - \sin(t) \end{bmatrix} \begin{bmatrix} 1 \\ -2 \end{bmatrix} \\
&= \begin{bmatrix} \cos(t) - \sin(t) \\ -2\cos(t) \end{bmatrix}
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \begin{bmatrix} \cos(t) - \sin(t) & -\sin(t) \\ 2\sin(t) & \cos(t) + \sin(t) \end{bmatrix}
\end{aligned}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \cos(t) + \sin(t) & \sin(t) \\ -2\sin(t) & \cos(t) - \sin(t) \end{bmatrix} \int \begin{bmatrix} \cos(t) - \sin(t) & -\sin(t) \\ 2\sin(t) & \cos(t) + \sin(t) \end{bmatrix} \begin{bmatrix} -\cos(t) \\ \cos(t) + \sin(t) \end{bmatrix} \\
&= \begin{bmatrix} \cos(t) + \sin(t) & \sin(t) \\ -2\sin(t) & \cos(t) - \sin(t) \end{bmatrix} \begin{bmatrix} -t \\ t - 1 \end{bmatrix} \\
&= \begin{bmatrix} -\sin(t) - t\cos(t) \\ (t-1)\cos(t) + (t+1)\sin(t) \end{bmatrix}
\end{aligned}$$

Hence the complete solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$= \begin{bmatrix} \cos(t) - 2\sin(t) - t\cos(t) \\ (t-3)\cos(t) + (t+1)\sin(t) \end{bmatrix}$$

30.2.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ -2 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -\cos(t) \\ \cos(t) + \sin(t) \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & 1 \\ -2 & -1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & 1 \\ -2 & -1-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 1 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = i$$
$$\lambda_2 = -i$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
i	1	complex eigenvalue
$-i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 \\ -2 & -1 \end{bmatrix} - (-i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 1+i & 1 \\ -2 & -1+i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1+i & 1 & 0 \\ -2 & -1+i & 0 \end{array}\right]$$

$$R_2 = R_2 + (1-i)\,R_1 \Longrightarrow \left[\begin{array}{cc|c} 1+i & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1+i & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \left(-\frac{1}{2} + \frac{i}{2}\right)t\right\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} \left(-\frac{1}{2}+\frac{i}{2}\right)t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t\begin{bmatrix} -\frac{1}{2}+\frac{i}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{2}+\frac{i}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -1+i \\ 2 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 \\ -2 & -1 \end{bmatrix} - (i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 1-i & 1 \\ -2 & -1-i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1-i & 1 & 0 \\ -2 & -1-i & 0 \end{array}\right]$$

$$R_2 = R_2 + (1+i)\,R_1 \Longrightarrow \left[\begin{array}{cc|c} 1-i & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1-i & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \left(-\frac{1}{2} - \frac{i}{2}\right) t\right\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} \left(-\frac{1}{2} - \frac{i}{2}\right) t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{2} - \frac{i}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{2} - \frac{i}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -1 - i \\ 2 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
i	1	1	No	$\begin{bmatrix} -\frac{1}{2} - \frac{i}{2} \\ 1 \end{bmatrix}$
$-i$	1	1	No	$\begin{bmatrix} -\frac{1}{2} + \frac{i}{2} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \left(-\frac{1}{2}-\frac{i}{2}\right) e^{it} \\ e^{it} \end{bmatrix} + c_2 \begin{bmatrix} \left(-\frac{1}{2}+\frac{i}{2}\right) e^{-it} \\ e^{-it} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} \left(-\frac{1}{2}-\frac{i}{2}\right) e^{it} & \left(-\frac{1}{2}+\frac{i}{2}\right) e^{-it} \\ e^{it} & e^{-it} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1}\vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} i e^{-it} & \left(\frac{1}{2}+\frac{i}{2}\right) e^{-it} \\ -i e^{it} & \left(\frac{1}{2}-\frac{i}{2}\right) e^{it} \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \left(-\frac{1}{2}-\frac{i}{2}\right) e^{it} & \left(-\frac{1}{2}+\frac{i}{2}\right) e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} i e^{-it} & \left(\frac{1}{2}+\frac{i}{2}\right) e^{-it} \\ -i e^{it} & \left(\frac{1}{2}-\frac{i}{2}\right) e^{it} \end{bmatrix} \begin{bmatrix} -\cos(t) \\ \cos(t)+\sin(t) \end{bmatrix} dt \\
&= \begin{bmatrix} \left(-\frac{1}{2}-\frac{i}{2}\right) e^{it} & \left(-\frac{1}{2}+\frac{i}{2}\right) e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} -\frac{e^{-it}((-1+i)\cos(t)+(-1-i)\sin(t))}{2} \\ \frac{((1+i)\cos(t)+(1-i)\sin(t))e^{it}}{2} \end{bmatrix} dt \\
&= \begin{bmatrix} \left(-\frac{1}{2}-\frac{i}{2}\right) e^{it} & \left(-\frac{1}{2}+\frac{i}{2}\right) e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \begin{bmatrix} -\frac{e^{-it}((-1+i)\cos(t)+(-1-i)\sin(t))t}{2} \\ \frac{((1+i)\cos(t)+(1-i)\sin(t))e^{it}t}{2} \end{bmatrix} \\
&= \begin{bmatrix} -t\cos(t) \\ (\cos(t)+\sin(t))\, t \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \left(-\frac{1}{2}-\frac{i}{2}\right) c_1 \mathrm{e}^{it} \\ c_1 \mathrm{e}^{it} \end{bmatrix} + \begin{bmatrix} \left(-\frac{1}{2}+\frac{i}{2}\right) c_2 \mathrm{e}^{-it} \\ c_2 \mathrm{e}^{-it} \end{bmatrix} + \begin{bmatrix} -t\cos(t) \\ (\cos(t)+\sin(t))\, t \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{((-1+i)c_2-t)\mathrm{e}^{-it}}{2} - \frac{((1+i)c_1+t)\mathrm{e}^{it}}{2} \\ c_1 \mathrm{e}^{it} + c_2 \mathrm{e}^{-it} + (\cos(t)+\sin(t))\, t \end{bmatrix}$$

Since initial conditions are given, the solution above needs to be updated by solving for the constants of integrations using the given initial conditions

$$\begin{bmatrix} x(0) = 1 \\ y(0) = -2 \end{bmatrix} \tag{1}$$

Substituting initial conditions into the above solution at $t = 0$ gives

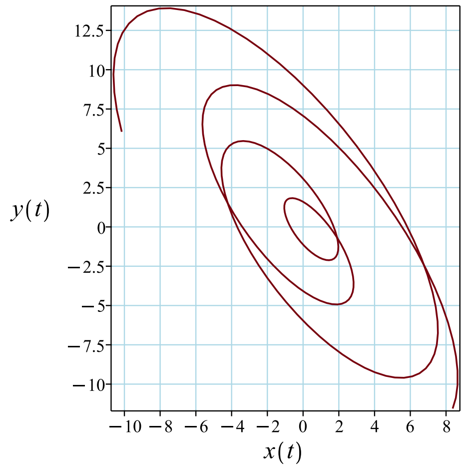
$$\begin{bmatrix} 1 \\ -2 \end{bmatrix} = \begin{bmatrix} \left(-\frac{1}{2}-\frac{i}{2}\right) c_1 + \left(-\frac{1}{2}+\frac{i}{2}\right) c_2 \\ c_1 + c_2 \end{bmatrix}$$

Solving for the constants of integrations gives

$$\begin{bmatrix} c_1 = -1 \\ c_2 = -1 \end{bmatrix}$$

Substituting these constants back in original solution in Eq. (1) gives

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{(1-i-t)\mathrm{e}^{-it}}{2} - \frac{(-1-i+t)\mathrm{e}^{it}}{2} \\ -\mathrm{e}^{it} - \mathrm{e}^{-it} + (\cos(t)+\sin(t))\, t \end{bmatrix}$$



The following are plots of each solution.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= y(t) + \tan(t)^2 - 1 \\
y'(t) &= \tan(t) - x(t)
\end{aligned}
$$

30.3.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \tan(t)^2 - 1 \\ \tan(t) \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} \cos(t)\, c_1 + \sin(t)\, c_2 \\ -\sin(t)\, c_1 + \cos(t)\, c_2 \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\, dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix} \int \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix} \begin{bmatrix} \tan(t)^2 - 1 \\ \tan(t) \end{bmatrix} dt \\ &= \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix} \begin{bmatrix} -\sin(t) \\ \cos(t) + \sec(t) \end{bmatrix} \\ &= \begin{bmatrix} \tan(t) \\ 2 \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$\begin{aligned} \vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\ &= \begin{bmatrix} \cos(t)\, c_1 + \sin(t)\, c_2 + \tan(t) \\ -\sin(t)\, c_1 + \cos(t)\, c_2 + 2 \end{bmatrix} \end{aligned}$$

30.3.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \tan(t)^2 - 1 \\ \tan(t) \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -\lambda & 1 \\ -1 & -\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 1 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = i$$
$$\lambda_2 = -i$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
i	1	complex eigenvalue
$-i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} - (-i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} i & 1 \\ -1 & i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} i & 1 & 0 \\ -1 & i & 0 \end{array}\right]$$

$$R_2 = -iR_1 + R_2 \Longrightarrow \left[\begin{array}{cc|c} i & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} i & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = it\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t\begin{bmatrix} i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} i \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} - (i) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} -i & 1 \\ -1 & -i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -i & 1 & 0 \\ -1 & -i & 0 \end{array}\right]$$

$$R_2 = iR_1 + R_2 \Longrightarrow \left[\begin{array}{cc|c} -i & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -i & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -it\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} -i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -i \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
i	1	1	No	$\begin{bmatrix} -i \\ 1 \end{bmatrix}$
$-i$	1	1	No	$\begin{bmatrix} i \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -i e^{it} \\ e^{it} \end{bmatrix} + c_2 \begin{bmatrix} i e^{-it} \\ e^{-it} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -i e^{it} & i e^{-it} \\ e^{it} & e^{-it} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1}\vec{G}(t)\,dt$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{i\mathrm{e}^{-it}}{2} & \frac{\mathrm{e}^{-it}}{2} \\ -\frac{i\mathrm{e}^{it}}{2} & \frac{\mathrm{e}^{it}}{2} \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} -i\mathrm{e}^{it} & i\mathrm{e}^{-it} \\ \mathrm{e}^{it} & \mathrm{e}^{-it} \end{bmatrix} \int \begin{bmatrix} \frac{i\mathrm{e}^{-it}}{2} & \frac{\mathrm{e}^{-it}}{2} \\ -\frac{i\mathrm{e}^{it}}{2} & \frac{\mathrm{e}^{it}}{2} \end{bmatrix} \begin{bmatrix} \tan(t)^2 - 1 \\ \tan(t) \end{bmatrix} dt \\
&= \begin{bmatrix} -i\mathrm{e}^{it} & i\mathrm{e}^{-it} \\ \mathrm{e}^{it} & \mathrm{e}^{-it} \end{bmatrix} \int \begin{bmatrix} \frac{\mathrm{e}^{-it}\left(i\sec(t)^2 - 2i + \tan(t)\right)}{2} \\ -\frac{\mathrm{e}^{it}\left(i\sec(t)^2 - 2i - \tan(t)\right)}{2} \end{bmatrix} dt \\
&= \begin{bmatrix} -i\mathrm{e}^{it} & i\mathrm{e}^{-it} \\ \mathrm{e}^{it} & \mathrm{e}^{-it} \end{bmatrix} \begin{bmatrix} \frac{\mathrm{e}^{-it}(i\tan(t)+2)}{2} \\ -\frac{\mathrm{e}^{it}(i\tan(t)-2)}{2} \end{bmatrix} \\
&= \begin{bmatrix} \tan(t) \\ 2 \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -ic_1\mathrm{e}^{it} \\ c_1\mathrm{e}^{it} \end{bmatrix} + \begin{bmatrix} ic_2\mathrm{e}^{-it} \\ c_2\mathrm{e}^{-it} \end{bmatrix} + \begin{bmatrix} \tan(t) \\ 2 \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -ic_1\mathrm{e}^{it} + ic_2\mathrm{e}^{-it} + \tan(t) \\ c_1\mathrm{e}^{it} + c_2\mathrm{e}^{-it} + 2 \end{bmatrix}$$

30.3.3 Maple step by step solution

Let's solve

$\left[x'(t) = y(t) + \tan(t)^2 - 1, y'(t) = \tan(t) - x(t)\right]$

- Define vector

$\vec{x}(t) = \left[\begin{array}{c} x(t) \\ y(t) \end{array}\right]$

- Convert system into a vector equation

$\vec{x}'(t) = \left[\begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array}\right] \cdot \vec{x}(t) + \left[\begin{array}{c} \tan(t)^2 - 1 \\ \tan(t) \end{array}\right]$

- System to solve

$\vec{x}'(t) = \left[\begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array}\right] \cdot \vec{x}(t) + \left[\begin{array}{c} \tan(t)^2 - 1 \\ \tan(t) \end{array}\right]$

- Define the forcing function

$\vec{f}(t) = \left[\begin{array}{c} \tan(t)^2 - 1 \\ \tan(t) \end{array}\right]$

- Define the coefficient matrix

$A = \left[\begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array}\right]$

- Rewrite the system as

$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$\left[\left[-\mathrm{I}, \left[\begin{array}{c} \mathrm{I} \\ 1 \end{array}\right]\right], \left[\mathrm{I}, \left[\begin{array}{c} -\mathrm{I} \\ 1 \end{array}\right]\right]\right]$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$\left[-\mathrm{I}, \left[\begin{array}{c} \mathrm{I} \\ 1 \end{array}\right]\right]$

- Solution from eigenpair

$$e^{-It} \cdot \begin{bmatrix} I \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(t) - I\sin(t)) \cdot \begin{bmatrix} I \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} I(\cos(t) - I\sin(t)) \\ \cos(t) - I\sin(t) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{x}_1(t) = \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix}, \vec{x}_2(t) = \begin{bmatrix} \cos(t) \\ -\sin(t) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

$$\vec{x}(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + \vec{x}_p(t)$$

☐ Fundamental matrix

  - Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(t) = \begin{bmatrix} \sin(t) & \cos(t) \\ \cos(t) & -\sin(t) \end{bmatrix}$$

  - The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$$\Phi(t) = \phi(t) \cdot \phi(0)^{-1}$$

  - Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} \sin(t) & \cos(t) \\ \cos(t) & -\sin(t) \end{bmatrix} \cdot \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}^{-1}$$

  - Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

  $\overrightarrow{x}_p(t) = \Phi(t) \cdot \overrightarrow{v}(t)$

- Take the derivative of the particular solution

  $\overrightarrow{x}_p'(t) = \Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- Cancel like terms

  $\Phi(t) \cdot \overrightarrow{v}'(t) = \overrightarrow{f}(t)$

- Multiply by the inverse of the fundamental matrix

  $\overrightarrow{v}'(t) = \Phi(t)^{-1} \cdot \overrightarrow{f}(t)$

- Integrate to solve for $\overrightarrow{v}(t)$

  $\overrightarrow{v}(t) = \int_0^t \Phi(s)^{-1} \cdot \overrightarrow{f}(s)\, ds$

- Plug $\overrightarrow{v}(t)$ into the equation for the particular solution

  $\overrightarrow{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \Phi(s)^{-1} \cdot \overrightarrow{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\overrightarrow{x}_p(t) = \left[\begin{array}{c} \sin(t)\left(-\cos(t) + \int_0^t \sin(s)\tan(s)^2\, ds\right) \\ \sin(t)^2 + \cos(t)\left(\int_0^t \sin(s)\tan(s)^2\, ds\right) \end{array}\right]$$

- Plug particular solution back into general solution

  $$\overrightarrow{x}(t) = c_1\overrightarrow{x}_1(t) + c_2\overrightarrow{x}_2(t) + \left[\begin{array}{c} \sin(t)\left(-\cos(t) + \int_0^t \sin(s)\tan(s)^2\, ds\right) \\ \sin(t)^2 + \cos(t)\left(\int_0^t \sin(s)\tan(s)^2\, ds\right) \end{array}\right]$$

- Substitute in vector of dependent variables

  $$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} \sin(t)\left(\int_0^t \sin(s)\tan(s)^2\, ds\right) + (c_1 - \cos(t))\sin(t) + c_2\cos(t) \\ \sin(t)^2 + \cos(t)\left(\int_0^t \sin(s)\tan(s)^2\, ds\right) - c_2\sin(t) + c_1\cos(t) \end{array}\right]$$

- Solution to the system of ODEs

  $$\left\{x(t) = \sin(t)\left(\int_0^t \sin(s)\tan(s)^2 ds\right) + (c_1 - \cos(t))\sin(t) + c_2\cos(t), y(t) = \sin(t)^2 + \cos(t)\right.$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = y(t)$$
$$y'(t) = -x(t) + \frac{1}{\cos(t)}$$

30.5.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 0 \\ \frac{1}{\cos(t)} \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \cos(t)\, c_1 + \sin(t)\, c_2 \\ -\sin(t)\, c_1 + \cos(t)\, c_2 \end{bmatrix}
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\, dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix}
\end{aligned}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix} \int \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix} \begin{bmatrix} 0 \\ \frac{1}{\cos(t)} \end{bmatrix} dt \\
&= \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix} \begin{bmatrix} \ln(\cos(t)) \\ t \end{bmatrix} \\
&= \begin{bmatrix} \cos(t)\ln(\cos(t)) + \sin(t)\, t \\ -\sin(t)\ln(\cos(t)) + t\cos(t) \end{bmatrix}
\end{aligned}$$

Hence the complete solution is

$$\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
&= \begin{bmatrix} \cos(t)\ln(\cos(t)) + \cos(t)\, c_1 + \sin(t)\,(t + c_2) \\ -\sin(t)\ln(\cos(t)) + (t + c_2)\cos(t) - \sin(t)\, c_1 \end{bmatrix}
\end{aligned}$$

30.5.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 0 \\ \frac{1}{\cos(t)} \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -\lambda & 1 \\ -1 & -\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 1 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = i$$
$$\lambda_2 = -i$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
i	1	complex eigenvalue
$-i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} - (-i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} i & 1 \\ -1 & i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} i & 1 & 0 \\ -1 & i & 0 \end{array}\right]$$

$$R_2 = -iR_1 + R_2 \Longrightarrow \left[\begin{array}{cc|c} i & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} i & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = it\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t\begin{bmatrix} i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} i \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} - (i) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} -i & 1 \\ -1 & -i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -i & 1 & 0 \\ -1 & -i & 0 \end{array}\right]$$

$$R_2 = iR_1 + R_2 \Longrightarrow \left[\begin{array}{cc|c} -i & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -i & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -it\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} -i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -i \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
i	1	1	No	$\begin{bmatrix} -i \\ 1 \end{bmatrix}$
$-i$	1	1	No	$\begin{bmatrix} i \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -i e^{it} \\ e^{it} \end{bmatrix} + c_2 \begin{bmatrix} i e^{-it} \\ e^{-it} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -i e^{it} & i e^{-it} \\ e^{it} & e^{-it} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{i e^{-it}}{2} & \frac{e^{-it}}{2} \\ -\frac{i e^{it}}{2} & \frac{e^{it}}{2} \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} -i e^{it} & i e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} \frac{i e^{-it}}{2} & \frac{e^{-it}}{2} \\ -\frac{i e^{it}}{2} & \frac{e^{it}}{2} \end{bmatrix} \begin{bmatrix} 0 \\ \frac{1}{\cos(t)} \end{bmatrix} dt \\
&= \begin{bmatrix} -i e^{it} & i e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} \frac{e^{-it} \sec(t)}{2} \\ \frac{e^{it} \sec(t)}{2} \end{bmatrix} dt \\
&= \begin{bmatrix} -i e^{it} & i e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \begin{bmatrix} -\frac{i(2\ln(e^{it}) - \ln(e^{2it}+1))}{2} \\ -\frac{i \ln(e^{2it}+1)}{2} \end{bmatrix} \\
&= \begin{bmatrix} \frac{(e^{-it}+e^{it}) \ln(e^{2it}+1)}{2} - e^{it} \ln(e^{it}) \\ -\frac{i(-e^{it}+e^{-it}) \ln(e^{2it}+1)}{2} - i e^{it} \ln(e^{it}) \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -i c_1 e^{it} \\ c_1 e^{it} \end{bmatrix} + \begin{bmatrix} i c_2 e^{-it} \\ c_2 e^{-it} \end{bmatrix} + \begin{bmatrix} \frac{(e^{-it}+e^{it}) \ln(e^{2it}+1)}{2} - e^{it} \ln(e^{it}) \\ -\frac{i(-e^{it}+e^{-it}) \ln(e^{2it}+1)}{2} - i e^{it} \ln(e^{it}) \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{(e^{-it}+e^{it}) \ln(e^{2it}+1)}{2} + i c_2 e^{-it} - e^{it}(i c_1 + \ln(e^{it})) \\ \frac{i(e^{it}-e^{-it}) \ln(e^{2it}+1)}{2} + c_2 e^{-it} + (c_1 - i \ln(e^{it}))\, e^{it} \end{bmatrix}$$

30.5.3 Maple step by step solution

Let's solve

$\left[x'(t)=y(t), y'(t)=-x(t)+\frac{1}{\cos(t)}\right]$

- Define vector

$$\vec{x}(t)=\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right]$$

- Convert system into a vector equation

$$\vec{x}'(t)=\left[\begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array}\right]\cdot\vec{x}(t)+\left[\begin{array}{c} 0 \\ -\frac{x(t)\cos(t)-1}{\cos(t)}+x(t) \end{array}\right]$$

- System to solve

$$\vec{x}'(t)=\left[\begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array}\right]\cdot\vec{x}(t)$$

- Define the coefficient matrix

$$A=\left[\begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array}\right]$$

- Rewrite the system as

$$\vec{x}'(t)=A\cdot\vec{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-\mathrm{I}, \left[\begin{array}{c} \mathrm{I} \\ 1 \end{array}\right]\right], \left[\mathrm{I}, \left[\begin{array}{c} -\mathrm{I} \\ 1 \end{array}\right]\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \left[\begin{array}{c} \mathrm{I} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$e^{-It} \cdot \begin{bmatrix} I \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$(\cos(t) - I\sin(t)) \cdot \begin{bmatrix} I \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} I(\cos(t) - I\sin(t)) \\ \cos(t) - I\sin(t) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{x}_1(t) = \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix}, \vec{x}_2(t) = \begin{bmatrix} \cos(t) \\ -\sin(t) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\vec{x} = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

- Substitute solutions into the general solution

$$\vec{x} = \begin{bmatrix} c_2\cos(t) + c_1\sin(t) \\ -c_2\sin(t) + c_1\cos(t) \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_2\cos(t) + c_1\sin(t) \\ -c_2\sin(t) + c_1\cos(t) \end{bmatrix}$$

- Solution to the system of ODEs

$$\{x(t) = c_2\cos(t) + c_1\sin(t), y(t) = -c_2\sin(t) + c_1\cos(t)\}$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = y(t)$$
$$y'(t) = 1 - x(t)$$

31.1.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} \cos(t)\, c_1 + \sin(t)\, c_2 \\ -\sin(t)\, c_1 + \cos(t)\, c_2 \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\, dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix} \int \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix} \begin{bmatrix} 0 \\ 1 \end{bmatrix} dt \\ &= \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix} \begin{bmatrix} \cos(t) \\ \sin(t) \end{bmatrix} \\ &= \begin{bmatrix} 1 \\ 0 \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$\begin{aligned} \vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\ &= \begin{bmatrix} \cos(t)\, c_1 + \sin(t)\, c_2 + 1 \\ -\sin(t)\, c_1 + \cos(t)\, c_2 \end{bmatrix} \end{aligned}$$

31.1.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -\lambda & 1 \\ -1 & -\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 1 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = i$$
$$\lambda_2 = -i$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
i	1	complex eigenvalue
$-i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} - (-i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} i & 1 \\ -1 & i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} i & 1 & 0 \\ -1 & i & 0 \end{array}\right]$$

$$R_2 = -iR_1 + R_2 \Longrightarrow \left[\begin{array}{cc|c} i & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} i & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = it\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t\begin{bmatrix} i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} i \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} - (i) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} -i & 1 \\ -1 & -i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -i & 1 & 0 \\ -1 & -i & 0 \end{array}\right]$$

$$R_2 = iR_1 + R_2 \Longrightarrow \left[\begin{array}{cc|c} -i & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -i & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -it\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} -i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -i \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
i	1	1	No	$\begin{bmatrix} -i \\ 1 \end{bmatrix}$
$-i$	1	1	No	$\begin{bmatrix} i \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -i\mathrm{e}^{it} \\ \mathrm{e}^{it} \end{bmatrix} + c_2 \begin{bmatrix} i\mathrm{e}^{-it} \\ \mathrm{e}^{-it} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -i\mathrm{e}^{it} & i\mathrm{e}^{-it} \\ \mathrm{e}^{it} & \mathrm{e}^{-it} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t) \, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{i e^{-it}}{2} & \frac{e^{-it}}{2} \\ -\frac{i e^{it}}{2} & \frac{e^{it}}{2} \end{bmatrix}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} -i e^{it} & i e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} \frac{i e^{-it}}{2} & \frac{e^{-it}}{2} \\ -\frac{i e^{it}}{2} & \frac{e^{it}}{2} \end{bmatrix} \begin{bmatrix} 0 \\ 1 \end{bmatrix} dt \\ &= \begin{bmatrix} -i e^{it} & i e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} \frac{e^{-it}}{2} \\ \frac{e^{it}}{2} \end{bmatrix} dt \\ &= \begin{bmatrix} -i e^{it} & i e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \begin{bmatrix} \frac{i e^{-it}}{2} \\ -\frac{i e^{it}}{2} \end{bmatrix} \\ &= \begin{bmatrix} 1 \\ 0 \end{bmatrix} \end{aligned}$$

Now that we found particular solution, the final solution is

$$\begin{aligned} \vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\ \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} &= \begin{bmatrix} -i c_1 e^{it} \\ c_1 e^{it} \end{bmatrix} + \begin{bmatrix} i c_2 e^{-it} \\ c_2 e^{-it} \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \end{bmatrix} \end{aligned}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -i c_1 e^{it} + i c_2 e^{-it} + 1 \\ c_1 e^{it} + c_2 e^{-it} \end{bmatrix}$$

The following is the phase plot of the system.

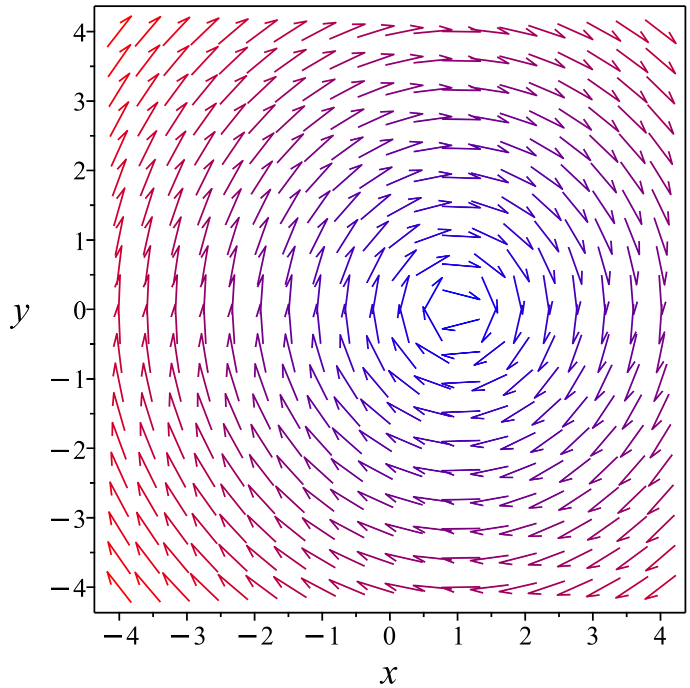

Figure 857: Phase plot

31.1.3 Maple step by step solution

Let's solve

$[x'(t) = y(t), y'(t) = 1 - x(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-\mathrm{I}, \begin{bmatrix} \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} \mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$\mathrm{e}^{-\mathrm{I}t} \cdot \begin{bmatrix} \mathrm{I} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(t) - \mathrm{I}\sin(t)) \cdot \begin{bmatrix} \mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} \mathrm{I}(\cos(t) - \mathrm{I}\sin(t)) \\ \cos(t) - \mathrm{I}\sin(t) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{x}_1(t) = \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix}, \vec{x}_2(t) = \begin{bmatrix} \cos(t) \\ -\sin(t) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

$\vec{x}(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + \vec{x}_p(t)$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(t) = \begin{bmatrix} \sin(t) & \cos(t) \\ \cos(t) & -\sin(t) \end{bmatrix}$$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$$\Phi(t) = \phi(t) \cdot \phi(0)^{-1}$$

- Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} \sin(t) & \cos(t) \\ \cos(t) & -\sin(t) \end{bmatrix} \cdot \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}^{-1}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

$$\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$$

- Take the derivative of the particular solution

$$\vec{x}_p'(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$$

- Substitute particular solution and its derivative into the system of ODEs

$$\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$$A \cdot \Phi(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$$

- Cancel like terms

$$\Phi(t) \cdot \vec{v}'(t) = \vec{f}(t)$$

- Multiply by the inverse of the fundamental matrix

$$\vec{v}'(t) = \Phi(t)^{-1} \cdot \vec{f}(t)$$

- Integrate to solve for $\vec{v}(t)$

$\vec{v}(t) = \int_0^t \Phi(s)^{-1} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \Phi(s)^{-1} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\vec{x}_p(t) = \begin{bmatrix} 1 - \cos(t) \\ \sin(t) \end{bmatrix}$$

- Plug particular solution back into general solution

  $$\vec{x}(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t) + \begin{bmatrix} 1 - \cos(t) \\ \sin(t) \end{bmatrix}$$

- Substitute in vector of dependent variables

  $$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} (c_2 - 1)\cos(t) + c_1 \sin(t) + 1 \\ \sin(t) - c_2 \sin(t) + c_1 \cos(t) \end{bmatrix}$$

- Solution to the system of ODEs

  $\{x(t) = (c_2 - 1)\cos(t) + c_1 \sin(t) + 1, y(t) = \sin(t) - c_2 \sin(t) + c_1 \cos(t)\}$

✓ Solution by Maple

Time used: 0.016 (sec). Leaf size: 28

```
dsolve([diff(x(t),t)=y(t),diff(y(t),t)=1-x(t)],singsol=all)
```

$$x(t) = c_2 \sin(t) + c_1 \cos(t) + 1$$
$$y(t) = c_2 \cos(t) - c_1 \sin(t)$$

✓ Solution by Mathematica

Time used: 0.007 (sec). Leaf size: 32

```

Problem number: 816.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = 3 - 2y(t)$$
$$y'(t) = 2x(t) - 2t$$

31.2.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & -2 \\ 2 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 3 \\ -2t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \cos(2t) & -\sin(2t) \\ \sin(2t) & \cos(2t) \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} \cos(2t) & -\sin(2t) \\ \sin(2t) & \cos(2t) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} \cos(2t)\, c_1 - \sin(2t)\, c_2 \\ \sin(2t)\, c_1 + \cos(2t)\, c_2 \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\, dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} \cos(2t) & \sin(2t) \\ -\sin(2t) & \cos(2t) \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} \cos(2t) & -\sin(2t) \\ \sin(2t) & \cos(2t) \end{bmatrix} \int \begin{bmatrix} \cos(2t) & \sin(2t) \\ -\sin(2t) & \cos(2t) \end{bmatrix} \begin{bmatrix} 3 \\ -2t \end{bmatrix} dt \\ &= \begin{bmatrix} \cos(2t) & -\sin(2t) \\ \sin(2t) & \cos(2t) \end{bmatrix} \begin{bmatrix} \sin(2t) + \cos(2t)\, t \\ \cos(2t) - \sin(2t)\, t \end{bmatrix} \\ &= \begin{bmatrix} t \\ 1 \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$\begin{aligned} \vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\ &= \begin{bmatrix} \cos(2t)\, c_1 - \sin(2t)\, c_2 + t \\ \sin(2t)\, c_1 + \cos(2t)\, c_2 + 1 \end{bmatrix} \end{aligned}$$

31.2.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & -2 \\ 2 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 3 \\ -2t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 0 & -2 \\ 2 & 0 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -\lambda & -2 \\ 2 & -\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 4 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 2i$$
$$\lambda_2 = -2i$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$-2i$	1	complex eigenvalue
$2i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -2i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & -2 \\ 2 & 0 \end{bmatrix} - (-2i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 2i & -2 \\ 2 & 2i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2i & -2 & 0 \\ 2 & 2i & 0 \end{array}\right]$$

$$R_2 = iR_1 + R_2 \Longrightarrow \left[\begin{array}{cc|c} 2i & -2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2i & -2 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -it\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t\begin{bmatrix} -i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -i \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 2i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & -2 \\ 2 & 0 \end{bmatrix} - (2i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} -2i & -2 \\ 2 & -2i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -2i & -2 & 0 \\ 2 & -2i & 0 \end{array}\right]$$

$$R_2 = -iR_1 + R_2 \Longrightarrow \left[\begin{array}{cc|c} -2i & -2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2i & -2 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = it\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t\begin{bmatrix} i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} i \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
$2i$	1	1	No	$\begin{bmatrix} i \\ 1 \end{bmatrix}$
$-2i$	1	1	No	$\begin{bmatrix} -i \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} i e^{2it} \\ e^{2it} \end{bmatrix} + c_2 \begin{bmatrix} -i e^{-2it} \\ e^{-2it} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} i e^{2it} & -i e^{-2it} \\ e^{2it} & e^{-2it} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1}\vec{G}(t)\,dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{i\mathrm{e}^{-2it}}{2} & \frac{\mathrm{e}^{-2it}}{2} \\ \frac{i\mathrm{e}^{2it}}{2} & \frac{\mathrm{e}^{2it}}{2} \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} i\mathrm{e}^{2it} & -i\mathrm{e}^{-2it} \\ \mathrm{e}^{2it} & \mathrm{e}^{-2it} \end{bmatrix} \int \begin{bmatrix} -\frac{i\mathrm{e}^{-2it}}{2} & \frac{\mathrm{e}^{-2it}}{2} \\ \frac{i\mathrm{e}^{2it}}{2} & \frac{\mathrm{e}^{2it}}{2} \end{bmatrix} \begin{bmatrix} 3 \\ -2t \end{bmatrix} dt \\
&= \begin{bmatrix} i\mathrm{e}^{2it} & -i\mathrm{e}^{-2it} \\ \mathrm{e}^{2it} & \mathrm{e}^{-2it} \end{bmatrix} \int \begin{bmatrix} -\frac{\mathrm{e}^{-2it}(3i+2t)}{2} \\ \mathrm{e}^{2it}\left(\frac{3i}{2} - t\right) \end{bmatrix} dt \\
&= \begin{bmatrix} i\mathrm{e}^{2it} & -i\mathrm{e}^{-2it} \\ \mathrm{e}^{2it} & \mathrm{e}^{-2it} \end{bmatrix} \begin{bmatrix} -\frac{\mathrm{e}^{-2it}(it-1)}{2} \\ \frac{\mathrm{e}^{2it}(it+1)}{2} \end{bmatrix} \\
&= \begin{bmatrix} t \\ 1 \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} &= \begin{bmatrix} ic_1\mathrm{e}^{2it} \\ c_1\mathrm{e}^{2it} \end{bmatrix} + \begin{bmatrix} -ic_2\mathrm{e}^{-2it} \\ c_2\mathrm{e}^{-2it} \end{bmatrix} + \begin{bmatrix} t \\ 1 \end{bmatrix}
\end{aligned}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} ic_1\mathrm{e}^{2it} - ic_2\mathrm{e}^{-2it} + t \\ c_1\mathrm{e}^{2it} + c_2\mathrm{e}^{-2it} + 1 \end{bmatrix}$$

31.2.3 Maple step by step solution

Let's solve

$[x'(t) = 3 - 2y(t), y'(t) = 2x(t) - 2t]$

- Define vector

$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$

- Convert system into a vector equation

$\vec{x}'(t) = \begin{bmatrix} 0 & -2 \\ 2 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 3 \\ -2t \end{bmatrix}$

- System to solve

$\vec{x}'(t) = \begin{bmatrix} 0 & -2 \\ 2 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 3 \\ -2t \end{bmatrix}$

- Define the forcing function

$\vec{f}(t) = \begin{bmatrix} 3 \\ -2t \end{bmatrix}$

- Define the coefficient matrix

$A = \begin{bmatrix} 0 & -2 \\ 2 & 0 \end{bmatrix}$

- Rewrite the system as

$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$\left[\left[-2\,\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ 1 \end{bmatrix}\right], \left[2\,\mathrm{I}, \begin{bmatrix} \mathrm{I} \\ 1 \end{bmatrix}\right]\right]$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$\left[-2\,\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ 1 \end{bmatrix}\right]$

- Solution from eigenpair

  $e^{-2\mathrm{I}t} \cdot \begin{bmatrix} -\mathrm{I} \\ 1 \end{bmatrix}$

- Use Euler identity to write solution in terms of sin and cos

  $(\cos(2t) - \mathrm{I}\sin(2t)) \cdot \begin{bmatrix} -\mathrm{I} \\ 1 \end{bmatrix}$

- Simplify expression

  $\begin{bmatrix} -\mathrm{I}(\cos(2t) - \mathrm{I}\sin(2t)) \\ \cos(2t) - \mathrm{I}\sin(2t) \end{bmatrix}$

- Both real and imaginary parts are solutions to the homogeneous system

  $\left[\vec{x}_1(t) = \begin{bmatrix} -\sin(2t) \\ \cos(2t) \end{bmatrix}, \vec{x}_2(t) = \begin{bmatrix} -\cos(2t) \\ -\sin(2t) \end{bmatrix}\right]$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

  $\vec{x}(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + \vec{x}_p(t)$

☐ Fundamental matrix

  - Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

    $\phi(t) = \begin{bmatrix} -\sin(2t) & -\cos(2t) \\ \cos(2t) & -\sin(2t) \end{bmatrix}$

  - The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

    $\Phi(t) = \phi(t) \cdot \phi(0)^{-1}$

  - Substitute the value of $\phi(t)$ and $\phi(0)$

    $\Phi(t) = \begin{bmatrix} -\sin(2t) & -\cos(2t) \\ \cos(2t) & -\sin(2t) \end{bmatrix} \cdot \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}^{-1}$

  - Evaluate and simplify to get the fundamental matrix

    $\Phi(t) = \begin{bmatrix} \cos(2t) & -\sin(2t) \\ \sin(2t) & \cos(2t) \end{bmatrix}$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

  $\overrightarrow{x}_p(t) = \Phi(t) \cdot \overrightarrow{v}(t)$
- Take the derivative of the particular solution

  $\overrightarrow{x}'_p(t) = \Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$
- Cancel like terms

  $\Phi(t) \cdot \overrightarrow{v}'(t) = \overrightarrow{f}(t)$
- Multiply by the inverse of the fundamental matrix

  $\overrightarrow{v}'(t) = \Phi(t)^{-1} \cdot \overrightarrow{f}(t)$
- Integrate to solve for $\overrightarrow{v}(t)$

  $\overrightarrow{v}(t) = \int_0^t \Phi(s)^{-1} \cdot \overrightarrow{f}(s)\, ds$
- Plug $\overrightarrow{v}(t)$ into the equation for the particular solution

  $\overrightarrow{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \Phi(s)^{-1} \cdot \overrightarrow{f}(s)\, ds\right)$
- Plug in the fundamental matrix and the forcing function and compute

  $$\overrightarrow{x}_p(t) = \left[\begin{array}{c} t + \sin(2t) \\ 1 - \cos(2t) \end{array}\right]$$

- Plug particular solution back into general solution

  $$\overrightarrow{x}(t) = c_1 \overrightarrow{x}_1(t) + c_2 \overrightarrow{x}_2(t) + \left[\begin{array}{c} t + \sin(2t) \\ 1 - \cos(2t) \end{array}\right]$$
- Substitute in vector of dependent variables

  $$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} t + \sin(2t) - c_2 \cos(2t) - c_1 \sin(2t) \\ (c_1 - 1)\cos(2t) - c_2 \sin(2t) + 1 \end{array}\right]$$
- Solution to the system of ODEs

  $\{x(t) = t + \sin(2t) - c_2 \cos(2t) - c_1 \sin(2t), y(t) = (c_1 - 1)\cos(2t) - c_2 \sin(2t) + 1\}$

✓ Solution by Maple

Time used: 0.031 (sec). Leaf size: 37

```
dsolve([diff(x(t),t)=3-2*y(t),diff(y(t),t)=2*x(t)-2*t],singsol=all)
```

$$x(t) = c_2 \sin(2t) + c_1 \cos(2t) + t$$
$$y(t) = -c_2 \cos(2t) + c_1 \sin(2t) + 1$$

✓ Solution by Mathematica

Time used: 0.126 (sec). Leaf size: 41

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = -y(t) + \sin(t)$$
$$y'(t) = x(t) + \cos(t)$$

31.3.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} \cos(t)\, c_1 - \sin(t)\, c_2 \\ \sin(t)\, c_1 + \cos(t)\, c_2 \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\, dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix} \int \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix} \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix} dt \\ &= \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix} \begin{bmatrix} \sin(t)^2 \\ \frac{\sin(2t)}{2} \end{bmatrix} \\ &= \begin{bmatrix} 0 \\ \sin(t) \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$\begin{aligned} \vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\ &= \begin{bmatrix} \cos(t)\, c_1 - \sin(t)\, c_2 \\ \sin(t)\, c_1 + \cos(t)\, c_2 + \sin(t) \end{bmatrix} \end{aligned}$$

31.3.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -\lambda & -1 \\ 1 & -\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 1 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = i$$
$$\lambda_2 = -i$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
i	1	complex eigenvalue
$-i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} - (-i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} i & -1 \\ 1 & i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} i & -1 & 0 \\ 1 & i & 0 \end{array}\right]$$

$$R_2 = iR_1 + R_2 \Longrightarrow \left[\begin{array}{cc|c} i & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} i & -1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -it\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t\begin{bmatrix} -i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -i \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} - (i) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -i & -1 \\ 1 & -i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -i & -1 & 0 \\ 1 & -i & 0 \end{array}\right]$$

$$R_2 = -iR_1 + R_2 \Longrightarrow \left[\begin{array}{cc|c} -i & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -i & -1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = it\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} i \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
i	1	1	No	$\begin{bmatrix} i \\ 1 \end{bmatrix}$
$-i$	1	1	No	$\begin{bmatrix} -i \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} i e^{it} \\ e^{it} \end{bmatrix} + c_2 \begin{bmatrix} -i e^{-it} \\ e^{-it} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} i e^{it} & -i e^{-it} \\ e^{it} & e^{-it} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{i e^{-it}}{2} & \frac{e^{-it}}{2} \\ \frac{i e^{it}}{2} & \frac{e^{it}}{2} \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} i e^{it} & -i e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} -\frac{i e^{-it}}{2} & \frac{e^{-it}}{2} \\ \frac{i e^{it}}{2} & \frac{e^{it}}{2} \end{bmatrix} \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix} dt \\
&= \begin{bmatrix} i e^{it} & -i e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} -\frac{e^{-it}(i\sin(t)-\cos(t))}{2} \\ \frac{e^{it}(i\sin(t)+\cos(t))}{2} \end{bmatrix} dt \\
&= \begin{bmatrix} i e^{it} & -i e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \begin{bmatrix} \frac{e^{-it}\sin(t)}{2} \\ \frac{e^{it}\sin(t)}{2} \end{bmatrix} \\
&= \begin{bmatrix} 0 \\ \sin(t) \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} &= \begin{bmatrix} i c_1 e^{it} \\ c_1 e^{it} \end{bmatrix} + \begin{bmatrix} -i c_2 e^{-it} \\ c_2 e^{-it} \end{bmatrix} + \begin{bmatrix} 0 \\ \sin(t) \end{bmatrix}
\end{aligned}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} i(c_1 e^{it} - c_2 e^{-it}) \\ c_1 e^{it} + c_2 e^{-it} + \sin(t) \end{bmatrix}$$

31.3.3 Maple step by step solution

Let's solve

$[x'(t) = -y(t) + \sin(t), y'(t) = x(t) + \cos(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} \mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-\mathrm{I}t} \cdot \begin{bmatrix} -\mathrm{I} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$\left(\cos(t) - \mathrm{I}\sin(t)\right) \cdot \begin{bmatrix} -\mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\mathrm{I}(\cos(t) - \mathrm{I}\sin(t)) \\ \cos(t) - \mathrm{I}\sin(t) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{x}_1(t) = \begin{bmatrix} -\sin(t) \\ \cos(t) \end{bmatrix}, \vec{x}_2(t) = \begin{bmatrix} -\cos(t) \\ -\sin(t) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

$$\vec{x}(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + \vec{x}_p(t)$$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(t) = \begin{bmatrix} -\sin(t) & -\cos(t) \\ \cos(t) & -\sin(t) \end{bmatrix}$$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$$\Phi(t) = \phi(t) \cdot \phi(0)^{-1}$$

- Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} -\sin(t) & -\cos(t) \\ \cos(t) & -\sin(t) \end{bmatrix} \cdot \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}^{-1}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

  $\overrightarrow{x}_p(t) = \Phi(t) \cdot \overrightarrow{v}(t)$
- Take the derivative of the particular solution

  $\overrightarrow{x}_p'(t) = \Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$
- Cancel like terms

  $\Phi(t) \cdot \overrightarrow{v}'(t) = \overrightarrow{f}(t)$
- Multiply by the inverse of the fundamental matrix

  $\overrightarrow{v}'(t) = \Phi(t)^{-1} \cdot \overrightarrow{f}(t)$
- Integrate to solve for $\overrightarrow{v}(t)$

  $\overrightarrow{v}(t) = \int_0^t \Phi(s)^{-1} \cdot \overrightarrow{f}(s)\, ds$
- Plug $\overrightarrow{v}(t)$ into the equation for the particular solution

  $\overrightarrow{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \Phi(s)^{-1} \cdot \overrightarrow{f}(s)\, ds\right)$
- Plug in the fundamental matrix and the forcing function and compute

  $$\overrightarrow{x}_p(t) = \left[\begin{array}{c} 0 \\ \sin(t) \end{array}\right]$$

- Plug particular solution back into general solution

  $$\overrightarrow{x}(t) = c_1\overrightarrow{x}_1(t) + c_2\overrightarrow{x}_2(t) + \left[\begin{array}{c} 0 \\ \sin(t) \end{array}\right]$$
- Substitute in vector of dependent variables

  $$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} -c_2\cos(t) - c_1\sin(t) \\ \sin(t) - c_2\sin(t) + c_1\cos(t) \end{array}\right]$$
- Solution to the system of ODEs

  $\{x(t) = -c_2\cos(t) - c_1\sin(t), y(t) = \sin(t) - c_2\sin(t) + c_1\cos(t)\}$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= x(t) + y(t) + \mathrm{e}^{t} \\
y'(t) &= x(t) + y(t) - \mathrm{e}^{t}
\end{aligned}
$$

31.4.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \mathrm{e}^{t} \\ -\mathrm{e}^{t} \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{1}{2}+\frac{e^{2t}}{2} & \frac{e^{2t}}{2}-\frac{1}{2} \\ \frac{e^{2t}}{2}-\frac{1}{2} & \frac{1}{2}+\frac{e^{2t}}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{1}{2}+\frac{e^{2t}}{2} & \frac{e^{2t}}{2}-\frac{1}{2} \\ \frac{e^{2t}}{2}-\frac{1}{2} & \frac{1}{2}+\frac{e^{2t}}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{1}{2}+\frac{e^{2t}}{2}\right)c_1+\left(\frac{e^{2t}}{2}-\frac{1}{2}\right)c_2 \\ \left(\frac{e^{2t}}{2}-\frac{1}{2}\right)c_1+\left(\frac{1}{2}+\frac{e^{2t}}{2}\right)c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(c_1+c_2)e^{2t}}{2}+\frac{c_1}{2}-\frac{c_2}{2} \\ \frac{(c_1+c_2)e^{2t}}{2}-\frac{c_1}{2}+\frac{c_2}{2} \end{bmatrix}
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At}\int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \begin{bmatrix} \frac{e^{-2t}}{2}+\frac{1}{2} & -\frac{1}{2}+\frac{e^{-2t}}{2} \\ -\frac{1}{2}+\frac{e^{-2t}}{2} & \frac{e^{-2t}}{2}+\frac{1}{2} \end{bmatrix}
\end{aligned}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \frac{1}{2}+\frac{e^{2t}}{2} & \frac{e^{2t}}{2}-\frac{1}{2} \\ \frac{e^{2t}}{2}-\frac{1}{2} & \frac{1}{2}+\frac{e^{2t}}{2} \end{bmatrix} \int \begin{bmatrix} \frac{e^{-2t}}{2}+\frac{1}{2} & -\frac{1}{2}+\frac{e^{-2t}}{2} \\ -\frac{1}{2}+\frac{e^{-2t}}{2} & \frac{e^{-2t}}{2}+\frac{1}{2} \end{bmatrix} \begin{bmatrix} e^{t} \\ -e^{t} \end{bmatrix} dt \\
&= \begin{bmatrix} \frac{1}{2}+\frac{e^{2t}}{2} & \frac{e^{2t}}{2}-\frac{1}{2} \\ \frac{e^{2t}}{2}-\frac{1}{2} & \frac{1}{2}+\frac{e^{2t}}{2} \end{bmatrix} \begin{bmatrix} e^{t} \\ -e^{t} \end{bmatrix} \\
&= \begin{bmatrix} e^{t} \\ -e^{t} \end{bmatrix}
\end{aligned}$$

Hence the complete solution is

$$
\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
&= \begin{bmatrix} \frac{(c_1+c_2)\mathrm{e}^{2t}}{2} + \frac{c_1}{2} - \frac{c_2}{2} + \mathrm{e}^t \\ \frac{(c_1+c_2)\mathrm{e}^{2t}}{2} - \frac{c_1}{2} + \frac{c_2}{2} - \mathrm{e}^t \end{bmatrix}
\end{aligned}
$$

31.4.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \mathrm{e}^t \\ -\mathrm{e}^t \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$
\det(A - \lambda I) = 0
$$

Expanding gives

$$
\det\left(\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0
$$

Therefore

$$
\det\left(\begin{bmatrix} 1-\lambda & 1 \\ 1 & 1-\lambda \end{bmatrix}\right) = 0
$$

Which gives the characteristic equation

$$
\lambda^2 - 2\lambda = 0
$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 2$$
$$\lambda_2 = 0$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
0	1	real eigenvalue
2	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 0$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} - (0)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 & 1 & 0 \\ 1 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} - (2) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -1 & 1 & 0 \\ 1 & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} -1 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
2	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$
0	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 2 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{2t} \\ &= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{2t} \end{aligned}$$

Since eigenvalue 0 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^0 \\ &= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^0\end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \mathrm{e}^{2t} \\ \mathrm{e}^{2t} \end{bmatrix} + c_2 \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} \mathrm{e}^{2t} & -1 \\ \mathrm{e}^{2t} & 1 \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{\mathrm{e}^{-2t}}{2} & \frac{\mathrm{e}^{-2t}}{2} \\ -\frac{1}{2} & \frac{1}{2} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} e^{2t} & -1 \\ e^{2t} & 1 \end{bmatrix} \int \begin{bmatrix} \frac{e^{-2t}}{2} & \frac{e^{-2t}}{2} \\ -\frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} e^{t} \\ -e^{t} \end{bmatrix} dt$$

$$= \begin{bmatrix} e^{2t} & -1 \\ e^{2t} & 1 \end{bmatrix} \int \begin{bmatrix} 0 \\ -e^{t} \end{bmatrix} dt$$

$$= \begin{bmatrix} e^{2t} & -1 \\ e^{2t} & 1 \end{bmatrix} \begin{bmatrix} 0 \\ -e^{t} \end{bmatrix}$$

$$= \begin{bmatrix} e^{t} \\ -e^{t} \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 e^{2t} \\ c_1 e^{2t} \end{bmatrix} + \begin{bmatrix} -c_2 \\ c_2 \end{bmatrix} + \begin{bmatrix} e^{t} \\ -e^{t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 e^{2t} - c_2 + e^{t} \\ c_1 e^{2t} + c_2 - e^{t} \end{bmatrix}$$

31.4.3 Maple step by step solution

Let's solve

$[x'(t) = x(t) + y(t) + e^{t}, y'(t) = x(t) + y(t) - e^{t}]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} e^{t} \\ -e^{t} \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} \mathrm{e}^{t} \\ -\mathrm{e}^{t} \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} \mathrm{e}^{t} \\ -\mathrm{e}^{t} \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right], \left[2, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \mathrm{e}^{2t} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{x}_p($

$\overrightarrow{x}(t) = c_1\overrightarrow{x}_1 + c_2\overrightarrow{x}_2 + \overrightarrow{x}_p(t)$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(t) = \begin{bmatrix} -1 & e^{2t} \\ 1 & e^{2t} \end{bmatrix}$$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$\Phi(t) = \phi(t) \cdot \phi(0)^{-1}$

- Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} -1 & e^{2t} \\ 1 & e^{2t} \end{bmatrix} \cdot \begin{bmatrix} -1 & 1 \\ 1 & 1 \end{bmatrix}^{-1}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} \frac{1}{2} + \frac{e^{2t}}{2} & \frac{e^{2t}}{2} - \frac{1}{2} \\ \frac{e^{2t}}{2} - \frac{1}{2} & \frac{1}{2} + \frac{e^{2t}}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

$\overrightarrow{x}_p(t) = \Phi(t) \cdot \overrightarrow{v}(t)$

- Take the derivative of the particular solution

$\overrightarrow{x}_p'(t) = \Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

$\Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- Cancel like terms

$\Phi(t) \cdot \overrightarrow{v}'(t) = \overrightarrow{f}(t)$

- Multiply by the inverse of the fundamental matrix

$\overrightarrow{v}'(t) = \Phi(t)^{-1} \cdot \overrightarrow{f}(t)$

- Integrate to solve for $\overrightarrow{v}(t)$

$\vec{v}(t) = \int_0^t \Phi(s)^{-1} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \Phi(s)^{-1} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $\vec{x}_p(t) = \begin{bmatrix} e^t - 1 \\ 1 - e^t \end{bmatrix}$

- Plug particular solution back into general solution

  $\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \begin{bmatrix} e^t - 1 \\ 1 - e^t \end{bmatrix}$

- Substitute in vector of dependent variables

  $\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_2e^{2t} + e^t - 1 - c_1 \\ c_2e^{2t} + 1 - e^t + c_1 \end{bmatrix}$

- Solution to the system of ODEs

  $\{x(t) = c_2e^{2t} + e^t - 1 - c_1, y(t) = c_2e^{2t} + 1 - e^t + c_1\}$

✓ Solution by Maple

Section: Chapter 3 (Systems of differential equations). Section 23.2 The method of undetermined coefficients. Exercises page 239
Problem number: 819.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 4x(t) - 5y(t) + 4t - 1 \\
y'(t) &= x(t) - 2y(t) + t
\end{aligned}
$$

With initial conditions

$$
[x(0) = 0, y(0) = 0]
$$

31.5.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 4 & -5 \\ 1 & -2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 4t - 1 \\ t \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} -\frac{e^{-t}}{4}+\frac{5\,e^{3t}}{4} & -\frac{5\,e^{3t}}{4}+\frac{5\,e^{-t}}{4} \\ \frac{e^{3t}}{4}-\frac{e^{-t}}{4} & \frac{5\,e^{-t}}{4}-\frac{e^{3t}}{4} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{x}_0 \\ &= \begin{bmatrix} -\frac{e^{-t}}{4}+\frac{5\,e^{3t}}{4} & -\frac{5\,e^{3t}}{4}+\frac{5\,e^{-t}}{4} \\ \frac{e^{3t}}{4}-\frac{e^{-t}}{4} & \frac{5\,e^{-t}}{4}-\frac{e^{3t}}{4} \end{bmatrix} \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\ &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned} e^{-At} &= \left(e^{At}\right)^{-1} \\ &= \begin{bmatrix} -\frac{(e^{4t}-5)e^{-3t}}{4} & \frac{5(e^{4t}-1)e^{-3t}}{4} \\ -\frac{(e^{4t}-1)e^{-3t}}{4} & \frac{(5\,e^{4t}-1)e^{-3t}}{4} \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} -\frac{e^{-t}}{4}+\frac{5\,e^{3t}}{4} & -\frac{5\,e^{3t}}{4}+\frac{5\,e^{-t}}{4} \\ \frac{e^{3t}}{4}-\frac{e^{-t}}{4} & \frac{5\,e^{-t}}{4}-\frac{e^{3t}}{4} \end{bmatrix} \int \begin{bmatrix} -\frac{(e^{4t}-5)e^{-3t}}{4} & \frac{5(e^{4t}-1)e^{-3t}}{4} \\ -\frac{(e^{4t}-1)e^{-3t}}{4} & \frac{(5\,e^{4t}-1)e^{-3t}}{4} \end{bmatrix} \begin{bmatrix} 4t-1 \\ t \end{bmatrix} dt \\ &= \begin{bmatrix} -\frac{e^{-t}}{4}+\frac{5\,e^{3t}}{4} & -\frac{5\,e^{3t}}{4}+\frac{5\,e^{-t}}{4} \\ \frac{e^{3t}}{4}-\frac{e^{-t}}{4} & \frac{5\,e^{-t}}{4}-\frac{e^{3t}}{4} \end{bmatrix} \begin{bmatrix} \frac{t(e^{4t}-5)e^{-3t}}{4} \\ \frac{(e^{4t}-1)e^{-3t}t}{4} \end{bmatrix} \\ &= \begin{bmatrix} -t \\ 0 \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$= \begin{bmatrix} -t \\ 0 \end{bmatrix}$$

31.5.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 4 & -5 \\ 1 & -2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 4t-1 \\ t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 4 & -5 \\ 1 & -2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 4-\lambda & -5 \\ 1 & -2-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 2\lambda - 3 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -1$$
$$\lambda_2 = 3$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
3	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 4 & -5 \\ 1 & -2 \end{bmatrix} - (-1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 5 & -5 \\ 1 & -1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 5 & -5 & 0 \\ 1 & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{5} \Longrightarrow \left[\begin{array}{cc|c} 5 & -5 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 5 & -5 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 4 & -5 \\ 1 & -2 \end{bmatrix} - (3) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 1 & -5 \\ 1 & -5 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 & -5 & 0 \\ 1 & -5 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 & -5 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & -5 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 5t\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} 5t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} 5 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} 5 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-1	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$
3	1	1	No	$\begin{bmatrix} 5 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{-t} \\ &= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{-t} \end{aligned}$$

Since eigenvalue 3 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{3t}$$
$$= \begin{bmatrix} 5 \\ 1 \end{bmatrix} e^{3t}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \mathrm{e}^{-t} \\ \mathrm{e}^{-t} \end{bmatrix} + c_2 \begin{bmatrix} 5\,\mathrm{e}^{3t} \\ \mathrm{e}^{3t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} \mathrm{e}^{-t} & 5\,\mathrm{e}^{3t} \\ \mathrm{e}^{-t} & \mathrm{e}^{3t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{\mathrm{e}^{t}}{4} & \frac{5\,\mathrm{e}^{t}}{4} \\ \frac{\mathrm{e}^{-3t}}{4} & -\frac{\mathrm{e}^{-3t}}{4} \end{bmatrix}$$

Hence

$$
\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \mathrm{e}^{-t} & 5\,\mathrm{e}^{3t} \\ \mathrm{e}^{-t} & \mathrm{e}^{3t} \end{bmatrix} \int \begin{bmatrix} -\frac{\mathrm{e}^{t}}{4} & \frac{5\,\mathrm{e}^{t}}{4} \\ \frac{\mathrm{e}^{-3t}}{4} & -\frac{\mathrm{e}^{-3t}}{4} \end{bmatrix} \begin{bmatrix} 4t-1 \\ t \end{bmatrix} dt \\
&= \begin{bmatrix} \mathrm{e}^{-t} & 5\,\mathrm{e}^{3t} \\ \mathrm{e}^{-t} & \mathrm{e}^{3t} \end{bmatrix} \int \begin{bmatrix} \frac{\mathrm{e}^{t}(t+1)}{4} \\ \frac{\mathrm{e}^{-3t}(3t-1)}{4} \end{bmatrix} dt \\
&= \begin{bmatrix} \mathrm{e}^{-t} & 5\,\mathrm{e}^{3t} \\ \mathrm{e}^{-t} & \mathrm{e}^{3t} \end{bmatrix} \begin{bmatrix} \frac{\mathrm{e}^{t} t}{4} \\ -\frac{\mathrm{e}^{-3t} t}{4} \end{bmatrix} \\
&= \begin{bmatrix} -t \\ 0 \end{bmatrix}
\end{aligned}
$$

Now that we found particular solution, the final solution is

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 \mathrm{e}^{-t} \\ c_1 \mathrm{e}^{-t} \end{bmatrix} + \begin{bmatrix} 5c_2 \mathrm{e}^{3t} \\ c_2 \mathrm{e}^{3t} \end{bmatrix} + \begin{bmatrix} -t \\ 0 \end{bmatrix}
$$

Which becomes

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 \mathrm{e}^{-t} + 5c_2 \mathrm{e}^{3t} - t \\ c_1 \mathrm{e}^{-t} + c_2 \mathrm{e}^{3t} \end{bmatrix}
$$

Since initial conditions are given, the solution above needs to be updated by solving for the constants of integrations using the given initial conditions

$$
\begin{bmatrix} x(0) = 0 \\ y(0) = 0 \end{bmatrix} \tag{1}
$$

Substituting initial conditions into the above solution at $t = 0$ gives

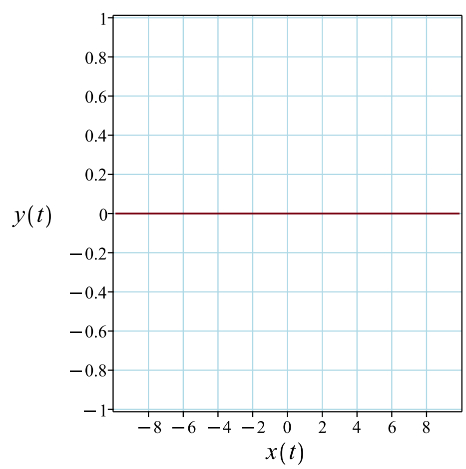
$$
\begin{bmatrix} 0 \\ 0 \end{bmatrix} = \begin{bmatrix} c_1 + 5c_2 \\ c_1 + c_2 \end{bmatrix}
$$

Solving for the constants of integrations gives

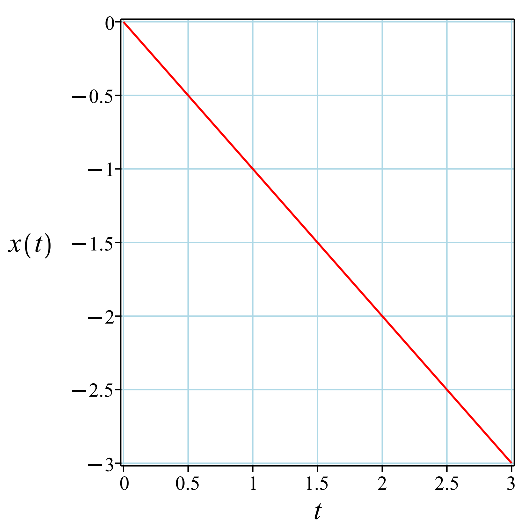
$$
\begin{bmatrix} c_1 = 0 \\ c_2 = 0 \end{bmatrix}
$$

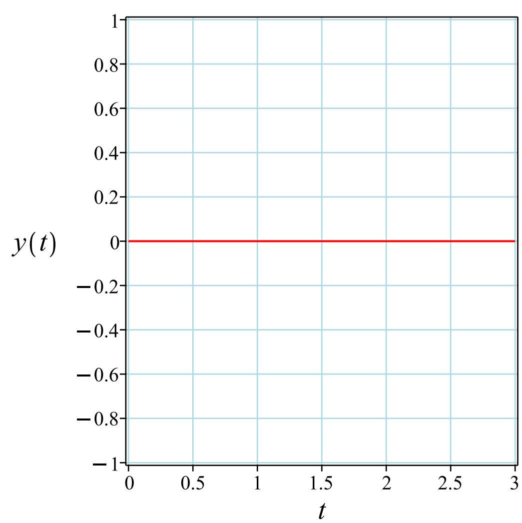
Substituting these constants back in original solution in Eq. (1) gives

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -t \\ 0 \end{bmatrix}$$



The following are plots of each solution.





✓ Solution by Maple

Time used: 0.032 (sec). Leaf size: 12

```
dsolve([diff(x(t),t) = 4*x(t)-5*y(t)+4*t-1, diff(y(t),t) = x(t)-2*y(t)+t, x(0) = 0, y(0) = 0
```

$$x(t) = -t$$
$$y(t) = 0$$

✓ Solution by Mathematica

Time used: 0.148 (sec). Leaf size: 12

```
DSolve[{x'[t]==4*x[t]-5*y[t]+4*t-1,y'[t]==x[t]-2*y[t]+t},{x[0]==0,y[0]==0},{x[t],y[t]},t,Inc
```

$$x(t) \to -t$$
$$y(t) \to 0$$

Problem number: 820.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = y(t) - x(t) + \mathrm{e}^{t}$$
$$y'(t) = x(t) - y(t) + \mathrm{e}^{t}$$

With initial conditions

$$[x(0) = 0, y(0) = 1]$$

31.6.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \mathrm{e}^{t} \\ \mathrm{e}^{t} \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{e^{-2t}}{2} + \frac{1}{2} & \frac{1}{2} - \frac{e^{-2t}}{2} \\ \frac{1}{2} - \frac{e^{-2t}}{2} & \frac{e^{-2t}}{2} + \frac{1}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{x}_0 \\ &= \begin{bmatrix} \frac{e^{-2t}}{2} + \frac{1}{2} & \frac{1}{2} - \frac{e^{-2t}}{2} \\ \frac{1}{2} - \frac{e^{-2t}}{2} & \frac{e^{-2t}}{2} + \frac{1}{2} \end{bmatrix} \begin{bmatrix} 0 \\ 1 \end{bmatrix} \\ &= \begin{bmatrix} \frac{1}{2} - \frac{e^{-2t}}{2} \\ \frac{e^{-2t}}{2} + \frac{1}{2} \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} \frac{1}{2} + \frac{e^{2t}}{2} & -\frac{e^{2t}}{2} + \frac{1}{2} \\ -\frac{e^{2t}}{2} + \frac{1}{2} & \frac{1}{2} + \frac{e^{2t}}{2} \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} \frac{e^{-2t}}{2} + \frac{1}{2} & \frac{1}{2} - \frac{e^{-2t}}{2} \\ \frac{1}{2} - \frac{e^{-2t}}{2} & \frac{e^{-2t}}{2} + \frac{1}{2} \end{bmatrix} \int \begin{bmatrix} \frac{1}{2} + \frac{e^{2t}}{2} & -\frac{e^{2t}}{2} + \frac{1}{2} \\ -\frac{e^{2t}}{2} + \frac{1}{2} & \frac{1}{2} + \frac{e^{2t}}{2} \end{bmatrix} \begin{bmatrix} e^{t} \\ e^{t} \end{bmatrix} dt \\ &= \begin{bmatrix} \frac{e^{-2t}}{2} + \frac{1}{2} & \frac{1}{2} - \frac{e^{-2t}}{2} \\ \frac{1}{2} - \frac{e^{-2t}}{2} & \frac{e^{-2t}}{2} + \frac{1}{2} \end{bmatrix} \begin{bmatrix} e^{t} \\ e^{t} \end{bmatrix} \\ &= \begin{bmatrix} e^{t} \\ e^{t} \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$= \begin{bmatrix} \frac{(2\,e^{3t}+e^{2t}-1)e^{-2t}}{2} \\ \frac{(2\,e^{3t}+e^{2t}+1)e^{-2t}}{2} \end{bmatrix}$$

31.6.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} e^t \\ e^t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -1-\lambda & 1 \\ 1 & -1-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 2\lambda = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -2$$
$$\lambda_2 = 0$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
0	1	real eigenvalue
-2	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix} - (-2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 & 1 & 0 \\ 1 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 0$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix} - (0) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -1 & 1 & 0 \\ 1 & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} -1 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-2	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$
0	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -2 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{-2t} \\ &= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{-2t} \end{aligned}$$

Since eigenvalue 0 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^0 \\ &= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^0\end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\mathrm{e}^{-2t} \\ \mathrm{e}^{-2t} \end{bmatrix} + c_2 \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -\mathrm{e}^{-2t} & 1 \\ \mathrm{e}^{-2t} & 1 \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t) \, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{\mathrm{e}^{2t}}{2} & \frac{\mathrm{e}^{2t}}{2} \\ \frac{1}{2} & \frac{1}{2} \end{bmatrix}$$

Hence

$$
\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} -\mathrm{e}^{-2t} & 1 \\ \mathrm{e}^{-2t} & 1 \end{bmatrix} \int \begin{bmatrix} -\frac{\mathrm{e}^{2t}}{2} & \frac{\mathrm{e}^{2t}}{2} \\ \frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} \mathrm{e}^{t} \\ \mathrm{e}^{t} \end{bmatrix} dt \\
&= \begin{bmatrix} -\mathrm{e}^{-2t} & 1 \\ \mathrm{e}^{-2t} & 1 \end{bmatrix} \int \begin{bmatrix} 0 \\ \mathrm{e}^{t} \end{bmatrix} dt \\
&= \begin{bmatrix} -\mathrm{e}^{-2t} & 1 \\ \mathrm{e}^{-2t} & 1 \end{bmatrix} \begin{bmatrix} 0 \\ \mathrm{e}^{t} \end{bmatrix} \\
&= \begin{bmatrix} \mathrm{e}^{t} \\ \mathrm{e}^{t} \end{bmatrix}
\end{aligned}
$$

Now that we found particular solution, the final solution is

$$
\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} &= \begin{bmatrix} -c_1 \mathrm{e}^{-2t} \\ c_1 \mathrm{e}^{-2t} \end{bmatrix} + \begin{bmatrix} c_2 \\ c_2 \end{bmatrix} + \begin{bmatrix} \mathrm{e}^{t} \\ \mathrm{e}^{t} \end{bmatrix}
\end{aligned}
$$

Which becomes

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} (\mathrm{e}^{3t} + c_2 \mathrm{e}^{2t} - c_1)\, \mathrm{e}^{-2t} \\ (\mathrm{e}^{3t} + c_2 \mathrm{e}^{2t} + c_1)\, \mathrm{e}^{-2t} \end{bmatrix}
$$

Since initial conditions are given, the solution above needs to be updated by solving for the constants of integrations using the given initial conditions

$$
\begin{bmatrix} x(0) = 0 \\ y(0) = 1 \end{bmatrix} \tag{1}
$$

Substituting initial conditions into the above solution at $t = 0$ gives

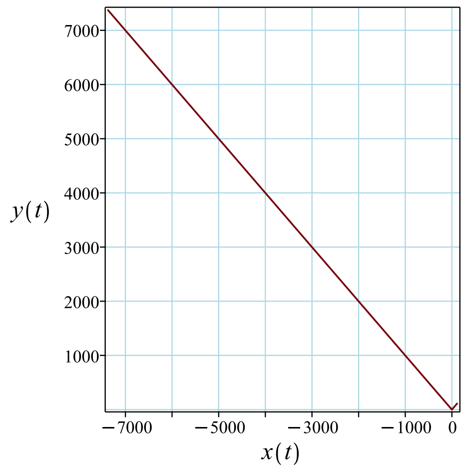
$$
\begin{bmatrix} 0 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 + c_2 - c_1 \\ 1 + c_2 + c_1 \end{bmatrix}
$$

Solving for the constants of integrations gives

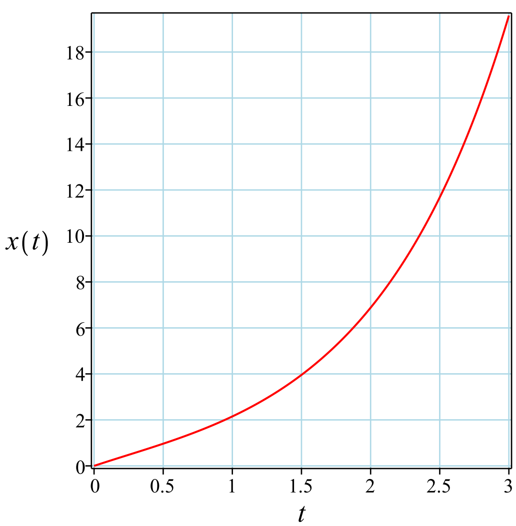
$$
\begin{bmatrix} c_1 = \frac{1}{2} \\ c_2 = -\frac{1}{2} \end{bmatrix}
$$

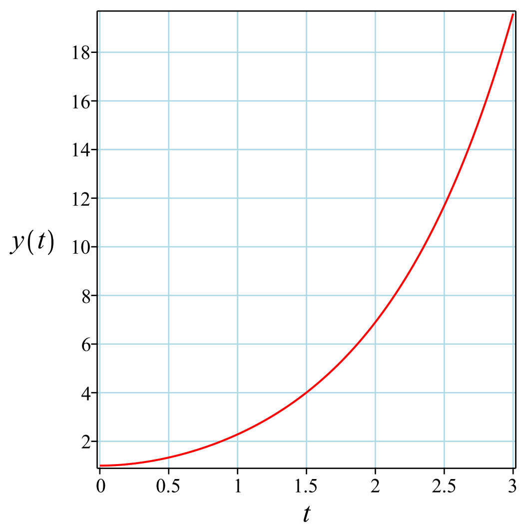
Substituting these constants back in original solution in Eq. (1) gives

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \left(e^{3t} - \frac{e^{2t}}{2} - \frac{1}{2}\right) e^{-2t} \\ \left(e^{3t} - \frac{e^{2t}}{2} + \frac{1}{2}\right) e^{-2t} \end{bmatrix}$$



The following are plots of each solution.





✓ Solution by Maple

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= t^2 - y(t) \\
y'(t) &= x(t) + t
\end{aligned}
$$

31.7.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} t^2 \\ t \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} \cos(t)\, c_1 - \sin(t)\, c_2 \\ \sin(t)\, c_1 + \cos(t)\, c_2 \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\, dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix} \int \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix} \begin{bmatrix} t^2 \\ t \end{bmatrix} dt \\ &= \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix} \begin{bmatrix} \sin(t)\, t^2 - \sin(t) + t\cos(t) \\ -\cos(t) - \sin(t)\, t + \cos(t)\, t^2 \end{bmatrix} \\ &= \begin{bmatrix} t \\ t^2 - 1 \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$\begin{aligned} \vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\ &= \begin{bmatrix} \cos(t)\, c_1 - \sin(t)\, c_2 + t \\ \sin(t)\, c_1 + \cos(t)\, c_2 + t^2 - 1 \end{bmatrix} \end{aligned}$$

31.7.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} t^2 \\ t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -\lambda & -1 \\ 1 & -\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 1 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = i$$
$$\lambda_2 = -i$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
i	1	complex eigenvalue
$-i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} - (-i) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} i & -1 \\ 1 & i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} i & -1 & 0 \\ 1 & i & 0 \end{array}\right]$$

$$R_2 = iR_1 + R_2 \Longrightarrow \left[\begin{array}{cc|c} i & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} i & -1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -it\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} -i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -i \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} - (i) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} -i & -1 \\ 1 & -i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -i & -1 & 0 \\ 1 & -i & 0 \end{array}\right]$$

$$R_2 = -iR_1 + R_2 \Longrightarrow \left[\begin{array}{cc|c} -i & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -i & -1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = it\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} i \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
i	1	1	No	$\begin{bmatrix} i \\ 1 \end{bmatrix}$
$-i$	1	1	No	$\begin{bmatrix} -i \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} i\mathrm{e}^{it} \\ \mathrm{e}^{it} \end{bmatrix} + c_2 \begin{bmatrix} -i\mathrm{e}^{-it} \\ \mathrm{e}^{-it} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} i\mathrm{e}^{it} & -i\mathrm{e}^{-it} \\ \mathrm{e}^{it} & \mathrm{e}^{-it} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1}\vec{G}(t)\,dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{i e^{-it}}{2} & \frac{e^{-it}}{2} \\ \frac{i e^{it}}{2} & \frac{e^{it}}{2} \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} i e^{it} & -i e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} -\frac{i e^{-it}}{2} & \frac{e^{-it}}{2} \\ \frac{i e^{it}}{2} & \frac{e^{it}}{2} \end{bmatrix} \begin{bmatrix} t^2 \\ t \end{bmatrix} dt \\
&= \begin{bmatrix} i e^{it} & -i e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} -\frac{t\,e^{-it}(it-1)}{2} \\ \frac{t\,e^{it}(it+1)}{2} \end{bmatrix} dt \\
&= \begin{bmatrix} i e^{it} & -i e^{-it} \\ e^{it} & e^{-it} \end{bmatrix} \begin{bmatrix} -\frac{(-t^2+it+1)e^{-it}}{2} \\ \frac{(t^2+it-1)e^{it}}{2} \end{bmatrix} \\
&= \begin{bmatrix} t \\ t^2 - 1 \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} i c_1 e^{it} \\ c_1 e^{it} \end{bmatrix} + \begin{bmatrix} -i c_2 e^{-it} \\ c_2 e^{-it} \end{bmatrix} + \begin{bmatrix} t \\ t^2 - 1 \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} i c_1 e^{it} - i c_2 e^{-it} + t \\ c_1 e^{it} + c_2 e^{-it} + t^2 - 1 \end{bmatrix}$$

31.7.3 Maple step by step solution

Let's solve

$[x'(t) = t^2 - y(t), y'(t) = x(t) + t]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} t^2 \\ t \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} t^2 \\ t \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} t^2 \\ t \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} \mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

  $e^{-It} \cdot \begin{bmatrix} -I \\ 1 \end{bmatrix}$

- Use Euler identity to write solution in terms of sin and cos

  $(\cos(t) - I\sin(t)) \cdot \begin{bmatrix} -I \\ 1 \end{bmatrix}$

- Simplify expression

  $\begin{bmatrix} -I(\cos(t) - I\sin(t)) \\ \cos(t) - I\sin(t) \end{bmatrix}$

- Both real and imaginary parts are solutions to the homogeneous system

  $\left[\vec{x}_1(t) = \begin{bmatrix} -\sin(t) \\ \cos(t) \end{bmatrix}, \vec{x}_2(t) = \begin{bmatrix} -\cos(t) \\ -\sin(t) \end{bmatrix}\right]$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

  $\vec{x}(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + \vec{x}_p(t)$

□ Fundamental matrix

  - Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

    $\phi(t) = \begin{bmatrix} -\sin(t) & -\cos(t) \\ \cos(t) & -\sin(t) \end{bmatrix}$

  - The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

    $\Phi(t) = \phi(t) \cdot \phi(0)^{-1}$

  - Substitute the value of $\phi(t)$ and $\phi(0)$

    $\Phi(t) = \begin{bmatrix} -\sin(t) & -\cos(t) \\ \cos(t) & -\sin(t) \end{bmatrix} \cdot \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}^{-1}$

  - Evaluate and simplify to get the fundamental matrix

    $\Phi(t) = \begin{bmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{bmatrix}$

□ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$
  $\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$
- Take the derivative of the particular solution
  $\vec{x}_p'(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$
- Substitute particular solution and its derivative into the system of ODEs
  $\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der
  $A \cdot \Phi(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$
- Cancel like terms
  $\Phi(t) \cdot \vec{v}'(t) = \vec{f}(t)$
- Multiply by the inverse of the fundamental matrix
  $\vec{v}'(t) = \Phi(t)^{-1} \cdot \vec{f}(t)$
- Integrate to solve for $\vec{v}(t)$
  $\vec{v}(t) = \int_0^t \Phi(s)^{-1} \cdot \vec{f}(s)\, ds$
- Plug $\vec{v}(t)$ into the equation for the particular solution
  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \Phi(s)^{-1} \cdot \vec{f}(s)\, ds\right)$
- Plug in the fundamental matrix and the forcing function and compute
  $$\vec{x}_p(t) = \left[\begin{array}{c} t - \sin(t) \\ t^2 + \cos(t) - 1 \end{array}\right]$$

- Plug particular solution back into general solution
  $$\vec{x}(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t) + \left[\begin{array}{c} t - \sin(t) \\ t^2 + \cos(t) - 1 \end{array}\right]$$
- Substitute in vector of dependent variables
  $$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} (-c_1 - 1)\sin(t) - c_2\cos(t) + t \\ t^2 + \cos(t) - 1 - c_2\sin(t) + c_1\cos(t) \end{array}\right]$$
- Solution to the system of ODEs
  $\{x(t) = (-c_1 - 1)\sin(t) - c_2\cos(t) + t, y(t) = t^2 + \cos(t) - 1 - c_2\sin(t) + c_1\cos(t)\}$

✓ Solution by Maple

Time used: 0.016 (sec). Leaf size: 32

```
dsolve([diff(x(t),t)+y(t)=t^2,diff(y(t),t)-x(t)=t],singsol=all)
```

$$x(t) = c_2 \sin(t) + c_1 \cos(t) + t$$
$$y(t) = t^2 - c_2 \cos(t) + c_1 \sin(t) - 1$$

✓ Solution by Mathematica

Time used: 0.061 (sec). Leaf size: 36

```
DSolve[{x'[t]+y[t]==t^2,y'[t]-x[t]==t},{x[t],y[t]},t,IncludeSingularSolutions -> True]
```

$$x(t) \to t + c_1 \cos(t) - c_2 \sin(t)$$
$$y(t) \to t^2 + c_2 \cos(t) + c_1 \sin(t) - 1$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= \sin(t) - \mathrm{e}^{-t} - y(t) \\
y'(t) &= -\sin(t) + 2\,\mathrm{e}^{-t}
\end{aligned}
$$

31.8.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & -1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \sin(t) - \mathrm{e}^{-t} \\ -\sin(t) + 2\,\mathrm{e}^{-t} \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} 1 & -t \\ 0 & 1 \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} 1 & -t \\ 0 & 1 \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} -tc_2 + c_1 \\ c_2 \end{bmatrix}
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\, dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \begin{bmatrix} 1 & t \\ 0 & 1 \end{bmatrix}
\end{aligned}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} 1 & -t \\ 0 & 1 \end{bmatrix} \int \begin{bmatrix} 1 & t \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \sin(t) - \mathrm{e}^{-t} \\ -\sin(t) + 2\,\mathrm{e}^{-t} \end{bmatrix} dt \\
&= \begin{bmatrix} 1 & -t \\ 0 & 1 \end{bmatrix} \begin{bmatrix} (-1-2t)\,\mathrm{e}^{-t} + (t-1)\cos(t) - \sin(t) \\ -2\,\mathrm{e}^{-t} + \cos(t) \end{bmatrix} \\
&= \begin{bmatrix} -\sin(t) - \cos(t) - \mathrm{e}^{-t} \\ -2\,\mathrm{e}^{-t} + \cos(t) \end{bmatrix}
\end{aligned}$$

Hence the complete solution is

$$\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
&= \begin{bmatrix} -tc_2 + c_1 - \sin(t) - \cos(t) - \mathrm{e}^{-t} \\ c_2 - 2\,\mathrm{e}^{-t} + \cos(t) \end{bmatrix}
\end{aligned}$$

31.8.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 0 & -1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \sin(t) - \mathrm{e}^{-t} \\ -\sin(t) + 2\,\mathrm{e}^{-t} \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 0 & -1 \\ 0 & 0 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -\lambda & -1 \\ 0 & -\lambda \end{bmatrix}\right) = 0$$

Since the matrix A is triangular matrix, then the determinant is the product of the elements along the diagonal. Therefore the above becomes

$$(-\lambda)(-\lambda) = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 0$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
0	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 0$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 0 & -1 \\ 0 & 0 \end{bmatrix} - (0) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 0 & -1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 0 & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 0 & -1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_1\}$ and the leading variables are $\{v_2\}$. Let $v_1 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_2 = 0\}$

Hence the solution is

$$\begin{bmatrix} t \\ v_2 \end{bmatrix} = \begin{bmatrix} t \\ 0 \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ v_2 \end{bmatrix} = t \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ v_2 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
0	2	1	Yes	$\begin{bmatrix} 1 \\ 0 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. eigenvalue 0 is real and repated eigenvalue of multiplicity 2.There are two possible cases that can happen. This is illustrated in this diagram

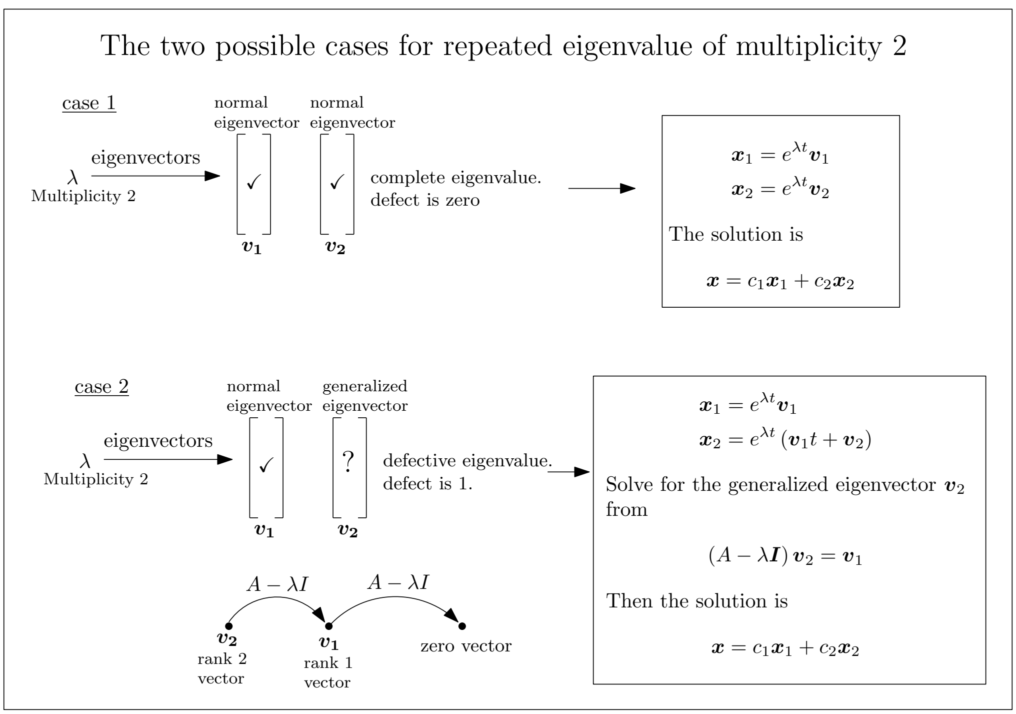

Figure 858: Possible case for repeated λ of multiplicity 2

This eigenvalue has algebraic multiplicity of 2, and geometric multiplicity 1, therefore this is defective eigenvalue. The defect is 1. This falls into case 2 shown above. We need to generate the missing additonal generalized eigevector $\vec{v}_2$ by solving

$$(A - \lambda I)\,\vec{v}_2 = \vec{v}_1$$

Where $\vec{v}_1$ is the normal (rank 1) eigenvector found above. Hence we need to solve

$$\left(\begin{bmatrix} 0 & -1 \\ 0 & 0 \end{bmatrix} - (0)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 0 & -1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

Solving for $\vec{v}_2$ gives

$$\vec{v}_2 = \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

We have found two generalized eigenvectors for eigenvalue 0. Therefore the two basis solution associated with this eigenvalue are

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{\lambda t} \\ &= \begin{bmatrix} 1 \\ 0 \end{bmatrix} 1 \\ &= \begin{bmatrix} 1 \\ 0 \end{bmatrix} \end{aligned}$$

And

$$\begin{aligned} \vec{x}_2(t) &= (\vec{v}_1 t + \vec{v}_2)\, e^{\lambda t} \\ &= \left(\begin{bmatrix} 1 \\ 0 \end{bmatrix} t + \begin{bmatrix} 1 \\ -1 \end{bmatrix}\right) 1 \\ &= \begin{bmatrix} t+1 \\ -1 \end{bmatrix} \end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} 1 \\ 0 \end{bmatrix} + c_2 \begin{bmatrix} t+1 \\ -1 \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} 1 & t+1 \\ 0 & -1 \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} 1 & t+1 \\ 0 & -1 \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} 1 & t+1 \\ 0 & -1 \end{bmatrix} \int \begin{bmatrix} 1 & t+1 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} \sin(t) - e^{-t} \\ -\sin(t) + 2\,e^{-t} \end{bmatrix} dt \\
&= \begin{bmatrix} 1 & t+1 \\ 0 & -1 \end{bmatrix} \int \begin{bmatrix} -\sin(t)\, t + 2t\,e^{-t} + e^{-t} \\ \sin(t) - 2\,e^{-t} \end{bmatrix} dt \\
&= \begin{bmatrix} 1 & t+1 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} (-3-2t)\,e^{-t} + t\cos(t) - \sin(t) \\ 2\,e^{-t} - \cos(t) \end{bmatrix} \\
&= \begin{bmatrix} -\sin(t) - \cos(t) - e^{-t} \\ -2\,e^{-t} + \cos(t) \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 \\ 0 \end{bmatrix} + \begin{bmatrix} c_2(t+1) \\ -c_2 \end{bmatrix} + \begin{bmatrix} -\sin(t) - \cos(t) - e^{-t} \\ -2\,e^{-t} + \cos(t) \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_2 t - \sin(t) - e^{-t} - \cos(t) + c_1 + c_2 \\ -c_2 - 2\,e^{-t} + \cos(t) \end{bmatrix}$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 2x(t) + y(t) - 2z(t) + 2 - t \\
y'(t) &= 1 - x(t) \\
z'(t) &= x(t) + y(t) - z(t) + 1 - t
\end{aligned}
$$

31.9.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 2 & 1 & -2 \\ -1 & 0 & 0 \\ 1 & 1 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} + \begin{bmatrix} 2-t \\ 1 \\ 1-t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \left[\begin{array}{ccc} \mathrm{e}^{t}+\sin(t) & \sin(t) & -\mathrm{e}^{t}+\cos(t)-\sin(t) \\ -\mathrm{e}^{t}+\cos(t) & \cos(t) & \mathrm{e}^{t}-\cos(t)-\sin(t) \\ \sin(t) & \sin(t) & \cos(t)-\sin(t) \end{array}\right]$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \left[\begin{array}{ccc} \mathrm{e}^{t}+\sin(t) & \sin(t) & -\mathrm{e}^{t}+\cos(t)-\sin(t) \\ -\mathrm{e}^{t}+\cos(t) & \cos(t) & \mathrm{e}^{t}-\cos(t)-\sin(t) \\ \sin(t) & \sin(t) & \cos(t)-\sin(t) \end{array}\right] \left[\begin{array}{c} c_1 \\ c_2 \\ c_3 \end{array}\right] \\
&= \left[\begin{array}{c} (\mathrm{e}^{t}+\sin(t))\,c_1+\sin(t)\,c_2+(-\mathrm{e}^{t}+\cos(t)-\sin(t))\,c_3 \\ (-\mathrm{e}^{t}+\cos(t))\,c_1+\cos(t)\,c_2+(\mathrm{e}^{t}-\cos(t)-\sin(t))\,c_3 \\ \sin(t)\,c_1+\sin(t)\,c_2+(\cos(t)-\sin(t))\,c_3 \end{array}\right] \\
&= \left[\begin{array}{c} (c_1+c_2-c_3)\sin(t)+(c_1-c_3)\,\mathrm{e}^{t}+c_3\cos(t) \\ (c_1+c_2-c_3)\cos(t)+(-c_1+c_3)\,\mathrm{e}^{t}-c_3\sin(t) \\ (c_1+c_2-c_3)\sin(t)+c_3\cos(t) \end{array}\right]
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At}\int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \left[\begin{array}{ccc} -\sin(t)+\mathrm{e}^{-t} & -\sin(t) & \sin(t)+\cos(t)-\mathrm{e}^{-t} \\ \cos(t)-\mathrm{e}^{-t} & \cos(t) & \sin(t)-\cos(t)+\mathrm{e}^{-t} \\ -\sin(t) & -\sin(t) & \cos(t)+\sin(t) \end{array}\right]
\end{aligned}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} e^t + \sin(t) & \sin(t) & -e^t + \cos(t) - \sin(t) \\ -e^t + \cos(t) & \cos(t) & e^t - \cos(t) - \sin(t) \\ \sin(t) & \sin(t) & \cos(t) - \sin(t) \end{bmatrix} \int \begin{bmatrix} -\sin(t) + e^{-t} & -\sin(t) & \sin(t) + \cos(t) \\ \cos(t) - e^{-t} & \cos(t) & \sin(t) - \cos(t) \\ -\sin(t) & -\sin(t) & \cos(t) + \sin \end{bmatrix}$$

$$= \begin{bmatrix} e^t + \sin(t) & \sin(t) & -e^t + \cos(t) - \sin(t) \\ -e^t + \cos(t) & \cos(t) & e^t - \cos(t) - \sin(t) \\ \sin(t) & \sin(t) & \cos(t) - \sin(t) \end{bmatrix} \begin{bmatrix} \sin(t) - e^{-t} - \sin(t)\, t + \cos(t) \\ e^{-t} + (t-1)\cos(t) + \sin(t) \\ -\sin(t)\, t + \sin(t) + \cos(t) \end{bmatrix}$$

$$= \begin{bmatrix} 0 \\ t \\ 1 \end{bmatrix}$$

Hence the complete solution is

$$\begin{aligned} \vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\ &= \begin{bmatrix} (c_1 + c_2 - c_3)\sin(t) + (c_1 - c_3)e^t + c_3\cos(t) \\ (c_1 + c_2 - c_3)\cos(t) + (-c_1 + c_3)e^t - c_3\sin(t) + t \\ (c_1 + c_2 - c_3)\sin(t) + c_3\cos(t) + 1 \end{bmatrix} \end{aligned}$$

31.9.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 2 & 1 & -2 \\ -1 & 0 & 0 \\ 1 & 1 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} + \begin{bmatrix} 2-t \\ 1 \\ 1-t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A-\lambda I\right)=0$$

Expanding gives

$$\det\left(\begin{bmatrix} 2 & 1 & -2 \\ -1 & 0 & 0 \\ 1 & 1 & -1 \end{bmatrix}-\lambda\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)=0$$

Therefore

$$\det\left(\begin{bmatrix} 2-\lambda & 1 & -2 \\ -1 & -\lambda & 0 \\ 1 & 1 & -1-\lambda \end{bmatrix}\right)=0$$

Which gives the characteristic equation

$$\lambda^3-\lambda^2+\lambda-1=0$$

The roots of the above are the eigenvalues.

$$\begin{aligned} \lambda_1 &= 1 \\ \lambda_2 &= i \\ \lambda_3 &= -i \end{aligned}$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue
i	1	complex eigenvalue
$-i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1=1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & 1 & -2 \\ -1 & 0 & 0 \\ 1 & 1 & -1 \end{bmatrix} - (1)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 1 & 1 & -2 \\ -1 & -1 & 0 \\ 1 & 1 & -2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 1 & 1 & -2 & 0 \\ -1 & -1 & 0 & 0 \\ 1 & 1 & -2 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{ccc|c} 1 & 1 & -2 & 0 \\ 0 & 0 & -2 & 0 \\ 1 & 1 & -2 & 0 \end{array}\right]$$

$$R_3 = R_3 - R_1 \Longrightarrow \left[\begin{array}{ccc|c} 1 & 1 & -2 & 0 \\ 0 & 0 & -2 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & 1 & -2 \\ 0 & 0 & -2 \\ 0 & 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1, v_3\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t, v_3 = 0\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \\ v_3 \end{bmatrix} = \begin{bmatrix} -t \\ t \\ 0 \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \\ v_3 \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \\ v_3 \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = -i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & 1 & -2 \\ -1 & 0 & 0 \\ 1 & 1 & -1 \end{bmatrix} - (-i) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 2+i & 1 & -2 \\ -1 & i & 0 \\ 1 & 1 & -1+i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 2+i & 1 & -2 & 0 \\ -1 & i & 0 & 0 \\ 1 & 1 & -1+i & 0 \end{array}\right]$$

$$R_2 = R_2 + \left(\frac{2}{5} - \frac{i}{5}\right) R_1 \Longrightarrow \left[\begin{array}{ccc|c} 2+i & 1 & -2 & 0 \\ 0 & \frac{2}{5} + \frac{4i}{5} & -\frac{4}{5} + \frac{2i}{5} & 0 \\ 1 & 1 & -1+i & 0 \end{array}\right]$$

$$R_3 = R_3 + \left(-\frac{2}{5} + \frac{i}{5}\right) R_1 \Longrightarrow \left[\begin{array}{ccc|c} 2+i & 1 & -2 & 0 \\ 0 & \frac{2}{5} + \frac{4i}{5} & -\frac{4}{5} + \frac{2i}{5} & 0 \\ 0 & \frac{3}{5} + \frac{i}{5} & -\frac{1}{5} + \frac{3i}{5} & 0 \end{array}\right]$$

$$R_3 = R_3 + \left(-\frac{1}{2} + \frac{i}{2}\right) R_2 \Longrightarrow \left[\begin{array}{ccc|c} 2+i & 1 & -2 & 0 \\ 0 & \frac{2}{5}+\frac{4i}{5} & -\frac{4}{5}+\frac{2i}{5} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2+i & 1 & -2 \\ 0 & \frac{2}{5}+\frac{4i}{5} & -\frac{4}{5}+\frac{2i}{5} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t, v_2 = -it\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ v_2 \\ t \end{bmatrix} = \begin{bmatrix} t \\ -it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ v_2 \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ -i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ v_2 \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ -i \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_3 = i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & 1 & -2 \\ -1 & 0 & 0 \\ 1 & 1 & -1 \end{bmatrix} - (i)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 2-i & 1 & -2 \\ -1 & -i & 0 \\ 1 & 1 & -1-i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 2-i & 1 & -2 & 0 \\ -1 & -i & 0 & 0 \\ 1 & 1 & -1-i & 0 \end{array}\right]$$

$$R_2 = R_2 + \left(\frac{2}{5} + \frac{i}{5}\right)R_1 \Longrightarrow \left[\begin{array}{ccc|c} 2-i & 1 & -2 & 0 \\ 0 & \frac{2}{5} - \frac{4i}{5} & -\frac{4}{5} - \frac{2i}{5} & 0 \\ 1 & 1 & -1-i & 0 \end{array}\right]$$

$$R_3 = R_3 + \left(-\frac{2}{5} - \frac{i}{5}\right)R_1 \Longrightarrow \left[\begin{array}{ccc|c} 2-i & 1 & -2 & 0 \\ 0 & \frac{2}{5} - \frac{4i}{5} & -\frac{4}{5} - \frac{2i}{5} & 0 \\ 0 & \frac{3}{5} - \frac{i}{5} & -\frac{1}{5} - \frac{3i}{5} & 0 \end{array}\right]$$

$$R_3 = R_3 + \left(-\frac{1}{2} - \frac{i}{2}\right)R_2 \Longrightarrow \left[\begin{array}{ccc|c} 2-i & 1 & -2 & 0 \\ 0 & \frac{2}{5} - \frac{4i}{5} & -\frac{4}{5} - \frac{2i}{5} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2-i & 1 & -2 \\ 0 & \frac{2}{5} - \frac{4i}{5} & -\frac{4}{5} - \frac{2i}{5} \\ 0 & 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t, v_2 = it\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ v_2 \\ t \end{bmatrix} = \begin{bmatrix} t \\ it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ v_2 \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ v_2 \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ i \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
1	1	1	No	$\begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}$
i	1	1	No	$\begin{bmatrix} 1 \\ i \\ 1 \end{bmatrix}$
$-i$	1	1	No	$\begin{bmatrix} 1 \\ -i \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^t \\ &= \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix} e^t\end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + c_3\vec{x}_3(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = c_1 \begin{bmatrix} -\mathrm{e}^t \\ \mathrm{e}^t \\ 0 \end{bmatrix} + c_2 \begin{bmatrix} \mathrm{e}^{it} \\ i\mathrm{e}^{it} \\ \mathrm{e}^{it} \end{bmatrix} + c_3 \begin{bmatrix} \mathrm{e}^{-it} \\ -i\mathrm{e}^{-it} \\ \mathrm{e}^{-it} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -e^{t} & e^{it} & e^{-it} \\ e^{t} & i e^{it} & -i e^{-it} \\ 0 & e^{it} & e^{-it} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -e^{-t} & 0 & e^{-t} \\ -\frac{i e^{-it}}{2} & -\frac{i e^{-it}}{2} & \left(\frac{1}{2} + \frac{i}{2}\right) e^{-it} \\ \frac{i e^{it}}{2} & \frac{i e^{it}}{2} & \left(\frac{1}{2} - \frac{i}{2}\right) e^{it} \end{bmatrix}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} -e^{t} & e^{it} & e^{-it} \\ e^{t} & i e^{it} & -i e^{-it} \\ 0 & e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} -e^{-t} & 0 & e^{-t} \\ -\frac{i e^{-it}}{2} & -\frac{i e^{-it}}{2} & \left(\frac{1}{2} + \frac{i}{2}\right) e^{-it} \\ \frac{i e^{it}}{2} & \frac{i e^{it}}{2} & \left(\frac{1}{2} - \frac{i}{2}\right) e^{it} \end{bmatrix} \begin{bmatrix} 2-t \\ 1 \\ 1-t \end{bmatrix} dt \\ &= \begin{bmatrix} -e^{t} & e^{it} & e^{-it} \\ e^{t} & i e^{it} & -i e^{-it} \\ 0 & e^{it} & e^{-it} \end{bmatrix} \int \begin{bmatrix} -e^{-t} \\ -\frac{e^{-it}(-1+2i+t)}{2} \\ \frac{e^{it}(1+2i-t)}{2} \end{bmatrix} dt \\ &= \begin{bmatrix} -e^{t} & e^{it} & e^{-it} \\ e^{t} & i e^{it} & -i e^{-it} \\ 0 & e^{it} & e^{-it} \end{bmatrix} \begin{bmatrix} e^{-t} \\ -\frac{e^{-it}(it-i-1)}{2} \\ \frac{e^{it}(it-i+1)}{2} \end{bmatrix} \\ &= \begin{bmatrix} 0 \\ t \\ 1 \end{bmatrix} \end{aligned}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} -c_1 e^{t} \\ c_1 e^{t} \\ 0 \end{bmatrix} + \begin{bmatrix} c_2 e^{it} \\ i c_2 e^{it} \\ c_2 e^{it} \end{bmatrix} + \begin{bmatrix} c_3 e^{-it} \\ -i c_3 e^{-it} \\ c_3 e^{-it} \end{bmatrix} + \begin{bmatrix} 0 \\ t \\ 1 \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} -c_1 e^{t} + c_2 e^{it} + c_3 e^{-it} \\ c_1 e^{t} + i c_2 e^{it} - i c_3 e^{-it} + t \\ c_2 e^{it} + c_3 e^{-it} + 1 \end{bmatrix}$$

31.9.3 Maple step by step solution

Let's solve

$[x'(t) = 2x(t) + y(t) - 2z(t) + 2 - t, y'(t) = 1 - x(t), z'(t) = x(t) + y(t) - z(t) + 1 - t]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 2 & 1 & -2 \\ -1 & 0 & 0 \\ 1 & 1 & -1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 2-t \\ 1 \\ 1-t \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 2 & 1 & -2 \\ -1 & 0 & 0 \\ 1 & 1 & -1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 2-t \\ 1 \\ 1-t \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} 2-t \\ 1 \\ 1-t \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 2 & 1 & -2 \\ -1 & 0 & 0 \\ 1 & 1 & -1 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} 1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} 1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^t \cdot \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} 1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-It} \cdot \begin{bmatrix} 1 \\ -I \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$(\cos(t) - I\sin(t)) \cdot \begin{bmatrix} 1 \\ -I \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} \cos(t) - I\sin(t) \\ -I(\cos(t) - I\sin(t)) \\ \cos(t) - I\sin(t) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{x}_2(t) = \begin{bmatrix} \cos(t) \\ -\sin(t) \\ \cos(t) \end{bmatrix}, \vec{x}_3(t) = \begin{bmatrix} -\sin(t) \\ -\cos(t) \\ -\sin(t) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2(t) + c_3\vec{x}_3(t) + \vec{x}_p(t)$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(t) = \begin{bmatrix} -e^t & \cos(t) & -\sin(t) \\ e^t & -\sin(t) & -\cos(t) \\ 0 & \cos(t) & -\sin(t) \end{bmatrix}$$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$\Phi(t) = \phi(t) \cdot \phi(0)^{-1}$

- Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} -e^t & \cos(t) & -\sin(t) \\ e^t & -\sin(t) & -\cos(t) \\ 0 & \cos(t) & -\sin(t) \end{bmatrix} \cdot \begin{bmatrix} -1 & 1 & 0 \\ 1 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix}^{-1}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} e^{t} + \sin(t) & \sin(t) & -e^{t} + \cos(t) - \sin(t) \\ -e^{t} + \cos(t) & \cos(t) & e^{t} - \cos(t) - \sin(t) \\ \sin(t) & \sin(t) & \cos(t) - \sin(t) \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

  $\overrightarrow{x}_p(t) = \Phi(t) \cdot \overrightarrow{v}(t)$
- Take the derivative of the particular solution

  $\overrightarrow{x}'_p(t) = \Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$
- Cancel like terms

  $\Phi(t) \cdot \overrightarrow{v}'(t) = \overrightarrow{f}(t)$
- Multiply by the inverse of the fundamental matrix

  $\overrightarrow{v}'(t) = \Phi(t)^{-1} \cdot \overrightarrow{f}(t)$
- Integrate to solve for $\overrightarrow{v}(t)$

  $\overrightarrow{v}(t) = \int_0^t \Phi(s)^{-1} \cdot \overrightarrow{f}(s)\, ds$
- Plug $\overrightarrow{v}(t)$ into the equation for the particular solution

  $\overrightarrow{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \Phi(s)^{-1} \cdot \overrightarrow{f}(s)\, ds\right)$
- Plug in the fundamental matrix and the forcing function and compute

$$\overrightarrow{x}_p(t) = \begin{bmatrix} \sin(t)^2 + \cos(t)^2 - 1 + \sin(t) - \cos(t) + e^{t} \\ (t-1)\cos(t)^2 + \cos(t) + (t-1)\sin(t)^2 + \sin(t) - e^{t} + 1 \\ 1 + \sin(t) - \cos(t) \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2(t) + c_3\vec{x}_3(t) + \left[\begin{array}{c} \sin(t)^2 + \cos(t)^2 - 1 + \sin(t) - \cos(t) + e^t \\ (t-1)\cos(t)^2 + \cos(t) + (t-1)\sin(t)^2 + \sin(t) - e^t + 1 \\ 1 + \sin(t) - \cos(t) \end{array}\right.$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} (c_2-1)\cos(t) + (1-c_1)e^t - \sin(t)(c_3-1) \\ (-c_3+1)\cos(t) + (c_1-1)e^t + (-c_2+1)\sin(t) + t \\ (c_2-1)\cos(t) + 1 + (-c_3+1)\sin(t) \end{bmatrix}$$

- Solution to the system of ODEs

$$\{x(t) = (c_2-1)\cos(t) + (1-c_1)e^t - \sin(t)(c_3-1), y(t) = (-c_3+1)\cos(t) + (c_1-1)e^t + (-$$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = -x(t) - 2y(t) + 2\,\mathrm{e}^{-t}$$
$$y'(t) = -y(t) - z(t) + 1$$
$$z'(t) = -z(t) + 1$$

With initial conditions

$$[x(0) = 1, y(0) = 1, z(0) = 1]$$

31.10.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} -1 & -2 & 0 \\ 0 & -1 & -1 \\ 0 & 0 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} + \begin{bmatrix} 2\,\mathrm{e}^{-t} \\ 1 \\ 1 \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \mathrm{e}^{-t} & -2t\,\mathrm{e}^{-t} & t^2\mathrm{e}^{-t} \\ 0 & \mathrm{e}^{-t} & -t\,\mathrm{e}^{-t} \\ 0 & 0 & \mathrm{e}^{-t} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{x}_0 \\ &= \begin{bmatrix} \mathrm{e}^{-t} & -2t\,\mathrm{e}^{-t} & t^2\mathrm{e}^{-t} \\ 0 & \mathrm{e}^{-t} & -t\,\mathrm{e}^{-t} \\ 0 & 0 & \mathrm{e}^{-t} \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} \\ &= \begin{bmatrix} \mathrm{e}^{-t} - 2t\,\mathrm{e}^{-t} + t^2\mathrm{e}^{-t} \\ \mathrm{e}^{-t} - t\,\mathrm{e}^{-t} \\ \mathrm{e}^{-t} \end{bmatrix} \\ &= \begin{bmatrix} \mathrm{e}^{-t}(t-1)^2 \\ \mathrm{e}^{-t}(1-t) \\ \mathrm{e}^{-t} \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} \mathrm{e}^{t} & 2\,\mathrm{e}^{t}t & t^2\mathrm{e}^{t} \\ 0 & \mathrm{e}^{t} & \mathrm{e}^{t}t \\ 0 & 0 & \mathrm{e}^{t} \end{bmatrix} \end{aligned}$$

Hence

$$
\vec{x}_p(t) = \begin{bmatrix} e^{-t} & -2t\,e^{-t} & t^2 e^{-t} \\ 0 & e^{-t} & -t\,e^{-t} \\ 0 & 0 & e^{-t} \end{bmatrix} \int \left[\begin{bmatrix} e^{t} & 2\,e^{t} t & t^2 e^{t} \\ 0 & e^{t} & e^{t} t \\ 0 & 0 & e^{t} \end{bmatrix}\right] \left[\begin{bmatrix} 2\,e^{-t} \\ 1 \\ 1 \end{bmatrix}\right] dt
$$

$$
= \begin{bmatrix} e^{-t} & -2t\,e^{-t} & t^2 e^{-t} \\ 0 & e^{-t} & -t\,e^{-t} \\ 0 & 0 & e^{-t} \end{bmatrix} \begin{bmatrix} t(e^{t} t + 2) \\ e^{t} t \\ e^{t} \end{bmatrix}
$$

$$
= \begin{bmatrix} 2t\,e^{-t} \\ 0 \\ 1 \end{bmatrix}
$$

Hence the complete solution is

$$
\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
&= \begin{bmatrix} e^{-t}(t^2+1) \\ -e^{-t}(t-1) \\ e^{-t}+1 \end{bmatrix}
\end{aligned}
$$

31.10.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} -1 & -2 & 0 \\ 0 & -1 & -1 \\ 0 & 0 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} + \begin{bmatrix} 2\,e^{-t} \\ 1 \\ 1 \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A-\lambda I)=0$$

Expanding gives

$$\det\left(\begin{bmatrix}-1&-2&0\\0&-1&-1\\0&0&-1\end{bmatrix}-\lambda\begin{bmatrix}1&0&0\\0&1&0\\0&0&1\end{bmatrix}\right)=0$$

Therefore

$$\det\left(\begin{bmatrix}-1-\lambda&-2&0\\0&-1-\lambda&-1\\0&0&-1-\lambda\end{bmatrix}\right)=0$$

Since the matrix A is triangular matrix, then the determinant is the product of the elements along the diagonal. Therefore the above becomes

$$(-1-\lambda)(-1-\lambda)(-1-\lambda)=0$$

The roots of the above are the eigenvalues.

$$\lambda_1=-1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1=-1$

We need to solve $A\vec{v}=\lambda\vec{v}$ or $(A-\lambda I)\vec{v}=\vec{0}$ which becomes

$$\left(\begin{bmatrix}-1&-2&0\\0&-1&-1\\0&0&-1\end{bmatrix}-(-1)\begin{bmatrix}1&0&0\\0&1&0\\0&0&1\end{bmatrix}\right)\begin{bmatrix}v_1\\v_2\\v_3\end{bmatrix}=\begin{bmatrix}0\\0\\0\end{bmatrix}$$

$$\begin{bmatrix}0&-2&0\\0&0&-1\\0&0&0\end{bmatrix}\begin{bmatrix}v_1\\v_2\\v_3\end{bmatrix}=\begin{bmatrix}0\\0\\0\end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 0 & -2 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 0 & -2 & 0 \\ 0 & 0 & -1 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_1\}$ and the leading variables are $\{v_2, v_3\}$. Let $v_1 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_2 = 0, v_3 = 0\}$

Hence the solution is

$$\begin{bmatrix} t \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} t \\ 0 \\ 0 \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ v_2 \\ v_3 \end{bmatrix} = t \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
-1	3	1	Yes	$\begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. eigenvalue -1 is real and repated eigenvalue of multiplicity 3.There are three possible cases that can happen. This is illustrated in this diagram

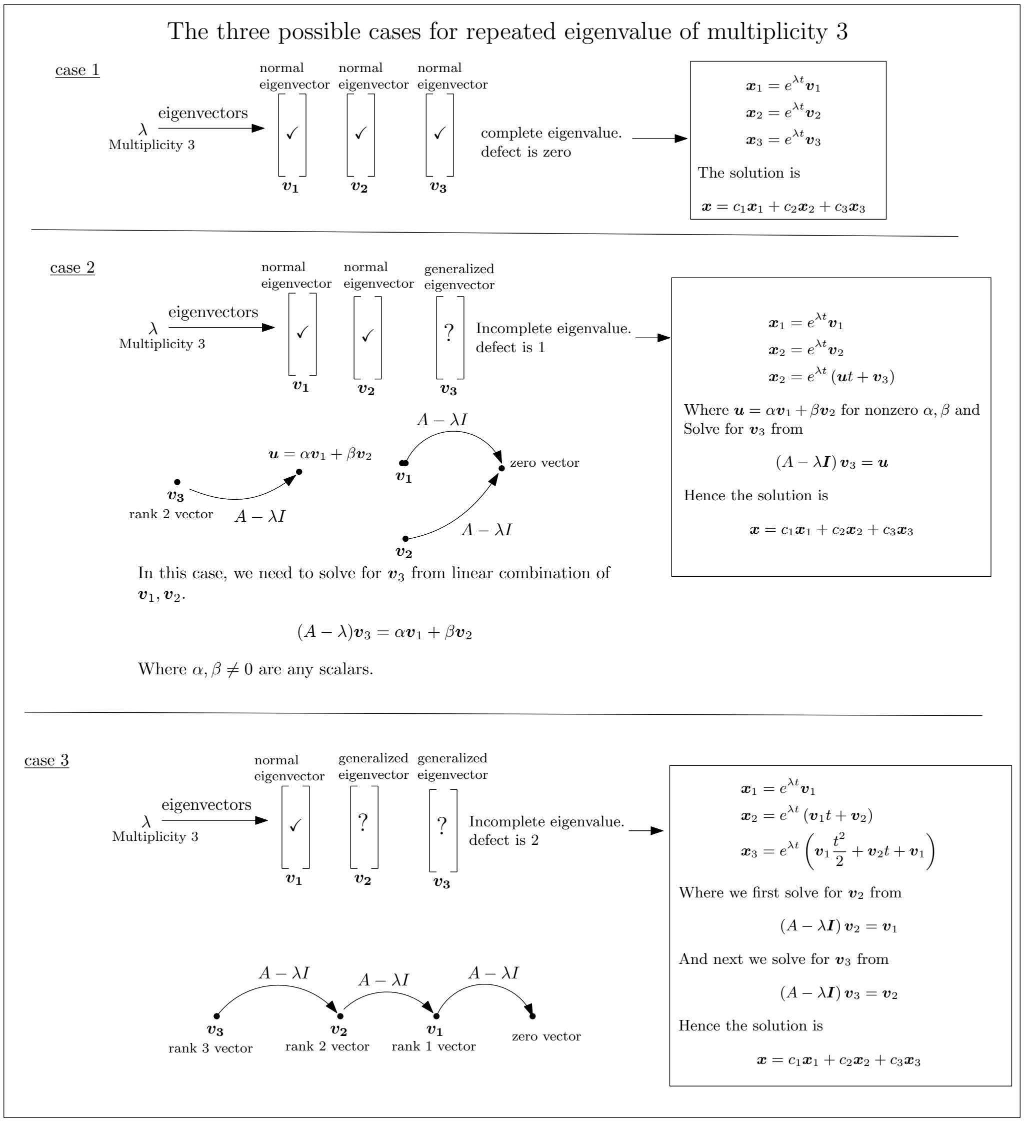

Figure 859: Possible case for repeated λ of multiplicity 3

This eigenvalue has algebraic multiplicity of 3, and geometric multiplicity 1, therefore this is defective eigenvalue. The defect is 2. This falls into case 3 shown above. First we find generalized eigenvector $\vec{v}_2$ of rank 2 and then use this to find generalized eigenvector $\vec{v}_3$ of rank 3.$\vec{v}_2$ is found by solving

$$(A - \lambda I)\, \vec{v}_2 = \vec{v}_1$$

Where $\vec{v}_1$ is the normal (rank 1) eigenvector found above. Hence

$$\left(\begin{bmatrix}-1 & -2 & 0\\ 0 & -1 & -1\\ 0 & 0 & -1\end{bmatrix} - (-1)\begin{bmatrix}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{bmatrix}\right)\begin{bmatrix}v_1\\ v_2\\ v_3\end{bmatrix} = \begin{bmatrix}1\\ 0\\ 0\end{bmatrix}$$

$$\begin{bmatrix}0 & -2 & 0\\ 0 & 0 & -1\\ 0 & 0 & 0\end{bmatrix}\begin{bmatrix}v_1\\ v_2\\ v_3\end{bmatrix} = \begin{bmatrix}1\\ 0\\ 0\end{bmatrix}$$

Solving for $\vec{v}_2$ gives

$$\vec{v}_2 = \begin{bmatrix}1\\ -\frac{1}{2}\\ 0\end{bmatrix}$$

Now $\vec{v}_3$ is found by solving

$$(A - \lambda I)\,\vec{v}_3 = \vec{v}_2$$

Where $\vec{v}_2$ is the (rank 2) generalized eigenvector found above. Hence

$$\left(\begin{bmatrix}-1 & -2 & 0\\ 0 & -1 & -1\\ 0 & 0 & -1\end{bmatrix} - (-1)\begin{bmatrix}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{bmatrix}\right)\begin{bmatrix}v_1\\ v_2\\ v_3\end{bmatrix} = \begin{bmatrix}1\\ -\frac{1}{2}\\ 0\end{bmatrix}$$

$$\begin{bmatrix}0 & -2 & 0\\ 0 & 0 & -1\\ 0 & 0 & 0\end{bmatrix}\begin{bmatrix}v_1\\ v_2\\ v_3\end{bmatrix} = \begin{bmatrix}1\\ -\frac{1}{2}\\ 0\end{bmatrix}$$

Solving for $\vec{v}_3$ gives

$$\vec{v}_3 = \begin{bmatrix}1\\ -\frac{1}{2}\\ \frac{1}{2}\end{bmatrix}$$

We have found three generalized eigenvectors for eigenvalue -1. Therefore the three basis solutions associated with this eigenvalue are

$$
\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^{\lambda t} \\
&= \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} \mathrm{e}^{-t} \\
&= \begin{bmatrix} \mathrm{e}^{-t} \\ 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

And

$$
\begin{aligned}
\vec{x}_2(t) &= e^{\lambda t}(\vec{v}_1 t + \vec{v}_2) \\
&= \mathrm{e}^{-t}\left(\begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} t + \begin{bmatrix} 1 \\ -\frac{1}{2} \\ 0 \end{bmatrix}\right) \\
&= \begin{bmatrix} \mathrm{e}^{-t}(t+1) \\ -\frac{\mathrm{e}^{-t}}{2} \\ 0 \end{bmatrix}
\end{aligned}
$$

And

$$
\begin{aligned}
\vec{x}_3(t) &= \left(\vec{v}_1 \frac{t^2}{2} + \vec{v}_2 t + \vec{v}_3\right) e^{\lambda t} \\
&= \left(\begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} \frac{t^2}{2} + \begin{bmatrix} 1 \\ -\frac{1}{2} \\ 0 \end{bmatrix} t + \begin{bmatrix} 1 \\ -\frac{1}{2} \\ \frac{1}{2} \end{bmatrix}\right) \mathrm{e}^{-t} \\
&= \begin{bmatrix} \frac{\mathrm{e}^{-t}(t^2+2t+2)}{2} \\ -\frac{\mathrm{e}^{-t}(t+1)}{2} \\ \frac{\mathrm{e}^{-t}}{2} \end{bmatrix}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t) + c_3 \vec{x}_3(t)
$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = c_1 \begin{bmatrix} \mathrm{e}^{-t} \\ 0 \\ 0 \end{bmatrix} + c_2 \begin{bmatrix} \mathrm{e}^{-t}(t+1) \\ -\frac{\mathrm{e}^{-t}}{2} \\ 0 \end{bmatrix} + c_3 \begin{bmatrix} \mathrm{e}^{-t}\left(\frac{1}{2}t^2+t+1\right) \\ \mathrm{e}^{-t}\left(-\frac{t}{2}-\frac{1}{2}\right) \\ \frac{\mathrm{e}^{-t}}{2} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} \mathrm{e}^{-t} & \mathrm{e}^{-t}(t+1) & \mathrm{e}^{-t}\left(\frac{1}{2}t^2+t+1\right) \\ 0 & -\frac{\mathrm{e}^{-t}}{2} & \mathrm{e}^{-t}\left(-\frac{t}{2}-\frac{1}{2}\right) \\ 0 & 0 & \frac{\mathrm{e}^{-t}}{2} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1}\vec{G}(t)\,dt$$

But

$$\Phi^{-1} = \begin{bmatrix} \mathrm{e}^{t} & 2\,\mathrm{e}^{t}(t+1) & \mathrm{e}^{t}t(t+2) \\ 0 & -2\,\mathrm{e}^{t} & -2\,\mathrm{e}^{t}(t+1) \\ 0 & 0 & 2\,\mathrm{e}^{t} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} e^{-t} & e^{-t}(t+1) & e^{-t}\left(\frac{1}{2}t^2+t+1\right) \\ 0 & -\frac{e^{-t}}{2} & e^{-t}\left(-\frac{t}{2}-\frac{1}{2}\right) \\ 0 & 0 & \frac{e^{-t}}{2} \end{bmatrix} \int \begin{bmatrix} e^{t} & 2e^{t}(t+1) & e^{t}t(t+2) \\ 0 & -2e^{t} & -2e^{t}(t+1) \\ 0 & 0 & 2e^{t} \end{bmatrix} \begin{bmatrix} 2e^{-t} \\ 1 \\ 1 \end{bmatrix} dt$$

$$= \begin{bmatrix} e^{-t} & e^{-t}(t+1) & e^{-t}\left(\frac{1}{2}t^2+t+1\right) \\ 0 & -\frac{e^{-t}}{2} & e^{-t}\left(-\frac{t}{2}-\frac{1}{2}\right) \\ 0 & 0 & \frac{e^{-t}}{2} \end{bmatrix} \int \begin{bmatrix} 2+(t^2+4t+2)e^{t} \\ -2e^{t}(t+2) \\ 2e^{t} \end{bmatrix} dt$$

$$= \begin{bmatrix} e^{-t} & e^{-t}(t+1) & e^{-t}\left(\frac{1}{2}t^2+t+1\right) \\ 0 & -\frac{e^{-t}}{2} & e^{-t}\left(-\frac{t}{2}-\frac{1}{2}\right) \\ 0 & 0 & \frac{e^{-t}}{2} \end{bmatrix} \begin{bmatrix} (2+e^{t}(t+2))\,t \\ -2e^{t}(t+1) \\ 2e^{t} \end{bmatrix}$$

$$= \begin{bmatrix} 2t\,e^{-t} \\ 0 \\ 1 \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} c_1 e^{-t} \\ 0 \\ 0 \end{bmatrix} + \begin{bmatrix} c_2 e^{-t}(t+1) \\ -\frac{c_2 e^{-t}}{2} \\ 0 \end{bmatrix} + \begin{bmatrix} c_3 e^{-t}\left(\frac{1}{2}t^2+t+1\right) \\ c_3 e^{-t}\left(-\frac{t}{2}-\frac{1}{2}\right) \\ \frac{c_3 e^{-t}}{2} \end{bmatrix} + \begin{bmatrix} 2t\,e^{-t} \\ 0 \\ 1 \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} \frac{e^{-t}(c_3t^2+(2c_2+2c_3+4)t+2c_1+2c_2+2c_3)}{2} \\ -\frac{e^{-t}(c_3t+c_2+c_3)}{2} \\ \frac{c_3 e^{-t}}{2}+1 \end{bmatrix}$$

Since initial conditions are given, the solution above needs to be updated by solving for the constants of integrations using the given initial conditions

$$\begin{bmatrix} x(0)=1 \\ y(0)=1 \\ z(0)=1 \end{bmatrix} \tag{1}$$

Substituting initial conditions into the above solution at $t = 0$ gives

$$\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} c_1 + c_2 + c_3 \\ -\frac{c_2}{2} - \frac{c_3}{2} \\ \frac{c_3}{2} + 1 \end{bmatrix}$$

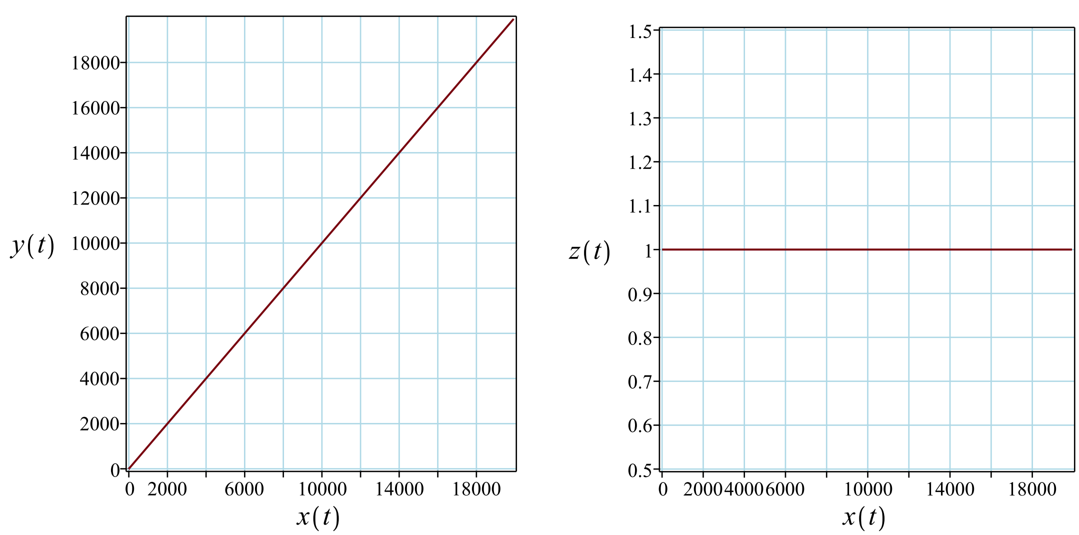
Solving for the constants of integrations gives

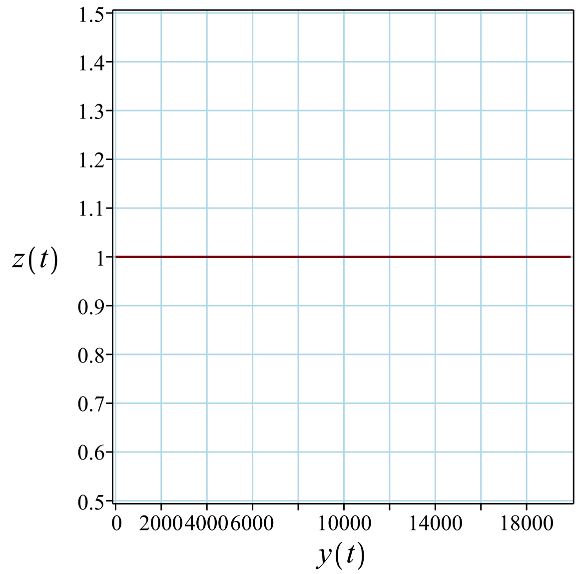
$$\begin{bmatrix} c_1 = 3 \\ c_2 = -2 \\ c_3 = 0 \end{bmatrix}$$

Substituting these constants back in original solution in Eq. (1) gives

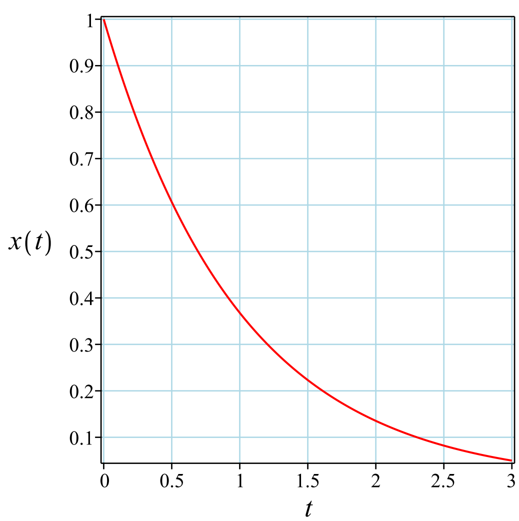
$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} \mathrm{e}^{-t} \\ \mathrm{e}^{-t} \\ 1 \end{bmatrix}$$

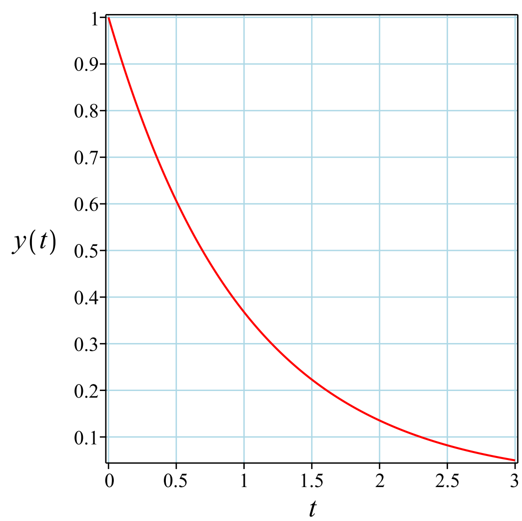
The following are plots of each solution against another.

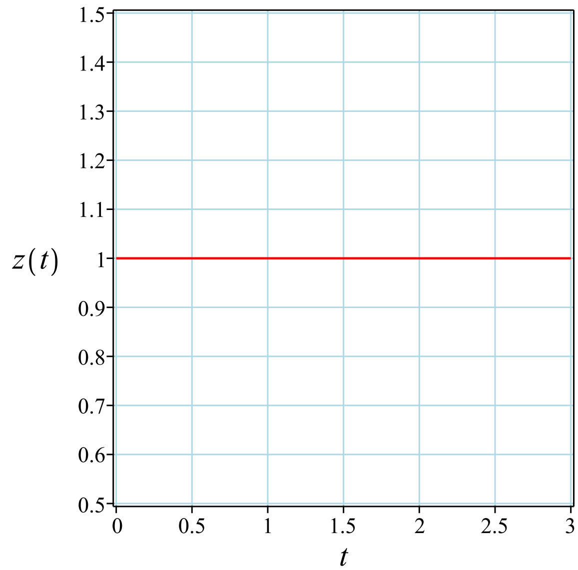




The following are plots of each solution.







✓ Solution by Maple

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 5x(t) + 4y(t) \\
y'(t) &= x(t) + 2y(t)
\end{aligned}
$$

32.1.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 5 & 4 \\ 1 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

For the above matrix A, the matrix exponential can be found to be

$$
e^{At} = \begin{bmatrix} \frac{e^t}{5} + \frac{4\,e^{6t}}{5} & \frac{4\,e^{6t}}{5} - \frac{4\,e^t}{5} \\ \frac{e^{6t}}{5} - \frac{e^t}{5} & \frac{4\,e^t}{5} + \frac{e^{6t}}{5} \end{bmatrix}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{e^t}{5}+\frac{4\,e^{6t}}{5} & \frac{4\,e^{6t}}{5}-\frac{4\,e^t}{5} \\ \frac{e^{6t}}{5}-\frac{e^t}{5} & \frac{4\,e^t}{5}+\frac{e^{6t}}{5} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{e^t}{5}+\frac{4\,e^{6t}}{5}\right)c_1 + \left(\frac{4\,e^{6t}}{5}-\frac{4\,e^t}{5}\right)c_2 \\ \left(\frac{e^{6t}}{5}-\frac{e^t}{5}\right)c_1 + \left(\frac{4\,e^t}{5}+\frac{e^{6t}}{5}\right)c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(4c_1+4c_2)e^{6t}}{5} + \frac{e^t(c_1-4c_2)}{5} \\ \frac{(c_1+c_2)e^{6t}}{5} - \frac{e^t(c_1-4c_2)}{5} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

32.1.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 5 & 4 \\ 1 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 5 & 4 \\ 1 & 2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 5-\lambda & 4 \\ 1 & 2-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 7\lambda + 6 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 6$$
$$\lambda_2 = 1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue
6	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 5 & 4 \\ 1 & 2 \end{bmatrix} - (1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 4 & 4 \\ 1 & 1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 4 & 4 & 0 \\ 1 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{4} \Longrightarrow \left[\begin{array}{cc|c} 4 & 4 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 4 & 4 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 6$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 5 & 4 \\ 1 & 2 \end{bmatrix} - (6) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} -1 & 4 \\ 1 & -4 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -1 & 4 & 0 \\ 1 & -4 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} -1 & 4 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & 4 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 4t\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} 4t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} 4 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} 4 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
6	1	1	No	$\begin{bmatrix} 4 \\ 1 \end{bmatrix}$
1	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 6 is real and distinct then the

corresponding eigenvector solution is

$$\vec{x}_1(t) = \vec{v}_1 e^{6t}$$
$$= \begin{bmatrix} 4 \\ 1 \end{bmatrix} e^{6t}$$

Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{t}$$
$$= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{t}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} 4\,\mathrm{e}^{6t} \\ \mathrm{e}^{6t} \end{bmatrix} + c_2 \begin{bmatrix} -\mathrm{e}^{t} \\ \mathrm{e}^{t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} 4c_1 \mathrm{e}^{6t} - c_2 \mathrm{e}^{t} \\ c_1 \mathrm{e}^{6t} + c_2 \mathrm{e}^{t} \end{bmatrix}$$

The following is the phase plot of the system.

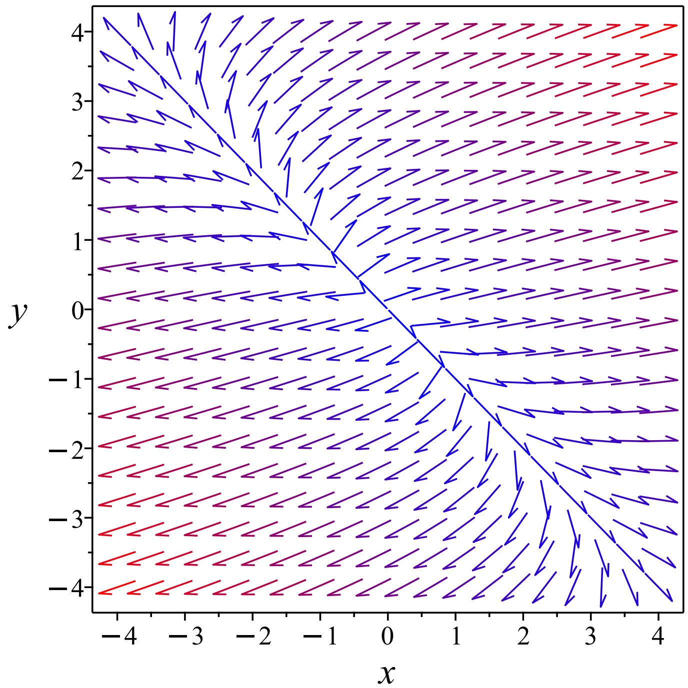

Figure 860: Phase plot

32.1.3 Maple step by step solution

Let's solve

$[x'(t) = 5x(t) + 4y(t), y'(t) = x(t) + 2y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 5 & 4 \\ 1 & 2 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 5 & 4 \\ 1 & 2 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 5 & 4 \\ 1 & 2 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right], \left[6, \begin{bmatrix} 4 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^{t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[6, \begin{bmatrix} 4 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \mathrm{e}^{6t} \cdot \begin{bmatrix} 4 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{x} = c_1 \vec{x}_1 + c_2 \vec{x}_2$$

- Substitute solutions into the general solution

$$\vec{x} = c_1 \mathrm{e}^{t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix} + c_2 \mathrm{e}^{6t} \cdot \begin{bmatrix} 4 \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -c_1 e^t + 4c_2 e^{6t} \\ c_1 e^t + c_2 e^{6t} \end{bmatrix}$$

- Solution to the system of ODEs

  $\{x(t) = -c_1 e^t + 4c_2 e^{6t}, y(t) = c_1 e^t + c_2 e^{6t}\}$

✓ Solution by Maple

Time used: 0.015 (sec). Leaf size: 32

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = 6x(t) + y(t)$$
$$y'(t) = 4x(t) + 3y(t)$$

32.2.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 6 & 1 \\ 4 & 3 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{e^{2t}}{5} + \frac{4\,e^{7t}}{5} & \frac{e^{7t}}{5} - \frac{e^{2t}}{5} \\ \frac{4\,e^{7t}}{5} - \frac{4\,e^{2t}}{5} & \frac{4\,e^{2t}}{5} + \frac{e^{7t}}{5} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{e^{2t}}{5}+\frac{4\,e^{7t}}{5} & \frac{e^{7t}}{5}-\frac{e^{2t}}{5} \\ \frac{4\,e^{7t}}{5}-\frac{4\,e^{2t}}{5} & \frac{4\,e^{2t}}{5}+\frac{e^{7t}}{5} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{e^{2t}}{5}+\frac{4\,e^{7t}}{5}\right)c_1+\left(\frac{e^{7t}}{5}-\frac{e^{2t}}{5}\right)c_2 \\ \left(\frac{4\,e^{7t}}{5}-\frac{4\,e^{2t}}{5}\right)c_1+\left(\frac{4\,e^{2t}}{5}+\frac{e^{7t}}{5}\right)c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(-c_2+c_1)e^{2t}}{5}+\frac{4\left(c_1+\frac{c_2}{4}\right)e^{7t}}{5} \\ \frac{(4c_2-4c_1)e^{2t}}{5}+\frac{4\left(c_1+\frac{c_2}{4}\right)e^{7t}}{5} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

32.2.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 6 & 1 \\ 4 & 3 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A-\lambda I\right)=0$$

Expanding gives

$$\det\left(\begin{bmatrix} 6 & 1 \\ 4 & 3 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 6-\lambda & 1 \\ 4 & 3-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 9\lambda + 14 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 7$$
$$\lambda_2 = 2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
2	1	real eigenvalue
7	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 6 & 1 \\ 4 & 3 \end{bmatrix} - (2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 4 & 1 \\ 4 & 1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 4 & 1 & 0 \\ 4 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 4 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 4 & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{t}{4}\right\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 4 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 7$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 6 & 1 \\ 4 & 3 \end{bmatrix} - (7) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -1 & 1 \\ 4 & -4 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -1 & 1 & 0 \\ 4 & -4 & 0 \end{array}\right]$$

$$R_2 = R_2 + 4R_1 \Longrightarrow \left[\begin{array}{cc|c} -1 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
7	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$
2	1	1	No	$\begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 7 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^{7t} \\
&= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{7t}
\end{aligned}
$$

Since eigenvalue 2 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_2(t) &= \vec{v}_2 e^{2t} \\
&= \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix} e^{2t}
\end{aligned}
$$

Therefore the final solution is

$$
\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)
$$

Which is written as

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \mathrm{e}^{7t} \\ \mathrm{e}^{7t} \end{bmatrix} + c_2 \begin{bmatrix} -\frac{\mathrm{e}^{2t}}{4} \\ \mathrm{e}^{2t} \end{bmatrix}
$$

Which becomes

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 \mathrm{e}^{7t} - \frac{c_2 \mathrm{e}^{2t}}{4} \\ c_1 \mathrm{e}^{7t} + c_2 \mathrm{e}^{2t} \end{bmatrix}
$$

The following is the phase plot of the system.

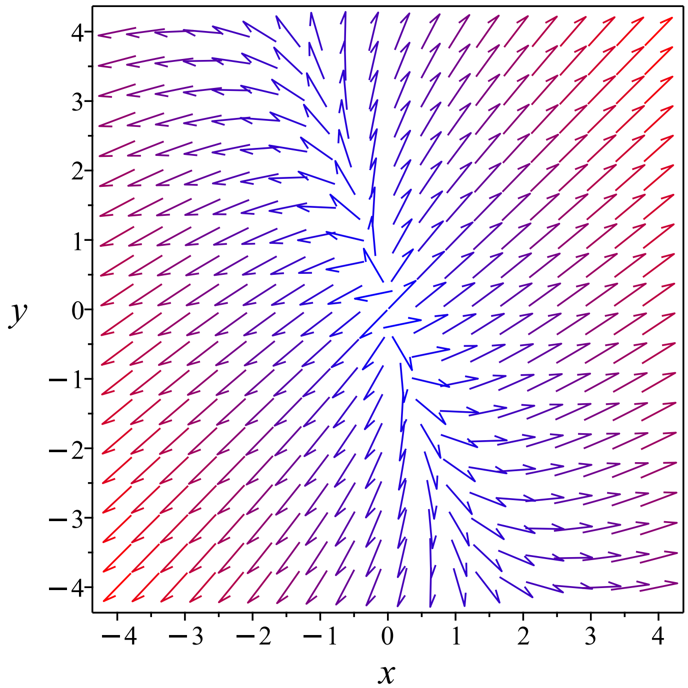

Figure 861: Phase plot

32.2.3 Maple step by step solution

Let's solve

$$[x'(t) = 6x(t) + y(t), y'(t) = 4x(t) + 3y(t)]$$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 6 & 1 \\ 4 & 3 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 6 & 1 \\ 4 & 3 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 6 & 1 \\ 4 & 3 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[2, \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}\right], \left[7, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = e^{2t} \cdot \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[7, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = e^{7t} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{x} = c_1 \vec{x}_1 + c_2 \vec{x}_2$$

- Substitute solutions into the general solution

$$\vec{x} = c_1 e^{2t} \cdot \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix} + c_2 e^{7t} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{c_1 e^{2t}}{4} + c_2 e^{7t} \\ c_1 e^{2t} + c_2 e^{7t} \end{bmatrix}$$

- Solution to the system of ODEs

  $$\left\{x(t) = -\frac{c_1 e^{2t}}{4} + c_2 e^{7t}, y(t) = c_1 e^{2t} + c_2 e^{7t}\right\}$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = 2x(t) - 4y(t) + 1$$
$$y'(t) = -x(t) + 5y(t)$$

32.3.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 2 & -4 \\ -1 & 5 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \left[\begin{array}{cc} \frac{4\,e^{t}}{5}+\frac{e^{6t}}{5} & -\frac{4\,e^{6t}}{5}+\frac{4\,e^{t}}{5} \\ -\frac{e^{6t}}{5}+\frac{e^{t}}{5} & \frac{e^{t}}{5}+\frac{4\,e^{6t}}{5} \end{array}\right]$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \left[\begin{array}{cc} \frac{4\,e^{t}}{5}+\frac{e^{6t}}{5} & -\frac{4\,e^{6t}}{5}+\frac{4\,e^{t}}{5} \\ -\frac{e^{6t}}{5}+\frac{e^{t}}{5} & \frac{e^{t}}{5}+\frac{4\,e^{6t}}{5} \end{array}\right]\left[\begin{array}{c} c_1 \\ c_2 \end{array}\right] \\
&= \left[\begin{array}{c} \left(\frac{4\,e^{t}}{5}+\frac{e^{6t}}{5}\right)c_1+\left(-\frac{4\,e^{6t}}{5}+\frac{4\,e^{t}}{5}\right)c_2 \\ \left(-\frac{e^{6t}}{5}+\frac{e^{t}}{5}\right)c_1+\left(\frac{e^{t}}{5}+\frac{4\,e^{6t}}{5}\right)c_2 \end{array}\right] \\
&= \left[\begin{array}{c} \frac{(c_1-4c_2)e^{6t}}{5}+\frac{4\,e^{t}(c_1+c_2)}{5} \\ \frac{(-c_1+4c_2)e^{6t}}{5}+\frac{e^{t}(c_1+c_2)}{5} \end{array}\right]
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At}\int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \left[\begin{array}{cc} \frac{e^{-6t}(4\,e^{5t}+1)}{5} & \frac{4\,e^{-6t}(e^{5t}-1)}{5} \\ \frac{e^{-6t}(e^{5t}-1)}{5} & \frac{e^{-6t}(e^{5t}+4)}{5} \end{array}\right]
\end{aligned}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \left[\begin{array}{cc} \frac{4\,e^{t}}{5}+\frac{e^{6t}}{5} & -\frac{4\,e^{6t}}{5}+\frac{4\,e^{t}}{5} \\ -\frac{e^{6t}}{5}+\frac{e^{t}}{5} & \frac{e^{t}}{5}+\frac{4\,e^{6t}}{5} \end{array}\right]\int\left[\begin{array}{cc} \frac{e^{-6t}(4\,e^{5t}+1)}{5} & \frac{4\,e^{-6t}(e^{5t}-1)}{5} \\ \frac{e^{-6t}(e^{5t}-1)}{5} & \frac{e^{-6t}(e^{5t}+4)}{5} \end{array}\right]\left[\begin{array}{c} 1 \\ 0 \end{array}\right]dt \\
&= \left[\begin{array}{cc} \frac{4\,e^{t}}{5}+\frac{e^{6t}}{5} & -\frac{4\,e^{6t}}{5}+\frac{4\,e^{t}}{5} \\ -\frac{e^{6t}}{5}+\frac{e^{t}}{5} & \frac{e^{t}}{5}+\frac{4\,e^{6t}}{5} \end{array}\right]\left[\begin{array}{c} -\frac{e^{-6t}}{30}-\frac{4\,e^{-t}}{5} \\ -\frac{e^{-t}}{5}+\frac{e^{-6t}}{30} \end{array}\right] \\
&= \left[\begin{array}{c} -\frac{5}{6} \\ -\frac{1}{6} \end{array}\right]
\end{aligned}$$

Hence the complete solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$= \begin{bmatrix} \frac{(c_1-4c_2)e^{6t}}{5} + \frac{4\,e^t(c_1+c_2)}{5} - \frac{5}{6} \\ \frac{(-c_1+4c_2)e^{6t}}{5} + \frac{e^t(c_1+c_2)}{5} - \frac{1}{6} \end{bmatrix}$$

32.3.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 2 & -4 \\ -1 & 5 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 2 & -4 \\ -1 & 5 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 2-\lambda & -4 \\ -1 & 5-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 7\lambda + 6 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 6$$
$$\lambda_2 = 1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue
6	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & -4 \\ -1 & 5 \end{bmatrix} - (1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 1 & -4 \\ -1 & 4 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 & -4 & 0 \\ -1 & 4 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 & -4 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & -4 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 4t\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} 4t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} 4 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} 4 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 6$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & -4 \\ -1 & 5 \end{bmatrix} - (6) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -4 & -4 \\ -1 & -1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -4 & -4 & 0 \\ -1 & -1 & 0 \end{array} \right]$$

$$R_2 = R_2 - \frac{R_1}{4} \Longrightarrow \left[\begin{array}{cc|c} -4 & -4 & 0 \\ 0 & 0 & 0 \end{array} \right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -4 & -4 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
6	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$
1	1	1	No	$\begin{bmatrix} 4 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 6 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{6t} \\ &= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{6t} \end{aligned}$$

Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^t$$
$$= \begin{bmatrix} 4 \\ 1 \end{bmatrix} e^t$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -e^{6t} \\ e^{6t} \end{bmatrix} + c_2 \begin{bmatrix} 4\,e^t \\ e^t \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -e^{6t} & 4\,e^t \\ e^{6t} & e^t \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{e^{-6t}}{5} & \frac{4\,e^{-6t}}{5} \\ \frac{e^{-t}}{5} & \frac{e^{-t}}{5} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} -e^{6t} & 4\,e^{t} \\ e^{6t} & e^{t} \end{bmatrix} \int \begin{bmatrix} -\frac{e^{-6t}}{5} & \frac{4\,e^{-6t}}{5} \\ \frac{e^{-t}}{5} & \frac{e^{-t}}{5} \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} dt$$

$$= \begin{bmatrix} -e^{6t} & 4\,e^{t} \\ e^{6t} & e^{t} \end{bmatrix} \int \begin{bmatrix} -\frac{e^{-6t}}{5} \\ \frac{e^{-t}}{5} \end{bmatrix} dt$$

$$= \begin{bmatrix} -e^{6t} & 4\,e^{t} \\ e^{6t} & e^{t} \end{bmatrix} \begin{bmatrix} \frac{e^{-6t}}{30} \\ -\frac{e^{-t}}{5} \end{bmatrix}$$

$$= \begin{bmatrix} -\frac{5}{6} \\ -\frac{1}{6} \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -c_1 e^{6t} \\ c_1 e^{6t} \end{bmatrix} + \begin{bmatrix} 4c_2 e^{t} \\ c_2 e^{t} \end{bmatrix} + \begin{bmatrix} -\frac{5}{6} \\ -\frac{1}{6} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -c_1 e^{6t} + 4c_2 e^{t} - \frac{5}{6} \\ c_1 e^{6t} + c_2 e^{t} - \frac{1}{6} \end{bmatrix}$$

The following is the phase plot of the system.

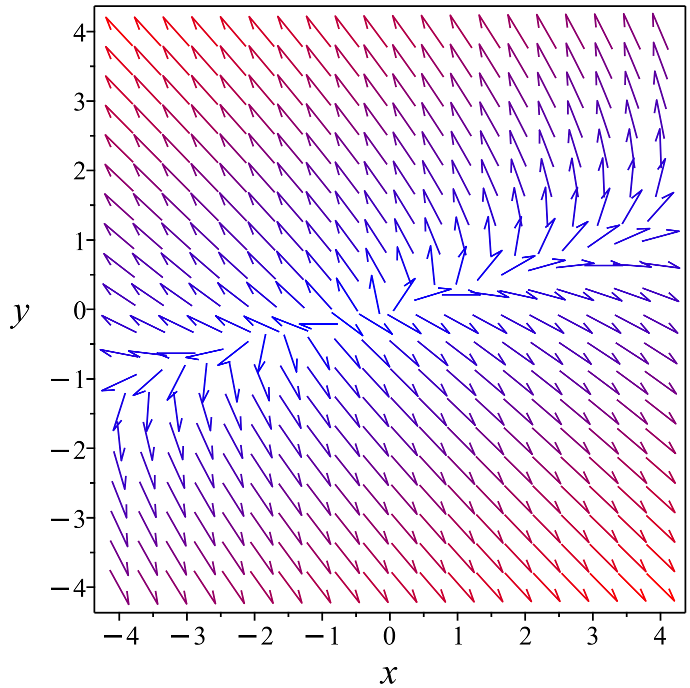

Figure 862: Phase plot

32.3.3 Maple step by step solution

Let's solve

$[x'(t) = 2x(t) - 4y(t) + 1, y'(t) = -x(t) + 5y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 2 & -4 \\ -1 & 5 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 2 & -4 \\ -1 & 5 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 2 & -4 \\ -1 & 5 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 4 \\ 1 \end{bmatrix}\right], \left[6, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 4 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^{t} \cdot \begin{bmatrix} 4 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[6, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \mathrm{e}^{6t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

$$\vec{x}(t) = c_1 \vec{x}_1 + c_2 \vec{x}_2 + \vec{x}_p(t)$$

☐ Fundamental matrix

  - Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(t)=\begin{bmatrix} 4\,e^{t} & -e^{6t} \\ e^{t} & e^{6t} \end{bmatrix}$$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0)=I$ where I is th

  $\Phi(t)=\phi(t)\cdot\phi(0)^{-1}$
- Substitute the value of $\phi(t)$ and $\phi(0)$

  $$\Phi(t)=\begin{bmatrix} 4\,e^{t} & -e^{6t} \\ e^{t} & e^{6t} \end{bmatrix}\cdot\begin{bmatrix} 4 & -1 \\ 1 & 1 \end{bmatrix}^{-1}$$
- Evaluate and simplify to get the fundamental matrix

  $$\Phi(t)=\begin{bmatrix} \frac{4\,e^{t}}{5}+\frac{e^{6t}}{5} & -\frac{4\,e^{6t}}{5}+\frac{4\,e^{t}}{5} \\ -\frac{e^{6t}}{5}+\frac{e^{t}}{5} & \frac{e^{t}}{5}+\frac{4\,e^{6t}}{5} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

  $\vec{x}_p(t)=\Phi(t)\cdot\vec{v}(t)$
- Take the derivative of the particular solution

  $\vec{x}_p'(t)=\Phi'(t)\cdot\vec{v}(t)+\Phi(t)\cdot\vec{v}'(t)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t)\cdot\vec{v}(t)+\Phi(t)\cdot\vec{v}'(t)=A\cdot\Phi(t)\cdot\vec{v}(t)+\vec{f}(t)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A\cdot\Phi(t)\cdot\vec{v}(t)+\Phi(t)\cdot\vec{v}'(t)=A\cdot\Phi(t)\cdot\vec{v}(t)+\vec{f}(t)$
- Cancel like terms

  $\Phi(t)\cdot\vec{v}'(t)=\vec{f}(t)$
- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(t)=\Phi(t)^{-1}\cdot\vec{f}(t)$
- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t)=\int_0^t \Phi(s)^{-1}\cdot\vec{f}(s)\,ds$
- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t)=\Phi(t)\cdot\left(\int_0^t \Phi(s)^{-1}\cdot\vec{f}(s)\,ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{x}_p(t) = \begin{bmatrix} \frac{4\,e^t}{5} - \frac{5}{6} + \frac{e^{6t}}{30} \\ -\frac{e^{6t}}{30} - \frac{1}{6} + \frac{e^t}{5} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \begin{bmatrix} \frac{4\,e^t}{5} - \frac{5}{6} + \frac{e^{6t}}{30} \\ -\frac{e^{6t}}{30} - \frac{1}{6} + \frac{e^t}{5} \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} 4c_1 e^t - c_2 e^{6t} + \frac{4\,e^t}{5} - \frac{5}{6} + \frac{e^{6t}}{30} \\ c_1 e^t + c_2 e^{6t} - \frac{e^{6t}}{30} - \frac{1}{6} + \frac{e^t}{5} \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = 4c_1 e^t - c_2 e^{6t} + \frac{4\,e^t}{5} - \frac{5}{6} + \frac{e^{6t}}{30}, y(t) = c_1 e^t + c_2 e^{6t} - \frac{e^{6t}}{30} - \frac{1}{6} + \frac{e^t}{5}\right\}$$

✓ Solution by Maple

Time used: 0.031 (sec). Leaf size: 34

```

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 3x(t) + y(t) + \mathrm{e}^{t} \\
y'(t) &= x(t) + 3y(t) - \mathrm{e}^{t}
\end{aligned}
$$

32.4.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 3 & 1 \\ 1 & 3 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \mathrm{e}^{t} \\ -\mathrm{e}^{t} \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{e^{2t}}{2} + \frac{e^{4t}}{2} & \frac{e^{4t}}{2} - \frac{e^{2t}}{2} \\ \frac{e^{4t}}{2} - \frac{e^{2t}}{2} & \frac{e^{2t}}{2} + \frac{e^{4t}}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned} \vec{x}_h(t) &= e^{At}\vec{c} \\ &= \begin{bmatrix} \frac{e^{2t}}{2} + \frac{e^{4t}}{2} & \frac{e^{4t}}{2} - \frac{e^{2t}}{2} \\ \frac{e^{4t}}{2} - \frac{e^{2t}}{2} & \frac{e^{2t}}{2} + \frac{e^{4t}}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\ &= \begin{bmatrix} \left(\frac{e^{2t}}{2} + \frac{e^{4t}}{2}\right) c_1 + \left(\frac{e^{4t}}{2} - \frac{e^{2t}}{2}\right) c_2 \\ \left(\frac{e^{4t}}{2} - \frac{e^{2t}}{2}\right) c_1 + \left(\frac{e^{2t}}{2} + \frac{e^{4t}}{2}\right) c_2 \end{bmatrix} \\ &= \begin{bmatrix} \frac{(-c_2+c_1)e^{2t}}{2} + \frac{e^{4t}(c_1+c_2)}{2} \\ \frac{(c_2-c_1)e^{2t}}{2} + \frac{e^{4t}(c_1+c_2)}{2} \end{bmatrix} \end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\, dt$$

But

$$\begin{aligned} e^{-At} &= (e^{At})^{-1} \\ &= \begin{bmatrix} \frac{e^{-4t}(1+e^{2t})}{2} & -\frac{e^{-4t}(e^{2t}-1)}{2} \\ -\frac{e^{-4t}(e^{2t}-1)}{2} & \frac{e^{-4t}(1+e^{2t})}{2} \end{bmatrix} \end{aligned}$$

Hence

$$\begin{aligned} \vec{x}_p(t) &= \begin{bmatrix} \frac{e^{2t}}{2} + \frac{e^{4t}}{2} & \frac{e^{4t}}{2} - \frac{e^{2t}}{2} \\ \frac{e^{4t}}{2} - \frac{e^{2t}}{2} & \frac{e^{2t}}{2} + \frac{e^{4t}}{2} \end{bmatrix} \int \begin{bmatrix} \frac{e^{-4t}(1+e^{2t})}{2} & -\frac{e^{-4t}(e^{2t}-1)}{2} \\ -\frac{e^{-4t}(e^{2t}-1)}{2} & \frac{e^{-4t}(1+e^{2t})}{2} \end{bmatrix} \begin{bmatrix} e^{t} \\ -e^{t} \end{bmatrix} dt \\ &= \begin{bmatrix} \frac{e^{2t}}{2} + \frac{e^{4t}}{2} & \frac{e^{4t}}{2} - \frac{e^{2t}}{2} \\ \frac{e^{4t}}{2} - \frac{e^{2t}}{2} & \frac{e^{2t}}{2} + \frac{e^{4t}}{2} \end{bmatrix} \begin{bmatrix} -e^{-t} \\ e^{-t} \end{bmatrix} \\ &= \begin{bmatrix} -e^{t} \\ e^{t} \end{bmatrix} \end{aligned}$$

Hence the complete solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$= \begin{bmatrix} \frac{(-c_2+c_1)\mathrm{e}^{2t}}{2} + \frac{\mathrm{e}^{4t}(c_1+c_2)}{2} - \mathrm{e}^t \\ \frac{(c_2-c_1)\mathrm{e}^{2t}}{2} + \frac{\mathrm{e}^{4t}(c_1+c_2)}{2} + \mathrm{e}^t \end{bmatrix}$$

32.4.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 3 & 1 \\ 1 & 3 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \mathrm{e}^t \\ -\mathrm{e}^t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 3 & 1 \\ 1 & 3 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 3-\lambda & 1 \\ 1 & 3-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 6\lambda + 8 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 2$$
$$\lambda_2 = 4$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
2	1	real eigenvalue
4	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & 1 \\ 1 & 3 \end{bmatrix} - (2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 & 1 & 0 \\ 1 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 4$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & 1 \\ 1 & 3 \end{bmatrix} - (4) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -1 & 1 & 0 \\ 1 & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} -1 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
2	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$
4	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 2 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{2t} \\ &= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{2t} \end{aligned}$$

Since eigenvalue 4 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{4t} \\ &= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{4t}\end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\mathrm{e}^{2t} \\ \mathrm{e}^{2t} \end{bmatrix} + c_2 \begin{bmatrix} \mathrm{e}^{4t} \\ \mathrm{e}^{4t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -\mathrm{e}^{2t} & \mathrm{e}^{4t} \\ \mathrm{e}^{2t} & \mathrm{e}^{4t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{\mathrm{e}^{-2t}}{2} & \frac{\mathrm{e}^{-2t}}{2} \\ \frac{\mathrm{e}^{-4t}}{2} & \frac{\mathrm{e}^{-4t}}{2} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} -e^{2t} & e^{4t} \\ e^{2t} & e^{4t} \end{bmatrix} \int \begin{bmatrix} -\frac{e^{-2t}}{2} & \frac{e^{-2t}}{2} \\ \frac{e^{-4t}}{2} & \frac{e^{-4t}}{2} \end{bmatrix} \begin{bmatrix} e^{t} \\ -e^{t} \end{bmatrix} dt$$
$$= \begin{bmatrix} -e^{2t} & e^{4t} \\ e^{2t} & e^{4t} \end{bmatrix} \int \begin{bmatrix} -e^{-t} \\ 0 \end{bmatrix} dt$$
$$= \begin{bmatrix} -e^{2t} & e^{4t} \\ e^{2t} & e^{4t} \end{bmatrix} \begin{bmatrix} e^{-t} \\ 0 \end{bmatrix}$$
$$= \begin{bmatrix} -e^{t} \\ e^{t} \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -c_1 e^{2t} \\ c_1 e^{2t} \end{bmatrix} + \begin{bmatrix} c_2 e^{4t} \\ c_2 e^{4t} \end{bmatrix} + \begin{bmatrix} -e^{t} \\ e^{t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -c_1 e^{2t} + c_2 e^{4t} - e^{t} \\ c_1 e^{2t} + c_2 e^{4t} + e^{t} \end{bmatrix}$$

32.4.3 Maple step by step solution

Let's solve

$[x'(t) = 3x(t) + y(t) + e^{t}, y'(t) = x(t) + 3y(t) - e^{t}]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 3 & 1 \\ 1 & 3 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} e^{t} \\ -e^{t} \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 3 & 1 \\ 1 & 3 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} e^t \\ -e^t \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} e^t \\ -e^t \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 3 & 1 \\ 1 & 3 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[2, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right], \left[4, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = e^{2t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[4, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = e^{4t} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{x}_p($

  $\overrightarrow{x}(t) = c_1\overrightarrow{x}_1 + c_2\overrightarrow{x}_2 + \overrightarrow{x}_p(t)$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

  $$\phi(t) = \begin{bmatrix} -e^{2t} & e^{4t} \\ e^{2t} & e^{4t} \end{bmatrix}$$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

  $\Phi(t) = \phi(t) \cdot \phi(0)^{-1}$

- Substitute the value of $\phi(t)$ and $\phi(0)$

  $$\Phi(t) = \begin{bmatrix} -e^{2t} & e^{4t} \\ e^{2t} & e^{4t} \end{bmatrix} \cdot \begin{bmatrix} -1 & 1 \\ 1 & 1 \end{bmatrix}^{-1}$$

- Evaluate and simplify to get the fundamental matrix

  $$\Phi(t) = \begin{bmatrix} \frac{e^{2t}}{2} + \frac{e^{4t}}{2} & \frac{e^{4t}}{2} - \frac{e^{2t}}{2} \\ \frac{e^{4t}}{2} - \frac{e^{2t}}{2} & \frac{e^{2t}}{2} + \frac{e^{4t}}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

  $\overrightarrow{x}_p(t) = \Phi(t) \cdot \overrightarrow{v}(t)$

- Take the derivative of the particular solution

  $\overrightarrow{x}_p'(t) = \Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- Cancel like terms

  $\Phi(t) \cdot \overrightarrow{v}'(t) = \overrightarrow{f}(t)$

- Multiply by the inverse of the fundamental matrix

  $\overrightarrow{v}'(t) = \Phi(t)^{-1} \cdot \overrightarrow{f}(t)$

- Integrate to solve for $\overrightarrow{v}(t)$

$\vec{v}(t) = \int_0^t \Phi(s)^{-1} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \Phi(s)^{-1} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\vec{x}_p(t) = \begin{bmatrix} -e^t + e^{2t} \\ -e^{2t} + e^t \end{bmatrix}$$

- Plug particular solution back into general solution

  $$\vec{x}(t) = c_1 \vec{x}_1 + c_2 \vec{x}_2 + \begin{bmatrix} -e^t + e^{2t} \\ -e^{2t} + e^t \end{bmatrix}$$

- Substitute in vector of dependent variables

  $$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -c_1 e^{2t} + c_2 e^{4t} - e^t + e^{2t} \\ (c_1 - 1) e^{2t} + c_2 e^{4t} + e^t \end{bmatrix}$$

- Solution to the system of ODEs

  $\{x(t) = -c_1 e^{2t} + c_2 e^{4t} - e^t + e^{2t}, y(t) = (c_1 - 1) e^{2t} + c_2 e^{4t} + e^t\}$

✓ Solution by Maple

Problem number: 829.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 2x(t) + 4y(t) + \cos(t) \\
y'(t) &= -x(t) - 2y(t) + \sin(t)
\end{aligned}
$$

32.5.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 2 & 4 \\ -1 & -2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \cos(t) \\ \sin(t) \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} 1+2t & 4t \\ -t & 1-2t \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} 1+2t & 4t \\ -t & 1-2t \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} (1+2t)\,c_1 + 4tc_2 \\ -tc_1 + (1-2t)\,c_2 \end{bmatrix} \\
&= \begin{bmatrix} (2c_1 + 4c_2)\,t + c_1 \\ (-c_1 - 2c_2)\,t + c_2 \end{bmatrix}
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\, dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \begin{bmatrix} 1-2t & -4t \\ t & 1+2t \end{bmatrix}
\end{aligned}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} 1+2t & 4t \\ -t & 1-2t \end{bmatrix} \int \begin{bmatrix} 1-2t & -4t \\ t & 1+2t \end{bmatrix} \begin{bmatrix} \cos(t) \\ \sin(t) \end{bmatrix} dt \\
&= \begin{bmatrix} 1+2t & 4t \\ -t & 1-2t \end{bmatrix} \begin{bmatrix} (4t-2)\cos(t) + (-2t-3)\sin(t) \\ (t+2)\sin(t) - 2t\cos(t) \end{bmatrix} \\
&= \begin{bmatrix} -3\sin(t) - 2\cos(t) \\ 2\sin(t) \end{bmatrix}
\end{aligned}$$

Hence the complete solution is

$$\begin{aligned}\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\ &= \begin{bmatrix} 2(c_1 + 2c_2)\, t + c_1 - 3\sin(t) - 2\cos(t) \\ -(c_1 + 2c_2)\, t + c_2 + 2\sin(t) \end{bmatrix}\end{aligned}$$

32.5.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 2 & 4 \\ -1 & -2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} \cos(t) \\ \sin(t) \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 2 & 4 \\ -1 & -2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 2-\lambda & 4 \\ -1 & -2-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 0$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
0	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 0$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & 4 \\ -1 & -2 \end{bmatrix} - (0)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 2 & 4 \\ -1 & -2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2 & 4 & 0 \\ -1 & -2 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{2} \Longrightarrow \left[\begin{array}{cc|c} 2 & 4 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & 4 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -2t\}$

Hence the solution is

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -2t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = t \begin{bmatrix} -2 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} v_1 \\ t \end{bmatrix} = \begin{bmatrix} -2 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
0	2	1	Yes	$\begin{bmatrix} -2 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. eigenvalue 0 is real and repated eigenvalue of multiplicity 2.There are two possible cases that can happen. This is illustrated in this diagram

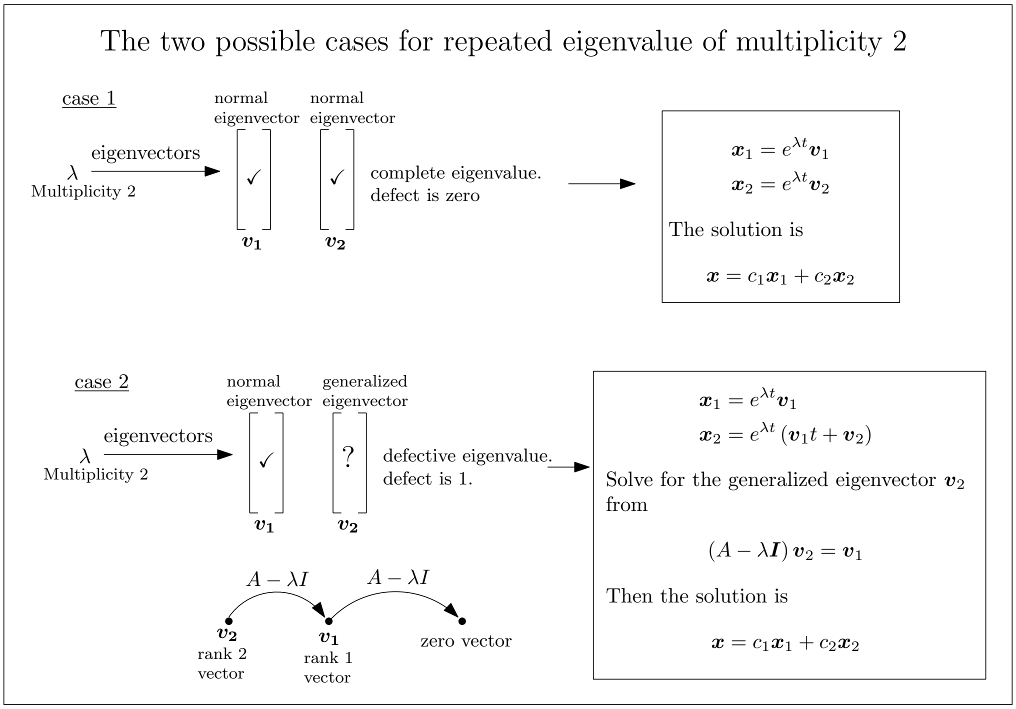

Figure 863: Possible case for repeated λ of multiplicity 2

This eigenvalue has algebraic multiplicity of 2, and geometric multiplicity 1, therefore this is defective eigenvalue. The defect is 1. This falls into case 2 shown above. We need to generate the missing additonal generalized eigevector $\vec{v}_2$ by solving

$$(A - \lambda I)\,\vec{v}_2 = \vec{v}_1$$

Where $\vec{v}_1$ is the normal (rank 1) eigenvector found above. Hence we need to solve

$$\left(\begin{bmatrix} 2 & 4 \\ -1 & -2 \end{bmatrix} - (0) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} -2 \\ 1 \end{bmatrix}$$

$$\begin{bmatrix} 2 & 4 \\ -1 & -2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} -2 \\ 1 \end{bmatrix}$$

Solving for $\vec{v}_2$ gives

$$\vec{v}_2 = \begin{bmatrix} -3 \\ 1 \end{bmatrix}$$

We have found two generalized eigenvectors for eigenvalue 0. Therefore the two basis solution associated with this eigenvalue are

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^{\lambda t} \\ &= \begin{bmatrix} -2 \\ 1 \end{bmatrix} 1 \\ &= \begin{bmatrix} -2 \\ 1 \end{bmatrix}\end{aligned}$$

And

$$\begin{aligned}\vec{x}_2(t) &= (\vec{v}_1 t + \vec{v}_2)\, e^{\lambda t} \\ &= \left(\begin{bmatrix} -2 \\ 1 \end{bmatrix} t + \begin{bmatrix} -3 \\ 1 \end{bmatrix} \right) 1 \\ &= \begin{bmatrix} -2t - 3 \\ t + 1 \end{bmatrix}\end{aligned}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -2 \\ 1 \end{bmatrix} + c_2 \begin{bmatrix} -2t - 3 \\ t + 1 \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -2 & -2t - 3 \\ 1 & t + 1 \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} t+1 & 2t+3 \\ -1 & -2 \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} -2 & -2t-3 \\ 1 & t+1 \end{bmatrix} \int \begin{bmatrix} t+1 & 2t+3 \\ -1 & -2 \end{bmatrix} \begin{bmatrix} \cos(t) \\ \sin(t) \end{bmatrix} dt \\
&= \begin{bmatrix} -2 & -2t-3 \\ 1 & t+1 \end{bmatrix} \int \begin{bmatrix} (t+1)\cos(t) + (2t+3)\sin(t) \\ -\cos(t) - 2\sin(t) \end{bmatrix} dt \\
&= \begin{bmatrix} -2 & -2t-3 \\ 1 & t+1 \end{bmatrix} \begin{bmatrix} (-2t-2)\cos(t) + \sin(t)(t+3) \\ -\sin(t) + 2\cos(t) \end{bmatrix} \\
&= \begin{bmatrix} -3\sin(t) - 2\cos(t) \\ 2\sin(t) \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -2c_1 \\ c_1 \end{bmatrix} + \begin{bmatrix} c_2(-2t-3) \\ c_2(t+1) \end{bmatrix} + \begin{bmatrix} -3\sin(t) - 2\cos(t) \\ 2\sin(t) \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -2c_1 + c_2(-2t-3) - 3\sin(t) - 2\cos(t) \\ c_2t + 2\sin(t) + c_1 + c_2 \end{bmatrix}$$

Problem number: 830.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{x' + 3x = e^{-2t}}$$

With initial conditions

$$[x(0) = 0]$$

33.1.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x' + p(t)x = q(t)$$

Where here

$$\begin{aligned} p(t) &= 3 \\ q(t) &= e^{-2t} \end{aligned}$$

Hence the ode is

$$x' + 3x = e^{-2t}$$

The domain of $p(t) = 3$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = e^{-2t}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

33.1.2 Solving as laplace ode

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\mathcal{L}(x') = sY(s) - x(0)$$

The given ode now becomes an algebraic equation in the Laplace domain

$$sY(s) - x(0) + 3Y(s) = \frac{1}{s+2} \tag{1}$$

Replacing initial condition gives

$$sY(s) + 3Y(s) = \frac{1}{s+2}$$

Solving for $Y(s)$ gives

$$Y(s) = \frac{1}{(s+2)(s+3)}$$

Applying partial fractions decomposition results in

$$Y(s) = \frac{1}{s+2} - \frac{1}{s+3}$$

The inverse Laplace of each term above is now found, which gives

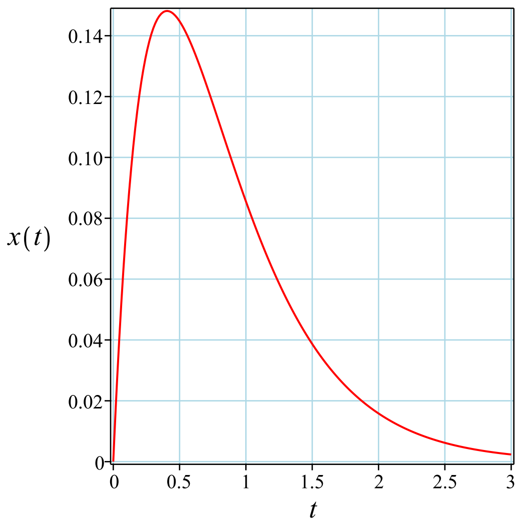
$$\mathcal{L}^{-1}\left(\frac{1}{s+2}\right) = e^{-2t}$$
$$\mathcal{L}^{-1}\left(-\frac{1}{s+3}\right) = -e^{-3t}$$

Adding the above results and simplifying gives

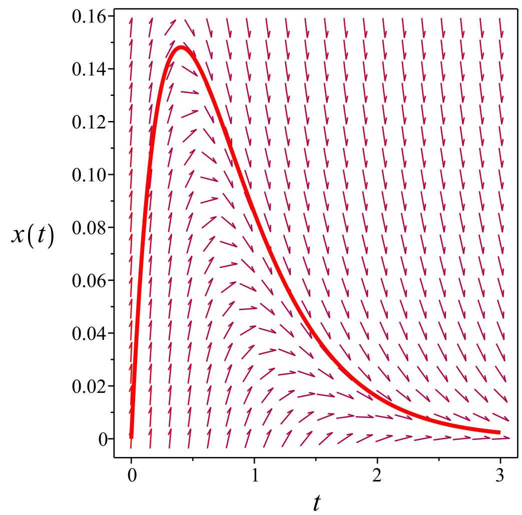
$$x = -e^{-3t} + e^{-2t}$$

Summary
The solution(s) found are the following

$$x = -e^{-3t} + e^{-2t} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$x = -e^{-3t} + e^{-2t}$$

Verified OK.

33.1.3 Maple step by step solution

Let's solve

$[x' + 3x = e^{-2t}, x(0) = 0]$

- Highest derivative means the order of the ODE is 1

  x'

- Isolate the derivative

  $x' = -3x + e^{-2t}$

- Group terms with x on the lhs of the ODE and the rest on the rhs of the ODE

  $x' + 3x = \mathrm{e}^{-2t}$
- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t) \left(x' + 3x\right) = \mu(t)\,\mathrm{e}^{-2t}$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,x)$

  $\mu(t) \left(x' + 3x\right) = \mu'(t)\,x + \mu(t)\,x'$
- Isolate $\mu'(t)$

  $\mu'(t) = 3\mu(t)$
- Solve to find the integrating factor

  $\mu(t) = \mathrm{e}^{3t}$
- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\,x)\right) dt = \int \mu(t)\,\mathrm{e}^{-2t} dt + c_1$
- Evaluate the integral on the lhs

  $\mu(t)\,x = \int \mu(t)\,\mathrm{e}^{-2t} dt + c_1$
- Solve for x

  $x = \frac{\int \mu(t)\mathrm{e}^{-2t} dt + c_1}{\mu(t)}$
- Substitute $\mu(t) = \mathrm{e}^{3t}$

  $x = \frac{\int \mathrm{e}^{3t}\mathrm{e}^{-2t} dt + c_1}{\mathrm{e}^{3t}}$
- Evaluate the integrals on the rhs

  $x = \frac{\mathrm{e}^{t} + c_1}{\mathrm{e}^{3t}}$
- Simplify

  $x = \mathrm{e}^{-3t}(\mathrm{e}^{t} + c_1)$
- Use initial condition $x(0) = 0$

  $0 = 1 + c_1$
- Solve for c_1

  $c_1 = -1$
- Substitute $c_1 = -1$ into general solution and simplify

  $x = \mathrm{e}^{-3t}(\mathrm{e}^{t} - 1)$
- Solution to the IVP

$$x = e^{-3t}(e^t - 1)$$

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{x' - 3x = 3t^3 + 3t^2 + 2t + 1}$$

With initial conditions

$$[x(0) = -1]$$

33.2.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x' + p(t)x = q(t)$$

Where here

$$\begin{aligned} p(t) &= -3 \\ q(t) &= 3t^3 + 3t^2 + 2t + 1 \end{aligned}$$

Hence the ode is

$$x' - 3x = 3t^3 + 3t^2 + 2t + 1$$

The domain of $p(t) = -3$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = 3t^3 + 3t^2 + 2t + 1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

33.2.2 Solving as laplace ode

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\mathcal{L}(x') = sY(s) - x(0)$$

The given ode now becomes an algebraic equation in the Laplace domain

$$sY(s) - x(0) - 3Y(s) = \frac{s^3 + 2s^2 + 6s + 18}{s^4} \tag{1}$$

Replacing initial condition gives

$$sY(s) + 1 - 3Y(s) = \frac{s^3 + 2s^2 + 6s + 18}{s^4}$$

Solving for $Y(s)$ gives

$$Y(s) = -\frac{s^3 + 2s^2 + 4s + 6}{s^4}$$

Applying partial fractions decomposition results in

$$Y(s) = -\frac{1}{s} - \frac{4}{s^3} - \frac{2}{s^2} - \frac{6}{s^4}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(-\frac{1}{s}\right) = -1$$

$$\mathcal{L}^{-1}\left(-\frac{4}{s^3}\right) = -2t^2$$

$$\mathcal{L}^{-1}\left(-\frac{2}{s^2}\right) = -2t$$

$$\mathcal{L}^{-1}\left(-\frac{6}{s^4}\right) = -t^3$$

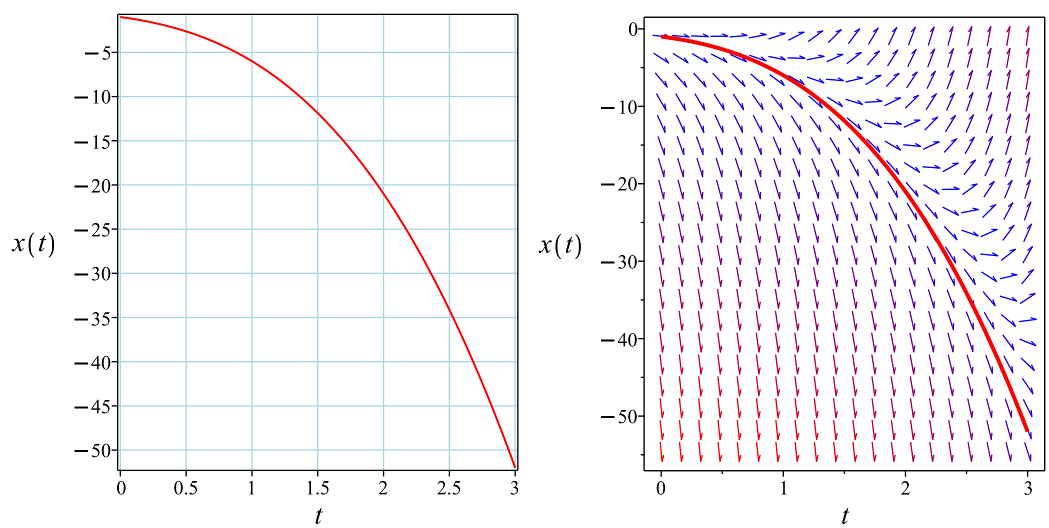
Adding the above results and simplifying gives

$$x = -(t+1)\left(t^2+t+1\right)$$

<u>Summary</u>

The solution(s) found are the following

$$x = -(t+1)\left(t^2+t+1\right) \tag{1}$$



(a) Solution plot (b) Slope field plot

<u>Verification of solutions</u>

$$x = -(t+1)\left(t^2+t+1\right)$$

Verified OK.

33.2.3 Maple step by step solution

Let's solve

$[x' - 3x = 3t^3 + 3t^2 + 2t + 1, x(0) = -1]$

- Highest derivative means the order of the ODE is 1

  x'

- Isolate the derivative

  $x' = 3x + 3t^3 + 3t^2 + 2t + 1$

- Group terms with x on the lhs of the ODE and the rest on the rhs of the ODE

The type(s) of ODE detected by this program : **"exact", "linear", "first__order__ode__lie__symmetry__lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{x' - x = \cos(t) - \sin(t)}$$

With initial conditions

$$[x(0) = 0]$$

33.3.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x' + p(t)x = q(t)$$

Where here

$$\begin{aligned} p(t) &= -1 \\ q(t) &= \cos(t) - \sin(t) \end{aligned}$$

Hence the ode is

$$x' - x = \cos(t) - \sin(t)$$

The domain of $p(t) = -1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = \cos(t) - \sin(t)$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

33.3.2 Solving as laplace ode

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\mathcal{L}(x') = sY(s) - x(0)$$

The given ode now becomes an algebraic equation in the Laplace domain

$$sY(s) - x(0) - Y(s) = \frac{s-1}{s^2+1} \tag{1}$$

Replacing initial condition gives

$$sY(s) - Y(s) = \frac{s-1}{s^2+1}$$

Solving for $Y(s)$ gives

$$Y(s) = \frac{1}{s^2+1}$$

Applying partial fractions decomposition results in

$$Y(s) = -\frac{i}{2(s-i)} + \frac{i}{2s+2i}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(-\frac{i}{2(s-i)}\right) = -\frac{i\mathrm{e}^{it}}{2}$$
$$\mathcal{L}^{-1}\left(\frac{i}{2s+2i}\right) = \frac{i\mathrm{e}^{-it}}{2}$$

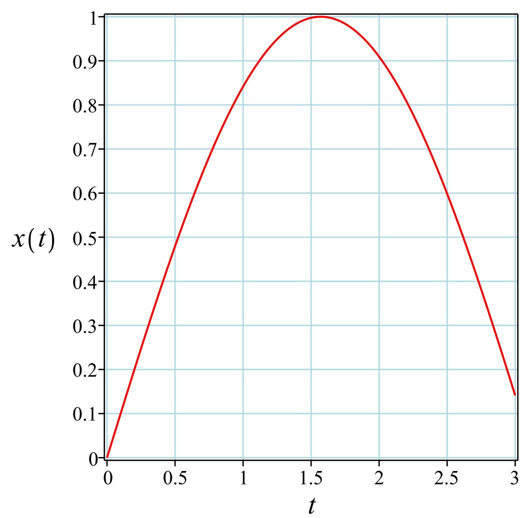
Adding the above results and simplifying gives

$$x = \sin(t)$$

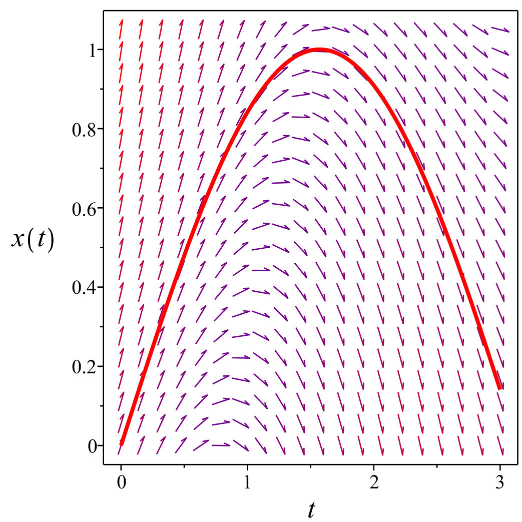
Summary

The solution(s) found are the following

$$x = \sin(t) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$x = \sin(t)$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 3. Section 24.2. Solving the Cauchy problem for linear differential equation with constant coefficients. Exercises page 249
Problem number: 833.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{2x' + 6x = t\,\mathrm{e}^{-3t}}$$

With initial conditions

$$\left[x(0) = -\frac{1}{2}\right]$$

33.4.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x' + p(t)x = q(t)$$

Where here

$$p(t) = 3$$
$$q(t) = \frac{t\,\mathrm{e}^{-3t}}{2}$$

Hence the ode is

$$x' + 3x = \frac{t\,\mathrm{e}^{-3t}}{2}$$

The domain of $p(t) = 3$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = \frac{t\,\mathrm{e}^{-3t}}{2}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

33.4.2 Solving as laplace ode

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\mathcal{L}(x') = sY(s) - x(0)$$

The given ode now becomes an algebraic equation in the Laplace domain

$$2sY(s) - 2x(0) + 6Y(s) = \frac{1}{(s+3)^2} \tag{1}$$

Replacing initial condition gives

$$2sY(s) + 1 + 6Y(s) = \frac{1}{(s+3)^2}$$

Solving for $Y(s)$ gives

$$Y(s) = -\frac{s^2 + 6s + 8}{2(s+3)^3}$$

Applying partial fractions decomposition results in

$$Y(s) = -\frac{1}{2(s+3)} + \frac{1}{2(s+3)^3}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(-\frac{1}{2\,(s+3)}\right) = -\frac{e^{-3t}}{2}$$
$$\mathcal{L}^{-1}\left(\frac{1}{2\,(s+3)^3}\right) = \frac{t^2 e^{-3t}}{4}$$

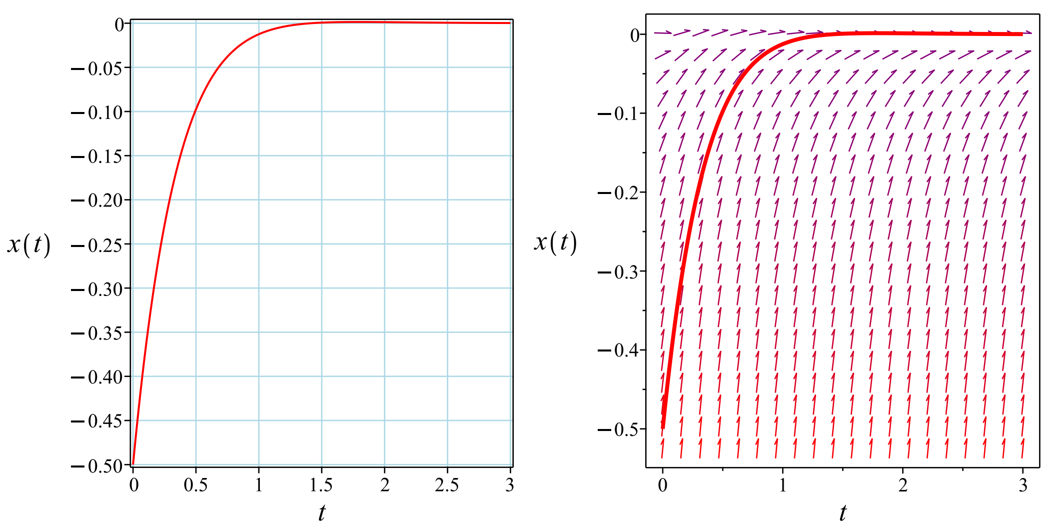
Adding the above results and simplifying gives

$$x = \frac{e^{-3t}(t^2-2)}{4}$$

Summary

The solution(s) found are the following

$$x = \frac{e^{-3t}(t^2-2)}{4} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$x = \frac{e^{-3t}(t^2-2)}{4}$$

Verified OK.

33.4.3 Maple step by step solution

Let's solve

$\left[2x'+6x=t\,\mathrm{e}^{-3t}, x(0)=-\frac{1}{2}\right]$

- Highest derivative means the order of the ODE is 1

  x'

- Isolate the derivative

  $x'=-3x+\frac{t\,\mathrm{e}^{-3t}}{2}$

- Group terms with x on the lhs of the ODE and the rest on the rhs of the ODE

  $x'+3x=\frac{t\,\mathrm{e}^{-3t}}{2}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\,(x'+3x)=\frac{\mu(t)t\,\mathrm{e}^{-3t}}{2}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,x)$

  $\mu(t)\,(x'+3x)=\mu'(t)\,x+\mu(t)\,x'$

- Isolate $\mu'(t)$

  $\mu'(t)=3\mu(t)$

- Solve to find the integrating factor

  $\mu(t)=\mathrm{e}^{3t}$

- Integrate both sides with respect to t

  $\int\left(\frac{d}{dt}(\mu(t)\,x)\right)dt=\int\frac{\mu(t)t\,\mathrm{e}^{-3t}}{2}dt+c_1$

- Evaluate the integral on the lhs

  $\mu(t)\,x=\int\frac{\mu(t)t\,\mathrm{e}^{-3t}}{2}dt+c_1$

- Solve for x

  $x=\frac{\int\frac{\mu(t)t\,\mathrm{e}^{-3t}}{2}dt+c_1}{\mu(t)}$

- Substitute $\mu(t)=\mathrm{e}^{3t}$

  $x=\frac{\int\frac{\mathrm{e}^{3t}t\,\mathrm{e}^{-3t}}{2}dt+c_1}{\mathrm{e}^{3t}}$

- Evaluate the integrals on the rhs

  $x=\frac{\frac{t^2}{4}+c_1}{\mathrm{e}^{3t}}$

- Simplify

$x = \frac{e^{-3t}(t^2+4c_1)}{4}$

- Use initial condition $x(0) = -\frac{1}{2}$

  $-\frac{1}{2} = c_1$

- Solve for c_1

  $c_1 = -\frac{1}{2}$

- Substitute $c_1 = -\frac{1}{2}$ into general solution and simplify

  $x = \frac{e^{-3t}(t^2-2)}{4}$

- Solution to the IVP

  $x = \frac{e^{-3t}(t^2-2)}{4}$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 3. Section 24.2. Solving the Cauchy problem for linear differential equation with constant coefficients. Exercises page 249
Problem number: 834.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{x' + x = 2\sin(t)}$$

With initial conditions

$$[x(0) = 0]$$

33.5.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x' + p(t)x = q(t)$$

Where here

$$\begin{aligned} p(t) &= 1 \\ q(t) &= 2\sin(t) \end{aligned}$$

Hence the ode is

$$x' + x = 2\sin(t)$$

The domain of $p(t) = 1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = 2\sin(t)$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

33.5.2 Solving as laplace ode

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\mathcal{L}(x') = sY(s) - x(0)$$

The given ode now becomes an algebraic equation in the Laplace domain

$$sY(s) - x(0) + Y(s) = \frac{2}{s^2+1} \tag{1}$$

Replacing initial condition gives

$$sY(s) + Y(s) = \frac{2}{s^2+1}$$

Solving for $Y(s)$ gives

$$Y(s) = \frac{2}{(s^2+1)(s+1)}$$

Applying partial fractions decomposition results in

$$Y(s) = \frac{1}{s+1} + \frac{-\frac{1}{2} - \frac{i}{2}}{s-i} + \frac{-\frac{1}{2} + \frac{i}{2}}{s+i}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(\frac{1}{s+1}\right) = \mathrm{e}^{-t}$$

$$\mathcal{L}^{-1}\left(\frac{-\frac{1}{2}-\frac{i}{2}}{s-i}\right) = \left(-\frac{1}{2}-\frac{i}{2}\right)\mathrm{e}^{it}$$

$$\mathcal{L}^{-1}\left(\frac{-\frac{1}{2}+\frac{i}{2}}{s+i}\right) = \left(-\frac{1}{2}+\frac{i}{2}\right)\mathrm{e}^{-it}$$

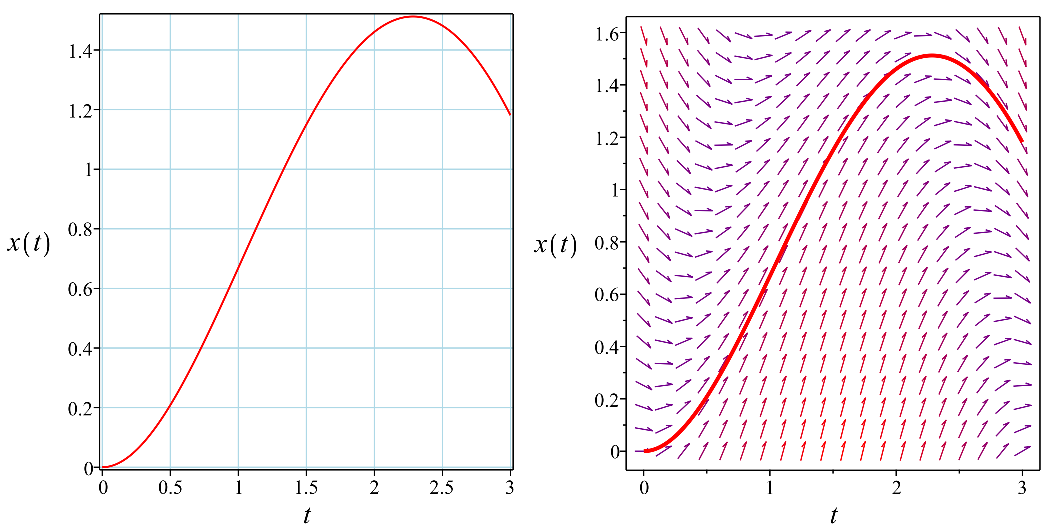
Adding the above results and simplifying gives

$$x = \mathrm{e}^{-t}-\cos\left(t\right)+\sin\left(t\right)$$

Summary

The solution(s) found are the following

$$x = \mathrm{e}^{-t}-\cos\left(t\right)+\sin\left(t\right) \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$x = \mathrm{e}^{-t}-\cos\left(t\right)+\sin\left(t\right)$$

Verified OK.

33.5.3 Maple step by step solution

Let's solve

$[x' + x = 2\sin(t), x(0) = 0]$

- Highest derivative means the order of the ODE is 1

  x'

- Isolate the derivative

  $x' = -x + 2\sin(t)$

- Group terms with x on the lhs of the ODE and the rest on the rhs of the ODE

  $x' + x = 2\sin(t)$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)(x' + x) = 2\mu(t)\sin(t)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,x)$

  $\mu(t)(x' + x) = \mu'(t)\,x + \mu(t)\,x'$

- Isolate $\mu'(t)$

  $\mu'(t) = \mu(t)$

- Solve to find the integrating factor

  $\mu(t) = \mathrm{e}^{t}$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\,x)\right) dt = \int 2\mu(t)\sin(t)\,dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\,x = \int 2\mu(t)\sin(t)\,dt + c_1$

- Solve for x

  $x = \frac{\int 2\mu(t)\sin(t)dt + c_1}{\mu(t)}$

- Substitute $\mu(t) = \mathrm{e}^{t}$

  $x = \frac{\int 2\,\mathrm{e}^{t}\sin(t)dt + c_1}{\mathrm{e}^{t}}$

- Evaluate the integrals on the rhs

  $x = \frac{-\mathrm{e}^{t}\cos(t) + \mathrm{e}^{t}\sin(t) + c_1}{\mathrm{e}^{t}}$

- Simplify

  $x = \sin(t) - \cos(t) + c_1\mathrm{e}^{-t}$

- Use initial condition $x(0) = 0$

  $0 = c_1 - 1$
- Solve for c_1

  $c_1 = 1$
- Substitute $c_1 = 1$ into general solution and simplify

  $x = e^{-t} - \cos(t) + \sin(t)$
- Solution to the IVP

  $x = e^{-t} - \cos(t) + \sin(t)$

Section: Chapter 3. Section 24.2. Solving the Cauchy problem for linear differential equation with constant coefficients. Exercises page 249
Problem number: 835.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_quadrature", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _quadrature]]
```

$$\boxed{x'' = 0}$$

With initial conditions

$$[x(0) = 0, x'(0) = 0]$$

33.6.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x'' + p(t)x' + q(t)x = F$$

Where here

$$\begin{aligned} p(t) &= 0 \\ q(t) &= 0 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$x'' = 0$$

The domain of $p(t) = 0$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned}
\mathcal{L}(x') &= sY(s) - x(0) \\
\mathcal{L}(x'') &= s^2Y(s) - x'(0) - sx(0)
\end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - x'(0) - sx(0) = 0 \tag{1}$$

But the initial conditions are

$$\begin{aligned}
x(0) &= 0 \\
x'(0) &= 0
\end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) = 0$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = 0$$

Taking the inverse Laplace transform gives

$$\begin{aligned}
x &= \mathcal{L}^{-1}(Y(s)) \\
&= \mathcal{L}^{-1}(0) \\
&= 0
\end{aligned}$$

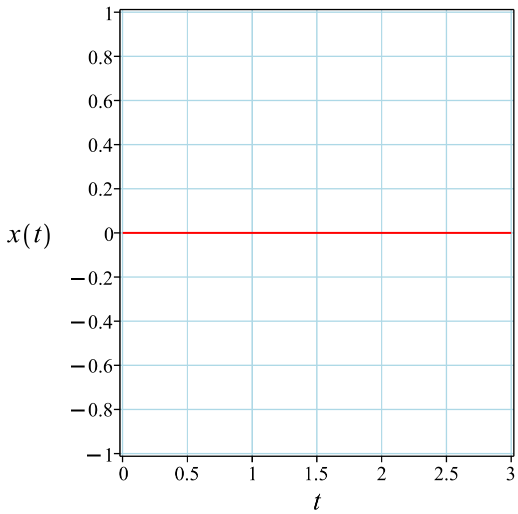
Simplifying the solution gives

$$x = 0$$

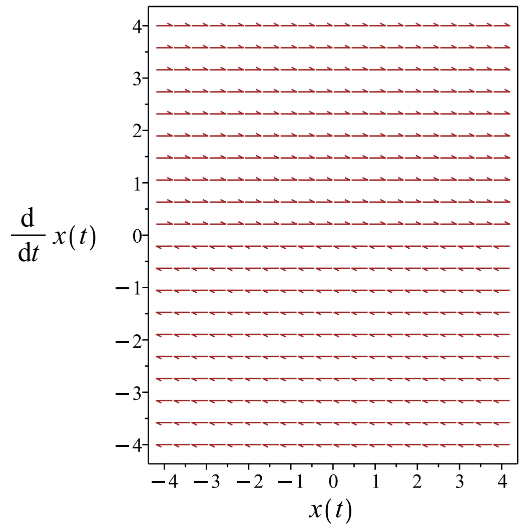
Summary

The solution(s) found are the following

$$x = 0 \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$x = 0$$

Verified OK.

33.6.2 Maple step by step solution

Let's solve

$$\left[x'' = 0, x(0) = 0, x'\Big|_{\{t=0\}} = 0\right]$$

- Highest derivative means the order of the ODE is 2

  x''

- Characteristic polynomial of ODE

  $r^2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{0})}{2}$

- Roots of the characteristic polynomial

  $r = 0$

- 1st solution of the ODE

  $x_1(t) = 1$

- Repeated root, multiply $x_1(t)$ by t to ensure linear independence

  $x_2(t) = t$

- General solution of the ODE

  $x = c_1 x_1(t) + c_2 x_2(t)$

- Substitute in solutions

  $x = c_2 t + c_1$

- ☐ Check validity of solution $x = c_2 t + c_1$
  - Use initial condition $x(0) = 0$

    $0 = c_1$

  - Compute derivative of the solution

    $x' = c_2$

  - Use the initial condition $x'\Big|_{\{t=0\}} = 0$

    $0 = c_2$

  - Solve for c_1 and c_2

    $\{c_1 = 0, c_2 = 0\}$

  - Substitute constant values into general solution and simplify

    $x = 0$

- Solution to the IVP

  $x = 0$

Maple gives the following as the ode type

```
[[_2nd_order, _quadrature]]
```

$$\boxed{x'' = 1}$$

With initial conditions

$$[x(0) = 0, x'(0) = 0]$$

33.7.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x'' + p(t)x' + q(t)x = F$$

Where here

$$\begin{aligned} p(t) &= 0 \\ q(t) &= 0 \\ F &= 1 \end{aligned}$$

Hence the ode is

$$x'' = 1$$

The domain of $p(t) = 0$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $F = 1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned}\mathcal{L}(x') &= sY(s) - x(0)\\ \mathcal{L}(x'') &= s^2Y(s) - x'(0) - sx(0)\end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - x'(0) - sx(0) = \frac{1}{s} \tag{1}$$

But the initial conditions are

$$\begin{aligned}x(0) &= 0\\ x'(0) &= 0\end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) = \frac{1}{s}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = \frac{1}{s^3}$$

Taking the inverse Laplace transform gives

$$\begin{aligned}x &= \mathcal{L}^{-1}(Y(s))\\ &= \mathcal{L}^{-1}\left(\frac{1}{s^3}\right)\\ &= \frac{t^2}{2}\end{aligned}$$

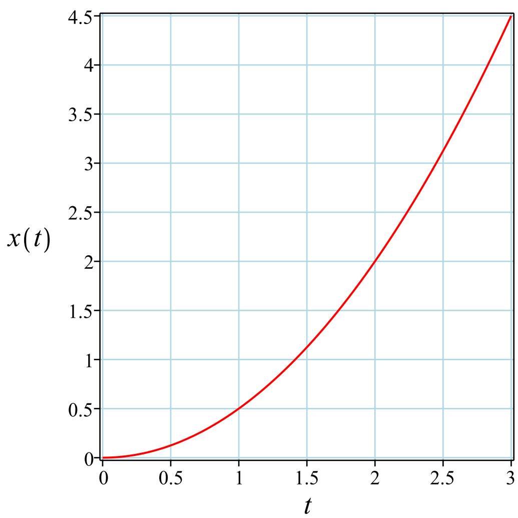
Simplifying the solution gives

$$x = \frac{t^2}{2}$$

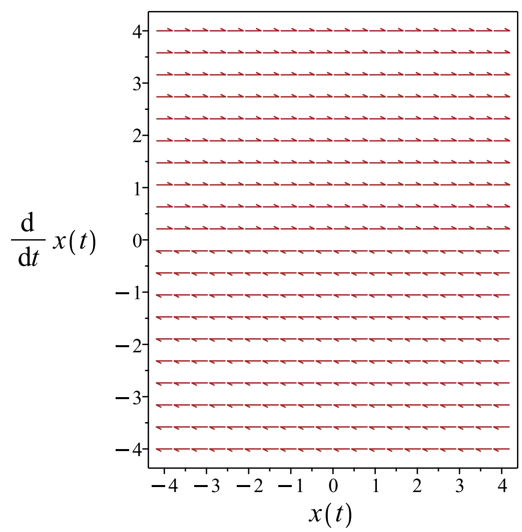
Summary

The solution(s) found are the following

$$x = \frac{t^2}{2} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$x = \frac{t^2}{2}$$

Verified OK.

33.7.2 Maple step by step solution

Let's solve

$$\left[x'' = 1, x(0) = 0, x'\Big|_{\{t=0\}} = 0\right]$$

- Highest derivative means the order of the ODE is 2

  x''

- Characteristic polynomial of homogeneous ODE

  $r^2 = 0$
- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{0})}{2}$
- Roots of the characteristic polynomial

  $r = 0$
- 1st solution of the homogeneous ODE

  $x_1(t) = 1$
- Repeated root, multiply $x_1(t)$ by t to ensure linear independence

  $x_2(t) = t$
- General solution of the ODE

  $x = c_1 x_1(t) + c_2 x_2(t) + x_p(t)$
- Substitute in solutions of the homogeneous ODE

  $x = c_1 + c_2 t + x_p(t)$

☐ Find a particular solution $x_p(t)$ of the ODE

  - Use variation of parameters to find x_p here $f(t)$ is the forcing function

    $\left[x_p(t) = -x_1(t)\left(\int \frac{x_2(t)f(t)}{W(x_1(t),x_2(t))}dt\right) + x_2(t)\left(\int \frac{x_1(t)f(t)}{W(x_1(t),x_2(t))}dt\right), f(t) = 1\right]$
  - Wronskian of solutions of the homogeneous equation

    $W(x_1(t), x_2(t)) = \begin{bmatrix} 1 & t \\ 0 & 1 \end{bmatrix}$
  - Compute Wronskian

    $W(x_1(t), x_2(t)) = 1$
  - Substitute functions into equation for $x_p(t)$

    $x_p(t) = -\left(\int t dt\right) + t\left(\int 1 dt\right)$
  - Compute integrals

    $x_p(t) = \frac{t^2}{2}$
- Substitute particular solution into general solution to ODE

  $x = c_1 + c_2 t + \frac{1}{2}t^2$

- Check validity of solution $x = c_1 + c_2 t + \frac{1}{2}t^2$
  - Use initial condition $x(0) = 0$

    $0 = c_1$
  - Compute derivative of the solution

    $x' = c_2 + t$
  - Use the initial condition $x'\Big|_{\{t=0\}} = 0$

    $0 = c_2$
  - Solve for c_1 and c_2

    $\{c_1 = 0, c_2 = 0\}$
  - Substitute constant values into general solution and simplify

    $x = \frac{t^2}{2}$
- Solution to the IVP

  $x = \frac{t^2}{2}$

Problem number: 837.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_quadrature", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _quadrature]]
```

$$\boxed{x'' = \cos(t)}$$

With initial conditions

$$[x(0) = 0, x'(0) = 0]$$

33.8.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x'' + p(t)x' + q(t)x = F$$

Where here

$$\begin{aligned} p(t) &= 0 \\ q(t) &= 0 \\ F &= \cos(t) \end{aligned}$$

Hence the ode is

$$x'' = \cos(t)$$

The domain of $p(t) = 0$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $F = \cos(t)$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned}\mathcal{L}(x') &= sY(s) - x(0) \\ \mathcal{L}(x'') &= s^2Y(s) - x'(0) - sx(0)\end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - x'(0) - sx(0) = \frac{s}{s^2+1} \tag{1}$$

But the initial conditions are

$$\begin{aligned}x(0) &= 0 \\ x'(0) &= 0\end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) = \frac{s}{s^2+1}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = \frac{1}{s(s^2+1)}$$

Applying partial fractions decomposition results in

$$Y(s) = -\frac{1}{2(s-i)} - \frac{1}{2(s+i)} + \frac{1}{s}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(-\frac{1}{2(s-i)}\right) = -\frac{e^{it}}{2}$$
$$\mathcal{L}^{-1}\left(-\frac{1}{2(s+i)}\right) = -\frac{e^{-it}}{2}$$
$$\mathcal{L}^{-1}\left(\frac{1}{s}\right) = 1$$

Adding the above results and simplifying gives

$$x = 1-\cos(t)$$

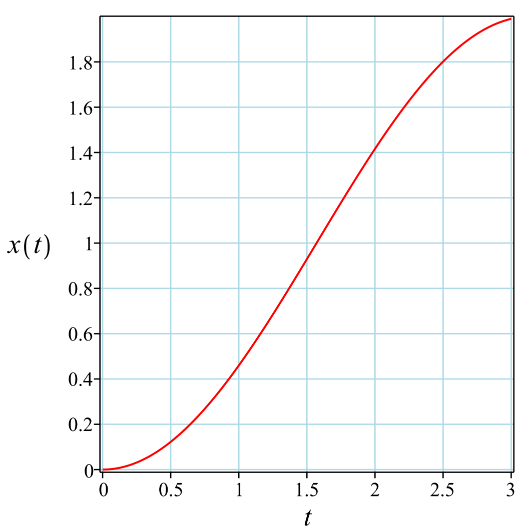
Simplifying the solution gives

$$x = 1-\cos(t)$$

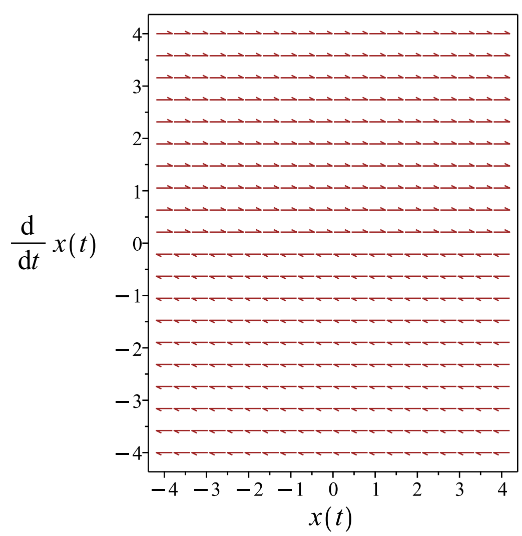
Summary

The solution(s) found are the following

$$x = 1-\cos(t) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$x = 1-\cos(t)$$

Verified OK.

33.8.2 Maple step by step solution

Let's solve

$\left[x'' = \cos(t), x(0) = 0, x'\Big|_{\{t=0\}} = 0\right]$

- Highest derivative means the order of the ODE is 2

  x''

- Characteristic polynomial of homogeneous ODE

  $r^2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{0})}{2}$

- Roots of the characteristic polynomial

  $r = 0$

- 1st solution of the homogeneous ODE

  $x_1(t) = 1$

- Repeated root, multiply $x_1(t)$ by t to ensure linear independence

  $x_2(t) = t$

- General solution of the ODE

  $x = c_1x_1(t) + c_2x_2(t) + x_p(t)$

- Substitute in solutions of the homogeneous ODE

  $x = c_1 + c_2t + x_p(t)$

□ Find a particular solution $x_p(t)$ of the ODE

  ◦ Use variation of parameters to find x_p here $f(t)$ is the forcing function

    $\left[x_p(t) = -x_1(t)\left(\int \frac{x_2(t)f(t)}{W(x_1(t),x_2(t))}dt\right) + x_2(t)\left(\int \frac{x_1(t)f(t)}{W(x_1(t),x_2(t))}dt\right), f(t) = \cos(t)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

    $W(x_1(t), x_2(t)) = \begin{bmatrix} 1 & t \\ 0 & 1 \end{bmatrix}$

  ◦ Compute Wronskian

    $W(x_1(t), x_2(t)) = 1$

  ◦ Substitute functions into equation for $x_p(t)$

$x_p(t) = -\left(\int t\cos(t)\,dt\right) + t\left(\int \cos(t)\,dt\right)$

- Compute integrals

  $x_p(t) = -\cos(t)$

- Substitute particular solution into general solution to ODE

  $x = c_1 + c_2 t - \cos(t)$

□ Check validity of solution $x = c_1 + c_2 t - \cos(t)$

- Use initial condition $x(0) = 0$

  $0 = c_1 - 1$

- Compute derivative of the solution

  $x' = c_2 + \sin(t)$

- Use the initial condition $x'\Big|_{\{t=0\}} = 0$

  $0 = c_2$

- Solve for c_1 and c_2

  $\{c_1 = 1, c_2 = 0\}$

- Substitute constant values into general solution and simplify

  $x = 1 - \cos(t)$

- Solution to the IVP

  $x = 1 - \cos(t)$

Section: Chapter 3. Section 24.2. Solving the Cauchy problem for linear differential equation with constant coefficients. Exercises page 249
Problem number: 838.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{x'' + x' = 0}$$

With initial conditions

$$[x(0) = 0, x'(0) = 0]$$

33.9.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x'' + p(t)x' + q(t)x = F$$

Where here

$$\begin{aligned} p(t) &= 1 \\ q(t) &= 0 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$x'' + x' = 0$$

The domain of $p(t) = 1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned}\mathcal{L}(x') &= sY(s) - x(0)\\ \mathcal{L}(x'') &= s^2Y(s) - x'(0) - sx(0)\end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - x'(0) - sx(0) + sY(s) - x(0) = 0 \tag{1}$$

But the initial conditions are

$$\begin{aligned}x(0) &= 0\\ x'(0) &= 0\end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) + sY(s) = 0$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = 0$$

Taking the inverse Laplace transform gives

$$\begin{aligned}x &= \mathcal{L}^{-1}(Y(s))\\ &= \mathcal{L}^{-1}(0)\\ &= 0\end{aligned}$$

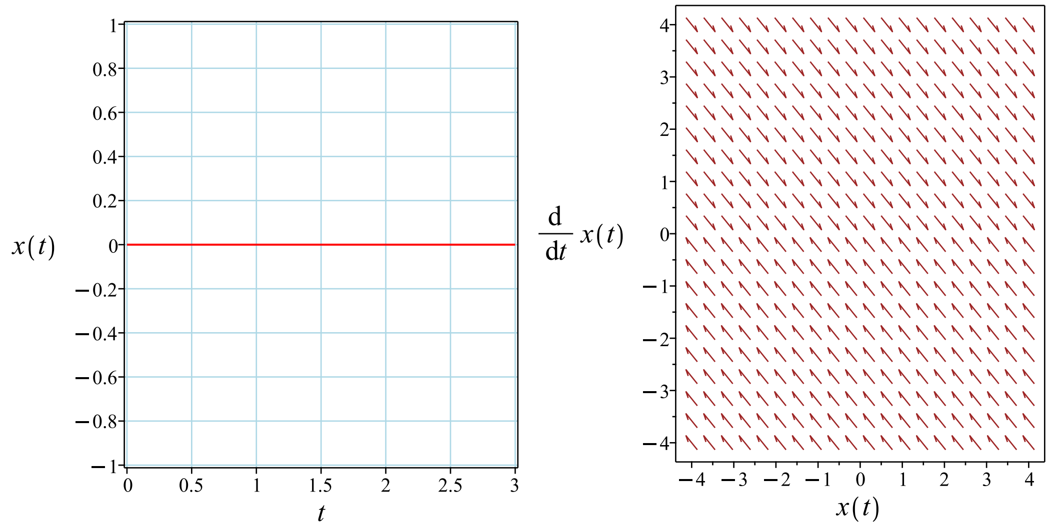
Simplifying the solution gives

$$x = 0$$

Summary

The solution(s) found are the following

$$x = 0 \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$x = 0$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_laplace", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{x'' - x' = 1}$$

With initial conditions

$$[x(0) = -1, x'(0) = -1]$$

33.11.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x'' + p(t)x' + q(t)x = F$$

Where here

$$\begin{aligned} p(t) &= -1 \\ q(t) &= 0 \\ F &= 1 \end{aligned}$$

Hence the ode is

$$x'' - x' = 1$$

The domain of $p(t) = -1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $F = 1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned}\mathcal{L}(x') &= sY(s) - x(0)\\ \mathcal{L}(x'') &= s^2Y(s) - x'(0) - sx(0)\end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - x'(0) - sx(0) - sY(s) + x(0) = \frac{1}{s} \tag{1}$$

But the initial conditions are

$$\begin{aligned}x(0) &= -1\\ x'(0) &= -1\end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) + s - sY(s) = \frac{1}{s}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = -\frac{s+1}{s^2}$$

Applying partial fractions decomposition results in

$$Y(s) = -\frac{1}{s} - \frac{1}{s^2}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(-\frac{1}{s}\right) = -1$$
$$\mathcal{L}^{-1}\left(-\frac{1}{s^2}\right) = -t$$

Adding the above results and simplifying gives

$$x = -t - 1$$

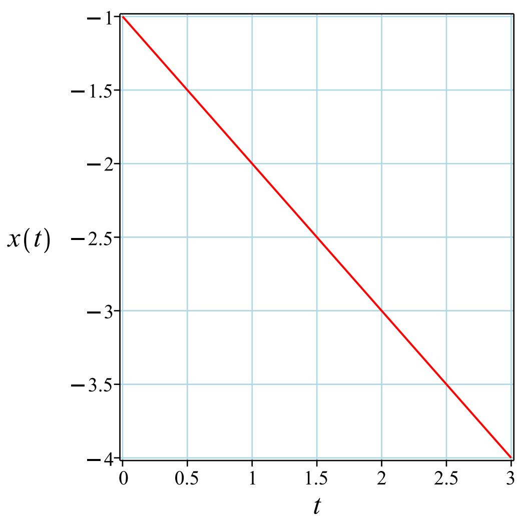
Simplifying the solution gives

$$x = -t - 1$$

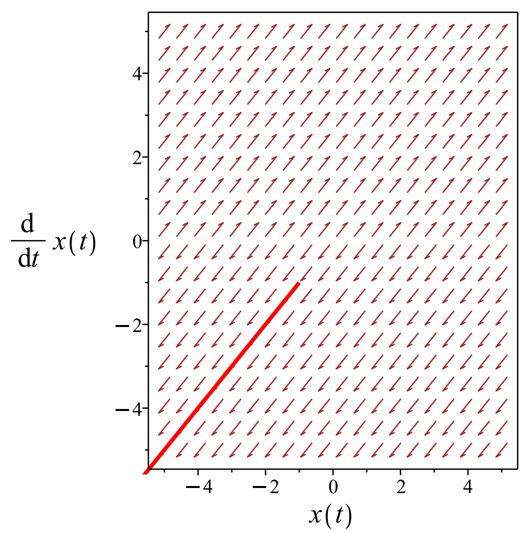
Summary

The solution(s) found are the following

$$x = -t - 1 \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$x = -t - 1$$

Verified OK.

33.11.2 Maple step by step solution

Let's solve

$$\left[x''-x'=1, x(0)=-1, x'\Big|_{\{t=0\}}=-1\right]$$

- Highest derivative means the order of the ODE is 2

  x''

- Characteristic polynomial of homogeneous ODE

  $r^2-r=0$

- Factor the characteristic polynomial

  $r(r-1)=0$

- Roots of the characteristic polynomial

  $r=(0,1)$

- 1st solution of the homogeneous ODE

  $x_1(t)=1$

- 2nd solution of the homogeneous ODE

  $x_2(t)=\mathrm{e}^t$

- General solution of the ODE

  $x=c_1x_1(t)+c_2x_2(t)+x_p(t)$

- Substitute in solutions of the homogeneous ODE

  $x=c_1+c_2\mathrm{e}^t+x_p(t)$

□ Find a particular solution $x_p(t)$ of the ODE

  - Use variation of parameters to find x_p here $f(t)$ is the forcing function

    $$\left[x_p(t)=-x_1(t)\left(\int \frac{x_2(t)f(t)}{W(x_1(t),x_2(t))}dt\right)+x_2(t)\left(\int \frac{x_1(t)f(t)}{W(x_1(t),x_2(t))}dt\right), f(t)=1\right]$$

  - Wronskian of solutions of the homogeneous equation

    $$W(x_1(t), x_2(t))=\begin{bmatrix} 1 & \mathrm{e}^t \\ 0 & \mathrm{e}^t \end{bmatrix}$$

  - Compute Wronskian

    $W(x_1(t), x_2(t))=\mathrm{e}^t$

  - Substitute functions into equation for $x_p(t)$

$x_p(t) = -\left(\int 1dt\right) + e^t \left(\int e^{-t}dt\right)$

- Compute integrals

  $x_p(t) = -t - 1$

- Substitute particular solution into general solution to ODE

  $x = c_1 + c_2 e^t - t - 1$

□ Check validity of solution $x = c_1 + c_2 e^t - t - 1$

- Use initial condition $x(0) = -1$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 3. Section 24.2. Solving the Cauchy problem for linear differential equation with constant coefficients. Exercises page 249
Problem number: 841.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x'' + x = t}$$

With initial conditions

$$[x(0) = 0, x'(0) = 1]$$

33.12.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x'' + p(t)x' + q(t)x = F$$

Where here

$$\begin{aligned} p(t) &= 0 \\ q(t) &= 1 \\ F &= t \end{aligned}$$

Hence the ode is

$$x'' + x = t$$

The domain of $p(t) = 0$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = 1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. The domain of $F = t$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned}
\mathcal{L}(x') &= sY(s) - x(0) \\
\mathcal{L}(x'') &= s^2 Y(s) - x'(0) - sx(0)
\end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2 Y(s) - x'(0) - sx(0) + Y(s) = \frac{1}{s^2} \tag{1}$$

But the initial conditions are

$$\begin{aligned}
x(0) &= 0 \\
x'(0) &= 1
\end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2 Y(s) - 1 + Y(s) = \frac{1}{s^2}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = \frac{1}{s^2}$$

Taking the inverse Laplace transform gives

$$\begin{aligned} x &= \mathcal{L}^{-1}(Y(s)) \\ &= \mathcal{L}^{-1}\left(\frac{1}{s^2}\right) \\ &= t \end{aligned}$$

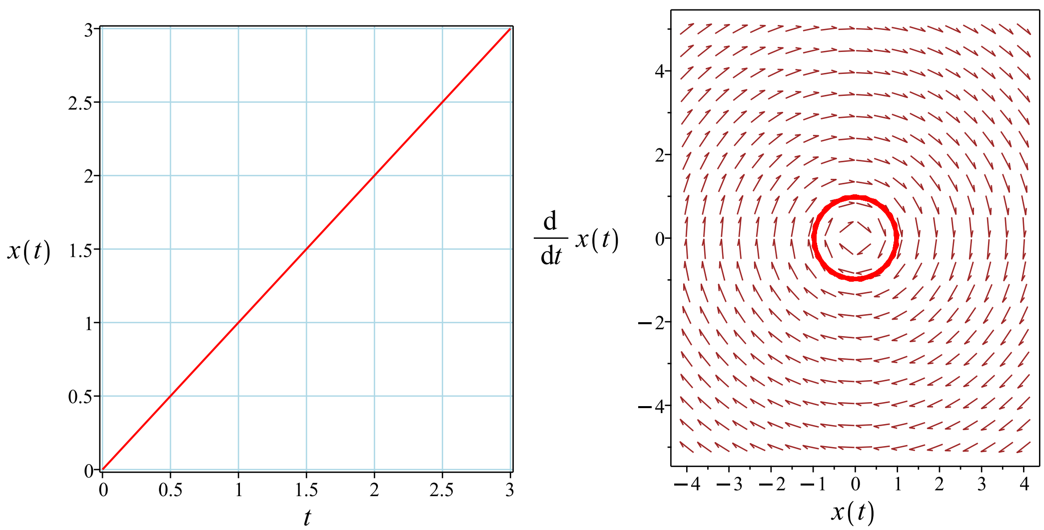
Simplifying the solution gives

$$x = t$$

Summary

The solution(s) found are the following

$$x = t \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$x = t$$

Verified OK.

33.12.2 Maple step by step solution

Let's solve

$$\left[x'' + x = t, x(0) = 0, x'\Big|_{\{t=0\}} = 1\right]$$

- Highest derivative means the order of the ODE is 2

  x''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $x_1(t) = \cos(t)$

- 2nd solution of the homogeneous ODE

  $x_2(t) = \sin(t)$

- General solution of the ODE

  $x = c_1 x_1(t) + c_2 x_2(t) + x_p(t)$

- Substitute in solutions of the homogeneous ODE

  $x = c_1 \cos(t) + c_2 \sin(t) + x_p(t)$

□ Find a particular solution $x_p(t)$ of the ODE

  - Use variation of parameters to find x_p here $f(t)$ is the forcing function

    $\left[x_p(t) = -x_1(t) \left(\int \frac{x_2(t) f(t)}{W(x_1(t), x_2(t))} dt\right) + x_2(t) \left(\int \frac{x_1(t) f(t)}{W(x_1(t), x_2(t))} dt\right), f(t) = t\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(x_1(t), x_2(t)) = \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix}$

  - Compute Wronskian

    $W(x_1(t), x_2(t)) = 1$

  - Substitute functions into equation for $x_p(t)$

$x_p(t) = -\cos(t)\left(\int t\sin(t)\,dt\right) + \sin(t)\left(\int t\cos(t)\,dt\right)$

- Compute integrals

  $x_p(t) = t$

- Substitute particular solution into general solution to ODE

  $x = c_1\cos(t) + c_2\sin(t) + t$

☐ Check validity of solution $x = c_1\cos(t) + c_2\sin(t) + t$

- Use initial condition $x(0) = 0$

  $0 = c_1$

- Compute derivative of the solution

  $x' = -c_1\sin(t) + c_2\cos(t) + 1$

- Use the initial condition $x'\big|_{\{t=0\}} = 1$

  $1 = 1 + c_2$

- Solve for c_1 and c_2

  $\{c_1 = 0, c_2 = 0\}$

- Substitute constant values into general solution and simplify

  $x = t$

- Solution to the IVP

  $x = t$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 3. Section 24.2. Solving the Cauchy problem for linear differential equation with constant coefficients. Exercises page 249
Problem number: 842.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{x'' + 6x' = 12t + 2}$$

With initial conditions

$$[x(0) = 0, x'(0) = 0]$$

33.13.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x'' + p(t)x' + q(t)x = F$$

Where here

$$\begin{aligned} p(t) &= 6 \\ q(t) &= 0 \\ F &= 12t + 2 \end{aligned}$$

Hence the ode is

$$x'' + 6x' = 12t + 2$$

The domain of $p(t) = 6$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $F = 12t + 2$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned}
\mathcal{L}(x') &= sY(s) - x(0) \\
\mathcal{L}(x'') &= s^2Y(s) - x'(0) - sx(0)
\end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - x'(0) - sx(0) + 6sY(s) - 6x(0) = \frac{2}{s} + \frac{12}{s^2} \tag{1}$$

But the initial conditions are

$$\begin{aligned}
x(0) &= 0 \\
x'(0) &= 0
\end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) + 6sY(s) = \frac{2}{s} + \frac{12}{s^2}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = \frac{2}{s^3}$$

Taking the inverse Laplace transform gives

$$\begin{aligned}
x &= \mathcal{L}^{-1}(Y(s)) \\
&= \mathcal{L}^{-1}\left(\frac{2}{s^3}\right) \\
&= t^2
\end{aligned}$$

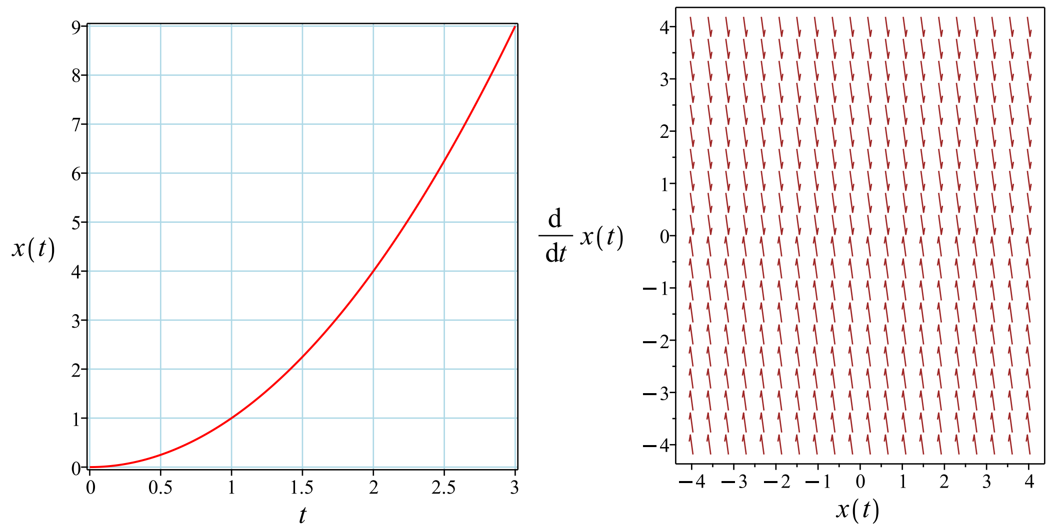
Simplifying the solution gives

$$x = t^2$$

Summary

The solution(s) found are the following

$$x = t^2 \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$x = t^2$$

Verified OK.

33.13.2 Maple step by step solution

Let's solve

$\left[x'' + 6x' = 12t + 2, x(0) = 0, x'\Big|_{\{t=0\}} = 0\right]$

- Highest derivative means the order of the ODE is 2

  x''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 6r = 0$

- Factor the characteristic polynomial

  $r(r+6)=0$
- Roots of the characteristic polynomial

  $r=(-6,0)$
- 1st solution of the homogeneous ODE

  $x_1(t)=\mathrm{e}^{-6t}$
- 2nd solution of the homogeneous ODE

  $x_2(t)=1$
- General solution of the ODE

  $x=c_1x_1(t)+c_2x_2(t)+x_p(t)$
- Substitute in solutions of the homogeneous ODE

  $x=c_1\mathrm{e}^{-6t}+c_2+x_p(t)$

☐ Find a particular solution $x_p(t)$ of the ODE

  - Use variation of parameters to find x_p here $f(t)$ is the forcing function

    $\left[x_p(t)=-x_1(t)\left(\int \frac{x_2(t)f(t)}{W(x_1(t),x_2(t))}dt\right)+x_2(t)\left(\int \frac{x_1(t)f(t)}{W(x_1(t),x_2(t))}dt\right), f(t)=12t+2\right]$
  - Wronskian of solutions of the homogeneous equation

    $W(x_1(t),x_2(t))=\begin{bmatrix} \mathrm{e}^{-6t} & 1 \\ -6\,\mathrm{e}^{-6t} & 0 \end{bmatrix}$
  - Compute Wronskian

    $W(x_1(t),x_2(t))=6\,\mathrm{e}^{-6t}$
  - Substitute functions into equation for $x_p(t)$

    $x_p(t)=-\frac{\mathrm{e}^{-6t}\left(\int(6t+1)\mathrm{e}^{6t}dt\right)}{3}+\frac{\left(\int(6t+1)dt\right)}{3}$
  - Compute integrals

    $x_p(t)=t^2$
- Substitute particular solution into general solution to ODE

  $x=c_1\mathrm{e}^{-6t}+c_2+t^2$

☐ Check validity of solution $x=c_1\mathrm{e}^{-6t}+c_2+t^2$

  - Use initial condition $x(0)=0$

    $0=c_1+c_2$

- Compute derivative of the solution

  $x' = -6c_1 e^{-6t} + 2t$

- Use the initial condition $x'\big|_{\{t=0\}} = 0$

  $0 = -6c_1$

- Solve for c_1 and c_2

  $\{c_1 = 0, c_2 = 0\}$

- Substitute constant values into general solution and simplify

  $x = t^2$

- Solution to the IVP

  $x = t^2$

Section: Chapter 3. Section 24.2. Solving the Cauchy problem for linear differential equation with constant coefficients. Exercises page 249
Problem number: 843.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{x'' - 2x' + 2x = 2}$$

With initial conditions

$$[x(0) = 1, x'(0) = 0]$$

33.14.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x'' + p(t)x' + q(t)x = F$$

Where here

$$\begin{aligned} p(t) &= -2 \\ q(t) &= 2 \\ F &= 2 \end{aligned}$$

Hence the ode is

$$x'' - 2x' + 2x = 2$$

The domain of $p(t) = -2$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = 2$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. The domain of $F = 2$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned}\mathcal{L}(x') &= sY(s) - x(0)\\ \mathcal{L}(x'') &= s^2Y(s) - x'(0) - sx(0)\end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - x'(0) - sx(0) - 2sY(s) + 2x(0) + 2Y(s) = \frac{2}{s} \tag{1}$$

But the initial conditions are

$$\begin{aligned}x(0) &= 1\\ x'(0) &= 0\end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) + 2 - s - 2sY(s) + 2Y(s) = \frac{2}{s}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = \frac{1}{s}$$

Taking the inverse Laplace transform gives

$$
\begin{aligned}
x &= \mathcal{L}^{-1}(Y(s)) \\
&= \mathcal{L}^{-1}\left(\frac{1}{s}\right) \\
&= 1
\end{aligned}
$$

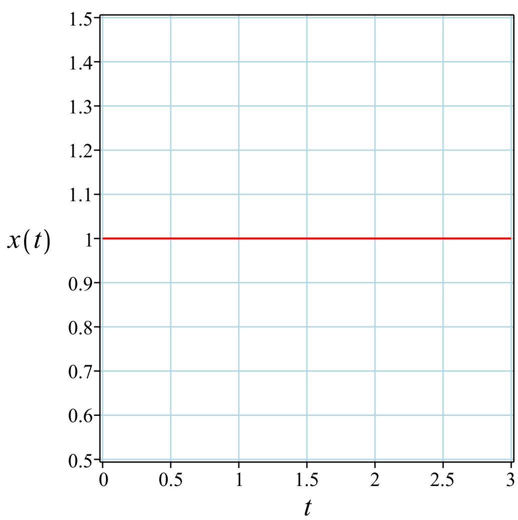
Simplifying the solution gives

$$x = 1$$

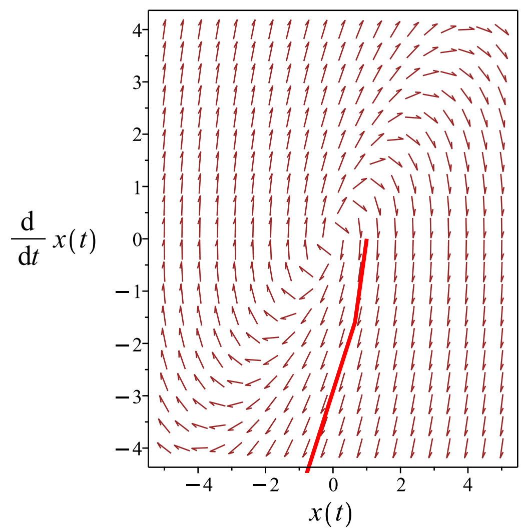
Summary

The solution(s) found are the following

$$x = 1 \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$x = 1$$

Verified OK.

33.14.2 Maple step by step solution

Let's solve

$\left[x'' - 2x' + 2x = 2, x(0) = 1, x'\Big|_{\{t=0\}} = 0\right]$

- Highest derivative means the order of the ODE is 2

  x''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{2\pm(\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (1 - \mathrm{I}, 1 + \mathrm{I})$

- 1st solution of the homogeneous ODE

  $x_1(t) = \mathrm{e}^t \cos(t)$

- 2nd solution of the homogeneous ODE

  $x_2(t) = \mathrm{e}^t \sin(t)$

- General solution of the ODE

  $x = c_1 x_1(t) + c_2 x_2(t) + x_p(t)$

- Substitute in solutions of the homogeneous ODE

  $x = c_1 \mathrm{e}^t \cos(t) + c_2 \mathrm{e}^t \sin(t) + x_p(t)$

□ Find a particular solution $x_p(t)$ of the ODE

  ∘ Use variation of parameters to find x_p here $f(t)$ is the forcing function

  $\left[x_p(t) = -x_1(t)\left(\int \frac{x_2(t) f(t)}{W(x_1(t), x_2(t))} dt\right) + x_2(t)\left(\int \frac{x_1(t) f(t)}{W(x_1(t), x_2(t))} dt\right), f(t) = 2\right]$

  ∘ Wronskian of solutions of the homogeneous equation

  $W(x_1(t), x_2(t)) = \begin{bmatrix} \mathrm{e}^t \cos(t) & \mathrm{e}^t \sin(t) \\ \mathrm{e}^t \cos(t) - \mathrm{e}^t \sin(t) & \mathrm{e}^t \sin(t) + \mathrm{e}^t \cos(t) \end{bmatrix}$

  ∘ Compute Wronskian

  $W(x_1(t), x_2(t)) = \mathrm{e}^{2t}$

  ∘ Substitute functions into equation for $x_p(t)$

$$x_p(t) = -2\,\mathrm{e}^t \left(\cos(t) \left(\int \sin(t)\,\mathrm{e}^{-t} dt\right) - \sin(t) \left(\int \cos(t)\,\mathrm{e}^{-t} dt\right)\right)$$

- ◦ Compute integrals

  $x_p(t) = 1$

- Substitute particular solution into general solution to ODE

  $x = c_1\mathrm{e}^t \cos(t) + c_2\mathrm{e}^t \sin(t) + 1$

- □ Check validity of solution $x = c_1\mathrm{e}^t \cos(t) + c_2\mathrm{e}^t \sin(t) + 1$
  - ◦ Use initial condition $x(0) = 1$

    $1 = c_1 + 1$

  - ◦ Compute derivative of the solution

    $x' = c_1\mathrm{e}^t \cos(t) - c_1\mathrm{e}^t \sin(t) + c_2\mathrm{e}^t \sin(t) + c_2\mathrm{e}^t \cos(t)$

  - ◦ Use the initial condition $x'\Big|_{\{t=0\}} = 0$

    $0 = c_1 + c_2$

  - ◦ Solve for c_1 and c_2

    $\{c_1 = 0, c_2 = 0\}$

  - ◦ Substitute constant values into general solution and simplify

    $x = 1$

- Solution to the IVP

  $x = 1$

Section: Chapter 3. Section 24.2. Solving the Cauchy problem for linear differential equation with constant coefficients. Exercises page 249
Problem number: 844.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{x'' + 4x' + 4x = 4}$$

With initial conditions

$$[x(0) = 1, x'(0) = -4]$$

33.15.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x'' + p(t)x' + q(t)x = F$$

Where here

$$\begin{aligned} p(t) &= 4 \\ q(t) &= 4 \\ F &= 4 \end{aligned}$$

Hence the ode is

$$x'' + 4x' + 4x = 4$$

The domain of $p(t) = 4$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = 4$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. The domain of $F = 4$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned} \mathcal{L}(x') &= sY(s) - x(0) \\ \mathcal{L}(x'') &= s^2Y(s) - x'(0) - sx(0) \end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - x'(0) - sx(0) + 4sY(s) - 4x(0) + 4Y(s) = \frac{4}{s} \tag{1}$$

But the initial conditions are

$$\begin{aligned} x(0) &= 1 \\ x'(0) &= -4 \end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) - s + 4sY(s) + 4Y(s) = \frac{4}{s}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = \frac{s^2 + 4}{s\,(s^2 + 4s + 4)}$$

Applying partial fractions decomposition results in

$$Y(s) = \frac{1}{s} - \frac{4}{(s+2)^2}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(\frac{1}{s}\right) = 1$$

$$\mathcal{L}^{-1}\left(-\frac{4}{(s+2)^2}\right) = -4t\,e^{-2t}$$

Adding the above results and simplifying gives

$$x = 1 - 4t\,e^{-2t}$$

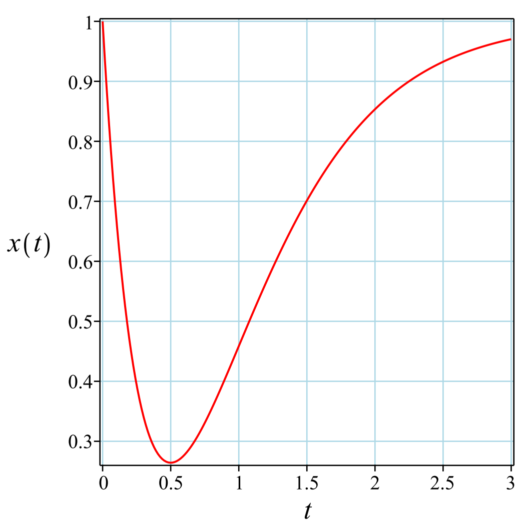
Simplifying the solution gives

$$x = 1 - 4t\,e^{-2t}$$

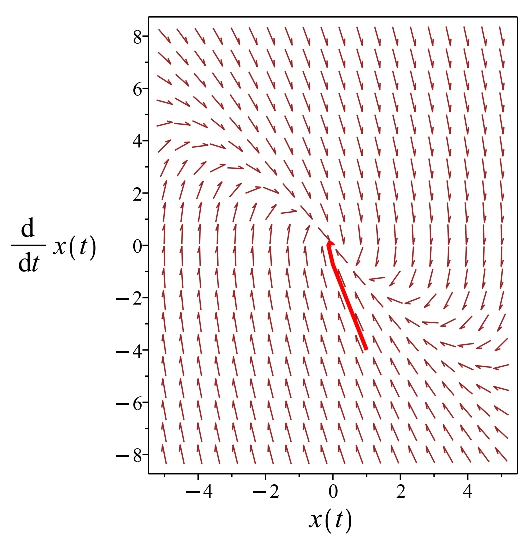
Summary

The solution(s) found are the following

$$x = 1 - 4t\,e^{-2t} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$x = 1 - 4t\,e^{-2t}$$

Verified OK.

33.15.2 Maple step by step solution

Let's solve

$\left[x''+4x'+4x=4, x(0)=1, x'\Big|_{\{t=0\}}=-4\right]$

- Highest derivative means the order of the ODE is 2

  x''

- Characteristic polynomial of homogeneous ODE

  $r^2+4r+4=0$

- Factor the characteristic polynomial

  $(r+2)^2=0$

- Root of the characteristic polynomial

  $r=-2$

- 1st solution of the homogeneous ODE

  $x_1(t)=\mathrm{e}^{-2t}$

- Repeated root, multiply $x_1(t)$ by t to ensure linear independence

  $x_2(t)=t\,\mathrm{e}^{-2t}$

- General solution of the ODE

  $x=c_1x_1(t)+c_2x_2(t)+x_p(t)$

- Substitute in solutions of the homogeneous ODE

  $x=c_1\mathrm{e}^{-2t}+c_2t\,\mathrm{e}^{-2t}+x_p(t)$

□ Find a particular solution $x_p(t)$ of the ODE

  ◦ Use variation of parameters to find x_p here $f(t)$ is the forcing function

    $\left[x_p(t)=-x_1(t)\left(\int\frac{x_2(t)f(t)}{W(x_1(t),x_2(t))}dt\right)+x_2(t)\left(\int\frac{x_1(t)f(t)}{W(x_1(t),x_2(t))}dt\right), f(t)=4\right]$

  ◦ Wronskian of solutions of the homogeneous equation

    $W(x_1(t), x_2(t))=\begin{bmatrix}\mathrm{e}^{-2t} & t\,\mathrm{e}^{-2t}\\ -2\,\mathrm{e}^{-2t} & \mathrm{e}^{-2t}-2t\,\mathrm{e}^{-2t}\end{bmatrix}$

  ◦ Compute Wronskian

    $W(x_1(t), x_2(t))=\mathrm{e}^{-4t}$

  ◦ Substitute functions into equation for $x_p(t)$

$$x_p(t) = -4\,e^{-2t}\left(\int t\,e^{2t}dt - \left(\int e^{2t}dt\right)t\right)$$

- Compute integrals

  $$x_p(t) = 1$$

- Substitute particular solution into general solution to ODE

  $$x = c_1 e^{-2t} + c_2 t\,e^{-2t} + 1$$

☐ Check validity of solution $x = c_1 e^{-2t} + c_2 t e^{-2t} + 1$

- Use initial condition $x(0) = 1$

  $$1 = c_1 + 1$$

- Compute derivative of the solution

  $$x' = -2c_1 e^{-2t} + c_2 e^{-2t} - 2c_2 t\,e^{-2t}$$

- Use the initial condition $x'\Big|_{\{t=0\}} = -4$

  $$-4 = -2c_1 + c_2$$

- Solve for c_1 and c_2

  $$\{c_1 = 0, c_2 = -4\}$$

- Substitute constant values into general solution and simplify

  $$x = 1 - 4t\,e^{-2t}$$

- Solution to the IVP

  $$x = 1 - 4t\,e^{-2t}$$

Section: Chapter 3. Section 24.2. Solving the Cauchy problem for linear differential equation with constant coefficients. Exercises page 249
Problem number: 845.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{2x'' - 2x' = (1+t)\,\mathrm{e}^{t}}$$

With initial conditions

$$\left[x(0) = \frac{1}{2}, x'(0) = \frac{1}{2}\right]$$

33.16.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x'' + p(t)x' + q(t)x = F$$

Where here

$$\begin{aligned} p(t) &= -1 \\ q(t) &= 0 \\ F &= \frac{(1+t)\,\mathrm{e}^{t}}{2} \end{aligned}$$

Hence the ode is

$$x'' - x' = \frac{(1+t)\,\mathrm{e}^{t}}{2}$$

The domain of $p(t) = -1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $F = \frac{(1+t)\mathrm{e}^{t}}{2}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\mathcal{L}(x') = sY(s) - x(0)$$
$$\mathcal{L}(x'') = s^2Y(s) - x'(0) - sx(0)$$

The given ode now becomes an algebraic equation in the Laplace domain

$$2s^2Y(s) - 2x'(0) - 2sx(0) - 2sY(s) + 2x(0) = \frac{s}{(s-1)^2} \tag{1}$$

But the initial conditions are

$$x(0) = \frac{1}{2}$$
$$x'(0) = \frac{1}{2}$$

Substituting these initial conditions in above in Eq (1) gives

$$2s^2Y(s) - s - 2sY(s) = \frac{s}{(s-1)^2}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = \frac{s^2 - 2s + 2}{2\,(s-1)^3}$$

Applying partial fractions decomposition results in

$$Y(s) = \frac{1}{2(s-1)^3} + \frac{1}{2s-2}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(\frac{1}{2(s-1)^3}\right) = \frac{t^2 e^t}{4}$$
$$\mathcal{L}^{-1}\left(\frac{1}{2s-2}\right) = \frac{e^t}{2}$$

Adding the above results and simplifying gives

$$x = \frac{e^t(t^2+2)}{4}$$

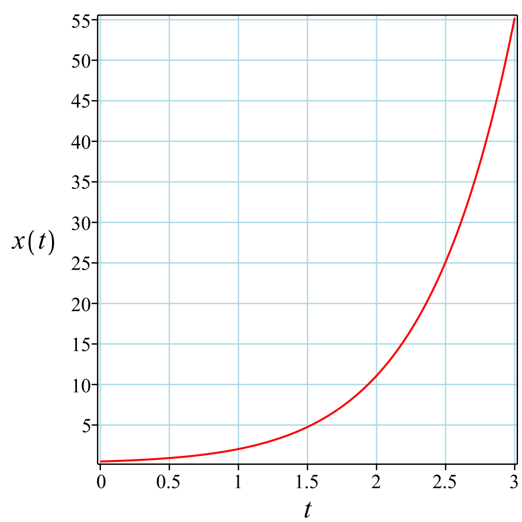
Simplifying the solution gives

$$x = \frac{e^t(t^2+2)}{4}$$

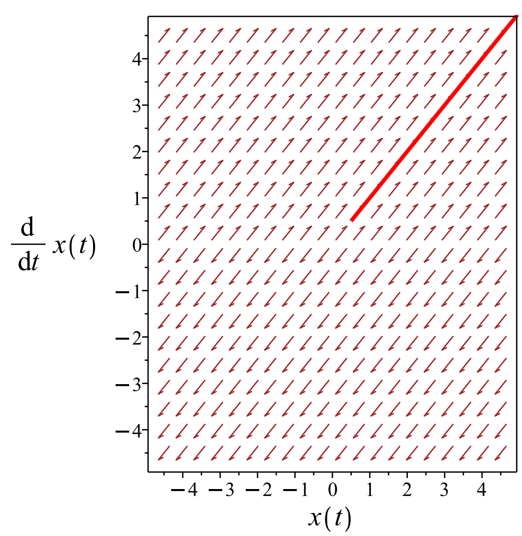
Summary

The solution(s) found are the following

$$x = \frac{e^t(t^2+2)}{4} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$x = \frac{e^t (t^2 + 2)}{4}$$

Verified OK.

33.16.2 Maple step by step solution

Let's solve

$\left[2x'' - 2x' = (1+t)\,e^t, x(0) = \frac{1}{2}, x'\Big|_{\{t=0\}} = \frac{1}{2}\right]$

- Highest derivative means the order of the ODE is 2

  x''
- Isolate 2nd derivative

  $x'' = \frac{e^t t}{2} + x' + \frac{e^t}{2}$
- Group terms with x on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $x'' - x' = \frac{(1+t)e^t}{2}$
- Characteristic polynomial of homogeneous ODE

  $r^2 - r = 0$
- Factor the characteristic polynomial

  $r(r-1) = 0$
- Roots of the characteristic polynomial

  $r = (0, 1)$
- 1st solution of the homogeneous ODE

  $x_1(t) = 1$
- 2nd solution of the homogeneous ODE

  $x_2(t) = e^t$
- General solution of the ODE

  $x = c_1 x_1(t) + c_2 x_2(t) + x_p(t)$
- Substitute in solutions of the homogeneous ODE

  $x = c_1 + c_2 e^t + x_p(t)$

□ Find a particular solution $x_p(t)$ of the ODE

- Use variation of parameters to find x_p here $f(t)$ is the forcing function

  $\left[x_p(t) = -x_1(t)\left(\int \frac{x_2(t)f(t)}{W(x_1(t),x_2(t))}dt\right) + x_2(t)\left(\int \frac{x_1(t)f(t)}{W(x_1(t),x_2(t))}dt\right), f(t) = \frac{(1+t)e^t}{2}\right]$
- Wronskian of solutions of the homogeneous equation

  $W(x_1(t), x_2(t)) = \begin{bmatrix} 1 & e^t \\ 0 & e^t \end{bmatrix}$
- Compute Wronskian

  $W(x_1(t), x_2(t)) = e^t$
- Substitute functions into equation for $x_p(t)$

  $x_p(t) = -\frac{\left(\int (1+t)e^t dt\right)}{2} + \frac{e^t\left(\int (1+t)dt\right)}{2}$
- Compute integrals

  $x_p(t) = \frac{t^2 e^t}{4}$

- Substitute particular solution into general solution to ODE

  $x = c_1 + c_2 e^t + \frac{t^2 e^t}{4}$

□ Check validity of solution $x = c_1 + c_2 e^t + \frac{t^2 e^t}{4}$

- Use initial condition $x(0) = \frac{1}{2}$

  $\frac{1}{2} = c_1 + c_2$
- Compute derivative of the solution

  $x' = c_2 e^t + \frac{e^t t}{2} + \frac{t^2 e^t}{4}$
- Use the initial condition $x'\Big|_{\{t=0\}} = \frac{1}{2}$

  $\frac{1}{2} = c_2$
- Solve for c_1 and c_2

  $\left\{c_1 = 0, c_2 = \frac{1}{2}\right\}$
- Substitute constant values into general solution and simplify

  $x = \frac{e^t(t^2+2)}{4}$

- Solution to the IVP

  $x = \frac{e^t(t^2+2)}{4}$

Problem number: 846.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{x'' + x = 2\cos(t)}$$

With initial conditions

$$[x(0) = -1, x'(0) = 1]$$

33.17.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$x'' + p(t)x' + q(t)x = F$$

Where here

$$\begin{aligned} p(t) &= 0 \\ q(t) &= 1 \\ F &= 2\cos(t) \end{aligned}$$

Hence the ode is

$$x'' + x = 2\cos(t)$$

The domain of $p(t) = 0$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = 1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. The domain of $F = 2\cos(t)$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(x) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned}\mathcal{L}(x') &= sY(s) - x(0)\\ \mathcal{L}(x'') &= s^2Y(s) - x'(0) - sx(0)\end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - x'(0) - sx(0) + Y(s) = \frac{2s}{s^2+1} \tag{1}$$

But the initial conditions are

$$\begin{aligned}x(0) &= -1\\ x'(0) &= 1\end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) - 1 + s + Y(s) = \frac{2s}{s^2+1}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = -\frac{s^3 - s^2 - s - 1}{(s^2+1)^2}$$

Applying partial fractions decomposition results in

$$Y(s) = -\frac{i}{2(s-i)^2} + \frac{i}{2(s+i)^2} + \frac{-\frac{1}{2}-\frac{i}{2}}{s-i} + \frac{-\frac{1}{2}+\frac{i}{2}}{s+i}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(-\frac{i}{2(s-i)^2}\right) = -\frac{it\,e^{it}}{2}$$
$$\mathcal{L}^{-1}\left(\frac{i}{2(s+i)^2}\right) = \frac{it\,e^{-it}}{2}$$
$$\mathcal{L}^{-1}\left(\frac{-\frac{1}{2}-\frac{i}{2}}{s-i}\right) = \left(-\frac{1}{2}-\frac{i}{2}\right)e^{it}$$
$$\mathcal{L}^{-1}\left(\frac{-\frac{1}{2}+\frac{i}{2}}{s+i}\right) = \left(-\frac{1}{2}+\frac{i}{2}\right)e^{-it}$$

Adding the above results and simplifying gives

$$x = -\cos(t) + \sin(t)(1+t)$$

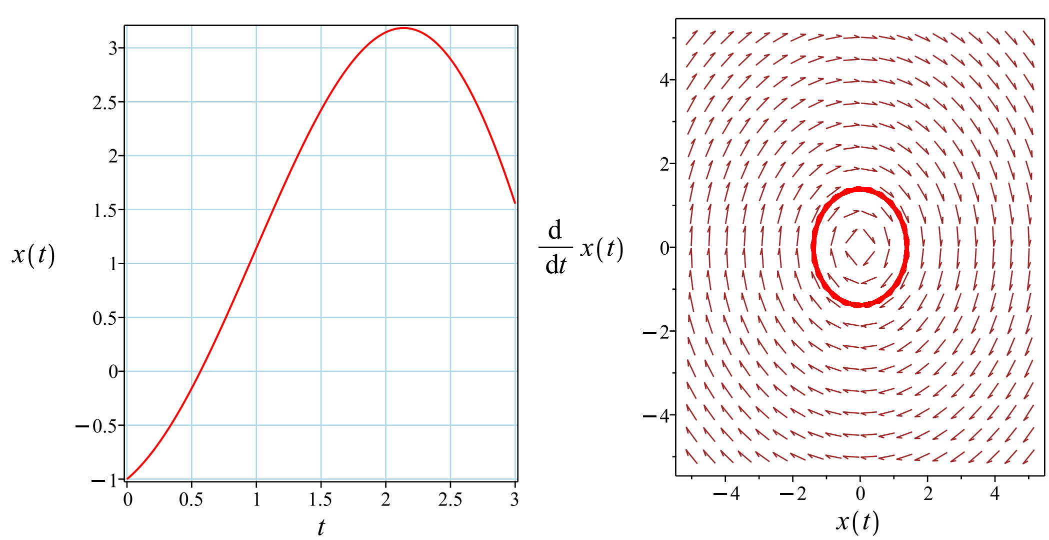
Simplifying the solution gives

$$x = -\cos(t) + \sin(t)(1+t)$$

Summary

The solution(s) found are the following

$$x = -\cos(t) + \sin(t)(1+t) \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$x = -\cos(t) + \sin(t)(1 + t)$$

Verified OK.

33.17.2 Maple step by step solution

Let's solve

$\left[x'' + x = 2\cos(t), x(0) = -1, x'\Big|_{\{t=0\}} = 1\right]$

- Highest derivative means the order of the ODE is 2

  x''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $x_1(t) = \cos(t)$

- 2nd solution of the homogeneous ODE

  $x_2(t) = \sin(t)$

- General solution of the ODE

  $x = c_1 x_1(t) + c_2 x_2(t) + x_p(t)$

- Substitute in solutions of the homogeneous ODE

  $x = c_1 \cos(t) + c_2 \sin(t) + x_p(t)$

□ Find a particular solution $x_p(t)$ of the ODE

  ◦ Use variation of parameters to find x_p here $f(t)$ is the forcing function

  $\left[x_p(t) = -x_1(t)\left(\int \frac{x_2(t) f(t)}{W(x_1(t), x_2(t))} dt\right) + x_2(t)\left(\int \frac{x_1(t) f(t)}{W(x_1(t), x_2(t))} dt\right), f(t) = 2\cos(t)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

$$W(x_1(t), x_2(t)) = \begin{bmatrix} \cos(t) & \sin(t) \\ -\sin(t) & \cos(t) \end{bmatrix}$$

- Compute Wronskian

  $W(x_1(t), x_2(t)) = 1$

- Substitute functions into equation for $x_p(t)$

  $x_p(t) = -\cos(t) \left(\int \sin(2t)\, dt\right) + 2\sin(t) \left(\int \cos(t)^2\, dt\right)$

- Compute integrals

  $x_p(t) = \frac{\cos(t)}{2} + \sin(t)\, t$

- Substitute particular solution into general solution to ODE

  $x = c_1 \cos(t) + c_2 \sin(t) + \frac{\cos(t)}{2} + \sin(t)\, t$

☐ Check validity of solution $x = c_1 \cos(t) + c_2 \sin(t) + \frac{\cos(t)}{2} + \sin(t)\, t$

- Use initial condition $x(0) = -1$

  $-1 = c_1 + \frac{1}{2}$

- Compute derivative of the solution

  $x' = -c_1 \sin(t) + c_2 \cos(t) + \frac{\sin(t)}{2} + \cos(t)\, t$

- Use the initial condition $x'\Big|_{\{t=0\}} = 1$

  $1 = c_2$

- Solve for c_1 and c_2

  $\left\{c_1 = -\frac{3}{2}, c_2 = 1\right\}$

- Substitute constant values into general solution and simplify

  $x = \sin(t)\, t - \cos(t) + \sin(t)$

- Solution to the IVP

  $x = \sin(t)\, t - \cos(t) + \sin(t)$
